Indian ginger has also been introduced. Rice has been shown to thrive remarkably well. As the Possession has almost all varieties of soil, and elevations varying from sea-level to 13,000 feet, it may, perhaps, be assumed that the country, extending as it does from the fifth to the twelfth degree of south latitude, could be made to grow any tropical product. Tobacco and sugar-cane require special remark. If tobacco is not indigenous to the country, it has been cultivated there for so long that for all practical purposes it may be considered to be so. It has been found growing on the spurs of the Owen Stanley Range, and on the Fly River, at over 500 miles from the sea. It is cultivated, as far as can be seen, by all agricultural tribes. It varies so little in appearance wherever grown that it is probably all of one species or variety. The leaf is very remarkable on account of its small size. It has been pronounced by London experts to be of great value. It grows so readily as to be rather troublesome as a weed at the Government Station of Mekeo.

Perhaps every tribe in the Possession that plant anything cultivates a certain amount of sugar-cane. Of this there are many varieties, of widely different sizes and colour. Individual canes are often met with that have been to some extent attacked by a boring insect; but no other disease has been noticed in it. It may be regarded as being indigenous.

It may be that the future of the Possession will depend as much on the coconut as on any other product. It would appear that, if it is possible to grow the coconut at a profit in any country, it should pay well in British New Guinea. Nowhere does this tree bear more fruitfully than it does in many of the districts of the Possession. There are already large groves of it in the country, sufficient to provide copra for direct shipment to Europe. There are long stretches of coast line and river bank suitable for this cultivation and available to the European settler. As hurricanes are unknown in the Possession, the coconut planter could depend on a continuous yield; and this most important point, together with the productiveness of the tree and the cheapness of local labour, ought to make this cultivation a most attractive industry for a man with some capital. It is an industry that would be specially suitable for a man that would at the same time fish for pearl-shell, and trade in copra, bêche-de-mer, and other native products. British New Guinea is not a pastoral country. The greater portion of its area is covered by a grassless forest. There are some limestone low hills in the Central and other districts covered by soft grass, but this is exceptional. The native tribes are too numerous, their cultivation too great and too widely distributed, to permit of the existence of large cattle runs. It is essentially an agricultural country. Then as to "Labour":—

The employment of native labourers is regulated by "The Native Labour Ordinance of 1892," which will be found on pages 20-31. Natives cannot be removed from the Possession except under such circumstances as are specially mentioned in that Ordinance. They can be engaged orally by an employer for periods not exceeding one month, provided that the natives are not employed ashore or afloat at a greater distance than twenty-five miles from their home.

They must be engaged before a magistrate if the period of engagement exceeds a month, or if they are to work at any place more than twenty-five miles from home. Natives may be engaged before a magistrate in any part of the Possession, to work in any other part.

Women cannot be engaged to work on board vessels. Persons not having a residence or place of business in the Possession cannot engage native labourers before a magistrate. The greatest period for which natives can be engaged as labourers under engagement is twelve months.

Natives employed by the Government receive the first year 10s a month in trade goods or money, and are "found." After the first year they receive £1 a month. They have been employed to do plantation work for private employers, at the eighth of a pound of tobacco a day, with food. The tobacco would cost about 2s 3d to 2s 6d a pound.

They appear to work well and faithfully, as a rule. They are easily managed, being as employees docile, and decidedly sharp. They are remarkably good-natured. Quarrels very seldom occur among those employed by the Government, although members of many formerly hostile tribes are brought together. Naturally, large numbers of them are addicted to stealing and lying; but many tribes are remarkably honest. On the whole, they are a mild and timid race, without any inherent disposition towards war and bloodshed.

We must not quote any more save the "Exports":—

The principal exports for the year last past were—

Copra	340 tons.
Bêche-de-mer	50 tons.
Gum	13 tons.
Pearl-shell	18 tons.
Turtle-shell	613 lb.
Sandalwood	42 tons.

The natives begin in some districts to prepare copra themselves. They have collected nearly all, if not all, the bêche-de-mer, gum, turtle-shell, and sandalwood that was exported. A great many coconuts that could be made into copra are not utilised yet. Many other articles will be added to the above list of exports as settlement progresses.

The rainfall seems to range from 53 to 113 inches. It is quite clear that British New Guinea, with its proximity to the Australian market, offers many attractions to the intending tropical planter—indeed for the pioneer with some capital it is possible that it may be preferable to East Africa, Mexico or even Java. We can spare one or two copies of the pamphlet to any persons specially interested.

STAPLE EXPORTS FROM CEYLON FOR TEN YEARS.

(The Chamber of Commerce Returns.)

Through the courtesy of the Secretary of the Chamber of Commerce in sending us early copies of the annual tables compiled in his office, we are enabled to offer some remarks on the results. We are also fortunately able to give the Review of our Special Planting Correspondent for the past year in respect of certain estate staples, amending his figures to correspond with the Chamber's return. Of course it will be remembered that in the latter return, only Exports for the two ports of Colombo and Galle are taken into account; but as a matter of fact from these alone are our principal products sent across the seas. At the same time there will always be a difference between the Customs' and the Chamber's returns for the calendar years, for this reason. The Customs enters in its Export return every shipment as it passes on board vessels in the harbour and on 31st December has in its total a good deal of produce that has not left our harbour; while the Chamber of Commerce makes no entry in its Export return until the vessel has cleared and left our shores. We published the total of our chief Exports for 1892 according to the Customs' figures on the 5th inst. and it will be interesting here to compare the same with the Exports as given by the Chamber of Commerce, thus:—

Staple Exports from Ceylon during 1892.

Chamber of Commerce.	Customs.	Difference.
TEA lb.	71,153,657	71,809,465 655,808
COFFEE cwt.	43,143	43,232 89
COCOA cwt.	17,327	19,174 1,847
CINCHONA BARK lb.	6,793,320	6,846,741 53,421

It will thus be seen that in each case the Customs' returns are in excess of those compiled by the Chamber, though this difference is but trifling in respect of coffee and cinchona, nor in tea is it very

appreciable. But a difference of 1,847 cwt. (or about ten per cent of the total export) in respect of Cocoa is more serious.

We have now to note especially that while between the extremes of the decade, tea has risen from 1,641,810 to 71,153,657 lb; yet the small increase over 1891 of less than three millions must be deemed a great check on the progress hitherto indicated. But if the return of 68,274,420 lb. for 1891 be treated as quite exceptional—as, in fact, ten million lb. above what it ought to have been,—then we get a fairly regular outturn rising since 1888 by 10 to 12 million lb. annually and this season would then show 13 in place of 3 millions of an advance. We must, of course, await the estimate of the Planters' Association before referring to the probable outturn for 1893; but we believe the general current of opinion points to a figure between 77 and 83 million lb. as the anticipated official estimate for the present year.

Coffee need not detain us long, the woeful falling-off of last year making it of less importance than ever; and yet how great the encouragement in good prices, to revive this industry, especially in Liberian Coffee, in the island. To think that between 1883 and 1893, the export of our old staple should fall from over 300,000 to only 43,000 cwt. is very lamentable indeed. Nor do we get much comfort from Cocoa, seeing that while we shipped over 19,000 cwt. in 1889, and 20,532 in 1891, only 17,327 were available last year. If this product is to give alternate crops, we ought to have an export of over 22,000 cwt. for 1893. In Cardamoms the returns are steadier, though the falling-off last year on the previous one was considerable.

Turning to native products, we find Cinnamon keeping up fairly well; while the exports of the various products of the Coconut palm show up exceedingly well, indicating indeed a wonderful increase last year in oil, copra, punac, and desiccated coconut. Here is a summary of the exports for 1892:—

		Shipping Tons.
Coconut Oil ... cwt.	550,977 equal to	34,436
Copra ... "	134,590 "	11,215
Punao ... "	204,166 "	10,208
Desiccated		
Coconut ... lb.	3,849,724 "	3,849
Coconuts ... Number	9,717,386 "	9,717
Coir Fibre ... cwt.	43,445 "	7,140
Do. Yarn ... "	101,375 "	13,000
Do. Rope ... "	7,895 "	986
Shipping tons...		90,551

Against say 71,153 shipping tons of tea—so that even if we add for coffee, cocoa, cinchona bark and cardamoms—which, last year, we reckon, gave together about 8,700 shipping tons—we only get a little below 80,000 shipping tons for all the produce of our "planting districts" in the usual acceptance of the term, against over 90,000 tons for the exported produce of our one leading palm and leaving out of view the enormous quantity of its produce consumed in the island. Here we remark that we fear the trade in "desiccated coconut" like so many new things started in Ceylon, has been overdone; but then we know how impossible it is to prevent competition having its full swing whenever there is a chance of profit from a new industry, in the present day.

Before leaving the Coconut Palm, we may attempt an estimate of the value of its produce exported in 1892 as compared with that of the Tea, Coffee, Cocoa, Cinchona Bark and Cardamoms credited to the plantations chiefly in European hands. Taking

generally the quotations found in the Chamber's latest Price Current, the following is the result—

	Nominal averages.	R
Coconut Oil...550,977 cwt. at R.15/50		= 8,540,143
Copra.....134,590 cwt. at 48 per candy		
	of 560 lb. "	1,292,064
Poonao204,166 cwt. at 88-75 per ton		905,960
Desiccated		
Coconut... 3,849,724 lb. at 21c. per lb.		808,442
Coconuts No. 9,717,386 at R38 per 1000		369,246
Coir Fibre... 43,445 cwt. at R6½		271,531
" Yarn... 101,375 cwt. at R9		912,375
" Rope... 7,895 cwt. at R9		71,055
	Total	R13,170,816
Treating "Estate products" in the same way we have a much more important return:—		
Coffee Plantation 40,604 cwt. at R80	=	3,248,320
Native 2,539 "	at 70	177,730
Cinchona 6,793,320 lb at 6c	=	407,599
Tea 71,153,657 "	at 45c	32,019,145
Cocoa 17,327 cwt. at R74		1,282,198
Cardamoms 372,510 lb at R1 25	=	465,637
	Total	R37,600,629

It will thus be seen that although the "shipping tons" of "estate" products worked out to a good deal less than those represented by the coconut-palm exports; yet that in value the former represent a sum nearly three times larger than is due to coconuts, even though tea is very moderately estimated.

We now pass on to PLUMBAGO and observe that last year's export of 426,761 cwt. showed a notable increase (26,500 cwt.) over that of 1891, although nearly 50,000 cwt. behind the unprecedented shipments of 1889. The future of the plumbago industry in Ceylon is full of interest, more especially when the application of European engineering skill with steam engines and improved pumps to some of the pits, is beginning to take effect. If the improved working is found to be a success financially, we may see quite a revolution in the industry all over our plumbago country. Meantime we have yet to see how far Travancore plumbago is to prove a rival to the Ceylon article.

There is not much to note in respect of some minor Exports—Ebony, Deer Horns, Sapan Wood, Orbellia Weed, Kitul Fibre,—in the Chamber's table. The trade in Ebony is but a fourth in magnitude of what it was seven to ten years ago, although last year showed a great improvement on 1891. On the other hand, Deer Horns made the poorest show on record in 1892; while the export of Sapanwood gave a great leap forward from an average of between 2,000 and 3,000 cwt. to a shipment of no less than 10,704 cwt., only reached before in 1883 when we sent 10,280 cwt. Orbellia Weed—the lichen common in Ceylon on trees in the sunted coast forests of the dry zone, on our North-west coast chiefly, and which is used for making litmus paper and for dyeing—fell off in 1892 to 120 cwt. against 774 the year before and 1,394 cwt. in 1887. Kitul fibre on the other hand gave a good return for 1892 in 2,491 cwt. against 1,899 the previous year. There remain but the two Essential Oils in the table before us, namely Citronella and Cinnamon. The former gives one of the highest exports on record, 13½ million cunecs in round figures for 1892, being only exceeded in 1890 when over 14½ millions were shipped. Of Cinnamon oil the export 106,303 ounces was a good average, though 16,500 ounces behind the shipments in 1891. Altogether, to judge by the Chamber's table, the Export of our Staple Products during last year was fairly satisfactory both in volume and value.

We have now to refer to the Distribution during the past year as compared with 1891 with such references as we may make to the distribution in earlier years. And first in respect of TEA, it is certainly a striking fact that although our total shipments for last year give an increase of nearly 3 million lb. the quantities sent to the United Kingdom in the two years show a difference very little in excess of a millionlb., thus:—

<i>Ceylon tea to the United Kingdom.</i>		
In 1892 ..	=	64,815,075 lb.
In 1891 ..	=	63,744,987 "

Increase .. 1,070,088 lb.

The great rise in our shipments home was, of course, in 1891 as compared with 1890 when only 43,756,912 lb. were sent and but 32,510,747 lb. in 1889. A rise of 100 per cent—nearly 32 million lb.—in two or three years is entirely phenomenal. It would have looked better perhaps had last year shown shipments to London, of 53 to 54 millions out of a total export of 58 to 60 millions and as bearing out such an anticipation, we have before us as we write, a letter which we sent on 17th Dec. 1888, to a high official who was seeking information as to the prospects of tea, and on that date we only ventured to put the probable crop of 1891-92 at 58 million lb.! On the other hand, as regards shipments to London, Mr. J. H. Roberts of Messrs. Rucker & Co. has held consistently to the view for many years back that, if we take the permanent benefit of the Ceylon Tea industry into account, the sooner we sent to the London market 80 million lb. of tea in one season, the better. Mr. Roberts of course means, that only with this quantity can we get such a hold of the market as to shut up China effectually and also take the pre-eminence over India. But then the planter who is dependent on each season's return as it comes, will ask what would the throwing of 80 million lb. from Ceylon in the present year mean, if it were possible, in regard to prices? There's the rub! If it meant a further fall in the average, most certainly we, in Ceylon, will feel it to be to our advantage rather to encourage the direct shipments to our Southern Colonies, and to the European and American Continents and to lessen as far as we can, the direct shipments to London, lest the prices should fall. And yet, it is possible that, even in the interests of current prices, this may not be the wisest policy if it encourage China buyers during the approaching season to trade freely for the London market. On this point our London Correspondent may be able to get us the opinion of Mr. Roberts and other experts on the present situation and prospects.

In respect of the Distribution of our Tea last year, assuredly the most satisfactory feature is the great increase in the direct shipments to Australasia (not "Australia" because New Zealand is included). These have mounted up as follows during the past four years:—

<i>Tea from Ceylon to Australasia and New Zealand.</i>			
In the year	1899	equal to	1,120,044 lb.
do	1890	do	2,559,901 lb.
do	1891	do	3,210,598 lb.
do	1892	do	5,166,154 lb.

Is it too much to expect that from 7 to 8 millions of our crop may this year be taken off for the Southern Colonies? Even then we shall not control one-third of their annual tea consumption.

If we turn now to America including Canada as well as the United States, the comparison is a very unsatisfactory one; until we remember that "direct shipments" thither are no test of the total quantity of Ceylon tea taken; for it is notorious how freely the trade of re-export from London

across the Atlantic has been expanding of late. The figures for the four years are as follows:—

<i>Ceylon Tea direct to America:</i>		
In the year	1889	.. equal to 42,252 lb.
"	1890	.. " 204,223 lb.
"	1891	.. " 163,137 lb.
"	1892	.. " 100,893 lb.

This is progress backwards with a vengeance. Let us hope that the next Export summary of Messrs. Gow, Wilson and Stanton may far more than make amends for the deficiency; while we all look to the £20,000 spent on the Chicago Exposition as bound to bear fruit in a largely increased demand for Ceylon tea as well as other staples.

Strangely enough, "India" shows up largely in our Tea exports, but the produce sent to Bombay must be intended chiefly for the Persian Gulf. The figures runs as follows:—

<i>Ceylon Tea to India:</i>		
1889	equal to 289,637 lb.
1890	" 144,631 lb.
1891	" 620,161 lb.
1892	" 523,037 lb.

"China" too is our customer to an appreciable extent—can the tea be for blends and re-export or mean a local consumption of Ceylon tea? To China we may add Singapore:—

<i>Ceylon Tea to China and Singapore:</i>		
1889	no separate return
1890	equal to 100,666 lb.
1891	" 166,659 lb.
1892	" 115,369 lb.

"Africa" which probably means Egypt more than Cape Colony, takes from 60,000 to 70,000 lb. of Ceylon tea and little "Malta" got its 18,326 lb. direct (mainly for the troops) last year.

And now we have left the Continent of Europe, of which Germany stands for the largest quantity 123,077 lb. last year, followed by Austria with 93,743. The total direct to the European Continent for the four years according to the Chamber's tables stands as follows:—

Ceylon tea direct to the Continent of Europe.

1889	equal to 54,743 lb.
1890	" 92,839 "
1891	" 227,677 "
1892	" 255,458 "

This shows a satisfactory increase on the whole; but we look for a much greater development shortly.

A RUSSIAN TEA BUYER IN CEYLON.

Mr. A. Maligin of Moscow was much pleased with his inspection of tea samples in Colombo (at the office of Messrs. Somerville & Co.) and with a trip to Nuwara Eliya where Mr. Cross took him to Naeby (of which tea he got some samples) and afterwards to the big Company's estate, "The Scrubs." Mr. Maligin hopes to be back in April on his way out to China again; but meantime he is to try to get orders for Ceylon tea from the great Russian dealers. He added though, gravely enough, that it is a very difficult matter to get the Russians to take to a new tea and that progress in introducing Ceylon tea must necessarily be slow. He is, however, hopeful of making some impression. The visit of Mr. Popoff and his party some years ago to Abbotford had been much talked of in tea circles in Russia and the samples then sent home were the subject of a good deal of speculation. Mr. Maligin is to interview the Planters' Agent M. Rogivue while at home, to estimate the progress made. Personally, Mr. Maligin would be well pleased to be sent to Colombo to buy, in place of Foochow or Shanghai; but the Russian buyers of the East have to obey orders. In time we have no doubt much Ceylon tea will be taken direct to

Russia.—Meantime; Messrs. Somerville & Co. are to send some Ceylon dust tea to Henkow by Mr. Maligin's order, and probably the intention is to try an experiment with it in the manufacture of "brick tea."

PLANTING REVIEW FOR 1892.

(By "Wanderer.")

TEA.—The year now under review has been on the whole a fair paying one for the tea planter. He has been well supplied with labour, and though he did feel a little uncomfortable when prices went down to 8½d, low exchange, cheap freight and plentiful labour enabled him to tide over that difficulty. The excellent prices ruling since the end of September, also combined with low exchange and cheap freight, have enabled him to spend a happy Christmas with less of carking care for the future than possibly any agriculturist in any other part of the world. The yield up to the last six weeks was decidedly less than 1891 considering the increasing age and size of the bushes. Hill planters blamed the wet cold weather since the S.-W. monsoon set in. A friend of mine, who went over his estate with his pluckers every nine or ten days found his leaf ever so much finer than usual, owing to the slow growth of the foliage in the last S.-W. monsoon. In the low-country the same excuse cannot be given, but all the same the yield of tea there has not been so great as in 1891, considering the increased age of the tea. In November and December there has been rather a rush of leaf especially on the hills. I believe more pruning has been done in 1892 than in 1891, which may also account in some measure for the crop being so short of estimate. If that is so, then we may look to a rather better crop than people are inclined to estimate for 1893.

SUPPLYING has been well attended to. We could not have had a better planting year than we have enjoyed in 1892. The planted area of tea has not been much extended in 1892.

TIMBER PLANTING has been carefully attended to. With what planting was accomplished up to 1890 the appearance of many estates has been improved. When the planting of the last two years shows up, absentees from the island for five years will scarcely recognize them, when they revisit their old haunts.

The following memo. of exports for the last three years tells its own tale:—

Exported tea	1890 ..	46,691,554 lb.
	1891 ..	68,274,420 lb.
	1892 ..	71,153,657 lb.

COFFEE.—Alas! This old product has now to take a very back seat. The price of the staple is simply magnificent, but if you have not got it, what good does that fact do you? The blossoms were late and the crop has followed suit. So much comes off suckers, the wood of which is very irregular in ripening blossom, that the gathering of crop is a slow, slow process. The orders now given in most cases to managers are to root out all coffee trees that do not appear likely to give crop in 1893. I expect your reviewer of 1893 will have an easy task before him as far as coffee is concerned:—

Exports (Coffee)	1890 ..	86,009 cwt.
	1891 ..	86,692 "
	1892 ..	43,143 "

COCAO.—All cacao planters are growing at the lateness of the crop. If we were to judge by the exports alone of 1891 and 1892 we would feel inclined to say what has come over this product? The year 1890, however, showed a decrease on 1889. We must therefore trust that this product, like

the flowing tide with its waves at times apparently receding yet ever gaining ground, is really advancing. Late blossoms have however a great deal to do with this apparent shortness of 1892, and the early part of 1893 will prove it. Much labour and skill has been expended by cacao planters in growing the right sort of shade, the fruits of which will be seen in the next two years. Cocoa stealing is exercising the Matala men. Corporal punishment seems to be the only cure:—

Exporte	1890 ..	15,981 cwt.
	1891 ..	20,532 "
	1892 ..	17,327 "

CINCHONA.—Exports in 1892 hold their own with 1891. Unless a lot of bark is stored in Colombo or upcountry, the exports must tumble down in 1893. One sees so little of it travelling in any part of the country:—

Exports	1890 ..	8,728,836 lb.
	1891 ..	5,679,339 "
	1892 ..	6,793,320 "

CARDAMOMS are a speciality, but the specialist seems to be keeping up the exports and the prices are good. I should not mind being a cardamon specialist, for he must be making money:—

Exports	1890 ..	387,940 lb.
	1891 ..	422,109 "
	1892 ..	372,510 "

VARIOUS NOTES.

DR. JUSTUS KARL HAESEKARL, the veteran cinchona pioneer, who is now living at Cleve, in Germany, has been awarded a gold medal by the Dutch Government in acknowledgment of the gift of his herbarium to Leyden University. The herbarium consists of over 20,000 botanical specimens, mostly collected by the donor and arranged by him. Dr. Haeckel has also presented to the same university his valuable collection of cinchona specimens.—*Chemist and Druggist.*

"THE GARDEN OF EAST AFRICA"—is described by Commissioner Keane as Nyassaland; and this is how he was reported by the daily *Graphic* recently:—

"From Matope to the Lake it is one long garden. The traveller passes fields upon fields of cereals of every description, interrupted here and there only by plantations of the biggest sugarcane I have ever seen. Blantyre is like a prosperous English village. If you were to see it you would never imagine that you were in Africa. It has a flourishing population of English and Scotch planters and employers of the African Lake Company, who live the European life in every respect, except, perhaps, that they do not wear top hats. The great question in African colonisation is always 'Can a white man live in the region it is proposed to settle?' Well, this question has been solved in Nyassaland. Not only can the white man live there, but he can prosper and multiply, which is more than he can do in India. In Nyassaland," added the Commander enthusiastically, "the white man can enjoy a rattling good time and make money."

"How it is," inquired our representative, "that there is no rush of emigration to this Canaan?"

"Fortunately for us, we have escaped the notice of the outcast and thriftless emigrant. The people who have settled among us are an exceedingly nice sort—young men with muscle and intelligence and a few hundred pounds of capital. We hope to make the country a kind of overflow reservoir for Ceylon, which is getting rather crowded now. Whatever can be grown in Ceylon can be grown in Nyassaland." "An overflow reservoir for Ceylon" may not be a bad description of Blantyre, and by-and-bye of the Uganda Planting district.

THE FIRST AND BIGGEST TEA PLANTATION COMPANY IN CEYLON.

This honour belongs to the Ceylon Tea Plantations Company, of which the late Mr. David Reid may have been said to be the founder, while Mr. H. K. Rutherford is now Managing Director in London and Mr. G. A. Talbot, Manager in Ceylon. The last-named gentleman is good enough to inform us that "the total outturn of tea for the Company in

1892 was 4,666,699 lb.
In 1891 it was 4,291,584 lb.
In 1890 ,, 2,939,766 lb.

Of course, there were several plantations purchased between 1890 and 1891. We suppose there is no Indian Tea Company giving an outturn in excess of the Ceylon Tea Plantations Company, although the outturn of the North and South Sylhet concerns is probably rather above than below 4 million lb. It is something for Ceylon to have the Premier Tea Company, and we feel sure that none in India can be better managed than is the Company under the care of Messrs. Rutherford and Talbot, in whom the shareholders have emphatically the right men in the right places.

THE CEYLON TEA CROP IN 1893.

THE OFFICIAL ESTIMATES.

A "keenly observant planter" writes:—

"Have the 'official estimators' taken into account the very severe drought now afflicting high and low tea? It may be said to have commenced on 20th November,—December only giving a fall of 3 to 6 in. When will it break up? We are entering the long dry season with dry tanks. Have responsible parties made it known in Mincing Lane?"

Mr. Wm. Smith of Dimbula expresses the opinion:—

"Had we had rain in December 80,000,000 would have been nearly touched. We are now in want of rain up here, and tea would flush to our hearts' content. We got from 200 acres 21,000 lb. made tea in December."

CACAO ABOUT KANDY—A WONDER!

A planter writing from a Kandy District, reports:—

We are much in need of rain, although the flush is far from stopping. Cacao is a wonder. Our crop should be about over now, but instead of that the trees are still full of pods in all stages, and blossom as well. This, too, in spite of a bigger crop in 1892 than we had in 1891. I am not sure, however, that this is the general experience, for the cacao autumn crop is late and only those who stood well in the spring months have found 1892 a season to pipe about.

SAPPHIRES AND RUBIES OF SIAM.

The report of the directors states:—Being anxious to avoid incurring any outlay for machinery until the value of the company's property had been ascertained, they approved of a temporary system of working the mines suggested by Mr. Gibbon, the company's chief agent in Siam, by granting licenses to selected diggers. The results obtained under this system have been sufficient to prove that the company possesses mines containing a large quantity of ruby-bearing earth, which, with suitable gem-washing machinery, there is every hope it will afford satisfactory returns. This trial system of working by means of certificated diggers has been

continued during the past year, but it has not been allowed to develop largely, owing to the growing suspicion with regard to the illicit detention of stones by the diggers, and particularly in view of the proposed adoption of machinery. Within the past few months a system of digging by labour paid for at daily wages has been tried with very promising results. Having regard to the state of Mr. Gibbon's health, which had been seriously impaired by severe fever, and to the desire of the Board to discuss with him personally the future policy of the company, the directors telegraphed to him to come home.

While the aggregate yield of stones under the system temporarily adopted has been considerable, it is clear that many first-class stones have been purloined, and, consequently, the necessity for adopting some theft-preventing machinery for washing and separating the gems has become imperative. The attention of the directors has recently been drawn to a gem-separator invented by Mr. W. S. Lockhart, Mem. Inst. C.E., who has had special experience in gemming. The advantages claimed for this machine are not only that it effectually separates the gems from the worthless gravel, but that it absolutely prevents theft.

During the past twelve months very considerable progress has been made in surveying and exploring the country within the company's concession. Those acquainted with the conditions under which surveys and works of this kind have to be conducted in the jungle districts of Siam will fully appreciate the value of the work done by Mr. Gibbon and his staff, often, unfortunately, at a great sacrifice of their health.

The directors have to announce the retirement from the board of Mr. F. W. Verney, owing to his time being fully engaged with other occupations.—*L. and C. Express*, Dec. 23, 1892.

PUNCH ON CEYLON TEA.

Under the heading of "Lays of Modern Home: the Muffin Man," *Punch* of the 24th Dec. 1892, after extolling the dainty "crisp my native-bred, my British muffin" thus concludes:—

"Then; brew my cup—the best Ceylon—
And, bidding care and chill begone,
Concentre heart and mouth upon
Thy warm perfections."

RUBBER IN BENGAL.—A native of Pará proposes to start the production of *mangabeira* rubber in the district of S. Simão, S. Paulo. He claims to have discovered that there are forests of the trees in the state, and that the result of the extraction of rubber will be very profitable. The botanical name of the *mangabeira* is *Hancornia pubescens*, which may lead to its identification in foreign parts.—*Rio News*.

A CEYLON PLANTER IN WEST AFRICA.—The last mail brought us letters from Mr. W. B. Hope, late of Yattiantota, who is now carrying on business in Liverpool with a Mr. Fletcher, under the style and title of Messrs. Fletcher and Hope. Mr. Hope had just returned from a trip to the English settlements on the West Coast of Africa, and is struck with the lethargy displayed by the British in that part of the world, and particularly with the absence of good roads. "Oh!" he says, "for a few years of Sir Arthur Gordon." Climatic influences, however, are said to be very adverse to energy and progress in that part of the world, whilst its unhealthiness to human life is proverbial. Mr. Hope's visit, however, is likely to be productive of much good to his firm now that he has established personal relations with the agents on the Coast.—*Local "Times,"* JAN. 12,

TEA PRODUCTION AND CONSUMPTION:
ANNUAL REPORT OF MESSRS. GOW,
WILSON & STANTON.

Messrs. Gow, Wilson & Stanton's Tea Report for the past year has certain features which call for some comment at our hands. Very true and forcible are the opening remarks in reference to the transfer of the English tea trade from China to India and Ceylon. Never was this shown more strikingly than in the figures adduced which tell us that out of every 100 lb. of tea used in the United Kingdom last year, 53 lb. were grown in India and 31 lb. in Ceylon, or 84 lb. in British Dependencies against only 16 lb. in China! Verily China has indeed at length "been nearly beaten out of the market." We are not so well-satisfied with the explanation given in the circular before us of the fall in prices of Ceylon tea last year: the average which was 10d for 1891 being only 9½d for 1892 against 10½d and 10d respectively in the same two years for Indian tea. This is considered by a contemporary to be very extraordinary in the face of the fact that our shipments of tea to London in 1892 were so very little in excess of 1891—why then should the price fall, with short crops both from India and Ceylon? But it will be observed that the deliveries of our tea last year were much in excess of those in 1891, the increase being no less than 13 million lb. Still, we want information on two points not referred to in the Report before us:—(1) if with shipments to London of from 63 to 64 million lb., the price for Ceylon tea falls to a point very near the remunerative limit, what will be the result of our sending the 80 million direct next year (or the year after) which some of our good tea friends in London have been urging us to despatch as soon as possible? It is true there are 16 million of China tea still to suppress in the United Kingdom; but we think the risk attending increased shipments to London too great, not to lead us at this end to cultivate the direct trade with Australasia and other countries by every means in our power. Secondly, we are a little disgusted to see in this annual Report from Rood Lane, not the slightest reference to the influence which big crops or anticipated big crops in India and Ceylon, might have had on the purchases and shipments of China tea. We are told that "the excessive crop estimates indulged in both from India and Ceylon" 'hung like a pall over the market'; but the actual outturn barely coming up to that of last season, there came a reaction in price to a more remunerative figure. But here surely was the place for expressing an opinion on what must have happened in China, had the estimates early in 1892 indicated that the India and Ceylon tea crops were to show no increase. Would there not have been larger shipments from China to London, and would the prices then not have tumbled down in the end, in place of in the beginning of that year?

It is satisfactory to see credit given for improved quality in Ceylon teas which, towards the end of the year "were particularly good, those grown at high elevations being noticeable for very fine delicate flavour." Let us hope that all through 1893 our teas may continue in similar good repute. It is also gratifying to note that flavoured kinds of Ceylon tea are finding a market in Russia at remunerative prices. This must mean a direct trade from London; but unfortunately no figures are given to enable us to judge of the extent of this trade, or the total of the tea re-exported from London to the Continent of Europe, America, &c. Such a return will no doubt come later on. Meantime it is very

satisfactory to note that the stock of Ceylon tea which stood in November 1891 at 14,966,572 lb. was, at the end of November last, no more than 12,205,854 lb. The stock of Indian tea was also below that at the same date in 1891, and there is therefore every reason to anticipate a good market during the present year, unless indeed China buyers make a great effort to secure a bigger share of the home consumption than was allowed them during the past year. Of this, we trust there is not much likelihood; for each year's experience of Indian and Ceylon tea must confirm the British taste for a product superior both in flavour and strength to the poor and oil-adulterated China teas.

COFFEE IN S. INDIA.

A correspondent of the *S. of India Observer* thinks that the failure of the N.-E. monsoon has resulted, or will result, in a loss of one-fifth of the coffee estimate on an average, and also in the spoiling of a certain amount of wood, which has already had, or is about to have, an untimely blossom. Tea has not suffered much, though the lack of rain and cold nights have lessened yield to some extent. As regards Cinchona he says that "there is a general belief that the worst is over, and that Java production will gradually lessen; at the same time it must not be forgotten that this idea is causing a good deal of Indian bark to be harvested, which will probably prevent any rise to speak of at present. Those who are wise will hold on for another year, at least."

THE AGRICULTURAL CONDITION OF SAMOA.

Mr. W. D. P. Keppel, (formerly in Ceylon?) writing to us from Samoa to register him as a subscriber to the *Tropical Agriculturist* as likely to be of great service to him, says:—"As nominal, unofficial, unappointed and unsalaried acting minister for agriculture for the Government of this little kingdom, but practically only a 'globe-trotter' of the botanical persuasion, I have 'stayed over' for over twelve months, endeavouring to raise the place from a bankrupt state, as a solitary export of about 4,000 tons per annum of copra to a low and falling market implies." We wish him every success in his efforts.

YOUNG ENGLISHMEN IN THE COLONIES.

NOT AFRAID OF HARD WORK.

Wonderfully invigorating is the "Old Students' Column" in that excellent little publication "Colonia," the Hollesley College magazine. The number for this winter session, dated December, 1892, has been forwarded us, and the first forty pages are devoted to letters from old students at the College, giving their experiences in Greater Britain. The forty pages will well repay perusal. The real, straight up-and-down tone in which everybody writes, and the utter absence of the smallest approach to pride, except the pride of doing one's duty, presents a striking contrast to the unreality of modern life in England. Here everybody is trying to be just a little bigger than he can afford to be: the young man who has begun to try his fortune in Australia or Canada has an evident contempt for anything of that kind. For example, Mr. A. C. Hardy writes from Ceylon telling how after three years' work in Australia he has come to Ceylon, where he hopes to manage a tea farm. "I booked my passage," he says, "to Colombo, and contented myself with a £10 steerage ticket, thereby keeping 20 golden sovereigns in my pocket. I had no cause to regret it. And here let me suggest to some of your embryo colonists that they too should let their false pride keep company with a few extra pounds in their pockets, and for a few weeks do in Rome as Rome does, or to use a Darwinian expression, 'correspond with their en-

vironment.' They will have ample opportunity to quit themselves like men and gentlemen, and need not think that they demean themselves by being kind and chivalrous to the weaker sex, though not clad in silks and satins." If only we could manage to let our false pride keep company with a few golden sovereigns in our pockets at home, how much better it would be for all of us.

There is the same manly respect for work, and the same manly contempt either for idleness or grumbling with the country and the times, when the fault is the want of energy or wit in the grumbler. Mr. G. E. Church writes from the North-West Territory:—"I see in 'Colonia' in talking about Colonial education they leave out one thing necessary, that is common sense, which is equal to everything else put together. Lots of people out here never think, they just go along anyhow; they have no aim beyond living. In breeding, for instance, they exercise no discretion, and it is the same with other things. They take the same crop off the same land year after year, and talk against the country when their crop fails." Contentment and hard work seem to be written on every page of this letter. Mr. H. P. Earnshaw writes from West Virginia:—"My brother and I arrived here two years ago today. We bought a farm of 530 acres this spring, and we are very well contented with our life and prospects." Mr. Macnoughton writes from Tasmania:—"I have now been five months in this country, and think it is a splendid place for any one with a little capital, but not less than £50 a year and a couple of hundreds to fall back upon. To anyone with no capital I should certainly advise New Zealand in preference, as I think he would have a better chance with pure farming." There is, he adds, certainly no poverty, if not much wealth. Mr. J. W. Reid, of British Bechuanaland, tells us that he is not doing badly; he has been able to make a comfortable living ever since I have been out here. But Mr. Reid's idea of a comfortable living is widely different to that entertained at home. The comfort is only purchased by real hard work.

"Things seem to be looking up a bit up country. There is plenty of work for men willing to put their shoulders to the wheel, but it is work. I don't know how some of the Colonials would like to work all day with pick and shovel, and then sit down to a meal of lung-sick ox and mealies (Indian corn). But a man must not mind little trifles like that if he wants to get on.

"I often think when I have been sitting down to a meal of hilly beef and mealies, of the grub we got at Holesley, and how some men used to grumble at it. How would they like to live on such tack for weeks, and nothing else, not even a pinch of salt to be had for love or money, for hundreds of miles round. I am not speaking of "Colonials" in particular, but of home-born fellows in general, who when they come out expect to find fortunes ready-made, and seem disappointed that they are only to be attained by hard work, energy, perseverance and steadiness."

Everyone out there has to turn his hand to manual labour, he be pser or peasant in the old country. Mr. Reid wishes one of his old College mates was with him, as anyone "who can shoe a horse properly and has a slight knowledge of carpentry could knock out £4 or £5 a day anywhere between the Crocodile and the Zanzibar rivers."

It is worth noticing the great attention that is being paid to fruit-growing by many of these young colonists. Alike in Australia and America, the writers allude to their own fruit plantations, or those of their neighbours. It is the English market most of them are catering for; would not the same care make the acres of apples or plums a profitable adjunct to a farm at home? There is a hint, too, for the agricultural labourer. Mr. Seth Smith writes from Oamaru, New Zealand, that a man who lives on the farm gets his board and lodgings, and between 3s and 5s a day—in some parts even more. Is it not a love of home carried to excess which alone prevents the English peasant from greatly bettering his condition?—*East Anglian Daily Times*, Dec. 16, 1892.

CHARACTERISTICS OF A GOOD MILKER.

At a recent sale of farming stock in Gloucestershire, England, the auctioneer says the *Farming World*, gave the following extempore description of a good milk cow:

Long in her sides, bright in her eyes,
Short in her legs, thin in her thighs,
Big in her rib, wide in her pins,
Full in her bosom, small in her shins,
Long in her face, fine in her tail.
She's never deficient in filling the pail.

A New York dairy farmer used the following ration in a herd of cows which produced 320 pounds per cow: Meadow hay, 12 pounds; oorn meal, 3 pounds; wheat bran, 8 pounds; linseed meal, 3 pounds; oat meal, 3 pounds. In commenting on this ration, Prof. Henry says in *Breeders' Gazette*: "In this ration, there would be of digestible albuminoids 2.03 pounds; carbohydrates 10.3 pounds; fat .63 pounds; the nutritive ratio being 1:5.7. This is a good ration, but it might be profitable to use the different foods in varying quantities. Oorn will probably be the cheapest food, dropping the oats if they are high, as the light crop seems to indicate they will be."—*Southern Planter*.

RICE CROPS IN BURMAH.

With the gloomy season prospects in most of the districts in this Presidency, and loss of crops owing to failure of rain it is gratifying to learn that the prospects in Burma are good, and that Lower Burma will be able to export rice to a very large extent to supplement the food supply of India. Crop prospects are everywhere good; seven districts estimate far more than a full average crop, while only the Prome district estimates less than a full average crop. It is estimated that there will be available for export 1,600,000 tons of cargo rice, equivalent to 27,118,645 cwt. of cleaned rice, including what is required for Upper Burma.—*M. Times*, Jan. 11.

NOTES ON PRODUCE AND FINANCE.

GREEN WOOD AND TEA CHESTS.—The condition of the wood from which tea chests are made is the subject of a warning note in the *Grocer*, which says:—"Our readers cannot fail to have noticed that tea in the present day deteriorates, through keeping, with greater rapidity than formerly; and this is particularly the case with that imported from India and Ceylon. But unfortunately an additional drawback has now been prominently brought forward, and consists in an objectionable flavour which some teas possess, and, from the evidence of experts who have had considerable experience in tea gardens, it appears that saw mills often form part of the plant of a garden. When the wood for the packages is used in too green a state the juices produce, in contact with the metal, an acid, which perforates through minute punctures into the tea itself, and creates what is commonly known as a 'cheesiness,' whereby the tea is seriously damaged. If the effect is not immediately developed, the buyer may not discover it until too late, and may be landed with a tea which is not only undesirable, but may lead to a whole blend being vastly effected. Under these circumstances it is evidently necessary that great care should be exercised in seeing that only properly seasoned wood is used, and we hope representations will be made to all growers of tea to secure this much-needed result."

A TEA PROPRIETOR'S VIEW OF THE RUPEE QUESTION.—The following quotation from a private letter gives the views on this subject of a gentleman who directs the affairs of one of the largest Indian tea concerns, and will be read with some interest.—"Mr. Christie, and no doubt Mr. Rutherford, see clearly the injury which would be inflicted on our producers

in Ceylon if the value of the rupee is artificially raised; but, fortunately for them, Ceylon is a Crown Colony, and not under the Government of India, and they may in consequence escape the threatened evil. But the people of India have no such escape. The only hope is that the Imperial Government may not yield to the pressure being brought to bear on them by the Indian officials. I do not think that the cruelty and injustice of the measure is generally known; but the great mass of the vast population of India are 'producers,' and it is clear that if these producers have to pay their rent, their labour and all their costs in rupees artificially raised in value, they are placed at a ruinous disadvantage as compared with their foreign competitors, who pay all their costs with silver at its natural price. This is the great evil of the scheme, but it however, affects all contracts and all debts. All debtors would be required to pay their debts with the dear rupees, all agriculturists would have to pay land rent with the inflated rupees. Can a more dishonest act be imagined on the part of any Government than, after settling the land rent in rupees, to legislate with a view to enhance those rupees?"—*H. and C. Mail*, Dec. 30, 1892.

CINCHONA BARK.

(From *C. M. & C. Woodhouse's Report*.)

LONDON, Dec. 22nd, 1892.

The statistical position continues to improve stocks of bark in London being under 40,000 packages, (more than half of which consists of South American of low analysis and light packages as compared with Ceylon and East Indian). The exports from Java from 1st January to 30th November shew a deficiency of about 1,750,000 lb. as compared with last year, and although Ceylon shipments are larger, yet this may be partly owing to the fact that for some months past East India bark from the Travancore district has been sent to London via Colombo, and has probably been included in Ceylon exports. It is also worthy of notice that at the last sale in Amsterdam on 8th instant. 4,543 packages Java were practically all sold, thus leaving no stock to be carried forward to next sales.

In spite however of the improving position of the article, we have to report a declining market during the past month. The demand at the public sales has been good and almost the whole of the supplies offered were sold, but the value of the unit of quinine has on each sale day been quoted slightly below that of the previous sales. At the last auctions the value of the unit was 1½d to 1 3-16th d per lb. This decline is probably in a great measure due to the prolonged description in the market for quinine, but this cannot last for ever and as consumption is undoubtedly increasing, and we are now coming to the season when during the last two years there has been an extensive demand for quinine in consequence of the influenza, it is not unlikely that (if Java exports continue moderate) we may before long see an improvement in prices both of bark and quinine.

Telegraphic advices from Java state exports during November were 747,000 lb., against 677,645 lb. in 1891.

The imports of quinine into British India for the last three years has been:—

	1892.	1891.	1890.
	lb.	lb.	lb.
1st April to 30th Sept. . .	13,646	10,244	9,115

Imports of Quinine into United States:—

	oz.	oz.
1st Jan. to 31st Oct. . .	3,004,105	2,200,606

Imports of Cinchona Bark into United States:—

	lb.	lb.
1st Jan. to 31st Oct. . .	2,835,699	2,168,778

The Board of Trade Returns give the imports, &c., or bark, as follows:—

	1893.	1891.	1890.
	Cwt.	Cwt.	Cwt.
Imports, 11 months	94,967	96,113	103,253
	£	£	£
Valued at	204,938	228,066	305,717
	Cwt.	Cwt.	Cwt.
Exported, 11 months	102,670	97,126	100,004
	£	£	£
Valued at	187,594	169,520	221,565

The present value of British sulphate of quinine (Howards') in bottle is 1s 2d to 1s 3d per oz. against 1s 3d to 1s 4d per oz. last year.

The present value of German sulphate of quinine (best marks) on the spot is 9½d per oz.

SCIENTIFIC NOTES.

That extreme cold paralyses every vital function is, of course, a piece of every-day knowledge, but it has been left to Professor Pictet, who has been conducting some experiments on this subject, to discover that at a temperature of 150 deg. below the centigrade zero there is no chemical action between nitric or sulphuric acid and potash, or between oxygen and potassium, though under ordinary circumstances the affinity of the latter metal for oxygen is so great that it will burn if thrown into water, owing to its combination with the oxygen in that fluid. But if the electric spark is played on bodies which have thus lost the power of chemical affinity, some new and curious combinations result. The latest investigation, the conclusions of which, however, have been theoretically pre-arranged for some years past, may, says the writer of *Science Notes* in the *Daily Chronicle*, require us to reconsider the question of the temperature of outer space, and the possibility of an atmosphere composed of gases in combination existing there.

One of the most remarkable of trees or shrubs, says the *Horticultural Times*, grows near some springs, about twelve miles north of Tuscarora. It is about 6 or 7 feet, high, with a trunk which at its base is three times the size of an ordinary man's wrist. It has numberless branches and twigs, and resembles somewhat the barberry. Its truly wonderful characteristic is its luminosity, which is so great that on the darkest night it can be plainly seen a mile away. A person standing near could read the finest print by its light. Its foliage is extremely rank, and its leaves resemble somewhat those of the aromatic bay tree in shape, size, and colour. The luminous property is due to a gummy substance, which can be transferred to the hand by rubbing, and with the transfer the phosphorescent light, while that on the leaf disappears. This luminosity is thought to be due to a parasitic form. The Indians regard it with superstition, and will not come near it, even in daytime. They give it a name which means "witch tree."—*Overland Mail*.

THE "KEW BULLETIN" gives the result of certain enquiries as to the composition and use of a preparation called *meing* used for chewing by the natives of Siam. The plant used in the preparation of *meing* is, it appears, none other than Assam tea. It is prepared by steaming the leaves and then burying them in the ground for 14 or 15 days. On being taken out the stuff is fit for use, and will keep good for two or three years. The chewing of *meing* is almost universal, it is stated, amongst the Laos; and it is highly esteemed for its sustaining qualities by those who have to perform hard physical work. On more grounds than one it would seem desirable to exhaustively enquire into and practically test the qualities of this *meing*.

THE CEYLON LAND AND PRODUCE COMPANY.

The visit to the island of the Chairman (Mr. J. Wilson) of this Company directs attention to its progress and position, and a few particulars may not be without interest to our readers. The Company was formed if we remember rightly about ten years ago, the moving spirits being Mr. Alex. Ross of North Matale and Dikoya, and Mr. T. J. Lawrance, formerly a well-known Dimbula planter. Several valuable properties were secured for the Company and Mr. James Wilson whose business connection had previously been with China, became Chairman of the Board with two or three capitalists as co-Directors; Mr. Ross became Manager and Inspector of Estates in Ceylon, and Mr. Lawrance, the Secretary to the Board. The strong point with the new Company was the cacao on their estates; but they quickly went in for tea to supplement the coffee and now they have altogether some 2,000 acres under tea, and about 800 in cacao and coffee. When Mr. Ross returned to Europe some years ago, the agency and management of the Company's business in the island was taken over by Messrs. D. Edwards & Co., Hatton, while Mr. Forbes Laurie became Inspector or Visiting Agent; and soon after another Secretary took the place of Mr. Lawrance though the latter retains a considerable interest in a Company which may be said to have originated with him and Mr. Ross. The Company has recently had a prosperous career and the latest Report, which we publish on page 530, announced an ordinary dividend for the year at the rate of 15 per cent besides 6 per cent paid on the Preference Shares. The strong point about the Company is its having several products on its plantations, and more especially cacao and Liberian coffee in addition to tea. We have no doubt that Mr. Wilson—who is a keen man of business—will be interested and pleased with all that Mr. Laurie has to tell him about the Company's properties, and what he may see in going round. These include that fine tea plantation New Peradeniya, with some 360 acres of the staple product; Fetteresso in Bogawantalawa with 329 acres; Rickarton in Maskeliya with 500 acres; the North Matale group covering 1,500 acres in extent with about 400 acres in tea and 600 in cacao, coffee and tea; besides some cardamoms; also Allooowihare and Dickeria in Matale West with about 550 acres of cacao, Liberian coffee and some tea; besides some minor properties. We hope the result of Mr. Wilson's visit will be to extend the Company's interest in such products as cacao and Liberian coffee and that he will have a pleasant time during his stay in the island.

TEA SORTING AND CUTTING.

MESSRS. DAVIDSON & CO.'S NEW MACHINERY.

There has been a good deal of talk lately regarding the application of the principle employed in Messrs. Davidson & Co.'s new cutting and sorting machines, many considering that the "rotary" sorter was a thing of the past, and one which could not be made to give satisfaction. We are now, however, glad to be able to congratulate Mr. S. C. Davidson on having overcome the difficulties previously experienced by the invention of his new rotary sorter, which, from all we hear, has turned out a great success, and which, we understand, is likely to be appreciated by the planting community in general. When it is taken into consideration that with this new machine the

customary weight of upwards of half a ton, which in other machines has to be shaken backwards and forwards in order to sort a few pounds of tea, is entirely done away with, the enormous saving in wear and tear, and power required to drive, will be fully appreciated. The new machine glides off without a vibration when the belt is moved on to the fast pulley, and it would practically be noiseless, were it not for a couple of iron balls which are placed on slides inside the revolving cylinder; as it rotates these balls drop with a sharp concussion twice in every revolution, thus imparting a shock to the mesh which knocks out any bits of tea that may be sticking in it. In practice, however, it is found that these balls are not absolutely required, for should any bits of tea stick in the mesh, a tap with the cooly's hand on the cylinder frame will do the needful.

The maker estimates that this machine will sort no less than 1,000 lb. of tea per hour. The new cutter and separator in its construction, workmanship and general appearance reflects the greatest credit on the firm from which it emanates. The following remark made by a well-known practical factory superintendent when reporting to his firm on the working of the machines speaks volumes in itself:—"The machines are out and away the best in the market." During a trial of the sorter and cutter in Mayfair Factory, Dikoya, the sorter turned out tea at the rate of 1,684 lb. per hour, thus working nearly 70 per cent over the maker's estimate. The quality of the work done was all that could be desired. That this machine is capable of manipulating such enormous quantities of tea in so short a space of time will be found a very great advantage. Large or small factories will be able to sort their tea in a few minutes daily or they need only work their machine once or twice a month, thus economizing power, labour, and wear and tear to belting, shafting and machinery.

The main feature of the cutters is that they cut the tea longitudinally thus giving it a wiry appearance instead of the usual "choppiness" observed in most cut teas. The knives and rollers can be regulated so as to cut to any degree of fineness and the separating sieve can be set at any required angle so as to take more or less fine tea out of the coarse. These machines can be controlled in every respect with remarkable nicety; and we again offer our congratulations to the inventor, who has spared neither time nor money in bringing them to perfection, and who has done so much for the tea industry in general.

VARIOUS NOTES.

A RECORD IN COFFEE.—Yesterday coffee in Singapore was sold at \$34 per picul. This is a record price so far. May it cease to be a record soon.—*S. F. Press*, Jan. 5.

IT APPEARS THAT TEA-CHEWING is really a more common habit than most people dream of, and I do not see why the *H. & C. Mail* should apply the adjective *infernal* to it more than to the chewing of tobacco. There is really a great deal of rubbish talked about tannin and the nerves. We know Australians who boil their tea for hours are not particularly nervous. I came across a man here the other day, a Queen's marksman who has perhaps gained more prizes for shooting than any other Scotchman; he says he is a great tea-drinker, insists upon having it 'drawn' for 20 minutes, and *chews continually* a mouthful of leaves! Yet this man is about the most perfect picture of health I have seen for many a day. Why should we discourage the habit? Rather prepare a special leaf for the purpose, well matured and dried something like hops.

CACAO AND LIBERIAN COFFEE.—We call attention to the practical letter of "Experto Crede" (on page 545) and earnestly back up his counsel to his brother planters to go in for these two products in addition to tea, wherever possible.

THE TRIUMPH OF ART over nature is illustrated in the fact that an artist recently made a painting of some beech trees in an old pasture that he sold for \$280. The owner of the pasture parted company with his property at about the same time for \$150, and called it a good sale at that. *Augusta (Me) Farmer.—American Grocer.*

THE FLORA OF CEYLON.—With reference to the advertisement of this work in four parts at £3 13s 6d in advance, there is a mistaken notion as to the price in proportion to the cost of printing and publication. The price is large, no doubt, but not really high as compared with similar books, indeed it is less than most of them. For, 100 quarto coloured plates must cost from first to last quite £1,200, and there is of course the text besides, probably involving another £500—a large expenditure altogether to be recouped by the sale of copies.

OUR TEA TRADE IN 1892.—This is how the *London Financial Times* of December 30th, 1892, reviews the year's tea trade:—

Tea producers have certainly reason to be pleased with the results of the year. Prices, it is true, were low, but that very feature is no doubt accountable for the very large home consumption of 207,000,000 lb. and was also probably a strong factor in substituting Indian and Ceylon teas for those of China. The change in the public taste has been very rapid during the past twelve months; and the consumption of Chinese tea has in consequence fallen from 52,000,000 lb. in 1891 to 34,000,000 in 1892, while the use of Indian tea increased from 99,000,000 lb. to 109,000,000 lb. and Ceylon teas from 51,000,000 lb. to 64,000,000 lb. in the same period. The increased consumption, combined with more remunerative prices, due to the crop barely equaling that of last year, is certainly encouraging to planters, while the danger of over-production is for the present indefinitely shelved.

FARMERS AND PLANTERS:—How far do they correspond may be asked after reading the following extract from a home paper:—

Are farmers the most docile of mankind? It would almost seem to be so if we understand aright the words quoted in the report on the Distribution of Grants for Agricultural Education in Great Britain just issued by the Board of Agriculture. At page 43 we read: "There are few farmers, it is to be feared, who will study or even perhaps read, steadily and attentively, through a report of agricultural experiments however brief. Not a few farmers appear to have an extraordinary lack of appreciation of the practical value of properly conducted experiment, as compared with their excessive reverence for a more or less unverified experience." This is certainly trenchant criticism, and there is nothing in the statement to indicate that it does not apply to the whole race of farmers without exception. The teachers and the funds necessary to instruct them in more scientific and therefore more profitable ways of farming are all ready, but in the words of the report they prefer still to be guided by their own uncertain and undefinable experience. There seems to be nothing for it but to catch the farmer young enough—in fact, before he has signed his first lease—and get some better ideas into his mind, and then, perhaps, he may think that after all there is something in scientific agriculture.

We suspect one reason why Ceylon planters have usually taken such an intelligent interest in all that concerns their branch of agriculture is that they begin their tropical work at an early age as a rule.

CEYLON TEA EXPORTS FOR 1892.—It is of interest to refer to the figures supplied by Messrs. Forbes & Walker in their closing circular for 1892. Thus in respect of the United Kingdom, this is how they show the exports of Indian and Ceylon tea to stand:—

Export to the United Kingdom.

From	1891	1892	Increase
India	94,750,000	96,000,000	1,250,000 lb.
Ceylon	63,300,000	64,790,000	1,490,000 "

Total 158,050,000 160,790,000 2,740,000 lb.

Much more satisfactory, for us in Ceylon, is it to turn to the figures for,—

Export to Australia and New Zealand.

From	1891	1892	
India	4,105,000	3,300,000	805,000 lb. (dec.)
Ceylon	3,200,000	5,105,000	1,905,000 "

Total 7,305,000 8,405,000 1,100,000 increase

To other countries, notably America, we have by no means so good a comparison; but then the exports of Ceylon tea to New York are chiefly made from London.

THE REPORT OF THE DIRECTORS OF THE GEMMING AND MINING COMPANY OF CEYLON (LIMITED) states that after the issue of the last report the directors came to the conclusion that it was expedient to pay off the European establishment at the mines, to stop all gem mining going on at own account, and lease the gem lands to the highest bidders. The result shows that the native miners know the value of the lands for precious stones, as the mining rights were at once let for £3,200 per annum to responsible parties. The rent has been paid regularly, and the first year's lease having nearly run out the gem lands will again be put up to public competition. Plumbago mining has met with varied success, 164 tons having been brought to surface and sold, producing to the company £28,733. The directors regret that they are unable to place a more satisfactory report before the shareholders, but they still hope that by success in plumbago mining, and the lease of their gem lands, the company may be placed in a better position and as the capital was low, and the shareholders objected to a further call, the directors felt that the best course to adopt was the one now submitted to the shareholders.—*Mining Journal*, Dec. 12, 1892.

TREES AND BIRDS IN THE TEA DISTRICTS.—Next to the cultivation of useful timber and fuel trees on our tea plantations as shelter belts (and disease preventives!) we place in importance the encouragement and "cultivation" of insect-eating birds. But indeed, the one is very much dependent on the other: plant and grow the trees and we shall soon see them occupied, though it may also be wise to introduce or encourage certain of the mere useful of insect-feeding birds. Here for instance is a paragraph to illustrate our meaning:—

Ladybirds are known at home as great wheat-pest destroyers. In America and the Colonies also they are numbered among "friendly insects." The Australian ladybird (*Vedalia cardinalis*) has cleared the Californian orange orchards of their most deadly enemy, and one of the field agents of the Entomological Division of the United States Department of Agriculture has lately visited the Australian Colonies in search of other friendly ladybirds and other insects which feed upon the scales and aphides that so greatly trouble the American fruit growers.

Now, we want the bird who will feed on the yellow tea mite (*Acarus translucens*) which troubled the Matale tea last year, and still more do we require to encourage every possible enemy of red spider and of the tea bug or *Helopeltis*.

A CACAO, TEA AND LIBERIAN COFFEE COMPANY.—We should be glad to see the Ukuwella Company, from whose prospectus we quote freely (see page 527) liberally supported, because it is to promote the cultures of Cacao and Liberian Coffee as well as Tea. The prospects, too, are very good with an assurance of 10 per cent dividend in 1896 and property then worth a great deal more than the paid-up capital. To have several strings to its bow should be a distinct recommendation for a Ceylon Planting Company in the present day.

“**COCOA: ALL ABOUT IT**”—is the title of a popular work by “Historicus” and published by Sampson Low, which affords some odd, out-of-the-way information respecting this product, accompanied by engravings, some of which are decidedly curiosities. These are reproductions of plates from old books (1680 is the date of one of them) on chocolate; but again there are interspersed a good many modern plates, some of them coloured, of the trees and pods. We have a history of the cultivation, use, analyses, and manufacture of cocoa (extracts respecting Ceylon being made from our Handbook). There is also a chapter and appendix on vanilla with useful information. But the great feature of the volume undoubtedly is the chapter on manufacture, devoted with coloured plates to an account of Messrs. Cadbury’s establishment at Bournville, the “Worcestershire Eden” which makes it look as if the book were got out in the interests of this firm—no doubt one of the very important manufacturing houses of cocoa and chocolate; but by no means the sole representative of British manufactures by a long way. However, the little book before us affords a great deal of useful information in a popular interesting way about cocoa and should help to promote the consumption of this food product considerably.

CHINESE LABOR IN BRAZIL.—The *Rio News* of Oct. 11 says:—

Now that it has been decided that the Chinese may be imported, Congress should lose no time in passing two necessary measures—one providing for their proper transportation to and from this country, and the other protecting them while here. The great distance at which they must be procured renders it necessary that stringent laws should be provided to prevent over-crowding and bad treatment during the voyage. If this is not done it is certain that we shall have to again record abuses and atrocities which will raise a storm of indignation throughout the civilized world. As for the second measure, it must be evident to every well-informed person that present labor laws will not protect the Chinese laborer in this country, and also that a very large proportion of employers will take advantage of their helplessness to rob them of the petty wages they may earn. The recent experiences of immigrant laborers here is a proof of this assertion, and if this is not enough we have only to call attention to the treatment which the freedmen received after emancipation. Of course, there are many planters who treat their laborers justly and humanely; of these we do not speak. But it is against the hundreds who are hard, cruel and unjust, that these helpless laborers must be protected. The government can now make the necessary provisions, for the traffic has not yet begun. Will it do so, or must we see slavery re-established in Brazil, with all its abuses and unrestrained oppression?

A COFFEE ASSOCIATION IN BRAZIL.—The *Rio News* of Sept. 27 says:—

The scheme now under consideration for the organization of a central association of all classes interested in the coffee trade, is so decidedly good that it needs no advocacy. For a branch of production and commerce representing so much money and such vast economic interests, an association of this character is a necessity, and it reflects very

little credit on those interested that such an organization was not long ago effected. The questions constantly arising as to production, transportation, grading and shipping are so important that they require the best study and solution that the whole trade can give them, and these alone demand co-operation. Such an association could easily undertake to secure information in details of planting and to encourage experiments tending to an improvement of the product, all of which would be of direct benefit to the country and to the reputation of its principal product. No such effort has ever been made, although its advantages are clearly apparent. In questions of transportation it could not help being of incalculable benefit, particularly at the present time. The costs of marketing the product and the obstacles met in handling it in this port, are also questions of pressing importance, and which will never be solved until all the classes interested are brought more closely together and are made to see that their interests are dependent upon each other, and not antagonistic. By all means let the association be formed and then let us have concerted action in carrying out improvements which all must admit are most necessary.

PORTUGUESE SULPHATE OF QUININE.—It may be remembered that about two years ago, when the relations between this country and Portugal became unpleasantly strained over the now almost forgotten Manica dispute, public opinion in Portugal ran strongly in favour of the emancipation of the kingdom from dependence upon British goods. We mentioned at that time that among the projects that were planned was one for the establishment of a factory in Lisbon, in which the Portuguese-grown cinchona from the Island of San Thomé should be converted into quinine. Since that time the imports of San Thomé bark into London have considerably increased but it would seem, nevertheless, that quinine making in Portugal has become an established fact, for Mr. David, in the course of a speech at a social gathering mentioned elsewhere, stated that he had recently had occasion to examine a sample of quinine manufactured in that country. Mr. Howard’s opinion of the product was not flattering, for he considered the specimen absolutely the worst he had ever come across in his experience. —*Chemist and Druggist.*

THE JAVA CINCHONA PLANTATIONS.—The quarterly report of the Java Government cinchona plantations for the three months July—September, which has just been published, states that the abnormal weather of the period described has caused a great deal of disease, not only among the young trees, but particularly among the nine and fifteen year old plantations. The disease manifested itself in the reddening of the leaves upon the young shoots and in root-cancer. The seed did not ripen this season, and no seed auctions have been held. Scarcity of labour accounted for the smallness of the bark output during the quarter under review, and had it not been for the employment of the regular hands upon the work of harvesting, that branch would have come to a standstill altogether. The new mode of harvesting, first adopted in 1891 and continued this year, consists in the scraping of the stems and branches of the smallest trees in the plantations, in order to limit their growth, and thereby to afford more room for development for the heavier trees, the bark of which is at present left intact. It is possible that the scarcity of labour referred to in this report may have made itself felt at the private undertakings in an acuter form even than at the Government plantations, and that therein, rather than in approaching exhaustion, lies the reason of the marked diminution in the Java cinchona exports which has been observed this season.—*Chemist and Druggist.*

PRESSED TEA.—The Mokhumpore tea estate management, at Debra Dun, have introduced a decided novelty in their pressed tea. It is simply tea, unmixed and unadulterated, compressed into a third of the space it usually occupies. Pressure makes a pound of tea take the size and shape of one of those peat blocks still to be found in the more remote West county villages. The aroma of the tea is preserved, and thus a cheering cup becomes much more easily obtainable on occasions when the bulk of the leaf would ordinarily make it impossible.—*Pioneer*.

UTILITY OF COUNTRY COKE.—A correspondent writes to the Editor of the *Englishman*:—"With reference to your interesting account of the large casting that was recently made at Jamalpur, I would point out that this shows what can be done with materials of Indian production, and in these times of low exchange the Government of India might save no inconsiderable sum if country coke were more generally used in its manufacturing departments. Large quantities of imported coke are at present used in the Ordnance, Marine and Public Works Department, the cost of which is three to four times greater than that of Indian coke. Allowing for the admitted superiority of English coke, there would still be a saving of at least one-half of the amount paid if Indian coke were used instead. As Government is anxious to foster local industries, it need only be pointed out to them where an opening exists for the exercise of their praiseworthy efforts."—*Indian Engineer*, Jan. 7.

EUCALYPTUS OIL.—One of the most remarkable instances of sudden inflation of value in the price of a drug occurred early in the year, when eucalyptus oil was seized upon by a panic-stricken public as a prophylactic for cholera and influenza. The rush upon the article took the importers unawares. The oil had been greatly neglected for a long period, and, as shipments had ceased to be profitable, the imports had fallen off considerably without anyone heeding the fact. So, when eucalyptus became the remedy of the day, there was very little available supply, and, though consignments were hurried forward, a hiatus supervened sufficient to enable holders to advance their prices to a point many times in excess of the anteprecursor days. Unlike other cleverly-boomed articles eucalyptus has stood the test of usefulness as an influenza prophylactic and disinfectant fairly well, and its employment has been materially extended as a result of the run upon it.—*Chemist and Druggist*, Dec. 31, 1892.

THE FIJIANS AS TRADERS.—The Consul at Suva, Fiji, reports to the Foreign Office that during the year 1891 Tonga was happily free from any political or religious disturbances. In February the Government ceased accepting copra by way of taxes, up to which date it had been received at the rate of 14lb. for 1s (or 8l per ton), while the large mercantile houses were giving 10l per ton to white collectors, and time bargains made then are still in force for 10l 10s per ton. As the year advanced the price of this export (practically Tonga's one) fell considerably, and at its close the natives were only receiving 1s for 20lb. or at the rate of 5l 12s per ton; and small traders, upon whom devolves the trouble of purchasing and collecting in small quantities were only able to obtain from 6l to 6l 10s from the exporting houses. Some few contracts were made for copra at 8l per ton to be delivered, free on board, at Vavau. At such low prices the natives have not cared to sell copra but preferred to wait for a rise in the market. Trade has in consequence been dull, and taxes have not been properly paid. The natives are unfortunately falling into arrears with their taxes. It was noticed during the year that owing to the

Samoan Government deciding not to accept German silver marks as legal tender, this coin in large quantities was again being introduced. Tonga is now the only place in the South Pacific where this inconvertible coin is accepted as currency, even at a discount. Although, for internal purposes the mark may be as useful as a shilling, still when it is considered that Tongan direct trade is exclusively with countries in which the German mark is not a legal tender, it is to be regretted that the Tongan Government does not wholly exclude it from circulation, as has been done with great commercial advantage in Samoa. During the months of November and December the islands suffered from a severe epidemic of influenza, causing the death of a great many of the natives. The epidemic was so severe as to greatly affect trade, little business having been done during the months specified.—*O. Mail*.

COFFEE CULTIVATION at Nellakotta is said to be progressing by leaps and bounds. The *Nilgiri News* states that in the last three years the area under coffee has been trebled, and that an addition has just been made to the planting community in the shape of a new superintendent; Mr. Walker, of Vayitri, having found it necessary to increase the number of those entrusted with his growing interests. By the way, that expression "growing interests" is aptly chosen.—*M. Times*.

TEA AND LIBERIAN COFFEE IN SOUTH WYNAAD.—The Crop dribbles on, it will not ripen properly, and stripping has already commenced on several estates. I heard a grewsome tale the other day of canker having broken out in arabica, but I think this must be a mistake. And I hope so, its quite bad enough to have it in our cinchona. I am accused of "wailing," but why "Fac's is stubborn things," but I am always only too ready to admit a bright side to our prospects, I am not, as your veracious correspondent, going to tell you that we are rapidly making our fortunes with arabica, because it would just be anything but the, "true word," but I am quite prepared to nail my colors to the mast, in defence of Liberian, and tea, and the future possibilities of Wynaad, if anybody will only come and realize how good a land it is, and how splendid a field of enterprise lies therein for those who have more money than they know what to do with! Unfortunately most of us are *not* in that position, but the few who have already been able to open for the new products are rightly full of pleasant expectations, which I firmly believe will in a few years time be realized.—*S. of I. Observer*, Jan. 11.

GRAND SCENERY IN NORTH QUEENSLAND.—The *London Times* has a special commissioner at present writing from Queensland. From his latest letter we quote the following passage:—

The falls of the Barron River, which flows out to the sea at Cairns, are counted as one of the most beautiful pieces of North Australian scenery. The falls themselves are about 600ft. high, and they occur in a narrow pass in the range of coast mountains 1,300ft. above the sea. With them the river drops into an irregular y-shaped gorge, of which the sides are densely covered with jungle and lined with bold spurs of red rotten slate. The railway line to the interior, of which only 30 miles or so have been completed, traverses this gorge, and is thrown on piles from spur to spur at a height of 500ft. or 600ft. above the bed of the river. There is scarcely a spot at which a handkerchief might not be dropped from the train into the water beneath, and as the line descends through the windings of the gorge the mountains on either side frame pictures of a landscape widening over Chinamen's gardens and acres of bananas and pineapples to the coast. Here the cane fields of Hambleton Plantation stretch in a sea of green across the feet of jungle covered hills. A little further down upon the Johnstone River the plantation of Goondi and Mourilian spread palm-rimmed from the banks of the river to the edges of the still uncleared scrub,

Correspondence.

To the Editor.

FRESHLY PLUCKED TEA SEED—HOW TREATED.

Colombo, 2nd Jany. 1893.

SIR,—A large quantity of tea seed locally grown is now bought. Can you or some qualified reader inform me how best to treat seed freshly plucked from the trees? Should it be put into a germinating heap at once or kept for a time? If the latter how kept and for how long?

Perhaps Dr. Trimen may consider the subject worthy of remark.—Yours, &c., B.

[What does our correspondent exactly mean? Dr. Trimen will tell him that tea-seed, like all other seeds and especially oily ones, should be sown as soon after it is fully ripe and plucked as possible. We cannot imagine any advantage in keeping it.—Ed. T.A.]

A WORD FOR CACAO AND LIBERIAN COFFEE.

Jan. 11th.

DEAR SIR,—Re prospectus of the new Cacao, Tea and Coffee Company and your appreciative notice of the same, the latter being in continuation of your recent writings on the same subject, you cannot too earnestly impress upon your readers the advisability of cultivating other products in addition to tea, and the very imminent danger there is of the latter being overdone.

That can never happen to Cacao, in Ceylon at least, the area of perfectly suitable land being very limited.

There is a wider field for Liberian Coffee, which in fairly warm and sheltered districts will give a fair crop up to 2,000 ft. above sea level. It gets leaf disease, of course, and bug but it is very hard to kill.

I have 20 acres planted 10 years ago among cacao, by which it is being slowly, but surely rubbed out. The parent trees had their home in Ceylon and suffered from bug and leaf disease from their infancy; and yet this coffee gave me 150 bushels dried cherry this last season, or 7½ bushels, value B35, to each acre: the cacao at the same time giving a full crop. Naturally better results would have been obtained from selected seed. Arabian coffee, too, will grow to pay well in land on which it has not been cultivated before; but fresh seed should be imported. Vacancies in tea after second year should be filled up with either variety according to elevation and climate, and the trees should be allowed to grow up at their own sweet will.

No topping, no pruning.

EXPERTO CREDE.

P.S.—Close planting is advisable. Liberian coffee 6 by 6; Arabian 4 by 4, supplemented in either case, where the climate suits, by cacao, 12 by 12.—E.C.

Kew Gardens.—A large bed of the Gladiola (Childsi) was seen in Kew Gardens last summer and attracted much attention. At that time they were not named, but Mr. Watson, the Curator, writing to the American paper, *Garden and Forest*, stated that "the raisers might be congratulated on the excellence of their seedlings; that some of the spikes were fully six feet high, well furnished with flower larger than any other Gladiolus previously seen, and that the colours were brilliant, as well as variable." Prices will be found in our Advertisement Pages.

STAPLE EXPORTS FOR TEN YEARS : DISTRIBUTION OF PRODUCTS OTHER THAN TEA.

Not much can be made out of our oldstaple "Coffee" and yet it is a matter of considerable interest, as showing how our trade with the Southern Colonies is growing, to note that out of our small export of the fragrant berry, no less than 9,856 cwt. or over 23 per cent of the whole, went last year to Australasia. The United Kingdom got 56 per cent of the total shipments and Austria direct, 6,200 cwt. or about 15 per cent. Of our Cocoa, Australia takes scarcely any and yet if the product were prepared in Colombo as it is by Messrs. Shand and Haldane, among others, in England, we feel sure there would be a good demand from Melbourne, Sydney and other big Southern towns. As it is all our Cocoa goes, practically, to London save last year, 1,106 cwt. direct to America and 1,029 cwt. to "Singapore" of all places. In "Cardamoms," India,—that is we suppose, Calcutta mainly—is almost as good a customer as the United Kingdom; for, in 1892, as many as 170,503 lb. went to the former against 174,096 lb. to London; while Austria, Germany and America took small quantities direct. The export of Cinnamon is much more freely distributed, the direct shipments to the Continent of Europe, especially to Germany, being very large; while appreciable quantities go to India, Australia, America and the Far East. This is also true of the produce of the Coconut Palm and the following summary statement is worth compiling for these staples:—

To	SHIPPED IN 1892.			
	Cinnamon lb. bales.	chips.	Coconut Oil cwt.	Copra cwt.
United Kingdom..	936,855	97,829	123,033	30,594
Continent of Europe	858,938	464,832	54,197	82,256
America ..	75,000	—	191,425	—
Australia ..	5,877	11,196	1,704	—
India ..	28,150	41,298	116,208	21,051
Far East ..	42,718	—	64,410	114
Other Places ..	—	—	—	575
Total ..	1,947,538	615,155	550,977	134,590

Of the new product, "Dessicated Coconut," while London took nearly 85 per cent, there were last year appreciable exports to Germany, America, Australia and "Africa." The latter surely means Egypt? And if so it may also have got the 650,000 coconuts down for "Africa." Australia, America and the Far East are also fairly good customers of ours for Coir, especially for "Coir Rope," none of which goes to Europe, though "Yarn" and "Fibre" are largely sent to London and the European Continent. Of Citronella Oil, America takes direct nearly as much as the London market; while India and Germany last year got considerable shipments.

Of the only mineral in the Chamber's table, Plumbago, America now takes direct a much larger quantity than is sent to London and this American trade showed a large increase last year over 1891, while the trade to London has gone back. Germany, Holland and Belgium are each entered for direct shipments on the whole showing an increase.

We have still to notice Cinchona Bark, the total export of which in 1892—notwithstanding all the prophecies of the Ceylon trade collapsing—was more than a million lb. in excess of that of the previous year. Where has this increase come from? Not, we are assured from Uva, nor from the Dimbula-Dikoya districts: there has been no increased "harvesting" in our planting districts, because in reality the harvest was not there to gather. The extra million or perhaps a couple of millions of lb, it seems, must have been drawn from

Colombo stocks, the attraction being not so much better prices at home as the very low exchange and freight which have latterly prevailed. Of course, in this connection, it would be interesting to know what stock of bark remains in Colombo and what prospect there is of further harvestings upcountry. About the latter we may have reliable information a little later; but meantime we think we may confidently say that there is no probability of Ceylon exporting 6, or even 5 millions lb. of cinchona bark during 1893. There can be no doubt, that the quinine and bark markets are once more approaching an interesting stage; for while the consumption of quinine has very largely increased, owing to its cheapness, and big profits are once more made by manufacturers, it is very doubtful if Java or the other bark-supplying countries will be able to go on shipping all the bark now required, at any rate without the inducement of better prices. There are not many in Ceylon now to profit to any great extent by an improved bark market; but still a rise in the unit of from 25 to 50 per cent. even, during the current year, would be acceptable to those who hold, or are able to harvest, bark. The following review of the "Quinine and Cinchona" markets during 1892 from the *Chemist and Druggist* is of interest, in this connection:—

The quinine and cinchona traders have not been greatly disturbed this year. "Association" and "syndicate" rumours were, indeed, as plentiful as usual, but up to the present nobody is one penny the worse or the better for them. In April it was reported that a syndicate of bark-buyers, with a capital of 25,000*l.*, had been formed in Amsterdam, but that syndicate, like certain chemical combinations, existed, if at all, in the nascent state only, and was never heard of again. About a month afterwards an elaborate preliminary prospectus of the "Cinchona Association (Limited)" burst upon the world, which did not seem to be greatly disturbed by its apparition. The "Association" was to have its headquarters in London and Amsterdam, and was intended to embrace all mercantile firms and planters interested in the bark-trade. Its actual incorporation, however, was not to come to pass until the unit had fallen below 1*d.* per lb., and as that contingency has not yet been realised, the Association still remains an ethereal essence. The direct consignments of cinchona-bark from Java to one of the German factories have ceased, and there has been a good deal of talk of the desirability of founding a quinine-factory in Java. Elaborate plans have been drawn up, showing that the profits of such an enterprise would probably be very great, and, with an improved market, might become almost fabulous. The Java planters' enthusiasm, however, has not yet reached the practical height of planking down the cash. Meanwhile the low quinine prices continue, and yet one of the principal German factories has paid a 30-per cent. dividend to its shareholders. We have not heard much of any discoveries of processes for the manufacture of artificial quinine, although an attempt to prepare methyl-cuprine, which is identical with quinine, from currea-bark proved successful. Unfortunately for the discoverer, it is at present much cheaper to manufacture quinine direct in the usual way.

THE GEMMING AND MINING CO. OF CEYLON, LIMITED.

A BETTER YEAR AND AN IMPROVED OUTLOOK.

The third ordinary general meeting was held at the offices of the Company, 184, Gresham House, Old Broad Street, on Thursday, the 22nd ult.

MR. THOMAS DICKSON

presided.

The Secretary having read the notice convening the meeting,

The CHAIRMAN moved the adoption of the report and accounts, and said that although the year 1891 had not been so prosperous as they could have wished, the directors had done their best by cutting down expenses and leasing the gemming ground to make both ends meet. The plumbago mining had enabled them to tide over their difficulties and put them in funds to the present time; and he was happy to find, from a supplementary statement which had been prepared and was now laid before the meeting, that the receipts this year from all sources amounted to 1,246*l.* 12*s.* 8*d.* whilst the expenses had been only 847*l.* 14*s.* 1*d.*, leaving them with

A CASH BALANCE IN HAND

this day of 398*l.* 13*s.* 7*d.* He hoped, therefore, that the year 1892 would, when completed, compare favourably with 1891.

A SHAREHOLDER suggested that in offering to lease the gemming land for another year, the Company would do well to fix a minimum sum, as there was no doubt a disposition on the part of the natives to get it as cheap as possible, whilst, perhaps, they might have such good finds in the shape of sapphires and rubies as to bring their profits up to a 1,000*l.* or more. He also thought as the meeting was very late in the year, the supplementary statement of accounts might have been issued with the audited accounts, so that the shareholders might see that the property was really doing better than they were led to suppose from the accounts brought up to the end of 1891.

The CHAIRMAN, in reply, stated that the suggestion as to placing a minimum figure on the lease should be attended to. They were already alive to the desirability of getting the natives to compete, and had instructed their agent at Colombo to have the property advertised in Cingalese and Tamil in the local papers. With regard to the meeting being later than last year, this was owing to

A CHANGE IN THE MANAGEMENT,

which caused an interregnum in the accounts, and as the auditors could not pass them in the time rendered, the books and accounts had to be returned to the present manager for completion. These have now been put in order and duly audited, as will be seen from the auditors' certificate to the balance-sheet.

The directors' report and accounts were then put to the meeting and carried unanimously.

Mr. James Wiseman was re-elected director, and Messrs. Lovelock, Whiffen and Dickenson re-appointed auditors.

ORANGE FLOWER WATER.

The orange growers in the south of France have long been dissatisfied with the terms paid them for their produce by the local distillers, who are their only possible customers. They have, therefore, decided to form a co-operative society for the distillation of their produce and the sale of oil of neroli, orange flower water, and the like. Each shareholder will undertake to deliver the whole of his produce to the society, and it is estimated that the output of the first season's work will be 600 kilos of oil of neroli and 600,000 liters of orange flower water. The sale price is expected to be 30*fr.* per kilo for the oil, and 0.50*fr.* per liter for the water, and upon this basis the society will be able to pay the growers 0.65*fr.* per kilo for their flowers and a dividend of 7 to 8 per cent. on the capital.—*Oil, Paint and Drug Reporter.*

FARMYARD MANURE.

A neat little pamphlet printed at the Happy Valley Orphanage Press is "An Essay on Farmyard Manure," a copy of which we have received from the writer Mr. E. T. Hoole, agricultural instructor. The essayist has carefully studied the opinions of home authorities for and against manure as a fertilizer and he gives a very good

summary of these showing how they apply or do not apply locally. The concluding part of the essay is worth quoting:—

In conclusion, let me point out the great ignorance and negligence that exist among most of our countrymen, about farmyard manure. They are blind as regards its valuable qualities. True, some of them manure their fields and gardens with it; but this is more the exception than the rule, especially in many parts of the South and West of our Island. It is astonishing to see the reckless manner in which valuable manure is wasted by the majority of our goiyas. They are nothing of the large quantities of droppings that may be had on the roads and compounds and from the public cattle stalls. This indeed is bad enough; but it is shocking to find that they do not make cattle sheds for housing their own animals at night and collecting the manure. They are sometimes tied in the open; but very often they are left to wander about on the roads, jungles, meadows, &c. Many villagers seem to have a prejudice against the use of farmyard manure.

In some places, the leaf of the "Keppetiya" (*Croton tacciferum*) which is easily procurable in the low-country jungles, is used for gardens as a favourite substitute for farmyard manure. I will not say a word against the use of this leaf as green manure. As such it has special virtues and deserves to be in good repute. But it is nonsense to suppose that it can supply the place of farmyard manure. An exhausting system of burning the land is also practised instead of manuring it.

JAVA CINCHONA AND CUBEBS.

The exports of cinchona and cubebs from Java during the four months from July 1 to October 31 have been:—

	1892	1891	1890	1889
Cubebs piculs	1,198	714	860	303
Cinchona, Govt. plantations lb	204,435	288,751	64,208	231,410
Cinchona, private plantations lb	2,040,943	3,488,974	2,035,890	1,600,888

Total ... 2,245,378 3,777,725 2,100,098 1,832,298

The quality of the cassia oil which has recently been brought to market in Hongkong has proved extremely unsatisfactory; the highest quality (No. 1) is wanting altogether, and the percentage of cinnamic aldehyde in parcels pretending to answer the test (70 per cent is required to attain the standard) is greatly deficient.—*Chemist and Druggist.*

THE AMSTERDAM CINCHONA SALES.

The bark auctions to be held in Amsterdam on January 12th will consist of 212 cases and 6,017 bales (about 530 tons), divided as follows:—From Government plantations, 49 cases and 324 bales (about 33 tons); from private plantations, 163 cases and 5,693 bales (about 497 tons). This quantity contains: Of *Druggists' bark—Succirubra*, quills, 212 cases; ditto broken quills and chips, 176 bales; ditto root, 47 bales. Of *Manufacturing bark—Ledgeriana*, broken quills and chips, 4,280 bales; ditto root, 860 bales; *Officinalis*, broken quills and chips, 74 bales; ditto root, 19 bales; *Hybrid*, broken quills and chips, 499 bales; ditto root, 62 bales.—*Chemist and Druggist.*

COFFEE.—Have any of our planting readers experimented with the *Maragogipe* coffee plant, and if so, to what extent and with what results? There is a very showy little field of this variety on the "Sophia Estate" at Kullutty, and the plants so far (nearly three years old) have developed a fine healthy and vigorous habit. They made a decided push of blossom at the commencement of the season, but of which they were promptly denuded from motives of policy. A good deal has lately been done in the way of putting out shade-trees on the above mentioned estate, and one of the best kinds with rapid growth would appear to be the species of jungle tree, the native appellation of which if we mistake not, is "howlegé" and is extensively utilized by Mysore planters.—*Nilgiri News, Jan. 4.*

THE KOLAR GOLD FIELD FOR 3 AND 7 YEARS.

MYSORE.—During last month 3,910 tons of quartz crushed at this mine produced 3,320 oz. 11dwt. of gold., while 817 oz. 8dwt. were obtained from 4,413 tons of tailings treated. The following are the monthly returns for the past three years:—

	1892	1891	1890
	Oz.	Oz.	Oz.
January	5,578	5,360	5,003
February	5,573	5,452	5,884
March	5,023	5,477	5,869
April	4,436	5,506	4,571
May	4,938	5,729	4,263
June	4,018	5,560	4,461
July	4,924	5,650	4,174
August	5,529	5,790	4,118
September	6,043	5,326	4,258
October	6,154	5,912	5,014
November	6,032	5,618	5,250
December	6,137	5,121	5,316

Total 64,385 66,501 58,181

The yield of the mine in the year just closed, viz., 64,385 oz., was worth a little over a quarter of a million sterling, or some £8,000 less than in 1891. This is not exactly satisfactory; but the comparatively poor result is mainly due to the small returns in April, May, June and July. During the last four months of the year, however, the returns were very encouraging, and it is to be hoped that the mine will continue to show as good results during the whole of the current year. As regards the price of the shares last year, there was considerable fluctuation. The highest figure reached was £5-7-6 in January, and the lowest £4-2-6, which was quoted in July, November and December. The present price is £4-5-0. In January 1891, the price of the shares was £6, and in December of that year, £5-2-6. The following table shows the quantity of ore crushed and the quantity of gold obtained—including that from the tailings—for the years 1886 to 1892 inclusive:—

Year	Ore tons.	Gold oz.
1886	7,166	15,917
1887	12,001	12,964
1888	20,189	19,077
1889	32,576	49,201
1890	38,812	58,181
1891	40,353	66,501
1892	45,482	64,385

Total .. 196,579 tons. 286,226 oz.

The average yield of gold over the whole period of seven years was thus 1 oz. 9 dwts. 2 grs.—*M. Mail.*

REMARKABLE WEAPONS OF DEFENCE.

The following extract from a letter from such a careful observer as Mr. E. E. Green is of such general and special interest as to require publication.

Mr. R. J. Pocock informs me that the Acaroid is almost certainly *Holothyrus coccinella*, Grev., a species that appears to be common in Mauritius, and that in the lateral membranous area between the carapace and the cephalothoracic limbs is a distinct orifice which was regarded by Dr. Thorell as of respiratory import, but in connection with Mr. Green's interesting discovery of the existence of offensive glands in this animal it is necessary to bear in mind the possibility of its being the outlet of these organs.

The mite has such a hard integument, that being taken into the mouths of the lizards and birds that would probably prey upon it in the situations it frequents, would probably do it little or no damage if it were speedily rejected.

G. F. HAMPSON.

The accompanying insects—apparently Orobatiid mites—were found by me in the district of Tallawakelle, Ceylon (alt. 4,600 feet), under stone and rocks in damp, shady situations. It was only by accident that I became aware of their remarkable weapons of defence—an exceedingly pungent secretion,

About five hours after handling one of these insects I accidentally touched my tongue with my finger. Immediately an extraordinarily pungent, galvanic sensation or taste commenced rapidly to spread over my mouth, quickly reaching my throat. Rinsing my mouth and gargling with hot water failed to arrest the progress of the sensation, which was accompanied with excessive salivation. The unpleasantness lasted for several hours, and then died away without any further consequences. I also unconsciously rubbed my face at the angle of the eye, with the same finger; after which a rather pleasant warmth spread over that part of my face, and was distinctly perceptible the following morning.

I could not for some time trace the cause of this effect. I at first put it down to the agency of a fungus that I had been carrying, but a further experiment negated this idea. I afterwards tested the insect, and found it to be the real agent. The experiment was repeated at my suggestion, by a medical friend—Dr. R. J. Drummond—who can testify to the result. He described the sensation as somewhat like that produced by the strongest menthol. We both noticed that it had a numbing effect upon the mucous membrane of the mouth.

It is evident that this property must be a very efficient protection to the insect. The rapidity with which the secretion acts would cause it to be very quickly ejected if picked up by either a bird or a lizard—the only enemies that would be likely to attack it.

E. ERNEST GREEN.

Eton, Pundulorja,* November.
—*Nature*, Dec. 29.

FEEDING FOR EGGS.

The profit of a poultry yard demands to a great extent as to how it is managed, says the *American Stockman*. This true of any business. The idea should be to make every fowl pay as large a profit as possible. There is a great difference in markets, and one should be governed by them: for instance, in one market there is more demand for eggs than fowls. Then it should be the business of the breeder to cater to the trade. As a rule, I think there is more profit in eggs than fowls.

With proper care and feed, one can increase the number of eggs to a great extent. Hens cannot lay or produce eggs unless their feed contains the elements of which the egg is composed. That is, a large share of albuminous or egg producing elements. In addition to the quantity of albumen required in the organism of the fowl, the laying hen requires an extra amount of ovarian organization, the white of a hen's egg being about twelve per cent. of albumen, and this must be furnished in her feed.

By making a chemical analysis of the different grains, you will find that wheat contains a larger amount of albumen than any other grain. Therefore it is the grain to make the base for egg-producing food. The other important items are when the fowls do not have a large field to range in, to give once a day, if possible, a feed of chopped meat and more or less green food.

Chickens are like the human family in one respect—in that they like a change of food. As a proof, take fowls that have been fed on one kind of grain for some time and do not seem to have the appetite that you would seem to think they should have, give them a little cooked food, such as cake made from coarse corn-meal and scraps together, or some other grain than you have been feeding, and you will see that they will jump at it and eat it in a style that will be satisfactory to the most exacting.

While wheat is one of the best feeds for producing eggs, it is one of little value for fattening purposes, compared with corn, as corn contains a great deal of fatty or oily substance, which puts the flesh on fowls in a very short time. Pure water is also a very essential item to the health of the fowls; or if you have milk to spare, that is better still, as it not only moistens the food, but also contributes albumen, which goes to the formation of the egg.—*Southern Planter*.

* The late form of Pundalorja.—Ed. T. A.

GOLD AND FRESH GOLD FIELDS.

In Utah gold is stated to have been "struck big" on the Colorado River, and in distant Tierra del Fuego, hitherto the most unproductive of semi-Antarctic wastes, the discovery is even more astounding if the tales told are only approximately true. Indeed though the information comes backed by the *immunitur* of Her Majesty's Chargé d'Affaires in Chili, it is so trying to the faith of simple folks that one prefers to reserve complete belief in the statement until it is confirmed by the production of the actual metal. For even with the precedent before us of the miners in Cariboo, who, after working for months without seeing "the colour," actually shovelled the gold off the "bed-rock" when they reached that long-looked-for obstacle, it verges on the fabulous to be told that on Lennox Island "two and a half tons" of nuggets were secured in the course of two months. The Chargé d'Affaires admits that the rumour needs corroboration, though it is clear, from the fact of his sending the tale told him to the Foreign Office, that he does not quite reject it. If further inquiry lends any countenance to the story, it is certain that, though Tierra del Fuego is hard to get at, and the half-bred Indians who are its present monopolists are extremely handy with the knife, it will not be long before Lennox Island will be as "live" a camp as if it was in the latitude of Ballarat or Grass Valley. There is, however, less reason to doubt the intelligence from the Colorado. For the spot where the new El Dorado is situated is within easy touch of the telegraph, and no great distance from Denver City. Gold is one of the most widely scattered of metals. There is scarcely a land in which some is not to be found; but it is sporadically distributed, one piece of ground being often rich in it, while another at a short distance does not yield enough to render worth undertaking the toil of washing the earth through which it is sprinkled. Again as the experience of Cariboo shows, the richest deposits are frequently very deeply seated. All the drift gold was originally embedded in quartz veins, having in the course of ages been separated from its matrix by the action of the weather crumbling down the rock. It is unnecessary to add that even in California only a trifling proportion of these hidden hoards has been got at, while in Australia, British Columbia, and Alaska, which is now known to be extremely auriferous, even the surface deposits have in many instances been left undisturbed.

But the regions mentioned are only a few of the recognised gold-producing countries. How much is annually turned out by the rich mines of Siberia and the Urals only the private cabinet of the Czar, to whom most of them belong, can tell. It is certain that, were a horde of old Californian or Australian prospectors let loose in these preserves, the figure would, in a few months, be quadrupled. West Africa so ancient a gold-yielding country that the old "guineas" took their name from the region—is still scarcely more than scratched, and while South Africa is every day becoming more and more rich in gold yield, East Africa, which, as Mr. Bent has shown, was one of the Old World's sources of wealth, is still among the speculative auriferous lands, so far as the modern prospector is concerned. It may yet be as rich as the Ophir which many consider it to be—if, indeed, the old Arab miners did not skin the surface deposits before they left for good. But none of these countries seems so promising as the Atlantic slope of the Andes. The border lands between Guyana and Venezuela are said at this moment to be yielding an amazing amount of dust to the rudest appliances; and from time to time strange tales come from the headwaters of the Amazon of the still untouched wealth of that land, rumoured to be so full of the metal that in Raleigh's day it was the fabled site of the Golden City of Manoa. During the times of the Incas, gold we know was prodigiously abundant. It covered the walls of the temples, and, as the implements found in the tombs prove, was employed in the fabrication of all manner of semi-sacred objects. A room is still shown in the Palace at Ouzco which Atahualpa offered to fill with

gold up to a mark pointed out on the wall, if Pizarro would spare his life: and it is known that Indians laden with the ransom were on their way to the capital when they heard of their Sovereign's death. The streams from which they washed it are still unprospected, and any white men attempting to penetrate the tropical forests through which they flow would be likely, if fever spared him, to end his career by a poisoned arrow. Without placing much dependance on the legends of the Indians, it is certain that these stolid folks know of secret deposits which they will not reveal, lest they should meet the fate which befell their ancestors. Old people were, until recently alive, who remember Pumacagua, the rebel descendant of the Lucas, coming to the meeting place of the conspirators dripping wet, but laden with the sinews of war, which he had taken from a cave in the bed of a river, the memory of which is preserved by carefully gnauded tradition. Indians still bring gold into Panama, but effect ignorance when they are asked where they obtained it, and quite recently Her Majesty's Minister in Quito reported that Indians from the Jivaro and Napo forest country use the metal to pay their taxes, exacted in the old manner by "repartamientos," or fixed purchases of Government goods, and then, if they have any surplus, toss it back again into the rivers, in terror lest their supposed wealth should subject them to the cruelties still traditional amongst them as the result of the greed of Pizarro and the "Conquistadores."—*Standard*.

LIBERIAN COFFEE IN MADAGASCAR ON TRIAL.

Mahanoro possesses at the present time only one single plantation of Liberian coffee, on the Estate "Cascades," where there are 8,000 plants which the owner hopes to increase to 12,000, in a few months. The trees are planted at 10 feet distance from each other, say: 400 coffee-trees per acre; the owner will confine his plantation, placing the trees at 12 feet distance from each other, and we are of opinion that that is too much, for we must suppose that trees like these, which, in a few years, attain some 25 to 30 feet in height, ought to have each a space of 12 feet in diameter.

The plantation on "Cascades" estate is eighteen months old, some of the plants have attained two feet in height; the leaves measure from 12 to 14 inches in length, and six inches wide.—They grow with a speed verily incredible, in spite of the great dryness now prevailing.

Mr. L. has since one or two months left Mahanoro for the upper part of Vatomandry, where he intends to try a plantation of Liberian coffee on a large scale, we wish him every success. The estate "Cascades," moreover, possesses a plantation of tea, 2,000 plants, which, also, the owner will augment by degrees.

Though there is no other plantations of Liberian coffee than that of "Cascades" at Mahanoro, we understand that several owners of different estates have already asked for seeds of that plant, and will begin to sow them as soon as received.—*Madagascar News*, Dec. 17, 1892.

CITRIC ACID AS A WATER-PURIFIER.—The well-known chemist M. Girard, chief of the Paris Municipal Laboratory, has lately been engaged in making researches concerning the bacilli of cholera and typhoid fever; in so doing he has once more proved the effects of acids in destroying microbes. He finds citric acid to be the most useful and powerful of all. One gramme he says, added to a quart of tainted water, will effectively destroy all the microbes that may be in it. Consequently he recommends the use of natural lemonade as an excellent beverage at all times, and especially during epidemics. If necessary, a little bicarbonate of soda can be added as a means of neutralising the acidity of the lemon.—*Chemist and Druggist*, Dec. 31.

UPPER FLOORS.

A correspondent asks us if we have ever considered the advantages which might be secured by the more free adoption of upper floors to residences in Ceylon. He writes that he believes we are in this island notably behind other tropical countries in which Europeans reside in the provision of houses so constructed, and he attributes to the sparsity of these, a prevalence of neuralgic and other similar complaints among many of the Europeans who live in Ceylon. He points out that much of the tendency to the ailments named is due to sitting in the strong draughts which are almost inseparable from the design of most of our dwellings. In order to secure a free circulation of air in such buildings, doors have to be left open on all sides of our living rooms, with the result that it is almost impossible to find a corner in them which is free from a direct draught of air, the consequences of which are pretty universally recognised. Now in houses possessed of upper stories the coveted circulation of air is secured by the freer movement of that element as elevation is increased, and our correspondent states it to have been apparent in his own case that neuralgia, to which painful complaint he had for years been a martyr, ceased when circumstances admitted of his living in a house provided with an upper storey. Independently of this, it will be recognised, our correspondent asserts, that it must be beneficial to sleep well above the influences of vapour arising from the soil of a tropical country at night, and he gives us his opinion that in no country within the tropics are Europeans so liable to neuralgic attacks as they are in Ceylon, and, as we have said, he attributes this largely to the paucity of upper floors to our dwellings.

We think that our correspondent has a *prima facie* case, and that it would be found good economy to pay a somewhat higher rent than is charged for single storey bungalows in order to secure the advantages mentioned. Of course we know that the single storied houses so largely used throughout the tropics were brought into common use mainly in dread of the effect of earthquakes upon buildings of loftier construction. But in Ceylon, and probably throughout the greater part of India, these phenomena are but rarely felt, and when they are so, scarcely to an extent which might influence injuriously a building of two stories. There is next to be considered the question of expense in construction, but we doubt very much if this would prove to be a very serious one if the design was made on scientific principles. For if the work of building walls of increased height is expensive, it may be remembered that the upper part of these may be largely reduced in thickness. Then, although doubtless timber flooring is somewhat costly, this would be largely compensated for by the diminished area of roofing required; while certainly a smaller plot of ground—often very costly in our large towns—would suffice for an upstorey building than for one which must provide all the accommodation required on a single floor. There is doubtless very much in what our correspondent has written about the sanitary advantages which can be secured by an upstorey house, and we cordially recommend those who invest their capital in the building of house property to consider his statement. Of late years there has been a marked advance in this direction in some of our larger and more progressive towns, but much yet remains to be desired in this respect, and the importance of the arguments employed by our correspondent is

increased in the case of residences built in situations around which there may be a dense growth of vegetation.

TREE PLANTING ON ESTATES.

(From a Planter.)

I am very glad to see you advocating tree-planting. Go on. The way that some districts have been cleared of every stretch of forest is a crying shame. Men are too grasping and greedy for filthy lucre. Thank God I live in a place where I can see all round, only a little of man and a great deal of His creation. Nature will surely rebel sooner or later if she is offended in this way by pulling off all her clothes; it is absolutely indecent only to allow her a close fitting chemise! I am planting up 3 to 5 acres of my waste land every year with trees, although I have a reserve of 120 acres of fine heavy forest, and dotting these copses all over the place, besides planting up roadside and exposed ridges in the tea. I hope to have wood of 20 acres in extent before long Eucalypts, Wattle, Grevillea and indigenous trees such as Sapus, Di. leniaceo, Pihimbia, (*Filicium decipiens*) and others, with gorse growing about the edges to add to the effect.

[Well done: may our friend's example be freely copied.—Ed. T.A.]

NEWS FROM THE CENTRAL PROVINCE : PLANTING AND OTHERWISE.

(Notes by Wanderer.)

20th Jan.

The Ceylon agriculturist, like his brother at home, is always on the grumble. In my travels last week, everyone was abusing the long-continued drought. In the beginning of this week I found myself in a district where two copious showers had fallen, and a planting friend remarked, if this confounded showery weather lasts, the flush will be stopping again.

TEA, as a rule, is flushing less in January than December, when some fine harvesting of leaf took place. The difference between the good grades of pekoes is now no little, that an experienced tea planter said he began to think the only way now was for all Ceylon Tea Factories to send home unassorted tea. He believed that this would put an end to the Blender who, he believes, is at the bottom of all the mischief.

China tea.—In your extracts in Tuesday's issue under "Notes on Produce and Finance" I notice the following:—

"It is at the Indian and Ceylon tea sales that these unruly scenes are principally witnessed, as the department for China teas, being more old-fashioned and select, is the quietest of any, and much of the uproariousness of the other auctions is due to the exuberance and youthfulness of the majority who are present."

I fancy the selectness and quietude of the China auctions arise from the fact that the days of China tea are about numbered, and so the buyers and sellers of that article have not the same reasons for excitement that exist in the Indian and Ceylon tea sale rooms.

SILVER.—Some of us did not quite follow the reasoning in a recent article in your columns on this tantalising metal. Presuming the rupee is worth in India and Ceylon 1s 3d, and its value in silver is only 1s. will not the China exporter score over his Indian and Ceylon rival by that 3d.* If by any legislative action you can fix the rupee at 1s 3d why not give it at 1s 6d or to meet the case of the

* Yes, but the argument referred to was based on the London Times' view that if silver is left alone by our legislators, it is never likely to fall lower than at present.
—Ed. T.A.

indebted Ceylon Civilian who seems always to have to remit money home, why not give it at 1s 9d. Such fixing can't be done.

The Ceylon Planter is never happy unless he is patenting something, so here is one of our number coming to the front:—

NEW PATENTS.—Applications in respect of the undermentioned inventions have been filed:—Mr W. A. P. Cosserat, Foreman, Bengal Nagpur Railway Workshops Nagpur, for improved joints or couplings for articles made of bamboo, cane and the like. Jessop & Co. and Mr. G. Roddick, for controlling pumps and other Direct-Acting Motors, to be called the "Positive Action Valve Gear." Mr. J. Bridges-Lee, M.A., Barrister at law, of Lahore, for an improved method for separating surplus liquor from Indigo during indigo Manufacture.—Mr. L. M. Torin, Tea Grower, of Aldourie Estate, Agra P. tea, Ceylon, but now residing at London, for an improved method of and means for the drying of the leaves of tea and other plants.

TEA EXPORTS TO AUSTRALIA.—An increase of 2,800,000 lb. in one year is very encouraging. If teas put up for sale in Colombo are bought for export to Australia I can see why a certain class of our tea finds a better market here than at home. But if tea is bought here merely to be shipped to England, the local buyer must have his profit which the planter would get if he shipped himself. Only half the quantity of tea (if so much) sold here goes to other markets than London. Is the local buyer a philanthropist?

POONAC.—I see our German friends take nearly $\frac{2}{3}$ of the stuff shipped, I can therefore understand the reason why I may get better prices for this article here than in London.

COFFEE finds its way to the extent of half the export to foreign ports.

CARDAMOMS must also from the same reason find a good local market.

TEA puzzles me—but then I am not a philanthropist.

CREEPERS.—I am glad to notice that attention is being drawn to the importation of these interesting young gentlemen by correspondents in your evening contemporary. The traffic should be stopped.

FREIGHT down at one time to 15s in tea and now reported to be rising to 35s—means something rotten in the management of those who provide their constituents with freight.

The Dimbula P. A. Report is a smart one, and I trust the remarks on the Hospital buildings will be well digested by the "Mortality in Hospitals" Commission.

HAIL ON BRAZIL COFFEE PLANTATIONS.

On the 17th Nov. a violent hail-storm struck the district of Rio Claro, S. Paulo. As is usually the case the hail was the size of hens-eggs, and the damage to plantations, gardens, etc. was heavy. Hail-stones in Brazil are rarely smaller than hens-eggs, and always play the mischief with coffee plantations.—*Rio News*.

GIELLE TEA COMPANY.—Outturn was during the season just closed 1,760 maunds against 1,700 estimated for, and quality very satisfactory, while expenditure was less than anticipated. The average obtained was a shade over 11½ annas. In the accounts the various book debts in reference to building, &c. are now wiped out and the reserve fund, Rs25,000, is intact and available as working capital. Revenue account is Rs32,371 to the good, and in adjustment in profit and loss Rs3 239 is available, from which a dividend of 8 per cent will be paid. The estimate for 1893 is 1,725 maunds at a total expenditure of Rs5 000. The scheme for amalgamating with the Teesta Valley Tea Company, that has been pending for some time, has fallen through.—*Pioneer*.

CEYLON MANUAL OF CHEMICAL ANALYSES:

A HANDBOOK OF ANALYSES CONNECTED WITH THE INDUSTRIES AND PUBLIC HEALTH OF CEYLON FOR PLANTERS, COMMERCIAL MEN, AGRICULTURAL STUDENTS, AND MEMBERS OF LOCAL BOARDS.

By M. COCHRAN, M.A., F.C.S.

(Continued from page 501.)

CHAPTER II.—RICE AND OTHER CEREALS.

ANALYSES OF RICE—JAPAN MARSH AND MOUNTAIN RICE—AVERAGE COMPOSITION OF CEREAL GRAINS—COMPOSITION OF THE ASH OF CEREAL GRAINS—NUTRIENT RATIO, ALBUMENONDS AND NUTRIENT VALUE IN CEREALS AND BUCKWHEATS—NUTRIENT RATIO, ALBUMENONDS AND NUTRIENT VALUE IN LEGUMINOUS SEEDS—RICE STRAW—AVERAGE COMPOSITION OF VARIOUS CEREAL STRAWS—ASH ANALYSES OF CEREAL STRAWS—COMPOSITION OF PARTS OF THE RICE PLANT—PARTS AND PRODUCTS OF CEREAL GRAINS—MANURING OF RICE.

MENTIONED that I was not aware that anything had been done toward the determination of the composition of Ceylon soils fertile for the paddy crop; neither do I find that Ceylon-grown rice grains have come under the investigation of the analytical chemist. It is therefore necessary to look elsewhere for analytical data. The following analyses of rice may be quoted:—

Analyses of Rice.

	Rice. (Graham.)	Cleaned Rice. (Church.)	Naked Rice. (Wrightson's Agricultural Text Book.)	Rice. (Church.)
Water ...	10.8	14.6	14.0	12.8
Fat1	.5	.4	.6
Cellulose2	.9	2.2	.4
Starch ...	78.8	76.0	75.4	78.3
Other non-nitrogenous substances ...	1.6			
Albumenoids ...	7.2	7.5	7.7	7.3
Ash9	.5	.3	.6
Loss4			
	100.0	100.0	100.0	100.0

Professor O. Kellner gives the following as the composition of Japan undressed rice, in the dry state. There, as in Ceylon, there are many varieties of rice; but they can all be grouped under two classes, the marsh rice and the mountain rice, the former being cultivated in irrigated fields, the latter on dry ground.

Of the marsh rice there are two principal kinds, the ordinary and the glutinous rice. The moisture in the marsh rice is 14.20 per cent, and in the mountain rice 12.77 per cent. The percentage composition of the dry matter is given below.

Analyses of Marsh and Mountain Rice.

(UNDRESSED.)

	Marsh Rice.		Mountain Rice.
	Ordinary.	Glutinous.	
Protein matter...	7.00	5.87	8.75
Fat ...	2.29	3.44	2.58
Cellulose ...	4.58	5.19	1.98
Starch and non-nitrogenous extract ...	84.76	83.89	85.53
Ash ...	1.37	1.61	1.18
	100.00	100.00	100.00

Other analyses are given according to which marsh rice contains 9.84 per cent of protein matter, and 1.571 per cent total nitrogen, while mountain rice contains 11.27 and 1.8 respectively. The mountain rice is thus shewn to be richer than the marsh rice both in protein compounds and in starchy matter, but not in mineral matter.

The following are Kellner's analyses of the mineral matter in rice:—

Ash Analyses of Rice.

	Marsh.	Mountain.
Potash ...	22.94	21.73
Soda ...	4.94	1.59
Lime ...	3.24	2.12
Magnesia ...	10.54	6.61
Peroxide of iron ...	1.03	1.66
Phosphoric acid ...	51.37	51.99
Sulphuric acid ...	1.85	2.08
Silica ...	3.14	9.63
Chlorine ...	1.05	4.49
Deduct oxygen equivalent to chlorine ...	100.10	101.90
	.24	1.01
	99.86	100.89

In these analyses of the ash of Japan rice, the predominance of phosphoric acid (already noticed in the chapter on soils) is conspicuous. Kellner's analyses of rice are remarkable, as shewing a much higher percentage of fat than in American or East Indian rice. They also shew a higher percentage of fat than that obtained by Kinch in Japan rice, viz., 2.0 per cent, but, as Kellner's analyses are of undressed rice, and that of Kinch is of cleaned rice, the results are not inconsistent. Compared with other cereals, rice, other than Japan rice, is very poor in fat. All kinds of rice are also deficient in nitrogenous matter. Rice is, however, one of the most digestible of grains, and those people who use it as a chief article of food have learned to supply those constituents

in which it is deficient by supplementing rice diet with vegetable or animal fats, and with various leguminous seeds, which are rich in nitrogen. Rice in the husk is still poorer in nitrogen than cleaned rice, hence the necessity of supplementing it with gram as food for horses. The proportion of mineral matter in most kinds of rice is also very low, but it is higher in Japan rice than in the others. A glance at the following table of the average composition of cereal grains from the article on "Cereals" of Mr. R. Warrington, F.R.S., in Thorpe's "Dictionary of Applied Chemistry" will enable the reader to compare the chemical composition of rice with that of other cereals. I also quote from the same source a table of the composition of the ash of cereal grains.

Average Composition of Cereal Grains. (THORPE'S DICTIONARY OF APPLIED CHEMISTRY.)

In the preceding table of the average composition of cereal grains, the last column may require explanation. It expresses what is called the nutrient ratio of the cereal grains, or the ratio of albumenoids to starch, and the word starch used in this sense includes the carbohydrates and the starch-equivalent of the fat. One part of vegetable oil or fat is regarded as equal to 2.5 parts of starch; hence, by multiplying the fat or oil by 2.5, we get the starch-equivalent of the oil. Professor A. H. Church, in his work "The Food Grains of India," adopts not 2.5 but 2.3 as the starch equivalent of oil. The ratio in a standard diet is 1 to 5; hence cereals which nearly approach this ratio of albumenoids to starch are capable by themselves of supporting the human frame in a state of health for a lengthened period, such, e.g., as Indian wheat in which the ratio is 1:5.2, while rice and still more so Kurakkan are deficient in albumenoids, the nutrient ratio in each case being respectively 1:10 and 1:13, so that both of these foods require to be supplemented by diet in which the albumenoids bear a higher ratio to the starch than 1 to 5.

Another expression that is met with in the valuation of foods is "nutrient value." This expresses the sum of the albumenoids and the starch in 100 parts of the food. Starch, in this sense also, includes the starch-equivalent of the oil or fat as well as the carbohydrates. From Professor Church's work on the "Food Grains of India," I quote two tables, one giving the nutrient ratio, albumenoids and nutrient values of Indian cereals and buckwheats, the other giving the same for the pulses or leguminous seeds. It will be observed that while, in the cereals, the ratio of albumenoids to starch is less than that of standard diet, in two of the buckwheats, and in most of the leguminous seeds, it is greater, so that cereals and pulse supplement each other.

Nutrient ratio, Albumenoids and Nutrient value in Cereals and Buckwheats. (A. H. CHURCH.)

	Nutrient ratio or Albumenoids to Starch.	Albumenoids percentage of	Nutrient value.
Kurakkan or Ragi (<i>Eleusine coracana</i>)	1:13	5.9	84
Koda Millet (<i>Paspalum scrobiculatum</i>)	1:11.7	7.0	89

Rice Straw.

The following are analyses by Kellner of Japan rice straw, both from irrigated and from dry land, together with co-efficients of digestibility.

Analyses of Rice Straw. (KELLNER.)

Constituents.	Rice straw from irrigated land.	Co-efficient of digestibility.	Rice straw from dry land.	Co-efficient of digestibility.
	20.79		10.33	
Moisture per cent. ...				
Dry substance:				
Albumenoids ...	6.80	46.54	6.75	43.84
Fat ...	2.17	41.45	2.16	51.90
Fibre ...	48.68	58.10	40.35	55.24
Non-nitrogenous extract ...	24.80	35.41	32.14	28.86
Ash ...	17.55		18.60	
	100.00		100.00	
Dry matter ...		43.86		39.18
Organic matter ...		49.88		44.03

Kellner remarks that both these straws surpass all others as fodder.

Further on I have calculated the above analytical results of dry straw into straw, with the respective amounts of moisture indicated above for the sake of easy comparison with published results of the analyses of other cereal straws: but first, I give another table of analyses of paddy straws from various districts in the Carnatic by Dr. VanGeyzel (formerly of Ceylon), now Chemical Examiner to the Madras Government; and further on I have re-stated his average results, so as to allow of easy comparison with other analyses of cereal straws.

(To be continued.)

VARIOUS NOTES.

NEARLY 1,900 TONS OF PARA RUBBER.—According to the annual report of Messrs. Norton & Co., of Para, the receipts of rubber at that port during the crop year amounted to 18,490 tons of 1,000 kilos, and the exports to 18,787 tons. Of the exports 11,605 tons were for the United States and 7,182 tons for Europe. The total value of the rubber exports from the Amazon districts has been given at from four to five millions sterling a year!

SINHALESE EMIGRATION TO EAST AFRICA!—We call attention to the further very interesting letter with which our correspondent "B." supplies us on this subject. We think our readers will agree with us that he goes on whetting our curiosity almost too far—as to the real explanation of the Sinhalese being so ready to leave their homes, cross the ocean and begin life and hard work, in unknown East Africa. What can it be? We must, however, wait till the official negotiation is ended, before demanding the answer. In one respect "B." is surely a little illogical if not inconsistent: he says the Sinhalese in some cases dread leaving their homes (to do local plantation work) because their property may be sold up and their house burnt down by their nearest friend and neighbour. How then do these same people volunteer to leave the island altogether? Perhaps they sell out of house and land beforehand? As regards the "educated" class referred to, we do not see why the slightest obstacle should be placed in their way by the Government or anybody else, if they wish to go to East Africa by the score or hundred; but as regards the ignorant goyia or agricultural labourer, the case is surely different—that is, if it be the fact that there is well-remunerated work available on the tea plantations. Surely planters can afford really good substantial lines, and regular food and pay to such Sinhalese workers? We shall, however, in any case continue to take a special interest in "B.'s Mission" and to wish him and his German friends all success. Nine years ago, a letter of ours in the *Pall Mall Gazette* attracted some attention in London; because on the faith of 24 years' watching of native and foreign Governments in Asia, it boldly averred that for Africa the very worst form of European rule—even a Russian despotism of the severest kind—would be far superior to the very best native Government—to Muhammadans with their slavery, or Dahomey with its cannibalism. We urged then, long before it was dreamed of, that the European Powers should combine to take possession of Africa and dividing it up, each take a part in administering and opening up large districts. Since then Great Britain, France and even Italy have made great strides in Africa; while Germany has come in for a big slice; Portugal has wakened up; and the Belgian-Congo State been fully established. How great a change will railways, telegraphs, roads and settled Government make within the next ten years in Africa

TEA.

[*Fireside Facts from the Great Exhibition, by the Editor of "Pleasant Pages": being an Amusing Series of Object Lessons on the Food and Clothing of all Nations in the year 1851, p. 52 et seq.*]

If you wish to find specimens of Tea in the Great Exhibition, you will find several in the CHINESE DEPARTMENT. I must repeat, however, before beginning our lesson, that tea is not strictly a tropical plant. It will grow inside the tropics, but not in the very warm climates. It is cultivated by the Chinese, particularly in the tract of land round about the 30th degree of latitude.

Here are some specimens for you to examine. You may begin by discovering the *qualities*, and the *uses*. Then, if you have paid attention to your part of the lesson, I will pay attention to my part, and see if I can give you an interesting *history*.

W. The first quality I observe in the tea is, that it is thoroughly *dry*.

Ion. It is also *brittle*—"crisp" would be a better word to use;—and it may be ground into a powder: it is *pulverable*.

L. It is *shrivelled*—that is a very good word to apply to it.

W. I do not see any more qualities. We have examined its appearance, and its substance; we cannot say anything of its shape, but we may add something of its colour, and something about its weight. It is *black*, and *green*, and in weight it is *light*.

Ion. We may add that it is a *vegetable substance*. It is really necessary to say that to describe it properly.

P. Why?

Ion. Because nobody would really think that it was a vegetable substance at first sight.

W. That is because it does not look natural. I suppose we must not call it a *natural* substance. We will say that it is *artificial*.

Ion. I don't think that that is correct. It is not made by man.

W. Well, I have heard that it *is*. Men dry and shrivel it up, in some way or other, to make it like this. Therefore I think that it is an artificial substance.

Ion. But at the same time, you see, men do not make it, they only alter its *shape*.

L. And they alter its *state*—from a moist green state to a dry state.

P. You say that it loses some of its moisture. By thus losing its moisture, it loses one of its *qualities*.

W. Yes. One of its natural qualities, papa.

P. Then it is no longer in quite a natural state. It has been changed by the art of man, so it is in an artificial state.

Ion. And yet, papa, the tealeaf is a natural substance, because men could not in any way make such a substance. When a substance is *compound* (that is, formed of two or three different substances—such as bread, which is made of flour, water, yeast, salt, &c.), then I call it an artificial substance. So this is what I should say of tea,—“It is a natural substance in an artificial state.” Will that do?

P. Perhaps that is the best way to express it. It certainly is not an artificial substance; and it is not in a natural state.

Ion. Then I will write down the qualities of the tea. “Tea is a *vegetable* substance, and is therefore *natural*; but it has been brought into an *artificial* state, for it is *dry*, *shrivelled*, *crisp*, *light*, and *pulverable*; sometimes it is *black*, and sometimes *green*.”

P. You have not made a complete list of the qualities. I think I have said before, there are many hidden qualities in a substance, which you cannot discover by observation.

L. You mean, papa, the qualities which we discover in using a substance. We call them its *effects*.

W. I know one effect of tea; it causes people to talk and be more lively. When people are dull, it serves to *stir them up*, just as coffee does. What is the Latin word for “stir-up?” I forget.

Ion. I remember it: *stimulare*, to stir up; and we call the coffee *stimulating*.

L. And, if you remember, we said that coffee is *refreshing*; and because it makes people glad, we call it *exhilarating*.

W. And because it acts as a medicine, and keeps the students from going to sleep, we call it *medicinal*.

P. Yes, you said that the coffee in its “effects” is refreshing, stimulating, exhilarating, and medicinal: and these effects also belong to the *tea*.

W. It is very easy to know that tea has such effects, because we can feel them, and can notice them in other people, but I should like very much to know *how* the tea does so. Do you know, papa?

P. What do you want to know?

W. *How* the tea exhilarates people, and refreshes them. What it does *inside* them, to change them so.

P. Well, I cannot say that I know, exactly, but I will tell you all I have learned about it. There is, both in the leaves of tea, and the berries of coffee, a peculiar substance, which produces these effects. Although this substance is found in both articles, we give it different names. When found in *tea*, we call it “theine”; and when found in coffee, we call it “caffeine.”

I have a little book on chemistry, written by a German gentleman named *Liebig*, and I will read you what he says of *Theine*. “When common tea-leaves are placed in a watch-glass, loosely covered with paper, and gradually heated on a hot iron plate, until they are brown, *long, white, shining crystals* appear on the paper, and on the surface of the leaves. This is *theine*.” You can now easily understand that, if instead of heating the leaves on a watch glass, they are heated in boiling water, the theine would not form dry crystals.

L. No, it would be dissolved in the water.

P. That is the case. So the next time you are going to drink a cup of tea, you may look at it, and remember that it is the theine dissolved in the water, which will refresh you.

W. Now I know something more, papa. But still you have not told us *how* the theine in the tea refreshes us.

P. I will tell you as much as I know of the subject. You have often heard how, when your food in being digested, it is dissolved by a fluid called the *gastric juice*. The food is afterwards acted upon by another fluid from the liver, which are called *bile*; but if we have not sufficient bile within us, what then?

L. Then our food will not be digested, I suppose.

P. And we shall feel unwell. Persons who do not take sufficient exercise, do not form sufficient bile; but the theine in tea will supply the substance required for the purpose. This fact explains why men who sit much, and study, and females who do not often go out of doors, are so fond of tea.

W. Then, we may say,—as the tea helps to form bile, the food is digested more quickly.

P. Yes, or the food is *assimilated*, as we say. By assimilation we mean that the food becomes part of our body, by being changed into blood. The bile helps in this process; and thus, when the theine of the tea helps to form bile—?

W. The bile helps to form the food into blood.

Ion. And the blood begins to circulate more quickly, and we feel more lively,—we are stimulated and refreshed. Most people feel lively after tea.

P. Thus, where food is difficult to digest, tea is often useful. Which kind of food have I told you is harder to digest—*Animal* or *Vegetable* food?

L. You said that vegetables were more hard to digest, and that grass-eating animals required salt to help their digestive organs.

W. Just as you said that we require pepper to help to digest cucumber and other raw vegetables.

P. Thus, we find that *tea*, also, is much used amongst nations which subsist principally on vegetables. The great chemist, named *Liebig*, whom I mentioned just now, says in one of his books, “Tea and Coffee were originally met with among nations whose diet is chiefly vegetable.”

Ion. But suppose, papa, that a nation could not procure any tea! The English people had no tea at one time, I suppose. What did they do then?

P. Then, they used something else which answered the same purpose by helping digestion: or by stimulating and refreshing their bodies. Let me tell you something which is worth remembering. If people would only live on proper food, and eat it

in proper quantities, and take proper exercise, they would seldom require such stimulants. But whenever people are poor, and are poorly fed, they make up for the "sinking feeling" which such want occasions, by tea, coffee, tobacco, opium, and worse still, beer and spirits. It is said that in Germany, those who receive the lowest wages, while they are obliged to live on bread and potatoes, always reserve a portion of their wages for coffee.

Ion. I quite understand why they do that!

P. I should like you to understand it very clearly. I will say it to you once more: "Where there is good and nutritious food (containing *azote*, a word which I will explain to you some day), and with such nutritious food exercise is taken, the *azote* in the food forms sufficient bile; but, where the food is poor, or hard to digest, and sufficient exercise is not taken, then sufficient bile is not formed, and men use the *theine* in tea, or the *caffeine* in coffee, or some other stimulant for the purpose."

L. Then the lesson we may make about tea, is, that if we took great care to have proper food and exercise, we might do without it, and other stimulants also.

P. Yes; but it is not very likely that this will ever be the case. Until *all* men give due attention to their food, there will be some people craving for stimulants, to make up for their carelessness. In another part of M. Liebig's book, there is a paragraph expressing this opinion. I will read it to you:—"It is a question whether, if we had no tea, and no coffee, the popular instinct would not replace them. Every people of the globe has appropriated some such means of acting on the nervous life,—from the shores of the Pacific, where the Indian retires for *days*, to enjoy the bliss of intoxication with *Koka*, to the Arctic Regions, where the *Kamschadales* prepare an intoxicating drink from a poisonous mushroom."

Ion. Or he might add, when the student in the university, who wants to study all night, prepares a decoction containing either *theine* or *caffeine*.

P. Yes, whether the university be in England or Germany, or elsewhere; or whether it be in the cottage or mansion, such stimulants are still in use. In the same book it is said concerning Germany—"In the Customs Union (*Zollverein*), more than 60,000,000 pounds of coffee are consumed every year; while in Europe and America *Tea* forms part of the daily arrangements of the poorest laborer and the richest landowner—and the consumption of this article is more than 80,000,000 pounds per year.

L. And a pound of tea will last as long as two or three pounds of coffee.

W. What a long lesson we are having on the uses of tea! Now I will sum it all up. "*Tea and other stimulants are very useful things, because they have refreshing qualities which make up for the most of good food.*"

P. Oh, indeed! Is that the lesson you make? I make out a very different case. Listen! Tea, and all other stimulants are (except in occasional cases) *bad* things, because they enable people to neglect their diet, and indulge in bad habits, without feeling the natural consequences. As long as men will use such stimulants to remove for a time the bad effects of their neglect, so they will not give the attention they ought to give, to their diet and exercise.

Ion. To be sure, Willie! Don't you see that? If the tea and other stimulants were taken away, then people would be obliged to take proper care of themselves.

P. Shall I show you another way in which tea and stimulants are bad?

W. Yes papa, please.

P. Because they *wear out* the body. We do not observe this fact so much, because we take them in small quantities, and their action is gradual: but as soon as the stimulants are used in a little more than moderate quantity, their effect becomes evident. It is said of the frequent use of *Tea*, that it answers the purpose for a time, but the object is attained at "a fearful price"—the destruction of health, and vigour of body and mind being the penalty. *Tea* is worse in this respect than coffee, as its effects are more permanent.

The property in tea which has such injurious effects, is weakened by keeping the leaves for a long time. Fresh tea is so stimulating, that it is seldom used until it has been kept twelve months. The injurious property may also be weakened by *heat*, for *green* tea is more exciting than *black*, because when being prepared it is not "roasted" so often.

Tea is a very improper drink for young children; it produces too strong an excitement, and causes a diseased state of the brain and nerves. It has been said by a well-known physician, that "it ought by no means to be the common diet of boarding schools. If it be sometimes allowed to the children as a treat, they should be informed that it might, if used frequently, injure their strength and constitution."

Before we leave the subject of tea, I must not forget to mention that, although it may produce bad effects, the effects of stimulants which contain *alcohol*, instead of *theine* or *caffeine* (such as beer and spirits) are far worse. So dreadful are many of the evils which these stimulants bring, that a great society, called the National Temperance Society, has been formed both in England and in Scotland, to induce the British Nation to abstain totally from their use.

L. Have many people abstained from using them?

P. Yes, great numbers; especially drunkards, who have suffered from their bad effects: and when these societies do more to teach poor people how to spend their money in buying the best food, and how to regulate their diet and exercise, then these people will be able to give up stimulants more easily,—they will not *want* them. It has been found in the reports of large towns, that when wages have been high, or food has been plentiful, there has not been much drunkenness: but that when there has been scarcity and poverty, drunkenness has increased; for when the poor cannot obtain the *natural* refreshment for the body from wholesome food, they get *artificial* refreshment from stimulants.

There! we must not go any further into the question of stimulants in general. We have made too long a subject of it already. I should, however, like you, when we print this lesson, to read it over several times. Then, perhaps, you will see that it will be one of your *duties* so to attend to the diet and exercise of your body, as to enjoy life without the help of stimulants.

(To be continued.)

PLANTING PRODUCTS.

(From the *Thirty-ninth Annual Report of the Ceylon Planters' Association held 17th Feb. 1893.*)

TEA.—The reason was an unfavourable one, and in most instances crops fell short of estimates. The abnormal season affected quality also—with poorer quality for the first half of the year, your teas had to compete with exceptionally fine teas, approaching fancy make from India, that the market took off freely for a time at high prices, which, however, gave way and the same teas fell 3s. a lb. later in the season: not only this but an exaggerated report of your cut-turn got abroad, and it was no wonder your average fell in July to 8½d., the lowest point touched. Your average in London for the first 9 months of the year was 9d., for the last 3 months 11d. The general average for the year being 9½d. against 10d. for 1891. The Chamber of Commerce returns show a total export for the year of 71,153,357 lb. as against 68,274,420 lb. for 1891, or an increase of 2,879,237 lb., the increase in 1891 over 1890 being 21,372,866 lb. Steady progress has been made in most foreign markets, i.e., other than London. Thus Australia shows the large and satisfactory increase of 1,955,556 lb. or 5,166,154 lb. in 1892 as against 3,210,598 lb. in 1891. Germany also shows an increase of 30,786 lb. or 123,077 lb. in 1892 as against 92,291 lb. in 1891, America on the other hand shows a falling off of 62,244 lb. viz: 163,137 in 1891 and only 100,893 lb. in 1892 of direct exports, the falling off in 1891 being 41,086 lb. as

against 1890. Your unremitting efforts should be given to forward the consumption in this country, and with the large amount subscribed to the Chicago Exhibition, placed at the disposal of your able Commissioner the Hon. J. J. Grinlinton, you may confidently look forward to better results in the near future. The increased consumption in this country and Russia are what is wanted for the continued prosperity of your staple, with a larger output to be expected during the next three years. The continued displacement of China in the London Market by your Teas is most satisfactory. Quoting from Messrs. Gow, Wilson & Stanton's report, the percentages in London of India, Ceylon and China compare as follows as from 1889 to 1892:—

	India.	Ceylon.	China.
1889 ...	52 ...	15 ...	33 ...
'90 ...	52 ...	18 ...	30 ...
'91 ...	49 ...	25 ...	26 ...
'92 ...	53 ...	30 ...	17 ...

Notwithstanding the lower market rates ruling, your Committee has pleasure in reminding you that your local companies have in all cases declared as good dividends as formerly, and in some cases even higher dividends than in 1891. With the reduced subscription now asked for, your Committee hopes that the Tea Fund will have your continued hearty support as it has done, and still continues to do so much for the spreading abroad of your Tea throughout the world. Labour was plentiful in all districts and good results are to be expected with regard to your future Labour Supply, by the able work done by your Commissioner, Mr. E. J. Young, backed as he was by the Local as well as by the Madras Government. For purposes of comparison and reference the statements furnished to the Association by the courtesy of the Hon. the Collector of Customs, showing the total export and distribution of your teas for the past three years are of much interest.

COCOA.—The cocoa crop for the year 1892 falls a little short of that shipped in 1891, but as was pointed out in last years report the year from the 1st of January to 31st of December is not a very good one for ascertaining the exact annual cocoa yield of the island, and in this instance it is particularly misleading. The wet cold weather at the beginning of 1892 retarded the blossoms both for the spring and autumn crops, and a great majority of the annual crop of 1892-93 will be picked in January, February and March, instead of as usual in October, November and December. It is probable therefore that the shipments of the earlier part of 1893 will quite make up for the deficiency of 1892. Taking this into consideration with the ascertained fact that cocoa crops show their increase in alternate years, and remembering that the shipments of 1891 were the largest on record, the crop of 1892 may be looked upon as progressive. Reports from all districts speak of the healthy condition of the trees, and confidence in this product is now greater than it has been for some years. There is not the same hesitation noticeable in embarking on this cultivation which was apparent some years ago, and it is beginning to be recognized that with a proper study of the requirements of the plant, cocoa may be much more generally grown than was supposed at one time to be possible. It is unnecessary here to refer to the necessary system of cultivation, these conditions are now very generally understood and attended to, and as their benefits are seen, it is probable the acreage and yield of cocoa will increase. Natives are planting to some extent, but the proportion of cocoa in bearing in native hands is very small. Cocoa stealing has assumed a very systematic and dangerous aspect. And your Committee hopes that your Association will keep in view the need for vigorous measures being taken for repressing this.

COFFEE.—The exports of this product which was once the staple of the country have been again reduced during the year. The amount shipped was 39,013 cwt. against an export of 82,324 cwt. in the previous year. Leaf disease and green bug have been severe and the crop has been disappointing, Liberian coffee from its hardier nature is able to resist the attacks of the disease and may be expected to show

better results. The falling off in the export of coffee has been very considerable as will be seen by a comparison of the last five years.

1888 ...	137,793 cwt.	
1889 ...	88,986 "	a reduction of 48,807 cwt.
1890 ...	81,334 "	" " " 7,652 "
1891 ...	82,324 "	" a slight advance of 990 "
1892 ...	39,013 "	" a reduction of 43,311 "

CARDAMOMS.—The past year has turned out disappointing to cardamom growers, both as regards quality and price. The shortness of yield may be accounted for in a great measure to drought in the early months of the S. W. monsoon, which is the most critical time for blossoming. The following statistics of exports will show that this has been the shortest crop for the last three years:—

Total exports for 1892...	372,510 lb.
Do	1891...	...	408,866 "
Do	1890...	...	395,576 "
Do	1889...	...	466,168 "

Though undoubtedly cultivation is contracting as far as Natives are concerned, it is being largely extended by Europeans, and particularly to the North of Kandy. The area being planted is, however, about counterbalanced by that going out of bearing; therefore, it is not likely there will be any large increase in the future exports. Probably the shipments for the current year will not exceed 350,000 lb.

CINCHONA.—All interest in this cultivation has now been given up, and even those parts of the country where it had been most largely planted have been almost entirely cleared of bark.

YATIYANTOTA TEA COMPANY, LIMITED.

FROM REPORT OF THE DIRECTORS.

The weather during the past year was not favourable for flush and the yield of tea was 24,200 lb. under the estimated quantity. The clearing of 33 acres referred to in the last Report has been successfully planted and the clearing of 30 acres planted in 1891, which from the beginning of this year will be treated as part of the Estate in bearing, is expected to yield about 250 lb. of made Tea per acre in the current season.

The whole crop of 225,800 lb. Tea has been sold locally at an average net price of 43½ cents per lb. against a cost of 21½ cents per lb. laid down in Colombo. After making the usual provision for depreciation of Buildings and Machinery, the net balance of profit for the year amounts to R36,308.47, out of which an interim dividend at the rate of 15 per cent (on R90,000) has been paid, absorbing R13,500. The Directors recommend that a final dividend for the year of 15 per cent on the present Capital of R100,000 be declared and made payable on the 18th February, that a sum of R7,500 be added to the Extension Fund and that the balance of R308.47 be carried forward to next year's account.

The capital of the Company was increased on the 20th August to R100,000 by calling up the final instalment of R100 per share.

At a Government sale held in May last the directors purchased at upset price three blocks of land called Mugumuwala in extent acres 723. 0. 26. The land contains a large quantity of good timber which was much needed for building and other purposes on Polatagama Estate and being situated close to this property, will form a valuable adjunct for further Tea Extensions. Having acquired this land the Directors deemed it advisable to dispose of the Abamalla property and, with the consent of the Shareholders at a Special General Meeting held on the 12th August, a sale to the Wé-Oya Tea Company Limited for the sum of R12,323.81, as on 30th June 1892, was effected. The sale involved an apparent loss to the Company of R1,790.61 which is charged in the Profit and Loss account of the year but as, in the place of Abamalla which originally cost over R30 an acre, the Company has acquired land more suitable for their pur-

poses at a cost of about R15 an acre, it will be seen that a distinct advantage has been gained. The Company now owns 1,422 acres of land, of which 251 acres have been planted in Tea. It has been decided to plant about 150 acres more land in Tea this year and the necessary arrangements for this clearing have been made.

The construction of a Grant-in-aid Cart Road to the Estate is progressing and will it is hoped, be completed about the middle of this year.

A large expenditure on new Machinery and extensions to the Factory was incurred last year. It is not expected that any further additions to the Factory will be required this year but a sum of R23,000 for new clearings and other expenditure on "Capital" account has been allowed for in the estimates.

The estimated crop expenditure on the Estate, season 1893, is R51,250 on a yield of 250,000 lb. of Tea.

THE DUNKELD ESTATE COMPANY.

FROM REPORT OF THE DIRECTORS.

The yield of Tea for the season has turned out a good deal less than was anticipated, the total crop being 110,925 lb., or 39,075 lb. under the estimated quantity. Owing to the unfavourable weather for flushing which prevailed during several months of the season Estates generally have yielded smaller crops in the past year than was expected. In this respect Dunkeld was singularly unfortunate, as in the early months of the year, when the weather was favourable, a large proportion of the acreage had been recently pruned; while during the months that the bulk of the estate was expected to be secured unfavourable weather prevailed. Under these circumstances the Directors are gratified at being able to recommend a substantial dividend for the year.

The Tea realized an average net price of over 51 cents per lb., which is satisfactory, considering the low prices ruling during many months of the year.

After writing off R4,175'73 to provided for depreciation of buildings and machinery, the net balance of profit available for dividend is R17,950'04, of which the sum of R7,500 has been absorbed in paying an interim dividend of 5 per cent. The Directors recommend that a final dividend of 5 per cent. be declared and made payable on the 18th February, that R2,750 be transferred to an Extension Fund, and that the balance of R200'04 be carried forward to the next account.

The paid up capital was increased in July last to R150,000 by the issue of 20 shares, which were not allotted on the formation of the Company. These shares were issued at a premium of 20 per cent. which appears in the annexed accounts.

The estimated crop expenditure, season 1893, is R39,350 lb. on 130,000 lb. of Tea, and a further sum of R2,250 has been allowed in the estimates for young clearings and buildings. The Factory is now fully equipped, and beyond the cost of ordinary upkeep, repairs no expenditure should be incurred under this head during the year.

DR. DUNKELD ESTATE WORKING ACCOUNT 1892. CR.

To Expenditure for years as per Superintendent's Reports..	R46,847 93	
Less Expenditure on Permanent Works transferred to Debt of Dunkeld Estate, viz:—		
On Buildings ..	R3,794 16	
On Machinery ..	R4,238 12	
On Clearings ..	R2,149 32	
On New Dam and Road ..	R 882 01

		<u>4,175 73</u>

To Balance transferred to credit of Profit and Loss account	1,198 33	
		<u>R59,158 38</u>
By Proceeds of Crop, viz:—		
110,925 lb. Tea ..	R56,652 20	
20,149 lb. Cinchona Bark ..	R 2,466 18	
2 bus. Coffee ..	R 40 00	
		<u>59,158 38</u>
		<u>R59,158 33</u>

GLASGOW ESTATE COMPANY, LIMITED.

(FROM REPORT OF THE DIRECTORS.)

The yield of tea in the year was satisfactory, the estimate having been exceeded by 6,400 lb. and as it was found advisable to cut down many cinchona trees which were doing harm to the tea, the quantity of bark harvested was very much larger than had been anticipated.

The season was unfavorable for coffee and the crop secured to the 31st December amounted to less than 300 bushels of parchment. In view of the small crop and of the uncertain prospects of this product in the future the Directors decided to plant tea without delay in all the land remaining under coffee. Eighty-six acres were successfully planted last year and the rest will be planted shortly.

Good prices were realized for the produce in the local market, the average net price of tea being 61½ cents per lb., of coffee R16 per bushel, and of cinchona bark 14½ cents per lb.

After writing off R3 131'50 to provide for depreciation of buildings and machinery, the net balance of profit for the year amounts to R27,375'38, of which R12,000'00 has been absorbed in paying an interim dividend of 6 per cent. In dealing with the remainder the Directors recommend that a final dividend of 6 per cent. be declared and made payable on the 18th February, that the sum of R2,846'66 be added to the Extension Fund and that the balance of R528'72 be carried forward to the next account. The amount at credit of the Extension Fund will then represent the expenditure on new tea plantations in 1891-92.

The estimate of expenditure on working account in 1893 is R36,318'00, against 105,000 lb. tea, 500 bushels coffee and 25,000 lb. cinchona bark; whilst a further sum of R5,350'00 has been allowed in the estimates for tea extension, additions to the factory and a wire bridge over the river.

ELEMENTS OF AGRICULTURE.*

ALL ABOUT SOILS AND MANURE: THE TEA TRADE AND SOIL.

This is a book which should be valuable to all who get their living by the cultivation of the soil. This, of course, is practised in the best and most scientific manner in general "farming" and gardening; but the principles are the same everywhere, so far as they apply to the mechanical (geological) and chemical nature of the soil, its fitness for any particular product, its preservation and fertilization. This book explains the science of tillage in language brought down to the level of the most ordinary intelligence, while it teaches all the elementary facts of the geology of the earth's surface, of agricultural chemistry, the practical cultivation of soil, as well as (for the farmer in Europe) a little about the live and dead stock he necessarily has to employ; and also how to know, and to treat, the insect and fungus pests that attack his crops. For the Ceylon Planter Parts I. and II., which deal with the "Soil" and the "Plant," are wholly interesting, and should be well understood by all who lay claim to a liberal education. The book has over 400 pages, is profusely illustrated, and provided with a good "Index," by means of which reference can be instantaneously made to any of the many subjects it deals with.

Some of these are, in Part I., "Origin and properties of soils, composition and classification, sources of loss and gain, moisture and manures;" while in Part II., we are instructed regarding "Seeds and their germination, the selection, functions and cultivation of seeds and plants, weeds, fungus and insect pests." It may be useful to notice a few of the lessons here taught:—

"All crops can be traced back to two primary sources, the soil and the atmosphere. The same is true of animals and their products.

"The soil can be regarded as derived from the sub-soil; air, moisture, temperature, plants and animals being the chief agents in effecting the change.

"Humus (organic matter). After having thoroughly dried a portion of soil of its moisture, weigh 1 lb. of it, and burn it on a red hot iron plate or old frying-pan: a strong smelling smoke will arise. After the smoke has ceased to appear let it cool. Weigh, and the loss was the humus (the decaying remains of plants and of animals.)

"Humus is of value because the final products of its decomposition—chiefly carbonic acid, ammonia and water—administer to the food requirements of plants. The quantity of humus in cultivated soils usually ranges from 2 to 9 per cent, and within these limits the soil will be the more fertile the more humus it contains. It is possible, however, for a soil to contain too much decaying organic matter; this is the case with peaty soils and boggy moorlands.

"Put another weighed quantity of the dried and powdered soil into a bottle of rain water—shake it well, and let it stand a day or so. Then carefully pour off the clear liquid into a saucer, or basin. The loss in weight (after again being dried) represents the SOLUBLE ingredients, and these may be obtained by evaporating the water in the basin. It is the soluble parts of the soil only that plants feed on.

"When water that has trickled through a soil flows away from it, some of the soluble matter—and in some cases a considerable portion of it—may be carried away in the water.

* "Elements of Agriculture."—A Text Book prepared under the authority of the Royal Agricultural Society of England, by W. Fram, LL.D. 3rd Edition. 2s 6d. John Murray, London.

"The constituent parts of a soil are for ever changing. —Crops are continually carrying away certain ingredients, whilst the fine earth of the soil is as constantly being added to by the decomposition, or decay of the stony fragments which the soil contains. In addition, the rain which falls upon the land brings with it from the atmosphere certain substances which are of much importance in cultivated soils."

Here the reviewer may stop to add that ground aqueous rocks is coming largely into use in England as manure.

"For many years past the reduction of rocks for manure has been carried on in a small way by a system of calcining, thus softening the rock, and afterwards reducing to powder by a primitive method of stamping. In a German standard work on vegetarianism I read: 'With Hensal's rock-flour as manure there has been obtained for years past the best and soundest crops without any addition whatever of nitrogenous substances.'—*English Mechanic.*"

The CLASSIFICATION OF SOIL into sandy, loamy, clayey, clay-loamy and strong clay is then shown to be a simple process. "Experience proves that a soil is best adapted for cultivation when it contains of—

Sand (siliceous and calcareous)	from 50 to 70 per cent
Clay	.. 20 to 30 "
Pulverized limestone	.. 5 to 10 "
Humus	.. 5 to 10 "

"It thus contains enough sand to make it warm and pervious to air and moisture; enough clay to render it moist, tenacious and conservative of manures; enough limestone to furnish calcareous material and to decompose organic matter; and lastly, sufficient humus to assist in supplying the food requirements of the plants, and to aid in maintaining the carbonic acid in the interstitial air of the soil.

"Nitrogen, phosphoric acid, potash and lime are the four ingredients that are liable to run short in a soil, and the deficiency of which has to be made good by the cultivator.

Soil, sustains loss in the crops it bears, and in the drainage water carrying away fine earth in suspension, and in solution. Experience has shown that expulsion of soluble salts from the soil takes place most freely when the percolation of moisture is the most rapid, so that a heavy rainfall, restricted to a few days, does far more harm in washing a soil, than would the same amount of rainfall spread over a month.

"The sources of GAIN to soils are in the land itself, in the atmosphere, in the residues of crops, and the application of manures, and of other dressings."

The above are a few of the elementary, but useful, lessons taught and fully explained in the early chapters of this book. From them and others the thoughtful reader may deduce much knowledge and solve problems that puzzle him in practice. Thus, near old coolly lines tea will seldom grow, because the soil has been "sour." We read:—

"Soils containing too much organic matters become what is termed 'sour' owing to the excess of organic acids. LIME by combining with such acids, renders them harmless."

We talk (it may be incidentally remarked) of the tea tree being a deep-feeder. Of course the roots wandering down into the sub-soil are in search of what they may devour; but this consists chiefly of moisture supporting the plant through droughts, though when such long whippy roots strike, or find a hole, or pocket of good soil, or food they develop at that spot a bunch of fibrous rootlets to absorb the nourishment. Generally, I

should say, the tea tree flourishes above ground in branch and flush in a ratio directly proportioned to the space occupied by its roots in fertile soil. In shallow soils manuring is necessary, and must be continuous; but one generation is not long enough to exhaust the riches contained in soils of great depth.

"Artificial Manures" (we quote again from the book) possess the advantage of presenting a large quantity of fertilizing material in a small bulk. Some artificial fertilizers contain only one valuable ingredient and are then spoken of as "Nitrogenous, phosphatic or potash manures," as the case may be. Others, such as Peruvian Guano, contain more than one. Then follows all about Peruvian Guano.

Fish Manure is the refuse of fish-curing establishments, and consists of fish offal, sometimes of whole fish, dried and ground. This "Fish-guano" yields from 8 to 10 per cent of Ammonia, and from 10 to 15 per cent; and even more, of phosphate of lime. They often contain fish-oil, which renders them less serviceable as manures, because it delays decomposition."

"Bones are essentially a phosphatic manure. Coarsely crushed bones decompose but slowly and occupy some years in yielding up their fertilizing ingredients." And so on in great detail concerning to various kinds of manures natural and artificial.

PLANTING IN GERMAN NEW GUINEA.

TOBACCO—COTTON.

(From a Correspondent.)

German New Guinea or the territory of New Guinea Company may be divided in two principal parts: the mainland of New Guinea, and the Bismarck Archipelago and Solomon Islands. Colonisation in New Guinea proper is still in its infancy. After many experiments, the New Guinea Company decided to open up the country around Astrolabe Bay, where the commodious and land-locked harbour "Friedrich-Wilhelms-Hafen" presents a favourable base of operations, and where the soil gives promise to yield first-rate tobacco. The first experiment with Sumatra tobacco was so favourable, that at once a German Company was started under the name of the "Astrolabe-Bay-Company" and work was commenced about a year ago. The results have so far proved successful; the tobacco of this year's crop is regarded as far superior to the best Deli tobacco. Preparations are at present being made for bringing four stations:—Jomba, Gorima, Erima, and Stephanort in proper working order. The great difficulty has been, and still is, the unhealthy state of the country. Fever and dysentery are prevalent, and about 50 per cent of the imported Chinese and Malay labourers have died of these diseases. Besides the tobacco plantations, a cotton plantation is started at Constantinhafen where the Sea Island variety is grown. The Bismarck Archipelago has been colonized since about 1875. Two German firms, Hershheim & Co. at Matupi, and a branch station of the German firm in Samoa at Miko, as well as the American firm of E. E. Forsyth at Ralum, have for many years carried on business in those parts for the purpose of collecting copra, tripping, and other island produce. The firm of E. E. Forsyth has also large plantations in New Britain, where first class Sea Island cotton is grown. The plantation comprises at present about 900 acres planted with cotton, between which, at intervals of 32 feet, coconuts have been planted. These latter already begin to bear. The plantation employs about 400 labourers and has a complete set of machinery for cleaning and packing the cotton and shipping it ready for the market. A few years ago, the New Guinea Company also started a cotton plantation at Herberts-hohe, which still is in its infancy. The labour question is not beset with so many difficulties in the

Bismarck Archipelago as in many other countries. The islands are densely populated, and the natives like to go away for a space. It is still the question whether they will continue to go to New Guinea when news of the unhealthy effect of the climate spreads to the different islands. Protestant and Roman Catholic missionaries labour among the natives, who to a great extent are still very dangerous and opposed to colonisation. Not a single year passes without murders by the natives. The firms in the Bismarck Archipelago sometimes suffer severely in this way as their traders on outstations are killed, the stock in trade robbed, and the produce, already gathered, burned. Very little is done to punish the offenders; a German war vessel will run down to the place, fire a few shells into the village, land a number of men, and burn the houses. The natives are so accustomed to these tactics, that they invariably leave their villages as soon as they see a war-vessel approach, and quietly return after it is gone, knowing that they will be left in peace in future. Under these circumstances, it is easily understood that many parts of the island are too unsafe for settlers, and the authorities openly acknowledge this by proclaiming that they are unable to protect settlers in certain parts of the islands, notably so in parts of New Ireland. On the other hand, settlers are not permitted to protect themselves in such cases, and not long ago a trader was kept imprisoned for about six months because he had fired upon natives in order to recover a certain quantity of trade, which had been stolen out of his boat. The man was eventually acquitted as being perfectly innocent of any guilt or offence, but it is not a very satisfactory thing for a trader to be imprisoned in case of any complaint being made against him justly or unjustly, and then to wait the decision of the Court, all the while being a prisoner. The taxes and duties levied by the New Guinea Company are not exorbitant. The firms and settlers, however, complain that they in many cases are hampered with petty restrictions on trade and communication, and that the taxes and duties go to pay the expenses of the New Guinea Company, which latter in no way does anything for the benefit of the islands. Even the steam communication which on every occasion is set forth by the Company as a great boon is not of so great a benefit as it on first sight might appear. The German firms get their supplies by sailing vessels direct from Germany. The American firm of E. E. Forsyth deals with Sydney, and the only benefit is a comparatively regular mail, although, through the nature of the business carried on in the Bismarck Archipelago, a regular mail certainly is a convenience but not a necessity to any of the firms. Lately a small trade has been opened up with Singapore but as far as the Archipelago is concerned, we do not think that it will be of any consequence.

There is unquestionably great scope for future undertakings especially in the plantation line, but German capitalists have up to date, with very few exceptions, been very reluctant about investing money in their own Colonies, and considering that a great deal of red tape is still in use here, foreign capital is not likely to be invested as long as better chances offer in other countries.—*Straits Times*.

NETHERLANDS INDIA.

The *Locomotief* calls attention to the prevalence of adulteration of food among Chinese dealers at Samarang. Butter, for instance, is mixed with plain flour and the aerated waters are of the foulest kind. All the falsified articles are in tins and bottles provided with counterfeit labels.

Papers just laid before the Netherlands Parliament give particulars of spice growing in the Moluccas, showing that, in some of the islands clove cultivation has been given up owing to unremunerative prices. In Banda, the nutmeg plantations still yield heavy profits. In south and central Halmahera, the nutmeg tree grows wild and so high, that only the fruit easily within reach is plucked. On the north coast of New Guinea, as well as on the western portion of the south

coast, the coconut palm is reported to grow luxuriantly. From there, copra was first exported on a large scale in 1891. In the Bargaal group, too, this article is prepared in large quantities and is bought up by Chinese from Gorontalo. The cultivation of coffee, formerly so widespread in the island of Ternate, has been abandoned owing to the variable climate hampering the fruiting of the trees. The trees show abundance of leaves and blossom but rain prevents fruit from being formed. The Sultans of Teravate and Tolore have taken steps at the prompting of Government to encourage coffee growing among the mountaineers in Halmaleira. The Government has undertaken to supply them with berries for the purpose. In the island of Bechian, the growing of tobacco has been unsuccessfully tried by two companies started in the Netherlands.

In Aceh, the year has closed quietly, as the Achinese proved less harassing than at the close of 1891. During the year tranquillity prevailed with the lines held by the army of occupation, who have also successfully balked the designs of the Achinese. On the coast, progress has been made in gaining the people over through the shipping regulation.—*Straits Times*.

COFFEE PLANTING IN COORG.

By far the greater number of European estates are situated in the great Bamboo or South Coorg District, where many of them lie contiguously grouped together, so much so in parts as to present vast sheets of continuous coffee extending over very large areas. It is this which lends so much force to the arguments in favor of running a railway from Mysore through S. Coorg on to Telicherry. The district consists for the most part of low undulating hills divided by valleys which have been terraced for the cultivation of paddy. These paddy fields form a beautiful feature in the landscape all over Coorg. The coffee is planted on flats or up gentle slopes, steep land being exceptional. The soil is exceedingly rich and it is altogether a splendid district for coffee, its only fault being that places down there have sometimes a bad habit of giving an excessively heavy crop one season and an extremely light one the next. The altitude of the country averages about 3,000 feet above sea level, and the rainfall to about 70 inches a year. Next in importance comes the Sun iroppa District of North Coorg, which resembles the Bamboo very closely in the undulating character of the country, the nature of the jungle, soil, climate etc.; but differs in regard to the estates not being so closely grouped and the crops being more regular. The third district consists of some large properties more or less scattered further North towards the Sowarpette (Monday Bazar) side of the country. I believe some of them are doing excellently. The Perambadi and Sampaji Ghauts and the region round about Mercara, the chief town in the country, which, once upon a time, were flourishing districts, have long since been almost entirely abandoned, and overrun as they are with lantana, present a scene of the most utter desolation. Some pieces of coffee are, I believe still kept up on the Perambadi Ghaut and three estates, one of which is a Cinchona estate, are still extant on the Sampaji Ghaut. Native gardens are to be met with almost everywhere. Having given a short description of the planting districts of Coorg, we may proceed to notice the position of the industry during recent years, and as it is at present. Its prospects in the near future may next be dealt with. During the great depression in the Coffee Market some years ago, which is still fresh in the memory of all of us, what with leaf disease, borer, small crops and low prices the position of the Planter had become well nigh hopeless. It was enough to make the stoutest love heart, nevertheless planters managed to keep things going buoyed up by the hope that better times were ahead; they came at last, prices mounted higher and higher, exchange went on steadily declining; and matters assumed quite an

altered complexion when estates, regaining some of their pristine vigour, gave the bumper crops of 1891-92. These crops came most fortunately for the Bamboo as they had been preceded by three bad seasons, the last of which the crops were so short on many places as not to pay working expenses. Probably the rigor in our economy that had to be practised during the depression alluded to was partly accountable for this state of things. Last year the highest price offered for parchment in the country was R14-8-0 per bushel delivered on the estate. This was considered sufficient inducement by some to sell, with the result that they sustained some loss as compared with those who sent their crops home to England. It was an ill-advised thing to do in the face of the prospects of a continued fall in exchange. The blossom showers of the present season were not entirely favorable. Nevertheless the crops which are now being picked on some of the North Coorg estates, will be a decided improvement on those of last season, while on all the others they will pay handsomely enough. The same cannot be said of the crops in the Bamboo, the gathering of which is probably nearing completion. The trees could hardly be expected to do much after their supreme effort of last season. However it is satisfactory to learn that no losses will be incurred. The highest price offered for parchment delivered on the estate that I have heard of this year, is R18 per bushel. A very good price no doubt, but general feeling seems to be in favour of shipping home, the object being to reap the benefit of any further decline in exchange that there may be. It is confidently predicted by people in Mercara that the price of native coffee, pounded and cleaned will fetch R400 per candy or R1,600 per ton! If this be the case the question may well be asked—"Wouldn't it pay planters to strip and sell their crops as native coffee? A saving would be effected in gathering which could be done at 2 annas a bushel and a number of other ways; and any apparent loss there may be, compared with prices obtained for parchment, would perhaps be more than made up for, by the increased vigour imparted to the trees which would enable them to bear better next year than will be the case with the present crop left to ripen upon them to the bitter end. It remains to be seen, however, whether these predictions will be verified. The highest price realised for clean native coffee last season was, I believe, R295 per candy. Owing to the high prices that have now been ruling for some time, lands which would otherwise have been left alone have been brought under cultivation. Several clearings were opened last year and are doing excellently; clearings that are well looked after come into bearing in the 2nd year. One estate three years ago, gave its 4 cwt. an acre in the 2nd year! Labor in S. Coorg has been quite up to requirements, but generally, places in North Coorg have not been quite so well off, indeed some places are shorthanded for crop, but I expect matters in this respect, will be notified by the influx of Pothur coolies which is now taking place. The losses from borer during the season just past have been very great, and the number of supplies put out enormous, amounting in many instances to 100,000 on places of 250 acres or so in extent. Leaf disease has also been very bad in parts, but good work has enabled the trees to throw it off and recover sufficiently to hold out fair promises of crop for the next season. On the whole, coffee is looking exceedingly well for crop next year, especially in the Bamboo, and now we await with anxiety the blossom showers in March, upon which the realisation of our expectations almost entirely depend.—*Nilgiri News*.

NOTES ON PRODUCE AND FINANCE.

TEA IN 1892.—Notwithstanding a lament from the Darjeeling district, last year was not a bad one for tea planters. Prices, it is true, were low, but that very feature is no doubt accountable for the very large home consumption of 207,000,000 lb. and was

also probably a strong factor in substituting Indian and Ceylon teas for those of China. The change in the public taste has been very rapid during the past twelve months; and the consumption of Chinese tea has in consequence fallen from 52,000,000 lb. in 1891 to 34,000,000 lb. in 1892, while the use of Indian tea increased from 99,000,000 lb. to 109,000,000 lb., and Ceylon teas from 51,000,000 lb. to 64,000,000 lb. in the same period. The increased consumption, combined with more remunerative prices, due to the crop barely equalling that of last year, is certainly encouraging to planters, while the danger of over-production is for the present indefinitely shelved.

THE CONSUMPTION OF VANILLA.—In view of the extended use, and, so far as household consumption is concerned, the frequent abuse, of vanilla, some statistics as to its consumption are interesting. A few years ago it was estimated that the world's consumption of vanilla was about 230,000 lb. per annum. There has probably been little increase in the requirements, as vanillin, the synthetic product, has usurped the place of the natural drug in many branches of manufacture. But, assuming that the consumption is now 250,000 lb. per annum, the depreciation which vanilla has undergone during the last two or three years appears fully justified by the increased output; for the crops of Bourbon, Mauritius, and the Seychelles alone are estimated at about 260,000 lb. in 1891, 200,000 lb. in 1890, 150,000 lb. in 1889, 150,000 lb. in 1888, and 350,000 lb. in 1887. And to this the Mexican production, which in good years is perhaps 100,000 lb., and it will be seen there is probably a sufficiency of old stock in the various centres to enable us to do without the 40,000 lb. a year or so which may be expected from Mauritius.—*H. and C. Mail*, Jan. 6.

TEA COMPANIES.

The writer of the article, which appears below, has taken a very superficial view of the situation of India and Ceylon Tea Companies, though that no doubt is natural enough. He has failed to notice the facts that whilst the date of Indian Companies goes some way back, most of the Ceylon Limited Liability investments are but of yesterday. On more than one occasion we have remarked in these columns on the small number of undertakings of this kind in the island, as compared to the total capital invested in the enterprise. Gradually all this has been changed, and for some time insular Tea Companies have been launched to a large extent, many of them having their office and agency staff in the island.

The method adopted by the local promoters of many of these companies is to begin by the purchase of one single property; having started it on its own basis of capital and working staff, the proceeds of crops are employed in its gradual extension, either by planting up spare land or by the absorption of some adjacent estate, which can of course be worked under the same supervision thus reducing that item of expenditure. The shareholders of these locally-formed Companies being to a large extent resident in the colony, are, as a rule, tolerably well informed as to the value of their acquisition and take care to keep themselves well posted up in all that relates to the property. They are mostly within easy reach of their estates and herein they have an advantage over those individuals who are chiefly resident in Europe or Calcutta, in any case a long distance from Assam.

No doubt all these conditions, as well as the opening of new land, go towards ensuring the success of Ceylon Tea Companies, nearly all of which are returning good dividends to shareholders; some few being remarkable instances of dividend-earning properties. The generality of these small companies, "limited" in more than one sense, are found most acceptable means for the investment of savings of persons of moderate means, who could not have taken up shares to any large extent, and thus would have been debarred from becoming estate proprietors on any scale such as prevails in India. We suppose none of the investors in the more for-

tunate Companies of Ceylon, anticipate a continuance of recent dividend earning exploits, but there is room for a sensible reduction on some late phenomenal distribution of profits, and at the same time leaving a very satisfactory account of profit and loss at the close of the year's operation. In India a return of 12 per cent is considered a remarkably good dividend, whereas in Ceylon the amount declared on each share ranges from ten to thirty per cent., one favoured Company having divided fifteen per cent. in six successive years with every prospect of a continuance of the rate.—*Ceylon Advertiser*."

INDIAN AND CEYLON TEA COMPANIES.

Of Indian companies, perhaps some of the best known are the Assam, Darjeeling, Doars, Jorhaut, Lebouy and Upper Assam. The £20 shares of the first-named are now quoted at 29 to 30. The Company has 9,341 acres under cultivation, and after the payment of 6 per cent. on the Debentures, the distribution on the Ordinary capital has been 10 per cent. for 1890 and 1891, and 6 per cent. for 1892—the yield at the present price being rather more than 4 per cent. The Darjeeling, with a cultivated area of 2,094 acres, has paid 6 per cent. in 1890 and 1891, and 5 per cent. in 1892. Its £20 shares stand at 18 to 20 and the return at this quotation is 5 per cent. The Doars, with 5,178 acres, after the payment 7 per cent. on the preferred capital, has distributed 10 per cent. on the Ordinary shares for three consecutive years, and at the present price the latter yield £7 11s 6d per cent., and the Preference £5 17s. The Jorhaut, with a rather smaller cultivated acreage, has paid dividends at a similar rate for 1890, 1891, and 1892, and at 30 to 32, the price now quoted, the return would exceed 6 per cent. Two properties, the shares of which are at a considerable discount, are reported to be on the improve, viz., the British India and Eastern Assam. The former is likely to pay 5s per share shortly, and it is deemed probable that the other may also come to the front again as a dividend-earning concern. Nothing has been paid since 1887. The Ordinary capital of the British India Tea Company, which originally was £240,000, has been reduced to £60,800, its market value at present quotations being not much more than £18,000. There are, however, £11,000 of Debentures bearing 10 per cent. interest. Of the Ceylon tea companies, that of the Ceylon Tea Plantations (Limited) stands high in public estimation, a dividend of 15 per cent. having been paid each year since 1887. The £10 shares stand at 15, and yield a return of 10 per cent.; while the Scottish Ceylon Tea Company distributed 15 per cent. in 1890, 18 per cent. in 1891, and has paid an interim dividend of 10 per cent. for the current year, the £10 shares being quoted 16 to 17, and giving a return at that price of £11 5s per cent. The results given above are good enough to tempt investors in this kind of security, but it must be borne in mind that sooner or later the supply may, and probably will, exceed the demand; and if the market price of tea gets down below a certain level, many estates not only cannot be advantageously worked, but dividend will fall off. Anyone, therefore, electing to buy shares in tea companies should be especially careful to select those which are of the highest class, and whose tea is thoroughly appreciated in the Mincing-line market.

CELLULOSE is being used as a protective covering for bottles. It is intended to take the place of the straw cases at present in very general use. Sheets of common cellulose are stamped with fairly deep indentations, oval in shape, about one inch long, less than half inch wide, and about the same distance from each other. The sheets are then cut into strips of the length of a wine bottle, and sufficiently long to go twice round it. They are then rolled round the bottle with the hand, so as to form a double shell, and are fastened together near the top and bottom with a metal spring, so that there is double protection to the bottle.—*Electrical Trade Journal*.

THE STEALING OF CACAO PODS FROM CEYLON PLANTATIONS.

The state of things revealed by Messrs. Martin and Gibbon on page 577 is simply monstrous and fully explains the necessity for the motion which Mr. J. H. Barber is to bring forward at the annual meeting of the Planters' Association. The Cacao planter is evidently worse off than ever his Coffee brother was, even in the palmy days of our former staple. And yet we can recall the time when on estates near Kandy, up the side of the Hantane range, the coffee thieves from town became so bold as to refuse to move from among the bushes even when the European Superintendent was close up to them. Nothing but the sight of a rifle in his hand frightened them; and even then we believe there was one case on Hopewell, where the thieves had a gun too, and threatened to fire if any attempt was made to capture them! The experience used to be, twenty to thirty years ago, that a certain (and sometimes a considerable) proportion of the coffee on the plantations around Kandy was bound to find its way through native thieving hands into the town bazaars, do what the managers would. And it seems now to be very much the same case in regard to the Cacao gardens in the Wattagama and Matale districts, with this difference: that proprietors now-a-days cannot afford to lose the percentage of their crop which they often scarcely felt out of their profits in the best days of coffee. We remember how Robert Boyd Tytler, the most humane of planting employers, urged that the evil of stealing produce from plantations had become so serious that nothing but permission to responsible Managers to pepper the culprits, found in the act in the fields, with "small shot" would stop it. Mr. Tytler seriously contemplated an appeal to Government for this permission to be granted in certain cases under a license from the Governor. But the "peppering with shot" suggestion was treated rather as a good joke. The punishment, it is clear, must be left in the hands of the Magistrates; but at the same time, it should be exemplary and deterrent; and it is evident that the stealing of cacao pods from the open field has got to such a pitch that only *flogging* can be expected to stop it. Considering the difficulty of capturing the thieves, we do not see why, after formal due proclamation round the villages, the infliction of lashes should not be ordered by Magistrates—if not for a first, most certainly for a repeated offence. It is evident that Government are waking up to the need of some step being taken; for the following circular has been issued by the Matale Assistant Agent:—

Matale Kachcheri, Jan 19th, 1893.

Sir,—I have the honor to request that you will be good enough to let me know, at your earliest convenience, about what number of cases of theft of cocoa there were on — estate during 1892, mentioning probable value of produce stolen.—I am, &c., G. SEXTON, The Superintendent, — estate, Matale.

We think there is a good deal in Mr. Martin's suggestion that better than the passing of a resolution bearing only on one side of the evil, would be the appointment of a small committee of planters—say Messrs. J. R. Martin, Vollar, C. Gibbon, Dewar, Barber, Pyper, with Mr. Philip as Secretary—to draw up a Report with suggestions as to special legislation and special executive precautions which could, after adoption by the Association, be laid before the Government. Such a Report could not fail to receive full consideration; for it is impossible to deny the urgency of the case already made out for special protection and relief at the hands of the authorities.

TEA.

TO THE EDITOR OF THE DAILY POST.

Sir,—Referring to your very interesting article in Tuesday's *Daily Post*, will you allow me to ask the writer or "any other man" how it is that after allowing the full claim of Indian and Ceylon tea being 50 per cent. stronger than China, by putting in the teapot half as much again or even double the quantity of China, we do not obtain the same milky appearance in the cold liquor as in the case of Ceylon and Indian, and why like port wine it clings to the sides of the cup in sinuous veins. As an amateur naturalist I have inquired of an analyst what that "something" is. Some have put it down simply to the extra strength; others that the two plants are of different species. From my own experience I am perfectly satisfied it is something more than extra strength, and something not findable in China tea at all. I am also very sceptical as to soil and climatic change evolving such an altogether new feature.—Yours, &c., E. F.

PLANTING IN THE EASTERN ARCHIPELAGO IN 1892.

Perak seems to have been the most prosperous among the Protected States. Roads have been extended, and surveys made for railways in prospect. Trade shows an improvement, having attained the respectable figure of \$18,500,000; while the export of tin (15,400 tons) was the largest on record. Progress has also been made in agriculture, numerous small lots having been taken up by Malays and Chinese, while Javanese are obtaining very satisfactory results with tobacco at S'itawan. European capital, however, is wanted to make planting an important industry, and the Government is urged to offer more liberal terms. Specimens of Perak tea have been sent home; but the better prospect seems to lie with Liberian coffee. There is enough tea in the world, whereas the demand for coffee is still insufficiently met. The Sultan has been made a K.C.M.G., in recognition of his successful administration. In Selangor, also, Liberian coffee promises well. The Utu Selangor extension railway was opened by the Governor in November. We have often urged that the Colony should be self-supporting as regards food, and gladly note that the Governor has addressed a circular to the several Residents of the Native States, desiring them to encourage rice, dholl, and grain cultivation. The development of North Borneo still proceeds slowly; but foundations are being laid for eventual prosperity. The immediate future seems bound up largely with tobacco, but not even yet can it be affirmed what will be the ultimate issue of this industry. There is no doubt that the soil will produce excellent leaf, but there is still some doubt about the climate. The probable reduction of the McKinley tariff is in favour of its commercial prospects. The North Borneo Development Corporation is casting

a wider net. Mr. Pryer hopes, at the end of the year, to have 1,000 acres under cultivation with hemp, Liberian coffee, sago, sugar, coconut and various experimental crops. He believes he can get sufficient labour at reasonable rates, and he has the unquestionable advantage of knowing how to manage natives. Alluvial gold has been found in Darvel Bay, but it remains to ascertain the value of the find. The ordinary trade and revenue continue to grow; but land sales have practically stopped, figuring for £841 only, against £39,942 in the previous year. As a consequence the accounts of the Administration for 1891 show a deficit. A concession has been granted for a railway, which would open up valuable territory; but the time is not opportune for floating schemes of the kind. The population has been estimated at 120,000. The frontier between British North Borneo and Dutch territory has been settled, and agreed to by the British Government and the Netherlands Chambers.

The experiment of tobacco-growing in Sarawak has conclusively failed, and the estate has been closed at a loss of \$600,000. The yield of sago is increasing, jungle produce is abundant, and the condition of the country generally, prosperous. The total value of the trade in 1891 was \$5,000,000, an excess of \$436,000 over the previous year. Ten thousand tons of coal were turned out of the Sadong mines.

Gold has also been found in the native State of Ootie; otherwise we hear little of Dutch Borneo. Trade throughout Netherlands India generally seems to have been fairly prosperous. Financial equilibrium has been restored besides providing for the expenditure on railways in Java and Sumatra, and on waterworks at Tanjung Priok. Dissatisfaction seems to have disappeared, and the population has been quiet. Sugar has been free from disease. A proposition to tax it was wisely rejected by the Colonial Minister. The Government policy as regards coffee appears to be still in a state of solution; but the tendency is evidently towards more liberal payments and eventual freedom. The present crop is estimated at 694,000 piculs. The yield of tobacco in Sumatra this year is estimated at 130,000 bales.—*L. and C. Express.*

MAURITIUS.

PORT-LOUIS, JAN. 10TH.

SUGAR.—The weather and the crop. The present hot and rainy season is very favorable to the plantation which is very fine all over the Island.

The Crop is over and it remains only to manufacture inferior syrups from the turbine. On the 31st December last, the number of bags received in town were less by 467,482, compared with the number received at the same corresponding period of 1991.

VANILLA.—The market is firm. A few small lots were sold at R20 to R23 per kil; Vanillons at R8 to R10. We entirely maintain our last as regards the outturn of the present crop which will not exceed 8,000 kilos. We quote nominally:—

		per kilo.	
1st quality	.. R.	20 to 23	} above 6 inches
2nd "	.. "	18 " 20	
Good to Middling	.. "	15 " 16	
Vanillons	.. "	1 " 10	

ALOE FIBRE.—The market is firm. We have to report the sale of 50 bales, first quality.

The following quotations are nominal.

1st quality	.. R.	250 to 275 per ton
2nd "	.. "	175 " 180

COFFEE.—Good quality have advanced owing to restricted importations and it is worth today R75 to 76 per 50 kil. Mixed triage qualities are nominal at R40 to 54 per 50 kilos according to quality. Reunion and Madagascar are wanting.—*Merchants and Planters Gazette.*

TEA FROM ASSAM.

The total outturn of tea from the Assam Valley during 1892 has been 44,617,676 pounds, against 467,373 pounds in 1891, or a decrease of 4,849,697 pounds.—*M. Times, Jan. 9.*

LIBERIAN COFFEE AND CACAO CULTIVATION IN NORTH-EAST MATALE LOWCOUNTRY:—

A LAND GRANT OF OVER 5,000 ACRES.

We think it must be nearly two years since we were enabled to report that Messrs. Wm Gow and E. Gordon Reeves (both of the K lebokka district) were in treaty with Government for a large grant of land in the lowcountry north-east of the Laggala range. We cordially support the application at the time and urged Government to afford the enterprising applicants every encouragement, their object being to give a fair trial to such products as Liberian Coffee and Cacao. Mr. Gow discussed the prospect of the enterprise very freely with us in London and he was sanguine of success both in a planting and financial sense. It is satisfactory now to learn that the grant has been officially conceded and that it covers a lease of no less than 5,014 acres alongside and west of a fine deep stream, the Kaluganga, which falls into the Ambanganga about 15 miles due east of Nalanda resthouse. One condition is that 500 acres of the block should be brought into cultivation within the first five years, and from the favourable reports passed on the land, among others by Mr. Wm. Mackenzie, there can be little doubt of this condition being fulfilled. Along with the two gentlemen already named, Messrs. Buchanan and Fraser are now associated in the grant, and all are determined to spare no pains to make this promising plantation a success. Mr. Gordon Reeves is naturally the one who knows most about the location, climate and outlet, and on these points he writes to us as follows:—

"The rainfall has been ascertained, having been carefully recorded since 1st March 1891 and is ample, fairly well distributed. I am now drawing up a comparative statement showing rainfalls of such cacao stations as Rajawela, Warriapola and D-a Ella, as compared with our Pallegama. The more that Pallegama is looked into the better will it appear. The result, will, I expect please you. The Kaluganga valley was some 1,6 0 years gone by, a most fertile well cultivated centre: as is still to be seen in the remains of great works and broad flats of old rice lands now much frequented by the beautiful naga, always a sign of ancient human habitation. The land is as well adapted for such cultivation as cacao, tobacco, and fibres of various kinds as any I have seen. The lay of the land and the depth and richness of the soil is, so to say, unrivalled and of the rainfall you shall judge by my returns which are absolutely reliable. We have, just as Dumbara has, our spell of very dry weather, July and August; but that cacao can stand a very severe drought when the soil is good has been amply proved, and I will certainly tack the Pallegama soil against any in Dumbara or elsewhere: moreover it is of such quality the land of such even lay that a drought would be of less danger than in a more exposed, gravelly, and hilly situation. We are practically on the flat; and on alluvial land where drought would take a long time to till, and where roots would work very deep."

We supplement the above with information given by Mr. Reeves in a letter to our evening contemporary as follows:—

"The rainfall very carefully taken for about three years, proves an annual, mean fall between 100 and 120 inches. Last year's fall was doubtless as everywhere else, exceptionally heavy, and amounted to 144½ inches! Of the average fall, say 110 inches, about 75 inches fell during November to April inclusive, in the N. E. monsoon; and the balance of 30 to 35 inches between April and November. We receive by the lease 5,014 acres, and are bound to cultivate 10 per cent. during the first 5 years. Our particular block is a long and very carefully selected strip, about 7 miles x 1 mile, with the Kaluganga, a large deep stream, for

its E-stern frontage, and a cart road (bridges not yet fixed) bisecting it longitudinally. There is some very fine land lying between our block and Palle-gama to the South, perhaps 1,500 acres, and more land with fine soil to the North; but the rainfall rapidly diminishes in this direction; in fact every mile would show a decrease of probably 10 inches as far as the Tamank-dua boundary, where the fall is probably not over 60 inches, of which 90 per cent. would come down in November, December, and January. Our land is very well sheltered, nearly the whole, quite 90 per cent., being heavily timbered and containing much valuable wood—ebony, halmilla, wewerani, etc. The soil is a rich loam, many feet deep, with a fair admixture of fine sand. The whole block is either nearly level or gently undulating, intersected West to East by a single low and rather gravelly ridge, perhaps $\frac{1}{2}$ a mile wide. That cocoa will grow in the district I took the trouble to ascertain for myself some years since, by distributing seeds of fine varieties obtained from Go-nambal, and the trees grown from this seed produced pods over 8 inches in length at 3 years old, with the beans well developed. We hope to work our concession almost entirely with local labor, employing Tamils only for special work. The climate is not really unhealthy much of the disease existing being clearly attributable to low living, bad food, miserable dwellings built with no regard for dryness of floor and wall. Palle-gama is an exception to the rule, being a very flourishing village of some 40 inhabitants with several fine stretches of luxuriant paddy, groves of coco nut, and areca palms, lying in a bend of the Kadung-ga. I have known this country for the last 18 years and have always believed that there was a future in store for it 1,000 years ago the valley of the Ka-u-ganga was probably one of the richest in Ceylon. I see no reason why it should not once more become the scene of prosperity. There is certainly no more beautiful corner in the island than the neighbourhood of Palle-gama; and it may fairly be called a sportsman's paradise, for it affords every variety of sport both with the hound, the rifle, and the rod."

There can be no doubt therefore of our being face to face with a most interesting, planting experiment in a new part of the country, and one which, if successful, may lead to a large extension of cultivation and to the great advantage of the local population as well as of the Government. The latter are to provide a decent outlet to join the Northern road at once, and it is in view of an extension of cultivation in this direction that we pleaded for the trending of the future Anuradhapura railway North-eastwards, so as to make it easy of access to the planters of the future by the Kaluganga, Ambanganga and Lake Minery and in the rich Tamaukaduwa district. There is no reason why this region should be exceptionally unhealthy when properly opened up, and as the beginning of a work which may be fruitful in important consequences, we wish the quartett of lessees all possible success in their venture. We fully approve of tea being excepted by Government from the list of products to be planted in the and thus specially granted.

THEFTS FROM CACAO PLANTATIONS.

We have received expressions of opinion in favour of a Sub-Committee being appointed at the Planters' Association Meeting to report on the best mode of dealing with the serious evil brought to light by Mr. J. R. Martin and Mr. C. Gobbon. One name that ought to be added to our Provisional Committee list is that of Mr. Melville White; but indeed the list of Cacao planters as shown in our Directory is a long one and includes besides those already mentioned, the following among others:—

Wm. Milre of North Matale; F. H. Davidson of North Matale; G. A. Wyatt, Matale; L. B. H. Dickenson, Matale; Thomas Jepp, Matale; E. Taylor Grigg, Matale; J. B. Tennant, Matale; J. Inch, Matale; Simon E. Purdon, Matale; W. Penny, Matale; R. J. Farquharson, Hantana; P. D. Young, Matale; A. J. Thomas, Morankanda; E. Scott, Morankanda; Alfred Payne, Kurunegala; D. M. Davidson, Huragery; C. H. T. Wilkison, Dumbara; C. W. Sinclair, Dumbara; Robert Brown, Raja; Hugh Miller, Teldeuiva; Dr. V. Duke, Kanda; J. Munton, Matale proprietor; J. A. Roberts, Pussellawa; H. C. Iman, Pussellawa; J. T. Hawke, Orion, Gamoola; R. Boustead, Wattegama; W. W. Parrinton, Wattegama; R. N. Anley, Wattegama; S. J. Sparkes, Passara; J. H. Betts, Passara; J. H. B. Cockburn, Buddulla; S. McNicol, Pandalnoya; F. H. Shelley, Madawalattenna; P. N. Braiue, Galagedara.

To these may be added the different Visiting Agents. One cacao planter writes:—"Your editorial is not one whit too strong, and I'll have to write myself in support of strong measures shortly." Another gentleman, who does not seem to have suffered so much as his brethren in the Wattegama and Matale districts, writes:—

"I am glad to see that you are giving the true note on the cacao question. Here we suffer too, but not to the extent evidently that they do in Matale and at Wattegama. My experience is that the robberies are committed by our own coolies, and much of it goes to be exchanged for arrack and toddy. I have had three thefts this year, and finding the watchmen had a good effect, for they hunted out the supposed rogue—a drunken fellow—who was cleared off the place at once, as there was no legal evidence against him, although the moral proof was strong enough, otherwise I should have had him up. As to selling to Moormen—there are Moormen and Moormen—I have done it, the cacao going straight to the station from the estate, and the price I have got for the produce in this way compared favourably with London prices. A lot which I sold in July last, 54 cwt., a sixth of which was No. 2, netted £4 13s 8½d a cwt. At the same date in London a shipment of No. 1 alone realized £4 8s 3½d.

"The watching of a cacao crop is a terrible worry and any means that could be devised to bring the petty pilferer to his senses, and the receiver to Government stone breaking would be a welcome relief. But after all the planter must depend very much on his own exertion, aided of course by every means which the Government can legitimately assist us with."

SUGAR IN BRAZIL.

Although coffee is the chief product of Brazil, its capacity for producing sugar is far greater. The cultivation has, however, been checked by the low prices prevailing for several years. Sugar refineries have been established under a State guarantee. The number of these factories is stated to be 53, the capital on which the Government guarantee interest being 38,950,000 milreis (4,381,875 £). In addition, there are 41 other sugar factories, which, although not enjoying a Government guarantee, are granted certain favours.

The Brazilian Minister of Agriculture states in his report for this year, that the results obtained from the granting of these concessions, have not answered to the expectations of the various Governments which have been in office since the promulgation of the law granting them in 1875. In order, therefore, to stimulate rivalry and lessen the burden falling upon the State through the guaranteed interest, a decree of October 4th, 1890, established the following prizes for such sugar factories as shall obtain the largest percentage of sugar at the smallest cost, namely, 50 centos (5,625 £) to those obtaining at least 50 per cent of sugar, with a distinction of quality; 30 centos (3,375 £) to those obtaining 11 per cent; and lastly, 15 centos (1,687 10s.) to those obtaining not less than 10 per cent of sugar.—*Bullionist*, Dec. 31st.

A MYSTERY IN FLORIDA.

Our excellent American contemporary *the Mechanical News*, is responsible for the following:—"From the centre of a large dense swamp, bordering on the Gulf Coast of Middle Florida, rises a mysterious smoke in the day, which changes to a reflection of light in the clouds at night, that is supposed to be a volcano. This mystery was observed by the earliest settlers of that portion of the State, and has remained visible ever since. The light is particularly bright during hazy weather, and can be seen for miles away, especially from the Gulf. Several attempts have been made by different parties to go in this swamp to its centre, and discover the cause of this mysterious smoke and light, but it is so dense and watery that all have failed to accomplish their purpose. Some distance in from its edge is growing perhaps one of the tallest pines in the State, which has been made use of by all the explorers. They nailed strips on it for steps, and ascended to its very top, from which point they could view at a distance the spot from which the smoke emanates and light reflects. They claim that the smoke does not rise in a steady flow, but in gentle puffs or billows, that appear to be white. Some claim that this is a bed of burning peat, others a vein of gas, but the general belief is that it is a volcano. The swamp is covered with rocks, all shaped as if they were deposited there in a molten state by a volcanic eruption, which confirms the idea of its being a volcano. In this swamp is also an Indian arrow point quarry, from which perhaps all the Indian tribes of Florida and South Georgia were supplied with arrow points."—*Discovery.*

NEWS FROM THE SEYCHELLES: PLANTING.

MAHE, Dec. 16th.

Immediately after the last mail left for Europe rain commenced to fall, and has continued almost without intermission up to the present. The vanilla crop is therefore saved, but is nevertheless estimated at 50 per cent less than would have been the case had the rains commenced a month earlier. A good yield may be expected, however.

There is a very valuable vanilla, clove, and hardwood timber estate at present in the market for sale, affording an excellent opportunity to an energetic and capable owner or manager of realising a fortune with a moderate amount of capital to work the concern.

Reports are frequently circulated in Seychelles that there is a want of labour, but experience has shown that where proprietors are prepared to pay fair wages, and treat their labourers with consideration as well as firmness, no difficulty is to be apprehended upon that score.—*Colonies and India.*

KAPOK.

Zanzibar.—The export trade in kapok in Ceylon is of very recent origin, probably not older than ten years. Previous to this the product had only a local demand for the purposes of stuffing pillows, cushions, &c., and this demand was so small that it did not even encourage the collection of the kapok found on the trees which were growing wild. Since an export trade has begun, the demand has increased so much that not only is kapok carefully collected from the trees growing wild, but great care is taken to preserve it, and plant new trees wherever the opportunity occurs. There is a large demand for the article in Australia, where it is used in the manufacture of pillows and cushions; and it is also exported to Holland and Fiji, where it is said to be used for the manufacture of cloth. Ceylon is not the only country where this article is produced, for Java, Samatra, and the adjacent island are also exporting it largely. The cultivation of the kapok-producing tree in Ceylon could be very much extended, not by growing it as a separate product, for then it would not pay, but by planting the trees at intervals in the low country plantations as shade and boundary-trees.—*British Trade Journal*, Jan. 1.

PLANTING NOTES.

Lower Dikoya, Jan. 30.

THE WEATHER here at present although apparently favorable—showers and sunshine alternating—is characterized by excessively cold winds at night which seem to prevent the bushes from flushing as freely as might be expected. One exception I hear of is when a neighbour thinks it necessary, for the strengthening of his bushes to allow the flush to run for 25 days. Some of us think with this leaf in the London market he might strengthen his purse more and thus compensate himself for any loss by harder plucking! The range of planting ideas in this district seems to differ as much as our rainfall: min. 195 ins. odd to a max. of 260 ins. for 1892, Nov. giving 6 ins. odd and Dec. only 1.58 in., with a start for 1893 of over 6 ins. to date. This is surely an unusual range of rainfall for one district?

TIMBER TREE PLANTING.—We have not yet been able to find the sort that will grow in our ravines principally composed of white clay, quartz, rock and swamp, &c., but have anticipated your suggestions in the *Observer* by having planted out as much as 200 acres on some estates with grevillea moluccana, wattle, iron bark, sapu, and jak, &c. A good few thousands of the last, now over 15 years old along boundaries and roads, show a good many fine specimens which will in time give some valuable timber. There can be no doubt the grevillea takes first place as being the most suitable for the varied elevations and soils of Ceylon. Perhaps 20 feet apart may be rather close for regular planting all over tea estates, but a simple remedy for this is always at hand.

OIL-DISTILLING IN GRASSE.—In an account of a visit to Messrs. Sozio & Andrioli's essential oil distillery in Grasse which appears in a French journal it is stated that an average quantity of 2,000,000 kilos. of orange-blossom, 1,800,000 kilos of roses, 3,000,000 kilos of violets, and 400,000 kilos of jasmine flowers is distilled every year by all the factories of Grasse combined.—*Chemist and Druggist.*

MATALE TEA, Jan. 25.—We have been having fairly good flushing weather until lately when the wind changed from moderate to what might be called immoderate, or a beastly wind, as you have got to hold on to your hat if you don't want to lose it, and be on the look-out at every corner to make sure of your progress. Under present circumstances the wonder is that tea flushes at all. The rainfall this month has been well distributed, 16 of the 25 will add to the year's total of wet days. We did not do so badly in that line last year with 154 days and 129.77 inches to which January contributed 51.18 inches in 26 days. Our driest months were:—

March	2 days	2.44 inches
May	7 "	3.92
June	2 "	2.26
July	2 "	3.72
Sept.	7 "	1.83

Although August with 2.06 inches had less rainfall than July, its record was for 21 days.—Jan. 26th.—With the rain last night which measured .37 inch, the wind has ceased and the weather looks like more rain. Coolies are leaving in gangs for the Coast many of them via Colombo as they can do the journey so much easier and quicker, it is reported that East Matale area of tea 5 years old is 5,145 acres

867 acres 2 years and upwards
719 acres 2 years

6,731 acres and the estimated yield 1,950,000 lb. for 1893.

COMPARATIVE STATEMENT OF RAINFALL IN THE CACAO DISTRICTS OF CEYLON.

We are indebted to Mr. Gordon Reeves for the following return of rainfall in the principal cacao-growing districts of Ceylon. The comparison is afforded for two years only, a period rather too short for absolutely safe conclusions, but there is enough evidence to show that Pallegama, where—the 5,000 acres grant of land is situated,—has as much and as well distributed a rainfall as the Dumbara Valley and Matale town:—

Name of estate and District.	1891.		1892.		Means.	
	Rainfall	No. of days.	Rainfall	No. of days.	Rainfall	No. of days.
Rajawella, Dumbara	41.09	136	57.67	153	59.21	120a
For 10 ms.						
Pallegama village, East Matale	89.56	113	159.21	144	134.38	138b
Matale Town	—	—	—	—	76.09	130c
Dea Ella, Madawalattenna	—	—	—	—	93.08	162d

Remarks:

a Means for 22 years. This record would hold good for Pallikele estate which adjoins.

b Approximate mean for 2 years. Taking the rainfall of January and February 1891, the 2 missing records at 20" on as many days.

c Mean for 6½ years. This station lies halfway between the estates of Berredewela, Suduganga N., Warriapola, S.

d This record is for 8½ years and is practically the same as Kurunegala town which shows about 80 inches on 165 days.

NATIVE EMIGRATION FROM CEYLON.

It is a curious fact, as once more made evident by our correspondent "B." (see page 578), that the Sinhalese—usually regarded as among the most conservative and stay-at-home people—are, in some parts of the island, very ready to offer themselves as emigrants to other lands. Be it Queensland or Central Africa for which plantation labourers are required, it seems to make no difference, they are ready in certain districts to offer themselves by scores and hundreds to any Emigration Agent who will pay their passage, promise good wages and perhaps (as one specially inducing cause?) who will give them an advance or indenting bounty before departure? This strange fact was first realized some twelve years ago when a Ceylon planter, Mr. H. St. Geo. Caulfield, engaged a shipload of Sinhalese to proceed to Northern Queensland to supersede or supplement Kanaka labour on the sugar plantations. Both official and unofficial observers were astonished at the readiness with which the Sinhalese then engaged themselves to cross the ocean to an unknown land. But it was soon discovered that a large proportion of these were adventurers in the sense of being old gaoi-birds; and the late Sir John Douglas,—entering into the humour of the situation, and thinking there would be no harm, as there was no law to prevent such emigration, in relieving the island of a proportion of her criminal class,—gave Mr. Caulfield the hint that he had better expedite departure in his case, as the Government was bound forthwith to pass an ordinance to regulate such emigration. Mr. Caulfield's shipload departed, and we all remember their reception and conduct in Northern Queens-

land. The less said about Sinhalese there to this day, the better! Then came the Ordinance No. 4 of 1882, to regulate the Emigration of Native labourers from this island under Contract of Service. This was absolutely necessary, because otherwise the Indian authorities would have stopped the free flow of Tamil coolies to Ceylon, seeing that they might thence be taken beyond seas without that control and regulation which are insisted on in respect of all cooly emigration save to Ceylon. It is, therefore, useless for any agent here to expect to engage Tamil cooly labourers, save under regulations as precise as those of the Indian Government. The ordinance of 1882 was, of course, intended to apply more particularly to Ceylon-born labourers, whether Sinhalese, Tamil or of other native races, and no contract with them to go abroad can be allowed unless emigration to the particular place or country has been previously proclaimed by the Governor in the Gazette as lawful. Now, we are not aware that any such notification has ever appeared up to this date? Therefore, it is clear that no emigration to East Africa or anywhere else can take place. But perhaps the Government at this moment are considering, under "B.'s" application, the propriety of making such a notification in the Gazette. If so, and the result is an approval of East Africa, then it will be lawful to enter into contract before a Police Magistrate with Sinhalese or other native labourers to proceed thither.

Thus so far is how the case stands; but now we have to consider the strange readiness of the Sinhalese in some districts to leave their country. One organ in the press and a certain section who are never done declaiming against the British administration (which has done so much for the Ceylonese) will, of course, say "Oh, such readiness is because the people are oppressed and have not enough to eat." The answer to this is afforded beforehand by "B" who testifies that, while the adjacent planter, who is ready to pay them well and to stand between them and oppression, cannot get the Sinhalese to pluck his tea or otherwise work or him, yet the same people are ready in large numbers to go to East Africa to work on plantations! The only explanation that occurs to us, besides that hinted above,—the desire for a bounty sum in advance, is that the people of this island, even the so-called conservative Sinhalese, are getting imbued with a love of travel and adventure. Why not? The inhabitants of islands (and particularly of comparatively small ones) are always among the readiest to move, to cross the sea, or to try a new life. Then, the Sinhalese have for well-nigh 400 years been overrun by successive European nations—by the Portuguese, the Dutch and the English, all teaching them so many object lessons about the ease with which the ocean is crossed and recrossed. While in these modern days, first at Galle and more recently at Colombo, thousands upon thousands of the people have watched the regularity of the arrivals and departures of steamers from and to Europe, China, Japan, Australia, &c., until these and other names have become familiar in village homes not simply in the Colombo district but in the more distant Kegalla and Kurunegala districts. There may possibly be a simpler and more cogent reason than we have hit upon, but we must await its elucidation until our correspondent "B." has one way or other settled his negotiation with the Government.

ASSAM—A PARADISE; AND CEYLON FAR BEHIND!

(From a planting correspondent.)

Two Assam tea planters who were here lately would have it that they live almost in a Paradise. Their factories were equipped with all the latest improvements. No machines in use in these parts but were obsolete in Assam, thrown out long ago! Coolies were plentiful. The average plucking was 80lb. a day, the leaves often rivalling in size the biggest you would find on cacao. And their Calcutta agents' one cry was "Don't spare expense." Prices were at the top of the market, so were salaries, not to mention substantial bonuses. The atmosphere about these fellows much resembled what some of our planters experience in trains—only it was more so. They had it that India was lying low, till Ceylon was played out, and then she would step in and take the cake. One of them when passing a swamp in the lowcountry, where some old cinnamon trees were struggling for life, asked "When was that tea abandoned?" They were in a carriage however, remember, and the train in this case had nothing to do with it.

WHAT THE NATIVES THINK OF VALUABLE COCONUT LANDS.

(From the "Dinakaraprakasa.")

It is seldom that valuable coconut properties can be purchased. Now there is an opportunity of buying such lands. Some valuable coconut estates situated near the Mahaaya and belonging to the estate of the late Mr. J. B. Daniel are advertised for sale on the 11th proximo at Colombo. On referring to the small book in which the accounts of these estates for the last 15 years have been entered it appears that 70 nuts was the average product of each tree. The portion of land of 81 acres is fully bearing, and those who know the value of coconuts will know the value of these lands. In the other properties, half of their extent contains fully bearing trees, and each tree produces on an average more than 50 nuts. As there are thousands of trees to becoming productive year by year these lands will become very valuable in the future. When the trees in Colombo lands are considered, and that even substantial banks do suffer heavy losses, there is no better way to invest money safely than in the purchase of coconut lands.

It is seldom people get an opportunity to buy such valuable properties as are to be sold now, and therefore we say that those who wish to invest their money safely ought to buy these properties. On reference to the account books now in the possession of the owners and auctioneers it appears that those who purchase these properties will be able to get the interest on the purchase amount safely.

The properties are to be sold to enable the exutors to act according to the last will of the late Mr. Daniel.

TEA PLANTING AND PRICES.

(From a Planting Correspondent.)

If we don't get better prices for fine tea, we must go in for coarser plucking. These pestiferous blenders and packet-men can only take so much of fine tea to mix up with ubbishy China and India tea.

AN AUSTRIAN SCIENTIFIC VISITOR.

Herr John Bolle, Knight of the Iron Crown 3rd Cl., Director of the I. R. Experimental Station of Agricultural Chemistry, Vice President of the I. R. Agricultural Society, from Görz, Austria, is on a visit of a few days to the island. He goes to Kandy and Peradeniya Gardens tomorrow, and to Nuwara Eliya and Hakgala and Tea Gardens on Monday and Tuesday, returning to Colombo on

Wednesday and leaving on the following day. Mr. Bolle is very anxious to see coffee leaf-disease (which he may do at Peradeniya probably) and also tea in the field and factory. We bespeak attention to this Agricultural savant during his few days up-country.

THE AREA OF LAND UNDER COFFEE CULTIVATION IN THE MADRAS PRESIDENCY.

The following are the figures published by the Government, as to the area, production, and cost of cultivation of Coffee in the different districts of the Madras Presidency for the year 1890-91, which is the last available. It will be observed that the area given for each District, is the amount taken up for cultivation, not the area of mature Coffee while the figures on which the average out-turn per acre is calculated are not given. The cost of production per acre varies so greatly in the different districts that it cannot be accepted. The great difference cannot be accounted for by the larger crop per acre which would entail greater cost per acre for the preparation and carriage of the crop, as the largest-bearing districts are by no means the most costly. While the statement of the total production of the Presidency by no means agrees with the statement of exports from the West Coast for that year, which amounted to nearly 15,000 tons. And although the fine coffee districts of Coorg and Mysore are not included in these figures for the Madras Presidency their crops would by no means account for so great a difference. While from so many small proprietors it must be possible to get reliable information. The total area of land in the Madras Presidency taken up for coffee cultivation is stated to be 192,000 acres of which 66,800 are under mature plants 9,200 under immature plants, and the remainder 116,000 acres not yet planted. This land is divided up into 16,676 separate plantations giving each proprietor 12½ acres of land as an average or 4½ acres of mature coffee each; the total production is put at 7,792,000 lb. say 3,500 tons or about 1 owt. per acre average all round and the cost of production is said to vary from R150 per acre in Malabar to R12 per acre in Tinnevely. With such statistic only at hand it is not to be wondered at that the Government and the Collectors desire further information. Probably the only reliable figures are with reference to the area taken up for cultivation, and number of plantations.

District.	Area in acres	No. of plantations.	Yield in Pounds.	Average per acre in lb.	Cost of production per acre.
Nilgiris	93-635	679	4,126,000	190	70

—Nilgiri News.

DAVIDSON'S SIROCCO DRIERS.—The number of down-draft Siroccos exported by Messrs. Davidson & Co. now amounts to over 2,700. We also learn that a large shipment of up-draft Siroccos has just been received in Ceylon. There is evidently a "boom" among planters in these machines.

TREE PLANTING ON TEA ESTATES.

(By Old Colonist.)

Your leading article in the *Observer* of the 5th ult on "The Great Tea Planting Industry" strikes a key which I trust will be taken up all over the planting districts. For, unquestionably, the planting and cultivation of useful trees for fuel, timber and shelter, is a matter of vital interest to the proprietors of tea estates. Nothing could improve the beauty and amenities of these properties so much, and nothing at so little cost could add so much to their value or tend to their duration. The planter who neglects this important duty is less than half a planter,—merely a "tea tota karum"! Indeed, the caution and advice has equal force for agriculturists in every part of the world, particularly where the cultivation of any one plant predominates; and nowhere is it more necessary than in our own beloved Scotland.

A few days ago I had to notice a work on forestry (as under), and in today's *Aberdeen Free Press* I am glad to note our distinguished neighbour, Sir Arthur Grant of Monymusk, in leading type reviewing the reviewer very appreciatively says "the example of financial success you give which attended a plantation in Athole, is, I believe, quite true," but pests have increased since then. He adds that he himself "plants from 300,000 to half a million trees every year," chiefly to give shelter and improve the climate, though he has four enemies to contend with, viz., "rabbits, squirrels, larch disease and lucifer matches."

The review referred to is as follows:—

TREE-PLANTING IN SCOTLAND.

THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY. Edited by Rev. W. Wilks and Mr. John Weathers. Offices: 117, Victoria Street, S. W.

To all who love the "good green woods"—and who does not?—the goodly volume of 588 pages, demy 8vo, constituting the "Journal of the Royal Horticultural Society," ought to prove interesting reading, and as a work of reference on its special subject it deserves a place in every Public Library.

The speciality of this volume (XIV) is a report on the Conifer Conference held at the Obiswick Gardens, October 7th and 8th, 1891, but unlike most books, it is more than it professes to be, containing, as it does very valuable papers by Dr. Maxwell T. Masters and Professor Carl Hansen, of Copenhagen, which they had carefully recast at their leisure, since the Conference was held. Both are reliable authorities on conifers, a subject a more intimate knowledge of which would be of the greatest importance to us in this country.

We well remember, some twenty years ago, our late keenly-intelligent townsman, Mr. George Reid, endeavouring to impress upon proprietors the advantage of planting up waste lands with conifers, instead of reclaiming them with the vain hope of profitably growing corn. He also addressed a communication on the subject to the Government of the day without eliciting any favourable response. He next addressed himself to the President of the United States, backing up his recommendation by the offer of a large consignment of suitable plants gratis, an offer which was at once accepted, and for which he received the cordial acknowledgments and thanks of the United States Ministers.

Mr. Reid's theory, as applied to Scotland, was that average moorland at a moderate altitude would, if planted, improve in value at the rate of about 20s per acre per annum up to 60 years, when the timber would be worth from £60 to £70 per acre. That this was a moderate estimate has already been incontestably proved in many instances, one of which we might quote:—

On Athole estate some bleak hillsides were planted up, which never yielded 2s 6d an acre

in rent. There was of course, little return for the first 25 years, but after this period the plantations yielded in thinnings sufficient to cover cost of planting and interest; and when 80 years old the timber was sold for £130 per acre, which sum, capitalised and invested at 3½ per cent., would give a perpetual rent of £4 4s per acre, in place of the half-crown for which it was formerly rented by a grazing tenant! Nor is this all the benefit to be derived from planting. The shelter to cattle and amelioration of climate locally, have helped as much as anything to the improvement of our stock.

There is still an absurd notion abroad, that the land and climate of Scotland are unsuited for timber-growing on an extensive and profitable scale, the fact being, that— notwithstanding the dictum of Dr. Johnson—there are few countries in the world more suitable for the growth of conifers. Let anyone who now doubts this listen to the chairman of the Conference in his opening address on the 8th October 1891.

Anyone, said Mr. Thibselton Dyer, C.M.G., who had not travelled in Scotland could form no idea of the extent of which rare conifers were cultivated in that country, and the splendid development which they attained. . . . Magnificent examples, 70, 80, and 100 feet high, were to be met with. Such trees could only be seen in Scotland, and were the result of a peculiar association of physical conditions. In the south-west of England it was impossible to find a parallel, though even on the sunbrent soil of Kew good specimens of the pines were occasionally to be seen. With regard to the abies, however—that section of conifers of which the spruces may be taken as a type—a state of things prevailed in Scotland which could not be rivalled in England.

We might also quote other sources—the opinion of M. Boppe, Inspector of French Forests, who visited and reported on the forests of Scotland on behalf of his Government. "North," he says, "of a line drawn from Perth to Greenock there are 5,000,000 acres regarding as waste which are capable of furnishing valuable timber forests. Everywhere, both at a few feet above sea-level and on the sides of mountain at an altitude of 2500 feet, in the sands of Forres and in the schists, sandstones, granite, and gneiss of the interior, we were struck by the wonderful aptitude of the soil to forest vegetations, favoured, as it is, by a regular climate and the constant humidity of the atmosphere.

There is, it seems, no country in the world of the same limited area where so many exotic species of coniferæ grow and thrive, and yet we cannot claim but 3 out of the 250 now cultivated as natives of Scotland, viz:—*On* Scotch pine, juniper, and the common yew.

As to the quality of the timber of our Scotch pine we would, by the way, differ *in toto* from one of the speakers—Mr. A. D. Webster—who declared that "the almost valueless timbers of this tree will always be a serious draw-back." This is entirely opposed to our own experience, and we venture to think to that of most others. The celebrated engineer Brindley declared it to be "as durable as the oak; beams which had been built in old castles in the Highlands were found quite fresh and sound after 300 years," while another equally good authority says, "the economic value of the Scotch pine as a timber tree is probably not surpassed in the aggregate by that of any other tree known."

Many who have not hitherto paid much attention to this subject must marvel at the variety and number of species which have here been called from every corner of the earth. From our own noble fir—(*Pinus Silvestris*), and a native of Upper De-side, to the beautiful cypress-topped pine (*Phyllocladus rhomboidalis*), which adorns the moist mountain-ranges of Tasmania; from the mammoth tree of California (*Wellingtonia gigantea*) to the Lilliputian junipers of Siberia, what a wealth of woods and interesting sylvan territory is represented! But the important lesson for us to learn from the report of this Conference is how to select

and utilise the most suitable varieties for our local requirements.

The only serious fault that we, as amateurs, are disposed to find with these savants is their nomenclature. And it is not merely the outlandishness of the names they choose to give but the ever-recurring tendency to change these names, however well established, often for no better reason than palpable petty jealousy. Take, for instance, the *Wellingtonia*, which we have just mentioned, a tree discovered and brought to England by an Englishman, very appropriately named this loftiest of trees after one of the noblest of men. But by-and-by the Yankee botanists began to express a desire that the tree should be called *Washingtonia*, while the savants shrugged their shoulders and said, "We do not love the name of *Wellington*." So a compromise has been made, and a fiat has gone forth that henceforth the mammoth tree shall be known by the name of—*Sequah*!—We beg its pardon—*Sequoia* is the spelling, and which may mean *Tenfelsdrück* for anything we know! Now imagine the result of this caprice—every botanical dictionary printed during the last 40 years is pronounced incorrect, every label in every botanical garden in the world upon which "*Wellingtonia*" is printed has to be replaced, and every nurseryman is urged to "correct" his catalogue. We doubt, however, if the average Briton will submit to this dictation, and more than suspect that "*Sequoia*" will be left very much to the French, German, and Dutch sages. We note also that the well-known *Abies Abertiana* is henceforth to be known as *Tsuga Mertensiana*, the Douglas fir to be transmogrified into the sweet-sounding *Pseudotsuga*, while dozens of other changes add to the inextricable confusion. One would imagine that these Continental experts delight in making the language of botany and horticulture as difficult, incongruous, and repellent as possible.

Not the least interesting pages of the work under review are the tables showing the heights of the various conifers growing in the United Kingdom from which we note that the loftiest *Wellingtonia* in Scotland is at Murtby Castle 66½ feet. (The two *Wellingtonias* planted by the Queen and the Prince Consort at Haddo House 36 years ago, are each 50 feet in height.)

Arucaria imbricata Reached height of 55 feet at Portalloch,

			Argyllshire.
<i>Abies Douglassii</i>	...	94 do	Dunkeld.
Do do	...	90 do	Durris.
Do <i>Nobilis</i>	...	82 do	Dunblane.
Do do	...	64 do	Haddo House.
Do <i>Pectinata</i>	...	110 do	Lnss.

Dumbarton.

(The loftiest in Scotland).

Only one specimen of *Dacrydium* (the celebrated *Huan pine*) is enumerated, 8 feet high. No *phyllocladus*, though specimens of this valuable and beautiful pine were said to thrive in County Down 30 years ago. The peculiarity of this tree is that its wood is unshrinkable. It may, and often is in Tasmania cut down one day and made into furniture the next, without fear of shrinkage or warping.*

A. S.

THE AMSTERDAM CINCHONA AUCTIONS.

(TELEGRAM FROM OUR CORRESPONDENT.)

AMSTERDAM, Thursday Night.

At today's bark sales a considerable proportion of the Java cinchona offered was bought in, only 3,690 packages being sold at an average decline of 5 per cent. on the preceding auctions, the unit being now 5-80c., or equal to just 1d per lb. Manufacturing barks in chips, broken quill, and dust brought from

* I would be glad to learn if this valuable tree (the *Celerytopped pine*) has been introduced into Ceylon. I sent seeds at one time, but never heard if they germinated.

5c to 80c (equal to 2½d to 7½d); druggists' barks in broken and whole quill, partly very fine, from 10c to 122c (equal to 2d to 1s 10d; ditto root, 10c to 16c (equal to 2d to 3d per lb.) The principal buyers were the Mann in Brunswick, and Auerbach Quinine-works, Mr. Gustav Brigleb, and Messrs. Matthes & Bormcester.—*Chemist and Druggist*, Jan. 14.

CHINESE TEA MILLIONAIRES.

There are, we understand, altogether in the various tea districts as many as eighteen reputed millionaires. The least wealthy of these is said to be possessed of two millions of dollars and the richest eight millions, all made out of the tea trade in its flourishing days. In spite of the adverse turn taken in the trade they still continue in it.—*Foochow Echo*, Jan. 14.

SPORT IN SOUTHERN INDIA AND JAVA.

A most handsome volume, copiously illustrated and well printed on good paper, has recently been added to the always increasing library of the chase, under the title of *Records of Sport in Southern India* by the late General Douglas Hamilton, M.D. (Porter) General Hamilton's experience in South India appears to have extended from 1839 to 1871, and consequently was chiefly with the muzzle-loader; indeed, it does not appear that he ever used a breech-loading rifle in India. Hence his book is useful rather as a record of what has been done than as a guide to what may be done now. And it is doubtful whether the increased advantages in weapons compensate for the decrease of game which is general over India save where it is specially preserved. In fact, one of the first things about this book to strike a sportsman as remarkable is the great variety and quantity of game found in a limited area. It seemed by no means uncommon that the author should go out in quest of one sort of game and return having killed or seen in addition four or five wholly distinct species. For some of the animals the name used by Madras sportsmen seem singularly inappropriate. Thus they invariably call the gaur (*Gaurus gaurus*) a bison, which is wrong; the author, curiously enough, p. 237, finding fault with Col. Campbell for saying that they call this animal a wild bull, which is right. Moreover, though a fire animal, it does not equal in size or spirit the wild buffalo (*B. arni*), whose horns instead of being from twenty to thirty-five inches, attain the prodigious length of six and half feet, and are used by it to charge, and even overthrow, a moderate-sized elephant. Again, the well-known barking deer (*C. aurcus* or *C. muntjac*) is miscalled "jungl-sheep"; the reason given for so doing sounds somewhat Irish—"the name being derived from the word *Jungle bakri*," which unfortunately means wild goat. The wild goat of the Nilgiri hills is styled ibex, a term which is, however, somewhat elastic and indefinite. Chap. iv. in which the reader is carried to Singapore, Java, and Labuan, has interest apart from that belonging to sport. In it several words are used which appear to form part of the colloquial speech of Java, and are not to be found in Yule's "Glossary." They would have greatly interested the accomplished author—now, alas! no more—of that mine of information; and as they may still be of service to his book, we quote the following (p. 78):—"These trees are generally planted in the centre of the Allon-Allon, the Javanese name for the open square before all the houses of the great men, on which they have their tiger fights and parades of troops, &c." Again p. 84. "There are open plains of low allony-allony* (a broad-bladed grass), up to a man's waist," and, p. 89, "the banting (*B. sondaicus*), somewhat like an Indian bison." Banteng is mentioned in Jordan's "Mammals of India" as the Burmese wild cow. We have difficulty in excusing the constant slaughter of females

* This should, of course, be "alang-alang," the illuk grass of Ceylon.—Ed. T.A.

of the various breeds by so experienced a sportsman, and it would seem that the pair was of an shot and left to decay in the jungle. There may possibly be reasons for this which are not stated. The killing of elephants also appears to have been indiscriminate; but this has probably, since those days, been regulated by Government.—*Athenæum*.

THE EUCALYPTUS-OIL INDUSTRY.

Of all the minor benefits to the community that came in the trail of last year's visitations of influenza and cholera, the magnificent business opportunities which these epidemics afforded to the originators of sundry new remedies were, perhaps, the most clearly definable. Scores of enterprising manufacturers knew how to take occasion by the hand, and have waxed fat accordingly. Among these the eucalyptus-oil distillers and their agents occupy a distinguished position; but while these gentlemen have reason to feel some measure of gratitude for the epidemics, they have probably long ago come to the conclusion that it was, for them, an ill-starred speculation that caused the price of eucalyptus oil to advance for a few brief spring weeks in 1892 from 3s to 12s per lb. What most people foresaw has come to pass. The production of the drug has out-distanced the demand at an enormous pace, and today the commercial outlook for the oil, from the producer's point of view, is as bad as it has ever been. There are few brands of proved excellence, the proprietors of which, aided by clever and free-handed advertising, have obtained a hold on the market so firm that it will carry them through the period of over-production upon which we have entered; but the mass of smaller or less enterprising producers who have shut up like weeds in all quarters of the world will assuredly have to face extinction after an ineffectual struggle to make their industry pay. Only a few weeks ago we announced the inauguration of several new distilleries in Tasmania, but in the neighbouring colony of Victoria the eucalyptus mania is developing still more alarming symptoms. All the Australian colonies are passing through a cycle of commercial depression almost unexampled even in new countries; and it is therefore but natural that industries which in better times attracted comparatively little attention should now be resorted to with something like the energy of despair. Still, the news that within the last few months from 30 to 40 new eucalyptus distilleries have been started in the Victorian districts of Bendigo and Gippsland, denotes a recklessness on the part of the persons concerned which is only ascribable to their absolute ignorance of the extent of the field of consumption of the oil. It is, therefore, in the interests of the misguided over-crowders, quite as much as of the established traders in the drug, that the newcomers should be warned not to cherish any hope whatever of making a living by the venture. There is much more eucalyptus oil produced now than there is an outlet for at present. We quite recognise that the Australian distiller commanding plenty of practically gratuitous material on the Crown lands of his colony, which it only requires a still of some sort to convert into what we will by courtesy call eucalyptus oil, can produce cheaply; but that is not all that is required. Most of the new distillers, if we are rightly informed, have little or no knowledge of the variety or quality of oil they produce; and, unlike the well-organised Australian and Californian companies, they cannot ship direct to London. They are dependent upon some trader in Melbourne or elsewhere who can only afford to pay them a starvation price, and who, in his innocence, mixes together all that he buys from his various clients and consigns the whole to Europe to be sold as well as may be. There are lots of such consignments in the market here now; they come in tins, in cases, and in kegs, they obtrude themselves to weariness at the public sales, and if sometimes they are ostentatiously "knocked down" at one auction, it is only to bob up serenely again on a subsequent occasion. There is more than one holder who would take 2s per lb. gladly for his stuff if he could but get an offer. But he cannot. Wholesale and retail dealers almost with-

out exception have stocked themselves full in anticipation of fresh epidemics this spring, and it would take an influenza on the scale of one of the plagues of Egypt to create a fresh scarcity of eucalyptus oil.

Much attention has lately been paid to the chemistry of this oil, and careful investigations, if perhaps not carried out altogether in the spirit of the philosopher to whom science is its own reward, have elucidated many points of considerable commercial value to those handling the article. The researches of Helbing and Passmore, for instance, to go no further, have established that an oil of eucalyptus to be medicinally trustworthy should yield "about 40 per cent of eucalyptol by crystallisation from the fractions obtained above 172° C.; and it is generally believed that the oils of high density should yield less than 5 per cent of distillate below 170° C., with only traces of aldehydic bodies"—a condition which necessitates careful redistillation. According to the same investigators, the manifestation of irritating action on the mucous membrane when inhaling the odour of a sample showing itself in a tendency to produce coughing indicates the presence of a volatile aldehydic compound which constitutes an impurity. Whether this opinion is correct or not is another matter, but it at least deserves consideration.—*Chemist and Druggist*.

COFFEE CULTIVATION IN MEXICO.

The *Bulletin du Musée Commercial* of Brussels for the 29th October extracts the following information respecting coffee cultivation in Mexico from a report addressed on the 30th September last to the Belgian Department for Foreign Affairs by M. Fedor Berns.

The cultivation and export of coffee will become very shortly one of the largest sources of wealth in Mexico. The climatic and topographical conditions of the country adapt themselves marvellously to the cultivation of coffee of superior quality, equal to the best Java product.

The districts where the best Mexican coffee is produced are situated on the slopes of the "Sierra Madre," as well as in the valleys to the north of Sinaloa and on the coasts of Yucatan and Tamaulipas. A large proportion of Mexican territory consists of elevated masses formed by the extension of the Cordillera and declining gradually to the Atlantic on the east and the Pacific on the west.

The whole of this vast stretch of land forms one of the richest and most fertile zones in the world. Owing to its geographical position, it enjoys a tropical vegetation, and its altitude above the level of the sea secures for it an unrivalled fertility and an enormous variety of natural products.

It has been sufficiently shown, by trials for more than 50 years, that the lands and climate of Mexico are adapted to the production of fine coffee; these trials have also shown that the profits for the coffee-grower and the quality of the product cannot be surpassed by any country in the world.

The lands suited to the cultivation of coffee in Mexico are almost unlimited. Labour is cheap, rarely exceeding 25 centavos per workman per day. The best coffee in the world is at present grown at Cordoba (Vera Cruz) and at Sinaloa, as well as in those lands of Guatemala which border on the States of Chiapas and Tabasco, to the south of Mexico.

The first-mentioned districts produce the best coffee, but the quantity of it is limited, whilst the others produce more, but the bean is of inferior quality. Cultivation is, however, very backward, and the modern methods are not employed for growing and preparing the coffee for market.

In the territory of Tepic, coffee is grown which rivals that of Mocha, and Cordoba produces a coffee superior in aspect, colour, and taste to the best Java. The coffee of Oaxaca surpasses in quality that of Jamaica and of the island of Ceylon, whilst that of Michoacan is superior to the different kinds of Maracaibo and to the best Indian coffee, so much appreciated in the English markets. The fact that Mexico does not occupy the first place among countries producing and exporting coffee is due to

many causes, independent of its capacity of production, climate, fertility, and the profits realised by the cultivator. But the situation appears to be on the point of changing, and the day is not far distant when her coffees will be met on all the markets of the world. The total exports of coffee amounted, during the year 1890-91, to 6,150,358 piastres, or 1,339,358 piastres more than during the preceding year, and an increase of 99 per cent. on the average of the last five years. The consignments were made by the following ports:—

Vera Cruz (5,554,365 piastres), Soconusco (202,328), Puerto Angel (176,478), Tampico (201,328), other ports (26,859).

The countries of destination were England (37,310 piastres), Germany (188,619), Spain (2,130), the United States (5,715,459), France (206,680), Italy (40), British Columbia (120).

The State of Vera Cruz, by reason of its privileged position and its ready communication with the United States and Europe, has become the chief centre of the cultivation of coffee.

The average cost price of coffee in the small plantations of the interior never exceeds, 12 piastres per quintal, and the exports effected last winter were made at the average rate of 24 piastres. Prices have even reached 27 piastres, leaving to the middleman an average profit of 13 piastres per quintal, or more than 118 per cent. If it be considered that a coffee plantation, worked under the above conditions, brings back, in five years at the most, what it has cost, it is seen that very few industries present such favourable conditions.

In those regions situated on the sea coast, as for example in the States of Vera Cruz and Tamaulipas, the owners, being able to export their products more easily, realise still larger profits. Thus the plantations in these States are yearly increasing to such an extent that, according to the estimate of M. Carlos Gris, it may be expected that in 12 years the exports of coffee from the State of Vera Cruz will be probably increased tenfold.—*Board of Trade Journal.*

CEYLON TEA.

(From I. A. Rucker and Bencraft's Weekly Circular.)

LONDON, Jan 12th, 1893.

TEA.—CEYLON.—The following table showing the relation between prices and deliveries for the past two years may be of interest:—

	1892.		
	Auctioned. packages.	Average.	Deliveries. lb.
January	68,000	9½d	4,729,000
February	64,800	9¼d	4,760,000
March	78,300	9d	5,158,000
April	50,500	9¼d	4,968,000
May	95,000	9½d	5,997,000
June	62,000	8¾d	5,487,000
July	73,100	8½d	6,166,000
August	92,200	8½d	6,502,000
September	71,500	9¼d	6,663,000
October	47,000	10¼d	6,183,000
November	47,600	11¼d	5,500,000
December	40,900	10¾d	4,202,000

	1891.		
	Auctioned. packages.	Average.	Deliveries. lb.
January	48,600	11¾d	3,565,000
February	54,400	1s	2,884,000
March	53,000	11¼d	2,770,000
April	77,400	10¾d	3,942,000
May	56,700	10d	4,578,000
June	85,600	9½d	5,480,000
July	63,900	9½d	5,420,000
August	68,800	9¼d	5,156,000
September	72,800	9¼d	5,277,000
October	59,800	10d	5,340,000
November	54,500	9½d	4,787,000
December	45,600	10d	4,282,000

The largest deliveries were in September, after two months of 8½d to 8¼d cost. The smallest were in December, after two months of 10¾d to 11¼d cost. The year 1893 has opened well for the tea trade. The position has continued to improve, and the article is now stronger than for many years. Telegrams from Colombo advising an export of 4,800,000 lb. for December have re-assured the dealers here, who are acting with confidence. We have often remarked on the tendency of prices for fine teas to fall in proportion as common teas go up, and this feature has been strongly accentuated in the past three months.

QUININE AND DRUG REPORT FROM MANNHEIM.

WALDH F, Jan. 9 h, 1893.

QUININE AND BARK.—In the beginning of last year there was a very lively demand for quinine on account of the Influenza, it having become evident, that quinine is the only really effective remedy against this epidemical disease without any of the evil consequences to the heart and kidneys, which have been observed with patients taking antipyrin and other similar preparations. At the same time large quantities of quinine were sent into France, a great augmentation of the duty on this article coming into force on the 1st February. In the following months however the market became very quiet with drooping value, and in July-August the price of quinine reached the lowest point ever known, business being done in London 8½d, in New York at 17 cts. per ounce and in Germany Mk. 24.—per kilo. From these low figures prices rallied only very slowly until in October suddenly a great speculative demand sprang up in London and large contracts for future delivery partly over all this year were made at rising prices from 9¾d to 10¼d. Since then the value kept fairly steady, manufacturers held for 10¼d, whilst second hand sold small quantities 9½d - 9¾d.

The position of quinine seems to improve. The consume has increased, arrivals of bark from Java, and stocks in London and Amsterdam are decreasing, second hand has no doubt sold a large proportion of its stocks of quinine. The quantities of bark offered in the auctions at London and Amsterdam find a ready sale, and go directly into consumption.

We may therefore look forward to a steady market which would be desirable in the interests of both manufacturers and dealers

Our official prices of Sulphate of Quinine in tins were last year

	d.	July	d.
January	11	10	10
March	11	10	10
April	11	10	10
May	11	10	10
June	10	11	11

We beg to call your attention to the following statistics, which might be of interest to you:—

PRICES OF SULPHATE OF QUININE IN LONDON.

COCAINE.—We have had in the beginning of last year large arrivals of the raw material, which caused a decline in prices of Hydrochloras of Cocaine, and only toward the end of the year, the larger part of the stocks of raw cocaine in Hamburg and London having been disposed off, prices began to recover.

The consum has been satisfactory and the stocks of the raw material having become small, there is every prospect of a further rise in the near future.

We note our list prices for Hybrid of Cocaine during last year per ounce:

January	23s 6d	July	19s 6d
March	22s 0d	August	18s 6d
April	21s 0d	September	18s 6d
May	19s 6d	October	18s 6d
June	19s 6d	November	19s 0d

C. F. BOEHRINGER & SÜHNE.

PLANTING IN PERAK.

There appear in the *Perak Government Gazette*, (Jan. 20th) the following Notes to Planters:—

Notice is given that the Circular of 22nd April, 1891, offering land on special terms to the first ten applicants is hereby cancelled, the whole of the land then offered having been taken up. The Government of Perak is, however, prepared to grant to a limited number of approved applicants the following special terms, that is to say—Leases in perpetuity for one block of land not exceeding 500 acres or for two blocks neither exceeding 500 acres. No premium; quit-rent 30 cents an acre after two years' free occupation. The Government reserves the right of levying an export duty on produce which may not exceed 2 $\frac{1}{2}$ per cent *ad valorem*. If selected with road frontage the depth to be three times the frontage; *bona fide* commencement to open to be made within 12 months from Government approval of selection; cost of demarcation and survey (to be made when required by Government) and registration fees to be borne by lessees. If desired by applicants, \$4 an acre and no quit-rent will be accepted. Minerals are reserved, and with the above exceptions, the land would be subjected to the general Land Regulations of the State, which will be forwarded on application to State Commissioner of Lands, Taiping, to whom all communications in connection with this circular should be addressed.

It being the wish of the Government to encourage the planting of fruit trees throughout the State, agriculturists requiring plants and seeds can obtain them on applying, with references, at the Government Gardens, Kuala Kangsar. A stock of the following plants is kept on hand:—Coconuts, Para Rubber, Liberian Coffee, Cocoa, Pomeles, Oranges, Lemons, Limes, Pepper Cuttings, and plants of Native Fruit trees.

THE DOCK CHARGES ON CINCHONA BARK.

At the cinchona sales on Tuesday, Mr. Samuel Figgis read a letter from a firm of importers of African cinchona bark in which they complained of the heavy charges made for re-weighing, and suggested that the matter should be brought before the buyers of the drug in order, if possible, to find the means of foregoing the necessity of having the bark re-weighed, in the case of parcels recently landed, in which there is practically no loss. Some little discussion ensued in which Mr. David Howard, Mr. Tabor, and Mr. Broicher took part, and it was ultimately proposed and carried without opposition, "That in future all barks that have been weighed within one month of the date of sale are to be taken and paid for at the landing weights." This will now apply to all barks offered at the cinchona auction, but it is not clear whether it will do so also to the Loxa, Huanoco, and red barks of the drug-sales. The charge for re-weighing is 4 $\frac{1}{2}$ d per cwt. and for re-housing also 4 $\frac{1}{2}$ d per cwt.—*Chemist and Druggist*, Jan. 14.

WASTE PRODUCTS MADE USEFUL.

By LORD PLAYFAIR.

In the *North American Review* for November there is a very interesting article by Lord Playfair under the above title. It is crammed full of facts illustrating the extraordinary progress that has been made by modern chemistry in the use of waste products. "Dirt," said Lord Palmerston, "is matter in the wrong place." Dirt, says Lord Playfair, is of money value if you only know how to get at it.

THE CASH VALUE OF A LUCIFER MATCH.

Phosphorus was formerly made from human sewage; it is now extracted from old bones. By the utilisation first of sewage and then of old bones, Lord Playfair calculates that every man, woman, and child in the country saves seventy-eight hours a year or ten working days, in the quickness with which

he can strike a light now as compared with the tedious method in use before phosphorus matches were invented. He estimates that the gain of these extra ten days represents for the United States alone an aggregate economy of sixty-two million pounds sterling per annum. Human liquid sewage is no longer in demand for phosphorus, but it is used for making smelling salts. 2,200 tons are daily taken out of the cesspools of Paris to be converted into ammonia.

THE RESURRECTION OF RAGS.

Lord Playfair lovingly describes the utilisation of rags. He considers that the competition for cotton and linen rags is a better indication of civilisation than even the consumption of soap. In 1887 England used 5 lb. of paper per head, the United States 10 lb. Germany 9 lb., France 8 lb., and Italy 4 lb. Black coats when they are used up beyond possibility of survival are sent to France, Russia, and Poland, to be made into caps. The British red jacket when worn out goes to Holland, where the Dutch imagine it to be the best protection against rheumatism, when worn on the chest.

When old woollen rags have reached their fourth stage of degradation, so that they are unfit for the shoddy maker, they are still economically useful. They are then mixed with other degraded waste, such as shavings of hoofs and horns, and the blood of slaughter-houses, and are melted in an iron pot with wood ashes and scrap iron. This process produces the material out of which the beautiful dye Prussian blue is made.

THE TRANSMUTATION OF SMELLS.

In the utilisation of waste substances it is very odd that some of the nicest things come out of the nastiest materials. For instance, fusel oil is the stinking product of the distillation of spirits. It is, however, utilised to make oil of grape and oil of cognac. Oil of pique-apple is made by the action of putrid cheese upon sugar, or by dissolving rancid butter with alcohol or oil of vitriol. The ladies' favourite, Eau de Mille Fleurs, is made from the drainings of cow byres. Gas tar, however, is the great resource of all utilisers of waste. It is from gas tar that they make saccharine, turkey-red, and all the aniline dyes. Coal tar has destroyed the cultivation of madder, which used to be used in making turkey-red, and at any moment it may destroy the whole of the Indian indigo industry. At the close of his article Lord Playfair says:—

THE UTILIZATION OF RATS.

Of all living things rats seem to be among the most repulsive; and when dead what can be their use? But even they are the subjects of production in industrial arts. In Paris there is a pond surrounded by walls into which all dead carcasses are thrown. A large colony of rats has been introduced from the catacombs. The rats are most useful in clearing the flesh from the bones, leaving a clean-polished skeleton fitted for the makers of phosphorus. At the base of the wall numerous shallow holes are scooped out just sufficient to contain the body of the rats but not their tails. Every three months a great *battue* takes place, during which the terrified rats run into the holes. Persons go round and, catching the extending tails, pitch the rats into bags, and they are killed at leisure. Then begins manufacture. The fur is valuable and finds a ready sale. The skins make a superior glove—the *gant de rat*—and are especially used for the thumbs of kid gloves, because the skin of the rat is strong and elastic. The thigh bones were formerly valued as tooth-picks for clubs, but are now out of fashion; while the tendons and bones are boiled up to make the gelatine wrappers for bon-bons.

Surely I have established my thesis that dirt is only matter in a wrong place.

THE MIRACLES OF CHEMISTRY.

Chemistry, like a thrifty housewife, economises every scrap. The horseshoe nails dropped in the streets are carefully collected, and re-appear as swords and guns. The main ingredient of the ink with

which I now write was probably once the broken hoop of an old beer barrel. The chippings of the travelling tinker are mixed with the parings of horses' hoofs and the worst kinds of woollen rags, and these are worked up into an exquisite blue dye, which graces the dress of courtly dames. The dress of port wine, carefully decanted by the toper, are taken in the morning as a seidlitz powder to remove the effect of the debauch. The offal of the streets and the wastings of coal gas re-appear carefully preserved in the lady's smelling bottle, or used by her to flavour blanc mauges for her friends. All this thrift of material is an imitation of the economy of Nature, which allows no waste.

In the *Engineering Magazine* for November Mr. Griswold has an article which is somewhat on the line of Lord Playfair's, entitled "What Engineering Owes to Chemistry." The writer maintains, not without good cause, that chemistry lies at the root of all civilisation.—*Review of Reviews.*

VARIOUS NOTES.

THE INDIAN TEA COMPANIES' Reports, that are now being published, says the *Calcutta Englishman* show a much better condition than was expected:—

So far, it is chiefly Darjeeling Companies that are thus early in the field with their reports, owing to the fact that the season begins and closes earlier, but from information that has reached us and from the many *ad interim* dividends that have been declared by Companies in other Districts, it seems that prosperity has not been confined to one District, and 1892 must be considered a prosperous year for the tea industry notwithstanding a short crop and an abnormal inclement season. In many instances advantage has been taken of a prosperous season to present a clean balance sheet and to make provision for a working capital with the object in time of eliminating the annual debit for interest which for years past has disfigured so many reports. It is premature yet to form an opinion as to the coming season, but the short crop of 1892 has proved that when the demand approximates to the supply, the planter is remunerated for his trouble, and investors receive a fair return for their money. It is only to be hoped that no effort will be made to flood the London market in the present year.

INDIAN TEA AT CHICAGO.—Indian planters are, I think, observes a writer in a *Calcutta* paper, not altogether hopeful of the Chicago Exhibition doing great things for their tea. The Americans have already got accustomed to cheap inferior tea, and it is a slow and difficult process to change the public taste. This was the difficulty experienced in Australia. All large employers of farm labour are obliged to give their men tea along with other rations, and it is obviously in their interest that the tea should be as cheap as possible. The country is, therefore, flooded with China tea and cheap Indian tea, but the superior infusions have no chance. It was long before pure Indian tea could be purchased in London, and some people argue that the "blends," with which the public were imposed on for many years, were a necessary education before the public could be got to drink the pure Indian beverage. The sellers of the blend may have been unconsciously educating the public taste, but their chief aim, I am afraid, was to make an unfair profit for themselves, and they deserve no praise for any good which resulted from their evil. Anyhow, the preference for Indian tea has got a hold on the English public now, and China is being steadily driven out of the market. It is to be hoped that in America the process of education, if slow, will be equally sure, and that the Exhibition will serve as a primary school. America is really a more promising market than Australia, and, if once a start is made, great things may be accomplished.—*Colonies and India*, Jan. 14.

Correspondence.

◆

To the Editor.

CACAO GROWING AND THEFTS—AN EXTRA-ORDINARY STATE OF THINGS.

Goonambil Estate, Wategama, Jan. 25th.

SIR,—Mr. Martin's letter in the "Times"* regard-

* Mr. Martin's letter was as follows:—

MR. MARTIN ON COCOA THEFTS IN MATALE.

SIR,—From your remarks on Mr. Barber's resolution to be proposed at the meeting of the P. A. on the 17th proximo, as to cocoa stealing, it is evident that you are not aware to what an extent it prevails. Those cases which are disposed of in Court, form no criterion as to the amount stolen, and I think very few cocoa planters will agree with you in thinking that the existing law affords sufficient protection.

It is not too much to say that the life of a cocoa planter in crop time, that is for six months of the year, is one perpetual struggle with theft. Stealing is done on an organized system and almost openly.

There are well-known receivers of stolen cocoa within hail of every estate, generally keepers of road-side boutiques with half a dozen cocoa trees growing behind them, and, once the planters' cocoa enters the boutique, the existing law is practically powerless, and in this district at least the planter may see his produce almost any day in crop time spread out on the high road in front of their places to dry, in lots ranging from a bushel to a few cwts. Receiving stolen cocoa has risen to the dignity of a profession. One of the favourite devices of the receiver is to get a kangany on a cocoa estate into his pay; this man then bribes the watchmen and store coolies and makes arrangements for the removal of such small lots of cocoa as the coolies can bring in daily from their work in their clothes and cooty sacks. I know of an instance of such a case where one of the store coolies received a present of R150, and where one of the small kanganies received R150. In default of the kangany, travelling Moormen do the business. The Ratemahatmaya of this district told me a few days ago that many are going about the district paying 60 cents per lb. for cocoa.

In the field, stealing is done by daylight, the cocoa trees themselves and the shade under which they are planted hiding the thieves. Sometimes one acre or so is stripped of its ripe produce, cocoa too unripe to be of value being easily taken; but more generally pods are taken from a tree here and there, and the husks are thrown into the chena to avoid detection. I know of an instance where a regular path was cut through the jungle belonging to an estate, in order to facilitate the removal of stolen cocoa.

The percentage of cocoa stolen every year is a large one, and is increasing, and I think you will find that the opinion of cocoa planters is that the existing law is quite unable to cope with the emergency.

To my thinking, Mr. Barber's resolution does not meet the case. It appears to me that the registration of buyers would only throw the profits of stealing business into fewer hands, and, by thus condensing organization, make it more formidable; and why should Colombo be exempted in any legislation? All stolen cocoa is eventually disposed of there, and it is, therefore, the very place where inquiry is most required. The question is so many-sided that I do not think it can be met by a resolution of the Planters' Association, but I do think that Government might be asked to confer with certain members of the Association with a view to adopting such measures as are advisable and possible.

We cocoa planters are not in the habit of taking up the time of the Association, and are quite content that it should be devoted mainly to subjects connected with the tea industry; but in this case we have a distinct grievance, and we hope for the support of our brother planters, and also for it in your columns.—
Faithfully yours,
JAS. R. MARTIN.

Yatawata, Matale, 22nd January, 1893.

ing the prevalence of cacao thefts has appeared none too soon. Only a horror of the "Cacoethes scribendi" has kept me silent on the point so long.

Mr. Martin's statements are absolutely true of this district as well as of Matale. Our coolies are employed, watchmen corrupted, kanganies bribed, storemen and kanackapulleys bought over (and in some cases conductors too) and there is a huge system of wholesale and petty robberies on a vast scale, carried on night and day, by ———? the ubiquitous Moorman (and in some cases Sinhalese traders).

Many proprietors and superintendents are much to blame for giving encouragement to this nefarious trade by the habitual selling of produce on the spot. I have heard of some who own to selling all their crop, good, bad, and indifferent, to the Moorman at their store doors!! Very high prices are occasionally given, simply that the trade may get possession of a little legitimately, to mix with that illicitly bought, ripe and unripe, fermented and unfermented! The one voucher he keeps in case he is questioned, but it does duty for several parcels!

Proprietors and Colombo agents should instruct their managers and superintendents on estates, to send down every atom of produce to Colombo direct, and prohibit strictly sales to Singalese or Moor traders. Every cocoa planter who respects himself and his fellow-growers should in future boycott the Moorman, warning him off their properties, and summoning him for trespass when he persists. His occupation like Othello's would soon be gone.

Lashes should be given to coolies and receivers convicted, and watchmen caught sleeping on duty. Licenses should be required for all native dealers in cocoa in Colombo, as well as elsewhere, who should be required also to account for every hundredweight passing through their hands.

Proprietors might with advantage form a "Cacao Growers Association" (which Cardamom growers might also join) for mutual protection, with a subscription based on bearing acreage, and so enter into a Defence League. Those refusing to join should be put in Coventry, as it is a most vital matter concerning every honest man, native or European, among planters (applying even to tea growers) for the ubiquitous Moor will buy any rubbish for mixing, hence some of the beautiful blends palmed off on passengers and others in your port.

On the round 250 acres of cacao in my charge, there have been last year SEVENTEEN distinct detected robberies, and this year over a dozen already; and this, despite seven to eight night watchmen, and five to seven day squirrel shooters and poachie-hunting coolies, who detect many of the robberies in the field, but of course fail to find the culprits. One villager was shot in the back, but disappeared from his quarters in the village (Udagoda.) Two men were caught on the Government road at 11 p. m. by Wategama Peace Officer carrying off a sack of newly-gathered cocoa, but struggling from him they got off, leaving a coat and sarong in his hands, and the cocoa (which I recovered) on the road. In the coat were found two tundus with the numbers and dates of case in Panwila Court, a maintenance case. The names are known, but parties not to be found by police!

The latest news is that the Ratemahatmaya close by, having been robbed of some cocoa, a Moorman boutique man on the Teldeniya road has been run in and convicted! This reminds of the suggestion made by Mr. Punch to place the Directors of Railway Companies on the engine buffers in order to avoid collisions. The headmen and police are now under the Government Agent. Let our Kandy G. A.

hold shares in Cacao properties, and we should soon find drastic measures adopted to detect or prevent theft!

In the robbery of B250 worth of clothes stolen from my bungalow in September 1892, not a single trace of blazers, handkerchiefs, tennis flannels, dress suits &c., has been found.

In January 1892 one of my Tamil watchmen on Eria gastenne was shot dead while watching, and as his money and silver chain were left on him, one may reasonably conclude that vengeance was the motive of the deed. The murderer has not been brought to justice yet! I unhesitatingly assert that if headmen were kept up to their duties crime would more often be detected and culprits brought to justice. The police alone are not to blame. But *special legislation* is required at once.—Yours truly,
CHAS. GIBBON.

EMIGRATION OF SINHALESE.

Jan. 26th.

DEAR SIR,—In your Notes and Comments in yesterday's issue you remark: "There is something anomalous in a Ceylon planter trying to send Sinhalas to East Africa while there is plenty of work here if they would only do it."

As the question of emigration is still *sub judice*, I am not at liberty to enter yet into details, and now write merely to remove the impression that your note might make, that I have an interest in promoting the emigration of Sinhalese labourers. This impression is altogether incorrect.

My endeavours were in the first instance made to obtain Tamil labour for service in East Africa, but owing to a misunderstanding of local Ordinances, it was found impossible without reference to the Government of India. There was no intention of taking coolies from any district in Southern India from which Ceylon obtains its present supply of labour, so that the proposal need not have caused any anxiety either to the local Government or to Ceylon planters.

As regards the emigration of Sinhalese coolies I fully agree with you that there is plenty of work for them in the island, if they would only do it. But in many districts it would seem that they prefer a life of semi-starvation to regular work on the estates. It is hard to say what the reason is, but it cannot be due to want of advertisement by local employers of labour; because I have, without issuing any notification whatever, been inundated with applications for employment in Africa, and this in spite of the warnings of numerous headmen, recently circulated against the dangers of enormous snakes, cannibals and other wild beasts.

One explanation of this anxiety for emigrating occurs to me; but it is not expedient just now to refer to it.—Yours faithfully,
B.

RAINFALL IN AGRAPATANAS.

Torrington, Agrapatanas, Jan. 28.

DEAR SIR—I send you herewith the rainfall records of these estates for the past 15 years, showing an average annual fall of 111.12 inches (elevation about 5,000 feet).

As you will see 1891 stands out as a year of excessive fall; the rainiest year of the whole 15 recorded. 1892 is notable for the unseasonable manner in which rain fell, as you will see from the following figures:—

	Rainfall 1892.	Average of 15 years.
Jan.-February	= 14.15	in 6.51 in.
March-June	= 21.20	" 41.04 "
July-October	= 70.79	" 46.97 "

—Yours faithfully,

A. ROSSI ASHTON.

Average Annual Fall 111.12.

TWO NEW MINERALS FOUND IN CEYLON.

Binoya, Ambagamuwa, Jan. 27th.

DEAR SIR,—I am sending you by this post a copy of "Natural Science" for December in which there is mention of two new minerals which have been found in Ceylon, and which will perhaps be of interest to you and some of your readers.—Yours etc.,
O. C.

A new mineral named Geikielite, in compliment to Sir Archibald Geikie, has lately been described before the Mineralogical Society by Mr. Allan Dick. In composition the mineral is a magnesian titanite, and it was brought from Rakwana, in Ceylon, by Mr. J. Baddeley. It was found in the form of a pebble, and was taken, with a number of other pebbles, to the Museum at Jermyn Street, and submitted to Mr. A. Fringlé for examination. The

particular specimen, now named Geikielite, was found by Mr. Pringle to differ in specific gravity and other "external characters" from any known mineral, and it was consequently handed to Mr. Dick for chemical investigation.

Among the store of pebbles collected by Mr. Baddeley, another new mineral was afterwards recognised by Mr. L. Fletcher, and this (as he announces in *Nature* for October 27) proves to be crystallised zirconia. He proposes for it the name of Baddeleyite, as the natural occurrence of this oxide of zirconium has not previously been noticed.

CACAO-GROWING AND THEFTS.

Jan. 29th, 1893.

DEAR SIR,—Mr. Chas. Gibbon's letter, like Mr. Martin's, on which he comments, "has appeared none to soon." Probably many planters in other districts have wondered how many years would elapse before the Matale and Wategama planters would assert their right to obtain justice. Last year, month after month, cases were instituted by them, and the affable Magistrate, intent on obliging the European prosecutor, regularly sentenced the accused to varying terms of imprisonment and a certain number of lashes, but the latter part of the sentence was never inflicted. The Magistrate ought to have known (even if the Matale planters and their proctors did not) that he had not the power to prescribe lashes as a cure for thefts of prædial produce.

The Kurunegala planters were wiser in their generation (perhaps made more vindictive by shorter crops and malarial fever), and they agitated for the infliction of lashes as the only cure for the systematic stealing of cacao. After a great deal of opposition, from quarters where it should least have been expected, the required ordinance was passed, but in such a manner as to avoid giving offence to thieves and receivers. Passed at the end of a crop which might have been a good one (the European grower can only judge by the export returns), its effect was somewhat modified, and it was found necessary very soon to agitate for the proclamation of the ordinance in the Kurunegala District. Without this, the ordinance so obligingly passed by the Legislative Council, after so much delay and deliberation, was absolutely null and void. Strange as it may seem to any mind which cannot properly appreciate the apparent burlesque of a Crown Colony's laboured legislation, the proclamation of this ordinance was opposed with considerable vigour, but since the provisions of the ordinance have been put in force, cacao-stealing in Kurunegala has been reduced to a minimum.

Why did not the Matale planters adopt the same course? Do they know of any method of circumventing Janus, the jungle proctor, and the pestilential parasites of a Minor Court, or did they suppose the Government would relent and refund all deficiencies on their crop estimates? It is late in the day for the merry men of Matale to call their brother planters to join them in a crusade, and while so doing to use disparaging remarks!

Mr. Gibbon runs a preliminary tilt at those who sell their crop locally to natives, especially those who sell at their store doors, and he argues that the crop so sold is mixed with any unfermented and overfermented rubbish bought from estate coolies and natives. Is the ubiquitous (or iniquitous) Moor man such an ass? I think not. And as to the vouchers given by those who sell crop locally, they are always I suppose dated; and I cannot see how (if they are ever shown to the police) they can be used a second time. But, supposing we

all give up selling produce locally as your correspondent suggests, what is to prevent the constant pilfering of estate coolies and the steady traffic in the bazaars?

In suggesting a "Cacao Growers' Association" your correspondent has forgotten that we should have to reckon with the native owners of small gardens, the corner-stone of every receiver's business. These gardens are of course unregistered as "estates," they are mostly hidden from the public view, and the crop they give are probably very good. The district receiver is their storekeeper and forwarding agent.

I agree entirely with your correspondent that "lashes should be given to coolies and receivers when convicted," but the difficulty is to obtain a conviction, as the law is entirely in favour of the thieves. I am glad to say I do not know the originator of an ordinance which presumed that all thieves were colour-blind or preferred unripe fruit: if a humorist, he has the satisfaction of knowing that most of those who trusted to him have had a bitter experience.

As regards remedial measures, I do not think that Messrs. Barber, Martin and Gibbon go far enough. After the exposure of the existing state of affairs, it is only natural to conclude that the local headmen and the police are in partnership; if the police are ignorant of the receivers' doings, they were better dead. The remedies I suggest are:—(1) All native buyers of cacao, coffee and cardamoms, and their houses should be registered and LICENSED: their dealings duly entered in books open to inspection; (2) No headman should be allowed to own, or have any interest in, any such boutique; (3) No cacao, coffee or cardamoms should be accepted at any railway station except under a registered mark and (4) every headman should be held responsible for the suppression of thefts in his district. Later on, when the police have been reformed, as was promised some years ago, it might be possible to sanction the search of suspected boutiques and houses by a constable, on information, without the farce of the planter's going to Court and publishing his suspicions to the whole district; and other more rational modes of procedure might be adopted, but as I share your correspondent's dread of printer's ink, I abstain from further suggestions.—Yours faithfully,
A KURUNEGALA PLANTER.

LIBERIAN COFFEE IN TRAVANCORE.

ENCOURAGING PROSPECTS.

Jan. 29.

DEAR SIR,—“Experto Crede” in his letter to you of 11th inst. says of Liberian coffee:—“It gets leaf-disease of course, and bug; but it is very hard to kill.” My experience here—I am happy to say—is very different. My old coffee is 1½ years of age, and was raised from selected seed from Ceylon. It is true the trees get leaf-disease, some badly, but the majority, however, suffer but little—“bug” it is quite free from. Crops have been good for some years, and I think your correspondent would be more successful if he did not advocate “No topping, no pruning.”

Plants now 2½ years old, grown from selected seed from my own trees, topped at an average of 5 feet have on them today a splendid blossom, and the plants appear to be vigorous enough to carry the crop (supposing the bloom all sets). These plants have never had a real dose of leaf-disease, and I attribute their healthiness to the careful selection of the seed they were grown from—Yours &c.,

VENTURE—TRAVANCORE.

THE CEYLON PLANTERS' TEA CO.

DEAR SIR,—The "C. P. T. Co." of America have sent an interesting New York publication in which a couple of their advertisements appear. Not long ago I received a batch of the leaflets issued by themselves, and that just after the Company was reported to have gone into liquidation! I do not know what proportion of shares are held by Ceylon men, but I thought at the time—having had a good deal of experience of Companies myself—that if as I understood all the capital sunk in the preliminary working and establishing the business had been found in America, the winding-up move was rather a sign of prosperity than of failure—prospective success of course but pretty certain! For why, thought I, should the two American firms spend their money and time only to share the profits with people here with whom they were so profoundly dissatisfied? I suppose they can out-vote all shareholders, and quietly done, such a winding-up would only mean a slight change in the Company's name for a new one, which would be the same minus the Ceylon shareholders. A dodge of this kind would be a trifle for any ordinary company promoter. But nothing of the kind has taken place or been contemplated it would seem. The late award of tea, let us hope, has removed the discontent and that all concerned will now share in the coming boom. I am not a shareholder, and this I fancy is why I am being looked up! as I do not see how otherwise I can serve the Company. I think, the Company is on the high-road to success, their strong card is the "nervousness" induced by the bad tea, badly made, in general use in America. It is an argument founded on unimpeachable truth: the Americans do injure their health by drinking badly made China tea. Teach them to cultivate a taste for a delicate flavor and a mild stimulant in place of a coarse raspiness and temporary excitement (followed by the inevitable reaction) and they will be the gainers both in enjoyment and health. This fact is slowly but surely asserting itself, as a vast number of testimonials by people of sense and position in letters to the Company prove. By being successful, the Company will do all America as well as themselves much good. The New York publication referred to is an interesting one, and affords a glimpse into New York life and architecture very instructive to a stranger. It is a book of 160 pages, of which fifty are full-page pictures of the most prominent churches in the city, including the projected new Cathedral. There is also a directory of every place of worship in New York, pastors' names and hours of services; the remainder is all advertisements. I see one greener says: "The Ceylon tea so much advertised lately we have been selling for the last ten years"!!!

Ceylon planters are not medical men and therefore cannot be expected to know all the virtues in their tea. There must be something to account for the hold it has taken on English and Australian tea drinkers, and a very important part of this explanation comes from America. E. Valentine Buck, M.D., writes to the Company in these words; "The tonic effect is distinctly apparent, and is explained, no doubt, by the fact that the soil upon which it is grown is rich in iron."

Another "M. D." (A. Van Der Veer) writes:—
"It is a good, nutritive tonic drink."

We now know, therefore, the professional authority, that our tea is not only a gentle stimulant and food, but it is also a "tonic." Dr. Buck has hit the right nail on the head in guessing at "iron" in our soil. He should see the red iron deposit staining the stones and

beds of all our streams to convince him of that. Query: is it not this "iron" which causes the milkiness in the cold infusions, which no China tea ever shows? J.

NATIVE EMIGRATION FROM CEYLON.

Jan. 31st.

DEAR SIR,—In your editorial notice in yesterday's issue there are one or two points which I think require some explanation, although, as I remarked in my letter of 26th inst. I am not yet at liberty to discuss the matter fully.

In the first place, as regards the inducement offered, you quote the shipment of Sinhalese to Queensland some ten years ago. The native agent who engaged these people (many of them, as you say, old jail-birds) received R5 per head as commission! In the present instance no commission has been offered to any agent, and no notice whatever has been published, but information has somehow leaked out that there is employment to be got in East Africa, and for months past I have had applications, written and personal, almost daily, for work there. No questions asked, in most cases, as to wages, and many applicants have come from a radius of 20 miles' distance. And this in spite of the notices posted up by some of the Kandyan headmen, Is this due altogether "to a love of travel and adventure"? I do not think so.

In the second place, as I have little experience of employing *resident* Sinhalese coolies, I am not qualified to speak as to their treatment on estates, and I merely said that "they seem in many districts to prefer a life of semi-starvation to regular work." In some cases this is doubtless due to their dread of leaving their homes: their nearest friend and neighbour may sell up their property or burn down the house! In other cases the style of the cooly-lines and the exposure to wet weather account for a good deal of disinclination to go to work on estates, at even a few miles' distance. But, as I hinted before, I think there is another reason.

So much as regards the native labourer. As regards the educated class, comprising conductors, clerks and skilled mechanics, the applications for employment, are, in proportion, much more numerous. It would shock the heads of departments if I were to reveal the number of applications received from their subordinates. Every branch in which education and technical skill are of use seems to be overcrowded and promotion, in consequence, very slow. You have lately, I believe, advised the transfer to British East Africa and other Colonies of surplus Civil Servants, and I feel sure I may rely on your pressing the claims for employment in German East Africa, under sufficient guarantees, of all natives of Ceylon who may wish to work there.

The opening up of the German Protectorate is likely to materially aid in the suppression of the slave trade.

A railway inland is to be begun in March (the trace is already cleared, I believe, for sixty miles), and I hope that the early sanction of His Excellency Sir Arthur Havelock will enable British subjects from Ceylon to help forward the work.—Yours faithfully, B.

From a leaf of the *Gazette for Zanzibar and East Africa*, sent by "E." we quote as follows:—

Mr. H. M. Stanley:—In Uganda we have a magnificent objective point. We have that immense lake the second largest fresh-water sea in the world (Lake Victoria), and round about it are other large

Lakes. On the shores are large populations which would contribute their productions to make the railway remunerative. There is a little railway about 140 miles long in West Africa, and the latest Consul report says that the natives freely patronise it and that the passengers traffic is already very large. Now, if there are 20,000 porters leaving the East Coast every month for the interior, those who are responsible for those caravans would naturally utilise the railway to get 700 miles further on their way. Among the customers of this railway would of course be the British, German and Congo States Administrations, the Roman Catholic mission, the Church, the London, and other religious missions, the Arabs with their caravans in addition to which we have European traders, Government agents, agriculturists, tea and coffee planters, hunters, and tourists. It is a three months' journey on foot to the lake from the sea; allowing one month to rest it makes a seven months' journey there and back which would be shortened to seven days if the railway were constructed. Further considerations are the economy of life, labour, and time, and that immense army of porters now wasted in carrying these goods would be utilised as policemen, soldiers, and food producers. Look at the money side of the question. It has cost the British East Africa Company 40,000*l.*, a year to retain Uganda. In ten years, with interest at 4 per cent., that is equal to 488,000*l.* and yet the Company is not richer by a penny because every possible profit has been absorbed in paying that extravagant freightage of 300*l.* per ton. The German Government is giving at least 50,000*l.* a year towards the development of the interior in support of her military stations exclusive of the coast. In ten years that means 600,000*l.* with interest. Then you have over a million pounds expended unremuneratively. There are the missions, which spend 30,000*l.* a year combined. That is 350,000*l.* in ten years paid for carrying supplies. We will not count the Arab traders. Put those three sums together, and you will see what a vast amount of money has been lost by not proceeding to build that railway. It would be a capital idea if the English and German Government could combine to construct it and make it a sort of international railway.

Baron von Soden, Governor of German East Africa, has issued an order with regard to the passage of caravans through the German protectorate. Most of the attacks on Europeans have been caused by the improper conduct of the members of the expeditions, whom the leaders are frequently unable to prevent from committing excesses against the inhabitants of the districts through which they pass. The result is that the natives either avenge themselves on other caravans, or withdraw from the trade routes and so render them impassable, owing to the lack of provisions. In order to put a stop to this state of things, Baron von Soden has forbidden all caravans to pass through the German Protectorate without permission from the authorities, and has ordered that they shall deposit a sum not exceeding twenty rupees for each of their members, as security for the indemnification of the natives, the damages to be fixed by an arbitrator, whose verdict shall be binding on the leader of the caravan. The security must, in every case, be deposited by caravans consisting of foreigners who are either not domiciled, or do not possess property in the Protectorate.

In a further article on the question of Lake Tchad, the *National Zeitung* points out that the Anglo-German Agreement fixes the Anglo-German boundary only as far as Jola, and adds that the commercial road north of the Benue, as far as Lake Tchad, must not be closed against either of the two Powers. England is, therefore, still able to take possession of the no-man's land between Jola and Tchad, especially as the energetic Royal Niger Company has already established a station at Garua, in the Ribago district above Jola. It is desirable that Germany should not wait to be surprised by Treaties concluded by England, that the question of *meum* and *tuum* be settled betimes, and that the continuation of the frontier from Jola to Lake Tchad be better done than the fixing of the

running from Rio del Rey to Jola, especially as Lieutenant Morgan describes the latter in his new book, "Through the Cameroons from South to North" is very disadvantageous to Germany.

The Katanga Company. At a meeting of the shareholders of the Katanga Company, held in Brussels on the 16th November it was unanimously decided to accept the proposals made by Commander Cameron who, at the meeting held on Saturday last, offered on behalf of the Transport Company established by him for South-East Africa, to conduct the whole of the transport work of the Katanga Company, by a service connecting that Company's territories with the East Coast by way of the Zambesi and the Great Lakes.—Ed. T.A.]

VARIOUS NOTES.

LIBERIAN COFFEE IN TRAVANCORE.—We call attention to the very encouraging account given by an old Ceylon planter, now in Travancore, of his experiences of Liberian Coffee. We trust his example and letter may encourage the further spread of the cultivation in Ceylon.

IVORY TRADE.—Owing to the increasing scarcity of ivory, manufacturers are putting on the market quantities of plated knife handles, known in the trade as "solid-handled, hard-soldered" work, which are being made to carry steel blades. These present a most durable appearance, and for ships, hotels, and restaurants are serviceable. They are, however, inferior to ivory or whole handles of any description. The tone of the ivory market for 1892 has been much firmer, yet the uncertainty which attends the acquisition of a supply sufficient to meet the great demand is such that manufacturing cutlers will have to look for a substitute in order to make themselves safe from possible surprises, as ivory is in increasing request.—*Work*, Jan. 14.

PERMAAD, Jan. 12.—My prophecy of some six months ago that coffee crops would be above average is, I am pleased to record, being fulfilled and I hear that as a rule, estimates will be obtained. I hear of more Liberian being planted up this season. One planter has put down five bushels of seed; it germinated well, and the young plants in the nurseries look promising. When down South, I met two or three. Planters, who have gone in for Liberian, and they are very cheerful at the fair promises of success in their venture. At a time when nearly every other planter you meet, is as strong in his depreciation of coffee of any kind as in his praise of tea, it was quite pleasant to meet with some who hold similar views to one's own.—*Madras Times*, Jan. 19.

GAME IN MYSORE.—A correspondent of the *Asian* says:—Heaven knows when the long-wished-for game laws are to be instituted in Mysore; it probably won't be done in this century. The other day two grand cock bustards, some dozens of pea-fowl and hundreds of quail and partridge were brought alive into the town for sale. The mild Hindu is not the only aggressor, other *jaths* occasionally come in. The shikari of a man here, who loves to pose as a sportsman, shot a doe-chital big with young, for his master, and also wounded and lost another. We are all aware of what the consequence will be of this sort of thing in the long run. Why can't the person who ought to "lep" on these people *ek dum*. *Apròpos* of chital, good heads cannot be had now unless by pure accident, as the bucks are either without horns or in velvet, and it is doubtful if a clean pair could be had till March or April. I am glad to hear Captains Fairholme and Lecky bagged fifty six couple of snipe in one day, but their score has been beaten. Something very close to that number has been lately made by one gun not very far from where they made their big bag.—*Pioneer*.

PRICES OF CEYLON TEA IN LONDON:
AVERAGES FOR EACH MONTH OF 8 YEARS.

The following table will, in the first place, make our tea planters of the present day, think of the good times there were in 1885-7 when the Ceylon average was so constantly above the shilling. The maximum in any one month was reached in October 1885 with an average of 1s 4½d. Of course the quantity of Ceylon tea then on offer was limited. The monthly minimum in our table was recorded at 8½d in July last year. May that depression not be experienced again for a long time if ever. The special practical lesson to be derived from our table is the constancy with which the middle of each year sees the lowest prices. July is the black month for Ceylon tea in five out of eight years as we may say, and June or August comes next. In the same way October usually sees the best prices: it is so, according to our table in five out of eight years, November and February sharing the pre-eminence in other years. Our table will be of interest, and it may prove of some practical service to our tea planting readers:—

SISAL HEMP INDUSTRY IN YUCATAN.

In accordance with instructions received from Sir Ambrose Shea, Governor of the Bahamas, Captain E. Jerome Stuart, the resident Justice of Long Island, has recently visited Yucatan for the purpose of comparing the soil of the Bahamas and its adaptability to the fibre industry with the soil of that State; to find out the different species of agaves planted, and their liability to disease; the character of the machinery used for extracting the henequen fibre and the cultivation and general management of the crop. In his report, which is published by the *Kew Gardens*.

Bulletin for November, Captain Stuart submits the following information:—

There are several species of agaves to be found in Yucatan, but two only are of chief commercial value.

The Henequen.—The kind of fibre plant growing in Yucatan, and known as the saqui or henequen is a different and distinct agave from that of the Bahama hemp.

The plant is hardy, and has, when cultivated, an average life of 18 years; and propagates itself by sending out "snickers" from its roots.

The henequen (*Agave rigida* var. *elongata*) requires from five to eight years' growth to produce a marketable length (3 ft.) of fibre. The leaf from which the fibre is extracted has a thorn at the point, and spines on its edges, and averages 3½ ft. in length.

The fibre of the plant is white, but being inferior to that of the Bahama hemp is rated in the market at from 6l. to 8l. per ton lower.

The Bahama Hemp.—The Bahama hemp (*Agave rigida* var. *sisalana*) differs from the henequen inasmuch as the leaves are without spines on their edges; and the fibre is superior in texture. The plant matures from two to three years earlier than the henequen, and has an average life of 12 years. Like the henequen it propagates itself from suckers, but is also capable of producing over 2,000 plants from the pole that grows from the centre of the plant.

The Bahama hemp is found both in Yucatan, where it is known as the yaxqui, and in Cuba, but it is not largely cultivated, as it requires a more congenial climate than these countries afford. In this colony the plant luxuriates, the length of leaf being 4½ ft. to 5 ft., weighing 1½ lb. to 2 lb. In Yucatan a leaf of the yaxqui from a plant of the same age would measure 3½ ft., and weigh 11 oz. only.

The henequen and Bahama hemp are the hardest of all the agaves. Their power to withstand drought is almost incredible. I have known plants of the Bahama hemp to lie on the ground for three months, exposed to the rays of the sun, and when planted to grow with the greatest vigor.

It has never been known for those plants to be troubled with any organic disease. No fungus or insect can apparently damage or affect them; and in 1883, when the locust devastated the State of Yucatan, the cattle and birds died of starvation, and men were on the eve of despair, the only green living plants to be seen were the different species of agaves, and they are now looked upon as the salvation of the State.

I walked through hundreds of acres of the henequen, but beyond noticing that a leaf here and there had a few inches dried on its end, similar to what is seen in this colony and Cuba the plants were perfectly healthy and free from disease.

There are several kinds of machinery used for extracting the fibre on the different estates.

Those cleaning less than 75,000 leaves per day use the large common wheels, Raspador and Barraclough; and those cleaning from 80,000 to 120,000 per day use the larger and more complicated machines, the Prieto, Villamore, Weicher, Death and Ellwood, &c.

The planters, if using one of the large machines, keep several of the Raspadors in reserve for use in case of accidents; for should the large machine break down or get out of order, leaving 70,000 or 80,000 leaves on hand, and there be no means of cleaning them, it would involve a loss of over 4,000 lb. of fibre.

Cleaning Machines.—The *Raspador* is a 54-inch "wheel," said to be invented and manufactured in Mexico. It requires a two-horse power engine to run it at a steady rate of 200 revolutions per minute, at which speed the best results are obtained. Capacity 500 lb. dry fibre per day of 10 hours requires the services of two men.

The *Barraclough*, constructed by T. Barraclough & Co., Manchester, England, is similar to the Raspador, but of superior make. Capacity 500 to 600 lb. dry fibre daily.

The *Prieto* machine is manufactured by Ping and Negre, Barcelona, Spain; requires a 16-horse power

engine and the services of two men and a boy. Capacity 7,000 lb. dry fibre per day of 10 hours. Cost 4,500 dols.

The *Villamore* machine, made by Karajewski and Pesant, 35, Broadway, New York; requires a 15-horse power engine and the services of two men and a boy. Capacity 6,000 lb. fibre per day of 10 hours. Frame made of wood. Cost 500 dols.

The *Weicher* machine, constructed by J. J. Weicher, 108, Liberty Street, New York, is fitted with a service pipe for throwing a stream of water on the fibre as it is being cleaned, and is claimed by the inventor to lose but 1½ per cent. only, as the leaves are fed into the machine endwise. Requires 12-horse power engine and services of three men. Capacity 2,500 lb. dry fibre per day of 10 hours.

The *Death and Elinwood* machine, constructed by W. E. Death, of Brixton, England, requires a 30-horse power engine to drive it at a velocity of 40 revolutions per minute, and washes the fibre when cleaning. Like the "Weicher," the leaves are fed into the machine endwise.

With the exception of the *Raspador* and *Barraclough* all the other machines are automatic; they rasp the pulp from the fibre on the same principle as the *Raspador*. Their wheels being smaller, require a velocity of 500 revolutions to the minute to give good results. Beyond cleaning a greater number of leaves they do not appear to do better work, as the percentage of loss is as great in the one as the other, and the fibre is equally as clean.

Press.—Most of the small estates use screw presses, baling from three to eight bales daily. The large estates, baling 16 to 30 bales daily, use hydraulic presses, constructed by Appleby Bros., London, and Fawcett and Preston, Liverpool.

The Estates.—There are 200 henequen estates in Yucatan, varying from 500 to 28,000 acres in extent, having a total number of 105,000 acres under cultivation, employing 12,000 Indian labourers.

The largest and best estates are on the rocky gravelly lands, and they are valued from 100,000 dollars to 500,000 dollars each. Each estate is managed by three principal men—the attorney, the manager, and assistant manager. The largest of them employ locomotives for hauling in the crop from the fields, others using tramway trucks or carts drawn by mules or oxen.

Estates with less than 800 acres under cultivation erect one *Raspador* for every 100 acres. Those of 1,000 acres use the large automatic machines.

Preparing the Fields.—The size of the cultivations on the estates range from 250 to 3,500 acres. They are laid out in fields or sections of 50 to 200 acres, and contain from 600 to 900 plants to the acre.

When preparing the fields the land is cut during the dry season, is then allowed to spring up, after which it is "sprig weeded" and burnt after the first fall of rain. The stumps are cut close to the ground, so as to be out of the way of the leaves of the plants, and to facilitate the running of the line for planting and getting the rows straight.

Planting.—The plants are "set out" on the different estates at various distances, being 6 ft. by 11 ft., 6 ft. by 11 ft., 4 ft. by 11 ft., 4 ft. by 10 ft., 5 ft. by 10 ft., 4 ft. by 10 ft., 6 ft. by 9 ft., 5 ft. by 9 ft., 4 ft. by 9 ft., 6 ft. by 8 ft.

The rows are kept perfectly straight, for if they be otherwise there would be the greatest difficulty in getting through the fields.

When planting, the labourers have a small line with the distances at which the plants are to be "set out" knotted on it, and a pole cut to the length that the rows are to be apart. A man and a boy are employed at each line. The boy drops the plants along the row at the distance marked on the line, and then removes the line to the next row, dropping the plants as before. The man does the planting, and is responsible for the rows being straight. When coming to a rock the planter does not turn aside, but goes on, and places the plant in the row a little beyond.

The row system facilitates weeding, admits a free current of air and sunlight, which is necessary to harden and give strength and texture to the fibre;

and allows the labourer to cut and bring out the leaf with despatch; and, what is of greatest importance, gives room for replanting the field when the life of the old plants is about to terminate, which cannot be done if the plants are growing over the fields irregularly.

Plants of less than 15 inches are not planted.

Cutting.—In Yucatan the henequen matures in five to eight years. In the Bahamas the Bahama hemp matures in three to five years.

To neglect cutting the leaves after the plant is matured retards its growth, which causes it to "pole," at the appearance of which the life of the plant is ended, and the planter, after reaping a few leaves only, must then plant his fields afresh. On the other hand, when the cutting is regularly attended to, the life of the plant is prolonged, the plant will produce a greater number of leaves, and fibre of a greater length and superior quality.

The plant is cut every three months, when seven to nine leaves are gathered. The leaf is taken from the plant with a "clean cut," making the cut down and inward at an angle of 45°.

Cleaning.—As soon as the leaves are cut they are taken to the machine for cleaning. The cleaning is so arranged that one-half of the leaves to be cleaned is taken from the cuttings of the day previous, and the other half from the cuttings of the same day, as in this manner the work can be commenced early in the morning, and steadily carried on without waiting for leaves to be brought in from the field. The leaves are not allowed to accumulate beyond half a day's cleaning, for if left to dry beyond the second day they become hard, and the fibre when extracted will be dark.

When the *Raspador* is used for extracting the fibre two operators are required; one stands to the left of the wheel and the other to the right. The operator on the left taking a leaf fastens the small end with a lever to prevent the whole of it being drawn into the machine; the larger end is inserted and cleaned; the other operator then hauls out and reverses the leaf, putting in the uncleaned end, at the same time taking a turn with the cleaned end of the leaf around a brass cleat which is fitted to the machine for the purpose, and managing a brake that regulates the pressure required for cleaning the leaf, finally drawing out the clean fibre. In this manner 14 leaves per minute, or 3,400 leaves are cleaned for a day's work.

When cleaning with the *Villamore*, *Prieto*, or other automatic machines, all that is necessary is to lay the bundles of leaves on a platform fitted for the purpose, when an endless chain draws them into the machine, the mechanism of which is so arranged that one wheel cleans one half of the leaf, the chain taking it along, where another wheel cleans the other half, and then throws out the clean fibre at the opposite end. Two men and a boy are employed at the machine, one man to see that the leaves enter the machine on their length and that they do not ride one on the other: one to attend to and regulate the machine, and the boy to receive the fibre as it is brought out by the endless chain.

As soon as the fibre is extracted it is dried, for if allowed to remain without being exposed to the sun immediately after cleaning it becomes dark and spotted.

Yield per Acre.—The yield of fibre from an acre of henequen is from 1,000 lb. to 1,470 lb. per annum. The number of plants usually set out in an acre is 650, giving an average of 33 leaves from each plant, and from 50 to 70 lb. of clean fibre to the 1,000 leaves. Making an average calculation of 650 plants to the acre, 33 leaves from each plant, yielding 60 lb. of fibre to the 1,000 leaves, the return would be as follows:— $33 \times 650 = 21,450$ leaves, yielding $60 \times 21,450 = 1,287$ lb. clean fibre per annum. The planters never speak doubtfully of their returns, as experience shows them that their crops can be relied on with almost complete certainty.

Cost of Working and Profits.—The planter estimates his crop to cost for cultivating, cutting, cleaning, baling, and marketing from 2½ cents to 3 cents per lb.

At the present price of fibre 5 per cent. per lb. taking 3 cents as the cost of production, and acre yielding 1,287 lb. would give a net profit of 25 dollars

NOTES ON PRODUCE AND FINANCE.

THE SALES OF INDIAN AND CEYLON TEA.—The sales of Indian and Ceylon teas during last week and this are the heaviest on record, and the work entailed on the brokers in consequence must be very great. Of course this state of things cannot last, and the sales will adjust themselves again soon. Outside Mincing Lane there is very little doing interesting to the tea industry. In a few weeks now the reports of some of the companies will be looked for.

CEYLON TEA IN AMERICA.—From a batch of newspapers received from New York and elsewhere we see that the business of advertising Ceylon tea in the United States is conducted on very enterprising lines. If our cousins do not take kindly to Ceylon tea it will not be for lack of clever advertising—but they will take to it.

CARDAMOMS.—The trade once done on arrival terms in Mysore, Aleppy, and other East Indian cardamoms is only a memory now, and the *Commercial Record*, discussing this, says:—"It is curious, and at the same time distressing, to notice how a trade which once proved remunerative to all parties concerned could almost entirely disappear. For years people in the trade followed a hand-to-mouth policy, buying their requirements in the open market in small lots at the time, instead of contracting ahead for larger quantities, until last year an attempt was made to revive the arrival business, but, although every inducement was held out to purchasers to support the movement, the transactions done, as far as Malabar berries were concerned, never acquired any importance, and this year they will in all probability be less. Ceylon, who entered the market last year in competition to the coast, was to some extent more successful, a fair quantity finding buyers; but, as these purchases mostly showed a loss already on or even before their arrival, owing to large supplies being thrown upon our market by Ceylon shippers and native consignors labouring under the delusion that the demand for arrival stuff was the outcome of an actual scarcity in London, buyers have so far resisted all temptations put before them in the shape of cheap offers by eager Ceylon shippers, and there can be but little doubt that last year's ventures in Ceylon berries will not be repeated this season. In the meantime the reports from the Malabar Coast regarding the prospect of the growing crop continue to sound highly unfavourable."—*H. & C. Mail*, Jan. 20.

PRACTICAL ADVICE ABOUT TEA.

Mr. Ernest Tye, the secretary of the Indian Tea Districts Association, writes us:—"I send you for publication a most interesting letter just received from one of the largest London wholesale dealers in Indian tea. I suppress his name, but you will render a service to the industry by giving its contents due prominence." The letter is as follows:—

"It must be evident to those who have made a study of the tea trade that one of the greatest hindrances to success, either as growers or importers of tea, is the excessive fluctuations which occur in the value of the different grades. For instance, during one season good and fine qualities command extreme prices, whilst common descriptions sell at heavy losses. The next season this will be reversed: Good and fine teas will be sacrificed, and common teas pay good profits. It is, of course, always the class which is in largest supply that involves the loss, the depreciation arising from the very abundance.

The question is, Can the cause of these ruinous fluctuations be removed?

To prevent fluctuations in the value of tea as a whole is impossible, but in my opinion the loss from the cause above noted can be very considerably remedied to the great advantage of all concerned in the trade.

If I am not wrong, the greatest cause of these fluctuations is the fact that growers of tea in India

and Ceylon now, as formerly in China, strive to produce the largest supplies of those qualities of tea which paid best during the previous season, and to reduce the supply of those which did not pay; when this is done it necessarily reverses the conditions, hence the great losses. The only remedy that can be found for this ruinous mistake is by a general arrangement amongst planters to supply the various classes of tea, year by year, as far as possible in the same proportions. Take for instance this rough calculation, that about 3-6ths of the tea consumed is under 10d. per lb., 2-6th between 10d. and 1s. 4d., and 1-6th above that price.

If the large growers would agree to produce tea year by year as nearly as possible in these proportions the fluctuations in the value of the various sorts would be comparatively small.

Of course, the price of tea as a whole must always be regulated by the supply, but the fluctuations would balance one another, and would not be nearly so serious as the perpetual fluctuations which now take place in the various classes.

This is a question which affects all persons in the trade, and the past year offers an example of the great injury these fluctuations inflict.

The extreme depression in "good common" to "medium" tea, which culminated in August last when Pekoe Souchong, worth on an average 9d per lb was sold at 5½d encouraged some of the cutting retailers to offer very low-priced canisters, which, as the quality was so good, threw the consumers off the higher priced teas, to the great detriment of growers and dealers.

I am quite aware that the matter is a difficult one to arrange, as it necessitates combination, and unfortunately there are always some objectionable persons who take a narrow view of their own interest, but it is of such importance to the tea-growing industry that it is worth while, at any rate, to make a strong effort to put production upon a safer basis. Another cause of great loss to growers and importers arises from their placing too great quantities on the market at one time. It does not seem yet to be realised that neither wholesale nor retail dealers will now hold the stocks they used to do, and any excessive offerings unduly depress prices. As an example I may quote the unnecessary fall of 15 per cent. which took place in November, entirely owing to the large amount of tea placed on the market at a favourable time, which must have cost growers and importers some thousands of pounds, simply because about 20,000 packages too many were put up for sale in one week."—*H. and C. Mail*, Jan. 20.

COFFEE LAND IN JAVA.—Landed proprietors in Java are evidently waking up to the probability of capitalists from Ceylon taking up land for coffee cultivation. It will be seen by an advertisement in our columns today that no less than 20,000 acres of first-class land are now on offer, either in one block or in divisions. It would be suitable for a strong coffee cultivating Company.

COCONUT PLANTING IN MIRIGAMA DISTRICT.—We have had very glowing accounts of the success which has attended Mr. W. H. Wright's cultivation of his fine Mirigama property. He has brought many of his trees of a fine large growth, into bearing within six years, and the whole plantation of some 350 acres is quite a picture of luxuriant growth and vigorous palms. Mr. Wright himself, now in his 70th year, is as fresh and vigorous-looking as the first day we saw him in Hspitale opening for coffee, over 25 years ago. Few more active or muscular planters are to be found in Ceylon or better able to get through a hard day's work. But Mr. Wright's delight, since he began life as a lad in Peradeniya Gardens, has been in an outdoor life and as a cultivator and planter. May his useful career, so valuable as an example to his countrymen, be prolonged for many more years.

TEA PLUCKING, CROP AND SHIPMENT PROSPECTS.

The announcement made by our contemporary of the "Times" the other day that the "coarse plucking" of tea was once more coming into vogue in the planting districts, created no little perturbation in some quarters. It was so far justified by the apparent better demand for the time, for the coarser teas, and the natural expectation was that, as a consequence, our tea shipments would begin rapidly to rise. We concluded at once to make inquiries upcountry and the result we are glad to say is entirely contradictory of the report that a season of "coarse plucking" had set in and still more that increasing shipments might be expected. One gentleman with extensive means of knowing what is going on in the tea districts, writes:—"I do not believe coarse plucking has commenced to any extent. A few places may have gone back to it; but it has not come under my notice except in a very few places, and I have just been all round the country." That seems decisive, and the opinion is backed up by that of another authority who writes:—"When tea prices rose a few months ago the plucking became a little coarser on some estates, but absent proprietors as a rule are so particular about the *quality* of the teas that go home from their estates that superintendents are obliged to be careful about the leaf. This at any rate is my experience, and if it is that of others also, there need not be much fear of an undue proportion of the lower grades finding their way to the London market from Ceylon, unless, of course, there is a great rush of leaf and not enough coolies to deal with it. The country at the present time however is abundantly supplied with labour."

We learn further that the latest reports received in Colombo from the higher districts are of unfavourable weather for the flush, the cold wind at night still prevailing. And as a matter of fact the receipts of tea here at present are not such as to warrant any increase in shipments. The conclusion arrived at therefore is that (notwithstanding the large shipment of nearly a million lb. by one vessel in this month as in last) the total export for February is not likely much, if at all, to exceed that for the month of January. Such is the effect of the information which reaches us from upcountry today checked by what we have learned in Colombo.

ADULTERATING COCOA

will certainly possess interest for many of your planters. In the days when coffee was king in Ceylon prosecutions of this nature were of almost daily occurrence. With tea superseding coffee one has heard but little of such cases as of interest to Ceylon; but it would now seem as if another of your leading products was to take the place of coffee in our police reports. If the practice of adulterating cocoa should appear to extend, it may become the duty of your Ceylon Association to renew the efforts it made to check the illegitimate advertising of rubbishy blends purporting to be pure Ceylon tea. Although those efforts were put a stop to for fear of harassing the trade and so creating a feeling among its members inimical to Ceylon teas, there can be no doubt that the precautions instituted by the Association did a great deal of good, and there are many among us who regret that its was deemed advisable, for the reason above mentioned, to discontinue them.

ADULTERATED COCOA.—At the Harlesden Petty Sessions, yesterday, James Henry Attfield, an oil

and colour man, of High-street, Harlesden, was summoned for selling cocoa adulterated with at least 40 per cent of starch and sugar. Mr. Lay appeared for the Middlesex County Council, and Mr. St. John Wontner defended. Walter Tyler, the inspector under the county council for the western division of Middlesex, and his assistant, Edward Reeve, proved purchasing a $\frac{1}{2}$ lb. packet of Epps's cocoa for 3d. at the defendant's shop. Mr. Bevan, the county analyst, had given his certificate that the portion of the cocoa sent to him contained at least 40 per cent of starch and sugar. The defence was that the label upon the packet showed that it contained a mixture of cocoa, arrowroot, and sugar. Mr. Wontner argued the case at great length, stating that cocoa must be adulterated to be made palatable. Mr. H. Epps said he was a member of the firm of James Epps and Co. The starch was certainly not ordinary washing starch, but the best West Indian arrowroot. The Bench said they must convict because they were of the opinion that the label did not show the packet to contain a mixture. There was a label upon the packet, but it was in learned and scientific language. The defendant must pay a fine of 40s. A case would be stated for a higher Court.—John Taylor, a chandler, of Kilburn, was also summoned for selling cocoa which contained 60 per cent of starch and sugar and about one third of the fat usual in genuine commercial cocoa. In this case the cocoa was a 2d packet of Fry's. Mr. Hood appeared for Messrs. J. S. Fry and Sons. The purchase and analysis were proved, but the Bench held that the wording of the label upon the packet was clear, and showed that the packet contained a compound; they therefore declined to convict.

—*London Cor.*, Jan. 20.

INTERESTING NOTES ON TEA.

(Specially collected for the "Tropical Agriculturist" by A. M. Ferguson, Jr., London.)

AFTERNOON TEA.—(16th S. iv, 49, 136.) In a sketch of the Count de Circourt (friend of Macaulay and Stanley), by Hubert Saladin, the *Salon* of Madame de Circourt comes prominently before as one of those frequented by the most intellectual Society of Paris in 1837. A reviewer in the *Revue Britannique* for this month suggests that to her (she was a Russian) we are perhaps indebted for the first 5 o'clock teas.—K. H. B. (*Notes and Queries*, 6th S., vi, Aug. 5th, 1882, p. 116.)

The reviewer of Mrs. Fanny Kemble's *Record of a Girlhood and Record of Later Life*, in the *Quarterly Review* for July, 1882, p. 117, says:—

"She dates, and (we think) somewhat antedates what has now become an institution, the afternoon tea, from a visit to Belvoir Castle, in March, 1842, when she received on several occasions private and rather mysterious invitations to the Duchess of Bedford's room, and found her with a small and select circle of female guests of the Castle busily employed in making and drinking tea with her Grace's own private tea kettle. 'I do not believe that now universally honoured and observed institution of 'five o'clock tea' dates further back in the annals of English civilization than this very private, and, I think, rather shame-faced practice of it.' It was not universally honoured or observed till many years further on."—JOHN CHURCHILL SIKES, 106, Godolphin Road, Shepherd's Bush, W. (*Notes and Queries*, 6th S., vi., Sept. 30th, 1882, p. 277.)

I first saw it at a large country-house about the year 1830 or 1832. The ladies only partook of it, and very few of them. It was a consequence of the later dinner hours, but was disapproved by the doctors.—P. P. (*Notes and Queries*, 6th S., vi., Nov. 25th, 1882, p. 438.)

When did this modern usage of afternoon or five o'clock tea first come into fashion? and did

not a similar custom prevail in the last century?—A. C. B. (*Notes and Queries*, 6th S., iv., July 16th, 1881, p. 49.)

I shall be glad to see what date may be fixed by a general consensus. My date would be 1848-9, my place the house of the then Lieutenant-Governor of Sandhurst; but the practice of having "afternoon tea" soon became very general, and then, one may say, universal.—GIBBS RIGAUD, 18 Long Wall, Oxford.

I remember very well the first time I saw afternoon tea brought in. There was a small archery party—croquet had not then been introduced. About five o'clock the butler came to us and said: "If you please, my lady, the servants are going to have tea, if you would like to have some." The weather was hot, and tea was brought out. After this the practice became a regular one at the house, and I suppose at other houses also. This was somewhere between 1845 and 1850.—E. LEATON BLENKINSOPP.

Sixty years ago it was common in Roxburghshire for the wives to take tea in the afternoon four hours after their mid-day dinner. Owing to this interval the tea taking got the name of "four o'clock tea."—C. (*Notes and Queries*, 6th S., iv., Aug. 1881, p. 136.) In a late number of *Chambers's Journal* (Nov. 20, 1875) it is asserted that "afternoon tea is a pre-emptive measure supposed to have first come into vogue during the last decade or so. Like many other novelties, however, it is merely the revival of a custom of the last century. Dr. Alexander Carlyle, in his *Autobiography*, p. 434, describing the fashionable mode of living at Harrogate, in 1763, writes:—"The ladies gave afternoon's tea and coffee in their turns, which, coming but once in four or five weeks, amounted to a trifle."

—H. A. KENNEDY, Junior, United Service Club. (*Notes and Queries*, 5th S., v., Feb. 19, 1876, p. 145.)

TEA AND SCANDAL.—In reading Congreve's "Way of the World," lately, I was amused to find how soon tea became popularly associated with scandal, a partnership which has, I fancy, not even yet been dissolved. Mirabell, in Act. iv. scene 1, says to Mrs. Millamant:—"Lastly, to the dominion of the tea table I submit,—but with proviso that you exceed not in your province; but restrain yourself to native and simple tea table drinks, as tea, chocolate, and coffee: as likewise to genuine and authorised tea table talk—such as mending of fashions, spoiling reputations, railing at absent friends, and so forth." As tea was at the date of the play (1700), comparatively new, and was even then an expensive luxury, it would seem that there must be a natural sympathy between tea and scandal. Can anyone point out a still earlier allusion to the union of this happy pair? A friend, to whom I mentioned the above passage, asks me, "Why did our forefathers invariably speak of a *dish* of tea?" I suppose there was no reason other than *sic volebat usus* [so usage willed it.—A. M. F., Jr.] when did people begin to speak of a *cup* of tea? They must have begun by Cowper's time—"the cups that cheer but not inebriate,—in 'The Task,' 1785. Did our ancestors ever say "a dish of coffee"? Pope, in the "Rape of the Lock," Canto iii., speaking of coffee, says, "And frequent cups prolong the rich repast." A passing character in "The Way of the World" I, 2, orders "two dishes of chocolate." The Retired Citizen in the 317th *Spectator*, in his delightfully "fusionless" diary, notes that he had "a dish of Twist" at the Coffee-house, what was this? There is a coarse tobacco called "Twist," but did our forefathers at any period speak of a *dish* of tobacco? The French as a nation are not, and I suppose never were, great tea-drinkers; and yet the poet, Jacques Delille (ob. 1813), who seems to have been as domestic in his tastes and habits as Cowper, in a passage in his poem "Les Trois Regnes," quoted in Chapsal's "Modèles de Littérature Française," mentions tea and coffee as though he considered them entitled to equal honours:—

Mon cœur devient le triste et ma tête pesante,
Eh bien ! pour ranimer ma gaîté languissante,
La fève de Moka, la feuille de Canton,
Vont verser leur nectar dans l'émail de Japon,

Dans l'airain échauffé déjà l'onde frissonne,
Bientôt le thé doré jaunit l'eau qui bouillonne,
Ou des grains du Levant je goûte le parfum.
In another passage Delille breaks out into absolute enthusiasm over coffee:—

C'est toi, divin café, dont l'aimable liqueur,
Sans altérer la tête, épanouit le cœur.
Whether this couplet was written before or after "The Task," I do not know. It is curiously like the well-known passage I have quoted above. Delille was well read in English literature; he translated "Paradise Lost" and the "Essay on Man"; but it may be merely a coincidence. Again:—
Viens donc, divin nectar, viens donc, inspire-moi,
Je ne veux qu'un désert, mon Antigone, et toi.
We must remember that it was French-made coffee that inspired the English coffee lines. A single cup of average siam would have quenched the poet's enthusiasm.—JONATHAN BOUCHIER, Ropley, W. Hants.

P.S.—Since writing the above I have met with 'a dish of coffee' in Swift's "Polite Conversation." Meg Dods, in 'St. Ronan's Well' speaks of a 'dish of tea' more than once. (*Notes and Q.*, 7th S., vi., Oct. 13, 1888, p. 282.)

Mr. Bouchier asks what was the "twist" of which the retired citizen took a dish. Hotteu's Slang Dicty. says that *twist* is gin and brandy mixed. In Pendennis, vol. ii. chap. i. we are told that "giu-twist and devilled turkey had no charms" for Mrs. Harry Fokes. Mrs. Mortimer Collins, in 'Frances,' chap. v., seems to use the word simply as a synonym for ordinary grog: "As Walter Carey smoked his evening pipe over his evening *twist*, he felt perfectly satisfied."—Geo. L. APERSON. (*Notes and Q.*, 7th S., vi., Dec. 22, 1888, p. 493.)

HAIR AND TEA.—It is commonly believed that we English, or at least the Mercian part of us, were once a fair-haired people, but that for some reason the hair has become darker each succeeding generation for a long time past. I know not whether this be so, nor am I able to suggest any means of settling the question. Assuming, however, that an increasing darkness in the hair be proved, I have heard it suggested that it may have come about by our habit of drinking tea. Tea taken in large quantities will, says a scientific friend of mine, darken the complexion, and therefore the hair. I should like to know whether this be mere dreaming, or whether there be truth therein.—A. MERCIAN. (*Notes and Queries*, 5th S., vii., April 28th, 1877.)

TEA.—The following notice of tea is copied from the *Relation of the Voyage to Siam by Six Jesuits in 1685*, London, 1688, p. 269:—"It is a civility amongst them to present betel and tea to all that visit them. Their own country supplies them with betel and areca, but they have their tea from China and Japan. All the orientals have a particular esteem for it, because of the great virtues they find to be in it. Their physicians say that it is a sovereign medicine against the stone and pains in the head that it allays vapours: that it cheers the mind: and strengthens the stomach. In all kinds of fevers they take it stronger than commonly, when they begin to feel the heat of the fit, and then the patient covers himself up to sweat, and it hath been very often found that this sweat wholly drives away the fever. In the East they prepare the tea in this manner: when the water is well-boiled, they pour it upon the tea, which they have put into an earthen pot, proportionably to what they intend to take (the ordinary proportion is as much as one can take up with the finger and thumb for a pint of water), then they cover the pot until the leaves are sunk to the bottom of it, and afterward give it about in China dishes, to be drank as hot as can be without sugar, or else with a little sugar-candy in the mouth: and upon that tea more boiling water may be poured, and so it may be made to serve twice. These people drink of it several times a day, but do not think it wholesome to take it fasting."—W.E.A.A. (*Notes and Queries*, 4th S., vii., 18th Feb. 1871, p. 139.)

SHEFFIELD EXPRESSIONS.—A curious expression, prevailing here, is the use of the word "gamest" as applying to the most direct road to a place. A

cabmen will tell you that he knows "the gamest" (meaning the shortest) road to such and such a place. Another curious phrase is that of "mashing" instead of making the tea. Is this a provincialism?—F. B. DOVETON. (*Notes and Queries*, 5th S., i, Mar. 14, 1874, p. 205.)

MASHING TEA.—(5th S., i., 205.) This phrase, meaning infusing tea, is not peculiar to Sheffield. It evidently had its origin from the brewer's *mash-tub*. In certain parts of Scotland the process of infusing tea is called *mashing*, probably a corruption of *mashing*.—W. A. C., Glasgow.

Mash is to infuse (*miscere*), familiar in the brewer's *mash-tub* but as applied to the tea-pot it is generally *mask*:—

Then up they gat the masking-pat,
And in the sea did jaw, man,
And did nae less, in full congress,
Than quite refuse own law, man.—*Burns*.

—W. G. (*Notes and Queries*, 5th S., i., Mar. 28, 1874, p. 255.)

TEA is said, in Haydn's *Dictionary of Dates* to have been brought to Europe by the Dutch, 1610. It is mentioned as having been used in England on very rare occasions prior to 1657, and sold for £6, and even £10, the pound! In 1666, it was brought into England by Lord Osory and Lord Arlington, from Holland, and, being admired by persons of rank, it was imported thence and generally sold for sixty shillings per pound, till our East India Company took up the trade. The following short poem by Edmund Waller is believed to be the first one written in praise of "the cups that cheer but not inebriate".—

Venus her myrtle, Phœbus has his bays:
Tea both excels, which she vouchsafes to praise,
The best of Queens, and best of herbes, we owe
To that bold nation which the way did show
To the fair region where the sun doth rise,
Whose rich productions we so justly prize.
The Muses' friend, tea, does our fancy aid.
Repress those vapours, which head invade,
And keeps that palace of the soul serene,
Fit on her birthday to salute the Queen."

Waller was born in 1605; died 1687, aged 82.

—FRED. RULE. Ashford. (*Notes and Queries*. 5th S. I. May 23rd, 1874, p. 405.)

TEA IN CUMBERLAND IN 1792.—Housman's 'Notes,' cited in Hutchinson's History of Cumberland (1794) i. 177, say of the Crunwhiton folk, in Eskdale Ward: "Tea, though a luxury stealing in upon them, is held in such detestation with some, that they would rather cherish a serpent than admit a tea-kettle." He also says, 'Not till this year, 1792, has a newspaper entered the parish, and now one solitary *Cumberland Packet* has been introduced. No taste for science or polite literature: books are regarded as puerile amusements.'—F. J. F. (*Notes and Queries*, 7th S. x., Nov. 22, 1890, p. 405.)

DUTCH TEA CADDY.—Can any amateur of old silver plate throw light on the history and present whereabouts of a small Dutch tea caddy which bears an inscription recording that one Dirk Jans did, on January 21st, 1725, with horse and sleigh, fetch the said caddy from Enkhuyzen?—G. W. T. (*Notes and Queries*, 7th S., xi., June 6th, 1891, p. 440)

TEA-POY.—A friend points out to me what he deems a slip in Webster-Mahn concerning this word. There *tea-poy* is defined as a table "inclosing caddies for holding tea," or "for holding a cup of tea, &c." the *tea* justifying the explanation. But is not *tea poy* (so well-known to Indian residents) really connected etymologically with *tripos*, the *tea* being no more the beverage than *cray fish* is a fish? I have not Col. Yule's "Glossary" at hand.—EDWARD H. MARSHALL, M. A., Hastings. (*Notes and Queries*, 7th S., xi., Feb. 7th, 1891, p. 106.)

TEA-POY.—(7th S., xi, 106.) The following extract is given in the "Imperial Dicty." revised and annotated by Annandale:—

Tea-poy is in England often supposed to have connection with *tea*; but it has no more than "Cream of Tartar" has with *Crim-Tartary*. It is a word of Anglo-Indian importation, viz. *tipd'i*

an Urdu or Anglo-Indian corruption of the Persian *sipai*, *tripos* (perhaps to avoid confusion with *seapoy*) and meaning a three-legged table, or tripod generally. *H. Yule.*—F. O., Birbeck Terry.

Mr. E. H. Marshall says.—"I read that in Webster-Mahn &c." The word is a Hindustani one, *thipai*, and has nothing to do with *tea*, though so misunderstood by "griffs," as newcomers are called in India.

I have heard a griff, knowing that *char* in Hindustani means *tea*, call for a *charpoy*, which means a bedstead, instead of a *teapoy*. Any kind of small table is called a *thipai* in India; but whether the word is "connected etymologically with *tripos*" as Mr. E. H. Marshall thinks, I cannot say. I fancy it is a Persian word, Hindustani or Urdu being composed mainly of Persian and Hindi.—D. P. WILLIAMS. (*Notes and Queries*, 7th S., xi., April 11th, 1891, p. 292.)

TEA-POY.—(7th S., xi., 106, 292.) Col. Yule's Glossary gives a very clear explanation of this word. It has nothing to do with tea, but is, as Mr. Marshall surmises, connected etymologically with *tripos*. It is compounded of the Hindustani *tin*=3, and the Persian *pac*, a foot, and means a three-legged table, and thence any very small table. Similarly *charpoy*, from Pers: *chihar*=4, and *pac*, signifies a four-legged bedstead.—W. F. PRIDEAUX. Kashmir Residency. (*Notes and Queries*. 7th S. xi., May 16th, 1891.)

TEA CADDY.—A lady of advanced age tells me that what is called a tea-caddy now was formerly called a tea-chest, and that the smaller boxes inside it were called caddies. If this word is derived, as no doubt it is, from the Chinese *katty*, a weight of something over a pound, this will probably be correct. Have we any recorded testimony of it?—R. C. A. PRIOR. (*Notes and Queries*. 7th S., iii., April 16th, 1887, p. 308.)

There is a story, which I think I have communicated to "N. & Q." but I cannot find a reference to it, which shows that "tea-chest" was in common use before 1741 to denote the whole box containing the tea for the use of the table. It is this:—

"Tu doces." A correspondent, observing this paragraph in a newspaper, "Harry Erskine, the Selwyn of Edinburgh, puzzled the wits of his acquaintance by inscribing on a tea-chest the words "tu doces," observes that this pun was on the tea-chest of J. Conson, F.R.S., above fifty years ago, when he was member of the mathematical free-school of Rochester. He was after that of Sidney College, Cambridge, and Lucian Professor of Mathematics." *Gentleman's Magazine*, Pt. 1., p. 259, March, 1791.—ED. MARSHALL.

Fifty years ago, when tea was dearer than in these days, my mother had a large locked box, with two metal-lined boxes with lids, and a cut-glass sort of large tumbler for the dear 'loaf' or 'lump' sugar of those days. The large box with the lock was always called the tea-chest, and the two boxes (for black and green tea) were called caddies or caddys, each meant, probably, to hold about a half-pound of tea. They were well-made, and lifted up out of the tea-chest, and their lids opened to take out the tea, with a small silver shell-form scoop.—ESTE.

The well-known punning inscription upon "what is called a tea-caddy now" loses all point of *tu doces* is to be translated "thou tea-caddy."—J. ROSE, Southampton. (*Notes and Queries*, 7th S., iii., May 28th, 1887, p. 435.)

TEA-CADDY.—(7th S., iii., 308, 435.) Sometimes a box without any compartments, and not metal-lined, is called variously "tea-box," "tea-caddy," never "tea-chest" to my knowing. I have heard some call a tinbox or chest, used to hold tea, a "tea-caddy," not having any divisions inside. On the other hand, a large chest, such as described by Este (7th S., iii., 435) is called a "tea-chest" the metal-lined boxes within it being called "caddies." Some of these large "tea-chests," one a very old one I know of, also contain an extra compartment, which serves as a small medicine-chest. But "tea-caddy" is sadly misused, as other names.—HERBERT HARDY, Thornhill Lees, Dewsbury

I noticed in one of your late numbers an enquiry as to the origin of the name "tea-caddy." I import tea from Shanghai, and this account is made out in

"cattys," a Chinese weight, equivalent, if I remember rightly to two and a quarter pounds. There is a similarity in the names "caddy" and "catty," which suggests the origin of the former, and its derivation from the latter. May I be excused, when writing on tea, if I draw the attention of those of your readers who are connoisseurs in tea to the remarkable fact that the greater merit of *sun-dried* tea compared with *high-dried* tea (that is tea dried by artificial heat) appears to be unknown to more than a few of the consumers in England, and to most of the tea-merchants. *Sun-dried* tea is superior to *high-dried* as an Havana cigar is to its English-made imitation. The high-drying process was invented many years ago, so I was informed by my friends at Shanghai (when the tea had to remain in the hold of a sailing ship for several months,) to protect it from mildew. If any of your readers are tempted to order *sun-dried* tea from Shanghai or Foochow or Ichang, &c., they will find a small packet of lime in each case. This is to absorb any moisture that may get in during the voyage, which, however, now lasts for only a few weeks. The Russian "overland" tea is sundried, hence its high character.—ALFRED P. RYDER, Admiral of the Fleet. (*Notes and Queries*, 7th S. iv. July 9th, 1887, p. 33).

TEA CADDY.—(7th S. iii., 308, 435 iv., 33.) *Catty* from the Malay. See Marsden's Dictionary.—R. S. CHARNOCK, St. Honoré-les-Bains. (*Notes and Queries*, 7th S., iv., Sept. 3rd, 1887, p. 195.)

TEA CLIPPERS.—Can any reader of "N. & Q." give me a hint as to the best book for information respecting the now almost obsolete "tea clippers"? RICHARD EDGEUMBE, Mount Edgecombe, Devonport. (*Notes and Queries*, 7th S., vii., Feb. 16th, 1889, p. 128.)

TEA CLIPPERS.—(7th S., vii., 128.) Mr. Edgecombe will find a brief notice of the so-called clipper sailing-ships, accompanied by a wood-cut illustration of one of them, in the first edition of "Chambers's Encyclopædia" (1862) vol. iii., p. 18. In the third volume of the *Lew* issue of the Encyclopædia just published, the notice is cut down to ten lines, an abbreviation accounted for by the fact that in the interval since 1862 the clipper has been superseded by the steamship, and is now little more than a memory. Fortunately, however, a competent author, who evidently writes from experience, has put on record a vividly realistic picture of the actual working of a China tea clipper, and of the life of a sailor on board. This is contained in "Spun yarn and Spindrift" by Robert Brown, published in 1886 by Messrs. Hulston & Sons. It purports to be a sailor boy's log, and is a narrative in the form of fiction of the voyage out and home of the "Albatross," a China tea clipper or barque of 722 tons. The race home of the three rival clippers from Foochow is a graphic and stirring bit of writing, and, apart from the now historic value of the book as a description of an obsolete state of things in the sea-faring world, the story shows that Mr. Brown is not unworthy to take his place among the best of our modern tea novelists.—JOHN H. NOBAL, Heaton Moor, Stockport. (*Notes and Queries*, 7th S., viii., April 13th, 1889, p. 295.)

AMERICANS AS RUBBER CONSUMERS.

The *India Rubber World* says:—"In order to show the respective standing of the countries which are the most important consumers of India rubber and gutta-percha, the following table is given showing the imports of crude gums for the first nine months of 1892, also the exports of crude material, after which is given the amount remaining, which represents stock or the consumption in manufactures:—

Details.	pounds		
	United States.	Great Britain.	German Empire.
Imports, nine months ...	27,407,233	26,373,424	7,506,180
Exports, nine months ...	734,710	11,740,806	1,661,880
Remaining for home use ..	26,672,523	14,902,618	5,844,300

It will be observed that of the amount consumed by the three countries named largely more than half is used by the United States. If allowance be made for the fact that of the rubber goods made in Great Britain a considerable share is exported, while by far the larger part of those made in this country are sold and used at home, it may safely be calculated even in view of our large population, that the use of rubber goods per capita is much greater in the United States than in any other part of the world. It may be added, by the way, that a similar fact exists with regard to almost every other commodity entering into general use in America—from iron to sugar, from paper to beefsteaks. Truly the buying classes in this country afford a wonderful market."

VARIOUS NOTES.

JAVA TEAS, which are of no value for exportation, are being improved in flavour by the flowers of *Jasminum sambac*, Aiton, *Aglaiia odorata*, Lour., and *Gardenia pictorum*, Hassk. According to *Rev. Internat. des Falsifs*, an industry has been started at Cheribon, Java, to prepare such teas in imitation of Chinese tea—*Amer. Jour. Phar.*

NORTH BORNEO.—We regret to hear bad accounts of the prospects of North Borneo: retirement is the order of the day to such an extent that all the leading Government servants, save three or four are under orders to leave. Of those retained, our old friend Mr. Henry Walker is one we are glad to say. We hope matters will improve before long in the settlement.

THE EUCALYPTUS OIL INDUSTRY.—We call attention to the interesting paper from the *Chemist and Druggist* in the *Tropical Agriculturist*, giving an account of the rush into this distilling business caused some time ago by the influenza epidemic in England. Of course, the first manufacturers in the field made a fortune—pity that some Ceylon owners of blue gums were not able to share in the profits—but now alas! the industry has been so overdone that it will take a long time to reduce stocks, unless indeed influenza become generally rife again, or what is more likely and more to be desired, new uses are found for the Eucalyptus oil.

GAMBIR AS A PLANTING PRODUCT.—Our attention has been called by Dr. Trimen to the number of the "Agricultural Bulletin of the Malay Peninsula" which contains an "admirable and exhaustive account of Gambir" prepared by Mr. H. N. Ridley, Director of Gardens and Forests at the Straits, and which he thinks ought to be reprinted in the *Tropical Agriculturist*. We very readily give effect to this request. Mr. Ridley's compilation is at once concise and exhaustive: it covers some 20 pages dummy, and gives a description and history of the plant and drug, and short chapters on "the uses of the Drug, the forms of Gambir, Planting, Nursing, Cuttings, Seedlings, Enemies, Cropping, Manufacture, Adulteration, Chemical Composition, Analysis, Cultivation for Profit," &c. The profit Mr. Ridley shows in certain cases to be equal to about £70 per acre. Gambir is the second most important vegetable product of the Malay Peninsula and the average annual export for five years is equal to 4,682,333 dollars; and yet this important cultivation has scarcely been touched by Europeans, being all in the hands of the Chinese and Malays. Now, with Mr. Ridley's paper before them on page 590, we do not see why Ceylon planters should not do something more in the lowcountry with Gambir. We are aware of experiments already made; but we think there is hope for greater success if attention be paid to Mr. Ridley's instructions.

NEW LOCAL INDUSTRIES IN CEYLON :
AND HOW THE GOVERNMENT ENCOURAGES
THEM.

Swift's apophthegm on the deserts of the man who makes two blades of grass to grow where there was only one before, is of world-wide quotation. Dealing with the "over production" of certain staples, in our lecture before the London Chamber of Commerce, we ventured to call in question, the wisdom of the Dean of St. Patrick, and to say that in the case of Ceylon at least, we had to be cautious in our praise of agricultural benefactors who, when they were good, were apt to become too good! More to the point perhaps, is the motto we have prefixed to our *Tropical Agriculturist* quoting Sir John Sinclair when he wrote:—"He who introduces, *beneficially*, a new "and useful Seed, Plant or Shrub into his district, "is a blessing and honour to his country." Canny Scot was Sir John: the introduction must not only be "beneficial," but the seed, plant or shrub prove to be a "useful" one, for the commendation to be merited. Many have been the illustrations in the planting history of Ceylon, however of the need of such qualifications, not only, in reference to the risk of over producing as in the case of cinnamon, cinchona, cardamoms and tea; but also of introducing innocently, seed or plant—like the white weed *ageratum*—which may prove a curse instead of a blessing.

But in turning from agricultural to mechanical industry, we come on far surer ground in the case of this Colony; for very apparent it is that the great want of Ceylon as of India and other Asiatic lands is in the direction of manufactures, mechanical industry, rather than in the extension of agricultural pursuits. This is most true, so that the man or firm, or limited Company successfully introducing a new and useful manufacturing industry for the employment and benefit of the natives in our towns or suburbs, can unquestionably be classed as a public benefactor. Under this designation indeed, came all the coffee planters on account of the large mechanical industry which they started and supported in cask-making for their produce, and in the preparation of the coffee bean in Colombo stores so giving employment to some 20,000 men, women and children. No less important to the people at large (though not to those of Colombo) is the box-making industry created by tea and the abundant employment afforded to masons, carpenters and other artificers by the many factories required for 260,000 acres of that product.

But it may be truly said that all such mechanical employment depends directly on Planting and has no independent footing of its own. It is in other and independent directions that we should seek out the men whom it ought to be the business of an enlightened Government to honour and reward. In the Australian colonies, where there is scope for new branches of agricultural development as well as for manufactures, the system of bonuses has, in many cases, been found to work well. Now why in Ceylon should not the colonist or native, or even the Firm or the Company that may start and establish a new beneficial industry, be rewarded with a substantial bonus, unless he should prefer a medal of honour which might be graded from "leather" up to the purest "gold" according to the importance of the industry claimed for. Such encouragement,—even to the voting, annually, of a substantial sum in the Supply Bill,—would prove true economy in the end. Here for instance, are we introducing at considerable expense a Technical Instructor who will require a little Establishment of his own if he is to make any progress. Altogether, the ex-

penditure on his account including house rent, and assistance cannot, we suppose, begin at less than R10,000 to R12,000 per annum. Now, the result aimed at must either be the improvement of existing industries, or the introduction of new forms. But if such can be promoted through unofficial agencies with a greater chance of permanency, it may be found advisable later on to make our Technical officer, an Inspector of such new branches, so that on his Reports it may be decided where official encouragement or honour should be bestowed on our Industrial pioneers.

We have been led into this train of speculation through the consideration of many minor as well as greater branches of industry introduced into Colombo of late years through private enterprise and without the recognition of, but rather in some cases, in the face of discouragement from Government. We are not prepared to give "facts and figures" or an exhaustive list at this time; but we may refer to what has already been noticed in our columns, "the nickel-plating" industry begun and in a fair way of establishment by Mr. George Armitage, giving employment in an extremely novel and interesting way to a number of natives. Why should not Mr. Armitage, after due inspection, have some recognition from Government? There is then Mr. E. B. Cressy's "plumbing" establishment, the necessary outcome to some extent of our Water Supply Works, but still leading native workmen into new employment. Still more interesting is it to learn how Messrs. H. W. Cave & Co. have succeeded in establishing two entirely new and interesting branches of mechanical industry at their Colombo Establishment. This firm has not only benefited the community by the importation of pianos and organs, and of pictures and others works of art on a large scale; but out of this business has arisen the steady employment of some score of native artificers in the work of repairing and refitting pianos and other instruments and of making and fitting frames to pictures. In respect of pianos, we are assured that under the instruction of a European assistant (tuner, &c.) the Sinhalese have developed such care, neatness and finish that instruments in need of repair and refitting can now be treated as successfully in Colombo as in England. Electrical and small scientific instruments are also dealt with. In picture framing, quite a large business has been developed by the same firm, so that as many as fifteen natives are now regularly employed to meet the demands of Ceylonese customers chiefly. This is most satisfactory; for both branches of art—music and pictures—are specially calculated to uplift the people. And this is the more notable, because the character of the pictures imported of late by Messrs. Cave is of a very high order. Engravings of some of the finest pictures in the Royal Academy of late years—such engravings as figure in certain Pall Mall windows—now form a most attractive gallery in the "Amen Corner" establishment in which any one can spend half-an-hour or more very instructively. Surely then, we may well ask how the Ceylon Government encourages gentlemen like those we have already mentioned in starting new industries? Why, of course, by *taxing their raw material at the Customs!* So that in the case of Messrs. Cave & Co. we have the comical experience that while all pictures, engravings and photographs imported, in or out of frames, are *free* of duty; yet, on the raw material for picture frames, the "moulding," "beading," "glass" &c. they have to pay 6½ per cent duty. What our authorities in effect, therefore, say, is "Get your pictures framed in England, and they will pass free; as we do not

care to encourage local industry in picture-framing by our Sinhalese!" But this is only in keeping with the experience of the various firms engaged in mechanical industry after a much more extensive fashion. We refer to our Iron and Machine Firms, in Colombo, Kandy, Hatton, Badulla, &c., who employ hundreds of natives; but who find all their raw material required for the construction of machines *taxed*, while if they choose to import the same machinery ready-made in England or elsewhere, it pays no Customs duty whatever! Such are some of the absurd anomalies of our Customs tariff which urgently call for rectification in the interests of the community at large and especially of mechanical industry and manufactures. But with "machinery," we have entered on a large branch of the subject which must be treated more fully in a future issue.

VARIOUS NOTES.

COTTON CULTURE IN CENTRAL ASIA.—It is reported from Odessa that several large new cargoes of raw cotton, grown in Russian Central Asia are to be shipped at Odessa for Danzig and other ports in Germany. The Russians are sanguine that the future will see a vigorous development of this new branch of trade. Should their hopes be realised, the raw cotton would hereafter be sent by rail, river, and canal, *via* Odessa and Warsaw, so as to avoid the long voyage round Europe. In competent quarters in Berlin, however, the *Standard* correspondent says, the hopes of the Russians are regarded as at present illusory. The quality of the cotton from Russian Asia is inferior. Still, it is reported that the quantity shipped to North Germany has, so far, amounted to about ten thousand bales.—*Pioneer*.

COFFEE PLANTING.—A correspondent writes to say that in order to obtain an experienced opinion on Mr. E. A. Watson's scheme for Government Coffee Plantations in Selangor, he sent all the cuttings relating to the matter home to a friend, a planter of 30 years' standing, and now a gentleman of England, who lives at home at ease. He appends that opinion which is as follows:—"I read your enclosures with interest and quite agree with the *Singapore Free Press* that no Government can push an industry, especially an agricultural one, satisfactorily. If the planting of coffee will pay at Selangor or elsewhere you may depend on it private capital will soon discover the fact. There are millions of pounds in London seeking investment, in many instances only wanting to be shown the probability of a return."—*S. F. Press*, Feb. 1.

THE JAVA COFFEE CROP.—According to a telegram from the Governor-General of Netherlands India, dated the 15th inst., the Government coffee crop in Java for this year is estimated at 144,496 piculs. The year 1893 promises thus to be again a year of total failure of the crop, as generally the output remains under the estimate. The first estimate of the crop of 1890 was 169,000 piculs, and the output was only the half of it. In connection with this decrease attention is fixed upon the Java finances, and the necessity is pointed out of increasing the revenue by the introduction of taxes, for which the Minister had already proposed some Bills, which were, however, withdrawn, owing to the satisfactory culture of the coffee crop of 1892. A deficit on the Budget of 1894 will for the greater part be covered by the balance of the current year; but it is advised that measures should be taken for a more reliable basis of the Java finances.—*L. and C. Express*, Jan. 27.

GAMBIR.

(From the *Agricultural Bulletin of the Malay Peninsula*.)

INTRODUCTION.

Of all the vegetable products of the Malay Peninsula, Gambir takes the second place only in importance. In the tanning and silk trades it is well known to be indispensable, and it is also used to a small extent in medicine. The larger portion of the drug which finds its way into the market is exported from Singapore, and the average value of the annual export for the last five years is \$4,682,333. The import into the British Islands in 1889 was, roughly speaking, of the value of £460,000, and the United States took in the same year nearly £180,000 worth. Nevertheless hitherto this important cultivation has been in the hands of the Chinese and Malays only. Europeans as yet have hardly begun to think seriously of undertaking it, and yet it is certain that a properly treated estate would bring a good profit. The reason of this neglect is, it seems, that the Malay Peninsula with the adjoining islands of Rhio, Lingga, Banka and some others, where alone the plant seems to thrive, has not yet come under the hands of the European planter to any large extent, and the few planters who have settled down in the Straits Settlements and Malay Peninsula have devoted themselves almost exclusively to coffee and tea cultivation.

There are signs, however, of an increasing interest in planting, and the attention of the planter is turning to other products than these, and among them to gambir, and indeed there is no reason why this plant should not be grown on a large scale. In the Malay Peninsula there is plenty of suitable land, the cultivation is easy and not expensive, the plant is quick-growing and will bring a return within a year or a year and-a-half after sowing, and the demand for the product is steady and constant.

It is true that, on the whole, the price of gambir has fallen in the last few years, but this is due entirely, I believe, to deterioration of the quality. The Native, working with rough apparatus and being very careless as to result, supplies the market with an inferior article unnecessarily loaded with water, often containing as much as from 30 to 50 per cent. In the hands of Europeans, with the aid of better methods of cultivation, and of improved machinery, a much superior class of gambir might easily be produced, while at the same time by doing away with the middleman, represented here by the Chinese *tokay*, the expenses of the product would be lessened.

Nor is the interest in the gambir cultivation confined to the Straits planter. Requests for seed and young plants have been addressed to the Botanic Gardens at Singapore from all parts of the world. To Borneo, India, Australia, Africa, the West Indies and other tropical colonies of the Empire, seed has been sent in quantity. In some of these countries it is probable that the gambir will not thrive well enough to bring profit by its cultivation, owing to the difference in climate, but this is impossible to decide till the experiment has been tried.

Comparatively little has been written on its cultivation and manufacture, and much of that has been published is inaccurate and misleading. I have, therefore, besides consulting all accessible works referring to the subject, visited plantations in different parts of the Straits Settlements, cultivated the plant myself, and with the aid of Dr. Bott, Government Analyst, made some experiments in improved methods of preparation. The information thus obtained I have set forth in order, so that this article may be as full as possible and may perhaps be of use to intending planters.

DESCRIPTION OF THE PLANT.

The Gambir plant (*Uncaria Gambir*, Roxb.) is a climbing shrub, clambering over trees and bushes to a considerable height by the aid of its recurved hooks. The stems are from one to three inches in diameter in the cultivated plant, but usually slenderer when the plant is allowed to climb as in a wild or half

wild state. The branches are slender, smooth, quadrangular and rather stiff, with a thin, reddish bark.

The leaves are opposite and arranged in one plane, in shape ovate, acute sometimes acuminate about four inches in length and two in diameter with short stout petioles a quarter of an inch long. They are dark green, and shining above, paler beneath, with the midrib and five lateral veins on each side prominent. The old leaves are stiff and firm in texture and possess a strong astringent taste. The stipules are light green, ovate lanceolate, blunt, three eighths of an inch in length.

The flowers are very numerous, in compact balls about an inch and-a-half through, on straight, stiff peduncles about one and-a-half inches long. These peduncles, which arise from a point a little above the pairs of leaves, are often converted into hooks. The flowers are about half-an-inch in length, sweet-scented in the evening.

The calyx is shortly tubular with five small lanceolate obtuse sepals not oppressed to the corolla tube but rather spreading, pale-green with darker points. The corolla is tubular half-an-inch long, slender, gradually increasing in size upwards, green or pale red, ending in a limb of five small lobate, blunt, spreading lobes, one-eighth of an inch long.

The stamens are five in number, alternating with the corolla lobes, the anthers sessile at the mouth of the tube linear. The style is long and slender, projecting a quarter of an inch beyond the corolla mouth, ending in an entire club-shaped stigma.

After flowering the pedicels of the flowers, previously very short, lengthen, and in the fruit are half-an-inch long. The fruit is a narrow fusiform capsule three-quarters of an inch long crowned with the calyx lobes. It splits on one or both sides longitudinally in the middle for the greater part of its length, and lets fall the exceedingly minute seeds, which are very copious. The seeds are thin and flat with an oblong papery wing at each end.

The flowers, which last but a short time, are visited by the small bees known as *kelulut* (*Trigona* sp.) in the search for pollen. As they creep over the flowers while gathering it, they do not fail to rub the abdomen sprinkled with pollen over the far projecting stigmas and so fertilize the flowers. For the greater number of flowers are fertilized and set fruits. The seeds, which are very light, are drifted to suitable spots by the wind.

There are about twenty species of *Uncaria* to be met with in the Malay Peninsula, but *U. gambir* is the only one which has been used to obtain the drug. It is possible that some of the allied species, however, might produce a certain amount. The *Uncarias* are usually found on the borders of jungle, climbing over the trees. Some, like *U. sclerophylla* and *U. pedicellata*, attain an enormous size, forming huge lianes, and are met with in the high jungle. One or two of these are water vines producing when cut a good supply of excellent water. *U. gambir* and the allied species are much more slender plants. I have rarely seen the plant in such a position that I could say that it was really wild. It remains on old cultivated ground long after that has reverted to jungle, and in these cases often looks different from the plant as seen in cultivation, being more slender, and narrower in the leaf. There can be little doubt, I think, that the plant is a native of the Malay Peninsula, and will probably be found in a really wild state sooner or later.

There seems to be some idea current that a plant described by Hunter under the name of *Nuclea acida* (*Uncaria acida*, Roxb.) is also cultivated for the production of gambir. What Hunter intended by this plant, it is impossible now to guess. His description is too meagre, and none of his specimens are extant. He found it in Penang, but he does not say in his paper that it produced gambir at all, or was used for that purpose.

HISTORY OF THE PLANT AND DRUG.

I have been unable to find any earlier reference to gambir than that of Rumphius (*Herbarium Amboinense*,

v. 63, t. 34) in 1750.* There is no mention of it in Garcia's *Historia Aromatum*, nor in Pomet's *Historie des Drogues* (1694), nor even in Steven's *Compleat Guide to the East Indies* (1766), although in that book the prices of goods at Malacca are given. Rumphius describes three species of *Uncaria*, under the name of *Dawn Gatta Gambir*, but his figures and descriptions are so bad that it is impossible to tell what the species were he had in view. Probably, however, the plant he called *Funis uncatius latifolius* was *Uncaria gambir*. This plant, he says, was very common in open country in Amboina, Celebes, Bali, and Sumatra near Palembang. It was called *Dawn Gatta* (and *Gitta*) *Gambir*, because its leaves had a taste of the lozenges called Gatta Gambir, although these were obtained from a different plant. The Ma'ays chewed the leaves with the betel (but did not at that time make the extract), and also cultivated it for the scent of its flowers. The Amboinese, however, used the juice for healing ulcers. The plant was thus first cultivated for its flowers and for the leaves as a masticatory.

The original Gatta Gambir referred to in Rumphius as being used in the form of lozenges was probably the product of *Acacia catechu*, which was imported into Malacca from Cambay as early as 1514 (Barbosa in Hakluyt's Voyages, 1866, p. 191) for use as a masticatory.

The Tamil name of this Catechu is *Kate*, which is spelt in Garcia's *Historia Aromatum* (Lib. I, 43.) Cate, and the variant Cato is said to have been the name of the drug in Malacca. Couperus (1780) gives Catjoe as the Dutch name in Malacca in his time, and of course Cachou and other similar names are mere variants of this.

Before 1750 the Malays discovered the use of gambir in place of cutch, which was too expensive for the poorer classes (Couperus, l.c.). It was probably at first called Katta Krambu, i.e., scented cutch, and the Tamils to this day in Singapore call it *Katta Krambu*, or *Kambu*. Much of the chewing gambir came at that time and still comes from Siak in Sumatra where it is made up with cloves, hence the product was called scented cutch to distinguish it from the *Acacia catechu*, common cutch. This name Katta Krambu was altered by the Malays into *Gatta Gambir*, and later into *Getah Gambir*, often incorrectly spelt Gambier by Europeans. The word Getah is not applied by the Malays to an extract made by boiling, but signifies a viscid milky liquid like that of *Dichopsis gutta* (Getah Percha).†

The earliest account of the cultivation of gambir in the Malay Peninsula was published by Abraham Couperus in the *Verhandelingen van het Bataavisch Genootschap* (1823, II, pp. 209-226). The paper is dated 1780. He says that the seed was first brought from Pontjan (Puntian in Johor) in 1758, and failed to germinate at Malacca. Young plants were then obtained, and proved so successful that many plantations were soon established. Chewing gambir only was produced, but in such large quantities that in 1780 gambir that produced from 26 to 28 *ryksdalers* a pikul fell to 6 *dalers*, and plantations which formerly fetched 800 *ryksdalers* sold for 60. I am indebted to Mr. J. Fleury, the Netherlands Vice-Consul, for a translation from the Dutch of Couperus' very interesting paper.

The next account is that of William Hunter (Trans., Linn. Soc., IX, p. 218, read in 1807). He

* Colonel Yule in "Hobson Jobson," however, quotes Derby for an earlier reference. This book I have not seen.

† Rumphius gives, however, another derivation, viz., from a word *Gambir*, which signifies a *Jasminum*, and says that the plant was so called on account of its being scented like jasmine, but this word is not used for the wild jasmine in the Peninsula, as far as I know, though Favre gives *Bunga Gambir* as the name of "*Jasminum grandiflorum*." I am more inclined to think the *Jasminum* in the case takes its name from the Gambir and not *vice versa*. Some of the wild Gambirs are called *Akar Kayet Kayet*, which is perhaps the same word as Cate.

describes the cultivation in Penang, by Chiuese and Malays. It was still only used for chewing and for medicine, but the cultivation seems to have revived a little by this time. Siak in Sumatra produced a large quantity for export, as it did in Couperus's time and still does. Good gambir now fetched 8½ dollars a pikul. About 1820 it began to be exported to China and Java as a tanning and dyeing material (Crawford, *Dict., E. Indian Islands*, Vol. iii, p. 415). It then fetched no more than 3 to 4 dollars a pikul in the Peninsula, and double that price in Java.

In 1819 the cultivation was introduced into Singapore, but so much was shipped from the adjoining islands, and the necessary supply of fuel diminished so rapidly from the destruction of the forests, that the cultivation began to decline rapidly. The first shipments to Europe from Singapore took place in 1830, when 3,234 cwts. were exported. In 1834 the export had fallen to 2,322 cwts.

Since that time the demand and exports have enormously increased, and in 1890, 769,704 pikuls, equalling 4,567 tons, were exported from Singapore alone. The greater part of this comes from the Dutch islands, especially Rhio, Lingga, Bintang, Carimons, and a little from Sarawak. Bangka gambir is apparently not imported into the Singapore market, or if it comes in, it does so *via* Rhio, as Rhio gambir.

In the Malay Peninsula the cultivation is by no means as extensive as might have been expected. In Singapore there are still a number of plantations, all small, but the great extent of country now covered withalang-grass shows how extensive the former cultivation was and how it has fallen off. Johor and Muar produce a large quantity, the best of which is obtained at Batu Pahat on the West Coast.

In Negri Sembilan are a few small plantations, where chewing gambir only is made. In Malacca there are two or three large plantations carefully cultivated by the Chinese, where export gambir is made, and some smaller Malay ones where a good deal of chewing gambir is produced. Perak, Penang, Province Wellesley and the East Coast States produce little or none. In Pahang some way up the river Tembeling is a small amount of cultivation for local consumption, which appears to have been going on for many years.

USES OF THE DRUG.

Gambir is, as stated above, one of the most important tanning materials. Mr. Evans informs me that it gives a peculiar gloss to the leather not produced by the other tanning substances. It holds the second place in importance, oak bark being naturally the most important. Sumach (*Rhus coriaria*), an European shrub, is almost of equal importance with gambir, and is produced in large quantities in Southern Europe.

It is also used as a brown dye and for strengthening canvas and making it waterproof, and a very large quantity is used in the silk works.

For these purposes, the greater part of the gambir exported from Singapore is sent to Europe and the United States. The amount exported has not fluctuated much of late years. Since 1886, the smallest yearly export was 672,183 pikuls in 1888, and the highest 769,784 in 1890.

Of this, the largest quantity goes to the British Islands, which took 2,789,975 dollars' worth in 1890—a distinct increase on former years. Germany and France since 1886 have both doubled their import, the former from 366,852 dollars' worth in 1886 to 677,554 in 1890, the latter from 397,752 to 797,443.

Italy, which takes a comparatively small amount, has fluctuated very much. The highest value it received during that period was 93,411 dollars' worth.

The United States have increased their demand since 1886 from 783,404 to 1,197,403.

British India's demand has increased from 79,627 in 1886 to 132,655 in 1890.

The Dutch Indies take also an increasing quantity, viz., from 530,000 to 778,170.

In Australia, however, the import has fallen very considerably, viz., from 59,152 to 1,050 dollars' worth. This is probably due to the larger use of Sumach, which is abundant in this country.

The price of gambir has fallen very considerably of late. The reason for this is not over production, for it appears that the amount produced is not much in excess of former years, but is due to decreased consumption, from depression in the silk trade.

The following table gives the exports of gambir from Singapore from 1886 to 1890, from the Straits Settlements *Gazette* of May 29th, 1891:—

1886,.....	673,718	pikuls.
1887,.....	732,962	"
1888,.....	672,183	"
1889,.....	720,931	"
1890,.....	769,704	"

This shows that there is, on the whole, a little increase in its cultivation.

Besides its use as a tanning material and a dye, gambir is used, to a small extent, in medicine under the name of *Pale catechu* as an astringent. It is efficacious in chronic diarrhoea and dysentery, and is thus used by the Malays, and also for uterine hæmorrhage and general mucous discharges, for bleeding of the nose, in the form of an ointment for ulcers, and in other cases where an astringent is required, and it is especially valuable for relaxed uvula and hoarseness. It is more powerful in its action than the catechu of *Acaria catechu*. Dr. TRIMEN in *Medical Botany* states that it is more commonly used in medicine in India and England than in America.

As a masticatory in place of areca-nut, it is very extensively used throughout the East, and is sold in all the small shops in the country. The chewing gambir is made chiefly by the Malays, but a large quantity is imported from Siak in Sumatra. The Siak manufacturers mix cloves and other ingredients with it, to improve the flavour, but the Malacca Malays make it quite pure.

Another use for gambir has been suggested by Mr. T. C. Drysdale in *Logan's Journal*, 1850, Vol. v, 162, namely, as a preservative of timber in sea water. He states that in 1848 the vessel *Ocean Queen*, while on a voyage from Singapore to London, was wrecked on the North-East coast of Linggin, and sank in nine fathoms of water. Four months after it was found that the whole upper decks were "riddled with barnacles" (probably *Teredo* is intended). There was a quantity of gambir in the hold, and when it was broken into the water all round the ship was saturated with gambir, whereupon all the "barnacles" died, and had not reappeared eight months afterwards. Acting upon this, a Mr. Clunis tested the effects of gambir by painting the bottom of a boat with a composition of dammar oil, gambir and chinnam, and observed that the mixture appeared to preserve the boat from barnacles and algæ for a considerable period. Attempts have also been made to use it as a preservative of timber against termites, and it seems to have some effect at first, but being soluble in water it appears to lose its efficacy soon, and furthermore as in all other liquid wood preservatives, it is useless to merely paint the outside of the timber as the termites attack the interior, and no method has yet been found by which the wood itself can be impregnated thoroughly with it.

(To be continued.)

INSECTIVOROUS BIRDS.—On page 599 will be found a reference to an order of the Madras Government and a list of 57 insectivorous birds which it is proposed to protect. This, as pointed out, is going a little too far, because the list includes a number of game birds in demand for food; but there can be no doubt that the policy indicated is a wise one in the interests of planting and of agriculture generally. One great advantage of tree culture on upcountry tea plantations in Ceylon is that they will afford shelter for birds which will return in great numbers to such districts as Dimbula, for instance, where the clearing of forest in coffee days nearly drove them all away.

TEA CROPPING—WEATHER ESTIMATES : INFORMATION FOR LONDON.

Our Badulla Planting Correspondent reports a poor month for tea in January, and the continuance of adverse weather for flushing up to date. It is becoming a matter of practical importance as to whether telegraphic reports of weather as affecting "flush," as well as of estimates monthly and otherwise should not be sent to London? One gentleman whose opinion we sought, writes:—

I believe I must have been the planter who first suggested wiring this scorching drought to London. I suggested it long ago to Colombo people; and while refusing to have anything to do with the "official estates," I recommended the Association here to leave what they did not know alone, and wire the short pluckings which they do know. But I find wires are sent by many for private purposes, rather than for the information of purchasing merchants in the Lane. The shipments are regularly wired and some firms wire at the middle of each month the shipments up to 15th and their estimate for 2nd half of month. An official wire from "Chairman, Planters' Association" of this scorching drought would, I believe, send tea up at once. February's pluckings will be miserable."

The Ceylon Tea Fund Committee ought certainly to authorise the Chairman to telegraph at once.

KURAKKAN.

Cereal from W. Ferguson's Notes on Ceylon Grasses (*Eleusine Coracana*). *Eleusine Coracana*, Gaert. Rox. Fl. Ind. 1. p. 342. *E. Stricta*, Rox. l. c. p. 343? *Cynosurus Coracanus*, Linn. Kurakkan, Sinhalese, Herman Mus. Zeyl. p. 58. Linn. Fl. Zeyl. No 458. p. 208. Knox's Ceylon, p. 22. Kayvaru, and Kelwaragu, Tamil. Natchne, Ragee, Hind. Raggi, of Madras. I can find no explanation of the meaning of the specific name adopted by Linnaeus and Gaertner, but can scarcely doubt that it is derived from the Sinhalese *Kurakkan*, under which it has been known to, and cultivated by, the natives time out of mind. There is no record of its having been found in a wild state. This is cultivated extensively by the Sinhalese from the coast up to several 1000 feet in the Kandyan country, especially in the cheenas— to what is called *Kumari* in the Madras Presidency "This is the most prolific of cultivated grasses, forming the chief diet of the poorer classes in some parts of India as Mysore, North Circars, slopes of the Ghauts, &c. It is considered by the natives to be the most nourishing and invigorating of cheap food. On analysis Raggi has been found to contain, on an average 6.53 per cent of nitrogenous matter, whereas rice contains 7.40 and wheat 13.42. In this respect Raggi stands last among the cereals of India. But Dr Forbes Watson thinks that the want of nitrogen is more than compensated by the mineral constituents of Raggi. It is rich in iron required for the blood corpuscles, and in potassa, lime and phosphoric acid essential to various tissues of the body. On the whole Raggi thus stand high in food value. See a very full account on this grain in the Supplement to the *Ceylon Observer* of 19th July, 1879, extracted from the *Madras Athenaeum*:—One variety of *E. Stricta*, Rox. gives 120-fold, and another 500-fold, whilst on two tufts, the produce of one seed, 50 culms grew, and no less than 81,000-fold was carefully calculated to be the produce of this plant. Five varieties of Kurakkan are cultivated by the Sinhalese.

UVA PLANTING REPORT.

Badulla, Feb. 3rd.

The past has been the driest January I remember, and we have had far more wind than usual. THE WEATHER here now is simply delightful. Bright hot days with a cool breeze, mornings and evenings bitterly cold.

TEA did very little in January, and the weather is still too cold and there is too much wind for much flush even now. But we shall probably get good flushes towards the end of the month. The district prices continue fairly good though we have had nothing very sensational lately. Factories are paying from 9c. to 11c. per lb. green leaf. A good deal of pruning has been done in the district this last month, and the habit of pruning in January is growing in favour.

COFFEE is if anything looking more wretched than when I wrote last. A few estates at medium elevations have a good blossom in spike, but crop this year will be woefully short from Badulla. Bug, which is usually dead at this season of the year, is still flourishing; and I am afraid we shall have another attack. I attribute this to the want of rain this year, for except in October and early part of November we have had none of the heavy afternoon showers we generally expect. Large acreages of coffee will go under tea this year, and I think even the most hopeful of us now realize that coffee is no longer to be relied upon. The two new cart roads have been commenced and the Spring-Valley-Naula road is making great progress.

LABOUR is fairly plentiful in the district, and health generally good.

TRAVANCORE TEA IN COLOMBO.

AN INTERVIEW WITH A TRAVANCORE PROPRIETOR.

No one in Colombo is more directly interested in Travancore than Mr. Donald Noble, the Manager of the local branch of the Bank of Madras, so that his views on the question of the advisability of remitting the import duty at present levied in Ceylon on tea have the merit of being those of one well up in the subject. As owner of a fine young estate in Travancore—the Glen Mary estate—and as largely interested in Ceylon tea, Mr. Noble is well qualified to express an opinion on the subject, though we certainly do not agree with what he says.

In answer to an inquiry as to the possibility of a large number of Travancore estates sending teas to Colombo, Mr. Noble said:—

"It all depends upon the duty. Abolish the duty and I feel sure a number of estates would ship teas here for public sale in Colombo. Anyone wanting their money soon would naturally do so. At present it is not worth the trouble. I have tried it, and so have others, and we have all stopped. Teas come here via Tuticorin, and, if they are damaged in transit, or require re-hooping or re-firing, or even re-bulking, it can't be done, as they have to be sold in bond or else duty has to be paid on them. This is a direct discouragement to the development of the trade of Colombo. The duty is absolutely indefensible. Let any member of Parliament put a question to the Secretary of State in the House of Commons, and an order to rescind the duty would be sent out at once. Ceylon puts a 6d. duty on Indian tea, and India allows 600,000 lb. of Ceylon tea yearly to find its way into consumption in India yearly free of duty! The anomaly is monstrous."

Asked about the cost of bringing down tea from Travancore, Mr. Noble said:—"It does not cost much. It is far cheaper in many ways, as cheaper freight to London is secured from Colombo than from India Coast ports. That the trade would grow I verily believe, if encouraged. You must remember that it is far nearer to Colombo from any port of the Coast of India than it is from one coast of India to the other. Have I made any representation to Government in the matter? Of course I have. I saw the Colonial Secretary last year, and even he did not attempt to defend the duty in theory. He promised his best assistance when the tariff was revised, but so far nothing has been done."

When the danger of Java and China teas being shipped to Colombo and mixed with Ceylon teas as soon as the duty was removed was pointed out to him, Mr. Noble expressed a confident

hope that rival merchants would expose such underhand practices and thus put a stop to it. "But in any case," said he, "the duty is quite indefensible. What have you got to say in its favour? The matter will shortly be taken up by the Travancore Planters' Association and by the Madras papers, all of whom will be down on you about this duty. The only way out of it would be by allowing Travancore teas in duty free whilst maintaining the duty against other teas, but do you think differential duties will be allowed? Not for a moment. There is no help for it—the duty must go."—Local "Times."

THE CINCHONA REWEIGHTS.

At Tuesday's bark-sales the question of the reweighing of recently-imported cinchona bark again came up for discussion. Mr. David Howard set the ball rolling by intimating that buyers would in future not be willing to content themselves with a statement of the weight of the packages upon their invoice, but would require a duplicate of the original weighing account from the Dock Company to be sent with it. On behalf of the importers, Mr. Rucker assented to this wish, and after a desultory discussion the proposal was unanimously agreed to.—*Chemist and Druggist*, Jan. 27.

WHY EGGS DON'T HATCH.

As a rule, those who purchase eggs look for them *all* to hatch, and blame the breeder from whom they were purchased if they do not do so. Nine times out of ten the reason for failure to hatch is the fault of the buyers or their faithful "hiddies." Hundreds, aye, thousands, of people *don't know how to set a hen*, and even after she has been successfully set, there are just as many thousands of people who do not know how to care for her, in fact, consider it a tiresome job to even "peep" at her, or throw her a handful of food.

Many times a setting hen is surrounded with lice. I remember a sight at the home of a thrifty farmer which I shall never forget. The farmer's wife was very much interested in poultry, and she would have her own way in setting the hens. These were placed on the ground and directly under the roosts, and on visiting the house at night with a light, I often saw the ground and the sides of the huddling literally alive with lice, spider lice, which hide away during the daylight, but, like bed-bugs, come out at night in myriads. Tormented with these lice, I saw the hens *standing* and the eggs cold. Thus they were spoiled, unnoticed by the attendant, as the faithful hen was true to her task in the day. Again, some hens do not know their business, and fail to turn their eggs. I have often noticed that when a good setting hen is through feeding and enters her nest, she steps carefully about as she turns around to take in the surroundings, and see if she is at home. After this the very first thing she will do is to "tuck under" the eggs from the *outside*. These are the hens that hatch the eggs. Again, a great many people put *too many eggs* under hens. Thirteen are plenty.

As a rule, eggs from young pullets do not hatch well. I prefer two-year-old hens for hatching from. The chicks are healthier and stronger. Eggs from fat hens never hatch well. Another reason for eggs from the heavy breeds not hatching is the fault of the male. A broken egg in the nest will spoil the balance, unless the whole lot be immediately washed in lukewarm water. A rotten egg will damage the whole hatch; and again, no matter how careful the breeder may be in packing and shipping eggs, they meet occasionally with very careless handling from railroad employees and others.

Last, but not least, some persons who purchase high priced eggs are too anxious and disturb the hens too frequently, especially during the last ten days, just the very time when they should be left alone. These are the people who seldom get a chick, but who are ready to "set upon" the man who sold them the eggs.

I have known of parties who paid regular visits to the nests, and each time shook each egg to see if it

rattled, just the way to make them bad, if not so; yet all the failures are charged to the breeder. These are some among the reasons why eggs don't hatch; and when I know all I do, it is almost a wonder that any hatch at all.

B. A. Fox.

—*Southern Planter*.

IMPORTANT SALE OF CEYLON COCONUT ESTATES.

YAKKEDGALLA.

The first estate on the list was Yakkedegalla also known as Yakkedegalle Haina, and regarding it details were given since 1888. When the plants were counted, in that year the number of trees in bearing and trees which had flowered was given as 199, young plants 4,034, and vacancies 941—total 5,174. The total crop for the year was 1,788 and the average nuts per tree 8. In 1889 the total crop was 2,480 and the average nuts per tree 12; in 1890 the total was 3,320 and the average 16; and in 1891 the total was 7,023, the average being 35. In July 1892 they were again counted and the figures were:—trees in bearing 345, young plants 4,980, vacancies 15—total 5,340, the total crop for the year being 7,788, and the average nuts per tree 37.

Mr. Arnold Dias started the bidding with R5000 and Mr. E. A. Daniel, and Mr. H. Van Cuylenburg followed each putting on R250. Mr. Dias put on a similarsum when he was again followed by Mr. Daniel, and Mr. U. D. S. Gunasekara, shortly after Ana Snappiyah Chetty had a look in bidding R7,000, Messrs. Daniel and Gunasekara then bid alternately till the sum had reached R8,250 when the Chetty again made an offer and competed with Mr. Daniel till R10,000 was reached when he retired leaving Mr. Daniel to carry on the sale with Mr. Arthur Alwis, who bid R10,500 and Mr. J. D. Bartholomew R11,500. The next bid was Mr. E. A. Daniel's and he became the purchaser of the property for R11,750.

"MAUSA."

The next on the list was the small piece of land known as "Mausa," the plants were counted in 1888. In 1888 the trees in bearing and trees which had flowered were 205, young plants 98, vacancies 20—total 323. The total crop for the year was 5,150 and the average nuts per tree 25. In 1889 the total crop was 6,500 and the average 31; in 1890 the total crop was 7,030 and average 34; and in 1891 the total crop was 9,214 and average 44. In July 1892 they were again counted and the figures were—trees in bearing and trees which had flowered 240, young plants 170, vacancies 20—total 430. The total crop for the year was 7,675 and the average nuts per tree 42.

For this property Mr. D. S. Senanaika started the bidding with R500, Mr. Gabriel de Croos following with R100. Mr. S. P. de Soysa at once offered R1,000 and by thousands the bidding was carried on respectively by Messrs. Van Cuylenburg, Senanaika, Croos, A. Dias, C. Perera, A. Dias, Croos and P. de Soysa till R2,000 was reached. Mr. Senanaika offered R2,100 and Mr. S. P. de Soysa R2,200 for which sum the property was knocked down to him for Lady de Soysa.

Mahaoya, Upper Kudaoyaa and Lower Kudaoya were then put up in one lot. The bidding which was started at R50,000 by Mr. R. Daniel was continued by Messrs. Alwis and Stevenson, each of whom put on R10,000 fetching the sum up to R70,000 when Mr. J. W. Jenkins offered R71,000, Mr. Alwis followed with R80,000, Mr. Stevenson offered R85,000 and Mr. R. Daniel R90,000. Messrs. Jenkins and Stevenson carried on the competition till R102,000 was reached. That sum was offered by Mr. Jenkins being R500 more than Mr. Stevenson but the sale was not concluded as it was arranged that the estates should be put up separately. The auctioneer accordingly called for bids for

LOWER KUDA OYA.

Also known as Polkatua Mookelana and Bogaha Haina (total extent—Ac. 74, 2. 8.) was afterwards

put up. In 1884 a count took place and the figures were—trees in bearing, and trees which had flowered 962, young plants 340, vacancies 1,416; total 2,718. The total crop for the year was 9,147 and the average nuts per tree 9; in 1885 the total crop was 7,756 and the average 8; in 1886 12,846 and average 13; and in 1887, 22,326 and average 23. In 1888 they were again counted and the figures were—trees in bearing and trees which had flowered 1,096, young plants 2,334, vacancies 242; total 3,672. The total crop for the year was 20,151 and the average 18. In 1889 the total crop was 19,721 and average 17; in 1890 28,838 and average 26, and in 1891 52,729 and average 48. In July 1892 there was another count and the figures were—1892 trees in bearing and trees which had flowered 1,384, young plants 2,994, vacancies 27; total 4,405. The total crop for the year was 55,186 and average 53.

Mr. Arthur Alwis started with R15,000—a price which was doubled when the hammer fell. Mr. Jenkins went as high as R29,500 but Agonis Appunhamy and U. D. S. Gunasekera went on by R500's till R31,500 was reached and at that price the latter became the purchaser.

UPPER RUDA OYA ESTATE.

Also known as Naragaha Haina and Kadurugaha Wette. (Total extent Ac. 52 2 22) came next. In 1878 account took place and figures were—trees in bearing and trees which had flowered 600, young plants 168, vacancies 2,545; total 3,313. The total crop for the year 4,250. The average nuts per tree 7. In 1879 the total crop was 9,400 and average 15; in 1880 14,300 and average 23; in 1881 8,000 and average 13; 1882 6,864 and average 11; in 1883 19,094 and average 31. In 1884 they were again counted and figures were—trees in bearing and trees which had flowered 688, young plants 72, vacancies 2,543; total 3,303. The total crop for the year was 20,541 and average 29; in 1885 the total crop was 24,310 and average 35; in 1886 25,252 and average 36; in 1887 26,099 and average 37. In 1888 there was another count and figures were: trees in bearing and trees which had flowered 760, young plants 2,538, vacancies 15 and total 3,313. The total crop for the year was 19,624 and average 25. In 1889 the total crop was 20,094 and average 26; in 1890 28,507 and average 37; in 1891 37,295 and average 49. In July 1892 there was another count and figures were trees in bearing and trees which had flowered 906, young plants 2,369, vacancies 29 and total 3,304. The total crop for the year was 40,964 and average 60.

The bidding started at R10,000—a price which was tripled when a sale was effected. Messrs. J. S. Sananaike, A. Alwis and Gabriel Croos were the highest bidders. The first mentioned went as high as R27,000, the second R29,000 and Mr. Croos R30,000.

MAHAOYA ESTATE.

Also known as "Jambugaha Haina," of the extent of 81 acres. In 1878 a count was made and the figures were—trees in bearing and trees which have flowered 3,134, young plants 130, vacancies 994; total 4,258. Total crop for the year 90,500, average nuts per tree 28; in 1879 the total crop was 131,815 and average 42; in 1880 154,826 and average 49; in 1881 97,000 and average 30; in 1882 123,572 and average 39; in 1883 179,748 and average 57. In 1884 there was another count and figures were—trees in bearing and trees which had flowered 3,134, young plants 130, vacancies 994; total 4,258. The total crop for the year 175,281 and average 56; in 1885 165,419 and average 52; in 1886 169,984 and average 54; in 1887 201,933 and average 64. In 1888 there was another count and the figures were—trees in bearing and trees which have flowered 3,240, young plants 24, vacancies 994; total 4,258. Total crop for the year 171,400 and average 52; in 1889 171,924 and average 53; in 1890 197,406 and average 60; in 1891 241,537 and average 74. In July 1892 there was another count and the figures were—trees in bearing and trees which have flowered 3,149, young plants 46, vacancies 1,152; total 4,347; and the total crop for the year was 221,712 and average 71 nuts per tree.

R40,000 was the first bid by Don Juanis Appoo When R60,250 was reached Mr. J. S. Sananaike retired and then Messrs. Gabriel Croos and Gabriel Silva fought the matter out Mr. Silva making the highest bid R70,250—the bid of Mr. Croos being R70,000.

The total realised for the three estates put up separately was R131,750 as against R102,000 when put up in one lot. The highest bidders separately were therefore the purchasers.

The total realised for the Fort property and estates together was R218,950.

The sale lasted about three hours.

THE INDIAN TEA DISTRICTS.

Our Kangra Valley correspondent writes on the 17th instant:—The new year is coming in splendidly. Rainfall 5.95 inches registered to date, and still coming down with a prospect of a fall of snow on the higher gardens. Pruning, hoeing and work generally in full swing. Every prospect of a good season. Temperature 55° maximum; 38° minimum.

Our Darjeeling correspondent writes on 18th January 1893:—For the last week we have experienced wretched days; no sun, and when it looked like heavy rain only a few drops fell. Thermometer very low, ranging at nights not above 36°. Pruning going ahead strong throughout the district.

Our Moriani correspondent writes on 21st January 1893:—Cold miserable; wet weather for the last week. Pruning all finished and hoeing in full swing.

Our Dera Doon correspondent writes on 24th Jan. 1893:—Last night we had 48 inches of rain and all the hills are covered with snow. It is still raining and is very cold.—*Indian Planters' Gazette.*

THE PRICE OF COCONUTS.

The price of Coconut writes our Negombo correspondent, is phenomenal, and bids fair to heat the record of all previous years. There is great competition among buyers at prices varying from R40 to R43. Owing to the drought of last year the crop of the latter end of 1892 and of the beginning of this year has fallen considerably. It might surprise some of your readers to hear that the coconut crop of the present season has fallen by half, and in some estates by more than half. The consequence is that the supply falls short of the demand, hence the unusual rise in the price of coconuts. Messrs. Vavasseur & Co. of Colombo are about the greatest purchasers. There is a gentleman here who has agents stationed in different localities in this and in Chilaw districts buying up all the available nuts without reference to quantity.

TEA IN SOUTH CAROLINA:

MR. HENRY COTTAM AGAIN.

It is amusing to see that in all the paragraphs circulating for many months back about Mr. Henry Cottam's trial of tea in the Southern States and the expectations of success, not one word is said about the one indispensable condition—cheap labour!

A recent issue of the *Canadian Grocer*, a trade journal published in Toronto, contains a short article which may give rise to some apprehension in the tea-producing districts of the world. A fresh attempt it appears, has been made to grow tea in South Carolina. Shortly after the War of Secession, the United States Minister of Agriculture instituted an experiment in tea-growing on an estate near Charleston; but the results were not encouraging, and after a short time the enterprise was abandoned. A Dr. Charles Shephard has now made a further attempt to raise tea on the same estate, and has been assisted by Cottam, a planter of considerable experience in Ceylon. Mr. Cottam states that the produce of this South Carolinian estate is fully equal in quality to the teas grown in India and Ceylon, and that in his opinion the United States can easily produce the

90,000,000 lb. of tea which it now consumes annually. There are, he says, millions of acres that are suitable for tea cultivation, notably the lands inside the yellow pine belt.

If India and Ceylon do not over-produce, we have not the slightest fear of the United States producing 5 million lb. a year of tea (in place of 93) within the next twenty years!

INDIAN TEA CROP ESTIMATES, 1892.

To THE EDITOR, "INDIAN PLANTERS' GAZETTE."

DEAR SIR,—In their Circular of the 17th September 1892 the General Committee reproduced the original estimate of the Indian Tea Crop in the following figures:—

Original Estimate of Crop of 1892.

	lb.
Assam	54,210,100
Cachar and Sylhet	39,208,652
Darjeeling, Terai, Dooars	25,691,617
Chittagong and Chota Nagpore	1,442,910
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native Gardens	4,000,000

129,053,278

They also published a revised estimate based upon actual results to the 31st August as follows:—

	Manufactured to 31st August 1891.	Manufactured to 31st August 1892.
Assam	29,305,908	27,260,859
Cachar and Sylhet	20,541,311	18,771,078
Darjeeling and Terai	7,048,694	6,539,686
Dooars	6,771,616	7,379,084
Chittagong and Chota Nagpore	722,591	567,719
	64,390,120	60,518,426

Revised estimate of crop of 1892.

	lb.
Assam	49,046,574
Cachar and Sylhet	35,772,048
Darjeeling and Terai	10,498,850
Dooars	13,125,350
Chittagong and Chota Nagpore	1,263,835
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native Gardens	4,000,000

118,206,657

They have now the pleasure to give you the figures showing the actual outturn of the Indian Tea Crop of 1892.

Actual Outturn of Crop of 1892.

	lb.
Assam	46,307,348
Cachar	16,110,506
Sylhet	17,744,557
Darjeeling	6,796,315
Terai	2,807,530
Dooars	14,889,006
Chittagong	830,293
Chota Nagpore	201,328
Dehra Dun, Kumaon and Kangra	4,000,000
Private and Native Gardens	4,000,000

113,686,883

The total shipments to all places from 1st May to 31st December 1892 are 99,883,106 b. The exports to the Colonies and other ports are estimated not to exceed 7 millions, which will leave 106½ millions for export to the United Kingdom.—Yours faithfully,
S. E. J. CLARKE, Secretary.—*Indian Planters' Gazette.*

POTATO CULTURE AND DISEASE.

(FROM A CORRESPONDENT.)

In order to ascertain the effect of applying a mixture of sulphate of copper and lime to potatoes for the purpose of prevention of potato disease, a series of experimental plots have been cultivated

in three areas in the Warminster district. The cultivation was carried on in connection with the teaching of the principles of agriculture and cottage gardening in Wiltshire, by a sub-committee of the County Council Technical Education Committee. One portion of the plot was dressed twice with a mixture composed of 2lb each of sulphate of copper, lime, and molasses in ten gallons of water. This mixture was sprayed over the foliage by an "Eclair" sprayer on July 20th and August 16th at the rate of 160 gallons an acre. The effect of the dressing in prolonging the life of the plants for weeks after the undressed foliage was decayed, was very marked.

The crop of potatoes which was raised and weighed on the ground in the presence of reporters and visitors, weighed on the undressed half perch of "Imperators" 175lb. large, 2½lb. small, 6½lb. diseased—total 184lb. The weight on the adjoining half perch which had been sprayed was 205lb. large, 3½lb. small, 1½lb. diseased—total 210½ lb., being at the rate of 30 tons 1 cwt. per acre gross, and an increase over the undressed area at the rate of over 4 tons per acre of sound tubers.

The extraordinary weight of potatoes raised from these and other plots has excited much surprise. It is alluded to by Sir John Lawes in terms of gentle irony. "We have," he says, "carried out experiments on potato growing for many years. As, however, our highest yield per acre does not amount to much more than half the lowest yield in the Warminster experiments, it is evidently quite time to bring ours to a close. If technical education can make such rapid progress in its infancy, what may we expect when it reaches maturity?" The experiments were carried out with every possible care, and the full report is now being published by the Wiltshire County Council. In explanation of the phenomenal weight of potatoes obtained from many of the plots, and particularly from the one illustrated, it may be stated that—(1) The cultivation was of the most thorough kind. (2) The land was allotment land, deep and rich, and Dr. Munro (who acted as consulting chemist to the committee) predicted from the analysis that a good crop would be yielded, even by the unmanured plots. One unmanured plot of "Beauty of Hebron" (a far less heavy crop than many of the sorts grown) yielded at the rate of nearly eleven tons per acre. (3) The sets were carefully selected of large size, and were planted at distances of 31 by 17½ inches apart; also the time of planting was sufficiently early. (4) The manure was at the rate of 4 cwt. per acre each of superphosphate of lime, kainit, and nitrate of soda, the latter being applied in two instalments five weeks apart. (5) "Imperators" have been recognised by Continental and American growers as the heaviest cropping variety in cultivation. (6) The steady and moderate rainfall during the latter half of the growth favoured this and other late varieties.—*Daily Graphic*, Dec. 22.

COMMERCIAL ENTERPRISE IN CENTRAL AFRICA.

INTERVIEW WITH CAPTAIN LOVETT CAMERON, R.N., C.B.

A couple of years ago every one in London was talking of the South African Company and of Mr. Rhodes. For the last three or four months we have all been discussing the East African Company and the railway projected by Sir Wm. McKinnon and his able co-directors. Now it seems probable that in the near future yet another company with similar aims may gain the public ear. The Central African and Zoutpansberg Exploration Company deserves more attention than has yet been accorded to it. First of all, it is an international undertaking with purely commercial objects. From the King of the Belgians it has acquired rights over that part of the vast *Hinterland* of the Congo Free State which abuts on Lake Tanganyika. The Portuguese Government has ceded to it valuable powers over the Por-

tuguese possessions which lie north of the Zambesi, and Colonel Serpa Pinto has joined its board as one of the foreign directors. These rights and powers, we are informed, give the Central African Company practical command of the great waterway from the Zambesi, by the Shiré river and lakes Nyasa and Tanganyika, to the Victoria Nyanza and the East African Company's territory on the Equator. For the purpose of utilizing this communication by water between its chief possessions the Central African Company has recently formed a subsidiary company entitled the African Flotilla and Transport Company, with a capital of £50,000.

As Captain Lovett Cameron is the chairman of the Central African Company, and also one of the directors of the Flotilla and Transport Company, one of our representatives called upon him for information as to the new undertaking.

"Transport by water," he said, "is cheaper—at least in all new countries—than transport by land. Even in England canals hold their own with railways. But in Africa the owner of the waterway has immense advantages. Take one example. It is said to cost £300 to transport one ton weight of goods from Zanzibar to Uganda, through the East African Company's possessions, across some 500 miles of land. And even now we can take it up the Zambesi and Shiré rivers by the lakes at half that price."

"But when Sir William McKinnon's railway is finished," I interjected, "surely the advantage will be with him?"

"It is not proposed to run the railway more than half-way; there are some awkward mountains to be crossed before the Victoria Nyanza can be reached, and my waterway taps nearly 1,500 miles of country as against 500—and such country! Why, on the Shiré alone one firm has a coffee plantation with nearly a million trees in bearing, and this within two hundred and fifty miles by water from the mouth of the Zambesi. Englishmen and Scotchmen, settled colonists like the Buchanans, will have to trade with us. At Tete, on the Zambesi, there is first rate coal in immense quantity on the surface. The Zambesi, too, offers the shortest and cheapest route to Fort Salisbury. And, to judge by the remains of old gold-diggings, our land north of the Zambesi is at least as rich in precious metals as Matabeleland."

"But what do you intend to do with the £50,000 of the Flotilla and Transport Company?"

"The sum seems to you small, but acorns produce oaks. We are now building at Messrs. Yarrow's light-draught stern-wheelers, and at Thornycroft's equally light-draught turbine screw boats. Commander Keane, who for two years has been in command of our gunboats on the Zambesi, has directed the construction of these vessels; they will be adapted to their purpose. I hope to have these steamers running on the Zambesi by the middle of February next. Then we shall put a steamer on Lake Nyassa, and so on."

"But the service on the Zambesi will be unhealthy?"

"Commander Keane's crews did not suffer. Health on the Zambesi, as in London, depends chiefly on careful living."

"But why do you suppose that these steamers will earn large profits?"

"The Congo companies are already paying satisfactory dividends. The Central African Company possess immense territories—highlands north of the Zambesi and along the Shiré—which are fit for immediate colonization by Europeans. On the east bank of the Shiré are the coffee plantations. The Zambesi taps far richer country than the Congo, and more quickly. Some British colonists on the Shiré have already made large fortunes; others are on their way out. Nothing has prevented the colonization of this country by Europeans, but lack of transport; we are about to supply that; the results can be foreseen."

"Your Flotilla and Transport Company, in fact, will help to develop the possessions of the Central African Company?"

"Yes, certainly. That is why the Central African Company found half the capital of the Flotilla Company."

"And you look forward to a prosperous future for both?"

"I do, and my opinion of the Zambesi and the lake waterway was formed when I crossed Africa in 1876. I then decided that this was the most fruitful field for enterprise in all Africa. Consider, too, that we have no watered capital; money is found at once for what is needed, without extravagance or waste of any kind; every step is taken on the best and most careful advice; the Central African Company means business, and business alone."—*P. M. Budget*, Jan. 19.

THE TRICHINOPOLY PHOSPHATES.

We understand that Dr. A. Völcker and Mr. J. Falconer King have reported on the Trichinopoly phosphatic nodules sent home by the Madras Government. The reports agree very closely with the results obtained in the Geological Survey laboratory at Calcutta. The average of the six analyses published in the records of that Department show that the nodules contain phosphoric acid equivalent to 59.68 per cent of tribasic phosphate of lime, whilst Dr. Völcker obtains 57 per cent and Mr. Falconer King 59 per cent. These gentlemen agree also in saying that the deposit may be reckoned as a valuable one, although not of the highest class, and that it would hardly pay to export to England during the present state of the market, although it might be used on the plantations of Southern India, either in its raw state, or in the form of superphosphate. This Report, it is satisfactory to observe, agrees precisely with the opinion expressed by Mr. Holland, of the Geological Survey, who examined the nodules in the laboratory last year.—*M. Mail*, Feb. 8.

COCOA.

LONDON, Jan. 20.

The auctions this week were much less extensive, the total of all growths being 2,704 bags, of which 535 bags were Ceylon, 720 bags Trinidad, 124 bags Grenada and other West India, 1,283 bags Guayaquil and 42 bags Caracas. Active competition took off all the freshly landed parcels of Ceylon at firm rates, the following being the details of sale:—
 Maria ... 99 bags...85 A at 112s 0d 14 B at 96s 0d.
 Gangawarily 19 " ...13 No. 1 at 112s 6d, 2 No. 2 at 91s 6d, 4 No. 3 at 57s 6d.
 Sunnyside 21 " ...10 No. bought in, 4 No. 2 sold at 95s 0d, 7 No. 3 and D 57s 6d to 58s 0d.
 Warriapolla 200 " ...99 sold at 116s 0d, 73 at 115s 6d, 6 at 105s 6d, 11 at 75s 0d, 11 at 58s 6d.
 Coodulgalla 58 " 37 No. 1 sold at 112s 6d, No. 2 at 100s 0d, 6 No. 3 at 76s 0d.
 Sundry ... 138 " chiefly in second hands, bought in.

LONDON, Jan. 27.

Auctions this week were restricted to 2,400 bags of growths. The demand keeps strong although the arrivals, per "Essequibo" and "Nonpareil" together 5,370 bags induced some of the trade to await the offering of the fresh supplies next week. Ceylon met with strong competition and a general improvement of 1s to 2s was established, whilst occasional lots of exceptional quality realised 3s to 5s advance.

CEYLON.—Yattawatte .. 93 bags, 89 No. 1 sold at 112s 6d per cwt.
 Bulatwate .. 41 bags, A No. 1 sold at 115s 6d per cwt.
 Ingurugalla .. 28 bags, A No. 1 sold at 119s 0d per cwt.
 Palli .. 80 bags, 76 bags at 115s 0d to 117 0d per cwt.
 Hylton .. 28 bags, 26 bags No. 1 sold at 120 6d per cwt.
 Glenalpine .. 4 bags, B sold at 80s per cwt.

Total 274 bags

OF OTHER GROWTHS—350 bags Trinidad sold, mixed red to good at 70s to 74s 6d, fine at 79s; 100 bags Grenada at 67s to 70s; 121 bags Dominica at 66s to 68s; 70 bags St. Lucia at 68s to 70s; 222 bags Jamaica at 66s to 66s 6d, with 12 tags fine red, cured like Java, at 80s; 180 bags St. Domingo, Sanchez at 67s to 68s, and Jeremie at 62s 6d to 65s, and 350 bags Guayaquil at 71s to 92s per owt. The African sold last week amounted to nearly 1,000 bags; this week further sales of 800 bags are reported at 68s to 69s, a few very low at 63s per owt:

TEA IN AUSTRALIA.—In one of the "Around the World" papers by Dr. F. E. Clark, of Boston, is an interesting description of a monster tea meeting in Melbourne, Australia. "There can be no doubt," he says, "about the national beverage of Australia. It is tea, beyond a question; tea in the morning, tea at noon, and tea between meals. Whenever a caller sits down for a few minutes, he is hospitably offered a cup of tea; and the last thing before going to bed at night we take our evening dram from the teapot.—*M. Times*, Feb. 18.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Jan. 26.

CINCHONA.—At Tuesday's cinchona-auctions a moderate quantity of bark was offered for sale, the catalogues being composed as follows:—

	Pkgs.		Pkgs.
Ceylon bark	1,150	of which	909 were sold
East Indian bark	623	do	423 do
Java bark	52	do	52 do
African bark	242	do	152 do
South American bark	402	do	144 do
	2,431		1,630

The assortment of bark was a mediocre one, and did not include any parcels calling for special notice. At first the tone was fairly steady, but it slackened off, pretty soon, and, upon the whole, the sales were slightly lower than the last, the unit averaging only about 1 1/2-6ths d. Nearly one-fourth of the bark offered was bought in.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam factory	147,256
Agents for the Auertach works	83,623
Agents for the Brunswick works	44,024
Messrs. Howards & Sons	35,195
Agents for the American and Italian works	30,738
Agents for the Paris works	30,095
Agents for the Frankfort o/M and Stuttgart works	13,125
Sundry druggists..	40,599

Total quantity of bark sold	424,725
Bought in or withdrawn...	113,393

Total quantity offered ... 538,118
It should be remembered that the weight of bark purchased is no criterion to the quantity of quinine acquired by the buyers.

AUSTRALIAN GEM STONES.

Many persons think that there is a prospect of valuable finds of gem-stones being made in these colonies, if only the work of searching for them was gone about in a systematic and proper manner. It seems that a dealer in precious stones in London has taken up a large area of land in Western Australia, in the belief that he will be able to find gem-stones in quantities that will warrant some considerable expenditure in the search for them. From time to time we hear of discoveries of precious stones in the various colonies, but the work of searching for them has not been carried on systematically anywhere except in New South Wales, and there with but a very moderate degree of success. Many years ago diamonds were found at the Ovens in Victoria, when the miners were sluicing the decomposed granite for gold, but the gems were small and were few and far between, like the proverbial visits of the angels. In other parts of Victoria gems have been found, and what are called rubies, that is garnets and topazes are tolerably plentiful in many places, leading to the belief that with proper management a commercial operation might be carried out in searching for them. It is estimated that in New South Wales the number of diamonds found in that colony to the end of 1887 was 50,000, the largest of which weighed 16·2 grains. In 1889 one company, near Tingha, found diamonds weighing 2,195 carats, valued at £878 5s. The business of searching for these stones does not, however, appear to pay, nor for emeralds, which have been found in some quantities. Sapphires, rubies, opals, garnets, topazes, and other stones have also been found in New South Wales, whilst in Queensland works for finding opals have been carried on for many years. In Tasmania gems have been found at various times, and probably many more would be if they were searched for, but the question is, could the work be made to pay? That there is a market for all sorts of gem stones appears from a letter recently addressed to Signor Bernacchi from C. B. Klein, of Lichfield-street, Christchurch, New Zealand, who seems to have an idea that such stones may be found at Maria Island. Mr. Klein states that he is prepared to buy regular supplies of yellow crystal, brown crystal, blue, brown, yellow and water-coloured topaz, blue sapphires, and other

varieties of stones. At present Mr. Klein obtains the greater portion of the stones which he uses from Brazil, but he finds the distance very inconvenient. This shows that there is a good market close at hand for all sorts of gem-stones, a fact which miners should bear in mind, as it may lead them not only to institute a search for such stones, but to more carefully examine than they usually do the tailings from their sluice-boxes.—*Tasmanian Mail*.

BANANAS AND BANANA MEAL.

To the Editor of the *Jamaica Gleaner*.

SIR,—Some time ago you published one or two articles on banana meal, as I was then preparing for a month's absence from this island there was not time for any reply, and as your subject has occupied the minds of shrewd men during the past 12 years I felt confident it would survive until my return.

Last January I had placed in my hands the affairs of a company incorporated in the United States for the manufacture of bananas into long-keeping products. The directors had previously produced samples of banana meal, dried bananas, and canned. The last two products were not to be considered as articles of commerce. Only the first was worthy of attention but no one knew the cost of production, the process by which it was obtained was by evaporation. No other process to my knowledge had ever been tried.

Ascertaining the cost of production by this process is a simple mathematical problem in which there need be no mistake. As bananas contain 80 per cent. liquid to 20 per cent. solid, and as the number of pounds of water that can be evaporated by one pound of coal is no mystery, it is readily seen that the first cost of producing banana meal by the top, cannot be less than four pence per lb. marketing price should be 10 cents per lb. in New York or London. This is \$20 per bar. of 200 lb. Considering that at this price 4 barrels of good wheat flour could be had for one barrel of banana meal, it is no wonder that the latter is more talked of than seen.

Soon after deciding that there was no money in making banana meal by this process, I made some experiments in another direction.

About that time His Excellency the Governor stated in his address at the opening of the Legislative Council last spring. "Experiments are now being made for the manufacture of banana meal which is successful" &c., &c., supposing the experiments were being made in Jamaica, I wrote to His Excellency that the business management of an incorporated company for that purpose was now located in Jamaica, and with ample capital ready to put in operation any profitable method for producing banana meal. By His Excellency's request I called at Kings House and then learned that the experiments were being made in Demerara and that the cost of production was 5 pence per lb. Unless I am mistaken, the Demerara experiments were being conducted by experts in the Government service. By the familiarity which His Excellency showed with the subject it was evident that he too had been wrestling with this problem about which so much has been said and nothing yet done.

Twelve years ago an extensive fruit drying establishment in Northern New York State, having every facility in Machinery and skilled labor made experiments in drying bananas, with the intention, if successful, of establishing a plant in some banana growing region in the tropics. The experiments proved the project to be unprofitable. Many experiments of a similar nature have been made in the United States, with like results. A few years ago before figuring the relation between the cost of fuel and the obtained solids of the banana a steam plant was set up at Port Limon. It ran a little while and was abandoned as unprofitable. Four years ago experiments were made up the Bluefields river in the Mosquito Reserve and abandoned.

About a year and a half ago experiments were made in Jamaica by men having large capital and skilled advice and as they are large growers and shippers they

had every incentive for pushing the experiments to success. But, they would not see any profit in banana meal.

It is singular that all these experiments should have been on the single idea of evaporation. No one appears to have considered the value of the juices evaporated.

Thirty years ago the only value of the cotton plant was the fibre. The waste of the cotton plantation then, is now as valuable as the fibre. About 20 years ago beets had no other value than that of cattle food, somebody conceived the idea of learning the value of its juice. The result revolutionised the sugar industry of the world. As the banana contains 80 per cent liquid to 20 per cent solid, any effort made for destroying the greater to obtain the less, must be a thoughtless and unscientific one, saving both is within the range of mechanics. The process is by compression. The following are some of the results of my experiments in that direction.

A banana when peeled may be so dry as not to moisten the fingers. Twenty of them were placed in the apparatus. Under a pressure of 100 lb. per square inch, they had the consistency of a thin tapioca pudding. At 200 lb. they became thin as cream, yet no sign of separation of the solid from the liquid. A third attempt was made, and a fresh lot of bananas were put under a pressure of 300 lb. per square inch and I obtained a colorless liquid sweet in taste, sticky in feeling.

The apparatus with which I worked was constructed partly in Boston and altered in Kingdon several times as experiments required. It was rudely made and unable to give any greater pressure, but it demonstrated that the juice can be pressed out of bananas. One mule power or the same in water or steam power will make more "banana meal" in an hour than a ton of coal by the evaporating process in two days.

Judging from the experience already gained I estimate that pressed dry banana leaves delivered at seaside in Jamaica shall not exceed 1½d per pound, first cost. These leaves will be as hard as bricks and as long keeping as wheat flour. This cost is with the supposition that the 80 per cent liquid pressed out, has no value, yet I have good reason for thinking that its commercial value is greater than that of the solid.

One more item of the value of the banana plant. During the past 25 years the cordage, coffee hags, hall mats, and a multitude of useful things used in the Republic of San Salvador's have been made from the stalk of the banana plant.

This subject had to be suspended for want of time until now when I find that it will have to be longer postponed, but I shall be pleased to talk with persons sufficiently interested to establish the business.—I am, &c.

D. F. MURPHY.

INSECTIVOROUS BIRDS.

While approving of the rules proposed by the Board for a close season for four-footed game and birds generally, within reserved forests, Government in July last asked the Board to amend the rules so as to protect insectivorous birds, which it considered should be protected at all times of the year, not in reserved forests only, but in all forest areas. Government intends to extend the rules as regards insectivorous birds not only in forest areas, but throughout the Presidency, and will address the Government of India on the subject of special legislation in the matter when the rules under the Forest Act for the protection of four-footed game and birds are submitted for the approval of the Government of India. Meanwhile, the Board of Revenue has drawn up a list of insectivorous birds and has circulated it to Forest Officers, Collectors, Mr. H. R. P. Carter, and the Superintendent, Government Central Museum, for any alterations or additions they may consider necessary. These officers have also been asked for their opinion as to whether the predatory birds which eat insects only when they cannot get flesh food should be protected, and if so, to distinguish them from other birds. The list drawn up by the Board contains the names of 57 birds, and if all are to be pro-

tected, as proposed by Government, throughout the Presidency, the people of this Presidency will have to deprive themselves of the best game that now graces their tables, and also be deprived of their best sport, as the list, which we give below, includes quails, partridge, teal, wild duck, pea-fowl, jungle-fowl, spur-fowl, guinea-fowl, turkey, snipe, woodcock, dove, rock-pigeon, &c.

IRIDS.	LATIN NAMES.
Sparrow	.. Passer Indicus
Common weaver	.. Ploceus baya
Myna and Paramyna	.. Acridotheres tristis
King-crow or common drungo.	.. Buchanga atra
	.. Dicurua macrocerus
	.. Dicurua albirictus
Crow	.. Corvus splendens
Madras bulbul	.. Pyconotus hemorhous
Jerdon's green bulbul	.. Jora zeylanica
Magpie	.. Copsychus saularis
Crimson-breasted barbet and common green barbet	.. Xantholewa Indica
	.. Megatoma caniceps
Indian hoopoe	.. Upupa nigrispennis
Consl or crow pheasant	.. Centrococcyu Rupipennis
Rufus backed shrike	.. Lanus Erythronotus
River or large pied wagtail	.. Motocilla Madraspatensis
The whole family of fly-catchers and bee-eaters	.. Musciapa and Meropidæ
The rollers including the blue jay	Coraciadæ
The egrets and the pond heron or paddy-birds, night heron and purple heron	.. Buphus Coromandus, Ardeola leucoptera, Myctiorax griseus and Ardea purpurea
The Indian jay and finches	.. Fringillus species
The parrot	.. Psittacus Erythacus

AMSTERDAM MARKET.

AMSTERDAM, Feb. 1.—The cinchona auctions to be held here on Feb. 16th will consist of 71 cases and 4,342 bales (about 341 tons), divided as follows: From Government plantations, 27 cases and 402 bales (about 41 tons); private plantations, 44 cases and 3,940 bales (about 300 tons). This quantity contains of druggist's bark: *succirubra* quills, 16 bales 64 cases; broken quills and chips, 149 bales 7 cases: root, 59 bales. *Officialis* quills, 1 bale; broken quills and chips, 2 bales. Of manufacturing bark: *ledgeriana* broken quills and chips, 3,067 bales; root, 471 bales. *Officialis* broken quills and chips, 51 bales; root, 1 bale. *Hybrid* quills, 198 bales; broken quills and chips, 162 bales; root, 96 bales. *Calsaya* quills, 42 bales; broken quills and chips 27 bales.—*Chemist and Druggist.*

LATEST TEA PLANTING NEWS FROM INDIA.

Our Dam Dim Correspondent writes on the 31st January 1893:—Pruning is now well ahead on all gardens throughout the district. Rainfall since 1st December last over 4 inches, and the weather still remains dull and unseasonable. Our local Meet comes off at Odlabarrie about the end of February and promises to be a successful gathering.

Our Ranchi Correspondent writes on 31st January 1893:—Owing to very reasonable rain pruning is now in full swing and an early flush anticipated. The extra cultivation given to the gardens last season has had a beneficial effect on prices generally. Some estates having an average of nearly three annas, Managers are sanguine of almost covering expenses. Health of coolies good.

Our Dehra Dun Correspondent writes on 31st Jan. 1893:—This last week we have had 2.09 inches of rain. This cold weather we have had altogether 8.68 inches of rain. Heavy snow has fallen in the hills and is still lying there. We are having heavy frosts at night, ice being found in the early mornings in some places one-fourth of an inch thick.—*Indian Planters' Gazette.*

VARIOUS NOTES.

TEA-MAKING.—The following poetic directions for tea-making are painted on many of the teapots used in the Celestial Empire: "On a slow fire set a tripod; fill it with clear rainwater. Boil it as long as it would be needed to turn fish white and lobster red; throw this upon the delicate leaves of choice tea; let it remain as long as the vapour rises in a cloud. At your ease drink the pure liquor, which will chase away the five causes of trouble, —*M. Times.*

COCONUTS IN THE KURUNEGALA DISTRICT.—Is it possible that a Kurunegala coconut plantation is going to "beat the record" in Ceylon for the bearing qualities of its trees? We hear from a recent planting visitor, most glowing accounts of Delgolla, once the famous cacao plantation of the Messrs. Laurie, now likely to be more famous under coconuts. The palms are described as loaded with nuts, and as yielding last year, in many cases on the authority of the Superintendent, no less than eighty nuts per tree! What do Messrs. W. Lamont and W. H. Wright say to this? One native gentleman of great experience throughout the Western province to whom we mentioned the return, simply denied its possibility over any considerable number of trees, and we know that 40 nuts a year is a good average—33 was the figure given for a fairly well cultivated plantation, and 20 the average for the island, by our intelligent native friend. What is the highest number plucked in one year from an acre by Mr. Lamont and Mr. Wright, we should like to know?

Correspondence.

To the Editor.

GINSENG.

Ontario, Canada, Nov. 7, 1892.

DEAR SIR,—Will you kindly answer the following inquiries from a former resident of Ceylon who was a planter in Ramboda about 20 years ago:—There is a plant found in the woods here called gin-sing or ginning,—not gentian mind,—the roots of which are eagerly bought up by a few local agents at a high figure, it is sent abroad somewhere we know, and sold we suppose at a very high figure, but the buyers refuse to give any information as to its final destination or the price they get for it, so the matter has been sent to me for solution.

Now I believe it to be used in India or China for medical purposes, and think if any of it is used in Ceylon you will be sure to know something about it. Ask anyone you may know, who corresponds with China or Straits Settlements. Here is the exact shape and size of an entire root; it is white and has a slight pungent taste (lots of people here say it is good for indigestion, but I don't find it much use myself).—Yours faithfully, F. N.

[In back volumes of the *Tropical Agriculturist* our correspondent will find information regarding ginseng. The *Treasury of Botany* has the following:—

GINSENG. The root of one or more species of *Panax*. It is also called Ginschen. Pereira gives *P. quinquefolium* as American Ginseng, and *P. Schinseng* as Asiatic Ginseng.

The name *Panax* is an adaptation of the Greek word *panakes*, signifying a panacea, or remedy for all complaints, in allusion to the supposed or real virtues possessed by some of these plants. The root of the N. Asiatic *P. Schinseng*, or *Ginseng*, is highly esteemed by Chinese physicians, who affirm that it is able to ward off or remove fatigue, to restore exhausted animal powers, to make old people young, and in a word to render man immortal if anything on earth can do so. At Pekin it is said sometimes to have been worth its weight in gold. In Europe the root has failed to produce any remarkable effects, though it is described as mucilaginous, bitter, and slightly aromatic. [The name *Ginseng* has been said to mean the 'Wonder of the World,' but Mr. Stronack informs us that the first syllable means 'humane,' the second uncertain, possibly meaning 'drug,' or 'root,' as it forms part of the name of this root, and of another drug which is also a root.] The roots of *P. quinquefolium*, a native of North America, and which has been sometimes confounded with the foregoing, are exported to China, but they are not so highly valued as the indigenous plant. *P. fruticosum*, *P. cochleatum*, and *P. Anisum* have all aromatic properties.

Wherever the Chinese abound, there is ginseng sure to be found.—Ed. T.A.]

TEA-GROWING IN AMERICA.

Sessay, Thirsk, Jan. 24.

DEAR SIR,—Enclosed please find a cutting from *American Investments*. Possibly you may think it amusing enough to insert in your paper. And it is only fair that the eyes of my fellow planters should be opened to the existence of so formidable a rival, and to success of tea growing in America as an "established fact."—Yours truly,

ARTHUR DUPUIS, late of Nayabedde.

The extract is as follows:—

SUCCESSFUL TEA-PLANTING IN AMERICA.

Mr. Charles U. Shepard, of South Carolina, brought to Baltimore recently samples of tea grown and cured

on the "Pinehurst" Farm, near Summerville, South Carolina. This is the first marketable tea that has ever been produced in the United States, and Mr. Shepard is much encouraged at the success of his experiment. The American tea was tested by an expert, who pronounced it equal to the best high-grade English breakfast tea, and superior to many grades that come from India and China. The samples brought here by Mr. Shepard are all of one quality and character—black, crisp, and well scented. It makes a strong beverage. This quality of the American tea is said to be due solely to its treatment in fermentation and curing. Other methods of curing the American product will produce tea similar to the several brands that come from India and China. Judging from Mr. Shepard's samples, the expert says he believes the successful growing of tea in the United States is established, and that the industry should be encouraged and fostered. Mr. Shepard only raised forty pounds of tea this year, which was cured in an ordinary fruit evaporator.

Mr. Shepard gave the following account of his tea raising: "For a number of years," said he, "I was the agricultural chemist in South Carolina, and became interested in the experiments the Government made to grow tea in that State. After the abandonment of the plantation by the Government I set to work to find out the causes of the failure and to see if they could be remedied. I informed myself on tea culture from the best sources of information, and after careful study and research I determined to take up the matter where the Government had left off. I secured twelve acres on the 'Pinehurst' Farm, which were carefully prepared and set out in tea plants. It requires three years of cultivation before a plant will commence to bear marketable tea. During the three years of growth I watched and attended to the cultivation of the small plantation in a way that I thought would produce good results. This is the first year that I have gathered and cured tea with the view of putting it on the market. Judges of tea say I have a good article, and I will therefore continue the work. I have gathered and cured forty pounds of tea. Next year I will get 160 pounds, the year after 240 pounds, the fourth year 400 pounds. So it will go on increasing each year as the plant expands and throws out more shoots. In gathering tea for market only the young and tender leaves are taken from the end of each sprout. As the leaves are taken off others soon appear in their place. This is what tea-growers call 'flushing,' and as many as six or eight gatherings can be made in one season. I have already called the attention of the Agricultural Department to my work, and have been promised assistance and encouragement from the Government. I will have an exhibit of American-grown tea at the World's Fair next year and will give visitors an opportunity to taste and test its quality.

"The 'Pinehurst' Farm is about twenty-two miles inland from Charleston, and is well adapted to tea-growing. The climate of South Carolina seems to be well suited to the growth of the plant with proper attention. Tea requires a great deal of moisture and unless we get from fifty to eighty inches of rainfall in a year the crop will not be prolific. I have ordered a steam curing apparatus, which I will put up on the farm, and from which I anticipate better results than from the crude methods of curing employed this year.—*Baltimore Sun*.

[Of course we have not the slightest fear of America growing tea in any appreciable quantity to a profit.—Ed. T.A.]

A PRACTICAL QUESTION FOR TEA PLANTERS.

Upcountry, Feb. 7th.

DEAR SIR,—Is it a fact that tea will not now run so long after pruning as it used to, and that after pruning the bushes take longer coming into full flush?—Yours truly,

AN OLD COFFEE STUMP.

TRAVANCORE TEA IN CEYLON.

The Grand Oriental Hotel, Colombo, Feb. 8.

SIR,—I have seen the correspondence in your paper with reference to the above subject; and I am glad to notice the strong support you have given to the proposal made as to the abolition of the duty on Indian tea imported into Ceylon. If Indian teas were allowed into Ceylon *free* there is no doubt Colombo would become a much more important "centre" than at present, and it is certainly the most suitable port for Travancore, being much nearer than any other.

Ceylon during the last two years has shipped about 1½ million lb. to India *free*; and it appears to me it would be a selfish policy to continue to block Indian tea from your market, while Ceylon is permitted to compete with India on equal terms. India at the present moment is the third best customer Ceylon has got. Ceylon has a fair field in India both as to labor and produce, and our planters there expect a fair field in Ceylon.—Yours &c.

HENRY M. KNIGHT.

P.S.—I am aware that the Dewan of Travancore takes a great interest in this matter.

TRAVANCORE PLANTERS' ASSOCIATION.

Feb. 9th.

DEAR SIR,—I have to request that the accompanying proceedings of a meeting of the T. P. Association be inserted in the columns of your valuable paper.—Yours faithfully,

J. E. FOWLER,

Hony. Secy.

Proceedings of the Travancore Planters' Association for year 1892-93. General Meeting held at the Club, Trevandram, 11th January 1893.

Present.—H. M. Knight (Chairman), Wm. Mar hall, Baron V. Rosenberg (President K. T. P. A.), T. Clarke, R. T. Mille, H. S. Buist, E. C. Chisholm, T. B. Berger (visitor), J. S. Valentine, Hon. Secretary.

Notice of meeting having been read the Chairman explained why this meeting was called, and it was unanimously agreed to make the present, the Annual General Meeting—and that in future it shall be held 3rd Wednesday in January.

The HONORARY SECRETARY then read his report for the year and the Chairman reviewed the past year's work and said the Association had never before been in such a flourishing state.

BARON J. VON ROSENBERG in flattering terms proposed a vote of thanks to Chairman and Hon. Secretary for the work done by them during the last few years. Mr. Knight having responded, he was again elected Chairman for current year, but a substitute had to be found for Mr. Valentine who goes on leave—Mr. J. E. Fowler being elected to the post.

The following resolutions were then carried:

(1) That the Madras Government be petitioned to extend the S. I. Railway from Tinnevely to the Travancore boundary, and that a committee consisting of Messrs. T. Clarke, E. C. Chisholm and Chairman be formed to draw up the petition.

(2) That the Chairman be asked to visit the congested District of Madras and make enquiries as to the best way to import labour into Travancore, make arrangements for starting an agency, and report results. That the Association guarantee Rs. 1,000 towards his expenses and that subscriptions be called for.

(3) That registration of Kanganies by the Association be adopted according to the scheme approved of by the registration Committee, Messrs. Knight, Clarke, Baron J. Von Rosenberg, Buist and Valentine—and that the following members form the standing Committee.

South.	J. Fraser
Central.	J. S. Valentine.
Forth.	T. Clarke.
Kanan Devan.	A. H. Sharp.
Peermade.	F. M. Parker.
With Chairman and Secretary.	

Registration if found possible, to commence from the 1st of April next.

Planters and Exchange. The reply of Wynaad Association to Government met with general approval. With the usual vote of thanks, the meeting closed.

HENRY M. KNIGHT, Chairman, Travancore Planters' Association.

CATTLE FOR CEYLON.

DEAR SIR,—If they want to improve the breed of Ceylon cattle, the Kerry cattle are the animals to import—splendid milkers, easily fed; where a Sinhalese beast can live these mountain cattle will thrive well. Their milk is known to be rich, none can beat them there. They are a healthy and sturdy breed of cattle, short-legged, square-bodied, and make excellent butchers' cattle.

KERRY MAN.

We take the following from the special agricultural correspondent of the *Dublin Evening Mail*, and it ought to be an inducement to the farmers and breeders of Kerries in this country—their native one—to go in for a better class than they have and not to be beaten out of the markets by those that are increasing every year; in fact Kerry is the last place that persons look for them now:—

Our little native cattle, Kerries and Dexters, are fast becoming spread over the world. It is not very long ago since they were entirely confined to their own green isle, but of late they have been taken up extensively in England, and have this year been shipped to Gibraltar and South Africa by Mr. James Robertson, of La Mancha, Malahide. Now we understand that a lot of ten have arrived at Victoria on the 4th of last month. They were selected in England by Mr. David Syme, and were to be located at his Kildare estate near Littledale when the period of quarantine had expired. One of the bulls is a Kerry named Best Man, of whose breeding we are told nothing; the other is a Dexter named Denham Melbourne, and is by Limglight, 12 (the famous winner of the Queen's gold medal at Windsor in 1889) dam Denham Molly, 66. By the name and pedigree we can trace Denham Melbourne to be from Mr. Swithinbank's herd at Denham Court, as also the Dexter cow Denham Olive, 67. Marguerite, Aster, and her daughter named Dahlia were, no doubt, selected from Mr. G. F. Roumie's stock. Two of the Kerry cows, Killarney 3rd and 4th, both by Uncrowned King out of Killarney, were bred in Ireland. Killarney was recommended and highly commended at the Royal Show at Warwick this year. The remaining cows are Lady Kenmare and Lady Clara. These are from the well-known herds of Mr. Adeane, Babraham, and the Express Dairy Company, Finchley. Lady Clara was purchased by the Express Dairy Company from Mr. James Robertson, and exhibited by the company at Warwick, where she was awarded second prize, and was so much admired, and had such a show of milk, that some anticipated first place for her.

PLANTING AND THE TREATMENT OF THE SOIL:

PRACTICE VS. THEORY PLUS SCIENCE.

DEAR SIR,—I think the practical man with a fair knowledge of a few of the fundamental laws of tillage is more likely to be successful than the scientific faddist. Considered from one point of view the conditions that present themselves for consideration are so many that no ordinary mortal could meet them all, as they vary in every field, aspect, lay, climate, condition and past history. There are farms at home, where the working and history of every field have been known for generations. All the farmer wants from the chemist in such a case, is a guarantee that the manures of commerce are what they pretend to be, and unadulterated. But to approach for the first time the scientific

cultivation of the many fields constituting a large estate would mean loss and disappointment as well as gain. I do not think it would be safe to go beyond the experience that has already been pretty generally acquired: that cattle manure, hones, poonac and castor-cake, judiciously applied are safe and sure, pretty nearly everywhere, leaving alone soils of great depth giving yearly good average returns. Shallow hurrying of weeds and prunings are good on easy lays of land. They always get well rotted and decomposed where the conditions allow the rain to sink in—air follows the moisture infallibly, for as the moisture sinks it leaves a vacuum which the pressure of the atmosphere as quickly fills up with air. Burying immense quantities of prunings together in one large, deep hole can only be for the purpose of getting rid of them, to the prejudice of a few neighbouring plants, unless soil is plentifully added and well mixed. Scientific cultivation of a large estate requires the purse of a Worms on a Rothschild estate.—Yours truly,
OLD PLANTER.

[The above was partly written with reference to an extract from Coorg Notes in the *Madras Mail*, of which we give the gist:—

PLANTING NOTES FROM COORG.

(FROM OUR OWN CORRESPONDENT.)

COORG, Jan. 23.—I thought it necessary in the interests of planting to call attention to the errors which "Planter" was led into in writing on the subject of the Weeding of Coffee Estates in the *Madras Mail* of the 10th of September last. "Planter's" observations were obviously the first-fruits of a perusal of Mr. Graham Anderson's letter on the same subject; but, as I said in some previous Notes, none of them were warranted by anything the latter had written. The following statements occur in the opening lines of "Planter's" letter:—"The burying of weeds is a mistake, favouring as it does fermentation rather than decay. Fermentation, unlike decay, is not a process of oxidation." It will be sufficient to quote what Dr. Fream has to say of fermentation in his "Elements of Agriculture," to convince him that these statements are erroneous. We learn that "fermentation is the name given to those chemical changes which result in making the manure 'ripe' or 'mellow' and better adapted to the immediate use of growing plants. It is a process of oxidation, and can only take place where there is free access of air. Heat is produced by the union of oxygen with the ingredients of the dung, and the more rapid the fermentation the greater is the heat. It is obvious then that fermentation may be controlled by increasing or diminishing the quantity of air that gains access to the heap, the oxidation being most active when the manure lies loosely, and least so when the heap is compressed." We see, then, that the burying of weeds would have the effect of checking fermentation to the extent to which it prevented access of air to them; and that fermentation resembles decay in being a process of oxidation. In fact, I think they may safely be taken as synonymous terms.

But first let us see what may be learnt as regards the changes which take place in the formation of silage that may aid in elucidating the matters here dealt with. In Fream we read that the object in silage is to imitate and improve upon the tightly pressed dung heap, and, by excluding the air, to prevent oxidation. Whether "sweet" or "sour" silage results from the operation is mainly dependent on the temperature at which fermentation takes place within the mass of herbage. When the precautions that have to be adopted to insure success in silage are considered, it is difficult to conceive how air could be so thoroughly excluded in "burying in" as is claimed to have been the case. It all depends on the depth of the earth covering put over the weeds. The operation as practised in Coorg was as it is described by Hull, *i.e.*, a shallow hole or trench was dug and all the weeds for

several feet round were scraped on to it and covered over. Hull speaks very highly of it as being an effectual plan in getting rid of weeds where they are high and rank, and yet in another place he says that weeds should not be turned in too deeply, as fermentation to separate the woody fibre is thereby prevented, so that he did not consider that "burying in" did harm in the same way. Sabonadiere says that closed trenching in Ceylon was attended with marked benefit, especially in stiff soils. This consisted of cutting a ditch across the entire length of the rows of coffee and filling them in with mana grass, the vegetable matter of swamps, &c., and covering them over with soil. Munro says that the decay of vegetable matter serves to keep soils open or porous by continually producing gas. We thus see how the supply of air would be kept up in "burying in." The air buried in with the weeds would start fermentation as it does in silage, and the gas thus generated would burst air passages through the covering of mould, provided it was not too dense.

Mr. Anderson's saying that "the proximity of semi-decomposed vegetable matter must be as hurtful to the living plants as a festering corpse is to a human being" is, to say the least, unhappy, for we are told (*Elements of Tropical Agriculture*) that the effect of alkaline substances in the soil is to counteract the evils arising from the accumulation of acid substances and other "pernicious combinations." If there be an insufficiency of these alkaline substances, the further natural decay of organic matter would be arrested and the soil would become sour. If there are any indications of this, however, matters are best remedied by the addition of lime, the duty of which is to keep soil permanently *basio*. In one estate here, lime has been mixed with cattle manure. This proceeding is countenanced by scientists and is bound to be beneficial; but planters generally still fight shy of it. It is not only in "burying in" that "pernicious combinations" are formed, as we read in the same book that they result when organic matter undergoes decay in the presence of air and water, so that they are formed in well worked soils as well. The great argument in favour of "burying in" was that the volatile products of the first stages of the decay of the weeds, instead of being dissipated in the air, was caught by the covering of mould and made to take new forms which are most valuable food for plants; and the surface was not robbed of organic matter as the humus particles were returned to the surface when the pits were reopened and in renovation pitting, &c. In another place Mr. Anderson speaks of a sample of vegetable matter completely bound together with fungoid filaments which, after digging, was altered in appearance and the fungus disappeared, and he asks:—"Does this prove that the food for the fungus has passed into a more advanced stage and has become food for a higher order of plant?" We will presently come to the work of fungi, but first let me say that this would seem to imply that after vegetable matter has crumbled into the humus stage it becomes a direct plant food. All agriculturists say this is not the case, but that the final products of its decomposition—chiefly carbonic acid, ammonia and water—are capable of administering to the food requirements of plants. "Planter" further said:—"Fermentation is always accompanied by the development of living organisms of the fungus class." We have an instance in sweet silage of high temperature fermentation *killing* living organisms. These living organisms the most familiar of which is the yeast plant, are productive of the greatest possible good to plants as they are instrumental, as Munro tells us, in bringing about nitrification, which is the name given to the production and accumulation of nitrate of lime, a most valuable plant food, in the soil. Soil exposed to much heat (over 140°F) results in the stoppage of the production of nitrate of lime, as this heat, as has been seen in silage, kills the living ferments. It is obviously undesirable therefore that weeds should be so exposed as to cause a high temperature fermentation.

After what has been said, we need say very little to show that burying manures is in no way harmful. In the first place "Planter" loses sight of the fact that the cattle manure generally made use of in estates is well rotted stuff in which state it is more immediately available as plant food, and in which fermentation has practically ceased. The burial of unfermented manure is not hurtful either. Its immediate action is not perceptible, but the ultimate benefit is said to be greater. I would be sorry if I were understood to be arguing in favour of "burying in" and against digging. I simply wished to show that the former was not hurtful in the way attributed to it. Digging is a most necessary work where it can be carried out safely; but "Planter" will be surprised to hear that there are some planters here who don't believe in it, although this looks so much like "discrediting any established scientific truth."
—Ed. T.A.]

THE ANSWER TO "A PRACTICAL QUESTION FOR TEA PLANTERS"—TEA PRICES.

DEAR SIR,—With reference to the inquiry in your issue of the 9th instant, I do not think there is evidence to show our tea is feeling the strain of plucking and pruning, or that we can ascribe the disappointing yields during the last eight months to such a cause. Young fields have been as backward as old, and unless we admit that the young fields are naturally weaker than those planted earlier, some other reason must be found. But we know that in the coffee districts tea was first planted in the weaker fields, and gradually and grudgingly put into better soil as coffee ceased to pay.

We have no difficulty in finding a cause for a short crop in February, viz., the very dry weather since middle of November. The decline in prices in London must, whatever may be said to the contrary, be due to a tacit combination among the few large packet people, none of whom will give way in prices charged to the public, even when the wholesale market shows good cause for a rise by retail.
EXPERIENCE.

MAXIMUM YIELD OF COCONUTS BY THE OLDEST EUROPEAN COCONUT PLANTER IN THE ISLAND.

DEAR SIR,—Your native referee would have been within his right, had he measured his statements by his own experience, but he exceeded his right when he called 80 coconuts per tree an impossible yield.* I have nothing to say against his averages: that of 20 nuts per tree is rather over than under the truth for the whole island, but I have myself gathered 250 nuts from a single tree in twelve months. Individual trees yielding over 100 nuts annually are by no means rare, and I know patches of several acres that fall very little short of that average. The Mahaoya field of the Nalla estate sold the other day for R888 per acre, gave an average yield per tree for the four years ending in 1891 of over 60, and in the year 1891 no less than 74 per tree. That coconuts grown on the rich crumbly loams common in the Kurunegala district should yield not only 80 nuts on per trees, but that average over acres is exactly what might be expected; and I have no doubt the report that reached you to that effect is perfectly correct.

Even on soils of inferior quality, such crops may be obtained by high cultivation, and at a cost that will yield a better return than most other investments of capital in the colony, but

to take all and give nothing, is the immemorial native system, and not even proved facts will change it.

I was asked by the trustee of the Daniel coconut estates for a valuation some months ago, and I gave one to the best of my judgment. I kept well within the true value, as I had no means of estimating the effects of the present boom, and of the rapid decline in the local interest of money. My valuation turned out therefore 27% under that of the Ceylon public.
W. B. L.

No. II.

DEAR SIR,—Referring to a notice in your issue of last Saturday on this product, I am not at all surprised to learn that 80 nuts per tree per annum has been the yield last year on the estate mentioned, and you are likewise correct in stating that 20 nuts per tree is the average for the island, for everybody knows what coconuts are like in a native garden in the midst of jak, mangoes and other fruit trees.

The sale of the coconut estates last Saturday clearly shows what ordinary cultivation will do, for to my own knowledge and that of one of your referees (Mr. Lamont) we know the abandoned condition these Nalla estates were in at the death of the testator; and the value then put upon it some 14 years ago was, I believe, only R20,000 for the whole extent which realized over R140,000.

The average per tree as given of the different blocks and the prices these properties realized at last Saturday's sale clearly shows what attention does and what value is set upon them by the people of the country.

There is no doubt Mr. W. H. Wright is a most successful cultivator, a born gardener, but his actual experience of coconuts is limited to its cultivation on the property he now resides on, which I learn is a model of an estate. I should however like to hear Mr. Lamont, who, I have no doubt, will tell you that coconut with fair treatment from their infancy and in favoured localities should give 100 nuts per tree, otherwise there is something radically wrong in its management.

Coconut plantations are now receiving more attention than hitherto, and it's a pity that more Europeans do not go in for it. Their cultivation is not now confined to Negombo, Chilaw and other maritime districts as in the past, but is extended across country from stations on the main line from Colombo to Polgahawela, across the Kelani river to the Kaluganga and the Bolgoda lake and with the most satisfactory results.—Yours faithfully,

A COCONUT ESTATE PROPRIETOR.

VARIOUS NOTES.

GROUND NUTS can be successfully substituted for coffee. The nuts when roasted and properly ground and manipulated in the same way as the genuine article, afford a pleasant and refreshing drink. Ground nuts have been used in America for many years as a substitute, and very largely for adulterating coffee.—*Nilgiri News*.

JAPAN TEA AT CHICAGO.—It is stated, the *Japan Gazette* asserts, that the application for permission to send a few girls to Chicago in order to give an exhibition of the tea ceremonial, floral arrangement and similar accomplishments at the tea stall was consented to by the Agricultural and Commercial department on certain conditions. But as the sending of these girls will necessitate a large expenditure, it is thought the proposal may not be carried into practical effect.—*O. China Mail*, Feb. 16,

* Over a "considerable area" remember.—Ed. T. A.

THE AGRA OUVAH ESTATES COMPANY, LIMITED.

(FROM REPORT OF DIRECTORS.)

The Directors have pleasure in submitting to the Shareholders the Accounts of the Company for the 31st December 1892, which show, after providing for all expenses incidental to the formation of the Company and payment of interest on purchase money to the vendor (amounting to R6,162.58,) a balance of profit of R530.92. This sum in terms of the Prospectus of the Company, has been applied towards reduction of the cost of the estates.

The estimated outlay on Working Account in 1893, which includes unusually heavy expenditure on repairs, tools and drains, is R67,419, against 138,000 lb. Tea, 1 800 bushels coffee and manufacturing &c. receipts estimated at R15,240.

With average weather the above estimate of tea should be realized, but it will be understood that the figures as regards Coffee must be considered nominal, for at this early period of the year it is impossible to frame anything approaching a reliable estimate. All things being favorable, a very much larger crop than that estimated is possible.

The above mentioned outlay is exclusive of the amount required to complete the Estate buildings, including the Factory and its equipment, for which it is expected that R13,200 will be required.

Agra Ouvah Estates Working Account for three Months to 31st Dec. 1892.

Dr.	R	
To Expenditure for three months as per Superintendent's Monthly Reports.....	R23,973.71	
To Less Expenditure on Permanent works transferred to debit of the Agra Ouvah Estates viz:—		
On Buildings.....	R 763.68

By Receipts for manufacturing outside leaf.....	2,945.83	
By Rents and sundry receipts on Estates	338.25	
	<u>21,698.24</u>	
	R21,698.24	

THE WE-OYA TEA COMPANY, LIMITED.

The following is the Report of the Directors which was presented to the annual ordinary general meeting of the shareholders this afternoon:—

The Directors have pleasure in submitting to the Shareholders the Accounts of the Company for the past year.

The Tea crop was 97,557 lbs, being 12,557 lbs. in excess of the estimate, and realized R41,031.37 or an average net price of 42 cents per lb., against an expenditure of R22,283.28 equal to 23 cents per lb.

After providing for depreciation of buildings and machinery, the net Profit for the year including the balance from 1891 and premium on issue of new shares, amounts to R21,003.21 out of which the Directors recommend that Dividends be declared and made payable on the 18th February of 20 per cent on old shares, absorbing R15,000, and 5 per cent on the new issue of shares absorbing R1,000. They propose that the profit of R5,000 derived from the issue of new shares be transferred to Depreciation account, to provide for

Factory extensions and that the small balance remaining be carried forward to the next account.

During the year the Directors effected the purchase from the Yatiyantota Tea Company Limited of their Abamalla property, consisting of acres 210 3 20 (48 acres of which had been planted in Tea) for the sum of R12,323.81 and they purchased at upset price from Government acres 15 1 25 of Forest land. Both of these lands adjoin We-Oya Estate and form very valuable additions to the Company's property. The acreage now owned by the Company consists of—

219	acres	planted in Tea	1888-1890
92	do	do	do 1892
5	do	Grass	
307	do	Forest	

Total. 623 acres

The young clearings promise well and arrangements have been made to plant 76 acres more land with tea this year, thus bringing up the cultivated acreage to nearly 400 acres.

To meet the cost of the purchases and clearings above referred to and to provide for any further extensions which may be decided upon, the nominal Capital of the Company has been increased to R105,000 by the creation of 300 new shares of R100 each, 200 of which were issued in September last, at a premium of R25 per share.

The Crop Expenditure in 1893 is estimated at R24,600 on 120,000 lb. of Tea and a further sum of R17,506 has been allowed for in the estimate to cover expenditure on clearings, new permanent lines, extension of Cart Road and other items on Capital Account.

In terms of the Articles of the Association, Mr. Eric S. Anderson now retires from the office of Director but, being eligible, offers himself for re-election.

The appointment of an Auditor for the current season will rest with the meeting.

To Expenditure for year as per Superintendent's Reports...	R 31,490.99
To visiting fee for year ...	403.00
	<u>R 31,890.99</u>
To Less Expenditure on permanent works transferred to debit of We-Oya estate viz:—	
On Buildings ..	1,233.91
On Machinery ...	566.01
On Clearings ...	7,807.79
	<u>9,607.71</u>
	22,283.28
On amount transferred to Depreciation account	
On account Buildings	609.99
On account Machinery	1,478.02
	<u>2,088.01</u>
On Balance transferred to credit of Profit and Loss account	16,660.08
By Proceeds of 97,557 lb tea	41,031.37

THE ACME TEA CHEST.

This improved tea chest which has been the subject of several notices in our columns—a specimen having been left on show in our office—is to be specially pushed in Ceylon. We learn that Mr. Andrew Polson is coming out per s.s. "Oroya" (due on Monday) as Agent for the Acme Tea Chest Syndicate, Ltd.; and in advance we attract attention to the advertisement which appears in our columns today. We have no doubt that Mr. Polson will do justice to his Syndicate and with a good article, secure a big sale for the Acme Tea Chest in Ceylon.

COCONUT CULTIVATION RETURN AND PROSPECTS IN CEYLON.

It would really seem as if a prosperous cycle were setting in for the great Coconut Planting Industry of Ceylon. In no other branch of planting, perhaps, has so much British capital been sunk unprofitably in this island in days of old as in Coconuts. At one time a considerable number of our merchants and a still larger number of European resident proprietors and managers were interested in Coconuts. There were settlements of such planters in the Batticaloa and Kalmunai districts of the Eastern Province, in the Jaffna Peninsula, and along our Western Coast at intervals between Negombo and Matara. How few of the once long list remain! How fewer ever got any return for their labour, and fewer still recovered even the capital they had sunk—not to speak of profits. The only prosperous period was during the period of the Crimean War, when the Baltic being closed against the Russian Export trade in tallow, coconut oil as one of the substitutes in candle-making and for other purposes, rose in value to £50 and £60 per ton, while of late years it has been down to half that rate. Gradually, most of the European proprietors of Ceylon coconut plantations sold out at a great sacrifice of capital, in some cases to their managers, in others to natives. A few only of the original proprietors have held by their plantations through good and evil report to the present day, but only the strictest economy has enabled them in most cases to make an income worthy of the name. As the late Dr. Sortain wrote to us when the question of a land-tax was proposed, perhaps twenty-five years ago, a levy of even a rupee an acre would mean, in his opinion, the abandonment of many hundreds if not thousands of acres under coconuts. That indicated an exceedingly poor state of things and of course as regards native cultivation, the wonder is that over large areas of "gardens" the palms grow or yield at all, so absurd is the overcrowding and so gross the neglect of every rule of proper treatment of the trees. Rather different is the case of the plantations owned by Ceylonese gentlemen who may be said to be the successors of the European pioneers. To the wealth brought to the island by the great coffee enterprise in the "fifties" and "sixties" and distributed through native hands, is mainly due the investment and opening up of the now extensive coconut region extending from Negombo inland along the valley of the Mahaoya towards Kurunegala and Kegalla. In this region may be found as well-cultivated plantations with native owners as any to be found under European management. But while the local demand for the coconut as a food product has always been uniform among the people, the export trade in the products of the palm continued for a long period after 1860 or so, to languish until at last prices for oil, coir, &c. fell to a rate that would scarcely pay the bare cost of production and manufacture. The recent revival in prices owing to demands for the oil and kernel in new directions and for novel purposes, has been most welcome and the gradual rise in the price of nuts until from less than R30 per 1,000, we now hear of sales at R50 per thousand, has no doubt had a good deal to do with the unprecedented prices paid the other day at the sale of Mr. Daniel's properties. We suppose that never before in the history of Ceylon has a coconut plantation realized over R800 per acre. At the same time, that the high prices were justified is made evident by the letter (page 604) of our correspondent "W. B. L.", probably the best authority on the subject as the one of most experience in the island.

Nevertheless "W. B. L." confesses that his valuations of the properties were, on the whole, 27 per cent. below the prices realized, and yet the native purchasers ought to be shrewd judges of the returns they can expect to recover from coconuts. Perhaps some of them calculate on the present high prices for nuts and oil continuing for a long time to come. We hope so for the sake of the industry and also because in the future reformed fiscal arrangements of this Colony, it is quite evident that coconut cultivation either by a direct tax or more probably by an export duty on surplus produce, must make a more distinct contribution to the general revenue.

But out of the present consideration of our Coconut Planting Industry, there has arisen an interesting practical question as to the maximum yield of nuts per acre from a well-cultivated coconut plantation. The proper number of palms to plant per acre being 70—certainly not more than 80—our recollection was that 30 to 40 nuts per tree per annum or a total of 2,500 to 2,800 per acre, might be considered a good average for well-managed plantations with good soil and in a favourable climate. When, therefore, we heard of 80 nuts per tree being gathered over the larger portion of Delgolla plantation in the Kurunegala district, we challenged the statement and asked for information from our older coconut planters. "W. B. L." has responded in a way which is very much to the point, and he convinces us that the soil being favourable, good cultivation might well secure a return even so high as 80 nuts per tree or 5,600 per acre over a considerable area say 50 to 100 acres. At the present maximum price of R50 per 1,000, that would mean R250 gross return per acre—and would, we suppose, beat the more prosperous tea plantations considering the comparatively smaller expenditure required? But surprise has been expressed by our contemporary of the "Examiner" that we did not at once satisfy our scruples about a large yield by a reference to the statistics of the Daniel estates, and our contemporary sums up these in a convenient form. We extract as follows:—

Curiously, our senior contemporary, in the same issue in which he publishes the particulars of the sale, seems astonished, and almost expresses incredulity, at 80 nuts being picked off trees on Delgolla Estate. Here we have 71 nuts off nearly 60 acres! Such high yields, though they do occur, are unfrequent; and the Proprietor who has purchased his land at a moderate figure and planted it up without extravagance, ought to be content with 30 to 40 nuts per acre, which should represent a fair rate of interest on his investment. The average yield for the whole Island, including Native Gardens, we are quite prepared to believe does not exceed 20 to 25 nuts per tree. It is well to bear in mind that heavy crops generally mean small nuts; and a Sinhalese gentleman mentioned to us that, while 900 of his Chilaw nuts gave him a candy of Copra, it required twelve to thirteen hundred Kurunegala nuts for a candy.

The following table we have compiled is likely to be of interest, and may prove useful for reference hereafter:—

	Acreage.	Trees per acre.	Trees in bearing.	Nuts per tree.	Price Rs.	Rate per acre Rs.	Rate per tree Rs.
Yakkedegalla ...	80	67	345	37	11,750	147	2.20
Mausa ...	5	86	240	42	2,200	440	5.12
Lower Kuda							
Oya ...	72	61	1,384	53	31,500	437	7.4
Upper Kuda							
Oya ...	54	61	906	60	30,000	555	9.2
Maha Oya ...	81	54	3,149	71	70,250	867	12.2

The yield of nuts here, it will be observed, varies from 37 to 71—the last-mentioned figure being got where the trees per acre only numbered 54 in place of the orthodox 70. But apart from this fact, we had been told that some of the estates referred to, had been quite exceptionally dealt with in respect of the application of manure during the past few years, and we were therefore ready to eliminate them from the discussion. Turning to our own "Coconut Planters' Manual" for instance, the most complete statement hitherto available for the yield of the coconut palm in Ceylon is the following:—

Tabular Statement of General Yield of Coconuts per Tree on the average of the various soils:—

Names of Soil	Average yield $\frac{1}{2}$ tree annually	Remarks
1—White poor sandy soils	15	In all these averages the trees are supposed to have reached from 14 to 20 years old, as the bearing of a coconut tree is very irregular until it attains a full bearing condition, except by manuring.
2—Dark mouldy "	30	
3—Reddish "	40	
4—Strong rich upland soil bordering the banks of a river....	50	

The above seems a very fair and reliable statement; and it is borne out in respect of general experience by most of the headmen in coconut districts who would consider 33 nuts per tree as a good average for plantations. But it is clear that it is possible under favourable circumstances to reach a much higher average. "W. B. L." shows that very plainly in his letter, and we suspect he was also the writer who, a good many years ago, argued that an expenditure of 50 cents per annum per tree (or R35 per acre) ought to keep up the annual yield of a good coconut plantation to 100 nuts per tree—(worth at the time he wrote R160 but now quite double that or R320 per acre!). Still, while we may be told of the extraordinary yield of 250 nuts from a single coconut palm in one year in Ceylon, we question if an average of 100 nuts per tree (70 trees to the acre) has ever been gathered in this island—and whether therefore the return of 80 from Delgolla is not the maximum so far attained over any considerable area? We suppose Mr. W. H. Wright's Mirigama property is as yet too young to come into competition; but we look to this gentleman to "beat the record" and to report to us when he has got his trees bearing at a rate equal to 5,000 to 7,000 nuts and upwards per acre per annum, that we may go there "to see!" Meantime the ordinary proprietor who gets a steady crop of from 2,500 to 3,000 coconuts per acre per annum in Ceylon may be well satisfied, while aiming by liberal cultivation at better results especially in these days of high prices.

CEYLON TEA IN AMERICA.

We are indebted to Mr. Mitchell for the following satisfactory news:—"By the mail of 27th Jan. from London, Mr. Grinlinton writes me as follows:—"I have received a very satisfactory letter from Mr. Elwood May from Chicago. He and Mr. Pineo have been travelling, and he reports well of his progress in placing orders for tea, but he has omitted to mention that I paved the way for Ceylon tea there and for his Company. This, however, is of no moment: what we have to regard is the progress made, come from whatever source it may, and I have good reason to be glad that I worked as I did in our tea interest for nearly two months last year in Chicago and elsewhere, giving away my own teas without stint."

THE INDIAN TEA COMPANIES hope much from the Chicago Exhibition. The Americans have got accustomed to cheap inferior tea, and it is a slow and difficult process to change the public taste. This was the difficulty experienced in Australia. All large employers of farm labour are obliged to give their men tea along with other rations, and it is obviously in their interest that the tea should be as cheap as possible. The country is, therefore, flooded with China tea and cheap Indian tea, but the superior infusions have no chance. It was long, says a correspondent of an Indian Paper, before pure Indian tea could be purchased in London, and some people argue that the "blends," with which the public were imposed on for many years, were a necessary education before the public could be got to drink the pure Indian beverage. It is to be hoped that in America the process of education, if slow, will be equally sure, and the exhibition will serve as a primary school. America is really a more promising market than Australia, and if once a start is made great things may be accomplished.—*Financial World*, Feb. 28.

Analyses of Paddy Straw.
 By Dr. VAN GEYZEL, M.B., C.M., F.C.S., F.I.C., Chemical Examiner, Madras.
 Agricultural Department, Madras, Bulletin No. 6 of 1889-90.

Average composition of various Cereal Straws according to Wolff, and of Rice Straw according to Kellner and VanGeyzel.

KIND OF STRAW.	Water.	Nitrogenous substance.	Fat.	Carbo-hydrates.	Fibre.	Ash.
Wheat	14.3	3.	1.2	36.9	40.	4.6
Spelt	14.3	2.5	1.4	31.8	45.	5.0
Rye	14.3	3.	1.3	33.3	44.	4.1
Oat	14.3	4.	2.0	36.2	39.5	4.0
Barley (Winter)	14.3	3.3	1.4	32.5	43.0	5.5
Do. (Summer)	14.3	3.	1.0	36.7	40.0	4.2
Maize	15.	3.	1.0	36.7	40.	4.2
Do. Cob	10.8	2.4	.5	54.7	30.4	1.3
Rice Japan (irrigated)	20.8	5.4	1.7	19.6	38.6	13.9
Do. (upland)	10.3	6.0	1.9	28.9	36.2	16.7
* Rice Carnatic	8.1	4.1	2.2	38.7	30.	16.9
† Do.	7.5	4.3	2.4	41.	28.5	16.3

It will be seen from the above that Japan rice straws surpass all other well-known cereal straws which have been analysed, in the amount of nitrogenous substances they contain. Rice straws also surpass the others in respect of the proportion of fat present. The amount of fibre in rice straw is low, and that of mineral matter higher than in other straws.

In one of the samples from the district of Madura in the Carnatic, Dr. Van Geyzel found about as much nitrogenous substance as Kellner found in Japan upland rice straw; but each of the others, and the average of all the samples analysed, show a smaller proportion of nitrogenous substance in rice straw from the Carnatic than Kellner found in straw of Japan upland rice; but Nos. 2, 3, and 8 compare well with Japan irrigated rice straw. On the other hand Dr. Van Geyzel found considerably less fibre and more carbo-hydrates in rice straws from the Carnatic than Kellner found in Japan straws.

Analyses of the ash of rice straw have not come under my notice. The determination of the composition of the mineral matter in rice-straw appears to be still a desideratum; but, if not already published, such analytical results will no doubt be available ere long, and they may then be compared with the following ash analyses of other cereals by Wolff:—

* Average of 6 samples. † Average of 8 samples.

Ash Analyses of Straw. (WOLFF.)

(THORPE'S DICTIONARY OF APPLIED CHEMISTRY.)

KIND OF STRAW.	Number of Analyses.	Pure ash in dry straw.	100 parts of pure ash contain								
			Potash.	Soda.	Lime.	Magnesia.	Peroxide of iron.	Phosphoric acid.	Sulphuric acid.	Silica.	Chlorine.
Wheat (Winter) ...	18	5.37	13.7	1.4	5.8	2.5	.6	4.8	2.5	67.5	1.7

Rice feeding meal mentioned in the above table consists chiefly of the external layers of rice which are separated in dressing. It will be observed that it is much richer in nitrogenous substance, in fat and in mineral matter than is the whole grain. In the matter of fat it stands higher than all the other feeding stuffs quoted in the following table of parts and products of

cereal grains from Mr. Warrington's article on "Cereals" in Thorpe's Dictionary of Applied Chemistry. There is also a good percentage of nitrogenous matter, and it is richest of all in mineral matter, with its 8 to 10 per cent of ash, of which 43 per cent is phosphoric acid. The proportion of ash in various husks is, of course, larger, but it consists mainly of silica.

Manuring of Rice.

Rice is commonly grown without manure; nevertheless, the manuring of rice lands has attracted some attention. The experience of C. C. Georgeson (Journal of the Chemical Society, 1889) was that there was considerable difficulty in manuring rice grown on irrigated land; but he had experimented on several plots with ammonium sulphate, potassium carbonate and superphosphate of lime. He found that the best results followed from an application of these three compounds according to the requirements of the plant as indicated by the composition of the soil. Ammonia greatly stimulated the growth of the plant, but did not increase the yield of the grain. Hence, if ammonia in the manure were in excess, the straw was increased; but the size and weight of the grain suffered. Superphosphate, on the other hand, increased the size of the grain; while the effect of potash was intermediate between ammonia and superphosphate.

Rice grown on volcanic tufa was not affected by nitrogenous manure; but the yield was increased by potash and superphosphate. The proportion of grain to straw was less than in the case of rice grown on irrigated land.

Professor O. Kellner and J. Sawano have experimented on the manuring of rice. (Journal of the Chemical Society.) One set of experiments had for its object to ascertain whether the rice plant preferred its supply of nitrogen in the form of nitrates, or of ammonium compounds. The conclusion arrived at was, that in presence of the necessary mineral ingredients, nitrates alone cause a very slow growth in the first few weeks of the plant's life; but that latter, the

growth is normal. Ammoniacal compounds, on the other hand, stimulate the growth much at first; but do not act so favourably afterwards; hence, the authors recommended that the manures for rice should contain nitrogen in both forms.

(To be continued.)

THE JAVA COFFEE CROP, short as it is this year, presents a dark outlook for next year owing to the prevalence of leaf disease.—*Straits Times*.

THE COFFEE CROP in Sungsi Ujong promises to be a heavy one. This in these days of high prices is a good thing for local planters.—*S. F. Press*.

THE USE OF TEA is yearly increasing at Venice. The inferior qualities of Russian teas sold by many retailers at high prices cannot compare with the finest China, India, and Ceylon teas now supplied direct to customers here, at very moderate prices.—*L. and C. Express*.

EXPORT DUTIES IN MANILA.—By our last advices from Manila we learn that there was expected to arrive by Spanish Mail steamer a decree enforcing the increase of export duties on hemp, coffee, indigo, cordage and leaf tobacco—that on hemp alone will be \$2.56 per ton, instead of \$1.56. The reason for this increase is to equalize the loss to the revenue caused by the cessation of the tax on coasting trade. Seeing that the export trade is almost in its entirety carried on by foreign traders and in foreign bottoms, while the coasting traffic is all carried by the nationals, it is evident the new law will give an immense advantage to the Spanish subjects to the detriment of the foreign traders generally.—*China Mail*.

PROPOSED TEA ANALYSES.

Some time back Mr. John Hughes, the well-known agricultural chemist, with whose work on behalf of Ceylon planters, most of our readers must be well-acquainted, submitted proposals to our Planters' Association for instituting a series of experiments with the object of determining to what extent tea might be classed as an exhausting crop, and as to the best method of returning to the soil the constituents extracted from it by the bush. We believe that the principle advocated by Mr. Hughes received endorsement by the Association, which, however, took no immediate steps towards giving effect to that gentleman's proposals. In this condition matters remained for some considerable time until a few months back, when it became understood that the Association had under its serious consideration the obtaining of the services of an expert analyst to conduct work here on the spot, and, as we then believed, on the lines laid down by Mr. Hughes in his letter to that body. From a conversation which is reported in our London Letter of this mail, it would seem to be the case that the proposal of the Association as to the character of the researches to be conducted by an analyst on the spot differs widely from that put forward by Mr. Hughes, and in view of the very considerable cost which must be entailed in getting out a competent man specially from England and of the inquiry he would be instructed to conduct, we think it advisable to counsel the Association to weigh well the remarks on this topic proffered to our London Correspondent by Mr. Hughes. Of course the necessity for the tendering of such advice must be dependent upon Mr. Hughes having rightly understood what it is that the Planters' Association has in contemplation to attempt. That expert's view was and is, that it must be most desirable to learn with the fullest accuracy possible the actual constituents, and their amount, withdrawn from the soil during the growth and bearing of a tea bush, and therefore to determine the best method for ensuring their replacement, so as to obviate all chance of ultimate exhaustion to the soil. It is pretty generally known, that as compared with the old days of coffee only a small quantity of manure is sent upcountry for the purpose of application upon tea estates. We published figures supplied to us by the Railway General Manager a short time ago which showed that in place of 4,200 and 5,400 tons as in 1882 and 1883 respectively—years when coffee was getting very low down—the railway for the past three years has not carried more than 3,500 tons per annum of manure. In the palmy days of coffee—in 1877 for instance—the manures sent upcountry by rail exceeded 27,000 tons! So far the general opinion has been that tea on fresh land does not require manure and that on old coffee land, it will not pay to apply it. Well, for that each planter must judge for himself: but there is Mariawatte surely as a standing illustration of the great use of, and profit to be derived from, manuring. That 104 acres should in twelve years, as a contemporary showed the other day, have yielded 1,143,000 lb. of made tea, can only be accounted for, we think, by liberal cultivation and manuring. We have no doubt there are tea estate proprietors who would gladly deal liberally by land which is yielding them 500 lb. and upwards of made tea per acre; but who hesitate to begin manuring so long as their bushes look in good heart and continue to bear well. This hesitancy is also, doubtless largely due to the limited knowledge possessed of the character of the ferti-

lizers best applicable in the case of tea cultivation. Until very recently it was generally—indeed universally—believed that nitrogen should be the ruling constituent of manure to be applied in the case of tea growth. But although no final and authoritative postulate is as yet possible, there is, according to Mr. Hughes, a growing acceptance of the theory that nitrogen is absorbed by leaf growth from the atmosphere more than through the rootlets obtaining it from the soil. In a great degree, therefore, it seems to be now considered that nitrogenous manures are not those most needed to replenish the soil of our tea estates. It seems to have been fully demonstrated by experiments conducted at home that leguminous plants, such as peas, beans, &c., derive their required supply of nitrogen direct from the atmosphere, and that they are for that reason independent of the soil for that particular nutriment. This was proved through no improvement in growth or yield being observable in cases where plants of that character had been liberally manured with nitrogenous fertilizers. It was chiefly to determine how far the tea tree partook of this independence that Mr. Hughes counselled the course of experimenting, he submitted to the Planters' Association.

Mr. Hughes is under the impression that what is now contemplated by that body goes far beyond the scope of his proposal. And that it is intended to undertake a locally series of analyses of teas grown and prepared on different estates situated very diversely as to elevation and character of soil. From such a course of experiment Mr. Hughes thinks we should derive little or no satisfactory result. Elevation, temperature, method of preparation, would all so far affect particular analyses, as to render it impossible to judge by comparative results. Each and all of those conditions must largely vary the constituents of samples submitted to analysis. This fact is so thoroughly recognised by manure manufacturers at home that each establishment keeps its special analyst, and determine its procedure solely upon the experiments conducted by him without reference to results obtained in other factories or by outside general experimenting. We have thus briefly sketched out the main purport of Mr. Hughes' statements so as to prominently point out the leading features of the case as put by him. These are sufficiently clear and important, we believe, to render it desirable that the Planters' Association, before going to the expense of bringing out a Chemist for general research, should pause and consider how far the cost of doing so would be likely to be recouped by the results of his work.

(From a London Correspondent.)

LONDON, Feb. 17.

It seemed to me to be desirable to learn what Mr. John Hughes might have heard respecting the resolution of your Planters' Association to obtain the services from home of

AN EXPERIENCED ANALYST

to conduct researches on the spot with reference to tea. It somewhat surprised me to learn that Mr. Hughes had not been communicated with on this subject, and he told me he had heard nothing certain as to the intention of the Association nor as to the object it had in view when contemplating the securing of an expert to work on the spot. He said that even should he be asked to do so it would be impossible for him to go out to Ceylon to conduct experiments. As to these, he pointed out to me that the proposals he had made to the Association differed in very material

respects from what he understood to be the objects of the resolution taken by it. Mr. Hughes observed to me:—"When writing as I did to the Planters' Association I contemplated the making of such analyses as might enable it to be determined how far tea exhausted the soil and the nature of the constituents it was desirable to return to it in the form of manure in order to prevent ultimate exhaustion. I was induced to suggest such a course because the returns by the railway seem to show that the amount of artificial manures sent up for application on tea estates is remarkably small, far less, I should say, than was the case during the era of coffee cultivation. Now we have full evidence that a leaf crop is far more exhausting to the soil than is a seed crop. This is fully recognised throughout English agricultural practice. Many farming leases contain clauses that insist that in the cases of certain crops distinct in character from seed crops, the products shall not be removed off the land except certain compensatory manuring is given to it. This is particularly the case with regard to hay and several other growths of a similar nature. But no such clauses are insisted upon with respect to crops of the nature of corn, that being essentially a seed crop. There can be no doubt that stripping a plant of its leaves deprives the soil of the fertilization which their natural dropping would return to it. When you denude a tree of its leaves you go against natural action. When you pluck coffee berries, or any other seed, you merely forestall what Nature would ultimately accomplish for itself, and do not by doing so rob the soil of what Nature intended to return to it. It is manifest from this that

THE PLUCKING OF THE TEA LEAF

is more exhausting to the soil than the gathering of the coffee berry. *Ergo*, it follows there is the greater necessity for furnishing artificially to the soil that which you have artificially deprived it of in the way of falling leaf. Upon this must follow the necessity for considering with exactitude the nature and character of the constituents of which you have deprived the soil. I proposed to do this by having an area of tea growth set apart over which by analysis the exhaustion of the soil after a certain period of cropping might be established. An important question has next to be dealt with. Until comparatively recently it had been thought to be of the first importance to provide by artificial manuring for a liberal supply of nitrogen to plants to be absorbed by its rootlets. Late home experience seems almost to have decided that vegetable growths absorb most of the nitrogen they require from the atmosphere through their leaves. It has been found that peas and beans for instance have not benefited in the least by the application of nitrogenous manures. Their growth and power of bearing experienced no improvement when such fertilizers were applied, and the conclusion was forced upon agriculturists that such growths must obtain their vital supply of nitrogen through some agency apart from their roots, and consequently from some source of supply apart from the soil. Now as the atmosphere is mainly composed of nitrogen it has naturally been deduced that that is the source of supply, and that the agent by which this is taken up is the leaf. I do not pretend to say that this fact is conclusively established, but it is one which now finds very general acceptance. Supposing the deduction I have mentioned to be a correct one, it must be manifest that in all cases when the leaf is systematically removed, as in the case of the tea bush,

the plant is deprived of the means of taking up from the atmosphere the supply of nitrogen required by it, and it must be given to it in some other way. It is to determine this and kindred points that I desire the opportunity suggested in my letter to the Planters' Association. How far that body proposes to work on that line by getting out a specialist to work on the spot I cannot say; but from what I have heard I conjecture that it is proposed to undertake

A SERIES OF ANALYSES OF TEA

grown and prepared on different estates. I doubt very much if this would be found to be a course likely to yield satisfactory results. The conditions for such analyses must vary so greatly that no general comparison of them could afford reliable information. Apart from the varying nature of the soils there must exist other different conditions which must effectually prevent useful comparison. There would be temperature, method of preparation, relative humidity, and many other minor conditions that must necessarily vary the chemical constitution to be ascertained by analysis. These difficulties are so fully recognised here at home that great manufacturing establishments to which correct chemical analysis is a constant necessity, such as factories for the preparation of artificial manures, invariably keep their own analyst and confine his work to their own preparations. The proprietors of such factories know very well that they can obtain no guidance from the analysis of manures prepared in other factories, the conditions as to which may differ materially from those under which they themselves are working. They therefore rely much more upon results obtained in their own works and from their own products than upon those obtained by the expert of any Government department or centralized union of their trade. This experience and its result should not be lost sight of by your Planters' Association if I have rightly conjectured what its aims and objects are in seeking to obtain the services of an analyst on the spot. I do not of course say that such services would be altogether fruitless; but they must, in my opinion, fail of such practical result for the reasons I have stated.

Mr. Hughes' statement to me as recorded above seems to be pregnant with sound advice, and to be based upon an experience so wide as to give it great value. My own entire ignorance of the subject dealt with must preclude me from offering any conclusion of my own beyond that of advising

FULL CONSIDERATION OF MR. HUGHES'S REMARKS

before your Planters' Association commits itself to any cause which must entail upon it heavy expenditure. The services of a thoroughly competent man could not be secured save at a considerable cost, and there must also be contingent expenditure of a serious amount. It would be a mistake, as it seems to me, if this outlay were incurred without the fullest estimation of what would be likely to be gained by it.

TEA IN CHINA.

(China Overland Trade Report, Feb. 22.)

Foochow, Feb. 11.—Since the 14th ultimo 560,000 lb. have been shipped in the calling steamers "Tele-machus", "Oopack" and "Gleugyle." With these shipments the season has come to an end, and the total export to Europe is 18,000,000 lb. against 20,336,000 lb. last season, showing a falling-off of 2½ millions of lb. The demand has been somewhat fitful during these last four weeks of the season, and the settlements, which aggregate 5,600 chests Congou, have been made at

intervals. Prices show no change. The total arrivals for the season were 327,500 chests Congou against 347,000 chests last season, and stock of 1,000 chests remains which will probably be carried over to next season.

SHANGHAI, 16th February.—(From Messrs Welch, Lewis & Co.'s report.)—Black Tea.—No business. Stock, 1,655 $\frac{1}{2}$ -chests. Green Tea.—Season closed.

CINCHONA BARK.

AMSTERDAM, Feb. 8.

Analyses for the cinchona-bark sales to be held here on February 16 have been published. The manufacturing bark contains about 14 tons sulphate of quinine, or 4.37 percent. on the average. About 11 tons contain 1 to 2 per cent.; 54 tons, 2 to 3 per cent.; 76 tons, 3 to 4 per cent.; 81 tons, 4 to 5 per cent.; 49 tons, 5 to 6 per cent.; 44 tons, 6 to 7 per cent.; 2 tons, 7 to 8 per cent.; 4 tons, 8 to 9 per cent.; and 2 tons contain 9 to 10 per cent. sulphate of quinine. As per telegram received today, the exports of cinchona from Java to Holland amount to 450,000 kilos. in January against 490,000 kilos. in December last. These figures refer to Government bark and from private plantations.—*Chemist and Druggist.*

LIME DEATH TO INSECTS AND FUNGI.—Another use of lime in the soil is its liability to destroy fungi and injurious insects that may attack the crop. The fungus which causes rust and similar parasites we believe will be greatly held in check by liming the land. This also leads to another point, that of potato raising. One of the most serious losses that is sustained in this industry is that of "dry rot." Lime scattered over the potato patch in small quantities will be one of the best of preventives. We have a stock well upon the place, which is mainly fed by surface water on account of which it holds more or less sediment, making the water muddy and not desirable for the stock to drink. We find that by throwing in small quantities of lime the sediment will collect and soon settle to the bottom and leave the water clear. In conclusion, lime practically applied on land may not be of much direct value as plant food, but its use mainly is to change the physical and mechanical character of the soil,—*Horticultural Times*, Feb. 18.

ROTHWELL, MARSHALL & Co., Brokers,

REPORT ON CEYLON COCOA.

LONDON, Feb. 1st.—During the past year the prices ruling for Ceylon cocoa although lower than those of 1891 were satisfactory, viz., 95s to 114s against 105s to 133s 6d.

The yield of the crop in Java was expected to equal about one-half that of Ceylon last year, this, however, was not realized, but a considerable increase is anticipated this year. Madagascar is commencing to export, the characteristics being similar to that of Ceylon, and one small parcel has sold up to 102s 6d, good red Ceylon being worth 110s, on the same date. Planting in India, especially in the Wynaud district, is being pushed forward, and the trees are said to be doing well, but little can be expected from this quarter in the near future. The attempts made in the West Indies to produce cocoa similar to Ceylon have, so far, not proved satisfactory or encouraging, the most successful at present being Jamaica, where with proper advice and guidance should be able to produce excellent results, a small lot, cured similar to Ceylon, having recently sold at 80s per cwt. whilst their ordinary quality realized only 66s on the same date.

EXPORTS OF COCOA FROM CEYLON AND JAVA.

	1893.	1892.	1891.	1890.

Java „ „	500*	380	370	220

COMPARATIVE PRICES OF GOOD RED CEYLON COCOA.

Jan. 1893.	Jan. 1892.	Jan. 1891.	Jan. 1890.
107s to 123s	103s to 110s	105s to 119s	95s 6d to 113s

The probable increase in supplies from the East, similar to Ceylon, need we think, cause no uneasiness as to the maintenance of remunerative values, if only this market is made the centre of supplies from the producing countries of the world, as the demand for this class of cocoa is steadily increasing, and would attract competition from all countries, in addition to our home manufacturers. The growing practice in Ceylon of shipping to ports other than London has already had the effect of bringing the value below that of Java, and should this unsatisfactory system continue, a further lower range of values must be looked for. During the prevalence of high values in 1890-91, strong, and partially successful, efforts were made in various quarters to obtain direct shipments, with the result mentioned above. We understand that renewed attempts to purchase in Ceylon for shipment to other ports than London are now being made, but trust that the past experience of this impolitic system will cause producers to hesitate before consenting to accept an apparent benefit, and will not sacrifice another of their unique products to the fetish of "direct" business. Further recent advices to hand state that orders for America and Germany have been in the Island at more than the current rates ruling in this market, but those who swallowed these "gilded pills," must now be considerably chagrined when they learn that good red has sold up to 123s per cwt. here for our home manufacturers' purposes.—*Lewis and Noyes.*

GOVERNMENT AND THE TEA DUTY.

The Editor of the Daily Chronicle.

SIR,—Why is the London Liberal Press silent, or nearly so, on the subject of the tea duties? The abolition of those duties means, of course, the fashioning of the free breakfast table and, thereby, the carrying into effect of one of the blessedest truths of the Newcastle program. To judge by the attitude of the London Liberal Press it matters not at all whether we get a free breakfast table now or a year or two hence. I venture to think it does, and that we want it at once. Chiefly because it would be the most outward and visible manifestation that the Liberal Government could possibly make of their profession of faith as the working man's friend. The gift of a free breakfast table in 1893 would immensely strengthen the hold of the Government upon the

popular vote, and would give it the good start that is now of overwhelming importance. The present Government is more dependent upon the vote of the working classes than any Government has ever been. What boon can Sir William Harcourt confer on the working classes that can compare in value and in immediate, intelligible, and widespread effect with the gift of a free breakfast table? If he does not give it now, the chapter of accidents—such, for instance, as a European war—may prevent him from giving it next year; and he may after all, have to confess at the next General Election that he has left undone what he ought to have done—and so be undone himself in consequence.

Why call it a gift? It would be the repayment of a debt long due to the working classes for having been forced, in times past, to finance us in various injurious military expeditions, by means of tea duties, &c. Many working men felt that Mr. Goschen had paid them back something when he reduced the tea duty by 2d in 1890, while Liberal Governments had declined to refund them a single sou since 1865. Hence a heavy retardation to the hoped-for Liberal majority at the recent General Election.

One word as to the economic effect of Mr. Goschen's "Twopence." I believe—and I ought to know something about it—that the consumer now gets, in consequence of the twopenny reduction, an advantage of 3d. per lb. at least, in the value of his tea. I know that since the reduction, the home consumption of China tea has fallen off by 45 per cent., while that of Indian tea has risen by 5½ per cent., and that of Ceylon tea by 105 per cent., that is to say, the reduction of duty was favourable to the consumption of the best and unfavourable to the consumption of the worst teas. It cannot be doubted, then, that the abolition of the remaining duty of 4d. per lb. would be a great stimulus to the further consumption of high-quality tea; to the disuse, by consequence, of low-class teas. As long as any duty is maintained it will act as a handicap *pro tanto* in favour of the worst and against the best article—a premium on rubbish, in fact. Is not that in itself an all-sufficient reason for abolishing the tea duty, in the interest of the community generally, by the 1893 Budget?—Your obedient servant,
C. J. ROWE.

National Liberal Club, Whitehall-place, S. W.

TEA IN AUSTRALIA.

(From *Alfred Harvey & Co's Monthly Tea Report.*)

MELBOURNE, Feb. 7th, 1893.

GENERAL.—A still further general advance in value of all leaf has to be reported. Very high prices are now being paid in both Calcutta and Colombo for all grades. The Customs having decided to allow full drawback upon duty paid stocks, a general improvement in deliveries may be looked for. Trade shows improvement in the country, and exports are fully up to the average.

CHINA.—Foochow market closed; exports to the Colonies 14,500,000 lb., with probably a little addition *via* Hongkong. Common congous have continued firm at 5½d, 5¾d, with heavy sales; market stronger at close, owing to 5,000 packages of low coarse grade being ordered by the Customs to be re-shipped to China, leaving but small quantities available in first hands. Good common has had good inquiry at 6d; fair flavoury, 6½d to 7½d; medium panyongs, 7½d to 8½d. All better sorts are practically in dealers' hands. Scenteds had sales at low rates; coarse pungent pekoes, 6½d to 7d; well-scented mediums, 8½d to 9d; Kooloos still in over-supply at lowest rates—viz., 8½d for light-scented common, up to 10½d for well-scented pungent brands. Buds are without inquiry; public sales have been unimportant, beyond showing that importers were firm; very little was sold at auction.

INDIA.—Calcutta shipments to date are 3,240,000 lb. or 1,100,000 less than at same time last year. The "New Guinea" having arrived with 340,000 lb., leaves only 1,000 packages afloat, and no direct

steamer circulated until the 26th. Supply being far below requirements, high prices now rule for all leaf under 1s, and there seems every probability of a still further advance. Public sales cover 3,400 packages, the whole of which was rapidly taken by the trade, at a good advance upon last month's prices. Common grades have risen $\frac{3}{4}$ d to 1d per lb., and better ones a full 1d; coarse common broken and milled souchongs sold from $6\frac{1}{2}$ d to $7\frac{1}{4}$ d; clean common whole leaf, 7d to $7\frac{3}{4}$ d; pekoe souchongs, 8d to $9\frac{1}{4}$ d; pekoes, $8\frac{1}{2}$ d to 11d; orange pekoes, $10\frac{1}{2}$ d to 1s 1d; fine quality 1s 2d to 1s 6d. Private sales, owing to the small stocks available, have not been as large as usual; the next auction catalogue printed is for the 23rd.

CEYLON.—Colombo shipments to date are 4,000,000 lb. The shipping market continues to advance, and so check exports to the colonies. Receipts so far, although 1,500,000 lb. more than at the same time last year, are well below requirements. Our market keeps firm at recent advance in values, with good buyers for all kinds up to 11d. Public sales show an advance of $\frac{1}{4}$ d per lb. upon teas selling at 8d and under, and 1d to $1\frac{1}{4}$ d upon better grades for the month. Sales were effected at $6\frac{1}{2}$ d to $7\frac{1}{2}$ d for fannings and broken; 7d to $7\frac{3}{4}$ d for bold leaf; $7\frac{3}{4}$ d to $8\frac{1}{2}$ d for clean whole leaf; $8\frac{1}{2}$ d to 9d for fair pekoe souchongs; 10d to 1s for pekoes, 1s to 1s 5d for good to fair orange pekoes. Public sales cover 1,200 packages, and a small catalogue is printed for to-day.

THE BURMA GOVERNMENT AND PEARL FISHERIES.

Thursday, Feb. 16.—Mr. Martin asked the Under-Secretary of State for India whether his attention had been called to the statement in the *Times* of Jan. 16 that the Government of Burma had claimed and sold the exclusive right of pearl fishery in the Mergui Archipelago, and, if so, in what manner, to what distance from the coast, and under what law; whether any British subjects had been warned off, or compelled to leave those waters; and whether Her Majesty's Government intended to exclude foreign fishermen from the waters in question.

Mr. G. Russell:—The legal question to which the hon. member draws attention was under the consideration of the Government law officers in India at the end of last month. The correspondence has not yet come home, and the Secretary of State can only say that the questions raised by the Burma Local Government on the subject have not yet been decided.—*O. Mail.*

MARKET FOR TEA SHARES.

Thursday evening, Feb. 1.—There has been considerably more activity among Tea Stocks during the past week, and prices continue steady, and in some cases quote an advance.

The *Scottish Assam Company* issues an interim report today, which is fairly satisfactory. There is a slight increase in crop, and the average realised to date is also rather better than last year.

The tea market opened the week with better demand, and, with again smaller offerings, this was maintained. Fine Darjeelings made good prices.

MARKET STOCKS.—*Assams* were done at 29 $\frac{3}{4}$, and the quotations remain the same. *Doors old Ordinary* have further advanced, and business was done as high as 14. They close about 13 $\frac{3}{4}$ buyers. A few of the *new Ordinary* were sold at 12 $\frac{3}{4}$, and 12 $\frac{1}{2}$ is now bid for shares. In the *Preference shares—old issue*—business at 13 $\frac{1}{2}$ —last price—and in the *new shares* at 13 $\frac{1}{2}$. In *Eastern Assams* there is nothing to report. *Jokais*.—We understand the shares lately offering at 15 have now all been placed, and there are no sellers under 15 $\frac{1}{2}$. *Lebongs*, after remaining quiet for some time, come to business this week. A hundred shares were offered and taken at prices between 10 $\frac{1}{2}$ and 10 $\frac{3}{4}$, and we believe shares could still be had at the latter figure. In *Luckimpores* there is still no business.

UNQUOTED SHARES.—The *Borokai* shares lately offering have been sold at 13 $\frac{1}{2}$. *Brahmapootras* were also done at 9 $\frac{3}{4}$. *Chandpore* shares are enquired for, but sellers' ideas, in view of the good report expected and the payment of 4 per cent interim dividend, are rather high. *Chargola* shares are offered, both *Ordinary* and *Preferred*, at rather higher prices, but holders are firm, and will not sell under their limits. Some of the *Ordinary* have been sold at par, and *Preference* shares at 23s. The company is expected to do well this season. *Doom Dooma B* shares have again been sold at £14. There are now *Dejoos* asking for a bid. Some *Indian of Cachar* shares are offered at 7 $\frac{3}{4}$. Also some *Lumbas* at 9. *Scottish Assams* are marked in the Aberdeen lists, business done at £5 18s 9d. There have been no dealings since the report.

CEYLON SHARES.—CEYLON TEA PLANTATIONS CO.—There was an inquiry for the *Ordinary* shares at the beginning of the week, and business was done up to 15 $\frac{1}{2}$. There are now sellers at 15 $\frac{1}{2}$. The *Prefs.* are buyers at 12. A few *Spring Valley Coffee* shares are asked for.—*H. and C. Mail*, Feb. 17.

PHEASANTS.—The pheasants imported from England by the Messrs. Orkes in November 1891 were destroyed to a bird on Monday night by jackals, and there only now remain a few of last year's young birds, which were reared in this country with much trouble, to represent them. Fortunately these last were at a distance from the scene of the jackals' banquet, or would have shared the same fate.—*Pioneer*, Feb. 16.

SEASONAL FORECASTS OF WEATHER:
THE ADVENT OF THE SOUTH-WEST
MONSOON IN CEYLON DEPENDENT
ON THE SUN SPOTS CYCLE.

Weather prophets all the world over have found it convenient to keep up the popular notion that it is almost impossible to forecast the weather for more than a day or two in advance, and certainly so far as England and other extra-tropical regions are concerned they are probably acting wisely not to attempt anything more. Out here, however, in the sub-tropical and equatorial zone as the ancient Indian classics have it, "the sun is at once the agent of light, the principle of thought and the motor of all things." And whether it may arise from his more direct rays or from the peculiar barrier to Arctic influences presented by the range of the Himalaya, the Indian area is peculiarly characterised by a series of constant weather conditions which change more regularly and periodically than those of any other region of the world. Even the dates on which the two great monsoons commence here and in India lie within tolerably well-defined limits, and the weather which corresponds can be reckoned on with respect to its general character in different parts of this island in a manner quite unknown to those who live nearer the poles. As our readers are aware, we have in our "Handbook and Directory" on the authority of the careful Master Attendant of Colombo, given the dates of the advent of the little and big monsoons at Colombo for a long series of years. But when we come to analyse the apparently regular set of conditions governing this greatest change in our seasonal year—from our dry hot period to the refreshingly cool rainy term—we find that the South-West monsoons differ a good deal in themselves and in their arrival in different years. Omitting all the minor inequalities in the weather from day to day incident upon the actual size of rain showers, clouds, strength of wind, we find both the dates of the first arrival as well as the total amounts of rain vary in different years, and at first sight there appears to be no law regulating such times and amounts. Indeed were such laws as a rule plainly visible, meteorologists would long ago have raised their science to the enviable level of accuracy and honour enjoyed by those of mathematics, astronomy, and physics. If, however, any advance towards accuracy in this science is ever to be attained it will only be by the investigation of these longer weather periods. For, the longer the period and the more the weather conditions are regarded with reference to their average for such period and not simply by their passing oscillations, the easier will be their correlation with slowly changing physical conditions either directly or indirectly due to astronomical or terrestrial factors. In other words, we shall find it easier to deal with seasonal changes than with those of merely one day's or one week's duration.

This principle which is well recognised in other sciences has not made much progress yet in its application to meteorology; but it may be within the recollection of some of our older residents that Ceylon colonists were among the first to recognise after a practical fashion, the existence of weather cycles. The late Mr. R. B. Tytler was among the first to name and dwell on the wet and dry cycles in Ceylon with their effect on the coffee crops, especially in the drier districts, such as Dumbura. Our late lamented senior followed up the hint and elaborated from the meteorological records available, the ten to twelve years' weather cycle which attracted the attention

of Mr. J. Norman Lockyer when he came to Ceylon with his Eclipse Expedition in 1881, and he connected the Ceylon weather with the sun spot cycle. Mr. Lockyer published a paper on the subject in *Nature* which attracted a good deal of attention. About the same time or soon after, Mr. Meldrum of Mauritius published elaborate tables establishing the law of sunspots and rainfall. Since that time, the Indian Meteorological Service which is recognised as being one of the finest in the world, because it has been administered hitherto by trained physicists, have given much attention to the subject. Anglo-Indian meteorologists, attracted no doubt by the fascinating nature of their field, have been among the first to travel out of the orthodox daily forecast and attempt to give some notion of what nature the monsoon is likely to be in different parts, its probable duration and intensity as regards rainfall, etc. Obviously anything approaching success in such a matter would be of immense value to agricultural industry throughout India, and especially to the rice-farmers; while we need scarcely refer to its interest or value for us in Ceylon. To be forewarned, is to be forearmed, and if by timely prescience the Government of India could avert a possible famine by sending supplies to threatened districts, we should all feel that a service which could prove itself to be such a useful factor in the social economy of the opposite continent, would deserve to rank with the highest administrative and executive departments of the Government. At present no doubt the officers of the Meteorological service are chary of predicting too certainly. At the outest a certain proportion of failures may be expected, especially if the predictions are made too particular; but enough has already been discovered to show that a little more systematic discussion of past data would yield valuable results and empirical if not rational laws for future guidance.

It was after the severe famine experienced in Madras in 1877, that the possible recurrence of drought and famine in periods corresponding with similar periods in the spotted area of the sun's surface, was put forward by Sir W. W. Hunter and Mr. Lockyer. A great deal of attention was naturally attracted to what was perhaps heralded at the time with too great a flourish of trumpets as a solution of the entire problem. And yet in spite of serious divergences from a regular law outside certain areas, and a fluctuation too small to be of itself enough to account for a dangerous drought throughout the entire province, there is no doubt that sunspots do affect the temperature and other weather conditions in every part of this earth. Dr. Meldrum of Mauritius, Dr. Hahn of Leipzig, Prof. Frith of Zurich and a host more have shown how the influence of sunspots ramifies through everything included under the head of weather. From the frequency of cyclones in the Indian Ocean to the length of glaciers in Europe, there are traces of some peculiar influence which apparently recurs periodically about every eleven years with the sunspots; and though up to the present sunspots alone have not been absolutely employed for the purpose of forecasting, the investigations which have been made of these parallel phenomena have yielded incidentally other results of considerable value to science. For example the remarkable period in the winter rainfall of Northern India known as Messrs. Archibald and Hill's law—discovered by the late Professor S. A. Hill of Allahabad and Mr. Douglas Archibald, formerly Professor in the Patna College, Bengal,—in the year 1876, was independently discovered while a comparison was being made between the course of the rainfall and the area of sunspots. It will be inferred from the above that Mr. Archibald Douglas, who was here the other

day on a mission about New Zealand frozen mutton, is an accomplished scientist, and that when in India (as more lately in Queensland) he acquired a high reputation as a Meteorologist. This is made evident by his name being so specially coupled with an established periodic law bearing on the India winter rainfall. Mr. Archibald, while in Ceylon, was much taken with the papers and statistics in our "Handbook"; and he maintains that similar laws to the Indian one probably remain undiscovered in other parts of the world. It is at all events an additional proof in favour of such a fact and a strong argument for using the influence of the sunspot cycle as a working hypothesis, that Mr. Archibald was able to bring to our notice a remarkable period in the dates of the arrival of our big monsoon which he considers to be quite as marked as that in the Calcutta winter rainfall which led him to shout "Eureka" in March 1876.

It is of course well-known that there are two periods of rain-burst in Ceylon, called respectively, the little and big monsoons. These answer to the "chota" and "burra barsats" of India. Confining our attention at first to the big monsoon we find from the table published in our "Ceylon Directory" page 256g, for 1892, a list of the dates on which the big monsoon made its first appearance at Colombo during the past 40 years. The average date for the arrival of our "big monsoon" at Colombo for the 39 years from 1853 to 1891 is May 19th. On arranging the years in three eleven-year groups commencing with 1856, a year of minimum sunspots, and ending with 1891, Mr. Archibald has found the following cycle of periodicity, for the average departures from the average date which we put into a table, so as to make it quite plain to our readers:—

Years.	Arrival of big monsoon at Colombo.	Sunspots.
1856-67; 1867-78; 1878-89=	7-50	days late minimum.
1857-68; 1868-79; 1879-90=	3-25	do late
1858-69; 1869-80; 1880-91=	2-00	do late
1859-70; 1870-81; 1881-92=	4-00	do late
1860-71; 1871-82; 1882-93=	2-00	days early maximum.
1861-72; 1872-83;	=10-33	do early
1862-73; 1873-84;	=4-00	do early
1863-74; 1874-85;	=2-00	do early
1864-75; 1875-86;	=1-33	do late
1865-76; 1876-87;	=3-25	do late
1866-77; 1877-88;	=0-00	average.

These figures in spite of not having been doctored in any way by smoothing, shew a remarkably regular oscillation. This may be roughly described as late monsoon about the time of minimum sunspot and before and after; and early monsoon commencing at the maximum epoch of sunspots and continuing for some four years after that date. These results were by no means unexpected or merely empirical. It has already been accepted as a canon of Indian meteorology that at and about the time of few sunspots, both the Bay of Bengal and Arabian sea branches of the summer monsoon are usually retarded, and that they are correspondingly accelerated about the epoch of many sunspots. The foregoing results for Ceylon are therefore in complete correspondence with the Indian observations. Mr. Archibald does not think it would be possible to predict the precise date of arrival or a given year of the burst of the monsoon, but taken in conjunction with the dates in the two immediately preceding years and the position of the year in the sunspot cycle, a very fair idea of the chance of the big monsoon being late or early, could be formed. Thus in the present year 1893, Mr. Archibald thinks the burst of our big monsoon

ought to be early,—two days earlier than the average—or to occur about 17th May, unless there has been any abnormal snowfall in the Himalayas. The dates for the little monsoon are found to be less regular but still to follow to some extent the same law. Thus all the greatest departures from the average occur at the critical epochs of solar spotted area, the early abnormal at maximum and the late abnormal at the minimum epoch; but there is a double oscillation which looked to Mr. Archibald, as if our little monsoon was due to a more complicated set of circumstances.

Without going further into these interesting questions, it is plain that investigations into Ceylon weather changes from year to year would prove fruitful whether by statistics, or synoptic charts. The latter the Queensland Government have decided to undertake on Prof. Archibald's recommendation as we learned from the *Brisbane Courier* some months ago. We may also hope that before long steps will be taken to discover the relations that exist between the Indian and Australian areas, so that the public may be able to understand how droughts in the one are coincident or otherwise with those in the other; and how, apart from all direct solar influences, such an indirect factor as an unusual influx of antarctic water into the southern ocean, may possibly cause an abnormal season in Ceylon. We hope that Mr. Archibald (who is a Vice-President of the Royal Meteorological Society of London) will follow up this interesting question and lay it before the Indian Meteorologists with whom he has worked so successfully in an unofficial capacity in past years.

CACAO IN ECUADOR.

REPORT BY CONSUL GENERAL SORSBY, OF GUAYAQUIL.

The preparation for planting the cacao bean consists in clearing the land of all underbrush and trees by cutting and burning, which is commenced about July and pushed until the rainy season, beginning in November, December or January. After the ground has been cleared of all debris, it is marked in rows about 3 yards wide, and in each row sticks are driven about 3 yards apart, and at the foot of each stick a hole about 3 inches deep is made, into which are put three or four beans, over which is thrown sufficient earth to cover them. The next step is to plant rice, bananas, or other cereals or plants of rapid growth and shade to protect the young cacao plant from the sun's rays. It is usual to thus protect the plant for three or four years.

The tree matures in six years, but begins bearing usually at four, after which the only care necessary is to cut out the weeds twice a year; and this is the only cultivation ever given the cacao tree in Ecuador.

An average of one thousand trees to the cuadra (about 1½ acres) are planted. The life of the tree is about 100 years, the height about 15 feet; the trunk is clear of branches for 5 or 6 feet from the ground, and the foliage is a rich green and abundant.

A heavy, deep, vegetable soil is required, because the cacao tree has but one main root or taproot, which grows straight down 7 or 8 feet. If this main root or taproot strikes a clay or gravel formation the usefulness of the tree ceases.

The total cost of the purchase and preparation of the land, purchase and planting of the seed bean, and caring for the plant until maturity or until it has reached a safe stage will not exceed \$300 per thousand trees.

The laborers to look after and care for the trees and to plant cereals or plants to shade the tree while young usually have the privilege of living upon and cultivating the land free of rent; there is not, however any fixed rule. If the owner personally supervises the work of the estate, the labor is employed by the day, month, or year, and the revenue from the culti-

vation of the land—the planting of cereals or plants to protect the young cacao plant—belongs to the owner.

The manner of gathering the cacao is by cutting the pods from the tree with a large knife fastened to end of a cane or pole. With these knives one set of laborers go ahead cutting off the pods, another follows gathering and throwing them into piles, another follows cutting the pods open, another follows scooping out the beans, and finally, another follows with mules to carry the beans to an open, cleaned, and dry place, where they are dried by being spread in the sun for about six days. It is estimated that the total cost of gathering and preparing the cacao for the market does not exceed \$3 per 100 pounds.

After gathering and drying, the bean is sent to Guayaquil in bulk or in sacks upon rafts, in canoes, or by steamers, at a minimum rate of freight, where it is disposed of by the planter to an exporter or commission merchant. After reaching Guayaquil the bean undergoes more treatment. It is unloaded from the rafts, canoes, or steamers by the laborers and taken to the warehouse (bodegas) where it is first cleaned by passing through a large sieve manipulated by two men. By this method the bean is cleared of the dust and dirt, leaving only the veins and hulls, which are picked out by hand, leaving, finally, the cleaned bean, which is spread in thin layers in the sun for four or five hours, when it is ready for sacking and shipment.

It is estimated that the loss in weight from handling after arrival at Guayaquil or final port of shipment is about 5 per cent., which is chargeable to the purchaser abroad, as the exporter, as a rule, buys only upon orders. In fact, every charge, from the time the cacao arrives at Guayaquil from the estate until it is placed on board of the steamer for shipment abroad, is charged to the foreign purchaser.

A commission of 2½ to 4 per cent., which constitutes the visible profit of the exporter or commission house, is charged to the purchaser abroad.

All of the refuse from cleaning the cacao, viz., the dust, pelotas and dried veins, has a market value and goes to swell the profits of the exporter or commission house here. The fine dust passing through the sieve is worth \$2 per 100 pounds; the hulls, or pelotas, \$4 per 100 pounds; and the veins, used for food for horses and mules, \$1 per bag.

There are three grades of cacao grown in Ecuador, as follows:—

The "Arriba," the first grade, is grown on the Guayas River and its tributaries above Guayaquil. This is the best grade, and represents about 65 per cent. of the whole crop, the main season for which extends from January to July.

The "Balao," the second grade, is grown below Guayaquil in a country adjacent to Port Balao, from which this grade derives its name, and equals about 10 per cent of the whole crop, the main season for which is from July to December.

The "Machala," the third grade, is grown still further south, adjacent to the port of Machala, and equals about 15 per cent of the whole crop, the principal season for which is the same as that of the second grade, Balao—from July to December.

The cacao district of Ecuador, as at present represented, embraces a radius of about 80 miles, with the city of Guayaquil as its base, though the best quality of cacao and the greatest yield per tree I have seen in the Republic was in the northern part of the province of Esmeraldas (where the placer gold regions are), where no attention is given to its culture; but the life of the plant is said to be of short duration, because the depth of the soil is not sufficient.

While it is true that cacao has its seasons, yet a little of each class is gathered and marketed outside of their respective seasons. That gathered after the principal crop is called "Rebuscoz," or gleanings, and often is as good as or better than that of the main season.

There are still two other classes or grades of cacao grown in Ecuador. One is known as the "Caraquez," grown in the province of the port Bahia de Caraquez, on the coast north of Guayaquil, which is about the same in quality as the Machala; and the other is

grown near the port of Esmeraldas, on the coast north of Bahia de Caraquez, and is superior to all other cacao produced in Ecuador, though the production is insignificant. The two latter grades represent about 10 per cent. of the total.

In round numbers there are 30,000,000 trees, and the annual production is from 28,000,000 to 30,000,000 pounds of cacao.

The value of a cacao estate is based upon the number of trees thereon, and not upon the amount of land embraced therein. The nominal value of a tree is one sucre (equivalent to 70 cents according to present rate of exchange). This is the nominal value—the price at which they can be purchased when the owner seeks a buyer, which is a rare occurrence; when the purchaser seeks the owner, he may have to pay as high as two sucres per tree. As a rule, cacao estates are not in the market. Taxes are nominal, the crop uniform, the profits great and sure, the labor cheap and reliable, and the immediate future free from danger of over-production.

The methods of cultivating the tree and gathering and preparing the bean for market are difficult, tedious, and crude, everything being done by hand and nothing by machinery.

From the moment the pod is cut until the bean is sacked and embarked the least possible time is lost. Everything is pushed as rapidly as the habits and customs of the people admit, and it may be safely assumed that were a little study and more attention given the method of cleaning and curing the bean could be immensely improved in quality.

Ten dollars an acre would be the maximum price of lands suitable for cacao culture, \$25 an acre the maximum cost of clearing and preparing, and 200 the maximum cost per acre of 700 trees—planting and caring for till maturity. Upon this basis an estate of 200 acres would cost:

Land	\$2,000
Clearing and cleaning	5,000
Planting and caring for	40,000
Interest on capital at 10 per cent. for five years (which is an over-estimate, because the \$40,000 need not be paid, except in instalments, amounting to say \$8,000 or \$10,000 per annum)	23,500
Total	70,500
Minimum market value of 140,000 trees at 70 cents each	98,000
Clear gain	27,500

The profits arising from production may be determined upon a basis of half a pound per tree for the fifth year and one pound thereafter by the following tables. By these tables it will be noted that the yield of the season, whether short or full, affects the value of the cacao, the market value rising and falling in sympathy with good or bad seasons; and what is lost in the yield is gained in the price. Thus it is that, with a poor crop in 1891 and unfavorable reports for 1892, the price today is \$18 per quintal for the best or Arriba grade. This state of affairs—the close proximity of price with yield—is easily accounted for when it is borne in mind that the world's product and supply is inadequate to the demand.

The estimate of the cost of an estate of 200 acres, it may be well to repeat, is a maximum estimate, it being impossible under favorable circumstances or by close, personal attention and management to make the amount stated in dollars represent sucres.

Table showing quantity of cacao received at Guayaquil during the past four years:

	Arriba.	Balao.	Machala.	Total.
1888.	19,480,598	3,091,926	5,090,604	27,672,128
1889.	16,737,512	3,165,393	4,734,339	24,637,304
1890.	25,001,572	4,596,566	6,793,632	36,391,770
1891.	15,050,696	2,690,343	4,339,593	21,080,632

CHINA SHIPPING TRADE AND TEAS.

But, of course, the China trade is not what it was now that Chinese tea is being steadily run out of the English market by Indian tea. Tea was always the best paying cargo, but the freights now common would have paralysed the old clipper-owners merely to think of. And just as the annual export seems to get less and less, so the competition for the carrying of it seems to get more and more. It is a remarkable business this tea trade, and it has had a curious history. As long ago as the time of Buddha, according to tradition, China exported tea to Japan, Corea, Tonking, Cochin, Siam, Burmah, Ceylon, and India, as well as to Arabia and Persia, both overland and over-sea in junks. This was when the world was young indeed, but everything in China is so old that one dare not doubt any of the records. A curious thing is that notwithstanding the enormous development of the trade with England and America, the total exports of tea are said to be smaller in the 19th than they were in the 17th century. If that were the case in the days of the tea-clippers, how much more so must it be today! Since 1870, say in twenty years, the China tea trade has fallen off about 75 per cent. By the China tea trade in this connection, we do not mean the exports merely, but the total production and consumption. Not only are Britons taking to Indian tea in preference, but even the Chinese are more and more taking to other beverages in place of their own once invariable brew, while the burden of taxation bids fair to crush the tea-grower out of existence altogether. What he has not to disgorge for taxes he has to pay over to the middleman, who advances him money at 10 per cent. per month on his growing crop who only takes that crop in payment at the prices current at time of delivery. When the time of delivery arrives, the tea-planter knows by experience that prices will be down to the bottom dollar. Even a Wall Street operator might find something to learn in China, of the tricks of "manipulating" a market. One effect of fleecing the tea-grower, however, has been to spoil the quality of his product, and Chinese merchants have been for the last twenty years doing their best to "kill the goose."

They have pretty well killed it already in some of the once favoured and prosperous tea-growing districts, but some other areas have been opened up—potably Formosa. The tea of Formosa is accounted by Americans, and some others, the finest in the world, and as the output of the Beautiful Island is steadily increasing we shall by-and-bye see a direct steam trade between Formosa and the United States and Europe. As present Formosa tea goes to Amoy and Hongkong for transhipment. And the tea for American consumption is now for the most part carried in British vessels and paid for through British bankers.—*Fair Play*, Jan. 13.

THE CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Thursday, the 16th day of February 1893, at (3 p.m.), 3 o'clock in the afternoon.

Present:—Mr. Giles F. Walker, Chairman Planters' Association of Ceylon; Hon. L. H. Kelly, Kandy; Messrs. H. M. Toller, Chairman, Maskeliya Association; James H. Barber, Kandy; J. Anderson, West Matale and Kandy; A. Melville White, Kelebohka and Kandy; W. D. Gibbon, Kandy; J. A. Spence, Medamahauwara; A. E. Wright, Maskeliya; and A. Philip, Secretary to the Planters' Association of Ceylon, Kandy.

The notice calling the meeting was read. The minutes of proceedings of a meeting of the Committee held at Nuwara Eliya on Friday, the 9th day of December 1892, were taken as read and were confirmed.

Read letter from Mr. A. L. Cross.

Read letter from Mr. John H. Starey, Manager, Eastern Produce and Estates Company, Limited, intimating that the Directors of the Company have authorized him to contribute to the Ceylon Tea Fund on the scale proposed.

Read letter from Mr. J. W. Gosset.

CEYLON TEA KIOSK.

Considered application by the Manager Syndicate Boat Company, Limited. Resolved:—"That the action of the Chairman in the matter be endorsed."

CEYLON TEA AT THE WORLD'S COLUMBIAN EXPOSITION AT CHICAGO IN 1893.

Read letter from the Special Commissioner for Ceylon to the Exhibition transmitting an early copy of the catalogue of Ceylon exhibits.

Read memorandum from the Government Printer inviting attention to the "Chicago Guide" or official handbook and catalogue of the Ceylon Courts, and requesting that if it is proposed to insert an advertisement to have a copy sent to his office at once. Resolved:—"That any advertising be left to the discretion of the Commissioner."

Read letter from Mr. W. Herbert Jones on the subject of his proposed lectures on Ceylon at the World's Fair. Resolved:—(I) "That a copy of Mr. W. Herbert Jones's letter be forwarded to Hon. J. J. Grinlinton with an expression of general approval by the Standing Committee of the Tea Fund of Mr. Jones's proposal as far as it relates to Chicago." Resolved:—(II) "That Mr. Jones's letter be acknowledged."

CEYLON TEA COMPANY OF NEW YORK.

Read letter from Messrs. Wattson & Farr acknowledging receipt of the minute and resolution passed by the Standing Committee of the Ceylon Tea Fund in reference to the Ceylon Planters' Tea Company of New York.

Read letter from the Secretary of the Ceylon Planters' Tea Company of New York (Mr. R. E. Pineo) conveying thanks for the grant of 9,000 lb. of Ceylon tea.

Read letter from Messrs. Darley, Butler & Co. (I) enclosing copy of a letter from Messrs. Wattson & Farr, New York, also acknowledging the grant of 9,000 lb. Ceylon tea from the Tea Fund; (II) transmitting invoice for 54 packages tea shipped per "Ethiopia" to the Ceylon Planters' Tea Company of New York amounting to Rs. 1,494.90. This being the second instalment of the grant of 9,000 lb. made to that Company.

CEYLON GREEN TEAS.

Read letters from Messrs. Darley, Butler & Co. (I) on the subject of the samples of 10 packages of choice growths of China and Japan teas received from America, and mentioning that the Government on being informed of the circumstances under which the teas have been imported passed the teas free of duty; (II) letter enclosing Mr. A. M. Gepp's Report on the Japan teas. Resolved:—"That Messrs. Darley, Butler & Co. be requested to make up 160 lots of samples (being a series of ten each) of those green teas, and to forward them at the earliest opportunity to the Secretary."

CEYLON TEA IN FRANCE.

Read letter from Mon. W. de Peyster. Resolved:—"That consideration of the correspondence be postponed to a future meeting."

CEYLON TEA IN GERMANY.

Considered letter from Messrs. Kroning & Schrader. Resolved:—"That Messrs. Kroning & Schrader's application be entertained, and that the amount of duty disbursed be remitted to them as suggested by the equivalent in tea."

CEYLON TEA IN RUSSIA.

Read and considered letter from Mr. M. Rogivue. Resolved:—"That a grant of 9000 lb. of Ceylon tea in three instalments of 3000 lb. each be made to Mr. M. Rogivue in acknowledgment and furtherance of his work in Russia, and that the purchase and shipping of these grants be intimated to the Ceylon Tea Company, Limited, to be selected on the lines indicated in Mr. M. Rogivue's letter."

CEYLON TEA IN THE TRANSVAAL.

Considered information supplied by Mr. A. E. Wright. Resolved:—(I) "That the Ceylon Tea Company Li-

mitted be requested to arrange for transmission to Messrs. Paddon & Brock, Johannesburg, and to Messrs. J. W. Becket & Co. of Pretoria respectively grants of the Company's three Standard Teas, viz. 50 lb. each grade in 2 lb. packets." (II); "That the above mentioned firms be advised of these grants, the objects for which they are forwarded and the cost of the teas in the Ceylon market."

CEYLON TEA IN CONSTANTINOPLE.

Read letter from Mr. Millingen.

CEYLON TEA AT THE IMPERIAL INSTITUTE.

Read letter from the Colonial Secretary with enclosure from Mr. F. R. Saunders transmitted by the Committee of the Planters' Association for the consideration of the Standing Committee of the Tea Fndd. Resolved:—"That the Standing Committee of the Tea Fndd will be glad to afford any co-operation in its power in the matter referred to, and will be prepared to consider any proposals that may be submitted with regard to the supply of good and pure Ceylon teas at the lowest rates to contractors or on any other points likely to further the objects in view."

CEYLON TEA FUND ACCOUNTS.

Submitted balance sheet of the Tea Fund for the six months ending 31st December 1892, also printed statements of accounts for the year ending 31st December 1893.

The Standing Committee of the Tea Fund then adjourned.

A. PHILIP,
Secretary to the Planters' Association of Ceylon.

NOTES ON POPULAR SCIENCE.

By DR J. E. TAYLOR, F.L.S., F.G.S., &C.

EDITOR OF "SCIENCE GOSSIP," &C.

In the last number of the *American Naturalist* there appears a paper by Dr. H. W. Connon "Some Uses of Bacteria." These organisms are in the position of the dog which got a bad name. People think of them as microscopic foes whereas, generally speaking, many of them are our best friends. Every farmer expects that he will have to keep a good breed of horses and stock, but few of them are aware how they require a good breed of bacteria as well. Indeed no farmer can get on at all unless he keeps a good stock of bacteria on his farm. He is aware that he cannot make butter and cheese without cows, but, until recently, he did not know that even if he possessed the finest herds of kine, he would not be able to manufacture these articles of food without bacteria. Tillage, whether in the garden or the field, would be absolutely thrown away without their aid, for it is they which render all sorts of nitrogenic manure available. Bacteria are amongst the most lowly forms of plant life, very nearly allied to the microscopic yeast fungi.

Sir John Lubbock, in a recent lecture on the "Habits of Ants," said that the question naturally arose whether ants were moral and accountable beings. They had their desires, their passions—even their caprices. The young were absolutely helpless. Their communities were sometimes so numerous that perhaps London and Pekin were almost the only cities which could compare with them. Moreover, their nests were no mere collection of independent individuals, nor even temporary associations like the flocks of migratory birds, but were organised communities labouring with the utmost harmony for the common good. The remarkable analogies which to our human societies they presented in so many ways rendered them peculiarly interesting to us, and we could not but wish to know more of their character—how the world appeared to them, and to what extent

they were conscious and reasonable beings. Various observers had recorded in the case of ants instances of attachment and affection. He had never, in the whole course of his observation, noticed a quarrel between two ants belonging to the same nest. Within the limits of the community, all was harmony. On the other hand, it must be confessed that ants not belonging to the same nest were always enemies, even if belonging to the same species. Sir John went on to give details of a number of interesting experiments and observations, which, he contended, might be able to prove the possession by ants of almost human intelligence. One result which he adduced was that even in the largest nests the ants all recognised their companions. He had invariably found that if a strange ant, even of the same species, was introduced into a nest she was sure to be attacked and driven out. He had also made some experiments on the power possessed by ants of remembering their friends, and he had found that after a year's separation they did so.—*Australasian*.

HORREKELLY ESTATE COMPANY, LTD.

The following is the report of the directors of this company for the year ending 31st December, 1892 which was presented at a meeting this afternoon:—

1. The accounts now submitted for 1892 shew that the profit on the year's working, after writing off R1,903.18 for depreciation of Plant and Machinery at the usual rate, amounts to R11,753.49, which with the balance of R2,457.38 brought forward from 1891, makes a total of R14,210.87 available for distribution.
2. The Directors recommend that a dividend at the rate of four per cent. be declared on the paid up capital of the Company, thereby absorbing R14,053.60 and leaving R157.27 as a balance to be carried forward to 1893.
3. It will be noticed that there has been a great falling off in the yield of copperah during the year, which may be attributed to the abnormally dry season experienced in 1892, the rainfall on the estate in that year having been only 45.62 inches, against 100.86 inches in 1891.
4. In 1893 the first results of the systematic course of manuring, which was commenced in 1891, should become apparent, and the Directors will then be able to decide as to its permanent adoption. Those portions of the estate already treated under this course show marked improvement, and encourage the expectation that the plan adopted will be a success.
5. The working of the seasons 1890, 1891 and 1892 compares as follows (the item of interest being excluded):—

	1890.	1891.	1892.
Expenditure on Estate and i			
Colombo Office R.	29,492.09	33,567.28	30,576.73
Quantity of Copra produced .. Candies	941	995	738
Quantity of Coir Fibre made .. Ballots	21,850	41,804	44,821
Average price obtained for Copra, per candy ... R.	39.94	41.08	40.59
Average price obtained for Coir fibre, per cwt. ... R.	6.16	3.65	3.02

6. Two Directors—Messrs. F. C. Loos and C. E. H. Symons—retire and are eligible for re-election. The shareholders have to appoint an Auditor for 1893.

The meeting was held at No. 22, Baillie Street. There were present Messrs. E. Dalton (in the chair), S. Green, R. L. M. Brown (Secretary), F.

C. Loos, Schnell, Owen Morgan, Longmire, Grigson and F. W. Bois.

On the motion of Mr. Dalton, seconded by Mr. S. Green, the report was adopted.

On the motion of Mr. Longmire, seconded by Mr. Schnell, the dividend recommended in the report was declared.

On the motion of Mr. Bois, seconded by Mr. Grigson, Messrs. C. E. H. Symons and F. C. Loos were re-elected as directors.

On the motion of M. Green, seconded by Mr. Morgan, Mr. Richmond was elected Auditor on the usual fee of R100.

THE CEYLON TEA FUND ACCOUNTS.

We have received from Mr. A. Philip, Secretary to the Planters' Association of Ceylon, a copy of the printed accounts of the Ceylon Tea Fund for the year ended 31st December last. The first statement shows the payments and receipts on account of the Tea Kiosk, the former amounting to R684.40 and the latter to R966.67. The payments made in Ceylon on account of Ceylon Tea in Austria are shown to be R346.70; on account of Ceylon Tea in Germany, R3,188.10; on account of Ceylon Tea in America—(Grant of Tea to the Ceylon Planters' Tea Company of New York) R2,365.87; on account of Ceylon Green Teas R751.51; on account of Ceylon Tea in Vienna R458.79; on account of Ceylon Tea in British Columbia R17.00; on account of Ceylon Tea in California R75.00.

The balance in New Oriental Bank Corporation, Ltd., at 31st December, 1892, was R9,205 and the balance in Bank of Madras at 31st December, 1892, R8,779.

PEACH-GROWING IN GEORGIA.

Peach-growing has become an important and profitable industry in the central counties of Georgia. It is said by the Baltimore *Sun* that "Houston county alone produced last year a fruit crop valued at \$350,000, the most of which sum was realized from the sale of peaches. Some of the orchards in the county contain 200,000 trees, and a large number of them contain 5,000 trees or over. The Georgia farmers who are now turning their attention to peach culture formerly raised cotton exclusively, and suffered financially from the lack of diversity in their crops. Some of the finest peaches grown in the United States are said to be produced in the country around the city of Augusta."—*Bradstreet's*, Jan. 13.

HAILSTONES IN CAPE COLONY.

We have frequently read of the damage done by hailstones in India and other parts of the world, but never before of their being driven by the force of wind through galvanized iron roofing, even though the size of hen's eggs! But this is stated in the following report in the *Natal Mercury*:—

A fearful thunderstorm passed over Xaleoga district early in January. Trees were shorn of the leaves, fruit and bark, and crops of wheat, barley, oats, mealies, and pumpkins were beaten into the ground. Hailstones, the size of hen's eggs, were driven by the wind through the galvanized iron roofs. A long stretch of country was devastated. Many poorer farmers are penniless, and have no provisions until fresh crops come on. Meetings are about to be held to petition Government for relief, otherwise many families will suffer starvation. The estimated loss in crops alone is from £3,000 to £4,000.

CEYLON COCONUT OIL.

Since the beginning of the year there has been a steady improvement in the position of Ceylon coconut oil. Prior to that the market had been unsettled, although the improved position of competing products should have had stimulating influence. During the months of August to November inclusive last year, Ceylon oil was sold for shipment at, probably, the lowest price ever touched, namely four and three-quarters cents per pound. The extremely low price brought Ceylon oil prominently to the attention of soap makers, and particularly those who had never, therefore, used it; at that time the upward movement in animal greases, which has since assumed remarkable proportions, was beginning to be seriously felt by users. The result was that in a short time the consumption of Ceylon coconut oil in the United States almost doubled that of the corresponding period a year ago.

The European soap makers, who for a number of years have been pressing their own coconut oil from the copra, were last year much larger consumers of that raw material than even before. As a consequence, unusually large quantities of copra were exported from Ceylon to Europe so greatly decreasing the supply in the primary market as to cause a very decided reduction in the output of oil there. This shortage began to be felt in American markets about the beginning of October, though as the oil previously purchased for American account, at low prices, had been coming along, it had no really appreciable effect on the local market until a comparatively recent date. In Ceylon, however, prices have advanced since October 1st fully five pounds sterling, per ton.

At the present time the market, spot and future, is in a very strong position and advancing almost daily. The last quotation here, on stock to arrive was close to six cents for February-May shipments from the coast, and even at that price the oil is offered in very small blocks. There is little reason to believe that the large advance in coconut oil would have been possible, but for the great scar-

city of tallow and other animal greases. With tallow selling in Chicago, at date of writing, at six and five-eighths cents per pound, Ceylon oil may be considered very cheap at the present price, as a soap-making material. Evidently the large soap makers hold that opinion, for instead of being frightened out of the market by the advance in values, they appear to have accepted the situation and have bought freely of spot oil and oil on vessels in transit. Probably a thousand tons spot oil to arrive have been taken by them within a week at prices ranging from five and an eighth to six cents, the latter being the ruling quotation at this date with fair prospects that a further advance is not far off.

If predictions made by those who are thoroughly informed as to the position of tallow are verified, there seems to be no good reason why Ceylon coconut oil should not sell from store within say, at least one half cent per pound of the predicted price of seven cents for tallow, as in spite of all contentions to the contrary it is asserted, by those in a position to know, that all soap makers who know their business, can with advantage use twenty-five per cent. of Ceylon oil in the manufacture of various grades of soap, when the present relative cost of the oil and tallow are considered.

In view of the fact that the new crop of copra will not be available at Ceylon much before the end of March there seems to be no possibility of a reaction in market prices during the next six months as the advance is based entirely upon supply and demand and has not been influenced at all by speculative operations. It is generally believed that the sharp advance in lard, tallow and other animal greases, while it may have been contributed to, to some extent, by speculative manipulation, is well warranted by natural causes and may be considered permanent, while those conditions continue to govern the market. If this is proved the strength of the position of coconut oil is unassailable, and the prediction of still higher prices will be no doubt be fulfilled.

In passing, reference may be made to the condition of the market for Cochin oil. Prices for that grade have also sharply advanced of late, and there are now very few sellers and they are only willing to dispose of small lots, at six and a half cents, which, by the way, may be considered a low price compared with the average for a number of years past. It is impossible at this writing to get a quotation on shipments, for the next six months, under six and a half cents, and from direct reports from Alleppy it appears that very little oil is being offered there for future shipment.

In London on January 1st the entire stock of coconut oil, including Ceylon and Cochin, amounted to but six hundred and eighteen tons, which is, perhaps, the smallest available supply in that market, at the corresponding date, in many years. The entire stock of both kinds, as for London, on January 1st, was only about 1,000 tons, so that the supply for that market from January to April, inclusive, is only a little over sixteen hundred tons. This may be considered a particularly strong feature, and another argument in favour of high prices.

The advance in the East Indian oils makes room for a larger production and consumption of the product of manufacturers on this side of the Atlantic. Doubtless the output of oil in the United States would be largely increased were it not for the difficulty of getting adequate supplies of raw material, for reasons already cited. The West Indian output, which has not had much of an influence in this market, should be stimulated, but it is doubtful if the Cuban manufacturers could send enough oil here in time to get the advantage of the comparatively high prices ruling in this market. Before they could put any considerable supplies into the United States, it is probable that the effect of the new copra crop and the fresh output of East Indian oil would have caused a downward movement in prices, sufficiently marked to make the importing of Cuban oil undesirable, if not unprofitable.—*Oil Reporter*, Jan. 23]

INDIAN TEA COMPANIES.

CALCUTTA, Feb. 4th.

TEA SHARES have been much out of the running this week, and there has hardly anything been done. A number of good companies have still to finally close accounts of the season, and submit reports to shareholders, and dividends have yet to be looked for in a few concerns.

SINGTON TEA COMPANY has done well. The crop weighed out 1,452½ maunds, which realised 10-7½ per lb. against 8-10½ in the previous season. Profit and loss account is R20,744 to the good, and a dividend of 12 per cent is recommended. The estimate for the current year is 1,500 maunds. The shares of this Company are nominally quoted 110, but none are to be had.

SELEM TEA COMPANY.—The accounts for 1892 show a profit of R16,481 available to meet overdue interest on the debenture loan. Owing to adverse weather, only 5,847 maunds were made, against 7,050 estimated for. The average obtained was 6-30 annas against 5-58 annas in the previous year. For the current year finance has been arranged on same terms as before. Profit and loss account, as rendered, shows R1,50,819 to the bad, inclusive of interest to 31st December on the debenture debt, which the Company is again unable to pay. Taken altogether, the concern is in a worse position than at the close of 1891.

RANGURH COMPANY has again experienced a disappointing season, only 412 maunds having been manufactured, against an estimate of 625. The average works out annas 6-1 against annas 4-6 in 1891. During the past season a net loss of R4,288 was made, thus increasing the total debit of profit and loss account to R36,126. It is under consideration to abandon a part of the 344 acres of cultivation and concentrate energies on about 250 acres, the idea being that it may prove more remunerative to do so.

SINGBULLI AND MURMAH TEA COMPANY.—The output for last year was 1,945 maunds, against 2,200 maunds, but quality showed considerable improvement. Expenditure was about R2,500 less than estimate. Average was 11-17 annas on sale of the crop. A dividend of 8 per cent is declared, and R6,000 added to reserve fund. Estimate for the current year is 2,000 maunds at a total cost of R77,694. An addition of 15 or 20 acres to the plant on Murmah division is intended, and the cost is included in estimate given above.

CENTRAL TERAI TEA COMPANY.—Owing to unfavourable weather and blight, output was 1,867 maunds, against 2,200 anticipated. Average obtained was 6-41 annas per lb. Profit on season's working was R6,186. Profit and loss account shows R6,487 to the good, and a transfer of R6,400 is made to reserve for payment of extensions. Indebtedness to the bank was reduced to R13,445. Estimate for season is 2,000 maunds.

MOHUNGONG TEA COMPANY made a profit on season's working of R234, thus reducing to R6,325 the previous debit balance. The crop was 1,559 maunds, realising an average of annas 6-10 per lb.

SPRINGSIDE TEA COMPANY earned R17,727 net, which, with previous balance, makes R18,851 available. An 8 per cent dividend is recommended, carrying R5,141 forward. The output was 927 maunds, that brought in an average of annas 11-8 per lb.

CALCUTTA, Feb. 18.

MATELLI TEA COMPANY.—Revenue Account shows a gain in the season of R1,56,110 obtained off 6-477 maunds of tea and 290 maunds of seed. Inclusive of balance carried over from previous year a total of R1,62,596 is seen in profit and loss account as the profit to be dealt with. The capital of the concern is only 2 lakhs, and an *ad-interim* dividend of 50 per cent was declared in November, which is now supplemented by a further 25 per cent, making in all 75 per cent of the season. The quantity of tea sold includes small lot manufactured at Matelli off leaf purchased from Moorte, an adjacent garden. The average prices realised were annas 10-7 for fine tea and annas 5-10 for coarse. The estimate for the current year is 7,000 maunds for an outlay of R2,18,350,

inclusive of R8,350 for tea seed, nurseries, and extensions. The area in full bearing is 753 acres, of which 50 acres are seed reserve; plant, therefore, yielded over 9 maunds of tea an acre.

CHALOUNI TEA COMPANY.—This is another high class garden. The total at credit of profit and loss is R89,623. A 20 per cent *ad-interim* was previously paid, and a final of 15 will make 35 for the year on the capital of two lakhs. To reserve for working expenses, R15,000 is appropriated, leaving R4,623 to carry forward. The outturn was 4,997 maunds and average obtained annas 9-3 per lb. A sale of 44 maunds of tea seed was also made. An extension of 59 acres is in progress which will make 675 acres of plant, and it is anticipated that 5,370 maunds will be manufactured this season.

SOOM TEA COMPANY.—Outturn was 1,487 maunds, and average on sales made in London up to date is the equivalent of 12½ annas. Revenue shows R33,714 to the good. In addition to the *ad-interim* of 5, a final of 6 is recommended, making in all a dividend of 11 per cent, which leaves a balance in profit and loss account of R2,460 to be carried forward. Taken altogether the Company has had a most successful season, having also been able to pay off out of profit the balance of R5,000 at debit of machinery account. The estimate for this year is 1,450 maunds, but this should be exceeded, with favourable weather. An additional 15 acres is to be laid out; the present measurement of plant is 425 acres.

DEHERA DOON TEA COMPANY.—The net probable profit on tea, zemindari and forest, is shown in the accounts as R40,241. A hailstorm in May damaged the bushes, and the outturn was 4,020 maunds, which is somewhat short of estimate. From zemindari and forest work prospects are stated to be more promising, but tea markets in the district are described in the report as verging on stagnation. A dividend of 4½ per cent. is recommended.

ATAL TEA COMPANY manufactured 1,418 maunds and realised an average of 8 annas a lb. Revenue results in R14,702 to the good. Profit and loss account in adjustment shows a credit balance of R11,879, which is transferred to block account, in reduction of the debt carried forward from last year. The concern has leased from the Sath Bbia Company for five years the property of the latter on favourable terms. Some additions to machinery are being made. The estimate is for 2,300 maunds, which if accomplished should prove satisfactory.

OKAYTI TEA COMPANY made 332 maunds and obtained an average of 10-81 annas. Expenditure exceeded revenue by R3,506. In adjustment in profit and loss this is increased to R5,800, which amount is transferred to block, the last named account being thereby increased to R1,34,405. The plant is now coming into full bearing, but the first profits will be placed to credit of reserve as a set-off against the excess of block over capital; by this method of treating the accounts, block will always show the actual original cost of the garden. The estimate for this year is 500 maunds tea and 20 maunds of seed.

KALACHERA TEA COMPANY.—In revenue account a profit in the season of R26,197 is shown, but as season 1891 closed with a balance of R47,587 at debit of profit and loss, the gain appearing is absorbed, and in adjustment it is seen that the concern is now R26,640 to the bad. The outturn was 2,215 maunds and the sales averaged annas 7-3 per lb. The total area of plant is 525 acres, from which it is estimated next season to obtain 2,650 maunds.—*Pioneer*.

CEYLON PLANTING REPORT.

(Notes by "Wanderer.")

Feb. 23rd.

ESTIMATE OF CROP, 1893.—The appended letter to the *Englishman* shows that Indian planters cavil at the Indian Tea Association's estimates. By pitching their minimum estimate at 74,000,000lb., I think the Ceylon Association gives itself away to the heathen Chinese. Why, that is only two and a half millions more than last year.

According to Forbes & Walker's circular we are to the 16th of February a million lb. ahead of last year at same date. Going on at that rate we should be 8 millions of tea in 1893 ahead of 1892.

To the Editor of the "Englishman."

Sir,—In the lately published Tea Crop Estimates of 1892, I note that the differences between "Original Estimate" and "Actual Crops," as given by the General Committee of India Tea Association amounts to no less than 16 million pounds.

It is to be hoped that greater discretion will be used in framing estimate for 1893 if the publication of such an estimate be of actual necessity. It is doubtful if such estimates be of advantage to any one. Certainly they cannot be of advantage to the seller; they may be to that of the buyer and speculator.

I submit that, in the interest of the Tea industry, no such "original," or preliminary Estimates should be published, as they must be simply guess work. A half-yearly, or quarterly, crop return should suffice for all purposes, if such a publication be deemed essential.

PROPRIETOR.

WEATHER.—Dikoya and Maskeliya have been fortunate to get good rains. Elsewhere every one is crying out. One hears of a terrible drought in South India; so we may look out for lots of coolies and high priced rice. Some of our enterprising Colombo merchants may see their way to get rice from Burma and thus save us from the Chetty.

"Mosquito BLIGHT" seems to be touching up our Indian brethren. Has it done any harm here as yet? The following letter to an Indian paper may be interesting:—

To the Editor of the "Englishman."

Sir,—Very erroneous ideas prevail as to the nature of the so-called mosquito blight, named from its fancied resemblance to that much abused insect. However, the one that attacks the tea-bush is not a bloodsucker, and the principal cause of its disastrous effects is not the amount it eats, although nearly every leaf bitten by it turns black and shrivels up, but the female is provided with a boring apparatus with which she bores a hole into the centre of the young succulent shoot just below the first leaf and deposits an egg; the shoot then turns black at this spot and soon dies off. This is not confined to the tea-bush alone. Last October I saw a vegetable garden at least two miles from any affected tea, in which the whole of the seedlings irrespective of kind were killed off by this devastating pest. Burning the prunings, which has been resorted to on many gardens, is useless to effect a remedy, as the egg and grub only exists in the young succulent shoots. Given suitable damp weather for their propagation, vigorous bushes are powerless to resist its effects. They only give a greater number of shoots for the female to deposit its eggs in, and instead of three or four in a shoot you will find, if there is a sufficient amount of young wood, (only one in each), the result is the same, the egg penetrates quite to the centre, and whether one egg or more the shoot always dies. The vigorous bush, of course, has the advantage if dry hot weather prevails, but when a garden is over badly attacked, it is very rarely the case that there is a sufficient long spell of it to do much good.

That the mosquito blight comes out of the jungle there can, I think, be no doubt, also that the immunity of the gardens on the Southern Tarai to this scourge is to be traced to the absence of that dense growth of jungle on the windward side of them which prevails closer under the hills.

SHAREHOLDER.

CHINA TEA.—I am glad to note that the Australians are putting their foot down on the importation of bad tea. A stoppage of 300,000 lb. of bad and spurious tea at the customs seems to be a very practical measure. I wonder if the home authorities are equally firm.

LOW PRICES FOR TEA at home are accounted for by an absence of country orders owing to the general badness of trade and agriculture.

TEA.

[*Fireside Facts from the Great Exhibition, by the Editor of "Pleasant Pages": being an Amusing Series of Object Lessons on the Food and Clothing of all Nations in the year 1851, p. 52 et seq.*]

(Concluded from page 558.)

L. Now, papa, will you please to give us the history of tea?

P. Yes. But before we leave the *qualities* and *uses* of tea, I may as well add that in the composition of the tea-leaf are found two metals, viz., iron and manganese,—of course in very small quantities. Again, you said that tea was astringent. This is because it contains the substance which I said was found in the bark of trees.

W. Do you mean *tannin*, papa!

P. Yes. I once heard a lecture from a chemist, in which he amused the company with a curious fact. You know that the *tannin* of the oak-bark is used in making leather. The lecturer showed us that when the tea with milk in it reaches our stomachs, the curds of the animal substance, milk, are often hardened by the *tannin* in the tea, so as to form a thin tough substance, like leather.

W. Then I won't take any more tea! I don't like the process of leather-making to be going on in my stomach.

P. The *tannin* in tea has, however, been rendered useful. There have been cases in which it has been used as an antidote to poison. Even *arsenic* has been decomposed by the astringent *tannin*.

The *natural history* of tea is the next point to engage our attention.

The Natural History of Tea.—Tea is brought from China, where it is grown principally on the hills, and in dry soils. It flourishes best with plenty of light, air, and a good sunny aspect. The plant is a species of *camellia*, and it is cultivated by means of seeds. The plan of culture is very simple. When a new plantation is required, the ground is carefully prepared, and a number of holes, about four or five inches deep, are made. The holes are about five feet distant from each other to allow space for the young plants to grow. The seeds sown are always such as are quite fresh, as from their oiliness they do not preserve well. Five or six seeds are sometimes dropped into each hole, as their growth is very uncertain. Frequently all of the seeds will grow: and as the plants rise and grow together, they form a large bush. After they are sown, very little trouble is necessary, except that of clearing away the weeds. The trees are left to grow for three years, when the plantation yields its first crop.

If you were to ask a Chinaman which are the best kind of leaves, he would tell you that those which are from the young wood, and are grown in exposed situations are the best. He might further inform you that the leaves are gathered three times in the year; those which are gathered in April being of a *bright* and *delicate* colour, and aromatic flavour, and without bitterness; the leaves which are gathered at Midsummer being of a *duller* colour, and less pleasant taste; "while" he would add, "the leaves of the third gathering are of a *dark green* colour, and very coarse and inferior." "As the trees become older" he would tell you, "the leaves are less valuable, and when they are seven years or ten years old they are cut down. Numerous young shoots then spring up, and give a good supply of young wood and leaves." Thus you see how many different qualities of tea there may be. The quality of the leaves depends on the time of gathering, the age of the plant, the soil, and the situation in which the trees grow.

W. And I should think, therefore, that it is very

easy to procure *bad* tea, when the good quality depends on so many points.

P. When the leaves are gathered, they are put in wide shallow baskets, and are exposed to the air or sun for some hours. The first dampness of the leaves is thus removed, and they are now ready for the drying-pan. The drying-pan is made of cast-iron, and is of a flat shape. When the Chinaman is going to dry his leaves, he prepares a fire of charcoal, and places the pan over it; he then puts in not more than half or three-quarters of a pound of leaves, and stirs them about quickly with a kind of brush. When they are ready, they are swept out of the pan into baskets; and, as soon as a basket is full, it is handed over to another workman, to undergo the operation of *rolling*. This he performs by carefully rubbing them between his hands. The fourth operation is that of *drying the rolled leaves*—they are again placed in the pan, but in much larger quantities; and are heated just sufficiently to dry them without scorching.

The fifth operation is that of *picking and cleaning*: when all the leaves that are imperfect, or not dried properly, are removed.

The last operation is that of *packing* it in chests, which are lined with tin-foil, and sent to England, and other countries. I might as well add that the Chinese preserve their own tea in porcelain jars, with narrow mouths, which they say give additional aromatic flavour to the tea.

W. You have told us, papa, of six operations: but I think you have left out the history of the *tea-picking*, which is the first thing.

P. Yes. And that is a very important business, especially when the finer sorts are being picked. The collectors of fine tea are generally men experienced in their business, and trained to it from a very early age. They are compelled to clean themselves three weeks before they begin their work; and they are forbidden to eat fish, or any other kind of food which is reckoned unclean, lest by their breath they should contaminate the leaves. They are also made to bathe two or three times a day; and when they gather the leaves they must not use their naked fingers, but must wear gloves.

W. There, papa! You have mentioned *seven* operations. The picking—drying in baskets—drying in a cast-iron pan—rolling—drying of the rolled leaves—picking and cleaning of the rolled leaves—and the packing of the leaves in tin-foil. So that we have learned the "qualities," "uses," and "description" of tea. Now will you please tell us of the different sorts?

P. Yes.

The different sorts of Tea.—There are *too* many sorts of tea! but they may be arranged in two divisions—the *good* sort, and the *bad* sort. Let us first name them according to their place. Beside the CHINESE TEA, there is a tea which, about twenty-five years ago, was discovered growing wild in a district of India called Assam. Assam is in the north-east corner of India, near Bengal and Burmah. The ASSAM TEA, when it first attracted public attention, became very celebrated, as it was grown in a colony belonging to England. On account of its novelty it sold at very extravagant prices.

The tea-plant may also be grown in England, being very common in our conservatories. It may be seen growing in Kew Gardens, or in Messrs. Loddige's gardens at Hackney.

The list of names of the Chinese teas is almost endless. It is said that in the catalogues of the Chinese merchants there are at least 150 names. Many of these names, however, are only invented to impose upon foreigners and obtain a high price.

The principal kinds of tea, however, are the BLACK TEA and the GREEN TEA.

The plants from which the Green Tea is picked are more hardy than the others, and will flourish when the snow is on the ground. The two teas are cultivated in different parts of the Empire. The principal difference between the green and the black tea is, that the green tea leaves are gathered without the stalks, and are not prepared like the black. It was supposed, at one time, that the green colour

of the leaves was owing to their being dried on copper pans, but this I believe is not correct. It is true, however, that the Chinese can so change damaged black tea by the addition of colours, &c., that it cannot be distinguished from the green. The principal black teas are named *Bohea*, *Congou*, *Souchong*, and *Pekoe*; and the principal green teas are *Singlo*, *Hyson*, and *Gunpowder*.

There is a species of tea called *Tile-tea*, because it consists of leaves and leaf-stalks, compressed in the shape of a flat cake or tile.

The *bad* kinds of teas are the coarse large-leaved teas, which are obtained in the third picking season. These are by no means good for common use, and are often used in *dyeing*. The poorer classes of Chinese also use them. But the worst kind of all are the *adulterated* teas. It is well-known that the Chinese use many strange substances to mix with their tea. It is adulterated still more in England, where the leaves of the elm, ash, hawthorn, sloe, and apple, are mixed with the tea. Old tea leaves are also dried, and chopped up with stalks of raisins. In Germany, green tea is adulterated with the very young leaves of the strawberry plant. It is singular that we cannot, in England, enjoy the very fine teas, in which the Chinese take so much pride, for they are always spoilt by the sea-voyage; the change of climate, and the dampness from the water, deprive them of their fine flavour.

Ion. Now, papa, that we have heard of the *different sorts*, will you give us the *history* of tea?

P. If we do not find the subject too long. I will try and make it as short as possible.

The History of Tea.—TEA has a separate history in the different countries in which it is used. The Chinese history of tea begins (like many more Eastern histories) with a fable. It is said that in A.D. 516 a good Indian prince, of religious habits, came to China as a Missionary, intending to set a good example to the natives and to teach them their religious duties. However, he was once so overcome with his long fasting and want of rest, that he fell asleep; he was then so angry with himself, that he cut off both his eyebrows and threw them on the ground. Both of these eyebrows grew, and became tea shrubs—the first ever known! The Indian prince soon discovered the virtues of the shrub, and recommended it to his disciples. They all declared that it gave their minds fresh vigour, and its use became general.

The *English History of Tea* may begin with an Act of Parliament. In an Act of Parliament of the year 1660 or 1661, it is ordered that 8*d.* per gallon duty be charged on all *tea*, coffee, or chocolate for sale. Thus you see that all three of our well-known drinks were then in use. Tea had perhaps been introduced to England some time—it is most likely that it was procured from the Dutch East India Company, who first sold it in Europe. It is likely that its use was known about the same time as that of coffee, which, you may remember, was first sold in England in the year 1652.

Ion. Yes, I remember, papa, your telling us of the Greek servant who opened a coffee-house near Cornhill.

P. The continuation of the history of tea is connected with that of the EAST INDIA COMPANY. It appears that its use was not very general for some time; for in the year 1664, they purchased, as a present to the king, *two pounds and two ounces of tea*. Five years later, in the year 1669, the directors ordered their servants in India "to send home by their ships *one hundred pounds of the best tea* they could get;" to be sent on speculation. In 1671, we read of their importing a package of 150 pounds—in 1678 they imported 4,713 pounds. It then became well worth the consideration of the company as an article of trade, for it still yielded the large price of 60*s.* per pound. The EAST INDIA COMPANY, therefore, obtained a "charter," by which they were allowed to keep the whole tea-trade of England in their own hands. Such a charter, which prohibits others from competition, is called a *monopoly*; its purpose is very unlike that of the Great Exhibition, and the Free Trade of the present day. On the

abolition of the Company's charter, in the year 1834, the tea-trade immediately improved. The yearly sale was then above 31,000,000 pounds, but it has since increased to more than 40,000,000 pounds per annum, and yields an enormous sum of money to Government as *duty*.

The history of tea in Scotland may begin with an anecdote. A pound of fine green tea was sent to a certain lady as a rare and valuable present. The lady took care to have it cooked! It was served up with melted butter and salted meat, but the cook found that the tea was not exactly "suitable." She complained to her mistress that "she had tried all manner of ways to cook them, and she didn't believe that all the cooking in the world would ever make those *foreign greens* tender!"

L. And now, papa, *end* the history of tea with an anecdote! will you? for I am getting tired of it.

P. Very well. Even in the present century people will stick to the idea of *cooking* tea. I told you of the quantity of coffee used in Germany, but the Germans, especially the "Rhinelanders," who live around the river Rhine, drink plenty of wine, and therefore know little about tea. A gentleman whom I know, and who is an artist, was travelling in Germany about 40 years ago, and had quite tired himself by sketching all day; so when he returned to his inn, he called for some *tea* to stimulate his weary frame. Poor man! his mouth was hot and dry; how long and anxiously he waited for that tea! At length it came! Yes! In came the maid, triumphantly bearing the smoking tea in a *tureen*. "Very odd!" he thought "to bring me my tea in a tureen; but, never mind, here is a ladle; they wish me to drink it like soup." No sooner had the German damsel turned her back than the thirsty man lifted up the lid joyfully, and—ah!—wha-a-a-at? The German cook was no better than the cook of the Scotch lady! The tureen was full of *tea leaves*, which formed a hard compact mass, for they had been carefully squeezed, so that *all the water had been drained off!* He was much surprised, but not half so much as the people of the inn, when he rang the bell violently, and insisted on their bringing him, instantly, *the water those greens were boiled in.* Fortunately it had not been thrown away; and, to the still greater surprise of the whole household, he exchanged his tureen for the steaming saucepan; placed it before him on the floor; and while they were gone for cup and saucer and milk and sugar, he laded some of "the water those greens were boiled in" into his drinking-horn.

So you see that the quality of tea may not merely depend on the soil, or the climate and country in which it is cultivated; it may depend on the people who prepare it. There! we have talked long enough about tea!

LESSON ON TEA.

TEA.—(Qualities). Tea is a light, dry, shrivelled, crisp, pulverable, black or green vegetable substance: It is a natural production, but is imported in an artificial state. In its effects it is stimulating, refreshing, and exhilarating.

The tea produces those effects by its action upon the nerves, because it contains a peculiar element called THEINE. This Theine is said to assist in forming bile, and thus to help digestion. Tea, it is said, has been much used in the countries where vegetable food is eaten, as such food is harder to digest than animal substances.

Natural History.—Tea is the leaf of a shrub growing in countries outside the Tropics, and particularly in China and India. The operations of picking, drying, rolling, and cleaning of the leaves are performed with great care and require much skill. The quality of the leaves depends on their age, and the age of the plant; it also depends on the situation and soil in which the plant is grown, and on the time of picking. There are three picking seasons in the year; the leaves of the first picking are the best. The two principal sorts of tea are the BLACK TEA and the GREEN TEA.

History.—Tea was introduced into England at nearly the same period as coffee, about two hundred years ago.

THE TALGASWELA TEA COMPANY.

ANNUAL MEETING.

The annual meeting of the Talgaswela Tea Company of Ceylon, Ltd., was held this afternoon in the offices of the Secretaries, Messrs. Baker & Hall, Colombo. Mr. T. C. Owen occupied the chair, and the others present were:—Messrs. T. W. Hall, J. F. Baker, G. Armitage, Shelton Agar, W. H. Davies and F. C. Loos, there being represented by proxy Mrs. J. J. Hall, Mrs. W. H. Davies, Mrs. J. F. Baker, Mrs. G. A. Borrett, Messrs. Richard Hall, R. & T. W. Hall, Jas. Labouchere, Robt. Patry, E. G. C. Mitchell, J. J. Cater and J. A. G. Cater, J. J. Cater, J. C. Sanderson, J. L. Mitchell, H. P. Cater, C. A. Cater, C. L. Scott, G. Chapman Walker, G. W. Suhren, A. T. Broadhurst, H. P. Rudd, James Forbes. The report of the directors for the year ended 31st December last was as follows:—

The Directors beg to place before the Shareholders their Fifth Annual Report, together with a duly audited statement of the Company's affairs and financial position as on 31st December, 1892.

In July last the Company's property was visited by Mr. Grigson, who then thought that a result not greatly below the estimate of 180,000 lb. would be obtained. Your Directors regret to state, however, that the crop is very largely short of the estimated amount, being only 118,070 lb. Tea.

June, July, and August, instead of being wet months, were dry and windy; whilst December has been almost rainless. The effects of such unfavourable weather in a low country district are very serious as regards yield of leaf. The tea realised an average nett price of 89.29 cts. per lb., a close approximation to the estimate of 40 cents.

The profit for the year has been R5,696.73 which, after writing off the balance brought forward from 1891, leaves R2,009.43 at the disposal of the Shareholders. This balance is insufficient for the payment of a dividend on the ordinary shares. The interest payable to preference shareholders has been provided for in the statement of accounts. It is with extreme regret that your Directors have to report such a disappointing result, but they feel assured that but for the adverse season, the estimated crop would have been obtained, and they hope for satisfactory results during the coming season.

The Railway has now almost been completed to Amblangoda, and will shortly reach Hikkaduwa, which will make Talgaswela more accessible and facilitate the transport of produce.

Messrs. Owen and Suhren retire from the Directorate, in rotation, and offer themselves for re-election.

Mr. HALL read the notice calling the meeting and the minutes of previous meetings.

The CHAIRMAN in moving the adoption of the report said all of them must feel very much disappointed at the unsatisfactory fact that they had not been able to declare a dividend for the past year. Circumstances had been very much against them. The season was an extraordinarily bad one, and he understood that almost all the estates in the Southern Province were short of their estimates. The south-west monsoon in June, July and August was almost a total failure; and the north-east monsoon during November and December was almost equally bad. In December, instead of being a very wet month, there were only two days of rain. These circumstances he thought explained to a great extent the short result of the crop. In July, when Mr. Grigson visited the place, he thought they would very nearly get their estimate and it was during the latter six months of the year, that the results had been disappointing. In spite of the fact that they only got two-thirds of the estimate they still had a result, which he thought not unsatisfactory on the whole. They had a substantial sum of money, which had put the

Company in a very much better position than last year. During the year Mr. Broadhurst proposed to go home, and the directors wished to allow him to go on full pay. He had worked very hard, and had had one or two severe bouts of illness, and there was no doubt it was most necessary he should get a change. He hoped therefore the shareholders would agree in granting leave. It was proposed that Mr. Stirling, the present assistant, should be Manager during his absence, as he knew the Sinhalese, and they seemed to know him, and Mr. Broadhurst thought he would be able to manage. Mr. Broadhurst was going home in May, and it was hoped that he would be able to return in the autumn and take up his work on the estate.

Mr. F. C. Loos in seconding said he must confess that the results were very disappointing, but that was through no fault of the directors or officers of the Company, but owing to the exceptionally bad weather, that had been experienced. That was a matter over which they had no control. And he was sure that the directors and officers of the Company had done their utmost to give satisfaction to the shareholders. The report was then adopted.

On the motion of Mr. DAVIES, seconded by Mr. ARMITAGE, Messrs. Owen, and Suhren were re-elected directors; and on the motion of the CHAIRMAN seconded by Mr. HALL, Mr. Guthrie was re-elected auditor.

The proceedings terminated with a vote of thanks to the Chairman, moved by Mr. HALL.

STOCKS, SHARES AND TRADE.

CALCUTTA, Feb. 11th, 1893.

NEDEEM TEA COMPANY.—This well-known concern in the Western Dooars is, for the fourth year in succession, given a 25 per cent dividend. The capital is 3 lakhs and the gain for the season R1,56,979. The actual amount available in profit and loss is R1,59,296. In writing off the cost of new machinery R14,058 is applied. Three-quarters of a lakhs goes towards addition to working capital, thus raising that account to 2 lakhs, and R10,237 is carried forward. Outturn was 11,768 maunds, and average obtained 8½ annas per lb. The estimate for this year is 11,800 maunds on a total area of 1,552 acres, or close on 8 maunds an area, but with favourable weather it is hoped the yield will be exceeded.

CARRON TEA COMPANY made a profit of R29,435 in the season. A sum of R3,466 is applied to block, being the excess in that account over capital, and a dividend of 10 per cent is proposed, which will leave R4,968 to carry forward. The crop weighed out 2,523 maunds, and realised an average of 8 annas 10 pies per lb. The concern has done well, having further provided for new machinery, value R11,082, out of revenue.

NAGAI SUREE TEA COMPANY.—Outturn was 3,520 maunds, averaging 8 annas 4 pies, off an area under plant of 600 acres, and this year the estimate is for 3,800 maunds. The net profit was R46,012. By application of R23,173 to block, that account is now equalised with capital. After payment of an 8 per cent dividend, the balance of profit will be carried forward.

HOOLUNGOORIE TEA COMPANY.—Gross profit was R39,595, and net balance in revenue account R26,318. In profit and loss account, including balance from last season and after adjustment, R34,438 is seen to be available. A 6 per cent dividend was previously paid, absorbing R24,000, and the balance of R10,438 is being carried forward. Outturn, 2,537 maunds, fetched an average of 9½ annas per lb., and this year it is intended to make 2,750 maunds and to extend 58 acres.

SINGELL TEA COMPANY.—The accounts show R33,200 to the good, which will allow of a dividend of 5 per cent. Outturn was 2,308 maunds, and the net average obtained was 8.87 annas per lb. The estimate of crop this year is 2,525 maunds. The manager's report on the condition of the garden generally will be satisfactory to shareholders.

PANKABAREE TEA COMPANY.—This concern worked to a loss during the past season. Unfavourable weather and mosquito blight led to only 432 maunds being manufactured, quality being also inferior. The balance at debit of profit and loss account is R1,465. The Company has leased for three years the gardens of Second Falloodhi. In action, it is believed, will lead to better results. The joint estimate is for 1,500 maunds of tea this season.—*Sponsor*, Feb. 11.

KOLA: THE LOWCOUNTRY PRODUCT OF THE FUTURE.

An esteemed correspondent writes:—

I enclose two slips about Kola from the *Jamaica Gleaner*, which may be useful, and Kola will probably be a paying lowcountry product of the future. Mr. Christy of London has sent me a tin of prepared Kola for trial, and it is simply delicious in boiled milk, and if not too dear, I should think would be drunk largely. From the extract we quote as follows:—

(*Jamaica Gleaner*.)

THE FURNITURE OF KOLA.

The thousand Kola plants offered at the price of two pence each by the Director of Gardens should be quickly bought up and planted in suitable soils. It is to be hoped that he has many more coming forward, for there can be no doubt that Kola has a future. Its value has been proved, and its relation to coffee and cocoa is the best of evidence, taken along with its peculiar properties, to ensure an extensive use at an early date. Mr. Kirkead has made from it, with aromatic herbs, a pleasant beverage that is finding its way into many homes. "Kola Champagne" is rather too fine a name for it, but the thing itself is excellent. The dried and ground nuts have been sold to be used as coffee but unfortunately in many cases, the failure to prepare it properly has led to a loss of the favourable reputation with which it was first begun. In homes in different parts of the island the knack of preparing kola as a beverage is understood, and there a cup of kola is at once palatable and refreshing. It has been proved that the nuts thrive here, and it is to be hoped that guided by what Mr. Fawcett has said of soil and climate suitable for the plant, the 1,000 young plants may soon find their way to the right places, and a few years hence be bringing grist to the planter's mill. Tea, coffee, cocoa have hitherto had it all to themselves, and they have had it long and over a wild field, kola will certainly take a place beside them and also fill a large place, such are its proved merits. It should in the near future take a good place among our exports.

COMMUNIQUE FROM THE DIRECTOR OF PUBLIC GARDENS AND PLANTATIONS: KOLA NUT OR BIS-Y.

The Kola Nut or Bissy (*Cola acuminata* R. Br.) is a native of western tropical Africa. It is a tree from 30 to 60 feet high, flourishing best in moist lands from sea-level up to 1,000 feet. A full crop of 120 lb. of nuts or seeds cannot be expected till the tree is ten years old, but in favorable situations fruit may appear after four years. Great care is taken in Africa in the selection of nuts for sale, they are carefully picked out, and damaged and worm eaten are removed. The sound nuts are packed in huge baskets made of bark, lined and covered with large thick leaves. The baskets hold each 3 cwts. With the leaves on the top kept moist; the nuts last well for a month; after that they are picked over again, washed and repacked, and will last for another month; this process being repeated every month. From the country between Sierra Leone and the Congo they are carried to Gambia where the merchants trading with the interior, purchase and dry them. It is said that by the time the nuts reach the tribes who live furthest from where they grow they are worth their weight in gold. The nuts are reputed to clarify and render healthy the most foul water, and to render tainted meat edible, and when chewed either fresh or as a dry powder and the saliva swallowed, to be a sure preventive against dysentery. They are also said to be good for the liver and to possess the property of enabling persons eating them to undergo prolonged exertion without fatigue. Dr. Neish says that the nuts, furnish "a nutrient and stimulant beverage, rich in the active principle of coffee, containing also a large proportion of theobromine, the active principle of cacao. These nuts, in addition, contain three times the percentage of starch contained in chocolate, and moreover, they also contain less fat, so that besides stimulant and nutritive properties, there is the probability that a chocolate prepared from them will more readily agree

with delicate stomachs. What enhances the value of kolanuts, is the fact that citrate of caffeine—a medicine now much employed for the relief of sea sickness, migrain, and other nervous complaints—can be readily obtained from these nuts, for the reason that the nuts contain more caffeine than coffee berries, and in the kolanut the caffeine is in the free or uncombined state." There are now about 1,000 stroug plants at Hope Garden, ready for distribution. They will be delivered in Kingston at the rate of 2d. each. Application may be made direct to Superintendent, Hope Garden, Kingston P.O. Not much has yet been done with the Kola-nuts in Ceylon; but it has scarcely had a fair trial in the lowcountry, save at Henaratgoda Gardens, and there it has grown to the satisfaction we believe of Dr. Trimmen. Who will give it a proper chance in the Awisawella, Kalutara and Galle districts.

OPPORTUNITIES FOR YOUNG MEN IN JAMAICA.

BY H. E. SIR HENRY A. BLAKE,
GOVERNOR OF JAMAICA.

The following appears in the *North American Review* for December:—

The Jamaica International Exhibition which was opened by H. R. H. Prince George of Wales in January, 1891, and remained open until May, resulted in the influx of a considerable number of observing visitors, and the dissemination of a large amount of information, through the English and American press, as to the Island its beauties, its progress and its capabilities. The interest aroused on both sides of the Atlantic has been shown by numerous letters received by me and by others in the colony asking for further information, especially as to the prospects of success for young men desirous of trying their fortune and the beautiful surroundings so often described, but whose infinite variety baffles the power of words to fully paint.

These inquiries resolve themselves into two divisions—those who have capital and those who have none. To the latter I have always replied that there is no opening for them. The inquirer with the capital I have advised to come to Jamaica, and to spend at least twelve months in examining the different parts of the island before investing his money. If he can get temporary employment on an estate or on a "pen," so much the better. He will learn how to deal with the people, and also find out if the climate suits him for practical work. It must be remembered that visiting a tropical country is very different to working in it. Even though the work be simply supervision. If he is satisfied, he can then choose whether he will invest in the purchase of a pen, and become a breeder of cattle, horses or mules, or all three; or whether he will purchase an estate, that is, a property on which the business is the cultivation of sugar, coffee fruit or fibre.

As to the kind of crops that can be produced in Jamaica, if we leave out the cereals, wheat, barley and oats, the island will produce anything that can be grown in the North American continent. Its soil, elevation and climate are so diversified that while sugarcane and pine apples are growing in the plains, English gorse is in bloom in the high hills, and wild strawberries abound on all the mountain paths.

It is not my intention to go into particulars of the various crops that now form the staple exports of Jamaica. Suffice it to say that they pay the growers well, when the profits are not swallowed up in the expenses attending the management of properties belonging to absentees. The average cost of management and commissions on such properties is about 10 per cent., at least one-half of which could be saved to a resident and industrious owner. But the crops may be divided into two broad divisions, those that pay best when grown extensively, and those suitable for small proprietors, of whom over fifty thousand are to be found in Jamaica. In the

former category we will have sugar, bananas, coffee, cacao, oranges, tobacco: and in the near future I hope to see the cultivation of the *agave rigida*, or sisal hemp plant extend. Small growers can profitably produce ginger, nutmeg, maize, tomatoes, yams, onions, potatoes and other vegetables suitable for the Canadian or American markets.

Grapes grow as freely as in California, and only require careful cultivation to yield very large returns. All these crops are capable of enormous expansion, but the carelessness of our people prevents them growing them with as much profit as might be made. The Jamaica oranges are the best in the world; there is no systematic care taken of their growing, picking, sizing and packing, as there is in Florida. So far there has been no attempt to grow separately the different kinds of bananas although the trade has expanded in 10 years from the export value of £44,215 to £531,726.

There are large coconut walks in the island. The nuts are sold for about three-fifths of the price given for Baracoa nuts. No care is taken, as in Mauritius and elsewhere, to thin the branches as grapes are thinned and thus give room for the nuts to grow. Everything is left to nature, and so bounteous is she that she yields with lavish hand, paying returns in defiance of a system that violates every canon of successful agriculture.

But, it may well be asked, if there are all these opportunities for the investment of capital, how comes it that while young Englishmen flock to Manitoba or Nebraska, the Cape, New Zealand or Australia, undeterred by distance or climate, and ready to begin a hard struggle by building a log hut, they neglect the island of Jamaica, in which they may find houses ready built, fences ready made and fields that only require the ordinary annual operation for putting in the crop? And, further, how is it that the owners of these small properties are so ready to part with them for a small consideration?

The answer is simple. When the work of a slave, with interest upon his value could be had for about £15 a year, and when sugar sold at £60 per ton, it paid for the reckless extravagance of the vicious and riotous living of many of the local managers and owners. It paid for the appalling waste of human life. Cargoes of young men came out year after year and were plunged into a fiery furnace of temptations that only a moral hero could withstand. By scores and hundreds the yellow fever claimed them, and if men lived now as they lived then, it may be assumed that yellow fever would become a perennial scourge. But the absentee owner in England drew a princely income and asked no questions. With falling markets incomes fell, and the manumission of the slaves accelerated the downward movement. Some managers refused to accept the dictum that emancipation involved the right to abstain from labour. They could not realize that to a slave whose life had been one long weary round of coerced labour relaxation from work must have been the greatest happiness, and they drove from the estates the people, who, from the first ecstasy of freedom, refused to give for a daily wage the same steady labour they had erstwhile yielded to the persuasion of the cow hide. Others claimed exorbitant rents for the mud hovels in which the now free labourer resided. Six shillings and eight-pence per week for each inmate over 10 years of age was* a not uncommon claim made for the rent of hovels, the erection of which had not originally cost a pound. The consequence might have been easily foretold by people less stupidly blind. Already great numbers of negroes had cleared patches in the unclaimed forests that clothed the hills. The people thus driven off joined their friends in the interior and there laid the foundation for the peasant proprietary that is so marked a feature in the social economy of Jamaica.

It was not long before the income of the absentee owner approached the vanishing point, and at length calls for remittances from him to enable his agents

to square accounts were not uncommon. Then in some cases properties were abandoned; in others they were sold for nominal sums to the local manager or overseer; and many have been kept on, just managing to pay a very small sum to the owner, the returns being absorbed in the payment of local supervision and charges. All this took place during the past generation. It is only 50 years since steam communication between England and Jamaica was established, and not one proprietor in a hundred thought it worth his while to make the voyage. The belief was accepted that property in Jamaica was valueless, and the memory of young men who had died out sugar estates in endless succession, and the recurring epidemics of yellow fever among the white troops, who were fed and clothed and overcrowded with all the ignorant brutality of our military system of 50 years ago, stamped the Island in the opinion of the English people as a white man's grave, to be carefully avoided. Hitherto no special means have been taken to dispel these illusions. Now, that soldiers are treated on more rational principles, the reports of the army medical officers show that Jamaica is almost the healthiest station for the British troops out of the United Kingdom, while the general health of the community is shown by the vital statistics, which give the average death rate per thousand for the past seven years as 23.9, a very low rate when it is remembered that the death of black children under five is abnormally high. But old beliefs are hard, and years after the extraordinary beauties of Jamaica had been described and its capabilities demonstrated by visitors who had braved the climate superstition and found here renewed health and strength, properties were being sold for less than the value of the stock that was on them, or in some cases for a tenth of the value of the logwood that grew upon them.

A "pen" is usually divided into guineagrass, common pasture and "wood and ruinate." The average value would be £4 for guineagrass per acre, £2 for common pasture and £1 for "wood and ruinate." It is not possible to give an average value for estates for crop cultivation, as everything depends upon position soil and water capabilities. At present mules are the best paying stock. A three-year-old mule can be bred for £7 and £8. The average selling price is about £17.

As to estates for the cultivation of crops, granting the proper condition of climate and soil, the yield will depend upon the industry and ability of the manager. In the cultivation of crops there are so many possible leakages that the fool and his money soon part.

But, besides the cultivation of the land, there are other ways of making money. The exhibition has shown that Jamaica has a large quantity of ochres that if treated on the spot would pay a fair dividend. The island also possesses pottery clay as good as any in England. The difficulty is that of obtaining skilled labour. A local company started a pottery and trained workmen were imported from England. But English tradesmen seem unable to resist the seductions of cheap rum in the tropics. The two leading hands spend their time between the lock-up and the gutters; the terra cotta works are suspended and the problem of reliable skilled labor that will last long enough to teach our own more sober people is still to be solved.

I find that I have not said anything upon an important factor—labour. To the question as to the abundance of labour, there will be as many answers as there are differences of disposition of employers. To secure a fair day's work the eye of the master is necessary, but I am satisfied that there is no necessity for apprehension on the score of labour.

I have put aside all temptations to embark in description of the beauties of Jamaica, and confined myself to a slight sketch of some of its capabilities; so that young men may realize that here, within a three days' sea journey from the United States, there is a British Island, where money can be made and where life and property are as secure as on any portion of the American Continent.

It is necessary to emphasise the fact that the people are singularly law-abiding, and that there is an entire absence of the reported crimes, that, if true, disgrace the Southern States of America for

* "Letter to the Marquis of Normandy relative to the state of Jamaica by the Marquis of Sligo," 1839.

there is a tendency of many writers to jump to general conclusions as to the negroes, from limited observations. I find the following passage in a book by Philip A. Bruce, on "The Plantation negro as a free man," published in New York. Having spoken of the reverting of the Haytian negro to African tribal customs, he says:—"Jamaica has sunk to an equally hopeless condition, one of the first parts of the globe, a part upon which nature has lavished without stint her greatest treasures and beauties, has declined to a tropical wilderness far more wretched, with its evidence of former prosperity, than when the foot of Columbus first touched the shores of San Salvador."

Now I can only say that this is ridiculously untrue. The aggregate amount of land in cultivation has been steadily increasing since the date of emancipation, and is still increasing. In 1870 there were 1,832,386 acres in cultivation, in 1890 there were 1,896,290, and while there is still ample room for improvement there is much reason for satisfaction with the social advancement of the people. They are fulfilling their duties as citizens quietly and well, and there are no grounds for apprehension that they will retrograde from their present position. Jamaica, beautiful, healthy and fertile, with a law-abiding population, and a good supply of labour, offers opportunities for investment that only require to be known to secure an influx of industrious capitalists whose advent must accelerate her material progress.

HENRY A. BLAKE.

PLANTING PROGRESS IN EAST AFRICA.

That the withdrawal of the British East Africa Company from the far interior is not without its compensations is evident from reports just to hand as to the company's operations in the regions accessible with comparative ease from the coast. Unhampered by anxieties concerning Uganda and the large expenditure required to maintain its position there, the company is able to devote its energies and its limited resources to the development of comparatively rich regions near the coast. It is evident that road-making is being carried out with creditable activity and efficiency from the main points of departure from the coast. Many miles of good roads have already been made from Mombasa and elsewhere, and if this laudable enterprise is persevered in within a very few years it will be possible to take vehicles and beasts of burden with the greatest ease from the coast to the great central station at Machakos, some 250 miles into the interior; and it is not likely that road-making will stop there. The company has had experts at work quietly for a considerable time, and their reports make it evident that with capital skilled and energetic planters, adequate labour, and cheap means of conveyance, the region between the coast and Lake Victoria, as well as between the rivers Tana and Juba, ought to yield very satisfactory returns to the company's shareholders. Their lies before us a short report on the products and capabilities of the various districts of the company's territories. These territories, for the purpose of the report are divided into three portions:—

The coast and low-lying districts; II. the inland hilly districts; III. the mountain ranges and plateaux. The following general statement as to the industrial capabilities of each section may be useful; even when the speculative element is eliminated it leaves a fairly solid balance of possibilities;—

The districts comprised in the first category are capable of producing all varieties of low-elevation tropical produce, such as rice, maize, millet, and similar grains, coconut, cotton, fibres, simsim ground nuts, tobacco, orchella weed, plantains, orange and other fruit trees, indiarubber, gums, hides, &c., and would afford a great field for the immigration of Hindoos, Chinese, and Easterners generally. Taken in order from north to south the districts are:—(1) Kisumu and Juba river; (2) Witn and Tana river; (3) Malindi and Sabaki river (4) Wanga and Umba river. The districts in the second category include the higher land of the interior, of an elevation of

3,000ft. and upwards, and would produce all tropical high-elevation products, as coffee, tea, sugar, cinchona, timber of many descriptions and would be suitable for the residence of planters and agriculturists interested in the same, besides being a country in which Southern Europeans would find a congenial home, these districts are:—(5) Ukambani; (6) Kikuyu; (7) Kavirondo; (8) Uganda and the Lake districts. The third and last division includes the lands of high elevation ranging from 9,000 to 19,000 ft., being the extensive regions around (9) Mount Kenia; (10) the Aberdare range; (11) the Mau Escarpment; (12) Mount Elgon. These are suitable for residence of Europeans generally and are considered capable of producing wheat, barley and the general produce of the temperate zone.

The products of the Kismayu and Juba rivers districts are referred to in detail, and the prices realized in the London market for the following articles are given:—Ivory, indiarubber, maize, millet, simsim, orchella weed, hides, rice. Besides these, such articles as cotton (in great abundance), tobacco, ground nuts and opium are produced on the coast; while in the interior are vast herds of cattle and sheep, besides ghee, gums, senna, ebony, Manilla fibre and ostrich feathers. It is even stated that in the Upper Juba rubies and emeralds are obtainable, and gold is said to have been found at Bardera. But putting all conjectural treasure out of consideration, it is evident that over all the coast regions, and up the Sabaki river, there is ample scope for plantation work. We know that to the south of Mount Kenia there are considerable districts of undoubted fertility and salubrity, but these must wait until the means of communication are improved.

In the Witn and Tana district cotton cultivation is stated to be making rapid progress, and a detailed account is given on the working and results of a plantation at Wange, near the port of Lamu, the crop of which amounted to 80,000 lb "lint cotton" (Sea Island), 140,000 lb. of cotton seed, and 20,000 lb. of refuse. With more efficient labour, it is believed the outturn would probably have exceeded 100,000 lb. Samples sent to Bremen were valued by brokers at 7 25-32d. to 9 12-32d. per lb., a higher assessment, it is stated, than that of American cotton then in the markets of the place. According to returns showing expenditure incurred in production, and a *pro forma* account of sales, the profit on an expenditure of under £1200 was £370, or over 30 per cent. Highly favourable reports are quoted from Liverpool respecting this cotton, which is pronounced "better than any but the best Egyptian." The natives themselves are said to be extremely anxious to grow cotton, and it is considered that it would pay a cotton planter to establish at the port of Lamu proper machinery for cleaning and pressing cotton for export. On the cotton estates 8,000 coconut trees have been planted and do not interfere with the cultivation of cotton.

Equally satisfactory reports are given of the results of tobacco cultivation at Witn. But space forbids our analyzing this interesting report in detail. Very full information is given as to the results and possibilities of cultivation of a variety of commercial products over all the coast region; and with regard to the interior, evidence of experts is given to show that the South and Central American rubber trees might be introduced and flourish as well as the indigenous *Landolphia*. The whole report is so full of detail and so useful that the company ought to print it for circulation. When all deductions are made it shows that Sir William Mackinnon and his friends have really got hold of a "good thing" commercially, which, with judicious, skilled, and liberal management may in the future yield satisfactory results.

One interesting point as regards slavery is brought out in the report. The company have granted freedom papers to date to 2,634 slaves. It was the practice of Government to grant a bonus of £5 per head to the mission societies who took charge of all slaves released by Her Majesty's cruisers, and,

as no allowance whatever is made to the company, the sum of £13,140 has been saved to the Treasury. In the same number of years, taking their *maximum* average results, the naval cruisers would have released 360 slaves. This shows the advantages of operations on land over those at sea for the suppression of slavery. In addition to this work there is the benefit of the law for self-redemption of slaves which the company put in operation, and which is working satisfactorily.—*Times Weekly Edition.*

THIBET AND TEA.

Among the many excuses put forward by the Chinese Government for preventing importation of India tea into Thibet, the most comical is the pretence that the Thibetans and Bluties dislike the article. Their affections are, it is declared, irremovably fixed on the brick tea which their ancestors, from time immemorial, consumed, and they will not be heldden to Hindostan in that connection. That would be a fair argument enough if it were proposed to compel these mountaineers to patronise the Indian variety. But there is no compulsion in the matter at all; all that the Indian planter asks is to be allowed to place his produce on the Thibetan market without governmental hindrance. He feels satisfied that its superior merits would very soon drive out brick tea, if the two were placed on the same footing. At all events he is quite willing to risk the chance of loss, and feels very little gratitude to the mandarins and honzes for protecting his interests against his own desire. Nor would the Thibetans themselves be sorry to be allowed to choose between the two sorts. Brick tea is a convenience for travellers, but it makes a wretched brew, being, as a rule, musty, flavourless, and scentless. But it comes from China, and the Pekin Government consequently has an interest in promoting its consumption by securing for it a monopoly throughout the Celestial Empire. Indian tea, on the country, has no friend at court of that kind. Hedged in on the north by Afghan and Russian duties, and shnt off from Thibet by the Chinese blockade, the Indian planter views with increasing apprehension the portentous growth of the industry in which his fortunes are embarked. The out-turn increases largely every year, and in default of new markets being found, price will be bound to fall to an extent leaving next to no profit. It is no wonder, therefore, that the Indian planter chafes sorely at his exclusion from such a tea-consuming country as Thibet, and would almost relish war with China on that account.—*Globe*, Jan. 31.

THE BRITISH INDIA TEA COMPANY, LIMITED.

The following is from the half-yearly report, Jan., 1893:—The directors now beg to submit to the shareholders the usual half-yearly report of the company's working during the past season, together with the statement of the quantity of tea sold to date.

The actual out-turn was short of the original estimate of 692,000 lb. by 92,033 lb. The decrease of tea made, as compared with that of the previous year, amounts to 85,657 lb. or 1,070 mds., and was caused by most unfavourable weather throughout nearly the whole year, with even an earlier close of the plucking season than was experienced in 1891. All the tea districts in India suffered alike in this respect.

392,384 lb. of tea have been sold to date at an average of 9.081 per lb. gross, against 7.76d for the same quantity disposed of last year. This better price is chiefly owing to the short crop producing a prospect of scarcity in the market. Owing to the low rates of freight in 1892 the margin of profit works out $\frac{1}{2}$ per lb. better than in 1891, making the increased difference about $\frac{1}{3}$ d per lb.

The directors being very disappointed and concerned at the great falling off in quantity and also in quality of the teas of the Assam division, considered

it was necessary to make a change in the management, and a new manager has been appointed, who, they have every reason to believe, will make a success of his charge.

The rate of exchange with India will be as nearly as possible 1s 4 $\frac{1}{2}$ d per rupee, as estimated. Owing to the diminished out-turn the cost per lb. will be increased by about a half-penny on the figure estimated, and will amount to nearly 7 $\frac{1}{2}$ d.

The total Indian tea crop for 1892 is now said to be about three million lb. less than that of 1891, while the consumption has been rather larger, and the quantity of Ceylon tea has not been increasing at the rate that was predicted.—*H. and C. Mail*, Feb. 3.

CEYLON TEA IN EGYPT.

The *Egyptian Gazette* of Feb. 13th says:—Messrs. Edgar Kirby & Co., have just received from the Ceylon Tea Growers Association, Colombo, a fresh shipment of Ceylon tea and, owing to the increased demand, they have arranged to supply from this date their numerous clients both in town and the interior with one pound of pekoe souchong and a half pound packet of orange pekoe for P. T. 17, both of which, mixed together, make an excellent blend which will be appreciated by all who are fond of an exquisite aroma. This blend is strongly recommended in cases of headache or lassitude.

NOTES ON PRODUCE AND FINANCE.

BOGUS TEA IN RUSSIA.—They have an original method of manufacturing tea in some parts of Russia, and M. Guleshambaroff, a Russian scientist, has been throwing some light on the matter. In some districts where there are certainly no tea plantations, the supply of tea sent to their railway station for delivery was considerably in excess of that received, and this occasioned some inquiry as to the origin and manufacture of bogus stuff known as "Caucasian tea." One enterprising merchant of Kutais had applied to the "Caucasian Society of Rural Economy" to give him their enlightened assistance in order to procure special privileges for the manufacture of "Caucasian tea," of which he furnished them with samples. The chemical analyst of the society discovered, however, that the so-called tea was nothing more than the leaves of the wild plant called "brussnik" (*Vaccinium acrostaphylos*), which grows in profusion in the forests round Kutais, and, in fact, over the greater part of Russia. The secret of the preparation of the leaves proved to be very simple, consisting merely in crumpling them in the hand, or treading them under the naked foot into a lump of "dirty green material," which was afterwards dried in the sun, under whose heat the leaves curled and shrivelled into a resemblance to ordinary tea. An infusion was made, but the taste was so bitter and abominable that nobody could be found to drink off a cup. Consequently the society refused its countenance decisively to the manufacture of Caucasian tea—a step which did not prevent the inventor from pursuing his happy idea, which soon found imitators. The extent to which this trade has grown may be guessed (says the correspondent of the *Standard*) from the fact that from one property, near Kutais, three thousand pounds were exported, at an average price of six roubles a pound. Considering that the cheapest tea on ordinary price lists is one rouble fifty copecks a pound, or fifty-six roubles a pound, the damage done to honest dealers by those who by the "Caucasian tea" to mix with their stock can easily be imagined. The best tea in St. Petersburg is quoted at four roubles, or eight shillings, the pound, and that generally drunk by the middle classes at about five shillings, and the consumption is enormous.

TEA AND THE RAILWAY TARIFFS.—The new ideas of the railway companies on the subject of freight generally, or tea in particular, and those of the London Wholesale Tea Dealers' Association on the same subject, do not harmonise at all. At a meeting of

the committee of the association held recently, the subject of the new railway rates was discussed, and a schedule of the various increases was taken into consideration, when it was unanimously resolved to draw the attention of the Board of Trade and the secretary of the Railway Companies' Association to the serious injustice of the rates now in force, which are in strict violation of a promise made by the railway companies at the Joint Committee of Lords and Commons. A letter addressed to a wholesale firm has since been received from Sir Henry Oakley, in which he intimates that the special rates for tea will be continued, but he is not in a position to state that they will be precisely the same as those charged before the new rates came into force. A notice from the railway companies with special reference to small consignments was read, and if put into operation as from the 1st instant, it is calculated, with the increased tonnage rate, to add one shilling per chest to the carriage to eighty-six northern towns, when tea is sent in lots of less than say four chests. The secretary was instructed to particularly bring this subject before the Board of Trade and others interested in the matter.—*H. and C. Mail*, Feb. 10.

VARIOUS NOTES.

THE ARTESIAN WATER SYSTEM is now being largely used in Queensland, and some very successful results have recently been obtained. On the Charlotte Plains run, near Cunnamulla, an enormous supply of water has been struck at a depth of 1,843 ft. It is estimated that the supply is between 4,000,000 and 5,000,000 gallons daily. This is believed to be the greatest artesian supply of water yet struck in Australia.

THE JAVA EXHIBITION.—The exhibition of industrial and natural products of the Dutch East Indies, which is to be held at Batavia in the course of this year, promises to be a decided success. The agricultural section will include extensive exhibits of cinchona, including flowering branches as well as dried bark, indigo and other dyestuffs, spices, gums and resins, essential oils and medicinal drugs of native as well as European use. Prizes are offered for the best treatises on the cultivation of and commerce in cinchona, pepper, cubebs, vanilla, cloves, and cinnamon, and for the best project for the establishment of a cinchona-factory in Java.—*Chemist and Druggist*.

ITALIAN ORANGES.—The produce of oranges and lemons in the south of Italy was last year very satisfactory to both producers and merchants, having reached the total amount of 57,000 tons of the value of 285,000*l*. The rise in the price for this article is principally owing to the great facilities granted by the railway companies, by which means a great quantity is exported to the north of Italy, where the fruit is largely consumed. No direct exportation of this product was from Reggio Calabria to foreign countries, effected during 1891, save a small quantity of salted citrons for Russia; although it is well to note that of the quantity of fruit exported from Messina to foreign countries, this district contributed for the most part, especially in the oranges, of which that province does not produce a great quantity. In fact, the returns for 1891 show an exportation of 97,000 boxes of fruit from this district to the port of Messina, wherein are not comprised the mandarines. Also important is the production of dried fruit in this district particularly of chestnuts and figs, the latter being considered as good as those produced at Smyrna. The quantity exported in 1891 was 3000 tons, of which 1000 tons were direct for Malta.—*Nilgiri News*.

INDIAN POTATO BLIGHT.—Dr. D. D. Cunningham's microscopical investigations into the Indian potato blight are still going on, and elaborate experiments are being pursued in the practical treatment of the crop and of diseased soils. The results are expected to be important, and will be made public in due course.—*Pioneer*, Feb. 17.

ENGINEERING FEAT AT NIAGARA FALLS.—Says Dr. J. H. Taylor in the *Australasian* :—

Before the Chicago Exhibition opens an event of enormous practical scientific importance will have taken place in America. Some weeks ago I gave a description of the enormous engineering feat which has been going on for more than two years past at the Niagara Falls. This was the boring of a sloping tunnel or tube through the solid rock from below the Falls to the Rapids above. Practically it was "tapping Niagara." The tunnel is now completed, and it is announced that the power-plant for transforming the energy supplied by the head of water into electricity will be in operation by March. It is anticipated that an electric current will be generated equivalent to 75,000 horse-power. This is an enormous supply, but a mere trifle as compared with the mighty energy which now wastes itself in tumbling over the Falls. Forty-five thousand electrical horse-power will be transmitted from the Niagara tunnel to the city of Buffalo, many miles away, and 30,000 electrical horse-power is to be conveyed to other places.

COFFEE: Coorg, Feb. 20th.—This season's crops in the Bamboo have, on the whole, been disappointing. Individual places could not have done better considering that the strength and resources of the trees had been somewhat severely taxed in the previous bumper season. One estate (Dubarie) of something over 300 acres—which, if I am not mistaken, is described as the "plum" of the Bamboo—gave 70 tons, or 80 I am told, which is very good after something over 100 tons the season before especially when the ills which coffee has to contend against in these days are taken into account. A crop of forty tons, which was considered a very good return for the acreage, was obtained off another place, and 17 tons off a third of under 200 acres in extent, which had given its 25 tons in the previous season. These are the strikingly bright spots in a dark picture. On some few estates, on the other hand, the crops were phenomenally short. One extraordinary instance may be mentioned where a place of over 300 acres gave a crop of only 5 tons! If I am correctly informed, this is one of the estates on which extra precautions are taken against borer in the way of having the flies caught and destroyed and washing the stems of the trees with a mixture which, from what I can learn of the matter, appears to be composed of lime and sulphate of copper. The best return at the coast curing works of the first shipments of coffee from the Sunkoppa District was 90½ bushels or so of parchment to the ton, which may be considered very good, as outturns sometimes range up to 95 and 97 per ton. The above outturns were obtained from the parchment of only two estates. The average even in these cases, calculated on the several shipments, will rise to probably about 93 bushels, if not more, per ton. Last season I stated that Duaked Estate had given the best outturns on record. I took the figures from information supplied to you some time previously by the Manager of the Oombatore Curing Works. I believe they gave rise to quite a commotion in the Bamboo. There was no reason for this, as the figures (79) were, I believe, quite a common outturn down the Ghauts in the old days. Nothing has been attempted in the way of drying coffee under shade. On one estate years ago it was noticed that the coffee was of better quality and always fetched higher prices than that of any of the neighbouring estates. This was attributed to a belt of trees on one side of the barbacues which cast a shade over the latter during the hottest part of the day.—*Madras Mail*.

GAMBIR.

(From the *Agricultural Bulletin of the Malay Peninsula*.)

(Continued from page 592.)

FORMS OF GAMBIR.

The Malays make four kinds of gambirs, viz.:—*Gambir papan*, *bulat*, *paku* and *dudur*.

The first two of these are chewing gambirs, the others are used for dyeing.

Gambir bulat (round gambir) is the most expensive of the chewing gambirs. The Siak gambir is usually of this form, but is much adulterated with rice dust and cloves. It consists of thin circular biscuits about $1\frac{1}{2}$ inch across (and about a line thick and valued at 9 or 10 dollars per pikul).

Gambir papan (lit. board gambir) is in the form of thin squares about an inch and a-half each way, and about one line thick. It is light brown, paler within, and rather crumbly in texture. It is valued at \$5.50 to \$6 per pikul. This is the form known in the Singapore trade as Flake Gambir.

Gambir paku (nail gambir) called in trade Finger Gambir is made in the form of sticks, about three inches long. It is rather a sticky, viscid material, and very dark in colour. Its highest value is \$6 a pikul.

Gambir dudur (dice or cube gambir) is made in small cubes an inch each way. There are two forms—No. 1 is of a light reddish brown outside, and a light yellowish brown on fracture, very homogeneous and fine grained, dry and easily powdered. It is valued at \$9 a pikul; No. 2 is darker, blackish brown, less homogeneous and shiny. It is of inferior quality and is valued at \$7 a pikul.

Van Romburgh also mentions a form manufactured for the inland market in West Java in round pieces, 24 mm. by 9 mm., which commands a higher price than the square flat cakes.

Some other forms are mentioned by Couperus as used in his time. The best quality, he says, has a triangular shape, each side having a length of about one and a-half (Amsterdam) inches, and a quarter of an inch thick. Another form obtained from Patabahan was bullet shaped, two inches through, black outside and full of bits of leaves. Kampar in Sumatra produced three kinds of gambir—one flat and round, four inches through, one the size and shape of a flint gun bullet, and one resembling the Siak form, but heavily adulterated. These forms seem to have died out, the fancy of the natives being for *gambir bulat*, *papan* and *dudur*.

The Chinese also make *Gambir papan*, *bulat*, *paku*, and *dudur*; and also bale gambir. This latter is the common form made by the small cultivators, and is usually made up on the field in the form of oblong blocks about eighteen inches long and eight thick. Each block is enclosed in a rush matting. The merchant makes it up into bales for export. It is the wettest of all the gambirs, containing an excessive amount of water, and is a sticky mass, dark brown outside, yellowish within.

PLANTING.

The greater number of cultivators prefer to grow the gambir on virgin soil, newly cleared of jungle. Some plant on old tapioca ground, or put tapioca into the fresh cleared jungle ground first and plant gambir on it after a year or two. I have seen good results from this, but I have also seen a plantation quite dead after about five years, which had been grown on old tapioca soil even after brushwood had been allowed to cover it between the cultivations. Neglect and excessive cropping may have been the cause of this destruction, but the soil had been a long time under tapioca, and was probably very poor.

Virgin soil is, however, doubtless the best for gambir, but in any case when the land has been under cultivation previously, whether with tapioca or any other crop, it should be fallowed and let to return to jungle for a time before re-planting. Old gambir ground if left soon reverts to secondary jungle if the soil is good and after a few years can be re-planted.

The soil most commonly found in Singapore consists of a yellow clay. Sandy soil is, however, better. In Bangka yellow sand mixed with clay is preferred. In the Rhio-Lingga Archipelago the soil is red loam mixed with sand and covered with a slight layer of humus.

From sea level up to about four or five hundred feet altitude is the proper range of cultivation; above this the plant does not seem to thrive.

In all plantations it is essential to retain belts of jungle close at hand to supply firewood and to act as screens for the crops. To make any crop requiring the use of firewood pay, it is essential to have the firing accessible and plentiful. The difficulty of getting wood close to the gambir and pepper fields in Singapore has led to the abandonment of much of the cultivation. In many parts of Malacca, abandoned land very quickly reverts to brush-wood and eventually jungle, but in Singapore a deserted plantation is immediately overrun with lalang (*Imperata arundinacea*), a useless grass which entirely prevents the growth of brush-wood for many years and which has to be entirely eradicated with the hoe before any further cultivation can take place. Lalang is easily kept out of the plantation by a belt of jungle, and this is an additional reason for keeping it surrounded by forest.

But indeed it is to be hoped that now the day has gone by when the planter, whether of tea, coffee or gambir, or of any other crop, on a large scale destroys all the forest on his property in order to get a little more acreage of cultivation. The disastrous results of such a practice are now well known to all intelligent European planters, and we may hope that the experience learnt at such expense in other colonies may not be neglected by planters in countries not yet injured by excessive denudation of forests.

SOWING.

The seeds are very minute and light. The capsules are gathered when they begin to split, and laid on a sheet of paper or cloth till the seeds fall out. The Natives say that they will not keep above twenty-four hours. This is incorrect, with care they can be kept as long as six months, but for this they must be kept in a dry, tin box so as to be free from the attacks of caterpillars, and must be dried in the sun at least once a week, or they will be destroyed by mildew. The duration of the seed much depends, I believe, on its dryness when gathered. However, it is better to sow the seed as soon as possible after it is ripe. In Singapore the Chinese rarely make seed beds or nurseries for the young plants, but sprinkle the seed loosely on any bare patch of ground, often among the pepper-vines, and do not even cover them with soil. They have a superstition that the seed must be sown by a man who never drinks spirituous liquors, or it will never germinate.

The better class of cultivators, however, form nursery beds for the young plants. The beds are made by preference on the low-lying, damp, black soil, by the streams in the valleys, and each bed is surrounded by a trench of water. The seed is carefully sprinkled over the bed and a little soil is in like manner sprinkled over it. The beds are shaded with coconut leaves supported on sticks about three feet from the ground. It appears to me, however, that the plants more fully exposed to the sun, viz., those at the edge of the beds, thrive better than the inner ones, which were more shaded. It is certain that gambir is a plant which, when fairly developed, wants as much light as it can get.

The seed takes from fourteen days to two months to germinate, or even longer. About half of what is sown comes up.

CUTTINGS.

In Bangka, according to Dr. Romburgh, the plant is propagated by cuttings only, in this manner, the bush is cut down and burnt, and twigs, not too young, of the old plant are cut into lengths and stuck in the bare ground. If necessary, they can be removed to a different part of the plantation when they

have developed into young plants. In the Peninsula and Rhio the plants are never grown from cuttings, and indeed I never found them to strike well.

SEEDLINGS.

The plants when about nine months old and a foot tall are removed from the nurseries and planted out in the future plantation. Small square holes are dug in the ground about 12 feet apart, and the plants put in so that the top leaves are on a level with the top of the hole, and a piece of fern is laid on the top to shade the little plant. This prevents any damage from a too sudden change from the shaded seed bed to the hot open field. The trees grow very rapidly, sometimes as much as a foot a month, and in a year, or better still a year and a-half, the first cutting takes place.

The plants are never manured at all, but in some plantations the used leaves are thrown back upon the soil and serve as manure. Manuring properly would probably make a great improvement in the yield, as the strain on the plant from cutting so heavily must be very great.

The soil that seems to suit the plant best is rather sandy and quite dry, with full exposure to the sun. Care must be taken that water cannot accumulate at the roots in any way, which is most injurious to the plant. It is, therefore, usual to select a hillside for the cultivation so that the water may escape as quickly as possible after rain.

The common cultivator takes no pains to keep his plantation free from weeds and grass, and underscrubs are allowed to grow up so as often to quite conceal the bushes. It is only cleared shortly before cutting for convenience of the gatherers. In the better plantations the ground beneath the bushes is kept absolutely clean of weeds. The advantages of this are obvious, but at the same time it must be remembered that in a hot and dry climate the rootlets of the plants are very liable to suffer from sun heat on the soil, if they are not shaded in any way. For this reason it is advisable to plant the seedlings close enough for their branches to touch each other when adult, and so throw shade over the whole ground.

It often happens that other plants get mixed in among the seedlings in the nursery bed, and there is among them especially a Rubiaceae plant (*Chasalia curviflora*), which is very common, and of which seedlings are liable to be mistaken for gambir plants. There is, however, an easy test for the true plant, apart from the taste of the leaf, which is unmistakable. Take a leaf of the suspected plant and rub it to pulp between the finger and thumb, when if it is gambir a white sticky liquid will presently exude and form a lather.

ENEMIES.

The plant is remarkably free from the attacks of insects and other pests. The deer do a small amount of damage by nibbling the young shoots, and it is due to their constantly visiting the fields at dusk and early dawn that the tiger is so frequently seen in or near the gambir plantations and not rarely attacks and kills the coolies at their work at these times.

The only insect I have observed on the plant is the larva of the common Atlas-moth (*Attacus Atlas*), a very destructive insect on account of the amount of foliage it devours. It is rarely found on the gambir, however, and usually seems to have attacked the tree after devouring all the leaves of some other plant upon which the eggs were originally laid, and finding itself then pressed for food.

CROPPING.

Although some cultivators take the first crop as early as six months after planting, it is much better to wait for a year and a half before taking the first crop. Many planters crop at the end of the first year without doing any apparent damage to the plant, but the crop taken then is very small, and it is much better to let the plant get to its full strength before cutting.

The small cultivator in Singapore crops three times in two years, but then crops very heavily. The more careful planter takes a smaller crop every four

months. As there are practically no seasons in Singapore, the time of the year when the crop is taken is of no importance, so long as it is not taken too soon after the last crop.

In extensive cultivations it is generally so arranged that different portions can be cropped in rotation, by which means a comparatively small boiling plant can be kept regularly at work all the year round, instead of having a press of work at one time and nothing to do at another. For this reason cropping on a small scale every four months is most suitable for large estates.

In the small cultivations pepper is usually cultivated with the gambir, the same apparatus doing for both, partially. In this case the two crops are allowed to alternate, so that while the pepper is growing the gambir is being cropped and boiled.

With ordinary care a plantation will last for from 13 to 20 years, but, as a rule, after 15 years it is nearly worn out. With really careful cultivation it will last from 25 to 30 years. It is at its best in about 8 years after planting.

The ordinary Chinese coolie crops the gambir with a curious little knife, the blade of which is curved and broad, and about three inches long. With the aid of this he breaks rather than cuts off the branches of the plant.

The Malay, on the other hand, plucks the leaves, saying that the Chinese cut the tree to death, but on enquiry I found that under their system the bushes are decidedly less prolific and live shorter lives. At the same time there can be no question but that the Chinese do in many cases over-cut the plants, and treat them very roughly. This is especially the case in small cultivation where, unless a large quantity is cut, the amount of gambir made is too small to bring a sufficient amount of profit.

It is probable that the cutting of the branches has the advantage over mere plucking of the leaves, in that it keeps down the excessive development of wood, and, in fact, takes the place of pruning. Like all species of the genus *Uncaria* the plant has a tendency to make wood very rapidly at the expense of the leaves, and this requires to be kept back, especially as the twigs produce but little gambir, and are to all intents useless in the production of the drug.

The Chinese on cutting the branches put them into large rattan baskets about three feet tall and carry them to the gambir shed. Here they are thrown into a trough and the bigger sticks removed. The rest—leaves, twigs, flowers and fruit—are all thrown into the boiling pan.

The bushes recover their mutilation with surprising rapidity, and young shoots are put out again very soon.

In cutting it is to be remembered that the old, dark green, firm leaves only produce the drug, the young leaves and buds little or none, at the same time the terminal shoots must be cut at least from time to time to keep the bushes at a convenient height (usually about four feet tall) for gathering. Whether it is preferable to cut the bushes comparatively lightly so that too great a strain is not put upon the plant, by which means the plantation might be made to last in good producing order for a great number of years, or whether to cut heavily (as the Chinese and Malays often do) and work out the trees in six or eight years, and then replant, will depend on the circumstances of the planter.

Gambir grows so rapidly that it is probable that the latter plan may pay best in many cases.

(To be continued.)

TEA.—Owing to the unsatisfactory quality of the tea tendered last month for the Commissariat Department, fresh tenders were again called for. These were opened last Saturday by a Committee of Officers with the result that the tender of Messrs. Octavius Steel and Co., of Calcutta, through their local Agents, Messrs. Parry and Co., was accepted. The tender is for a supply of 122,000 lb. of tea.—*M. Mail.*

THE CASTLEREAGH TEA COMPANY OF CEYLON, LD.

The annual ordinary general meeting of shareholders was held at the offices of the Company, No. 13, Queen Street, Fort, on 28th February 1893 at 4 p.m.

Present:—Messrs. J. H. Starey (Managing Director) in the chair, V. A. Julius, W. Moir, B. G. L. Bremner (Secretary), J. R. Fairweather, W. Mackenzie, J. A. Martin, Hon. L. H. Kelly, and by proxy Messrs. C. A. Martin, A. H. Dingwall, Hon. G. S. Williams, G. M. Fowler, H. D. A. Macleod, E. H. Skrine, E. Rosling, R. Reid, K. Rollo, and James Anderson, and Mrs. B. B. Richard.

The Secretary read the notice convening the meeting. The minutes of the meeting held 26th November were read and confirmed.

The report of the Directors was taken as read.

The MANAGING DIRECTOR proposed its adoption, saying there was little to be said that was not in the Report. It was subject of regret that the Directors were unable to declare a dividend of 8 per cent for the year, as anticipated at the time of the interim dividend. There was a large item of R2,772 charged in the accounts as preliminary expenses which will not occur again. The profit was R18,682, and that the proprietors should get 6 per cent in the first year is not very unsatisfactory, though small in these days compared with the large dividends by some other concerns. The estate was not nearly at full maturity. The estimate as reduced in August had been obtained. The profit per acre was R40 and yield 280 lb. per acre. The profit for present season will depend more on the prices than the yield. The yield for present year could only be spoken of with much diffidence. In January and February it has been poor and less than at the same time last year in consequence of cold nights and drought. The north-east monsoon has practically failed and its failure was very much felt on such a thirsty soil, but the weather and the yield in the last few days has improved and a little rain has fallen. When visiting the estate about end of January and in consultation with Mr. Mackenzie, the speaker came to the conclusion that 112,000 lb. tea might be secured in 1893. Every economy is being studied as the estimate of expenditure shows. If the tea sells at 50 cents the earnings should be 7 per cent.; at 55, 9 per cent.; and at 60 cents 11 per cent. To date the tea has sold at about 54 cents. The 476 acres tea represented in capital account at R505 per acre. The number of shareholders is now 83, and the lowest price paid for shares is R105, the highest price being R120. He moved that the Directors' report and the accompanying accounts as at 31st December 1892 be received and adopted.

Hon. Mr. KELLY seconded the motion. He took upon himself the seconding because he promoted the Company. As old superintendent and proprietor he had to state that all the tea was formerly in coffee. He certainly thought when coffee was cut out that tea would have pulled round sooner than it did. He held the largest number of shares in the Company, thereby proving his faith in the Company. Though the Company has not done what he expected it to do, (no one could be more disappointed than he) he had the most implicit faith in the Company and its present management. He took some blame to himself for being too sanguine, but he honestly believed that there is a good future before the Company.

Mr. J. R. FAIRWEATHER asked for an explanation of the difference between the estimates of 180,000 in the prospectus and the present estimate of 112,000 lb. for 1893.

Hon. Mr. KELLY said he might have been absolutely wrong in anticipating the figures stated in the prospectus, and if so he would be one of the principal sufferers. The first year's working has been very disappointing, but many things had to be considered. He was certain that gentlemen who retained their shares would not be sorry for it; and as to the management he was perfectly satisfied with things as they are.

The motion was then put to the meeting and carried.

Mr. MACKENZIE then proposed:—"That a dividend of R2 per share be declared and made payable on the 2nd March. Seconded by Mr. J. A. MARTIN. Carried.

Mr. J. A. MARTIN proposed:—"That Mr. John H. Starey be re-elected a Director." Seconded by Mr. J. R. FAIRWEATHER. Carried.

Mr. STAREY thanked the meeting for re-electing him.

Mr. J. R. FAIRWEATHER proposed:—"That Mr. John Guthrie be elected auditor at a fee of R50." Seconded by Mr. W. Moir. Carried.

Hon. Mr. KELLY said on the part of the shareholders he was very glad to see the present management continue, and proposed a vote of thanks to the Directors and the Manager of the estate. The Chairman thanked Mr. Kelly for his remarks and said their best endeavours would be directed to attain the success that Mr. Kelly so confidently anticipated.

REPORT.

The Directors submit herewith the Balance Sheet and Profit and Loss Account for the period of thirteen months ending 31st December, 1892, duly audited.

The balance of profit is R18,633 64. Of this sum R9,600 was absorbed in paying an interim dividend at the rate of 4 per cent. leaving R9,033 64 for disposal. The Directors propose to write off the whole of the expenses connected with the formation of the Company, amounting to R2,772 25, to declare a further dividend at the rate of 2 per cent, payable on 2nd March, absorbing R4,800 00, and to carry forward to 1893 account R1,461 39.

In consequence of unfavorable weather, which lowered the yield of Tea in all up-country districts, the crop secured was only 112,120 lb. The cost of the Tea delivered to buyers was 40 55 cents. The net value realized from sales was 52 29 cents per lb.

The crop of coffee was 239½ bushels parchment, sold for R3,973 07; and of cardamoms 894 lb. sold for R882 14; and of cinchona bark 18,193 lb. sold for R2,021 19.

The Company's property consisted of:—

Tea	{	376 acres	Tea over 4 years old
	{	84 "	" "
	{	16 "	" "
	{	50 "	Forest

526 acres

Another large Tea Roller has been added at the Factory.

Mr. John Helps Starey retires from the board by rotation, in terms of the Articles of Association, and being eligible offers himself for re-election.

The Shareholders will be asked to elect an Auditor for the current year.

YATADERIA TEA COMPANY OF CEYLON, LIMITED.

The fifth annual ordinary general meeting of this Company was held at the offices of the Company, 13 Queen Street, Fort, on the 28th February 1893, pursuant to notice. Mr. H. V. Masefield was in the Chair, and the following shareholders were present:—Messrs. D. Fairweather, J. H. Starey (managing director), B. G. L. Bremner (Secretary), J. A. Martin and P. E. Rogers, and by attorney Messrs. W. W. Church and H. W. Hornby. The Secretary read the notice convening the meeting.

The minutes of the annual general meeting held 25th February 1892, and the extraordinary general meeting held 12th August 1892, were duly confirmed.

The report of the directors having been taken as read Mr. MASEFIELD moved its adoption, viz., "That the report of the directors and accounts for the year 1892 be received and adopted."

The MANAGING DIRECTOR in seconding the motion commented upon the accounts and business. The balance brought forward was R11,236 against only R1,751 last year, and if the report were adopted the balance carried forward would be about the same, viz., R11,217. The amount written off for depreciation was rather larger than last year owing to some machinery coming on for its share of writing off,

The crop was 59,900 lb. more than last year giving increased value of R7,550. The capital cost of the area now stood at R279 per cultivated acre as compared with R331 last year showing R52 per acre improvement, a large reduction caused by the 121 acres of one year old tea being brought into the reckoning. As there would still be capital outlay upon this young tea, the figure might be higher next year. The profit earned exclusive of balance brought forward is about 30½ per cent against 31 per cent last year, and the profit per acre is R87 which is satisfactory, the same dividend as in the previous year is proposed, and to place R10,000 to a reserve fund. The reasons for proposing this reserve were that even after writing down liberally, the amount invested in land, buildings and machinery was more than the paid-up capital, besides which there were large coast advances outstanding and the lock-up in the new O. B. C.; and by placing this sum to reserve there would be the necessary provision of working capital; besides this a proposal had been made to pay a quarterly dividend and if it were the general wish of the shareholders the directors might adopt that plan; but more working capital would of course be necessary in order to avoid borrowing. The new season to date had not been favorable, though a slightly larger quantity of tea, viz. 69,400 lb. against 68,300 lb., had been secured than at the same date last season, still the increase was not proportionate to the increased total estimate. The market last year was comparatively low for teas of this class, though good in the later months, and it was satisfactory to see the average sale price slightly better than the previous year. There had been a good increase in the yield per acre, particularly in the 100 acres of 1888, which gave 775 lb. and the 41 acres of 1889 which gave 708 lb. per acre. There are now 700 acres tea of which 527 acres were under leaf, the profit last year being R87 per acre. The number of shareholders was reduced by 3, to 41 in all. The value of the shares had steadily increased, the highest price paid being R240 and the lowest price R200.

The MANAGING DIRECTOR would be glad to give any further information that the shareholders might desire.

Mr. J. R. FAIRWEATHER proposed as an amendment:—"That a bonus of 5 per cent be paid instead of a reserve fund being created," but the proposition not meeting with a seconder the Chairman put the original motion, which was carried.

Mr. J. A. MARTIN proposed:—"That a dividend of R13 per share for the half-year ended 31st December 1892 (making, with the interim dividend of R12 per share paid in August 1892, 25 per cent. for the year 1892) be declared and made payable on 2nd March 1893," and Mr. P. E. ROGERS seconded and it was carried.

Mr. J. A. MARTIN proposed:—"That Mr. David Fairweather, who retires by rotation, be re-elected." Mr. H. V. MASEFIELD seconded, and it was carried.

Mr. J. A. MARTIN proposed:—"That the directors' remuneration be increased by R100 for each one per cent of dividend or bonus paid over 20 per cent per annum" saying, he thought the directors fully deserved the increased remuneration.

Mr. P. E. ROGERS seconded, and it was carried, the Managing Director explaining that a similar resolution had been adopted by another Company.

Mr. J. R. FAIRWEATHER proposed:—"That Mr. John Guthrie be re-elected auditor at a fee of R100 per annum." Mr. D. FAIRWEATHER seconded, and it was carried.

The proceedings terminated with a vote of thanks to the Chair, which was acknowledged by Mr. Masefield, who thanked the shareholders for their attendance and assistance in the business.

REPORT.

The Directors have the pleasure to submit the Balance Sheet and Profit and Loss Account for the year ending 31st December, 1892, duly audited.

The balance of profit (including R11,236.29 brought forward from last year, after writing off for depreciation of buildings and machinery, and also 25 per

cent. of the amount in the New Oriental Bank Corporation, as shown by the accounts) is R68,717.25. Of this sum R22,800.00 has been absorbed in paying an interim dividend at the rate of 12 per cent.; and the Directors propose that a further dividend of 13 per cent, absorbing R24,700.00, be declared and made payable on the 2nd March, that R10,000.00 be carried to Reserve Fund, and that the remainder of R11,217.25 be carried forward.

It will be seen that the property representing capital stands in the Balance Sheet at approximately R279.00 per acre cultivated, as compared with about R331.00 in the previous year's accounts.

The additional Roller referred to in the last report was erected, but it will be necessary to provide this year another large Roller and another Drier. The permanent bungalow for the Superintendent has not yet been built.

The total Tea crop was 450,553 lb., or 10,553 lb. more than estimated in the last report; and but for unfavorable flushing weather in the later months of the year the excess might have been larger. The plucking area was 527 acres, with a small quantity from the 52 acres of 1891.

The total quantity of Tea for disposal was 450,404 lb., which was all sold locally. The cost of the tea delivered to buyers, including all charges and depreciation of buildings and machinery, was 24.09 cents per lb. (being .82 of a cent more than in 1891). The net value realised from sales was 37.84 cents per lb. (being .37 of a cent more than for the previous crop).

The Company's property (with no new purchases to record during the year) consisted at the 31st December 1892, of:—

700 ACRES TEA—VIZ.—

		lb. per acre.
172 acres Tea planted in	1885; yield in	1892 945
208 " " "	1887; " "	852

121 " " "	1892 (not in bearing)	
253 " " "	Forest, &c.	

— 953 acres

The Directors do not propose any extension in 1893.

The estimated crop for 1893 is 482,700 lb.

Mr. David Fairweather retires from the board by rotation in terms of the articles of Association and being eligible offers himself for re-election.

The Shareholders will be requested to elect an Auditor for the current year.

By order of the Directors, B. G. L. BREMNER,
Secretary. Colombo, 18th Feb. 1893.

INDIAN PATENTS.

The 26th Jan. 1893.

No. 13 of 1893.—William Bull, Civil Engineer, at present residing in Calcutta, for an improvement in the burning of bricks and tiles.

No. 16 of 1893.—Alexander Tasker McIsaac, Engineer, Doodputlee Tea Estate, Cachar, for improved tray racks and trays for use in withering fresh tea leaf.

The 2nd Feb. 1893.

No. 19 of 1893.—William Charles Wilkinson of No. 32 Dalhousie Square in Calcutta, India, Engineer and Contractor, for an improved pulveriser and converter for minerals, more especially for mica.

The 26th Jan. 1893.

No. 167 of 1892.—John Jonas, of No. 38, Lime Street, in the city of London, England, Engineer, for improvements in apparatus for plucking tea. (Filed 17th Jan. 1893.)

No. 282 of 1892.—Felix Bernhardt Fremerey, Civil Engineer of Galveston, in the County of Galveston

and State of Texas, United States of America, for improvements in machinery for decorticating jute, ramie, and other fibrous plants. (Filed 17th Jan. 1893.)

The 26th Jan. 1893.

No. 52 of 1888.—William Jackson, of Thorn Grove, Mannofield, Aberdeen, Scotland, Engineer, for improvements in machinery or apparatus, for reducing or breaking tea. From 4th Jan. 1893 to 3rd Jan. 1894.

Whereas the inventors of the undermentioned inventions have respectively failed to pay within the time limited in that behalf by the fourth schedule to the Inventions and Designs Act (V of 1888) or within the further time allowed under section 8, sub-section (4) of the said Act, the fees hereinafter mentioned, it is hereby notified that, under the provisions of section 8, sub-section (2) of the said Act, the exclusive privilege of making, selling, and using the said inventions in British India, and of authorizing others so to do has ceased:—

No. 33 of 1888.—Mr. A. Andrews' invention for "Improvements in the metal package suitable for the packing storage, and carrying of tea and other substances of a like nature." Specification filed 21st Sep. 1888.

9th Feb. 1893.

Applications in respect of the undermentioned inventions have been filed during the week ending the 4th February, 1893, under the provisions of Act V. of 1888, in the office of the Secretary appointed under the Inventions and Designs Act, 1888:—

No. 28 of 1893.—Samuel Cleland Davidson, of Sirocco Works, Belfast, Ireland, Merchant, for improvements in apparatus for drying tea or other vegetable substances; or other material.

The fee prescribed in Schedule 4 of Act V. of 1888 has been paid for the continuance of exclusive privilege during the period 6th March, 1893 to 5th March, 1894, in respect of the undermentioned invention:—

No. 90 of 1888.—Samuel Cleland Davidson, of Sirocco Works, Belfast, Ireland, Merchant, for improvements in apparatus for employing heated air in drying or baking vegetable or other substances.—*Indian Engineer.*

INDIAN TEA DISTRICTS.

Our Kangra Valley Correspondent writes:—During the month of January the rainfall exceeded 11 inches and instead of the one fall of snow predicted, we had two, we are now having our third, the whole of the district being heavily covered, with a prospect of still more. This winter has been the most severe that the Kangra Valley has known for many years, and some of our old planters say that it reminds them of twenty years ago. There is little doubt but that we shall have an early spring, and a good full crop for the year, most gardens will have to push ahead their cultivation and pruning in order to be ready for the manufacturing season. The gardens in the district generally are looking very well for the time of the year.—*Indian Planters' Gazette.*

SUNNYGAMA (CEYLON) TEA ESTATES COMPANY, LIMITED.

[The following is the Tea Company of a semi-private character alluded to in our London Letter.]

Capital £50,000, divided into 5,000 shares of £10 each. Objects: For the sale and purchase of tracts of ground and the tea plantations thereon, situate in the Ruanwalla and Dehiowitz Divisions of the Kelani Valley District in the Island of Ceylon, and known as the Sunnycroft and Pambagame estates; to acquire other tea plantations, and to carry on the business of tea planters in all its branches. The subscribers are (each with one share):—J. C. Kinmond, Cardney, Dunkeld, N.B., tea planter; Robert Lyell, 138, Leadenhall-street, London E.C., merchant; Wal-

ter on Grondwater, 138, Leadenhall-street, London, E.C., George T. White, 31 Fenchurch-street, London, E.C., tea broker, R. B. Major, 138, Leadenhall-street, London E. C., merchant, William Gow 13, Rood-lane, London, E.C., tea broker; H. Scutt, 3, Nottingham-street, London, W. The number of directors is not to be less than three nor more than five, the first being James Crichton Kinmond, William Forsythe and Robert Lyell. Remuneration £50 per annum to be divided as they themselves determine.

DRUG AND BARK REPORT.

(From the *Chemist and Druggist*).

London, Feb. 9.

CINCHONA.—The bark-auctions held on Tuesday were of very small extent. For the first time several months no African bark was offered, and counting even some 300 bales of Cuprea, which are not meant to be sold, though periodically included in the sales, the entire assortment barely reached half the size of an average auction.

The catalogues included:—

	Packages	Packages
Ceylon bark ...	807	of which 684 were sold
East Indian bark...	342	" 342 "
Java bark ...	95	" 95 "
South American bark	81	" 81 "
Cuprea bark ...	301	" — "

1,626 1,203

The sale proceeded without any noteworthy features, competition being fairly steady, and the bulk selling without any alteration in price. The unit remains at 1 l-16d per lb. The following are the approximate quantities purchased by the principal buyers:—

Agents for the	Lb.
Mannheim and Amsterdam works	... 79,790
Auerbach works 54,220
American and Italian works...	... 41,290
Frankfort o/M. and Stuttgart works...	... 33,710
Brunswick works...	... 30,800
Messrs. Horward & Sons 18,238
Agents for the Paris works 16,760
Sundry druggists...	... 28,335

Total quantity of bark sold	... 303,143
Bought in or withdrawn	... 66,270

Total quantity offered 369,413
----------------------------	-------------

TRAVANCORE TEA AND CEYLON IMPORT DUTY.

The following is the conclusion of the editorial column-and-a-half which the *Madras Mail* devotes to this subject:—

The *Ceylon Observer*, however, does not abate one jot or tittle from its demands, and argues that the import duty has tended to injure the trade of the town and port, and should be forthwith abolished. It alludes to the admission of Ceylon teas into India duty free; to the fact that Travancore has made a concession to Ceylon, which Ceylon ought to, but will not, reciprocate, and inveighs against the want of enlightenment on the part of Ceylon administrators. Mr. Noble, the Manager of the Colombo branch of the Bank of Madras and owner of a tea estate in Travancore, is of opinion that were the import duty abolished a number of Travancore estates would ship teas to Colombo for public sale there. By this, we presume, he does not mean that there would be any blending in Colombo, but simply a sale of the Travancore teas which would be re-shipped as such. He adds:—

"Anyone wanting their money soon would naturally do so. At present it is not worth the trouble. I have tried it, and so have others, and we have all stopped. Teas come here *via* Tuticorin, and, if they are damaged in transit, or require re-hooping or re-firing, or even re-bulking, it can't be done, as they have to be sold in bond or else duty has to be

paid on them. This is a direct discouragement to the development of the trade of Colombo. The duty is absolutely indefensible. Let any member of Parliament put a question to the Secretary of State in the House of Commons, and an order to rescind the duty would be sent out at once. Ceylon puts a 6d. duty on Indian tea, and India allows 600,000 lb. of Ceylon tea yearly to find its way into consumption in India yearly *free of duty!* The anomaly is monstrous."

The anomaly certainly does seem absurd, and we hope that, in the interest both of the Travancore planters and the port and trade of Colombo, steps will soon be taken either to abolish the import duty—which course the *Observer* considers the Ceylon Government will certainly adopt when memorialised by the planters of Travancore—or to allow foreign teas to be imported and taken out of bond for purposes of re-firing, etc., under the conditions mentioned above. The Island Government is not acting with that generosity towards the Travancore planters which the nature of the case demands. It realises next to nothing out of the import duty, and surely it is not too much to expect that some provision might be made against the adulteration, in the island, of Ceylon teas. We hope, therefore, that the Travancore planters will strongly urge upon the Ceylon Government the hardships which they now suffer owing to the embargo laid upon their teas, pointing out the vital importance to Ceylon of the cheap Indian labour supply and suggesting the need for reciprocity of treatment where both parties may reap so much advantage, and where the interests of Ceylon planters are not likely to be interfered with.

THE INDIAN TEA TRADE.

The good quality of the crop, says a Calcutta Exchange, was a characteristic feature of the season now brought to a close. Depressed by a low range of prices obtained for a large portion of the crop of the previous year, growers relinquished their original estimate of 129 million lb. for the season, and, instead, set themselves to produce a crop of high-class quality, which was secured with a probable out-turn of 113 million lb. tea. This is 6 million lb. less than the quantity packed during the previous year, and marks a falling-off in the production of Indian tea that had not occurred in any previous year. The system of plucking pursued did not wholly account for the deficiency, as the weather both in Assam and Cachar and the Dooars districts was unseasonably wet during a portion of the year, growth being thereby checked, the early arrival of the cold weather abruptly terminated manufacture. In Upper Assam and Cachar the rainfall was about 40 per cent. greater than the previous year, with a low temperature, and floods occurred in the Dooars. Customs returns do not disclose any deficiency in the export of tea from this port, either during the twelve months ended 31st ultimo or from the beginning of the season dating from 1st May. In the one case the export approaches 111 million lb. against 109 million lb. cleared during the year 1891 and in the other case the two periods correspond with an export of about 96 million lb. This season's crop, it is believed, has come more quickly to market and the reduction in supplies will become apparent in the balance of the crop to be received during the first quarter of the new year. The imports by rail during the past three months show 4 million lb. of tea in excess of the traffic for the corresponding months a year ago, and if the total crop is to be measured by 113 million lb. the balance obtainable from all sources after 31st December will be only 12 million lb. compared with 16 million lb. received last year. Of this quantity 106 million lb. may be available for export to the United Kingdom, and will be 4 million lb. short of the export of season 1891. A remarkable falling off in the export of tea to Bombay has taken place, amounting to no less than 3½ million lb. since May last. The offtake for Australia has been reduced by ½ million lb. while exports to America have made no progress, and but for this reduced offtake by other markets the quantity available for export

to London would have been still further reduced. Ceylon growth has entered the Bombay market to the displacement of the Indian product at very low prices and it is fully believed that the experiment has not been attended with financial success to the producer. It is doubtful if the demand for America will increase until the method of distribution is perfected, and this the efforts of private individuals, following the introduction through the Chicago Exhibition, it is to be hoped, may forward. The value of the crop of 1892 disposed of at public auction in this market approaches an average of As. 8-9 per lb. for upwards of 426,000 chests. This is As. 2 per lb. above the price realised for the crops of the two preceding seasons disposed of in this market during the same period. On the whole the trade has very fairly recognised the improvement in the quality of the crop through the better prices paid.—*Money and Trade.*

THE SUPPLY OF IVORY.

The recent investigations into the probable supply of ivory to the European markets do not support the generally supposed fact that it is only a question of an early date before ivory becomes an object of great cost. In the Congo district these investigations show that there is probably enough ivory stored among the native chiefs, within reach of the High Congo, to supply the whole world for a century to come. It is further estimated that in Central Africa there exists at least 200,000 elephants. The stock in hand, however, does not depend on these living elephants; for these petty kings have had handed down from their ancestors large piles of elephant tusks, which have been stored for trading purposes. This is known as "dead ivory," and is carried now to the Congo trade centres on the shoulders of natives for long distances, such as 250 miles. The average tusk is about 65 lb. weight, and forms the load for one man; but it is not unprecedented for single tusks to weigh as much as 200 lb., when they are carried by four men. It is interesting to see them coming into Matadi, often to the number of 500 carriers on a day, each with his load of ivory. Some of this "dead ivory" was grown on elephants killed so long as a hundred years ago, and has lain in heaps ever since. The chief receives and places on the top of the pile each tusk of "live ivory" as it comes in to him, only sending for trade the bottom tusks of the heap, although "live ivory" realises a better price than the "dead" or old tusks. It is said that a few months ago a State officer of the Congo visited, with an expedition, a native king in the interior, to whom on leaving he presented a uniform coat, cocked hat, and sword. The king in return presented to the officer 150 tusks of ivory, averaging 220 lb. each, and provided carriers to take them to the river. So familiar are the natives in these regions with the piles of ivory, which until recently has been unmarketable among them, that they laugh at the modern European who desires to buy tusks from them. Some of the kings have had stockades of ivory tusks built round their dwellings.—*Field*, Jan. 28.

THE BOOM IN EUCALYPTUS OIL.—The Melbourne *Argus*, describing a recent visit of a party of Victorian legislators, to Mr. Bosisto's distillery, states that the season is a remarkably favourable one for eucalyptus oil. During the previous week 142 gallons had been distilled, which is the largest yield yet reached, the weekly average being about 10 gallons. There are about 5,000 acres of land on which the mallee is cultivated, by rolling down the larger growth and allowing the shoots to grow for about eighteen months; when they are in the best oil-producing condition. The produce of about 1,000 acres is distilled every year. About fifty men are on the place at present, but twenty are about the regular number.

BRITISH RAILWAY RATES AND TEA.

We must all recollect how actively a few years back a crusade was preached against the severity and inequality of the rates charged by the Railway Companies at home upon divers articles. So strong and persistent—and in many cases, no doubt, so just—were the complaints made, that a Special Commission was appointed to inquire into the whole question, and very recently its decisions have been made known to the home public. It cannot be said that these have given satisfaction. So far from having accomplished this, it is now alleged that in many departments the new rates have illustrated the old adage of having "leapt from the frying pan into the fire." More especially is it complained that the revised rates bear with undue and exceptional weight upon the agricultural industries of England, the extra burthen imposed amounting, it is said, to in some cases as much as several pounds per acre annually. However, the matter has appeared hitherto to be one with which we in Ceylon had nothing to do. The new rates, it was supposed, would not affect any of our industries; but it would appear from the intelligence conveyed to us by our London Correspondent in his last letter, that the tea planters of Ceylon may turn out to be very seriously affected by the new rates imposed. These rates, as regards the carriage of tea by railway, must have been very seriously raised to have evoked the action proposed by the London Chamber of Commerce. This body, which watches so carefully over the interests of all trades within the United Kingdom, appears to entertain the fear lest the charges now to be made for the inland carriage of tea will place a very undue burthen upon the grocery trade, that which is, of course, the main and final distributant of our own staple product. We, in Ceylon, cannot afford to lightly regard anything which injuriously affects this particular trade. It is perfectly well-known that, owing to excessive competition in that trade, the margin of profits upon teas—except in very particular cases and as regard special qualities—that is left for the retailer is very narrow indeed. It may sound well to say that the retailer invariably almost sells tea at from fourpence to sixpence per pound in advance of the cost at which he obtains it, but it has to be remembered that rent, rates, taxes, and general business expenses have to be deducted from that amount before any return remains to the trader on which he and his family can depend for maintenance. We doubt very much if the absolutely net profit exceeds 1½d to 2d per pound when all such deductions are made. Hitherto the cost of the inland carriage of tea, even to the most remote towns of Great Britain, has been so small as to enable the trader to reap a fair profit. But this, it would seem, is, under the revised rates to be altogether altered, and it is natural therefore that the grocery trade throughout the kingdom should feel the pinch and is justified in its complaints that, should it be compelled to raise retail prices, a check must ensue to that increasing growth of the consumption of tea that has been such an important feature of the last few years within the United Kingdom. Here in Ceylon even, we have felt how imperative has been the demand for some reduction in the cost of carriage by the railway of the staple product of our estates. The producer feels the weight of this charge alike with the retailer, and to enable our planters to obtain a return upon their industry, it has been decided to afford them relief in this direction. This is identical with what the grocers at home now seek from the several Railway Companies to which they entrust

the carriage of their tea. We can only hope that in the endeavor to obtain this reduction, they may be successful. If the retailers are hampered as to the profitable distribution of tea, it is certain that the tea planters of Ceylon must feel the result in no insensible degree.

THE COCONUT PALM INDUSTRY IN CEYLON.

We call special attention to the long and instructive letter in another column, of our Correspondent "W. J.," well-known as one of the soundest and most experienced authorities in the island on the subject of Coconut cultivation. His opinion added to that of Mr. W. B. Lamont and Mr. W. H. Wright as to the great benefit and profit accruing from manuring, is decisive. But, of course, it is taken for granted that the soil is worth working up in this way and capable of responding and that the planting was fairly carried out in the first instance. There is a vast extent of native gardens where the first operation towards good culture ought to be a thinning out of trees. It is extraordinary how Sinhalese villagers even in the neighbourhood of Colombo, cling to the idea that the more palms or other fruit-trees they can crowd into their acre, half or quarter acre, the better off they are as proprietors! Between Colombo and Panadure the value of the Coconut cultivation, omitting a few exceptional plots, would be vastly improved if Government passed a law which would enable them to send out, say the present intelligent Mudaliyar of the Colombo Kachcheri with power to pull out or cut down all superfluous or sickly-dying palms and to show the people the proper distance at which they ought to cultivate and the great benefit that would accrue to them from a little—even a very little—regular cultivation, the burying of rubbish round the roots and the clearing of the tops of the trees. Indeed, if each District Mudaliyar were empowered to offer two or three prizes annually for the best kept coconut gardens, good might result.

We have said there are exceptions on the seaside between this and Panadure to the ordinary state of "hugger-mugger" in which most native gardens are left. One of the most notable is the ten-acre piece of coconuts belonging to Mr. de Soysa and leased to the Galkissa Peace Officer, opposite the Mount Lavinia Hotel. This is one of the best bearing, as it is one of the best cultivated, plots of coconuts in the island. If we mistake not, it was planted under the personal supervision of the Rev. J. G. Macvicar, Scottish Chaplain at Colombo, between forty and fifty years ago. Mr. Macvicar had bought the Mount Lavinia residence from the Government for "a mere song"—(the sale of the satinwood doors and windows repaying most of the purchase money)—and the piece of land opposite must have been included, or separately bought or leased. At any rate Mr. Macvicar, who was a great agriculturist as well as an eminent scholar, had it most carefully planted with coconuts, seeing that the nuts selected were large ripe ones (a most important matter) and that the holes for the young plants were of a proper size. The result, as we have said, is seen in some of the finest trees in the island, and crops which have averaged for a long time we are creditably informed about 4,000 nuts per acre. That should be close on 60 nuts per tree and a very good return it must be considered. Beyond Panadure and towards Kalutara especially, the coconut palms are devoted not to nut-growing, but to toddy-yielding, and therefore, apparently, it is not considered of so much importance to have the trees at the usual distance apart.

It is very interesting to hear from our correspondent about the Irrigation experiment of Messrs. Akbar Brothers on the side of the Mahaoya. We have no doubt it has proved a very profitable investment for these enterprising proprietors utilise their steam engine for timber sawing machinery when in the wet season, it is not required to drive the pumps. We are only surprised that their example has not been more freely followed in the dry Maha-oya district, by the owners of properties bordering on the river.

The coconut palm is a wonderful plant and it has evidently found a home in the South-west maritime belt of Ceylon which it loves as dearly as any spot on the face of the globe. The original habitat of this palm, according to Decandolle, must have been in the Eastern Archipelago, whence nuts no doubt floated to the Pacific islands on the one side, and to Ceylon, Madagascar, and Africa on the other. Be that as it may, not very much progress was made in spreading the cultivation of the palm in this island before the advent of the Dutch; for we know that even the seaside strip of palms between Colombo and Kalutara was first planted about 140 years ago under the direction of a Dutch Governor who levied Rajakariya on the adjacent villagers, that is, forced them each to plant up a portion of what had been previously waste land, for their own eventual good. The great extension of planting in Jaffna, Batticaloa and about Madampe and Calpentin has all been within British times; while the vast planting industry which has spread inland from Negombo up the Valley of the Mahoya, had its commencement quite within the present generation or from the "Sixties" onwards. Coconut cultivation is now about the most important as it is the most stable of agricultural industries in the island, and we may expect under the present stimulus of high prices for the produce, a considerable extension of planting. But the difficulty now is to procure first-class suitable land. Very little of this description remains, we suppose, in the Western Province? Wherever there is any, Government should have no hesitation in hurrying it into the market; for whatever may be said about tea, the planting with palms is in every sense, better for the island and its people, than the maintenance of the forest. Perhaps the only extensive reserve that is gradually but surely being encroached on for coconut estates is that alongside the coach road between Chilaw and Puttalam. Already a considerable area north of the Deduru-oya—soon to be spanned by a permanent bridge—has been taken up and planted, and before many years elapse, we may expect to find a continuous grove of palms all the way from the Deduru-oya to Puttalam. Although the region is an exceptionally dry one, the soil is one in which the palm seems to flourish, and not many feet down there is a moist stratum which helps to keep vegetation in heart even through a prolonged drought. Where else in the island, we would ask, is there any considerable area of Crown land suitable for coconuts? Of course, the neighbourhood of the tanks and also of the streams or rivers in the North-Central Province can be planted, as indeed much has already been cultivated there under Mr. Ievers' fostering direction. In Tamankaduwa and all along the lowcountry course of the Mahaveliganga, the palm ought to prosper; and there must also be unoccupied tracts very suitable for coconuts on the banks of the large rivers running through the Southern Province? If the Agents and Assistant Agents, in conjunction with the Surveyor-General,

were asked at this time to give a rough estimate of the area of Crown land in each district and province that they considered suitable for coconut cultivation, the return could not fail to excite interest and to be of considerable practical service.

VARIOUS NOTES.

THE GENERAL SCARCITY OF IVORY is said to have induced various firms in Sheffield to lay in a quiet stock of that commodity. In one cellar alone, in that town, ivory is stored away to the value of £20,000. It is also said that to supply a single Sheffield firm with ivory, the annual produce of 800 elephants was required, a few years since. But this demand has grown to such proportions that the same firm now have need of the tusks of 1,280 elephants per annum. If this sort of thing continues the elephants will soon have to follow the example of the unicorn and become extinct.—*Invention*, Feb. 28.

A NEW INDUSTRY.—A curious industry noticed at some length in Mr. J. L. Kipling's memorandum on industrial occupations has sprung up of late years in the Punjab. Large quantities of kerosine oil are imported from Russia and America, and tin cases when empty are sold at a cheap rate. They are eagerly purchased by the Punjab whitesmith, always a Mahomedan, who manufactures from them a variety of articles, useful and ornamental, including lanterns, despatch boxes, bird cages, watering cans, lamps, cans for the growing manufacture of jams and preserves in the hills, kettles and jewel boxes for Native ladies. Packing cases arriving from Europe are frequently lined with tin, and these are also used for the same purposes. The industry in tin is likely, in Mr. Kipling's opinion, to undergo considerable expansion. There is already a flourishing firm in Mooltan which imports the best qualities of tin, and turns out a variety of japanned despatch boxes and other wares; which for finish and price could challenge comparison with European articles.—*Pioneer*.

COFFEE PROSPECTS.—Much as a return to lower prices is to be desired in the interests of the home trade, it is feared that prices will continue to range high for some time to come, and buyers must be prepared for the worst if they do not wish to be placed altogether in a disadvantageous position. Although stocks in Europe are believed to be much heavier than they were in February last, a circumstance like this is of little moment when weighed against the probability—yea, almost certainty—of falling supplies through a deficiency, in the world's crops; and while the disparity between the quantities produced and those consumed exists, no relief from the present strained situation of the article can reasonably be expected. What renders the maintenance of stiff rates for coffee an almost foregone conclusion is the fact that the production generally is contracting rather than expanding, and the scarcity complained of is more the result of a prolonged absence of supply than of any sudden or marked increase of demand. The latter, if too brisk or extensive, might be kept under efficient control, and so moderated as to bring it within necessary bounds; but over the aggregate supplies from different countries no influence can be exercised beyond that of repeatedly advancing quotations for the berry, and, when these fail to attract the requisite shipments hither, there is no help for it but to pay the utmost money for the best assortment that can be got. In times of dearth, great inconvenience and difficulty are experienced, and that, too, for a whole season or more, as the coffee plant requires several years before it is fairly matured and capable of bearing any amount of berries; and let it be as eagerly wanted as may be, its cultivation is one that is always tardy, and which cannot in the least be hurried.—*Grocer*.

NOTES FROM OUR LONDON LETTER.

LONDON, March 7th, 1893.

Some time back you devoted several articles to discussion of the question as to how far it might be practicable to locally manufacture

A HYDRAULIC CEMENT IN CEYLON

to take the place of the large importation now made into your island of home-prepared Portland cement. I notice that there has just been discovered in Tasmania a natural cement stone which yields a product quite equal to—if not surpassing—the product of home artificial manufacture. Specimens of this cement sent home for testing have yielded results as to strength and setting power quite up to the highest standard known to experts here. You could probably get all the details from your Tasmanian papers, and it would be well worth the while of some of your mineralogists to get specimens of the stone and to compare them with such as are to be found in your island. There might be specially mentioned among these last the magnesian limestone found in such large quantities in the Jaffna peninsula, which I knew by personal experience to be possessed of some considerable amount of hydraulic qualifications.

Your former resident naturalist,

PROFESSOR MARSHALL WARD, F.R.S.

recently read a paper before the Royal Society entitled "Experiments on the Action of Light on *Bacillus Anthracis*. This paper has been very widely noticed, I believe, by scientific journals. I cannot pretend to be qualified to in any way describe it to you usefully in detail. It must content me to refer to the experiments described as evidencing that the direct solar rays seem to possess great power in retarding the growth of bacteria, and that by far the most patent factor in the purification of the air and rivers from these pests of the human race is the sunlight. This has long been suspected, but has hitherto only been very vaguely stated.

CORUNDUM.

Dr. H. Warth, Officiating Superintendent of the Government Central Museum, has asked the Board of Revenue to procure specimens of corundum for the Museum. The Museum has at present specimens of corundum from 24 different places in the Madras Presidency and in two principalities of Southern India, and as this mineral has since many years been an important mining produce and has of late been much inquired after as an article of export, Dr. Warth is desirous to exhibit corundum in the Museum from as many localities as possible. Such a collection would not only be a welcome source of information for the trade, but it would also form the basis for a future study of the geological conditions under which corundum occurs in the Madras Presidency. Collectors of districts have consequently been requested to comply with Dr. Warth's request and to send samples from each locality where corundum exists. Should there be any doubt whether any particular sample is the true corundum (the polishing material equal to emery and in main substance the same as ruby and sapphire, aluminium oxide) such sample is to be forwarded to the Museum for examination. In his "Geology of India" Mr. Ball remarked that since the name corundum is derived from the Hindi word *Kurand*, it is most probable that the stone first became known in Europe from having been imported from India. He stated also that at all the known localities in India where it occurs it has been worked by the natives and that there is reason to believe that the first discoveries date back to very early periods. Most of these localities are situated in Southern India.—*M. Times*, Feb. 21.

TRAVANCORE.

The total quantity of Coffee and Tea exported from Travancore during the year 1892 was 3,725 cwts. 43½ lb. of the former, and 7,491 cwts. of the latter, and the exports of Coffee from Cochin during the same period amounted to 219,102 cwts.—*M. Times*. [But most of the coffee sent from Cochin was of Travancore growth.—*Ed. T.A.*]

SEASON PROSPECTS IN SOUTHERN INDIA.

The Season Reports in the last *Gazette* showed that the crops in the parts of Tinnevely where rain fell last week had slightly improved, but otherwise they remained unaltered. Harvests so far have been poor, and prices of food grain both in Tinnevely and Madras, the two Districts that are suffering most, are still double the normal prices. It is satisfactory to know that Government is fully alive to the seriousness of the situation, and has already provided for the employment of the distressed in both Districts.—*Madras Mail*, March 3.

THE MAHA UVA ESTATE CO., LD.

Application has been made for the registration of this Company which is being formed with the object of purchasing the Maha Uva estate situate in Udapussellawa for the sum of R220,000. The property, we find, on a reference to our Directory, belongs to Mr. T. C. Kellock, and comprises 875 acres, of which about 500 acres are in tea, coffee and some cinchona. The capital of the Company is R300,000 divided into 600 shares of R500 each.

INDIAN TEA IN CEYLON.

Mr. Knight, the Chairman of the Travancore Planters' Association, telegraphs to us as follows from Colombo:—"The South Indian planters will accept nothing less than as perfectly free a market in Ceylon as Ceylon enjoys in India. The Quarantine laws, as suggested as an alternative measure, will not meet requirements. The Hon. Mr. W. W. Mitchell moved and carried a Resolution at the meeting of the Chamber of Commerce for a Commission to revise the Customs Tariff, especially referring to Indian tea and cinchona." This telegram, we presume, is by way of rejoinder to the article we published on the 24th ultimo, in which we said that it was to be hoped that steps would soon be taken to either abolish the import duty altogether, or to allow foreign teas to be imported into Ceylon and taken out of bond for purpose of re-firing, etc., if necessary, under the conditions we mentioned. The South Indian planters, however, are uncompromising opponents of any scheme that will not put them on the same footing as their Ceylon *confreres*. We sincerely hope that the Ceylon Government will accede to their reasonable demands and revise the duties in the manner desired. As we remarked in our previous article, provision might surely be made to protect Ceylon teas against adulteration without imposing an import duty on foreign teas.—*Madras Mail*, March 3.

NOTES ON PRODUCE AND FINANCE.

HOP TEA AND TOMATO COFFEE.—Under the title of "Snelling, Limited," a company has just been registered, with a capital of £100,000, in 2,000 founders', 20,000 seven per cent cumulative preference, and 29,020 ordinary shares of £1 each, no particulars being given of the remaining shares. The object is to acquire a certain patent relating to the combination of tomatoes with coffee, and to develop and work the same, also to acquire the business of tea dealers hitherto carried on at St. George's House,

Eastcheap, under the style of H. A. Snelling and Co. the Assurance Tea Company, &c., in accordance with an agreement made with the said H. Snelling; and, further, to acquire the interest of C. H. Craggs in a patent relating to the combination of hops with tea, coffee, cocoa, and other substances, and the business of manufacturing the same, now carried on by C. H. Craggs at St. George's House, Eastcheap, under the styles of Charles & Co. and the Hop Tea Company; and, with a view thereto, to adopt and carry into effect an agreement made between Charles H. Craggs of the one part and this company of the other part; generally, to carry on the businesses, both wholesale and retail, of manufacturers of and dealers in tea, coffee, cocoa, hops, &c., wine and spirit merchant, drysalters, &c., in all or any of their respective branches. The first signatories, who take one share each, are:—H. A. Snelling, St. George's House, Eastcheap, E.C.; C. J. Page, 8, Eastcheap, E.C.; J. Carter, 6, Eastcheap, E.C.; C. Scott, 19, Regent's Park Terrace, N.W.; J. E. Davies, 71, King's Road, Peckham; W. S. Lambert, 23, Simpson Street, S.W.; E. M. Mackie, 20, Prideaux Road, Clapham Rise, S.W. There shall not be less than three nor more than seven directors. The first are H. A. Snelling, C. J. Page, and C. J. Ash. Qualification, £400. Remuneration to be fixed by the company in general meeting.

CLOVES.—The speculative movement in Zanzibar cloves is growing, and some American buyers are reported to have entered upon the scene, and prices following the double pressure of home and American buying have rapidly advanced, thousands of bales changing hands at each rise. Rumour of a probable failure of the crop imports additional interest.—*H. and C. Mail*, Feb. 17.

THE AMSTERDAM CINCHONA SALES.

(Telegram from our Correspondent.)

AMSTERDAM, Thursday Afternoon.

At today's cinchona auctions 3,045 packages of bark sold at a slight but all-round decline, the average unit being 5½ cents or as nearly as possible 1d per lb. Manufacturing bark in quill, chips, and ground, brought from 8 to 55 cents (=1½d to 10d per lb.); ditto root, from 15 to 42 cents (=2½d to 7½ per lb.); druggists' bark in entire and broken quill, from 18 to 45 cents (=3½d to 8d per lb.); ditto in root, from 9 to 14 cents (=1½d to 2¼d per lb.). The principal buyers were the Brunswiok, the Mannheim, and the Auerbach Quinine Works.—*Chemist and Druggist*, Feb. 18.

INDIAN TEA DISTRICTS.

Our Morianie Correspondent writes on the 18th February 1893:—Splendid tea weather.

Our Ranchi Correspondent writes on 20th February 1893:—Weather seasonable, rainfall to date 1.05. Since our last report the mosquito blight and green fly whose advent was anticipated has arrived, so far in only a limited number, but sufficient to cause planters the utmost concern for the future. Red spider has taken a firm hold and evinces a more pronounced partiality for the tea than "consumers" have hitherto done.

Our Darjeeling Correspondent writes on the 22nd February 1893:—A somewhat higher temperature has been registered the last few days. With high winds in the afternoon the nights are still very chilly though. Pruning about come to an end throughout the district. Rainfall since November last has been about 1.60 of an inch, which has been fairly evenly distributed over the different months to date.

Our Kangra Valley Correspondent writes:—At last we can see the "sun," and I trust we may be favoured with a good visit. We have had nothing but incessant rain and snow during the day and heavy frost at night. Rainfall over 6 inches in February to date. The question is, How are we going to pay for this moisture? We can certainly do with a light monsoon, but are we to have a late monsoon and not a drop of rain between whiles?—*Indian Planters' Gazette*.

INDIAN TEA COMPANIES.

Ellebarrie Tea Company.—Outturn was 3,436 maunds, and the average price obtained was annas 8-4 per lb. A gain of R46,720 is the result of the season, which, on the capital of 1½ lakhs, is most satisfactory. In absorption in profit and loss account a total of R55,324 appears. An adinterim of 10 was paid and a final of 15 is proposed, making in all 25 per cent of dividend for the year. To working capital R10,000 is transferred and a balance of R7,824 is carried forward. All the young tea is favourably reported on, and a further small extension is contemplated. The estimate this season is for 3,200 maunds.

Mahurgong Tea Company.—Outturn was 1,559 maunds and average obtained annas 6-10 per lb. Like all Terai gardens blight has been to blame, to which must be added cholera in July and excessive rain in August and September. The net profit was R234. The balance at debit of profit and loss account is R6,325. The Managing Agents state that as the garden on its present footing is never likely to do more than exist, they are prepared to give their best consideration to any proposal the shareholders may submit for supplying funds for the purpose of planting out 300 acres of new land within the grant with high class indigenous plant.

Sapaketi Tea Company, owing to unfavourable weather and difficulty in labour, made only 690 maunds, and obtained an average of annas 8-9 per lb. Revenue account shows a gain of R5,265 and profit and loss account a balance at debit of R15,316. This is a class of garden that never appears to make any headway, and is habitually in debt to those who are good enough to finance it from season to season.

Longview Tea Company.—Outturn was 2,158 maunds and average 8-1. Revenue account shows a profit of R3,001, after applying R5,155 to depreciation of machinery. In adjustment in profit and loss account a balance to the good of R1,007 is carried forward. In this season it is estimated to make 2,850 maunds, and off Kallabarree, an adjoining garden that has been leased, 480 maunds.—*Pioneer*.

DRUG AND BARK REPORT.

London, Feb. 16.

ANNATTO.—Seed is tending just a little lower—today holders accepted a bid of 2½d per lb. for 64 bags good bright Ceylon seed.

ARECA.—Six bags from Penang sold today at 26s 6d per cwt, showing a somewhat easier tendency. Another lot was bought in at 30s per cwt.

CALUMBA.—In fairly good demand at rather irregular, but upon the whole steady, prices. Of 137 bags 55 brought 29s to 30s for fair yellow sorts, and 17s to 17s 6d per cwt. for dark brownish and watery ditto.

OILS (ESSENTIAL).—A parcel of 10 tons Citronella oil in iron drums, shipment up to the end of May, has been sold recently at 10½d per lb., c.i.f. Liverpool. On the spot the price for usual quality native brands is 13-16th d per oz. Lemongrass oil on the spot is held for 1½d per oz.

CINNAMON.—Rather dearer. For arrival 100 bales "usual assortment" Ceylon, January-March steamer shipment, have been sold at 6½d per lb. c.i.f. terms.—*Chemist and Druggist*.

TEA BLIGHTS.

The Tea Association lately considered a letter of 19th January, from Messrs. Begg, Dunlop & Co., suggesting in the event of the Association retaining the services of Mr. M. K. Bamber, that one of the abandoned Terai gardens might be utilised for prosecuting a special investigation of blights under his superintendence at the general expense of the tea industry. The Chairman stated that Mr. Bamber had obtained an appointment under Government, and he feared his services would be no longer available after the close of his agreement.—*Englishman*.

SCIENCE NOTES.

In a late number of *Insect Life*, Mr. L. O. Howard publishes a note upon the use of kerosene against them, the substance of which is as follows:— On the surface of a pool of water, containing about 60 square feet, he poured 4oz. kerosene. This formed a very thin oily film on the surface of the water. On the 5th of July the pool was teeming with animal life, but for the next 10 days that the pool was under observation no living insects were observed. At the end of this time, a count of the insects on a small portion of the surface, from which was estimated the total number, showed 7400, 370 of which were mosquitoes. The kerosene remedy was tried this last summer on the swamp meadow pools of Stratford, Conn., with much success.—*Sydney Mail*.

In the last number of the *American Naturalist* there appears a paper by Dr. H. W. Conn on "Some uses of Bacteria." These organisms are in the position of the dog which got a bad name. People think of them as so many deadly microscopic foes, whereas, generally speaking, many of them are our best friends. Every farmer expects that he will have to keep a good breed of horses and stock, but few of them are aware that they require a good breed of bacteria as well. Indeed, no farmer can get on at all unless he keeps a good stock of bacteria upon his farm! He is aware, of course, that he cannot make butter or cheese without cows, but until recently he did not know that even if he possessed the finest herd of kine he would not be able to manufacture these articles of food without bacteria. Tillage, whether in the garden or the field, would be thrown away without their aid, for it is they which make all sorts of nitrogenic manures available. Bacteria are amongst the most lowly forms of plant life, very nearly allied to the microscopic yeast and other similar fungi. It is more than probable that we owe more to these microscopical members of the vegetable kingdom than to its larger and more advanced species.

One of the most important chemicals used all over the world is caustic soda. Hitherto the process of its manufacture has been slow and roundabout. Now an altogether new method has been discovered by which caustic soda, chlorine, and other chemical products can be made from the brine directly by the aid of electricity. The new process is also a more economical one by at least 50 per cent. as compared with any or all of the present methods. It is much simpler the caustic soda being produced in one operation instead of two. The valuable chlorine is also saved and utilised for the production of bleaching powder (chloride of lime) and other by products. Our most eminent chemists have pronounced this new method of manufacture a complete success, and the chemical industries of the North of England promise well in the future in consequence.

What is the difference between an annual and a perennial plant? A thoughtless person will at once tell you that one never lives more than a single season, and the other for perhaps many. But this is not an explanation; it is only a statement of facts. Annuals are remarkable as being free-flowering plants. We grow many species of them in our gardens on account of the abundance and beauty of their flowers. Flowering is an act of vegetable expenditure, whereas leafing is one of vegetable accumulation. Annuals are in reality plants which expend their substance in riotous floral living and seeding. They wear themselves out in a single

season thereby. They have spent all they have, and there is no vegetable surplus left over to carry them through the winter and enable them to start business again when spring reappears. On the other hand, perennial plants of all kinds bear more leaves than flowers. They save something out of every summer's existence, and put it into their vegetable savings bank—as in the increasing size of a tree's trunk for example. If we could only induce annual plants to be a little more thrifty, a little less lavish in their floral expenditure, perhaps we could alter their habits of life, and convert them to the perennial condition.

This is what Professor Meehan, a distinguished American botanist, claims to have done, and he has just read a paper on his method before the Philadelphia Academy of Sciences. It is a very simple plan, and consists in cutting down the flower stems as soon as they appear. Thus no expenditure can take place, only vegetable accumulation. An annual plant gets transformed into a perennial, and by continuing to cut down the flower stem the perennial condition can not only be secured, but possibly may be inherited.

The waste of a great city might easily feed its desperate poverty. Chemists turn scrap iron into ink; old bones into lucifer-matches; the shavings of the blacksmith's shops into Prussian blue; fusel oil into oil of apples and pears; the drainings of cow-houses into fashionable perfume; cesspool filth into ammonia; and tar waste into aniline dyes and saccharine. In Paris they first utilise rats to clear the flesh from the bones; then kill the rats, use up the fur for trimmings, their skins for gloves, their thigh-bones for toothpicks, and their tendons and bones for gelatine wrappers.

Last week I was lecturing in Cumberland and Westmoreland, opening the sessions of the local literary and scientific societies. I was taken to Troutbeck, one of the largest stream-feeders of Lake Windermere. It comes brawling from the hills, through cataracts of weathered stones, overhung by beech-woods, which latter glowed in the vivid slanting sunlight of the November afternoon like the burning bush of Moses. The old picturesque mill water-wheel, sketched by generations of dead artists, has gone. The energy that turned it to grind expensive corn, and to manufacture still more expensive bread, will never go; for the old mill-race which ground the people's corn 500 years ago is now utilised to work a turbine to provide electric light and power for the adjoining villages of Windermere and Bowness. The neighbouring hills are formed of strata infinitely more ancient than our coal-bearing mines. There is nothing in them of the nature of coal, but on the outside of their hilly flanks, where the mists accumulate and the rains descend in torrents to fill the beckes and burns and ghylls, we have a modern energy quite as powerful, and as equivalent for practical working purposes for ages to come as if a quarter of those hill masses were composed of coal.—*Australasian*.

VEGETABLES IN INDIA AND CEYLON.—Were people strictly to adhere to vegetables and fruit as part of their ordinary diet, the services of the doctor would not be so frequently required. In the matter of vegetables celery, onions, cauliflower asparagus, carrots, parsley and watercress should be at all times freely used, and surely they are easily enough obtained.—*Nilgiri News*,

IMPORTS OF TEA INTO THE UNITED STATES.

From the *American Grocer* we take the following figures which, in some respects, are far from satisfactory:—

Year.	Net imports. Pounds.	Value. Dollars.	Per head of population: Pounds.
1880 ...	69,894,769	18,983,368	1.39
1881 ...	19,130,849	20,225,418	1.54
1882 ...	77,191,060	18,975,046	1.47
1883 ...	69,597,945	16,278,894	1.30
1884 ...	60,061,944	12,313,200	1.09
1885 ...	66,374,365	13,135,782	1.18
1886 ...	78,873,151	15,485,265	1.37
1887 ...	87,481,186	16,365,633	1.49
1888 ...	83,944,547	13,154,171	1.40
1889 ...	79,192,253	12,561,812	1.28
1890 ...	83,494,956	12,219,643	1.33
1891 ...	82,395,924	13,639,785	1.32

Thus, although the total importation of tea has increased in the 12 years by about 13½ million lb., the consumption per head per annum has positively decreased! Thus if the people of the United States used tea now at the same ratio per head as in 1880, they should require over 100 million lb. in place of 83 to 85 millions at the present time. The fall in value is also noteworthy: the average being over 1s 2d per lb. in 1880 against about 9d in 1891 if we take the dollar at its full value of 4s 6d, though this is of course, too high now. We can only hope that our American cousins may awake to a true appreciation of the value of really good pure tea and that the Chicago Exposition may aid largely in promoting an increased demand for our Ceylon produce. Altogether during 1892, the United States and Canada as well as South America took of Ceylon tea:—

From Ceylon direct to "America" ...	100,893
From London to United States ...	710,365
Do. to Canada ...	613,817
Do. to S. America ...	200,113
	1,625,188

Say that 800,000 lb. of the above was for the States, it does not make one per cent of the present total importation! There is therefore immense scope for the increased use of Ceylon tea in the United States of America.

TROUT OVA FOR NUWARA ELIYA.

Mr. Fowler, Assistant Agent at Nuwara Eliya, is imitating the public spirit of his predecessor in getting out consignments of trout ova, and Mr. Tringham is now in Colombo to meet a fresh supply which he expects to convey safely to Nuwara Eliya by Monday next. When, as is fully expected, success attends the experiment and fry are ready for distribution, the same will be made available at a moderate charge for gentlemen who may be interested in different streams throughout the hill-country.

THEFT OF TEA PLANTS.

P. O. Urugalla, 357, Police Constable 301, Sundera complainant, v. Tennepettegedera Kalua, defendant.

Messrs. Jonklaas and Williamson for the accused.

The accused was charged with committing theft of about 400 tea plants of the value of R6, the property of Douglas Donald, Esquire, in breach of the 367th section of the Penal Code.

JUDGMENT.

The defence in this case proves nothing. It may or may not be that the accused some years ago wrote out a transfer for this land in favour of his son, but that is not a very extraordinary thing to do.

Many natives write out deeds for their lands in favour of their sons, or wives and friends; and they have no doubt various purposes in view in doing so. It may be that the deed in favour of accused's son is a deed intended for the son's advancement; but there can be no doubt (for it has been proved not only by the witnesses for the complainant but by witnesses for the defence) that the land is still in the possession of the accused, and has been dealt with by the accused as if it were his own. The very man who, the accused says, planted the land shows that about three months ago the accused gave him some tea plants to plant out, and that he planted them for the accused. That is a fact which undoubtedly shows that in spite of the deed the accused is in possession. No doubt the planting will be to the benefit of the son, but the important fact remains that the accused has been planting the land or getting it planted. How does that fact affect this case? I think that fact affects this case most materially. On the night of the 4th October last one of Mr. Donald's tea nurseries, planted out (amongst other kind of tea plants) with tea plants of Manipuri jāt (as the technical phrase goes) was robbed. On the morning of the 5th October (by a mistake of mine written as ult., a mistake which however, I have corrected) Mr. Donald finds, that a whole bed of his Manipuri tea-plants (numbering about 6,000 plants) was robbed, and every plant in it carried away. Within 12 days after that the constable (complainant), who had been sent to try and trace out this wholesale theft, finds in passing over accused's garden there are plants growing there which the kanakapulle of Mr. Donald's estate recognises at once as his master's tea plants. I have no doubt that men like the kanakapulle who have constantly to do with the planting and nurture of tea plants, would at once be able to recognize the different varieties of plants which they have to tend. A few of these plants (those in the parcel Ed A.) were taken from this garden to Mr. Donald and he recognized them at once as plants of the kind that were stolen. He proceeds to the spot the next day and finds in a small corner of the garden (now proved conclusively to be accused's garden) about 400 plants, so exactly like those stolen from his garden, not only in age, size, appearance and variety, but also in respect of certain marks of disease on the leaves, and all so recently planted; that he undertakes to the best of his belief to swear that they are his plants. I am not prepared to say that he is not able to swear to these plants. Such specific knowledge though not possible to me, is, I have no doubt, possible to gentlemen whose speciality it is to watch the growth of plants put out by them and thus to be able by ocular inspection to discriminate between plants of different varieties, and to speak with a high degree of certainty with reference to them. In a case of this kind I could not say that a higher degree of certainty as to the plants being Mr. Donald's tea plants, would be necessary. The recent and unaccounted for possession of stolen property is evidence of theft. It is incumbent on the party in whose possession such property is found to prove how he came by it; and where that is not proved, it is a fair presumption that he came by it feloniously. In this case no attempt has been made to prove it; and the accused instead of that has been trying to throw off the responsibility that presses so heavily upon him by saying that the land belongs to his son. This defence, I hold, has failed. It is true that when the garden was first visited by complainant and the kanakapulle the accused was not in. He of course would not always be in the garden; for he lives a mile away from it as the Ratamahatmaya says. However, that he knew of this visit, and that he was meditating a defence which looked like trying to implicate the constable in a fraudulent attempt to get him into trouble, appears from the fact that on the 25th November (4 days before the summons was served on him) he went to the Ratamahatmaya and voluntarily made a statement which shows that he was cognizant of what was looming against him. He seems to have abandoned the though

of trickery on the part of the complainant, and finally settled on the fact that the land did not belong to him, and therefore no responsibility attaches to him. For the reasons I have given above, I think differently. I find the accused guilty on the charge framed against him by me,—of theft of about 400 tea plants,—and I sentence him to undergo rigorous imprisonment for a period of three months.

(Signed) J. H. EATON, P. M.

In Appeal the conviction was affirmed by Withers, J., who held as follows:—"This conviction must be affirmed. The identity of the tea plants was sufficiently well established, and their possession by accused was of such a character, and in time recent enough, as to justify the inference of theft"

26th January 1893.

LONDON SALES OF PRODUCE: MOTHER-O'-PEARL SHELLS.

(Monthly Report from M. L. Spiegel & Son.)

LONDON, Feb. 14th, 1893.

A generally good demand prevailed and nearly the whole sold. Unusually large supplies of Queensland sold steadily for good, but 5s to 10s cheaper for the lower kinds; thin medium brought firm rates. The moderate supply of West Australian met a good demand, bold sizes about 5s dearer, thin medium steady, chicken 5s to 7s 6d higher. Manila sold at steady prices. Larger supplies of Bombay mostly sold, bold at irregular prices, medium and small at full rates to 5s dearer. An increased supply of Egyptian was also offered and with a good demand, nearly all sold, bold at firm prices, medium and small 5s to 10s dearer. Black-edged met a strong demand, and the few lots of Tahiti sold dearer, Gambia and Auckland full to 10s higher, Fiji 5s to 10s and Banda about 5s dearer. Panama brought about previous rates.

QUEENSLAND AND SYDNEY.—2,036 cases, 18 boxes, 1 cask, 29 bags almost entirely sold, bold and medium shells, chiefly Torres Straits character, fair to good white mostly clean, at £7 7s 6d to £8 5s one lot fine white at £9 7s 6d ordinary partly wormy £6 5s to £7 5s inferior £5 10s to £5 17s 6d thin medium selected, ordinary to good £8 5s to £9 5s a few lots fine £9 7s 6d to £9 12s 6d; 2 cases chicken £10 to £10 2s 6d bold wormy pickings 7s 6d to 9s 6d stale and dead 2s to 7s 6d, broken pieces £5 5s to £6 7s 6d, one lot £6 12s 6d.

MANILA.—Bold and medium, fair part yellow to good fair £7 15s to £8 2s 6d, ordinary £7 7s 6d chicken £6 17s 6d to £7 bold wormy defective 90s to 95s, broken £5 5s.

MACASSAR.—Of 19 cases indirect import 8 cases defective picking sold at 90s.

PENANG.—Heavy bold partly wormy at £6 5d to £6 7s 6d, thin medium £7 to £7 7s 6d, chicken £7 7s 6d to £7 12s 6d, heavy wormy, defective 70s to 72s 6d.

BOMBAY.—Heavy bold and bold at £5 to £5 7s 6d, thin bold and medium £6 2s 6d to £7, medium £6 10s to £6 15s, thin medium and small £5 15s to £6 7s 6d, small sizes £5 to £5 17s 6d, thin small and oyster 80s to 90s, oyster 60s to 72s 6d, broken 55s to 65s, stale and defective pickings 25s to 57s 6d.

LINGAH SHELLS.—Fair to good small 12s to 17s, ordinary 7s to 10s 6d, one lot fine 22s 6d. Of 1,542 bags ordinary Ceylon 1,000 bags sold at 3s 6d to 4s 3d. 100 cases Japan partly sold at 7s 6d per cwt.

MUSSEL SHELLS.—The large supply of 692 cases 17 casks 2,553 bags met a good demand at a decline of 2s to 3s medium and small at 35s to 38s, medium sizes 40s to 44s 6d, bold and medium 45s to 47s 6d, good to fine bold 49s to 57s 6d per cwt.

EAR SHELLS.—480 cases sold at previous rates to soko advance for the better kinds, trimmed bold and medium good to fine stout 70s to 90s, mixed part crinkly 42s to 67s 6d, inferior thin and small 18s to 39s per cwt.

GREEN SNAIL SHELLS met a good demand at firmer rates. Of 121 baskets 373 bags Penang and Singa-

pore 40 baskets 300 bags sold, bold 100 shells weighing 192 to 211 lb. at 7½ to 7¾d, 170 lb. at 7d; medium 100 shells 110 lb. at 5d to 5¼d, and 100 shells 92 lb. at 4¾d; small, 66 to 73 lb. per 100 shells at 3d to 3¼d, 56 to 59 lb. at 2¾d. 39 bales Japan sold, 210 lb. per 100 at 8¼d to 8¾d, 120 lb. per 100 at 5¼d to 5¾d; chicken 3d. 19 bags Sydney sold, 256 lb. per 100 at 6d each.

TORTOISESHELL.—The supplies of all kinds brought forward in auction on the 9th were moderate, and with a good demand nearly everything sold, in several instances at higher prices. Nasau and West India; shell very firm to 2s advance. Hoof 2s to 4s dearer. Yellowbelly very irregular and 3s to 6s dearer on the average. Zanzibar and Bombay; sound shell 1s to 2s dearer; defective steady. Sydney and Fiji; shell par to 1s dearer. Penang and Macassar; shell about 1s to 2s dearer. Seychelles 1s to 2s dearer.

WEST INDIA SHELL.—(Nassau, Havana, Honduras, &c.) Selected, part reddish 31s to 42s; Nassau, Honduras and Belize sorts, fair to good mottle part stout 20s 6d to 23s 6d; W. I. sorts with heavy plates, good dark mottle (one lot good bold heavy 25s), 18s 6d to 23s 6d; pickings fair to good heavy 14s to 17s 6d; ditto part thin 9s 6d to 13s 6d; chicken 11s to 12s. Hoof—about 880 lb. offered and sold; Nassau and Belize pale clean, fair to good (one good clean lot 28s 6d), 24s to 26s; W. I. pale heavy part scabby (3 lots of good heavy 26s 6d to 27s 6d), 13s 6d to 22s; scabby and burnt, ordinary to fair 10s to 15s. Yellowbelly—About 597 lb. offered and mostly sold; Nassau and Belize, good pale bold stout 30s, 30s 6d to 36s 6d, ordinary to good fair 16s to 25s, very ordinary 13s 6d; W. I. dark reddish to good heavy 16s 6d to 23s, part thin 9s to 13s, very common 2s 6d to 7s.

ZANZIBAR AND BOMBAY.—Medium to bold dark not mottle part heavy 18s 6d to 21s 6d; pickings fair 11s 6d to 12s 6d, ditto Bombay, ordinary thin to fair 8s 6d to 10s 6d.

SINGAPORE, PENANG AND MACASSAR.—Fair to good sorts 14s to 19s, defective 10s; hoof dark and burnt 13s 6d.

SYDNEY AND FIJI.—Medium to bold, fair to good substance with plates 19s to 23s 6d; pickings, defective common to fair heavy 9s 6d to 15s, yellowbelly very common 1s; hoof, part burnt 14s.

SCARCITY IN RAMNAD: REASON FOR NOT EMIGRATING TO CEYLON.

Owing to the scarcity in the Ramnad Zemindary, numbers of people have begun to emigrate into the adjoining district of Tanjore in search of employment. In his fortnightly report submitted to the Board of Revenue on 1st February, the Collector of Tanjore wrote as follows:—"I find that throngs of people from Ramnad are streaming northwards in search of work. They follow the line of *chattrams* along the coast where cooked food is served. At Mammelkudi *chattram* alone over 4,900 immigrants from Ramnad have been fed during the last two months on their road to the delta. The immigrants are now mostly travelling in companies of from 30 to 60, the men, being followed by their wives and children. Some of the companies are taking their bandies cattle, goats and tOWls. One company of 60 Maravars, whom I have just spoken to, have with them 4 bandies, 20 bullocks and about 40 goats. They say they left their villages five days ago and that they are going to Negapatam 'to carry rice sacks.' Yesterday and today I have spoken to five or six gangs of this sort, and have met besides a large number of families and individuals, all of whom return the same answer, that there is no food in their country for man or beast, and that they are going north in search of food and work. The immigrants are chiefly Maravars and Idaiyars, but I have also met Pallars, Naikars and Ravuthars. The men hope to get work as porters at Negapatam and the women hope to get work in pounding paddy. I asked some of the men why they did not emigrate to Ceylon or the Straits. The answer was men can emigrate one by one, but what are we to do with our wives, children

and cattle?" The Collector of Tanjore was afraid that if this invasion should continue there would be no demand for work in Tanjore and relief works will have to be opened. He therefore, directed the attention of the Collector of Madra to the emigration. The Collector of Madra urged the immediate starting of works in Ramnad to be paid for out of a loan to be advanced by Government to the Zemindar. The Board of Revenue as soon as they obtained this information communicated with the Zemindar on the subject and the latter informed them that he had estimates ready for the repair of irrigation works to the amount of upwards of R98,000 and that he was prepared to expend that sum in giving work to his tenants on the Zemindari if he be allowed to postpone payment till next fasli of an equivalent of peishansb. Accordingly, at the instance of the Board the Government have agreed to postpone the payment of the peishcush to an amount not exceeding one lakh of Rupees, provided the money be paid into the Collector's Treasury to be laid out on the repair of irrigation works in the Ramnad Zemindari and have deputed a competent officer to take charge of the relief works in the Zemindari. It is much to be regretted that such a rich Zemindar as the Rajah of Ramnad is not in a position to spare a lakh of Rupees from his purse for relief works without applying to Government for the postponement of the peishcush.—*Madras Standard*, March 3.

PLANTING NOTES FROM BADULLA :

COFFEE, &C.

March 8.

THE WEATHER has been very dry for February, no rain at all having fallen until the 27th. Since then we have had a few good showers and some thunder. The rain is working up from the north-east still and it will do everything good.

THE COFFEE BLOSSOMING SEASON for autumn crops has so far been quite perfect, and all coffee in fairly good heart which has escaped hug, at low and medium elevations is full of spike; and a very fine blossom burst yesterday. Alas! that so few of our fine fields of coffee are in a condition to profit by the season we have had. Hundreds of acres are still leafless; and I greatly fear must before long go into tea. I believe autumn crops have turned out fairly up to estimate, but what spring crops there are will, I expect, as a rule, prove disappointing.

TEA, which was commencing to feel the drought, is now showing signs of responding; and with the showers we have had during past few days, and as we are not now likely to have any more, really dry weather will, I expect, continue flushing well, as it ought to do, during next four months. The cold winds in January and February have not however suited tea: February was not such a good month as it was either in 1891 or 1892; and March has commenced badly. Fields which are due to be pruned in July moreover (when they will have run two years) are not looking as well as they should, and we want a good deal more warmth before unpruned tea will 'jump.' Pruned fields are flushing freely.

THE NEW ROADS in the district are being pushed ahead fast, and another three months will see most of the earth-work finished. The Railway (it is said) is to be opened on 1st May, and a large gathering from the whole Province will assemble on the occasion.

We had a very successful meeting of the Association in February, and the Chairman had reason to be proud of the record of work done during the past year. With the railway coming into the district, the present should be a still busier year.

It was with the greatest regret that we saw the sad news of our old Chairman, Mr. KARSLAKE's death. He was for years closely connected with those districts in which he lived and was so much respected. He did much for the Province; and in his capacity as Chairman of the Association was able to carry many important matters to us all to a successful conclusion. Everyone respected him and everyone will regret his death.

NEWS FROM THE CENTRAL PROVINCE: PLANTING AND OTHERWISE.

(Notes by "Wanderer.")

March 10.

PRICES OF TEA.—There are too many 8d and 9d in the last mail's tea circulars to please those interested in Ceylon tea. The exigency of the cheap tea canister causes a greater demand for Japan and China stuff than the dearer Ceylon pekoe souchong.

WEATHER.—Fine rains are falling everywhere, so the end of March and April will now be a busy time for the planter, and the busy time may extend to July, if we have not a very heavy burst of the S.-W. monsoon.

TEA EXPORTS.—To 6th March 1893	12,960,768
as against 1892	11,226,061

Excess ..	1,734,707
-----------	-----------

If we go on at this rate we shall export at least 7,000,000 lb. more than last year. Australia is however doing so well for us that our London friends need not be apprehensive that we will flood their market.

AMERICA seems to be anxious to stop the export of gold; and so she will have to part with her silver freely to attain this object. Will this make silver dearer or cheaper? Messrs. T. C. and A. M. W. will no doubt enlighten us.

TEA COMPANIES seem to be favourite investments with those who have spare cash. So long as tea remains about 10s and exchange does not go above 1s 4d, a seven years' purchase on these lines on a sufficient quantity of tea per acre is by no means a bad investment.

CACAO.—99l per cwt. on the estate is not a bad price; so, lucky is the cacao proprietor now-a-days, the moth (*Helopeltis*) and the thief notwithstanding!

FREIGHT at 25s is also in favour of the tropical agriculturist—15s was too good.

CHICAGO EXPOSITION.—There are doubters in planting circles of the advisability of spending so much money on what they call a "pure advertisement of Ceylon tea." Has a scheme for the supply of such tea as is exhibited in the Exposition been devised? Why tantalize the American with your tonic teas grown on ironstone soil, if he cannot get what you assure him is so good for him? Does not your advertising benefit cheap canister men who have done Ceylon tea produce a good deal of harm in the old country?

DAIRY FARMS.—When is the Ceylon Government to follow the example of the Indian Government in encouraging the supply of untainted milk in town especially where there are garrisons? Enteric fever is not unknown in Ceylon.

SALE OF CACAO PROPERTY.

We learn that Mr. J. H. Barber has taken over his partner's (Mr. Vanderstraaten's) $\frac{1}{2}$ share in the "Grove" estate, Ukkuwala for K25,000. The estate is about 200 acres and is all planted with cacao, arekanuts and pepper. The large cacao beans of this estate carried off the Governor's special prize at the last Colombo Show. The trees are all *Forasteros* of the best sorts. Mr. Barber pioneered the district for cacao in 1886; since then Mr. T. C. Owen and others, and now the Ratwatte Cacao Company have secured land there. It will be all cacao in that neighbourhood shortly.

INDIAN TEA FOR CHICAGO.

Minutes of meetings of the Chicago Exhibition Committee, held on 16th and 27th January, and 3rd, 10th and 17th February, were placed before a meeting of the Tea Association the other day, and the Chairman stated that the tea sent in for exhibition and distribution had been shipped, freight free, per "City line steamer, and a collection of first-class photographs in connection with the tea industry had also been forwarded. He had engaged the services of ten khitmutgers, and was arranging for their clothing and passage at reduced rates by British India Steam Navigation Company. Mr. Blechynden had been in London, but had now returned to Chicago. A pavilion was being erected and the London Committee had expressed themselves satisfied with Mr. Blechynden's arrangements generally.—*Englishman*.

NATAL TEA PRODUCTION.

Our special tea correspondent at Kearsney writes.—Unless something very extraordinary happens, such as a visitation of locusts, or a withering blast of red spider, the outturn of January has put our original estimate within easy reach, and the whole Natal crop for 1892-3 should considerably exceed half a million pounds. During January, in both rainfall and cold weather, we have had our full share, but the bushes are "flushing" away merrily, and the difficulty is to get the leaf off fast enough. Even if we get another long drought, as we did last year, there is sufficient moisture in the ground now to tide us over a large proportion of the remaining season. The total outturn for Natal may now be safely raised from 560,000 lb. to 600,000 lb.—*Natal Mercury*, Feb. 8,

NATAL TEA.

TO THE EDITOR OF THE "BRITISH AND SOUTH AFRICAN EXPORT GAZETTE."

Dear Sir,—In a recent issue of your valuable "Export Gazette" you made reference to Hulett's Natal Tea. While much appreciating your kind notice, I beg to draw your attention to the fact that there was an error in the figures you gave as to the output. Instead of the weight you gave, it should have been very much more, viz. 355,000 lb. for the 1892-93 season. I beg to enclose you some particulars of the Kearsney teas—which you may be interested to learn have just been awarded a gold medal at the Kimberly Exhibition—as well as special prizes for individual classes of teas.—I am, dear sir, yours truly, C. HAITH, For J. L. Hulett & Sons, Ltd., Natal.

VARIOUS AGRICULTURAL NOTES.

THE VALUE OF EGGS as food is an important reason why fruit growers should go in largely for fowls. Six large eggs will weigh about a pound. As a flesh producer one pound of eggs is equal to one pound of beef. About one-third of the weight of an egg is solid nutriment, which is more than can be said of meat. There are no bones and tough pieces that have to be laid aside. Practically an egg is animal food, and yet there is none of the disagreeable work of the butcher necessary to obtain it.—*Horticultural Times*.

MR. T. WALKER AND FROZEN MEAT.—We are glad to welcome so enterprising a colonist as Mr. Walker back to our midst and in good health though he does not give much credit to the trying climate of the old country. Mr. Walker, we are pleased to learn, has by no means given up the idea of supplying frozen meat to Colombo and though at present, negotiations are not ripe enough to be discussed, we hope ere long to be able to indicate that Mr. Walker is in a fair way to confer, what we certainly consider will be a great boon on the meat-eating community, even if the price for prime Canterbury mutton should not be less than 50 cents a lb;

CEYLON TEA IN MASHONALAND.—We call attention to the letter of Messrs. Gow, Wilson & Stanton announcing their introduction of Ceylon tea into Mashonaland: we think the Rood Lane Firm deserves a vote of thanks from the Tea Fund committee for their enterprise in this and other directions in introducing our teas into new markets.

TEA IN AUSTRALIA.—We call attention to the interesting Tea Report furnished by Messrs. Alfred Harvey & Co. of Melbourne under date 7th Feb. given on page 615. It will be observed, they speak in a very encouraging way of the market and prospects. Stocks are certainly very moderate and there is plenty of room for Ceylon to cut out China which still sends at least 10 million lb. too many to the Southern Colonies.

PLANTING IN EAST AFRICA.—We call attention to the letter of Mr. W. H. Cowley from German East Africa, giving an encouraging account of the position and planting prospects of the settlement. We hope to have many more interesting letters from Mr. Cowley. He is the gentleman who wished to indent for Sinhalese labourers, and under his care, we feel sure they would be well treated and carefully looked after. As regards coffee seed from Arabia, we would recommend Mr. Cowley to apply to Messrs. Luke Thomas & Co. of Aden as the best quarter we know, whence to procure fresh Mocha seed.

TREE PLANTING ON ESTATES.—We call attention to the interesting and practical letter which our correspondent "Fuel" forwards on this subject. The figures given in respect of requirements in fuel for tea-making, and steam engine (where used) seem well on the safe side, and are therefore the more reliable; while his estimate of $h2\frac{1}{2}$ per acre for planting up an estate with useful quick-growing trees at the rate of 100 trees per acre cannot be grudged by any proprietor. We shall be glad of any criticism if required. Of the great importance which we attach to the discharge of this duty of tree-planting by all upcountry plantation proprietors, we need add nothing to what we have already written.

THE PADDY CROP, 1892-93, IN MADRAS AND BURMA.—The final official reports may be summarized as follows:—

"According to the latest figures—those up to the end of January 1893—the area sown or planted with paddy during the current season in Government villages in this Presidency was larger than has usually been reported up to the corresponding date by 278,400 acres or 5.3 per cent. Taking the probable crop, the outturn will amount to 51,787,400 cwt. or about two-thirds of an average crop on the area sown this year. No really accurate data exist for calculating the actual outturn of past years. Converting the probable outturn into its equivalent of cleaned rice, the yield of the year may be put at nearly 15 per cent more than estimated last year and nearly 9 per cent more than the average of the estimates of the last five years. Bearing in mind the very unfavourable character of the season over the southern half of the Presidency, the exportable surplus is likely to be very trifling if there be any."

To make up for the bad news in the last sentence, we have the official report from Burma:—

"The area under paddy cultivation is now estimated at 4,467,438 acres, or 252,415 acres more than the actuals of last year, and 15,800 acres more than the estimate given last month. Considerable increases in area are reported from Amherst and Pegu, while the Bassein estimate has decreased. The estimates of outturn given last month are unchanged. It is estimated that there will be available for export 1,637,000 tons of cargo rice equivalent to 27,746,000 cwt. of cleaned rice including what is required for Upper Burma.

THE BURMA RUBY MINES (Limited) state that the results of the last three months' washing are:—Number of loads, 6,493, producing 11,163 carats, worth R41,710, or £2,780 13s 4d, at the exchange of 1s 4d. This is equal to 81s 6³d per load. The January results included in the above have been received by telegram, and are not yet confirmed. The rumour that a satisfactory arrangement has been concluded with reference to the rent of the mines is incorrect. The question is, the *Times* is informed by the Secretary of the Company, still pending before the Government of India.—*Pioneer*, March 1.

INDIAN AND CEYLON TEA IN AUSTRALASIA.—While the export of Indian tea to the end of January is a million lb. short as compared with the same date previous season, our Ceylon exports this year so far show an increase of nearly half-a-million lb. Here are the figures from Messrs. Forbes & Walker's Circular today:—

INDIAN EXPORTS, SEASON 1892-93.	
(To Australia and New Zealand.)	
To end of January	3,329,840 lb.
Same period last year	4,352,416 „
EXPORTS OF CEYLON TEA.	
(To Australia and New Zealand.)	
Total export from 1st Jan., 1893, to date	811,000 lb.
Same period last year	325,000 „

TOBACCO CULTIVATION IN THE NORTH.—The cultivation of tobacco is being vigorously carried on, but the crop expected is likely to fall short of the demand, not because a less extent than that for the last year is cultivated, but because the number of tobacco traders, large and small, has greatly increased within the last few years. The trade, whether in the leaves bundled and exported to India or in the cigars manufactured here and supplied to the boutiques in Colombo, Kandy, and other southern towns of the island is no longer the eminently paying and profitable venture it once was. The cigar trade is of comparatively recent date, having been started about 35 years ago. If it does not pay so well as it did formerly, it is owing to its being overdone. The cultivators, I think are much better off now than the traders.—*Cor.*, "Jaffna Guardian."

JOINT STOCK ENTERPRISE.—There is, however, one aspect of Joint Stock enterprise which cannot be regarded as satisfactory; and the unsatisfactory feature is more apparent in plantation affairs than in other investments and branches of business. With Banks and Hotels for instance, the knowledge that most of the profits go to absentee capitalists, is modified by the conviction that foreign capital is essential to the business which they do—that to some extent the lack of local capital, and to some extent the absence of special experience and training in those lines would render success more qualified, if not altogether problematical. Further, we have got to be as familiar with the drafts of such institutions from the Island, as with the carriage by the continuous streams of Tamil immigrants on their return home, of savings from their labours here. The effect of the multiplication of Plantation Companies has, on the other hand, the effect of diminishing the number of resident proprietors to which we have been accustomed. To be sure, there is an immense proprietary of local landlords, whose numbers and aggregate possessions are often underrated by people owing to their infinitesimal individual influence, and the smallness of their separate possessions. These happily remain to us, and we are glad to think that there is a steady improvement in the numbers, intelligence and influence of at any rate such as own an appreciable acreage. But we refer to European Proprietors—or Colonists as they are misnamed. In the sixties and seventies—and even in the latter years of the eighties, after the scare caused by the collapse of coffee had subsided—there was an appreciable increase in the number of Proprietors—of men who, if they were not Colonists in the fullest sense, had settled down in the island resolved to work in it and to hold property in it, until at least they should

have acquired a competence, or disposal of their land preparatory to retirement in old age to the mother country. The effect of Joint Stock enterprise is to give to a large number even a more evanescent interest in the land of their adoption. With such capital as they have distributed over a number of Companies, or invested in the one which has taken over their property with others, they go home to live on dividends; or even if they remain here they have not their time and attention devoted to a property or properties which they can call their own. The drawbacks under the old system of absentee mortgagees who took away the better part of the profits of estates, are aggravated by the absence, or rather the diminution of a proprietary personally interested in lands, resident on them and supervising their cultivation. While this is undoubtedly a drawback, having reference to the general interests of the country, it is a great advantage that under the influence of Joint Stock enterprise a larger extent of land than might otherwise be possible is brought under cultivation, and thus contributes to the general prosperity of the island.—Local "Examiner."

[We are of opinion that, as a rule, the Resident Manager of a Limited Company's plantation or plantations—generally a shareholder in the Company as well—is quite, as useful a member of the local planting community as a Resident proprietor-manager. In fact, there is very little difference.—Ed. T.A.]

CHINESE LABOUR FOR BRAZIL.—We see from the *Rio News* that at a meeting of planters in Sao Paulo on the 31st Dec., for the purpose of discussing measures for the introduction of Chinese labour, a committee was appointed to communicate with the municipal councils of the state and with Congress to find what assistance can be procured, and to study the question for the purpose of reporting at a future session. From inquiries made in London it had been found that it would cost £25 per capita to bring the labourers from China, and that they would want £4 per month as wages. It had also been found that difficulties would be encountered in procuring such labourers.

FORESTS IN RUSSIAN TURKESTAN.—According to the February number of the *Geographical Journal*, Russian Turkestan is so poor in forests, and the existing woodland have suffered so much of late from reckless cutting, that attempts are now being made to replant, partly in the mountains and partly in the Steppes. It is estimated that of the total area of Turkestan (162,000 000 acres,) the territory has but 945,000 acres of forest land in the mountains, and nearly 16,000,000 acres of bushland in the Steppes. As to the plantations of trees which are met with in all native towns and villages, they cannot even satisfy the wants of the steadily increasing population for building purposes. The saxaul tree has been pitilessly exterminated all along the banks of the Syr Daria, and for a great distance around the centres of population, and as natives say, "the saxaul has fled into the depth of the Steppes." The forests in mountains were also recklessly cut down till the year 1879. At the same time, the whole of the region is from some physical change, generally undergoing desiccation. Both glaciers and rivers are decreasing; the lakes dry up; the extremes of temperature become more marked; and the moving sands are increasing in areas. The recent attempts at planting forest trees, without irrigation, which were made in the province of Samarcand in 1880, have proved quite successful; so also the attempts made in the dry Steppe in the south of Samarcand, between the Shaar-sabiz Mountains and the Dargh Canal, where nearly 400 acres were planted. Since 1880 the system has been improved, the young trees being now planted on the slopes of the hills in terraces, which follow the contour lines.—*Pioneer*, Feb. 23

Correspondence.

To the Editor.

THE CEYLON-AMERICAN PLANTERS'
TEACOMPANY.

Feb. 10.

DEAR SIR,—We beg to inform you that the business of the Company has increased very considerably. Last week we were 25,000 packets behind in filling orders. We have made a beginning with some of the largest houses in Boston, New York, Chicago, St. Louis, Cleveland, Washington, Baltimore, Philadelphia, etc. One house alone claims to supply 20,000 retail stores in the South-Western States. This will all have to be supplemented, and these merchants require tea for distribution free. If we can find a way to sustain them, we will not only have built the foundation, but a good-sized story as well.

Through the personal efforts of our President we have succeeded in getting—to the exclusion of all others—our tea and coffee upon the "Wagner Palace Car Company's" system of dining and buffet cars, and upon every menu our brands of "Bhud" tea and "Lanka" coffee, together with the name of our Company, will appear. As these cars will entertain thousands upon thousands of people going to and coming from the World's Exposition, we, here, look upon it as a more direct, and a greater introduction of our tea than anything that will be done with the hurried masses after they reach the Fair at Chicago.—We are yours faithfully, J. ELWOOD MAY, President,
R. E. PINEO, Secretary.

COFFEE-PLANTING IN EAST GERMAN
AFRICA: AN EX-CYLON PLANTER ON HIS
WORK AND PROSPECTS.

German East Africa, Feb. 12.

DEAR SIR,—Many thanks for yours of the 7th ulto. You may rest fully assured that I shall very much appreciate the contents of both the *Overland* and *T.A.*; for every scrap of news I can get hold of here I devour with avidity. Though I take in a fair number of English newspapers they arrive very irregularly, generally taking a trip down the coast and over to Zanzibar before landing here—or rather at Tanga, so that I find time hang very heavily at times.

Muchly regret to hear of the death of your senior editor, who has passed away full of years and full of honour.

I'll drop you a line now and again as to our doings here. So far everything has gone well: transport being the only worry to one. I had the pleasure of planting out the first coffee for the Company on the 2nd October last, and have now about 40 acres all doing well in spite of a queer monsoon. Last year was a dry year such as the natives had not seen since 1884-5 so that I trust the next dry year may not come round till 1902—as it is quite thirsty enough now.

In the way of temperature the thermometer shows up well—at nights it is from 12°-13° Celsius 53 to 55° Fahr. and from 9 till evening about 30 to 32° Celsius = 86-89 Fahr. I don't mind the heat so much, but the cold is the difficulty, as the bungalow, all iron, resembles a refrigerator in the mornings. Natives don't like it at all at first. All coolies, I'm glad to say, with only one or two exceptions, and my colony of English, German,

Tamil, Sinhalese and Malays all well. Quite got over the terrors of Africa.

All sorts of products growing here—but this place will grow coffee principally; for cacao I shall have to move down miles from this—quite in the lowcountry.

Railway line from Tanga to within 20 miles of this has been sanctioned and operations I hope commence in two or three months' time. This will be the beginning of a line that will ultimately go to Kilimanjaro I believe. Anyone coming *this* way had better change at Fega where three bananas can be got for a pesa equal R1'64 and perhaps a "Tanga" Times.

Tanga is a very pretty little harbour, (according to all accounts the prettiest along the coast by far) and likely to become in time the Planting Capital. With an enterprising Governor such as we have now stationed there Tanga ought to be quite a centre of industry soon.

Do you know of anyone who could tell me the best way of getting coffee from Arabia. That is to say, do you know of any one who knows someone else stationed out there who knows coffee well enough to obtain a good sample for seed purposes. I am writing to the German Consul there, but you may know of other channels.—Yours faithfully,
W. H. COWLEY.

CINCHONA BARK AND INDIAN TEA AND
THE CEYLON IMPORT DUTIES:
MORE ANOMALIES.

Colombo, Feb. 13.

DEAR SIR,—Before the question of the import duty on tea came under discussion in the local newspapers I suppose few planters in Ceylon knew that such a duty remained in force and perhaps fewer still know that there is an import duty on cinchona bark.

That the abolition of the duty on Indian teas will do Ceylon or its teas the slightest injury directly or indirectly, I do not for a moment believe, and I do not think Indian planters in asking for the freedom of this market for their produce are making an unreasonable request seeing that Ceylon planters have a perfectly free field in India where not one cent of duty is levied on tea or bark.

Some days ago I imported from India some 25,000 lb. of cinchona bark which I intended to sell locally as soon as the market suited me. To avoid needless charges I desired to clear and store it where charges would be less than at the Wharf; but this I was informed I could not do until such time as I paid duty at the rate of 6½ per cent. The Collector of Customs is of course only carrying out the law as it stands, but surely it will be considered a bad law and one that requires alteration which brings in no revenue and tends only to hamper the business of the island.—Yours truly,

TRAVANCORE PROPRIETOR.

The correspondence referred to is as follows:—
Sir,—I have the honour to inform you that 264 bags of cinchona bark, lauded ex s.s. "Bhundara" from Cochin are my property and have been brought over to Ceylon for sale.

On a former occasion you were good enough to allow the bark to be removed from the Wharf premises for re-baling and reshipment without the imposition of any import duty, and I trust you will be good enough to extend the same indulgence in this instance and allow the bark to be treated as transhipment goods.—I have

the honor, sir, to be your obedient servant, —

Customs, Colombo, 10th Feb. 1893.

Sir,—In reply to your letter of the 8th instant, I have the honour to inform you that as the cinchona had been duly manifested to Colombo with Bill of Lading as local cargo intended as you state for sale at this port, I cannot by any interpretation of the Ordinance and Proclamations now in force recognise it or treat it in any way as re-shipment cargo.

I conclude you wish to avoid the usual charges on imported cargo such as rent and harbour dues.

These concessions are allowed by law to reshipment cargo if shipped within five days free of harbour dues also. Local cargo can only be disposed of by payment of duty and allowing it to pass into the local market or by bonding for exportation under clause 76 of Ordinance 17 of 1869. When in bond I can allow samples to be taken under section 71, but the usual export duties must in any case be paid by the exporter.

The importation into Colombo for sale of course renders it impossible to treat it as reshipment cargo, and this department can take no notice of a change of owners, it merely detains the goods pending payment of all legal duty and dues.

I may add that I cannot allow samples to be taken from reshipment cargo landed in the reshipment warehouse provided by Government.—I am, sir, your obedient servant,
R. REID, Principal Collector.

A NEW MARKET FOR CEYLON TEA : MASHONALAND.

London, Feb. 17.

SIR,—It will perhaps interest some of your subscribers to know that Ceylon tea has already found its way into that new country about which so much is being written at the present time, we mean Mashonaland. Believing thoroughly that in course of time this country will become an important British Colony we were anxious to get the name of Ceylon tea known there amongst the first pioneers, so had some fine Rickarton Orange Pekoe compressed into cakes thus reducing its bulk by two-thirds, and gave a good supply to some of the leaders of the principal expeditions to that country. This happened nearly two years ago, and we have lately seen one of these gentlemen who has returned home for a holiday, and he tells us that the tea was very highly appreciated both for its quality and for the convenient form in which it was sent. Having proved the utility of tea in this form when really good quality is used (to compress), we are now endeavouring to make arrangements for some friends to send out a regular supply, that this market may be secured in its infancy, and we hope that in time Mashonaland will become a not unimportant consumer of Ceylon tea.—We are, yours faithfully,
GOW, WILSON & STANTON.

[A sample of the "compressed tea" may be seen at our office.—ED. T.A.]

PLANTING OF TREES ON PLANTATIONS, FOR FUEL SUPPLY, &c.

A PRACTICAL LETTER.

DEAR SIR,—The question of fuel supply upcountry is not so serious as it at first appears, as any estate can in 5 years have an ample supply of fuel grown along its roads and drains.

Grevillia and iron bark trees 7 years from seed give about $\frac{1}{2}$ of a yard of fuel on an average, or say 200 lb. of well-dried fuel, but for the purposes of cultivation put it at 150 lb. a tree and take the quantity of fuel required to cure a lb. of tea where there is water power at 3 lb. and where engines are used at 5 lb. On an estate giving 500 lb. per acre, we would thus require 10 trees to the acre per annum (in conjunction with water power) in seven years

equal to 70 trees per acre for a continuous supply of fuel or with an engine $16\frac{2}{3}$ by 7 = 117 trees per acre.

The quantities estimated are much larger than any seller of machinery admits is necessary, but it is better to be on the safe side. Supply baskets should always be used for this purpose as the trees make at least an extra year's growth compared with ordinary planting and no failures occur.

Take a 200 acre estate and estimating 100 plants an acre = 20,000 trees required	R
20,000 baskets at R7 on the spot—	140
200 coolies cutting holes	80
150 coolies planting and carrying baskets	60
Cost of seed	50
Nursery work	100
Contingencies	20

R450

What a trifling sum to expend with the certainty of having a constant fuel supply in a few years, and still many people neglect it.

Properly chosen trees do not do the tea a bit of harm and jak at lower elevations under which tea flourishes, grows even more quickly than the trees named.—Yours faithfully,
FUEL.

COCONUT CULTIVATION IN CEYLON:

THE ADVANTAGES OF MANURING—AND OF IRRIGATION—
THE LIMIT TO NUT-BEARING—REMINISCENCES OF OLD
PLANTERS.

Pamban, Feb. 27.

DEAR SIR,—I was much interested in your editorial remarks and reminiscences on "Coconut Cultivation, &c." in your issue of the 16th instant, in connection with the sale of coconut properties belonging to the estate of the late Mr. J. B. Daniel. The heirs may be congratulated on the fine prices realized; and so far as my recollection serves me the figure given for "Mahaoya"—R867 per acre—is the highest ever paid for any extent of cultivated coconut property in Ceylon. Fine as most of the estates in the "Mahaoya Valley" are, and well cultivated as the group of estates just sold have been, it will take the purchaser of "Mahaoya" all he knows, and perhaps more, to enable him to get a reasonable interest upon his money. To give him the least chance of it he *must* manure; to treat the estate as too many estates in native hands are treated, or even to plough and keep it clean only would not do; such a course would be sure to reduce the yield by probably one-half and his bargain prove a loss. A yield of 70 nuts per tree was not got without general good treatment and *manure*. I do not think I have the pleasure of the acquaintance of the purchaser of "Mahaoya," yet I give him these hints free, and he is at liberty to profit by them if he thinks them sound! With manuring, the bearing capabilities of the coconut tree are enormous. In a chekku yard, on an estate in the dry climate of Jaffna, where the working cattle used to be tied to the trees throughout the year, I have picked from 250 to over 300 nuts per tree in one year. In this instance the trees had more manure than was needed, and I doubt if there was room on the stalks for more nuts to hold on and mature. I quite agree with your veteran and experienced correspondent "W. B. L." that on *fairly good soil*, with mechanical working of the soil, and the application of proper manures, it would be possible to make the trees over a large acreage produce from 80 to 100 nuts per tree; and I hold that for every rupee judiciously spent on manuring—up to a certain limit—two are returned

in the way of crop, one to pay for the manure and one profit. For the encouragement of those who are still hesitating I may mention that in addition to the extra yield the nuts from a well cultivated estate will sell for from R2 to R3 per 1,000 more than those from an unmanured one. Purchasers of coconuts for conversion into copra know pretty accurately what they can afford to give for the coconuts of each estate or garden from which they have been in the habit of buying and regulate their prices accordingly. The more highly an estate is cultivated the fewer nuts will it take to make a candy of copra. At the same time it is undeniable that if trees are forced by manuring to bear beyond say 70 nuts each, the nuts will not be so large as if the trees produced, with a less amount of manure only 60 nuts. My idea of the reason of this is, that although the material is there, in a condition available for absorption by the rootlets, the trees have to make greater effort to elaborate the crude sap into pabulum fit to be laid down as fruit &c. Hence in my opinion any fruit brought to perfection beyond a certain number, which must be ascertained by observation, will be at the cost of a greater expenditure of energy by the tree than it took to produce each fruit up to that point. For the same reason the cost of production of each nut beyond that ascertained number would be greater than for each of those produced up to that number, and the profits on outlay consequently from that point a diminishing ratio.

I would therefore be inclined to limit the efforts at production to about 70 nuts per tree; this is for ordinarily good soil; for inferior soils 50 to 60 should be the limit. Of course I would not mention these numbers if I was not aware that they have been obtained by good cultivation over considerable areas. Some soils are like some human beings; no matter how well they are fed they show no signs of improvement; both are radically defective, and until the defect is ascertained and cured do not waste money upon them! The number of nuts a tree will produce without adventitious aid from man, in the shape of tillage and manuring, but by simply keeping the ground free of jungle growth and fallen leaves, will vary with the richness of the soil; and my belief is that, with rare exceptions, the highest yield over any large acreage is not more than 40 nuts per tree. Delgolla is exceptionally favoured. Its soil is good; the lay of the land perfect; and the rainfall ample and well distributed. It has also excellent facilities for manuring, and if the trees said to have produced 80 nuts each were manured, I have no difficulty in believing it, but if otherwise I am very sceptical, and would require to be authoritatively put right. The heaviest bearing tract of coconuts I have ever seen was about 100 acres on the Badalgama estate, then leased by the late Mr. David Wilson; this portion had the Mahaoya for one boundary, and the Kudaoya for the other. During the south-west monsoon rains, and sometimes again during the north-east, the Maha Oya would overflow its banks and inundate this land, leaving on subsidence a deposit of from half-an-inch to three inches in depth of rich soil. The growth of weeds after these inundations was astonishing, and men with ketties had to be sent ahead to chop them down before the ploughs could be put in. It was a complete cover for pigs, pythons, and all kinds of snakes and vermin, so we may safely say that the soil was rich and the climate forcing. The trees on this land bore very heavily, and the old kankanama who was then in charge assured me that they averaged over 100 nuts per tree, which I could well

believe; and I should not be a bit surprized to learn that now, after 33 years, they are as fruitful as of yore.

The finest bearing trees I have seen, of recent years, over any considerable acreage, are those of Messrs. Akbar Bros. in the Mahaoya Valley. When I visited their estate about two years ago, after a spell of drought, the trees were looking as green and vigorous as it was possible for trees to look; there was hardly a decaying leaf to be seen, and the trees were laden with nuts. The contrast between the appearance of this estate and those on each side of it was very marked; and the difference was almost entirely due to irrigation. Whatever it may have cost Messrs. Akbar Brothers to erect the machinery and lay out the ground for irrigating, was, I feel convinced, well spent; and will prove a most profitable undertaking. Their enterprise is most praiseworthy. Mr. W. H. Wright, erst of Peradeniya, Koslanda and Makaldeniya, and now of Mirigama, is a worthy and wonderful old gentleman, with the pluck and energy of many who are 30 years his juniors. There are few of his countrymen like him, with his appetite for hard work, dogged determination, straightforwardness, cheerfulness and kindness of heart. In 1864 in Haputale, when alone and ill and quite a stranger to him, he took me in hand and very soon put me all right again, for he is a famous doctor in addition to his other qualifications. Whatever Mr. Wright has put his hands and intelligence to, has prospered and his last venture will not prove the least of his successes. It is too soon yet to say how great a success it will be; but it will be such as to amply reward him for his unstinting labour and outlay. May he long enjoy the fruits of his labours; and may he never be molested by the ghostly heads and limbs of the unfortunates whose mutilated trunks tradition says lie buried somewhere on "Kandanganuwa." Coconut proprietors are in luck just now with such handsome prices ruling for coconuts, copra, oil and poonac, which should in a measure compensate them for short crops, which is no doubt the main cause of the present boom, though no doubt there is a greater demand for all the products of the nut. With the advent of big pickings in May and June prices are likely to fall, though not to last year's figures. Coconut property is looked upon by the natives as one of the soundest and safest investments for their money; much safer than having it in a bank. And that is one reason why gentlemen of means sometimes pay fancy prices for a really good estate, looking more to the safety of their money than hoping for big profits.

W. J.

INTERESTING NOTES ON TEA:— CURIOUS LOCAL EXPRESSIONS.

Kandy, March 1.

DEAR SIR,—In your morning edition of the 6th February I noticed under the heading of "Interesting Notes on Tea" a paragraph headed "Sheffield Expressions," referring to the use amongst the inhabitants of that town of the words "gamest" and "mashing." The former is quite wrong, as the word in use amongst Hallamsbire men, meaning the shortest road to such and such a place, or the nearest to such and such an object is "gainest." I think it may possibly be derived from the word "against" i.e. in the sense of "close to" or "nearest."

"Mashing" is in common use with regard to tea making. When I was at home the usual way in my part of the country was to put a certain amount of tea into a tea cup, fill the cup up with boiling water, put a saucer on top, and place the whole on the hob or on the top of the oven to "mash" or brew,

Both words "gainest" and "mashing" are in general use not only in Sheffield itself but also in the surrounding district of South Yorkshire and North Derbyshire.—Yours very sincerely,

HALLAMSHIREMAN.

March 3.

SIR,—I have read with interest the letter by "Hallamshireman" on this topic. When I came across the word "mashing" I thought your P. D. had been up to some of his pranks again and by substituting an "h" for a "k" had converted the expression "masking" which is very common in some parts of Scotland as a term applicable to the brewing of tea, into a word which is descriptive of the doings of the la-di-da sort of young man who is popularly termed "a masher." I have looked up the article to which "Hallamshireman" referred and I find the "h" is used there also, and I conclude that I am wrong in the supposition I first formed of a typographical error having been committed. The similarity between the two words is striking, and I thought I might just draw your attention to it. "Mash" is given in the latest edition of Webster's International Dictionary as meaning brewing I think, and one can therefore quite understand the applicability of the word to tea making. How "masking" comes to be used in the same connection I cannot explain, but I assure you the word is in common use.—Yours,

MACSPORRAN.

COCONUT PLANTING: PRACTICAL QUESTIONS.

March 6.

DEAR SIR,—Coconut planters owe you thanks for your trouble in collecting so much information about the industry of late.

I want to ask some of your experienced correspondents one or two questions:—

(1.) It has been asserted that Kurunegala nuts are smaller than the nuts from Mahaoya and Chilaw districts. *Is this so?*

(2.) What nuts would "W. J." recommend for planting in Kurunegala? Are Golapokuna nuts in the first flight?

(3.) Does it harm coconuts to plant coffee and cacao among them? I have seen tea flourishing among coconuts closely planted and both in full bearing; but would *cacao* or *coffee* do is what I want to know,

COCONUT.

PLANTERS AND RAILWAY LINES.—The Government has just given voice to a ruling of some considerable importance to Planters on the Coonoor ghaut whose land has been taken up for the Nilgiri Railway. In certain cases paths to the Planters' estates cross the line of rail and the spoil thrown out of deep cuttings often blocks up these paths. The Government has ruled that if any path which is blocked by spoil is so blocked within the limits of the land acquired and paid for by the Railway Company, the principle of compensation for severance has come into play, and the estate owner having been duly paid for this must himself keep his path open. It is only in cases where the block happens to be at a spot or spots on a path which are outside the acquired land belonging to the Railway that the Government will hold itself responsible for removal of the obstruction. The above facts will, it is believed, be new to most of the Planters concerned.—*Madras Times*, March 7.

LIME IN THE GARDEN.

The present time of the year, together with early spring, being suitable for the application of lime, it may not be out of place to consider briefly what are its manurial properties, what classes of soils are most likely to be benefited by its addition, and in what form it can be most advantageously used. This is the more desirable, as the usefulness of compounds of calcium seems somewhat liable to be overlooked or under-rated.

It is well to remember, in the first place, that the function of lime in the soil is two-fold—it is direct plant-food, and it also possesses a remarkable power of rendering other inert matter suitable for the nourishment of plants. Besides this, it is capable of making considerable modifications in the physical condition of soils—a matter quite as important to the cultivator as its chemical composition.

LIME AS A PLANT FOOD.

It is scarcely necessary to point out here the fact that calcium is one of the elementary bodies that are absolutely necessary for the complete growth of plants; but it is not always borne in mind that some garden crops remove comparatively large quantities of this substance; and that, moreover, lime is a body which, to adopt the common phrase, "sinks" in the ground, thus rendering its application from time to time advisable. That leguminous crops, such as Peas and Beans, need large quantities is fully recognised, as is indicated by their popular description as "lime" plants. But there are many vegetables, which from their marked preference for manures containing other elements, are rather liable to be starved in the matter of lime, although the latter may be no less necessary for their full development. Turnips, for instance, need much phosphoric acid and potash, but analysis of their ash shows about 49 per cent. of lime (13·024 per cent. in the roots, and 35·65 per cent. in the leaves*). Potatoes, again, show only 3 per cent. of lime in the ashes of their tubers, but their haulms contains about 17 per cent.; and it is upon the leaves, be it remembered, that the tubers have to depend for their supply of starch. Many other instances might be given of the importance of lime as a minor constituent.

It was stated above that lime sinks in the ground. The explanation of this is very simple. Rain-water holds in solution carbonic acid gas, which it has absorbed from the air, and thus charged, it has the power of dissolving the carbonate of calcium in the soil, and carrying it away off the surface and through the drains or porous subsoil. Moreover, the carbonic acid formed in the soil by the decomposition of organic matter dissolves the carbonate of calcium, which is carried away by drainage water. The nitrates and chlorides of calcium are likewise readily diffusible, and easily lost. It may be noted in passing that the alkaline base soda suffers from this washing-out process in common with lime, while most fertile soils are strongly retentive of ammonium and potash. Hence the reason why lime must be added in larger quantities, and more frequently than a calculation of the actual amount removed by any given crops would seem to warrant.

WHAT SOILS ARE MOST LIKELY TO BE IMPROVED BY LIME?

Briefly, all deficient in calcareous matter, stiff clays, and sour peaty soils are particularly responsive to its application. Stiff clays are lightened and rendered warmer and more friable, and the soluble plant foods are increased by quicklime; whilst, on the other hand, the retentive power of light sandy soils is increased by the addition of slaked lime (calcium hydrate), chalk (carbonate of calcium), or marl. On soils containing a large amount of peat, quick or slaked lime, is of great value, counteracting the "sourness" due to excess of organic acids, and assisting the decomposition of woody fibre, &c. There is another case in which lime may be applied with

* From Dr. A. B. Griffith's Analyses in the *Journal of the Chemical Society*, 1893-87.

very marked results, namely, to old garden ground which has year after year received heavy dressings of farmyard manure, and which have become sour and profitless. Mr. J. Wright, in a paper read before the Royal Horticultural Society in 1889, described a striking but by no means uncommon instance of this. When he took possession of the garden in question, he found it like a mass of humus, nothing would grow satisfactorily, the soil being "poisoned with humic acid." He gave it a good dose of lime (a bushel per rod), together with potash and bone meal. "The effect," says Mr. Wright, "was magical, and the crops of Potatoes and Peas, where they would not grow before, were remarkable." The late Mr. Shirley Hibberd, on the conclusion of the above paper, remarked on the too frequent neglect of lime as a corrective of acidity; and Mr. G. Wythes—than whom, perhaps, no one knows better how old garden soils should be treated—expressed himself in favour of lime, soot, and wood-ashes, where organic manures alone had been given for a long series of years.

THE VARIOUS FORMS OF LIME.

As a general rule as indicated above, *quick-lime* (put on in its caustic condition, or slaked by adding water, or by leaving it exposed to the atmosphere for a time), is preferable for heavy soils, and may be applied at the rate of from 2 to 9 tons per acre. It should never be applied with manures containing ammonia, the latter being liable to be driven off thereby.

Chalk is suitable for light sandy soils, and can be given in about twice as heavy dressings as caustic lime.

Marls, being variable mixtures of carbonate of lime and clay, are suited to light land, the dressing being regulated by the proportion of lime contained.

Gypsum, or sulphate of calcium can be used with ordinary manure, as it is a "fixer" of ammonia.

Gas Lime is simply slaked lime which has been used in the purification of coal-gas. It contains, when fresh from the works, calcium sulphide and sulphite, and these substances are injurious to plants. After exposure to air, however, they are oxidised and form sulphate of lime (gypsum), and consequently become innocuous. Gas-lime is useful for mixing in the "rot-heap," hastening the decomposition of leaves, weeds, &c.

It should be remembered that bones, bone-meal, dissolved bones, and superphosphate all contain more or less calcium; therefore, liming is not so necessary where any of these are applied in quantity.—C. W. HERBERT GREAVES, Marlborough Lodge, Bournemouth West.—*Gardeners' Chronicle*.

PINEAPPLES.

A meeting of pine-apple growers was recently held in Brisbane, under the auspices of the Department of Agriculture, to discuss the question of shipping pineapples to England and other places. The necessity of finding good markets for Queensland pineapples has, it appears, been keenly felt, and it was pointed out that as the harvests in the two hemispheres occur at different times of the year there was a good opening for such fruit in the northern hemisphere. It was also announced as the result of experiments which have been carried on with the Queensland fruit that the extreme limit of time during which a pine-apple would keep was about nine weeks: a few of the pines decayed, but the remainder were good and sweet, though the fruit in all cases shrank about 25 per cent. of weight. The price of the pine-apples in San Francisco from July to September was stated to be from 8d to 16d, and for the rest of the year the average price was 1s 8d to 2s 4d. They commanded the highest prices from October to April, as in the summer the people were deluged with local fruit. The voyage from Brisbane to San Francisco was thirty days, and pines, it was said, would certainly keep that time with ease.—*S. F. Press*.

THE WHOLESALE TEA DEALERS' ASSOCIATION AND GRADES OF TEA.

Although Mr. Peek's letter to the Secretary of the Ceylon Association in London on the subject of the grading of teas, was not written on behalf of the Association of which that gentleman is President, it is impossible wholly to separate that body from the advice tendered. Mr. Francis Peek's name is so well known to all who are engaged, or are interested in the tea trade, that we are certain that his advice will be read with attention, and that it will receive from Ceylon planters, especially, its due meed of consideration. We are ourselves the more inclined to give full consideration to the letter, because the advice given in it, coincides in material particulars with suggestions we have ourselves made on previous occasions. It will be universally acknowledged, that Mr. Peek is correct in assigning great importance to the question of how to prevent or modify frequent and considerable fluctuations in the price of tea. These have of late years been so serious and so numerous, that it has become very difficult for tea growers to calculate beforehand with any certainty upon the amount of the return they may look forward to obtaining for their season's work. Necessarily this constitutes a great obstacle to the equitable prosperity of our tea enterprise. The fluctuation to the producer results far too often in financial disappointment, to be pleasing to him. Any course, therefore, which may tend to remove the cause of this will, we are sure, be readily adopted by the planters should it be found by them to be practicable to follow it. The quotations from Mr. Peek's communication given in our London Letter today should enable our readers fully to realize, not alone the cause assigned by that gentleman for the injurious fluctuations referred to, but the method by which he proposes, in a very considerable degree, to put a stop to them. Briefly stated it may be said that the attempt made by our planters to accommodate their production to the latest demands of the home market as to the qualities of tea, is assigned as the most fruitful cause of constant variation in price. This we have on more than one occasion ourselves pointed out, and we have mentioned how confusing, and often misleading, the advice given by the Circulars of well-known London Brokers has proved to be. It seems to be only natural and proper, that with inferior grades of tea selling almost on a level as to price with those of a higher kind, our planters should devote their attention mainly to the preparation of the first-mentioned sorts. The last twelve months have seen the coarser teas rise in price from a *minimum* of fivepence to a maximum of tenpence. What more natural then, than for our planters to assume that it would pay them better to pluck coarsely and obtain the benefit of prices so satisfactory as those recorded. The result a year ago, it will be remembered, was that the home market was depleted to a great extent of the finer sorts of tea, while the common grades poured into it with a profusion which threatened to reverse the whole existing condition of the trade, and prices for the lower grades were soon forced down, while those for the better kinds correspondingly tended to rise. The cry then became one for "fine teas" and accordingly very stringent were the orders given in many cases for Ceylon plantations to have no "coarse" plucking—"fine" or "medium" to be the rule. But what is the result? A scarcity, we are now told, of cheap teas in the home market, while Broken

Pekoes and fine teas generally are now absolutely neglected! The natural temptation once more will be for planters to go in for an abundant supply of cheap teas, if no remedy is speedily applied. The conclusion is so obvious a one that it does not need the exercise of argument to prove its logic.

We next have to deal with Mr. Peek's remedial suggestions. He advises a combination among the planters binding them individually to produce certain proportions of each grade, and to confine their output in such a way as to maintain a steadiness of supply in each kind. This is in itself advice easy to understand; but very difficult to apply! Our planters, we may be sure, are sufficiently alive to their own interests, to be willing to enter into such a combination could they be sure that all would accept the arrangement and faithfully carry it out. But then, even if the Ceylon planters did so, what about other tea-producing countries—India especially—accepting similar limitations. The peculiarities of the retail trade at home are well-known and appreciated here. A sudden demand for teas of the cheaper description occasionally does arise, and should there not be a sufficiency of Ceylon of that kind in the market, the dealers must perforce meet the deficiency by buying other descriptions which, in some instances, would certainly be foisted upon the public as Ceylon teas. This would probably not have to be so much apprehended with respect to the higher qualities. These find a more educated *clientelle*, and are judged by more practised tastes. But even in the latter case it may be foreseen that a scarcity of supply at any particular juncture, might have the effect of inducing buyings apart from our own production. Would it not then be of some assistance to Ceylon planters to have rather more detailed information as to "stocks" in hand in London from time to time. At present the figures given represent the total of all qualities. If it were possible to say how much is of fine or higher grades—'Broken Pekoes' and 'Pekoes'—and how much 'Pekoe Souchongs' and 'Broken' &c.—would the figures not offer an index as to the plucking and manufacture for succeeding despatches? We fear though that to make such a distinction in 'stocks' will be deemed impossible, even if in our shipping return from Ceylon a similar division between "fine" and "ordinary" teas were set up? And yet why should it be more difficult than the distinction which is made in our Export returns for different grades of "cinnamon" and "cinchona bark"? We invite the opinions of practical men on this point. How far the Planters' Association could aid to bring about a combination to secure regularity of output it is difficult to judge; but we should be glad to hear that it had at least given due consideration to a question of so much practical importance. The other remedial measure indicated by Mr. Peek of regulating the supply placed on the market at each sale—so as not to have 20 000 packages one sales day and only 8,000 next—is surely more easily arranged for. And yet, we know there are practical difficulties in the way, for with tea arriving home on what appears to be a falling market who—agents or brokers—will not be condemned for delaying its being exposed to sale?

BUTTER, BREAD AND NUT TREES.

There may yet be something new under the sun, in spite of the assertion of the wise man to the contrary, as the outcome of gardeners dabbling in poience. It is said that there is a butter tree in

Africa which produces as much as 100 pounds at once, only to be renewed in a few months. This secretion, when hardened and salted, is difficult to distinguish from fresh sweet butter. It is not very easy to see how it is deemed necessary to salt this kind of produce to make it like fresh butter, but it is not well to be hypercritical, and perhaps some of our tropical friends might be able to include this valuable tree amongst their "semi-tropical" produce. We would recommend the residents to bind the bread-fruit tree on to this tree, the resulting combination of bread and butter would have manifest advantages. Whether such a combination being produced upon a tree, would entitle the product to be considered as a "fruit" is uncertain. Perhaps its position might bear some resemblance to the tomato, when two gentlemen dining at a restaurant asked the waiter whether the tomato was a "vegetable" or a "fruit," and he replied that it was neither one nor the other but a "hextra."—*Horticultural Times*.

VARIOUS AGRICULTURAL NOTES.

IF CAPE WINE AND CAPE FRUITS are not of the choicest qualities it is, according to Professor MacOwan, the Government botanist, mainly the fault of the Cape fruit farmers, who live an isolated life, never interchange ideas, and are antiquated and conservative in all their ways. Mr. MacOwan has never yet found an ordinary Western Province market gardener who took in a gardening periodical or cared to learn what is being done in other countries. The desire to improve the output is materially checked by the immense demand for cheap, coarse fruit among the colonised lower orders in Capetown. So that the grapes are dirt cheap, it does not matter to them how dirty they are, nor are they disgusted at seeing the same baskets that carried the grapes into town piled up among the stable manure the cart takes back to the farm in the afternoon. In no other public of fruit consumers (adds this authority) is quality so little thought of, and hence the producer is satisfied to grow crops from seedling trees fit only for stocks. They sell somehow, and the Cape market gardener is content.—*Daily News*.

PLANTING TREES.—The Government of Bengal has issued copies of the late Mr. Worsley's note on the planting of trees on roadsides, the advice in which may be adopted with advantage throughout Bengal:—If trees are not planted out by the sides of the roads until they are 5 or 6 feet high, and if they are planted out at commencement of the rainy season, they will not require, in a climate like that of North Bihar, to be watered in the following hot season. The holes in which the trees are to be planted by the roadside ought to be carefully prepared some months beforehand, and some old manure, where available, should be mixed with the earth. These holes should be at least 2½ feet wide and 2 feet deep, but if money be available larger holes, say 4 feet in diameter and 3 feet deep, are preferable. The height of the gabion is of great importance. The two evils to be guarded against are (1) "the poisonous tooth," as Virgil calls it, "of the accursed goat," which is certainly more injurious to the young tree than winter cold, and summer heat, and (2) the mischievous habit which travellers have of breaking off the young shoots of the mango and some other kinds of trees, and using them as tooth-brushes. In places where the white ants abound, it is a good plan to smear with tar the ends of the posts before fixing them in the ground, and a daub or two across other parts of the posts will deter villagers from extracting and appropriating them for their own use. If it is intended eventually to sell the fruit of fruit-bearing trees year by year, it will be most convenient to plant a few miles of each road with each of the valuable kinds of fruit trees, e.g., five miles with *mangifera indica*, five miles with *artocarpus integrifolia*, five miles with *bassia latifolia*, etc. This is the principle which I adopted in Munzaffarpur town where I planted about 12 miles of avenues with 12 different kinds of trees, fruit-bearing and timber, allowing one mile or so for each kind of tree.—*Englishman*.

THE ABNORMAL RAINS which we have been getting in Colombo during February and March seem to be experienced also in Northern India. The *Pioneer* of March 7th has the following:—

“Heavy rain, more like the customary autumn deluge than the spring showers of ordinary years, fell at Allahabad on Sunday evening for several hours. By yesterday morning the skies had cleared; but the crops must have suffered to some extent.”

CARP IN PLANTATION PONDS.—There is a large pond on the Bilicil Estate well-stocked we believe, with fish, principally Carnatic Carp, but the difficulty is to induce them to take bait. On the one or two occasions when four and five pounders were caught the means adopted were, living minnows on hooks, attached to floating bottles, and these “took” during the night.—*Nilgiri News*.

CEYLON TEA IN SOUTHERN INDIA.—The total crop of tea in Southern India—the Nilgiris, Wynnaad and Travancore—so far does not exceed between 3 and 4 million lb. per annum and until of late nearly all this production found a local market. So much is this the case that the Calcutta estimates for Tea Exports from India, takes no notice of Southern India at all. Well it is into this local demand for Nilgiris and Travancore tea that “Ceylon Tea” has cut in to the extent (including the Bombay market) of 600,000 to 700,000 lb. last year. Taking advantage of open markets with no duty, Ceylon tea has found its way to every port in Southern India we are credibly informed; and very creditable to local enterprise this fact undoubtedly is. But it is none the less galling to South of India Tea Estate proprietors; and does it not look rather like adding “insult to injury” for the Travancore men who want to use the Colombo market, to be told by the very producers who send 700,000 lb. tea to oust theirs in India—“Oh no! we can't have your tea here; we have a Customs duty expressly to shut you out and we mean to maintain it too.”

SUGAR PLANTING IN THE NORTH-WESTERN PROVINCE.—For many years past the only spot where sugar planting has been carried on in Ceylon has been at Baddegama, in the Southern Province. As many of our readers are doubtless aware, sugarcane growing on a large scale has been tried in many parts of the rich alluvial lands in the south of the island, in the Western Province, and even on the banks of the Mahavilla ganga at Kandy; but we do not know that any attempt has ever been made to grow cane in the North-Western Province. Few industries have had so much capital expended upon them for so little purpose as sugar production here has. All that care and skill and experience, combined with large pecuniary resources, could do has been done to establish the industry in Ceylon but without success. It was not that the cane would not grow or that the best varieties were not tried. On the contrary, the finest varieties known were planted, and the growth was most satisfactory. It was in the vats that the produce showed up so badly, the saccharometer only showing a small percentage of saccharine. This excess of moisture in the canes without a corresponding amount of saccharine was generally believed to be due to the high rainfall and humid atmosphere of the island. Whether this characteristic will disappear in the case of cane grown in a drier district, such as that lying between Chilaw and Negombo, remains to be seen; but the experiment is certainly worth trying if Government are inclined to offer facilities for such a trial and this, we believe, is about to be suggested to them.—*Local Times*. [This refers to the opinion of an experienced sugar planter in favour of experimental cultivation in the neighbourhood of Rajakadalawa beyond the Deduru-oya. Of the benefit which would come to the people in a very poor neighbourhood, there can be no doubt and on that account the pioneer deserves special encouragement from Government.—Ed. T.A.]

TASMANIAN APPLES.—To accommodate the growing demand for cool space in the mail steamers from Australia for the conveyance of fruit, chiefly Tasmanian apples, the Orient Company have recently made large additions to the refrigerator holds of the Orient Line steamers which will be leaving during the next fruit season. The first of these, the twin s.s. “Ophir,” is due to reach England about the middle of April.—*Colonies and India*.

CENTRAL ASIAN COTTON.—The export of cotton from Central Asia during 1892, the Odessa correspondent of the *Daily Chronicle* says reached nearly 50,000 tons. During 1891 it was a trifle over 42,000 tons, and in 1888, when the Transcaspian line was first opened to Samarkund only 18,800 tons. This cotton is almost entirely consumed in Russia, being shipped from the Eastern Caspian ports to Astrakhan, and thence up the Volga. American long staple cotton is gradually taking the place of native cotton all over the Central Asian provinces.—*Pioneer*, March 8.

TRANSMISSION OF ELECTRIC ENERGY.—Now that it has been shown that electric energy can be transmitted over a distance of fifteen miles with a loss of only some four per cent, why should dwellers in the country be denied the advantages of the electric light? Earl Russell and Mr. Thwaites who treat of this subject jointly in an article in the *National Review* propose that the owners of country houses should combine for the purpose of establishing at some fixed place (say near to a railway station) a station at which to generate the force. A skilled working electrician should be engaged to supervise the generating plant and that involved in the utilisation of the energy. Each house could be connected with the generating station which would become a “telephonic exchange.” At the central station a steam-engine, or a fuel-gas-engine, would drive two alternating dynamo machines. The electro-motive force developed at a low pressure would be transformed into one of greater pressure, and suitable for the distance to be traversed between the station and the houses. The pressure of the current would be reduced at each house to the measure appropriate to the character of the work to be done. Each householder would be supplied with a meter, and the electric energy used would be charged against him.—*Public Opinion*.

COPPERNUT AND COCONUTS.—Our commercial correspondent writes:—There has been a good enquiry for the article both in London and here; but we have not recently heard of any large orders being placed. There is the usual demand for the Oil Mills, and shipments from Jaffna have been sold. Advices from London state that there seems to be a scarcity of the article from all parts of the world. The value to arrive of good ordinary stuff which was as low as £12 15s in the middle of last year, has ever since gradually advanced till the quotation at present is £17 15s per ton to arrive ex. steamer, at which we hear a sale has been made and more is wanted at that figure without, however, leading to business. Coconuts are wanted in any quantity for the Desiccating Mills; and so long as there is a demand for the manufactured article, there will be a diminution in the conversion of the nuts into Coppernut. Nuts for culinary purposes in the bazaars are selling at 5 to 5½ cents each, and even 6 cents has been paid for a large sized nut. The shipments of desiccated coconut came to about 3,400,000 lb. during last year; and as an average 3 nuts go to a pound, the quantity of nuts used in this industry was something like 10,200,000; add to this the quantity of nuts exported during 1892, which may be put down as 9,500,000 and the enormous quantity of about 20,000,000 coconuts have been sent out of the Island in one shape or another during last year, and there is still an increasing demand for ‘Ookernuts’ from England!—*Local Examiner*.

HOME RAILWAY RATES ON TROPICAL PRODUCE.

We felt so convinced that the importance of the above matter would receive full appreciation by those at home who are interested in the welfare of the Ceylon tea industry, that we never for a moment imagined when we wrote our previous article on the subject that it would be regarded with lukewarmness by the members of the Ceylon Association in London. Such, however, appears to have been the case, and although the Secretary of that body had been asked to obtain the presence of two of its members at the Conference of the London Chamber of Commerce upon the subject, Mr. Leake had found it impossible to persuade any of them to attend it. We can hardly understand how it is that men so conversant with the Ceylon tea trade and with everything relating to it, can have failed to see how important a bearing discontent and difficulty among retail distributors must have upon the demand for our staple product, and consequently upon the prices that may be obtainable for it. This consideration, however, would seem to have been entirely overlooked. Those who were requested to attend remarked that the question could not possibly affect them, and that the wholesale and retail grocers might well be trusted to look sharply and carefully after their own interests as affected by the newly imposed railway rates for tea. Such replies seem entirely to have ignored how largely dependent the increasing consumption of tea must be on the facilities available for its cheap distribution. If these be encroached upon in any sensible degree, doubtless the retail trade will find its remedy as affecting its own interest. But in what direction is it most likely to seek this? It will not, we may be sure, be content to submit to any diminution in its own profits, for those in the grocery trade have already been reduced by competition among its own members and by that of the numerous co-operative stores to an exceedingly fine point. It seems certain that relief will be sought in efforts to reduce the purchasing price of teas at the Mincing Lane Sales. It requires no particular acumen to realize what such a course must mean to tea-growers all the world over. If this could not be accomplished and retail prices have to be put up, is it not matter of certainty that consumption must be checked and that our own interests, now so concerned in the opening up of new markets, must be thereby seriously affected? We are well aware that when formerly writing on this topic we employed both these arguments to emphasize the case we desired to put before our readers. But in the light of late information it cannot be useless to reiterate them, for we believe it must be the case that due consideration has not been given at home to the full bearing of the question. It was said, we are given to understand, that but little attention is paid at home to the numerous trade meetings held almost every day under the auspices of the London Chamber of Commerce. Probably this neglect may in some instances be justified; but just now, when the question of a reduction in railway rates is to be pressed upon the British Parliament, we can hardly consider it to be prudent that any help it would be possible for our London Association to give should be withheld. It must be patent that this question is not confined to a merely local bearing, or to the affecting of local interests only. We have shown how probable—how almost certain—it is, that we shall have to suffer if increasing difficulties occur in the course of the distribution of our chief product.

On February 17th, a Deputation representing the London Chamber of Commerce waited on the President of the Board of Trade; and the language used in reply by Mr. Mundella may have its lesson in some respects for the Ceylon Government in connection with its Railway management as well as for English Railway Companies. We quote as follows:—

It was a matter for great regret that such a mistake had been made, and that the trade and commerce of this country should have been subjected to so much loss and irritation. The English trader, in his (Mr. Mundella's) opinion, had a right to trust to the good sense and enlightened self-interest of the railway to adopt a line which had been so successful in other departments of their traffic—that of reducing rather than increasing rates. Where they had reduced rates and increased facilities so in proportion had they prospered. It was the greatest mistake in the world to suppose that the amount of goods to be carried in any given year was a fixed quantity. On the contrary it fluctuated according to the cost and facility of transit. It appeared to him that the self-interest of the Companies would have induced them to meet very much more reasonably the advances of the traders than they had, according to the statements brought before him that day. He knew that some of the Companies had called this a fictitious agitation got up by traders through selfishness. Well, he was bound to say, being behind the scenes, that the representations and complaints he received came not from members of Parliament greedy to catch votes, but from many of the highest authorities in both Houses of Parliament, from those who represented such classes as the small cultivator and the market gardener, whose industries at this moment were threatened with ruin, and who were thoroughly disheartened by the rates charged for the carriage of what they put into the soil and of what they took out of it. He had no more desire to interfere with the business of the Railway Companies than with that of the traders. If the companies, having regard to the position they held with reference to the State, would only act reasonably, the Board of Trade did not want to interfere with them, and did not want the increased powers the traders desired to thrust upon it. But he could not help recognising the gravity of the situation, and all he could ask them was to be patient a little longer. The Board would do what it could to impress on the companies the importance of the crisis. If after the Companies had exercised what they regarded as their powers it was found that the state of things was not sufficiently ameliorated so as to put an end to what he was going to call the injustice, at any rate the impediment, to business now existing, he hoped, with the aid of Parliament and the support of the trading and agricultural portion of the community to be able to devise some remedy.

INDIAN PATENTS.

THE 1ST MARCH 1893.

Applications in respect of the undermentioned inventions have been filed during the week ending the 25th February 1893, under the provisions of Act V. of 1888, in the Office of the Secretary appointed under the inventions and designs Act 1888:—

No. 56 of 1893.—Richard White, of 35, Queen Victoria Street, in the City and County of London, England, Merchant, for improvements in apparatus for drying cacao, coffee, tea, bark, malt and other substances:—

No. 59 of 1893.—John Ashington Thompson, Tea Planter, but at present of 53, Chowringhee Road, Calcutta, for drying and withering green tea leaves by means of centrifugal action.

No. 61 of 1893.—William Stronach Lockhart, Civil Engineer, of London, England, for an improved process and apparatus used therein for the washing and separating of gems or other substances from the earthy and other mineral matters containing them.
—*Indian Engineer.*

NOTES FROM OUR LONDON LETTER.

LONDON, Feb. 24.

A letter written by Mr. Francis Peek, who is well known as the Chairman of the

WHOLESALE TEA DEALERS' ASSOCIATION.

You should be told that Mr. Peek commences his letter by acknowledging that he has written it solely in his individual and private capacity, and that it must not be taken as expressing any official view held by the Association of which he is Chairman. Mr. Peek draws attention to the fluctuations which have of late been so common in the auction prices of tea, and states his conviction that these are principally the result of the inequality in the supply of the different grades received from all tea-producing countries. He expresses the belief that these constant fluctuations constitute one of the greatest hindrances to success both to growers and importers. He remarks that this inequality arises out of the desire to meet the last demand in the Mincing Lane market and to reap the benefit of the prices created by it. During one season, he observes, coarse teas pay best, while during that succeeding the finer sorts proves to be the most remunerative. When the season closes with an active demand for the first, every tea planter plucks coarsely and ships a larger proportion of lower grade result. Conversely, when the market closes with a briskness in favour of fine teas, the planter makes his arrangements in favour of those descriptions. It is this course which accounts, in Mr. Peek's view, for the fluctuation of which all complain, and he puts as a query if an alteration cannot be brought about in this practice. He admits that the unequal supply cannot altogether be remedied, but suggests that planters might enter upon a combination as a body to agree to supply the same proportion of all grades year by year. He instances that, taking the import of tea all round, probably three-sixths may be valued as below 10d, two-sixths as between 10d and 1s 4d, and one-sixth at above that price. If the supply was made on the basis of these figures with regularity, he believes it would put a stop to the excessive fluctuation he mentions. The letter quotes the last year as affording special evidence as to these. It acknowledges that there may be difficulty in obtaining combined action, but asserts it to be of the first importance that an effort should be made in that direction. Mr. Peek next notices the further difficulties that arise from too great quantities of tea being placed on the market at one time. He points out that neither the wholesale nor the retail trader will now hold the heavy stock that they used to do, and that the consequent excessive offering diminishes prices. He asserts that during last year a fall of 15 per cent took place owing entirely to the large quantity of tea placed at one time upon the market at an unfavorable juncture. Thousands of pounds, he writes, must have been lost because about 20,000 packages too many were put up to auction in one week. We know that you yourselves have often previously referred to this objectionable practice and advised its discontinuance.

Unfortunately Mr. Peek's letter does not offer any suggestion as to how it might be remedially dealt with. Possibly your Planters' Association might find it to be practicable to deal with both the suggestions made by Mr. Peek. Conversing with a friend well experienced in the trade with reference to these, he remarked to me that your planters must be perfectly aware of the losses produced to themselves by both of the practices to which Mr.

Peek refers, and that he should think that as a matter of self-defence they would see no objection to entering into some mutual agreement which might lead to their discontinuance. Of course my limited knowledge as to matters of this kind must prevent my offering any remarks as to the practicability of the proposals made. But it is so evident to the commonsense of any outsider that Mr. Peek must be correct in much that he has stated in his letter, that there can be no presumption in my suggesting that an effort should be made to deal with the questions he has raised, and I should say that nobody could be better fitted to undertake this than the Association which so jealously guards the interests of all your planters.

With this is forwarded to you a copy of the report, issued yesterday only, of

THE COLOMBO COMMERCIAL COMPANY.

You will observe that as usual it enters into but little detail. Although a profit was made during the year of £4,092 9s 2d the directors do not recommend the payment of any dividend except upon the 6 per cent preference shares of the Company which will absorb £1,089 leaving a balance, inclusive of the amount brought forward from last year of £4,091 3s 5d. The report states that "the Directors considers it advisable to carry forward the above balance, as a lawsuit to which the Company are parties has not yet reached its final stage. If the suit goes in favour of the Company, a dividend will be declared out of the balance carried forward. The case being still before the Court, the Board are precluded from making any reference to it beyond stating that, even should the result be unfavourable to the Company, the extent of their liability in the matter is defined and substantially provided for." The fall of silver is stated to have somewhat reduced the profits for the year made upon the general trading operations of the Company. Tea did well, it is reported, but the average price obtained for it is not given. The area under its cultivation has now been extended to 1,542 acres. The Board is said to attach little importance to the small return from the limited acreage under coffee and cinchona. The report may be held to be of a satisfactory character, for it is evident that, had not the legal difficulty hindered it, a dividend of 5 per cent. might have been paid out of the balances available on the £70,000 paid up on the ordinary shares.

THE BUSINESS OF THE AMERICAN CEYLON TEA COMPANY.

We hardly think that Mr. Elwood May would have penned the communication he has done to Mr. Leake and to ourselves, unless he felt satisfied that he had good grounds for the satisfactory anticipations he professes. It was only very recently that we seemed to have cause for writing rather dolefully with respect to the prospects before the Company whose title heads this article. At that time we had just been told that everything looked dark for it, so much so indeed that it was further stated on what seemed to be the best possible authority, that without extraneous help its affairs would have to be wound up! It appeared too that if this had to be done, Ceylon planters would have to bid a long farewell to any hope of successfully pushing the sale of their teas among our transatlantic brethren. We soon, fortunately, received assurance that we had been greatly misled and that those

who had entered with so much vigour and perseverance upon the attempt to introduce the public of the United States with a taste in tea superior to that which has so long dominated them, were prepared to at least carry on their work until the Chicago Exposition had become a thing of the past. But if we may trust to what Mr. Elwood May has but recently written, we need no longer to content ourselves with so limited an expectation. Apparently the tide which has so long been adverse has taken a decided turn in favour of Ceylon teas. Mr. May tells us that custom has flowed in of late to an extent which his resources have been unable to meet, and that in one single week he was behindhand in meeting requirements to the extent of 25,000 packets! Without pretending to be able to say with certainty what should be the exact meaning to attach to this statement, it is at least evident that orders have suddenly begun to flow in upon the Company to an extent for which—at all events at that particular time—it could not have been prepared. Other evidence of a start of prospective prosperity for the Company—and, consequently, for Ceylon teas—are afforded by Mr. May's letter. He has evidently so far succeeded in overcoming the prejudice of the American public in favour of the common and "faced" teas of Japan and China, that the dealers throughout many important States of the Union have at length felt themselves compelled to arrange for the regular supply to them of Ceylon teas. This is undoubtedly a great step in advance, and it is one upon which we can well understand Mr. May's congratulating himself. Once the barriers of long-established prejudice yield to the conviction among the American public that they have, in respect of good tea, too long remained in outer darkness, we may be sure the demand must increase by leaps and bounds. We think that we may well believe that this result will soon become evidenced by a large increase in the shipments of Ceylon tea to America. We do not like to be too sanguine, but it would really appear as if Mr. May's long-continued efforts were at length about to bear abundant fruit. Our planters have anticipated great results from the approaching advertisement of their teas at the Chicago Show. Apparently, they will not have to wait for that before obtaining an assurance that their teas have secured a foothold in America from which we may be sure they will not be easily driven. While congratulating them upon the prospect thus disclosed, we would take the opportunity afforded by Mr. May's letter to once again acknowledge the importance of the service he has rendered to Ceylon. It is impossible to overlook the connection of the promised prosperity with Mr. May's individuality. He has prophesied strenuously and persistently that the day for this would come, and he has fought manfully against many depressing conditions until at length his prognostications appear to be in a fair way of realisation; and we sincerely trust for his sake, as well as for that of all concerned, that the realization may be complete.

COFFEE AND TEA IN HAWAII.

We have received a copy of an interesting report by a Committee on the prospects of coffee and tea in the Hawaii islands. It is no wonder though our American cousins should feel a strong interest in these fertile sub-tropical lands, for they are as capable of producing large quantities of coffee (if not tea) as of sugar and coconuts. Of coffee already, a good deal has been planted in the different islands. On the principal one, Hawaii

itself, there are 1,300 acres of coffee growing and the new Kona Coffee Company has already 120 acres out and 200,000 plants in their nurseries. Chinamen as well as natives grow coffee on their own account, and besides a large local consumption, it is expected there will be a million lb. of coffee for export this year. It is clearly the beginning of an enterprise likely to extend rapidly under the influence of American capital and perhaps Chinese labour. Then about tea, in Hawaii we recognise a far more serious rival than in the Carolinas where Dr. Shephard and Mr. Cottam are at work. There has been started a Hawaiian Coffee and Tea Company and tea seed has been got from Ceylon—five acres cleared and planted at 2,000 feet are reported to be doing exceedingly well and further clearings are to be at once seen to; crop is counted on in two years. This Company is also planting cacao. Altogether the Hawaiian planters are enterprising and go-a-head. They have a Planters' Labour and Supply Company; they read the *Tropical Agriculturist*, and this Report shows they are on the way to prosperity. Labour is still a difficulty and they think a variety of crops will simplify it; but we should look to a large influx of Chinese as the best solution.

LAND CONCESSIONS FOR PLANTING AND AGRICULTURAL PURPOSES IN SIAM AND NEIGHBOURING COUNTRIES.

For some time past it has become known to European planters that the soil and climate of some portions of the Western States of Siam offer very favourable opportunities for the profitable growth of tobacco, coffee and other products. The recent agitation in favour of the construction of the Singgora railway has drawn a good deal of attention to that portion of the Malayan peninsula, more especially as it is proposed to continue the line after crossing the peninsula, by way of Kedah—through Province Wellesley—to a spot on the mainland just opposite Penang. After travelling through the whole of the Siamese Western States, as well as the Straits colony and the protected Native States, we learn that a selection was made in the neighbourhood of Singgora by a very experienced planter from Sumatra, who thereupon proceeded to Bangkok to ask for a concession from the Siamese Government. He anticipated but little difficulty in obtaining what he wanted, as the Governor of that district was inclined to help him or at any rate professed to be so inclined, and the King of Siam, during his visit to his Western States some two or three years ago, had been enabled to contrast their condition with that of the neighbouring States under British protection, and had expressed his wish to see the prosperity and enterprise so evident in those territories extended to his own dominions. Notwithstanding this expression of willingness on the part of His Majesty, the applicant for a concession of land on which to grow tobacco, failed to meet with the encouragement that might have been expected, and it was only after long and weary waiting with continual postponements in coming to a decision, that he at last induced the Government to give him a decided answer. The conditions under which he was to be allowed to take up the land for cultivation, cannot be looked upon as by any means favourable, or indeed to merit the name of "concession" at all. When they are compared with the terms offered by the Government of other places

similarly situated, or even more favourably so as regards means of communication, it will be easy to conclude that the Siamese Government does not as yet see its way to giving encouragement to capitalists engaged in agricultural pursuits.

The terms offered are these:—the payment of a premium and an annual tax over the whole area taken up at one and-a-half "salungs" per "rai," and an export duty—on the produce—at present undefined, but which may amount to 12 per cent *ad valorem*. Taking the $1\frac{1}{2}$ "salung" as 24 cents of a dollar with $2\frac{1}{2}$ "rai" to the acre, we get the 60 cents of a dollar as the annual rent per acre or say R1 35. This, of course, is not a rent on the acreage under cultivation only, but on the acreage of the whole concession, whatever its size may be.

Here then we have the land lying idle, as it has done from time immemorial—and likely to remain so for an indefinite period in the future—of no use whatever to any single mortal, and at present far distant from any port where the produce could find transport, and yet, before the capitalist is allowed to commence operations, he is bound to pay a considerable annual rent in advance, a rent of R1 35 an acre. In Sumatra we learn that the area of estates is computed by the *bouw* or the equivalent of $1\frac{1}{5}$ acre English measurement, and on this a tax of 4 pence per *bouw* is levied by the Dutch Government to begin with, and rising by successive annual increments for five years until it totals a guilder, or 1s 8d sterling, and at this rate it remains permanently. In addition to this an export duty of one cent (of a guilder) per lb. of tobacco is levied; coffee and all other produce being free. In New Guinea the annual tax is equivalent to 6d per acre. In Perak you may purchase your land outright at \$3 per acre without any levy of annual rent or tax, or you may rent it for 30 dollar-cents per annum, payable after two years from commencement of cultivation. In Johore, planters may get their land rent free, and in Borneo free for several years. In pursuing this course it has adopted, in this instance, it is difficult to understand why the Siamese Government is so reluctant to make the concession. It seems to us that it is a case with the Government of, "heads I win, tails you lose"; for every cent of the money spent by the concessionaire is paid away in the country, and if the venture prove a success, the revenue and the people profit accordingly; while if it proved a failure the Government and the country are none the worse for it, unless by a certain degree of exhaustion of soil in the experiment. We need hardly add that after becoming acquainted with the decision of the Siamese Government, the applicant for the land dropped the matter without further parley. This must be considered very unfortunate, as discrediting Siam as a field for agricultural investment at a time when that country is brought rather prominently forward in its political as well as its commercial relations.

The commencement of the long-talked-of Railway system marks an era of advance which must be very gratifying to the friends of Siam, and one which is regarded very jealously by her neighbours in Annam and Tonquin. There seems every prospect, too, of the various gold and gemming companies making a new beginning with more reasonable prospects of success. It is true that the formation of a Tobacco Company has resulted in anything but success, but we are not aware that the Government have lost anything by it, unless indeed it was foolish enough to subsidize it; and this—we may as well state—was not proposed for his undertaking by the applicant

to whom we refer above. We cannot see that the circulation of money in the country can do it any harm—and there being practically an unlimited supply of uncultivated land—the clearing of a few acres of it may be looked upon as a matter of no importance whatever.

We may add that one great advantage possessed by the Western States over the greater portion of Siam is the perennial rainfall with which it is favored in common with the whole of the Malayan Peninsula. The high lands of Keddah and the Jenna Hills attract a great quantity of rain from the westward, whilst the mountain ranges lying between Tenasserim and Siam proper, intercept the moisture brought by the monsoon from the Bay of Bengal, and the wind descends to the plain as a dry and scorching blast. Nothing much is as yet known about the rainfall and general meteorological condition of the country in the neighbourhood of Korat, nor will much information under that heading be obtainable until the line has been completed, but in the meantime agricultural enterprise will apparently remain in abeyance.

AN EX-CYLON PLANTER IN AUSTRALIA.

MALLEE AND WHEAT GROWING.

The Barrier, N. S. W., Feb. 11, 1893.

I wonder if the plan adopted for clearing the mallee-country for wheat-growing would be any good in Ceylon for clearing lantana and small jungle on easy land. They have a huge stone roller and yoke a number of oxen to this and simply roll down the mallee, knocking it out by the roots. The mallee is like a gum tree. It is a species of eucalyptus and grows sometimes into a good-sized tree. The mallee-country down at Warrack-na-beal has become a great wheat country. Having cleared a great space of ground by rolling down the mallee and burning it off, they plough the ground by stamp-jumping ploughs drawn by horses and sow the land also by machinery, and finally reap the harvest by that wonderful machine, the American reaper and binder. Another method is to use a machine, also American, which catches all the heads of the wheat and winnows and cleans the seeds and bags it all in the field. Machinery has been brought to a great height of scientific invention. I see you in Ceylon are beginning to pluck by machinery. Ceylon will be soon in the van of tea-growing.

I fear the influence of the working-white-man will prevent due justice being done to the fine tropical lands in the north of Australia. ABERDONENSIS.

NOTES ON PERAK.

The pontoon bridge "Gertak Khasanah Shah" at Enggor, 1,500 feet in length, is a very successful engineering work, and has lately withstood a rise of 15 feet in the Perak river, when the protecting chain was broken by the floating timber brought down by the flood.

The Kamuning Estate, about 300 acres of Liberian coffee and pepper, looks exceedingly well, and has a heavy crop.—*Perak Government Gazette*, March 3.

FRAUDS IN PEPPER AND GINGER.

As so-called ground Black Pepper is still being extensively sold, at prices which are simply impossible, except at a heavy loss, or unless the commodity is not what it professes to be, it is well for the grocers to be on their guard. The lowest market cost price of whole light dusty Penang, which is the poorest quality that can be ground, is 2½d. per lb. The lowest cost of grinding with loss on warrant weights and putting into barrels, is 3d. per lb. The lowest ground Pepper must thus actually cost the wholesale dealer 3½d. per lb. Allowing ½d. per lb. for

the dealer's profits, this Pepper could not be sold under 3½. Such a quality is quite unfit for the table use, and is only suitable for manufacturing purposes. In the same way, the lowest Penang White Pepper now costs, after the recent fall, 3¼d. per lb. The cost of grinding, loss of weight, and barrels, is ½d. per lb., the loss in weight being heavier than with Black Pepper. This would bring the first cost up to 4½d., or, allowing ¼d. for the dealer's profit, to 4¾d. per lb. Both in Black and in White Peppers it is notorious that far lower prices than the above are current. In some cases the opportunity for actual comparison is given by the quotation of the lowest Pepper, whole, at a considerably higher price than the simultaneous offer for ground Pepper. Everyone knows that ground Pepper must inevitably cost more than whole. The question therefore arises of how the natural state of things can be reversed.

It is to be hoped at a time when there is so strong an agitation for the improvement of the Adulteration Acts, that the grocers will support the legitimate wholesale trade, and refuse to encourage such a disreputable system of trading. The case of Ginger is even worse, now that its place is being so extensively taken by the refuse of Ginger beer making. The grocers might, from the point of view of the law, just as well sell exhausted Tea leaves for Tea, as much of the so-called ground Ginger that is now being offered. The worst of the matter is that price is not so direct a guide with spent Ginger as it is in the case of the lowest Pepper, for the operation with the former goes further. It is well known to the wholesale trade that spent Ginger is not only fraudulent mixed with common qualities, but with the better qualities as well, in order to obtain an illegitimate profit. With the lower sorts, however, it must be clear to anyone that genuine ground Ginger cannot be sold below the cost of the raw roots, inasmuch as the cost of grinding and barrels is 8s. per cwt. Nor can bogus guarantees of quality or warranties excuse a respectable trader in his own eyes from buying such commodities. With the higher-priced Ginger the fraud is less easy to detect, though the palate at once shows any extensive adulteration.—*Produce Markets' Review.*

NOTES ON PRODUCE AND FINANCE.

TEA CULTURE IN AMERICA.—Shortly after the War of Secession, the United States Minister of Agriculture instituted an experiment in tea-growing on an estate near Charleston, but the results were not encouraging, and after a short time the enterprise was abandoned. Dr. Charles Shephard has now, according to a writer in the *Canadian Grocer*, made a further attempt to raise tea on the same estate, and has been assisted by Mr. Cottam, a planter of considerable experience in Ceylon. Mr. Cottam states that the produce of this South Carolinian estate is fully equal in quality to the teas grown in India and Ceylon, and that in his opinion the United States can easily produce the 90,000,000 lb. of tea which it now consumes annually. There are, he says, millions of acres that are suitable for tea cultivation—notably the lands inside the yellow pine belt. There will be no difficulty, he adds, in securing cheap labour, since Dr. Shephard has a school on his estate in which he gives a free education to the children of the district, and thus has them resembled so as to bring their labour to bear easily and cheaply upon picking. Men will be required only to look after the machinery. It will be interesting to learn the result of this curious attempt to obtain cheap labour in a country where the use of the mere phrase is enough to excite an outburst of popular wrath.

ANOTHER SUBSTITUTE FOR SUGAR.—Alleged substitutes for sugar are very frequently announced, but beyond that fact very little is heard of them. The latest comes from Germany. The *Handels-Museum* states that at the last meeting at Hanover of the Brunswick-Hanover Society of Beet Sugar Makers a Berlin doctor made an interesting communication relative to a new substance called *valsin*,

which, it was stated, would appear to be about to supplant saccharin, and will, perhaps, be a serious competitor to the sugar industry. This substance, discovered in 1883 by a Berlin chemist, is at present produced in that town according to a patented process. It will be about 200 times sweeter than sugar, and will not have certain disagreeable properties of saccharin. Several experts are engaged in examining this substance.

GUM KINO.—An example of the extraordinary fluctuations which frequently take place in the markets for drugs has just occurred in the sudden advance of the price of East Indian "gum Kino" to £15 per cwt. Eighteen months ago the quotation was only 37s 6d per cwt. and the rise appears to be due to a stoppage of supplies. In India "Bengal Kino," the gum of the *Butea frondosa*, is extensively used as an astringent, as a substitute for the true Kino, and is in some respects preferred to it, because it yields a stronger astringent in water than in spirit.—*H. and C. Mail*, Feb. 24.

DRUGS AND OILS IN LONDON.

(From the *Chemist and Druggist*.)

London, Feb. 23.

CINNAMON is still advancing. One hundred bales Ceylon usual assortment, December-February shipment, have been sold at 6½d per lb c.i.f. term.

CINCHONA.—The periodical auctions were moderately heavy this week. The nine catalogues, totalled up, gave the following figures:—

	Packages.	Packages.
Ceylon cinchona	1,574 of which	1,418 were sold
East Indian cinchona	855 "	686 "
Java cinchona	61 "	40 "
West African cinchona	21 "	21 "
South American cinchona	276 "	16 "
	2,787	2,181

Most of the bark was of poor quality, and the highest figure realised by any lot in the sale 6d per lb. Grey barks were not very largely represented; but there was a considerable quantity of Indian Ledgeriana chips. In the Ceylon kinds red barks still predominated. The tone was very sluggish, scarcely an occasional flicker of competition enlivening the selling throughout the auctions. Several Parcels were bought in, as it was impossible to approach the limits fixed by the owners, and the general view is that the unit value rarely surpassed, and generally failed to reach, 1d per lb, showing a decline of 8 to 10 per cent upon the preceding auctions. In some quarters it is stated that this sale marks the lowest point yet touched in the history of the trade.

The following are the approximate quantities purchased by the principal buyers:—

Agents for the Frankfurt-o/Main and Stuttgart works	...	164,956
Agents for the Mannheim and Amsterdam works	...	84,490
Agents for the Brunswick factory	...	58,915
Agents for the Paris factory	...	49,918
Messrs. Howard & Sons	...	49,040
Agents for the American and Italian works	...	36,430
Agents for the Auerbach works	...	31,059
Sundry druggists	...	54,648
Total quantity of bark sold	...	528,456
Bought in or withdrawn	...	118,074

Total quantity offered ... 642,330
ESSENTIAL OIL.—Lemongrass oil has been the subject of some speculation this week. We are told that one firm has bought up the bulk of the supply on the spot and available until next September. The may not be so; but at any rate, prices are notably higher. Business has been done in ordinary native qualities at from 1½d to 1¾d per oz., and today 2d per oz. is asked.

CHEMICAL PRODUCTS and raw materials for the manufacture of porcelain and glass are included in the list of products which are to be exempt from the customs duty under the Bill recently passed by the Bulgarian Government for encouraging industry in that country, by ceasing to tax industrial establishments having an invested capital of 2,000 francs, and abolishing the duties on certain raw materials not produced in the country itself.—*Chemical Trade Journal*, Feb. 18.

SCENT PRODUCING IN INDIA.

Some time ago attention was directed by a contemporary whose columns are devoted entirely to agricultural subjects to the production of indigenous oils and essences from the resources of India; but despite the floral wealth of the country, there is but a limited assortment of scented shrubs at the disposal of those who would wish to attempt the manufacture of scents. It would be as well, therefore, if attention were directed to the introduction of suitable plants and herbs that should give us pure scents, so necessary in the plains of India during the hot weather and rains. The purely Indian perfumes, such as attar of roses, jasmine and other plants, are too over-powering for most tastes, even when freely diluted, while their extreme unctuousness renders their application to the clothes or handkerchief out of the question. In 1851 Dr. T. Oldham of the Geological Survey recommended the distillation of orange flower water from the groves of that fruit in the neighbourhood of Sylhet, and, though this matter was reventilated last spring, no one seems to have deemed it worth while essaying, though there can be little doubt the local demand would, in the summer months, be enormous, and a considerable export trade, outside Bengal, might reasonably be anticipated. So overdone has been the planting of the orange tree in the district alluded to that the blossom is but of nominal value. It is just as well to mention that mechanical means of gathering the flowers would have to be restored to, the formidable spikes and dense growth of the tree precluding any possibility of climbing; but that is a mere trifle and half a dozen contrivances are now available for gathering both fruit and flower at considerable heights from the ground that no difficulty should be encountered in the collection. There are, certainly, a few orchids that give out a fragrance, such as *Dendrobium formosum*, but it is far too faint and delicate for general purposes. Moreover, these plants do not exist in large enough quantities or sufficiently concentrated areas to render their use scent producers feasible. While most of the more prolific plants of this order, such as *Saccolabium*, are inodorous, *Arides odorata*, though plentiful in North Borneo and the adjacent countries, would be needed in very large quantities, to furnish any appreciable amount of scent either by maceration or distillation.

We have, therefore, to consider what would be the best scent producing plants and shrubs to import, which might be expected to have a reasonable chance of success in providing the raw material for the manufacture of what may be considered a necessity in this climate from April till September. Lavender and violets, with other strongly scented flowers, will grow luxuriantly in all the hill tracts of India, but though shewing greater vigor under the brilliant tropical sunlight of the more southern mountain ranges, as far as growth goes, will be found far more deficient in scent than their congeners grown in the semi-tropical and more temperate northern latitudes. Both plants, we have adduced as pioneer perfume producers, are sub-tropical in origin, though from their hardiness have been acclimatised in countries one would have thought to possess not the slightest hopes of their thriving in; but "matter in the wrong place" is as much the rule in botany as geology. Suitable tracts for the propagation of all plants are best indicated by observation of the indigenous flora, and wherever such is found at all approaching that of Europe, reasonable hopes of success in the introduction of these two plants named may be anticipated. Now as the flora indicated extends all through the outer Himalayas, it will be seen over what a vast field scent-producing plants may be propagated for, though mentioning lavender and violet as examples, there are others whose introduction will readily suggest themselves to any one acquainted with Southern European botany. Of course there are extracts, tinctures, and essences to be had from many Indian plants, but as these partake more of purely commercial character we leave them unnoticed, our present remarks being directed more in the hopes of reviving

the glories of the *still rooms* of our great grandmothers than actual trading for whatever the present profits may be on scent, the price is so small and the trade so restricted that were our suggestions taken up by energetic people we might look for overproduction in the near future, but overproduction of cooling perfumes in India most people would look upon as a boon, the demand growing with the supply. If any one cares to study the question it will at once be apparent that no El Dorado need be expected from the manufacture of Indian perfumes though their concoction would afford occupation for pensioners and others, who may be inclined to settle in the more salubrious of our Indian hill ranges. With regard to lavender the demand would be almost unlimited even in the state in which it is usually hawked about the streets at home, and though it possesses no qualities of such insecticides as camphor or datura, the scent it imparts to linen or clothing is far preferable to either. Extracting scent from violets or other flowers is best accomplished by maceration in clean animal fat, in conjunction with alcohol, the process being fully explained in the columns of our contemporary the *Indian Agriculturist* about a year since; and lavender water, when required in a highly concentrated form, may be obtained in the same way, though as quantity would be mostly sought for in the hot weather, the usual plan of obtaining the scent by distillation had better be adhered to. The necessary spirit for maceration can be made from so many different sources that this detail is hardly worth dwelling upon. Even the imported white alcohol from the low countries and German ports—generally denominated "potatoe spirit"—is so cheap that it might be used for maceration either rectified or in the state it reaches us, though many indigenous tubers and roots could furnish spirit for the purpose of superior quality. In connection with this matter it might be as well to ascertain how far the "cherry," from the fruit of our coffee plants, is capable of meeting requirements in this line, for it would be far preferable to obtain what we need from a waste product than from edible roots, grain or tubers. The subject of manufacturing these luxuries from our own internal resources is one of considerable interest in the present days of depreciated currency, and there cannot be two opinions as to the advantages of obtaining such matters we write of, fresh and unadulterated, for few will deny that the bazaars teem with scents and waters that have been so long on the shelves as to prove next to useless when opened. —Asian.

COFFEE AND COCONUTS IN BRITISH NORTH BORNEO.

Mr. Hy. Walker writing to Mr. W. D. Gibbon says:—"I visited Toritipan on the 2nd Feb. and found 66 acres planted with coffee, 15 with coconuts. The older coffee was planted in Jan. 1892, and in Jan. 1893 there were a few spikes of blossom. I am glad to say the young coffee is looking remarkably well, the older trees are about 3 ft. to 3 ft. 6 in. bushy and sturdy, all the plants are healthy and strong and I have no doubt the estate will do well. The manager (Mr. T. J.) is very sanguine about coffee and is now felling 40 acres for June planting. Mr. J. is known in Ceylon, he was a pioneer tobacco planter under my old friend M. on the Mahaweliganga but after three months he resigned and returned to Sumatra. Tobacco planting brought him to our territory, but the estate having closed I induced him to take up coffee and I do not think he will regret it. Mr. J., while planting tobacco, put in 15 acres of coffee which is now 3 years old and is bearing very heavily. So far we have every reason to congratulate ourselves upon the success of coffee in North Borneo. Our coconuts are doing well and I have not the slightest doubt about their paying. I do not suppose there are 10,000 trees in North Borneo, and we have to import nuts for domestic use, and pay 4 to 8 dollar cents for nuts. How would you like to pay such a price in Ceylon!"

TEA IN INDIA.

Our Dehra Doon correspondent writes on 23th February, 1893.—The last two days have been nice and sunny. We have had a total of 12.39 inches of rain this year; and 1.80 inches on 30th December, 1892.

Our Dam Dim correspondent writes on 23th February, 1893.—Rain fell last week again. The weather is getting warmer now and an early season is anticipated. Our meeting came off last week and was a decided success throughout. The annual inspection of our local corps takes place early next month and it is to be hoped there will be a good muster of our gallant defenders.

Our Darjeeling correspondent writes on 1st March 1893.—Over another inch of rain, since my last to you, which fell on the 22nd ultimo and temperature went down with it for a few nights to something like 35°. An upward movement though has taken place in the last two days, some decent sun having shown itself in the mornings chiefly.—*Indian Planters' Gazette.*

SUGAR IN JAVA.

NETHERLANDS INDIA.—The Sourabaya Courant of the 2nd February reports favourably on the standing sugar cane crops in East Java. Very few traces of root disease have been noticed, and there is every prospect of a satisfactory yield this year.—*Straits Times.*

PLANTING IN SOUTH WYNAAD.

Our coffee crop is pretty well over, and most of the bark has been sent off. Those who have pepper are now busy harvesting it. This crop I am glad to see is a very good one. There can be no doubt about pepper thriving here, at any rate. No rain, up to date, but the clouds are creeping up every day. I think I am safe in saying, that in Wynaad the idea has pretty generally been that nothing can supersede cattle manure if you can only get enough of it. All of us who possess anything in the way of grazing grounds keep as large herds of cattle as we can, and those who are wise take every precaution to preserve the sweepings out of their cattle pens in properly constructed pits. Failing cattle manure, I think that bone and poonac are considered the most efficacious—in proportions of one of bone to two of poonac—about one pound of the mixture being put annually to each tree. It passes one to understand how anyone can expect a coffee tree to give a decent yield every year when he only manures it once in two years, or even in three years which was considered often enough 15 or 20 years ago. The bone of course remains available in the ground as required, but the poonac rapidly loses its value and after one season in the ground must all be taken up and expended by the tree if it gets hold of it at all. It is of the greatest importance I think to dig the stuff, whether cattle or poonac manure, thoroughly into the ground and mixed up so far as possible with a large extent of soil round the tree, so as to encourage the tree's roots to travel about and extend themselves ever as large a space as possible. I have seen coffee ruined, by having the manure all put into miserable little tea-cuppits close up to the stem of the tree. The roots all converged into this small space, sucked up all there was in a couple of months and then decay and ruin set in, and the trees, having nothing else to go on with, died back. A planter sometimes says that poonac and bone has done his coffee harm, but I think it will generally turn out that he has expected his trees to do 3 years on one year's supply, or has applied it badly. Potash in some form should be put in with poonac and bone and I believe that in Coorg the nitrate has been used satisfactorily. I have used the *muriate* for some years at the rate of 2 ounces to each tree with 1 lb. poonac and bone, but I cannot say that I found it make much difference, and it is certainly expensive. Trenching up the soil at South Coorg is the sort of thing we ought to go in for much more extensively, but as Rudyard Kipling says, "that is another story."

SEEDS FOR CENTRAL AFRICA: MESSRS.

JAMES CARTER & CO. OFFER A CORRECTION.

(The Editor, "Tropical Agriculturist," Colombo, Ceylon.)

LONDON, 10th March, 1893.

SIR,—We feel sure you will not mind our calling attention to an injustice that has been done us unintentionally, in your Journal for January last.

If you will kindly refer to page 460, you will observe a reprint of a letter from the Botanist to the British Central African Administration and in the paragraph referring to English Vegetables, your compositor has translated what should have been the words "Carter sends" to "Castor seeds."

We had the pleasure to supply a large assortment of seeds to this important Administration through the kind offices of Mr. Whyte, and feel sure you will see the legitimacy of our claim, and if you are pleased to reprint the paragraph in association with this letter, we shall further esteem the favor, as it is important for Colonists to know where to obtain products that are likely to prove reliable in any climate for which they may be required.

We are, Sir, Your obedient servants,
JAMES CARTER & Co.

[The paragraph referred to, which we readily reprint, is as follows:—

As to English vegetables they do splendidly here and "castor seeds" (*Carter sends*) out the best of seeds. I have raised magnificent potatoes from his seed (not sets) and have noted something like 500 varieties to select from. They are producing at the rate of 5 tons an acre without manure, and there is no trace of disease.

—Ed. T.A.]

VARIOUS AGRICULTURAL NOTES.

COMPLETE MANURES are those which contain nitrogen, phosphoric acid and potash. For different crops these ingredients should exist in different proportions.—*Horticultural Times.*

COFFEE PLANTING, CROPS AND YIELD IN JAVA.—A Java coffee planter under date of Feb. 3rd writing to the *Tropical Agriculturist*, among other information affords the following:—

I thank you for your remarks in answer to some enquiries I made last year about *Ficus glomerata* and *Grevillea* as shade for coffee. These trees are now two years in the ground, and, so far, the *ficus* does not look a likely tree for its purpose. I trust, however, it will grow quicker, branch out here, and that the coffee will really do well under its shade, bearing nearly as much as if under the *dadap* shade, the best shade I know for coffee. A pity an unknown disease kills off the *dadap* here. Last year we reached our estimated crop of 5,000 piculs of clean coffee, and so, perhaps, the taxation piculs of 3,000 piculs may also be within the mark. 1893

KAPOK to be spun into yarn by *Litch* machinery, is a statement of some interest to us in Ceylon. The *Indian Agriculturist* of Jan. 3th has the following:—

The Cotton tree, the native *Kapok*, which is very common in Burmah, is now said to be receiving much attention as an article of cultivation, and to be ousted by coffee from that province. The lack of suitable machinery to clean the fibre has hitherto stood in the way of its development as an industry, but the obstacle is said to have been recently removed. The cotton trees of Burmah are of three species, two of which are known among the natives as the male and female trees, and are very common, and grow to a height of from 80 to 100 feet. Though grand-looking trees the wood is soft and worthless, and the cotton fibre attached to the seeds has hitherto been used only for stuffing pillows and cushions. If, however, the machinery, which is a Dutch invention, about to be introduced, will enable it to be spun into yarn, Burmah will develop a very important industry.

THE FIBRE INDUSTRY which was at one time very brisk, is somewhat slack just now. It has been a regular Godsend to the poor people all over the Jafina peninsula; for with the almost entire failure of the last paddy crops, they would have had little or nothing to eat. In the place of paddy they have money; for I am credibly informed that close on R700,000 worth of fibre has been bought in the place; and all this money is now circulating in the Peninsula.—*Ibid.*

TEA IN THE CAROLINAS.—Once more Mr. Shephard and Mr. Coffam are to the front as witness the article on page 659. Nothing could be more vigorous than the solitary tea plant we saw in the garden of the Government Agricultural Department in Washington in 1834; but "one swallow does not make a summer," nor is there the slightest chance, in our opinion, of the Carolinas or the Southern states as a whole, giving one million, much less 90 millions, lb. of tea to a profit for home consumption. As the ex-Ceylon planters, with whom we stayed in Florida, said of their orange garden of 10 acres,—who can keep a place clean, much less extend the planted area, with Negro labour at a dollar a day—and dear at that!

A SERIES OF EXPERIMENTS, to test the comparative fire-resisting qualities of different kinds of flooring, have been conducted in Hamburg. In each case the floor was laid with unplanned pine, the boards ranging from 1½ to 2½ inches in thickness. A floor of single boards burnt through in 30 seconds. A double floor with parallel joints with two layers of asbestos paper placed between the boards burnt through in 64 minutes. With thick asbestos felt between the boards, instead of paper, the floor only lasted 9 minutes longer. A double floor with joints crossing at right angles, with nothing between the boards, took 82 minutes to burn through. A similar floor with roofing felt between the boards only resisted 72 minutes. A double floor, composed of 2½-inch planks, covered with one-inch match boards, the joints at right angles, nothing being placed between the two lots of boards, resisted the fire for 144 minutes, this showing that the crossing of the joints was more effective than inserting asbestos paper or felt between the floors.—*Indian Engineer.*

RUBBER, &c., IN MEXICO.—A concession has recently been granted by the Government of Mexico for a large tract of land in the States of Tabasco and Chiapas for colonisation purposes. These are the most southern and, except to the representatives of a few firms dealing in mahogany and india-rubber, the least known States of the Republic. The mahogany interest has gradually been worked back from the coast to the mountains, making it much more expensive to get the logs out, as so many are lost and broken in floating them down the mountain streams. There is, however, still a large district covered with mahogany timber on the upper waters of the Tabasco (or Grijalva) River to be opened up when increased means of transportation are procured. The eastern slopes of Chiapas and Tabasco appear to be singularly favourable to the growth of rubber trees, which grow quickly and well. With some systematic plan of planting young trees, and by not tapping the trees until they have attained a sufficient growth, this should become one of the most important rubber districts of America. Upon leaving the low coast land—about 100 miles in width—there is a sudden "jump up" on to a very broken plateau. On this plateau there are very valuable gold and silver mines just beginning to be developed. The two great wants in this district at present are decent roads and labor. The Government of Mexico has lately been utilising the troops stationed at Chiapas for road building, and in a few years there will be a good road completed from the capital of Chiapas to the low coastland of Tabasco, over which there are good water routes to Frontera or Carmen.—*Indiarubber Journal.*

VALUATION OF CEYLON TEA PLANTATIONS.—No one can say that tea plantations are being valued too highly, for purchase or Company purposes. In the reports of two well-known Visiting Agents lately published, the valuation is based on an estimate of profits extending over six or seven years only. "Seven years' purchase" in fact seems to be the rule at the present time for estate valuations.

INDIAN TEA EXPORTS.—It seems rather late in the day for Messrs. Gou, Wilson & Co. to give us in their tea circular, the figures for Indian Tea Exports to 30th April last. Still it is interesting to be reminded how direct exports to places outside the United Kingdom go on increasing:—

1889-90 equal to	lb. 5,388,500
1890-91	.. 6,286,416
1891-92	.. 9,275,473

For 1892-3 we may add the figures are likely to be very much less satisfactory; for up to 22nd February 1893 the direct exports were only 4,751,666 lb. against 8,263,020 lb. to same date last year. For Australia, the difference was 1 million less; but for "Bombay and Persian Gulf" the falling-off was over 2,300,000 lb! Can "Ceylon" be the cause of this, in cutting out "India" to a great extent?

THE ROYAL BOTANIC GARDENS.

[EXTRACTS FROM THE REPORT OF THE DIRECTOR FOR 1892.]

1.—STAFF.

In response to an application at the commencement of the year, Government agreed to the formation of a new class of *employés* under the title of "Upper Gardeners." These posts are intended to attract youths of some education who desire to qualify as skilled gardeners, and so be fitted to take superior places in private employ. Three posts of this class were accordingly made, on an ascending scale of pay, and suitable appointments made to them. At present the senior is employed at Pérádeniya and the two juniors at Hakgala.

2.—PÉRÁDENIYA GARDENS.

Visitors.—The beauty of the Gardens and the interest of their contents are becoming more and more recognised, and few travellers who can spare time leave Ceylon without paying a visit to them. During the year 1892 no less than 1,966 such visitors entered their names in the book kept at the Lodge for the purpose. I find the labels to the trees very much appreciated, and hope to greatly increase their numbers on a general system; but this involves much expense, and can be only done gradually.

The third edition of my little Hand-Guide to the Gardens, published in 1890, is already exhausted, and a new one is urgently called for. This will be undertaken as soon as I can find time for the work, and I hope to improve it by a somewhat fuller treatment of the subject.

3.—HAKGALA GARDEN.

Progress is being steadily made in the improvement and upkeep of this interesting Garden every year; but several matters continue to retard its development.

A water supply, in spite of efforts to afford it, is still a desideratum, the new reservoir being at the present time completely useless. Its construction was "completed" by the Public Works Department at the end of April, but on being filled it was found to leak badly. Efforts to stop the leaks were made in May, July, and August, but on each occasion without success, the cause apparently being the existence of springs in the floor of the reservoir. It is hoped that a further and successful effort will soon be made. A further expenditure will then be necessary to convey the water to the various parts of the Garden where it is needed. I applied for a vote for this purpose during the year, but (owing to my absence in England) my application was received too late for consideration with the Estimates. I shall renew the application, and trust that it will be granted, such means of distribution being a necessary part of a proper water supply to the Garden.

The following are extracts from Mr. Nock's Report for the year:—

Nurseries.—The imported weed, *Oxalis violacea*, has become a real pest, and is most difficult to eradicate on account of its numerous bulbils, which are reproduced in a very short space of time. To give an idea of the rapidity with which this plant propagates itself, I have counted as many as 32 bulbils at one root, and the plant was probably not more than six weeks old. When it is considered that each young bulbil is only about an eighth of an inch in diameter, the difficulty in picking them out will be understood. During the year no less a quantity than 138 bushels of these, including the stalks and leaves, have been collected and burned. But it is impossible to eradicate it from among nursery stock, and the lower part of the nursery ground has been given up for the present.

64,414 plants and seedlings of ornamental trees and shrubs, general garden plants and annuals, were set out during the year for the supply and upkeep of the garden. This is considerably in excess of last year, which is accounted for partly by the addition to the fernery, but chiefly to the bad weather at the beginning of the year, which killed off large quantities of succulent plants, and to the ravages of the black grub among the bedding-out plants in November and December.

750 plants of English oak and 100 *Eucalyptus* were set out on the patana on the south side of the garden, and most of these have grown, but as the plants were not fenced they have been damaged by cattle and elk.

Black Caterpillars.—These insects have been much more destructive this year than usual. Hand-picking seems to be the only effectual means of destroying them. In this way hundreds were caught nearly every morning during the months of November and December. Burrowing just underneath the surface of the ground they attack the young plants and bite them through at the collar, and in this way large quantities of plants have been destroyed. The only way to prevent this is by placing round each plant small pieces of tin or zinc, 2½ to 3 inches in diameter and 2 to 3 inches in depth, and fastening them together by a small clip formed by the edges being bent back so as to slip into one another.

4.—HENARATGODA GARDEN.

This branch maintains its character as a well-managed experimental garden, and is full of plants of economic interest, most of which are doing well.

5.—ANURÁDHAPURA GARDEN.

The remarks made last year on the growth of plants in this garden may be repeated. Cacao of the Forastero variety was fruiting fairly well at the end of the year, shaded by *Erythrina*

umbrosa ; sandalwood trees, about 12 ft. high, are again flowering, and the young teak growing well (seven years old, 19 in. in circumference at a yard above ground). The new mahogany (*Swietenia macrophylla*) and Jamaica cedar (*Cedrela odorata*) both do well here. Now that these and other trees are growing up the place is becoming a beautiful spot, and forms an additional attraction to the town. The conductor continues to do his work with diligence, and keeps the garden in good order.

6.—BADULLA GARDEN.

The garden progresses satisfactorily, and is now a great ornament to the town. We have a regular water supply, and the plants are all making as good growth as can be expected. We much need manure ; none was obtained from the town this year, with the exception of a few cartloads in October.

At the request of Government a large nursery of twenty beds was formed in June for the rearing of seedling trees (the seed being supplied from Pérádeniya) suitable for planting in the grounds of the new Civil Hospital, Badulla. A number of these were successfully raised and planted out in their places in October, the cost of this being met by the Civil Medical Department.

9.—NOTES ON ECONOMIC PLANTS.

Under this head I find but little of novelty to report for the past year. My absence from the Colony partly accounts for this, but the tea industry has now so overshadowed all other cultivations that there is little room for trial or experiment with smaller products on estates, and thus little stimulus to investigate them here. To continue, however, the records of past years in these reports, I give, as usual, particulars of the principal cultivations, premising that much of what follows is derived from sources generally available.

Tea.—As I anticipated would be the case, the increase in the export was a great falling off from that recorded for the past few years. The export for 1892 was 71,153,657 lb., *i.e.*, less than 3,000,000 lb. above that for 1891. A generally dry season had much to do with this, whereas in 1891 we experienced a remarkable and continuous rainfall, which caused an exaggerated yield. The average price obtained in the London market was about 9½d. per lb., a very slight diminution on the previous year.

It is satisfactory to read in the statistics of tea consumption in England that of every 100 lb. consumed in 1892, 84 lb. were of British growth, *viz.*, 53 in India and 31 in Ceylon, only 16 lb. being the produce of China. One also sees with pleasure the great increase of nearly 2,000,000 lb. in the direct export of our tea to Australia, *viz.*, 5,166,154 lb. against 3,210,598 lb. in 1891 ; and one feels that we may reasonably expect that the costly advertisement at the forthcoming Exhibition in Chicago will lead to a large sale in the future in America. We urgently need this ; for while there is no reason to fear any drawback to continued success as far as cultivation and manufacture are concerned, there is a real danger of over-production ; and its consideration as a possibility, by no means remote, makes it my duty earnestly to recommend those concerned to devote some portions of their land to other cultivations. In the low-country especially much caution should be exercised in opening further land in tea estates.

Coffee.—There is a melancholy interest in noting that the total export of this was but 43,143 cwt., *i.e.*, less than half the quantity of the previous year. There was a moderate increase in Liberian coffee, 979 cwt. against 894 in 1891 ; and I feel sure that the culture of this product ought to be very greatly extended in the low-country, where it is likely to prove more profitable than tea.

Cacao.—It is with regret that I note a considerable diminution in the export for the year of this product, only 17,327 cwt. against 20,532 cwt. in 1891 ; and it is to be hoped that this is a merely temporary fluctuation. There are several possible causes : the dry season was against a heavy crop, and the general failure of the south-west monsoon stopped the formation of fruit from the first show of flowers ; the rising popularity again of the “ Old Red ” kind probably somewhat lessened quantity. Cacao also suffers from many enemies, and much crop is destroyed by squirrels and other animals, which are more numerous in some seasons than others.

I have continued a gratis distribution, through the Assistant Government Agents of Mátalé and Kégalla, of seeds of cacao to the poorer villages of those districts. As this is a matter in which His Excellency the Governor, as well as myself, takes much interest, I may here offer a few remarks on the subject in continuation of those of the last two years. Towards the end of the year Government called for reports from the Government Agents of the Central and Sabaragamuwa Provinces, and from these it would appear that but little success has been met with in most districts. But in the Kégalla District, where, as I mentioned in my last Report, the distribution has been made personally and with care and discretion by the Assistant Agent, the results have been very satisfactory. Mr. Davidson writes to me : “ The cultivation of cacao is being taken up readily in the villages of Four Kóralés Out of 1,816 pods distributed to date [February, 1893], the history of all of which is being kept, a very high percentage are growing well.” In the Ratnapura District the climate appears to be too wet for successful cacao growing.

As regards Kandy the pods seem to have been distributed entirely to Ratémahatmayás and a few Kachchéri clerks (not at all the sort of people it was desired to benefit), and it is stated that the poor villagers in Pata Héwáheṭa did not like to take the seed, thinking that they would be called upon to pay for it. Failure is generally reported, and the last lot of 100 pods which I sent in December were returned to me as "not required."

In Mátalé South cacao trees may now be seen growing in many native gardens, which it is supposed are the result of the large quantity of seed distributed. In this district the subject is unfortunately rather complicated by the great prevalence of stealing cacao-pods off the trees on estates and selling them to the small village shopkeepers. It is to be feared that too many villagers prefer this means of obtaining cacao pods to growing them, and that the few trees round their cottages are often used as a pretext to account for the possession of stolen pods. Still I do not regard this as a sufficient reason for ceasing to encourage cultivation by the free gift of seed; it is to be hoped that means may soon be found to show the people that it is more to their interest to grow cacao than to steal it.

In response to a request from the Queensland Government a case of 4,000 seeds was sent to the State Nurseries at Cairns in that Colony.

Cinchona.—It is astonishing to observe that the export of bark for 1892 (6,793,320 lb.) actually exceeded that for 1891 by more than a million pounds. As cinchona trees seem nowhere now numerous, it is difficult to understand whence all this quantity has been derived; and one is driven to suppose that much of it is bark that has been for some time stored at Colombo in the expectation of better prices or reduced freight.

Indiarubber.—Para Rubber (*Hevea*). Our plantation at Henaratgoda supplied the Forest Department with 30,000 seeds for the extension of the experimental plot in Sabaragamuwa, and about 16,000 more seeds were sold to private purchasers.

A further bleeding was made this year of the tree at Henaratgoda which was tapped in 1888 and 1890. The mode of procedure was the same as on those occasions, and the amount of dry rubber obtained was 2 lb. 13 oz. This tree is now fifteen years old, and has a circumference of 6 ft. 5 in. at a yard from the ground. Its yield has been as follows:—

In 1888	1 lb. 11 ³ / ₄ oz.
In 1890	2 lb. 10 oz.
In 1892	2 lb. 13 oz.

giving a total of 7 lb. 2³/₄ oz. in six years. The tree is in vigorous health, and in no respect the worse for the treatment. The interval of two years between the tappings allows the bark to completely heal over the incisions. I have sent home 2 lb. of the rubber that its present market value may be ascertained.*

Panama Rubber (*Castilloa*).—This is not so promising in Ceylon as *Hevea*. The largest tree at Henaratgoda is but 3 ft. 7¹/₄ in. in circumference, and its yield of rubber is here much less than that of *Hevea*. We had occasion in March to cut down a tree at Pérádeniya—a healthy male specimen which had been planted as a cutting in 1882, and had a circumference of stem of about 3 ft. 7 in.—and the opportunity was taken to obtain from it as much rubber as possible. The result was very disappointing: very little "milk" could be obtained, and this consisted chiefly of a black watery fluid in which was suspended a white flocculent matter which did not solidify. From this a small quantity of caoutchouc spontaneously separated, but we could not get half a pound from the whole tree. The little obtained, however, appears to be of first-rate quality, very pure and elastic, but has a very dark colour. This result is much the same as that at Henaratgoda recorded in my last Report.

Cubebs.—Three of the plants from Buitenzorg were planted out at Henaratgoda and two at Pérádeniya against *Erythrina* trees in March, but they make scarcely any growth. Two have produced flowers, but unfortunately the plants prove to be male.

Gambir.—The plants at Henaratgoda have flowered well, but little seed was matured owing, I think, to their being in too shaded a situation. This can be easily remedied, and I hope to form a nursery of seedlings soon.

I may call attention to a very useful and nearly exhaustive account of this product by Mr. Ridley, Director of Gardens and Forests at Singapore, which was published as No. 2 of the "Agricultural Bulletin of the Malay Peninsula," dated February, 1892.

Kola-nut.—I suspect the climate of south-west Ceylon will prove too wet for this. Two trees at Henaratgoda are now 28 ft. high, and have never flowered, and I believe the only ones in this country which have produced fruit are four on an estate in Mátalé. These were planted in 1876, and first flowered in 1883. They continue to blossom profusely, but rarely set any fruit. This

* The Report of Messrs. Hecht, Levis, & Kahn, dated 7th February, 1893, on the sample is as follows, and most encouraging:—"The quality of this Rubber is very good indeed, and the curing of the same seems to have been effected in the proper manner. This quality would be easily saleable, and we estimate its value to-day as being about 2s. 3d. to 2s. 6d. per lb., according to whether the Rubber would be dry or damp. It would be easily saleable in large quantities." [Note added 14th March, 1893.]

year, however, they yielded 18 lb. of seeds, which were sent home for report, and Mr. T. Christy, of London, informs me that he finds them to contain a large percentage of the "Kola-red," to which principle much of the sustaining power of this food is ascribed.

Caryocar nuciferum.—Seeds of this, the "Souari" or Butter-nut of British Guiana, were received from Kew in 1891, but as none had germinated by the end of the year, it was not included in last year's notes. The large seed has an extremely hard woody shell, and it was advised to assist germination by the removal of a part or the whole of this. All the seeds treated this way were lost, falling a prey to rats and other rodents, which no doubt found these oily seeds much to their liking. But I am glad to report that of the seeds sown in their natural state three have in due course germinated at Pérádeniya and one at Henaratgoda, and have made healthy seedlings. This tree gives a valuable timber, besides the food afforded by the large nut-like seed.

Fruit Trees at Hakgala (Apples, Pears, Plums, and Peaches).—Mr. Nock reports :—

The plants made very good growth during May and June. At the end of June those from Japan looked particularly well ; probably this was due to the dry weather which prevailed all through the month. The strong cold winds of August put a stop to this promising growth, and the fruits which had set on many of the apples and plums were nearly all destroyed. However, one of the Japan plum trees ripened a single beautiful fruit of remarkable size and delicious flavour. It measured $6\frac{1}{2}$ in. in circumference, and had a flavour between the green-gage and apricot. So that, when they get used to the climate, and with a favourable season, we may reasonably expect them to do well. The English blackberries fruited fairly well, but the American varieties only flowered sparsely and ripened very few berries.

I may here mention that Mr. A. J. Kellow, of Albion estate, has grown some remarkably fine apples this year. His plants are of the same ages and varieties as some of those we have here. The estate is about 200 to 300 ft. lower down and well sheltered, the soil particularly rich and free, and the climate, though the estate is only two miles away, is much drier. One tree, a "Kentish Fillbasket," bore eighteen very fine fruits—the largest measured $12\frac{1}{2}$ in. in circumference and weighed 12 ounces.

Strawberries at Hakgala.—The Superintendent reports :—

In February packets of six of the best and hardiest varieties of strawberries—viz., "President," "Waterloo," "Sir Charles Napier," "Crescent Seedling," "Vicomtesse Hericet de Thury," and another with the name lost—were received through the Royal Gardens, Kew, and from the Royal Horticultural Gardens, London. They were at once sown, and seedlings of each variety were raised. These were planted out in October in specially prepared beds in the new nursery, and at the end of the year have grown into fine bushy plants showing a abundance of flowers, and promise, should the weather be favourable, to give a good crop. A few plants flowered in seven months from the time of sowing. If these prove to be productive, they can easily be propagated and distributed in quantity. We have also received a few plants of a good fruiting variety from Mr. Reginald M. Knight, of Annfield, Dikoya, which are having a trial in the same beds.

Pineapples.—In answer to a request from Mr. Medley Wood, Superintendent of the Botanic Gardens at Natal, 4,000 shoots of the large pine grown here under the name of the "Kew Pine"—the real name of which I believe to be the "Smooth Cayenne"—were forwarded to that Colony at the commencement of the year. Owing to a series of unfortunate delays *en route* the consignment reached Natal in but poor order, but Mr. Wood reports that between a half and three-quarters will grow. Though these large pines are much thought of elsewhere, yet so little are they cultivated in Ceylon that it was a matter of some difficulty to make up the number sent. Mr. Wood informs me that a large trade in fruit is springing up at Natal with the Transvaal gold-fields.

Lucerne or Alfalfa (*Medicago sativa*).—Mr. Clark, of Pérádeniya, brought back with him from the Peruvian Andes seeds of this valuable fodder, which were sent to Hakgala at once, and Mr. Nock now reports on it :—

The weather being wet when the seed was received it was not sown until the 12th of March ; it germinated quickly and freely, but bad weather kept it back until July and August, when it began to grow fast. By the 7th of September it was 18 inches to $2\frac{1}{2}$ feet high, and beginning to flower. On this date, six months after sowing, I made the first cutting, taking the best square yard I could find ; it produced exactly 5 lb. weight of green fodder. On the 7th of November this same space was again cut. The produce of green fodder was again 5 lb. At the end of December another cutting was taken off, which for the third time gave 5 lb. Thus, one square yard produced 15 lb. of green fodder, or equal to 4 lb. of dry, in nine months. This yield is equal to a little over 32 tons of green fodder, or $8\frac{1}{4}$ tons of dry fodder to the acre, which is up to the highest yields in England ; the average for that country being 3 to 5 tons. This is most satisfactory, but it must be stated that the soil in which it is growing is exceptionally good, and has been liberally dressed with lime. Lucerne is essentially a lime-loving plant : it is useless to attempt its cultivation in land poor in this mineral without adding it abundantly. Mr. Clark informed me that this variety appeared to him to be more hardy and robust than that generally grown in Europe ; and this may be so, as I have tried seeds from England on several occasions without success. It should be sown in shallow drills 8 to 10 inches apart, and cut as soon as it shows signs of flowering. When established in Ceylon, in good soil, I believe that at least six cuttings a year could be obtained.

English Oak.—It is worth putting on record that one of the young oaks raised from seed received from Kew at the end of 1883, at Hakgala, has this year produced acorns. When ripe these were gathered and sown, and three of them have germinated. The parent tree is 16 ft. high with a stem girthing at the base 18 in., and 9 in. at a yard from the ground, perfectly healthy and growing well.

CEYLON MANUAL OF CHEMICAL ANALYSES.

A HANDBOOK OF ANALYSES CONNECTED WITH THE INDUSTRIES AND PUBLIC HEALTH OF CEYLON FOR PLANTERS, COMMERCIAL MEN, AGRICULTURAL STUDENTS, AND MEMBERS OF LOCAL BOARDS.

By M. COCHRAN, M.A., F.C.S.

(Continued from page 611.)

CHAPTER III.

PRODUCTS OF THE COCONUT PALM.

USES OF THE COCONUT PALM—SEA-BREEZE FAVOURABLE TO THE GROWTH OF THIS PALM—ANALYSIS OF A CEYLON COCONUT—"MILK" OF UNRIPE AND RIPE NUTS—ANALYSIS OF TODDY—MINERAL INGREDIENTS DRAWN FROM THE SOIL BY THE DECIDUOUS PARTS OF THE COCONUT PALM—TABULAR STATEMENT OF YIELD OF COCONUT TREES ON VARIOUS SOILS—TABULAR STATEMENT OF QUANTITIES AND COST OF MANURES FOR COCONUT TREES, ALSO OF ANNUAL VALUE PER ACRE OF COCONUT ESTATES—COPRA—COCONUT POONAC—COCONUT AND PALMNUT MEALS—COCONUT BUTTER—COCONUT WASTE—OIL IN COCONUT SHELLS—ARRACK—DESICCATED AND PREPARED COCONUT.

THE Coconut palm (*Cocos nucifera*), which flourishes along the Western and Southern sea-borde of Ceylon, and for a considerable distance inland, is one of the most important products of the country. There is perhaps no plant in the world for

which a greater variety of uses has been found, and there is no part of the tree but has its use or uses. The root is employed by the natives as a medicinal agent, the stem for house construction and articles of furniture. The plaited leaves have many uses. The sap of the tree is diverted from its natural function of producing flower and fruit, and made to yield the form of sugar called jaggery, which, in its turn, by fermentation and distillation, yields the intoxicating spirit called arrack. Lastly, when a tree happens to fall, the growing part or "cabbage" forms a very palatable vegetable.

The tree flourishes best near or at no considerable distance from the sea, in a free soil, where the roots have access to a plentiful supply of moisture. The saline particles in the sea-breeze are commonly regarded as favorable to the growth of the tree. The value of common

salt as an application to the soil of coconut estates has been much debated. Some cultivators strongly recommend it for inland coconut estates, and assert that on estates too far inland to profit by the sea-breeze the trees are more apt to drop unripe nuts, than is the case near the sea-coast. Quantities of common salt from half a ton to a ton and a half per acre are said to have been used with benefit; but the claim of common salt to be recognised as a coconut manure is by no means universally acknowledged. The following is the analysis of a Ceylon coconut by W. Lascelles Scott, M.S.A., from the *British and Colonial Druggist*:—

Analysis of a Ceylon Coconut.

Exterior fibre or coir ...	32.65
Shell	17.30
Flesh or edible portion...	26.40
"Milk"	23.65

100.00

The edible portion gave the following results:—

Analysis of edible portion of Coconut.

Nitrogenous (albumenoid matter)	6.48
Fatty matter	67.11
Sugar and gum	5.89
Mineral matter...	3.65
Cellulose and color matter	9.76
Water and loss	7.11

100.00

The interior fluid or "milk" gave these results:—

Analysis of interior fluid of Coconut.

Nitrogenous matter	7.12
Gum acid trace of fatty matter	3.05
Sugar	4.150
Mineral matter	2.61
Water	94.572

100.000

The following is a partial analysis of the liquid from a Ceylon drinking coconut, made by the author:—

Analysis of liquid from a Ceylon drinking Coconut.

Specific gravity	1.0188
	per cent.
Fat	2.30
Salts	6.10
Sugar and other constituents	3.560
Water	95.600

100.000

The following is a table of more elaborate analyses of the liquid from unripe and ripe coconuts, the most striking feature of which is the change of the glucose of the unripe nut into sucrose or cane sugar in the ripe nut:—

Analyses of "Milk" of Unripe Coconuts.
(BY L. L. VAN SLYKE, AMERICAN CHEMICAL JOURNAL.)

	1.	2.	3.	4.	5.	6.	7.	8.

Toddy.

The following is the only analysis of toddy (the sap which is drawn off from the spadix of the coconut tree) which I have seen. It is by M. Jules Lepine. I quote it from "All about the Coconut Palm," compiled by Messrs. A. M. & J. Ferguson:—

Analysis of Toddy.

Specific gravity from	1.018 to 1.030
	per cent.
Sugar ...	14.60
Gum ...	0.56
Oil ...	0.04
Albumin ...	0.12
Chloride of sodium	0.26
Acetate of potash	
Sulphate of potash	
Phosphates of soda and lime	
Silex ...	84.42
Water ...	100.00

Mineral matter taken from the soil by the Coconut Palm.

The next table, shewing the weight in pounds Troy of mineral ingredients abstracted from the soil per annum by the deciduous parts of the coconut palm, is based on the same analyst's figures, the calculations having been made by a Jaffna planter, a correspondent of the *Ceylon Observer*, who points out that the results should

be divided by 3, as 26 to 30 nuts per tree are much nearer the average crop than 80, the number adopted by M. Lepine. In the original the figures were extended to five places of decimals, in place of two as I have given.

Total inorganic and fixed matter drawn up annually by the deciduous parts of the Coconut tree from an acre of land by 75 trees bearing 80 nuts per tree, calculated by the late Mr. Davidson of Jaffna from analyses by M. Lepine. ("All about the Coconut Palm.")

	Troy pounds.						
	Peduncle.	Spathe.	Husk.	Shell.	Kernel.	Water.	Total.
Chloride of sodium ...	3.82	1.70	34.17	1.40	9.07	3.62	53.78
Salts of potash ...	21.46	8.61	450.24	27.92	47.46	4.82	560.51
Phosphate of lime ...	5.54	4.20	6.03	.70	18.84	2.01	37.32
Salts of lime ...	1.67	10.59	112.56	2.10	1.40	—	128.30
Salts of magnesia ...	2.67	—	—	—	—	—	2.67
Silex22	4.20	8.04	—	—	—	12.46
	35.38	29.30	611.04	32.12	76.77	10.45	795.06

The following are two other interesting tables drawn out by the late Mr. Davidson for the *Ceylon Observer*, and here quoted from "All about the Coconut Palm":—

Table No. 1.
Statement of General Yield of Coconuts per Tree on the Average of the Various Soils.

Character of Soils.	Average yield per tree annually.	Value per acre at the rate of 70 trees to the acre, and at £2.10-0 per 1,000 nuts.		
		£	s.	d.
(1) White poor sandy soil ...	15	2	10	0
(2) Dark mould ...	30	5	0	0
(3) Reddish ...	40	7	0	0
(4) Strong rich upland soil bordering the banks of a river ...	50	8	15	0

In all these averages the trees are supposed to have reached from 14 to 20 years old, as the bearing of a coconut tree is very irregular until it attains its full bearing condition, except by manuring.

Table No. 2. Statement of the Manures, Quantities, Cost and Annual Value of each, in the order of Table No. 1.

	Quantity of manure per tree in pounds.	Cost per tree including transport in sterling.	Number of nuts, annual average, per tree.	Annual value in sterling of No. 1 soil per acre of 70 trees.	Quantity of manure per tree in pounds.	Cost per tree including transport in sterling.	Annual average number of nuts per tree.	Annual value in sterling of No. 2 soil per acre of 70 trees.	Quantity of manure per tree in pounds.	Cost per tree including transport in sterling.	Annual average number of nuts per tree.	Annual value in sterling of No. 3 soil per acre of 70 trees.	Quantity of manure per tree in pounds.	Cost per tree including transport in sterling.	Annual average number of nuts per tree.	Annual value in sterling of No. 4 soil per acre of 70 trees.
(1) Hantsdorf Mills compost	112	0 4 0	60	10 10 0	75	0 3 0	75	13 2 6	60	0 2 1	80	14 0 0	56	0 2 0	100	17 10 0

(3) Tying a pair of bullocks for ten nights to a tree	50	0 0 4½	40	7 0 0	50	0 0 4½	50	8 15 0	50	0 0 4½	55	9 12 6	50	0 0 4½	60	10 10 0
(4) One cart load of husks	560	0 0 4½	40	7 0 0	560	0 0 4½	50	8 15 0	560	0 0 4½	55	9 12 6	560	0 0 4½	60	10 10 0

Determinations of Moisture and Oil in Commercial Copra.

	1.	2.	3.	4.	5.	6.	Average.
Moisture	7.4	7.35	6.05	4.25	5.85	5.22	6.02
Oil	63.47	63.50	63.62	63.92	64.38	65.15	64.01
Other constituents	29.13	29.15	30.33	31.83	29.77	29.63	29.97
	100.00	100.00	100.00	100.00	100.00	100.00	100.00

The following are partial analyses of Copra, the kernel of the coconut. For commercial purposes, it is usually sufficient to determine the amount of water and of oil present:—

In a sample of Copra highly desiccated the author found moisture 1.75, oil 70.97, other constituents 27.28 per cent.

In the following the ash, as well as the moisture and oil, were determined. In these cases the Copra was probably dried artificially:—

Partial analyses of Copra.

Moisture...	3.00	2.0
Oil	64.27	69.1
Ash	1.60	1.70
Other constituents	31.13	27.20
	100.00	100.00

The following analyses made by London analysts give also the amount of sugar in addition to the above constituents:—

Partial analyses of Copra.

Moisture...	2.46	2.48
Oil	70.70	68.70
Ash	2.04	1.76
Sugar	3.00	2.50
Other constituents	21.80	24.56
	100.00	100.00

Coconut Poonac.

The extraction of oil from copra on the commercial scale is performed by first crushing and afterwards pressing the same. The residue of the copra, deprived of the greater part of its oil, is called poonac. Coconut cake or poonac is classified as chekku and mill poonac, according as the extraction of the oil has been performed in the native mill or chekku, or in mills where hydraulic pressure is used. As a rule the chekku-made poonac contains more oil than the mill poonac, which gives the former a higher value as a feeding stuff for cattle.

The author has made a great many determinations of oil in samples of mill poonac, and the following may be taken as representing the minimum maximum and average amounts of oil left in Ceylon-made poonac:—

Determinations of Moisture and Oil in Mill Coconut Poonac.

	Per cent.	Per cent.	Per cent.
Moisture	15	11·2	11·71
Oil ...	8·0 (min.)	16·0 (max.)	11·59 average.

The following are determinations of moisture and oil in two samples of chekku poonac:—

Determinations of Moisture and Oil in Chekku Coconut Poonac.

	Per cent.	Per cent.
Moisture...	13	11·8
Oil ...	16·7	14·5

I believe, however, the chekku or native mill is capable of removing more oil from the copra than is represented by these two analyses. In a sample analysed by Mr. John Hughes, that analyst found moisture 13·04, and oil 10·93 per cent. In France, by a steaming process in addition to hydraulic pressure, considerably more oil is removed from the copra than is effected by the Ceylon mills.

Coconut poonac is largely used in Ceylon as a cattle food. In London, this substance is also sold, and is sometimes guaranteed to contain oil 15 per cent, albumenoids 19 per cent, and carbohydrates 40 per cent.

The following may be taken as fairly representing the composition of coconut poonac in Ceylon:—

Composition of Coconut Poonac.

	Mill.	Chekku.
Moisture...	11·7	12·4
Oil ...	11·6	15·0
Albumenoids ...	19	18·0
Carbo-hydrates ...	43·2	41·0
Woody fibre ...	6	5·6
Ash ...	8·5	8·0
	100·0	100·0
Nutrient ratio ...	1 : 3·75	1 : 4·36
Nutrient value ...	91·2	96·5

In calculating the nutrient ratio and nutrient value I have taken the starch equivalent of the oil at 2·5.

Coconut poonac, as represented by the London

analysis given above, would have a nutrient ratio of 1 : 4·08, and a nutrient value of 96·5.

In Biedermann's "Centralblatt für Agricultur-Chemie," as quoted by the "Journal of the Chemical Society," occurs an analysis of coconut-meal which differs chemically from coconut poonac only in having a smaller proportion of the original oil or fat left in it. This substance and also palm-nut meal have been used mixed with oats as food for horses. The writer in the publication mentioned says: "Some of the horses of the 7th Cuirassiers were fed with a mixture of oats and meal, and compared with others fed on oats only. The results in the former case were most satisfactory; the reduction in the cost of horse keep amounting to 50 frs. per annum." The following are the analyses referred to.

Analysis of Coconut and Palmnut Meals.
BY A. PETERMANN.

	Coconut meal.	Palmnut meal.
Water ...	13·11	10·59
Albumenoids ...	19·16	14·98
Fat ...	6·70	5·08
Mucilage digestible fibre &c.	43·91	50·49
Fibre ...	7·40	15·05
Ash ...	9·72	3·81
	100·00	100·00
Nutrient ratio ...	1 : 3·16	1 : 4·22

To these figures I might add the nutrient value calculated in the usual way for coconut meal 79·82, for palmnut meal 78·17.

Coconut Butter.

Of late years a new article has been placed upon the market called coconut butter. A published analysis represents it as having the following composition:—

Analysis of Coconut Butter.

Fatty matter ...	99·632
Mineral matter ...	·011
Water ...	·357
	100·000

This substance is said to be prepared according to Dr. Schlink's method by treating coconut oil with alcohol and animal charcoal. This treatment removes the fragrant fatty acids of the aromatic oils, leaving a white product of the consistency of butter, which melts at 25°C. and possesses a sweet agreeable taste. It is said to be an easily-digested vegetable fat, remarkably free from the tendency to turn rancid, so characteristic of the oil from which it is made.

Coconut Waste.

The following is a partial analysis of coconut waste, the substance removed from the coconut husk in preparing coir fibre. The analysis had for its object to ascertain the proportion of cellulose or indigestible fibre present. The analysis reveals the great capacity of this substance for containing moisture. It may contain above 80 per cent of water without exhibiting a moist appearance. Hence it is useful, especially if first dried, as an absorbent for sanitary purposes:—

Partial analysis of Coconut Waste.

	Natural condition.	Dry substance.
Cellulose or indigestible fibre	5.77	31.71
Carbo-hydrates and other constituents	11.41	62.69
Ash	1.02	5.60
Water	81.80	—
	100.00	100.00

Oil in Coconut Shells.

Freshly-powdered coconut shell yielded only 43 per cent of a greenish fatty solid, when extracted with ether; but powdered shells which had been allowed to ferment yielded 8.7 per cent of a brown oil of specific gravity .912.

Arrack.

From the fermented juice of the coconut palm a very pure spirit may be and is distilled called arrack. In various parts of the East Indies a less pure spirit, also known as arrack, is distilled from rice or sugar fermented with the juice of the coconut. Some of the liquors are said to be rendered more intoxicating by the addition of poppy heads, hemp leaves, juice of stramonium &c. ("Dictionary of Applied Chemistry.")

Four samples of commercial arrack submitted to the author shewed a strength of 22.5, 23.75, 23.75 and 25 per cent under proof respectively. In one the amount of extractive matter was determined and found to be only .022 per cent.

Desiccated and prepared Coconut.

A proportion of the coconuts exported from Ceylon to Europe is for the use of biscuit manufacturers and confectioners. This export, however, is rapidly being superseded by that of the dried and prepared kernel of the coconut. The chemical composition of desiccated coconut does not appreciably differ from that of highly-desiccated copra, of which analyses have already been given, but the drying being conducted rapidly the flavour of the fresh nut is preserved. Other forms of desiccated and prepared coconut are also exported, differing in composition from that of dry copra.

NEWS FROM THE CENTRAL PROVINCE:

PLANTING AND OTHERWISE.

Notes by "Wanderer."

March 24th, 1893.

TEA PRICES are really too worrying. Everyone thought that we were bound to have good prices till May; and the average has now tumbled down to 9d, very nearly the same figure as last year at same date. However as 1½d is the outside figure for London charges, and the 1d=7 cents, 7½d net means 54 cents, and that is better than the Colombo selling average from which you have to take off merchants' or brokers' commission.

EXCHANGE begins now to frighten the greatest gainer at present, viz. the producer. He begins to think the high price he is giving for rice, bazaar stuffs, catt'e feeding stuffs has to be set off against what he gets for his produce. £1 equal to R16.80 is rather a jar also to the "Home for he Holiday" man.

EXPORTS OF TEA.—Chamber of Commerce returns show an export to date of 15,631,666 against 13,513,619 at same date last year. At this rate we will export 8,000,000 lb, more in 1893 than

1892. There is however comfort in the fact that tea to Australia has already doubled its export by 600,000 lb., China 18 000 lb. I presume this latter means tea sent to Hongkong for transhipment to Vancouver; and Spain is coming to the front with an extra export of 10,000 lb., Germany has taken 20,000 lb. more. Is this through the action of the Ceylon Planters' Tea Company, in establishing a large agency there? Italy and Holland have commenced the current year well by taking 3,400 and 3,100 lb. respectively to 20th March.

SUGAR AND MILK TEA PLANTS.—The accompanying extract from the *Indian Agriculturist* may induce some of our enterprising planters to go in for the sugar and tea, or the milk and tea plant. What will the English Grocer say to Ceylon Planters sending him home a tea that will do him out of his profit on sugar—or, *vice versa*. The milk and tea plant will reduce the risk of typhoid fever germs finding their way through the favourite channel of doctored milk:—

In the mountainous region of Kiating, Mr. Barber discovered two remarkable varieties of natural sugared and buttered teas. The monks of Mount O-mi, or Mount O, use a plant which produces an infusion naturally sweet, and tasting, as brewed, just like coarse Congou with a large addition of brown sugar. This is natural tea-and-sugar. The plant is grown on the mountain slopes near the monastery, and does seem to be known elsewhere. The leaf is to all appearance just like that of an ordinary tea leaf, and probably the saccharine essence may be due to the soil. The other curiosity is a natural tea-and-milk. This is a wild plant, growing in an elevated region without cultivation, and yielding an infusion which tastes just like tea and milk, without sugar, or perhaps more like tea and butter. This plant is found in an uninhabited region west of Kiating at an elevation of 6,000 feet and upward, and in leafy shrubs about 15 feet high. Not merely the leaf, but the whole plant is used to make the infusion. Even the wood when chopped up and boiled along with a few dry leaves yields a strongly-coloured tea, with much the same flavour as the Tibetans produce from their bricks and butter. Botanists may be able to explain these phenomenon, and perhaps to classify the plants in some other family than the tea plant.

PATENT TEA ROLLERS.—The shareholders of the Colombo Commercial Co. will not bless the combatants in the famous Tea Roller case; for it took up a large sum that would have given them a nice dividend.

WEATHER all that is desirable for tea flushing—but it is not favourable for those who have anything to do with coffee.

Road between Dimbula Gap and Craigie Lea is in very bad condition.

CEYLON AND TRAVANCORE TEA.

To the Editor of the *Madras Mail*.

Sir,—In your issue of the 11th instant you fully support the demands of the Planters in Southern India for a perfectly free and unfettered market in Ceylon. Our demands are now before the Government of Ceylon, and will, I feel sure, meet with the fairest consideration. Briefly stated our case is as follows:—Ceylon has a free and unfettered market (which I am glad to know is a growing one) in India. Indian teas in Ceylon are subject to a duty of 4 annas per pound, a charge to which we naturally object. Southern India produce, I think some 3 million pounds of tea, the greater portion, of which need to find a good sale in Madras and Bombay for local consumption, but last year Ceylon plumped down in those markets about 700,000 lb. of her teas to compete with ours. We don't object to fair competition, but we say to Ceylon:—"You must not sweat us by your competition in India where we admit your teas free of duty, and sweat us also in Ceylon by taxing our teas 4 annas per pound."

TRAVANCORE PROPRIETOR,

PROPOSED LINE OF TEA SHIPS.

The following correspondence has been circulated to tea garden proprietors:—

103, Clive Street, Calcutta, 15th March.

DEAR SIR,—I have received a letter from Messrs. Danoan, Brothers & Co., dated 14th instant, of which a copy is enclosed, proposing to run a first class line of steamers under an agreement to carry teas at a certain fixed rate. As most firms have already referred the question of tea freights to London, I am desired to ask you to request your London friends to communicate with the Committee of the Indian Tea Districts' Association, and to authorise them to make such terms on your behalf as may be considered best in the interests of tea shippers.—Yours faithfully, (Signed) J. N. STUART,
Chairman, Tea Shippers' Committee.

From Messrs. Danoan, Brothers & Co., to Mr. J. N. Stuart, Chairman, Tea Shippers' Committee, dated Calcutta, 14th March 1893:—

DEAR SIR,—Referring to your circular of 9th ultimo regarding tea freights and to our subsequent interviews, we now beg to state that acting on behalf of, and under telegraphic instructions from, our principals on home side, we shall be prepared to provide a service of steam vessels of the highest class at Lloyd's, or equal thereto, and to regulate sailings suitably for the carriage of tea from Calcutta to London in terms of the resolution passed at the meeting of Tea Shippers held on the 28th January last viz:—"An agreement to be entered into for the term of three years, freight to be calculated at 10s above the average rate for wheat, linseed and jute, ruling during the previous month with a minimum rate of 30s; no rebate clause." This undertaking is conditional on shipments being guaranteed not to fall short of 60 million pounds for any one season, and is also subject to immediate reply.—*Madras Mail*, March 21.

TEA AND BUDDHISM IN TIBET.

At the meeting of the Royal Geographical Society held 20th Feb. Captain H. Bower read a paper in which he gave an interesting description of his journey across Tibet. Regarding the Buddhist religion he says that, as seen in Tibetan countries, it has nothing in common with the pure morality preached by Gautama Buddha. The doctrines of the founder are too abstract, he thinks, for the average Tibetan mind, and this has led to innovations which have developed until the grossest superstition, little better than African fetishism, and hardly bearing any resemblance to the original precepts, is all one meets in this stronghold of Buddhism. The nomads are described as greedy, faithless, and suspicious. Their suspicions, however, do not attach only to foreigners, as every camp seems to view every other camp as not only a possible but a very probable enemy. Though provided with Chinese passports, considerable difficulties were experienced in crossing portions of the country, the people fearing death as the penalty of receiving strangers. These difficulties were, however, invariably overcome by boldness and tact. At one camp tea was produced. "They drank it in Tibetan fashion, mixed with salt and butter; but, having found out from our servants the European fashion, they gave us some plain. After a considerable consumption of tea, bowls of mutton, boiled with rice and onions, were brought in. It was really excellent, but," adds, Capt. Bower, "eating rice with chopsticks is an art that requires practice." Many questions were asked about England, and the people were much surprised to hear that it was surrounded by water, and that people went to it in ships. They had not the faintest idea what a ship was, and asked if it went through the water touching the bottom the whole way. Like true nomads, they were particularly curious also about the water and grass,

It would seem that the vendor of lotions for forcing the production of hair has a new field opened to him, for Captain Bower says: "The Kushok rather astonished me one day by expressing admiration of our beards, and asking if we had any medicine that would make his grow. . . . The Lama was very anxious to know if we had any English poisons. Poisoning is very prevalent in Tibet. If one offers a man tea, he generally refuses it unless some one first drinks some in his presence, and when offering anything to eat or drink, a Tibetan invariably ostentatiously takes some to show there is nothing to be afraid of." Captain Bower heard marvellous tales from the Tibetans of countries peopled by men who possessed only one arm and one leg, and of others where the people had pigs' heads, but no one would allow that he had seen any of these interesting people. Captain Bower estimates the population of Tibet proper, i.e. the country under the rule of the Deva Zhung, at about four millions. Chinese Tibet probably holds another four millions, and of these eight million Tibetans nearly half a million are monks. The dress of the common people consists generally of a long sheepskin robe, very dirty and greasy, which serves the double purpose of clothes by day and bedding at night. The country is described as bearing a great resemblance to many parts of Kashmir, and as being at least equal to it in beauty.—*Daily News*, Feb. 21.

THE TEA DISTRICT OF NATAL.

A BIG TEA VALLEY.

The following account of a visit to the one Tea Valley of Natal, is from the *Natal Mercury*:—
Ten miles beyond, with Stanger midway, is Kearsney, the home of

THE PLANTER PRINCE,

James Liege Hullett, M.E.C., where hospitality is dispensed with a generous hand, from whom I had a long-standing invitation. The way to Kearsney is a gradual ascent, amid lovely country, well-wooded and well-watered, bearing tea and sugar. Through a long avenue of gum and cypress is reached the family mansion, with its broad verandahs, wide balconies, spacious apartments, noble hall and stairs, and cathedral windows—the foundations of the house of Hullett in the midst. From the tower is gained a panorama of much beauty, bounded by the Umvoti and Tugla valleys and margined by the sea, 800ft. below, 10 miles away. Underneath sweep high and low the 5,000 fertile acres of Kearsney and Kinkley Vale, with Bulwer's 4,000 to the north, of which 600 acres are under cultivation, besides other lands of other owners in the neighbourhood of Nonoti. Fruit of all kinds is prolific, and on the tennis ground beside the little church, I was introduced to Mr. Chesterton, who has come out from England to manufacture jam. Durban was well represented on the tennis court by Messrs. Henderson, Holwell, and Haith (Kearsney's recent representative at Kimberley), and when Mr. and Mrs. Hullett and six Messrs. Hullett, jnr., were present, and Mr. and Mrs. Hindson called, I came to the conclusion I had alighted upon the home of the H's. I fear 13 H's, are unlucky, for it rained during most of the next two days; but with music and magazines and social converse a dull day without is not a dull within, at Kearsney House. Four years ago I was a confirmed water drinker, but I have been reclaimed. I have reformed. Having tasted, on the Lower Umzimkulu, tea from Barrow Green, I felt it to be my duty for the encouragement of colonial industry to become in habit and profession a teatotaler.

A CUP OF GOLDEN PEKOE

from the opposite extremity of Natal confirmed my noble resolution, in which I am strengthened by the reflection that in the interval the consumption of tea has increased almost fourfold, and this season will produce upwards of half-a-million pounds. Mr. Hullett

has been engaged in tea culture for some 15 years, and the gardens have grown and the output increased until Messrs. Hulett & Co., now employ 350 Indians—men and women, and boys—in tea production. About a million and a quarter bushes—2,000 to the acre, yielding in maturity 6ozs. each of tea from the 18 pickings—have to be despoiled of their flushings from October to May; and the pickers may be seen each day in picturesque colours among the regular green rows on the hillsides filling their baskets with the delicate shoots, the biggest loads of which average 70 lb. per diem. When the bell rings, the coolies hasten home and spread out their leaf upon tables to wither, the process manufacture which ensues being under the superintendence and management of Mr. Drummond. The Kearsney factory receives the product of some 10 estates, altogether 1,200 acres, and so can realise the conditions of good blending. The withered leaf is placed under steam rollers for half an hour, and the brown mass is then allowed to ferment for an hour, turning purple in the process. The leaf now passes into dryers, long revolving cylinders in a current of hot air. The fine tea, the bud of the plucking, falls through perforations in the pan, and is called Golden Pekoe. The remainder is taken to a series of sieves, each with a narrower netting and through these the tea is sifted until the lowest shelf receives the tea of second quality, the first and smallest leaf, Flowery Pekoe; the next, the second leaf, Pekoe; third leaf, Pekoe-Souchong; fourth leaf, Souchong. Thus Kearsney produces five varieties of tea, of which Golden Pekoe is the choicest, and Souchong the coarsest, another brand, the Popular, being made by mixing. The final stage is reached in the packing, in which a dozen lads make up a ton of 1lb packets in a day. The factory work is especially suited to children, and many are employed, and the premises exhibit a hot and aromatic and animated scene. Tons of tea, in cellar, chest, and garret, are on every hand—reduced to one-fourth in weight since it came from the fields. Five of Mr. Hulett's sons are engaged on the estate and in the works, and splendid machinery is in use whereby rough logs are transformed into boxes, and the *pinus insignis* is being planted to supply the box wood of the future. This season will result in over 400,000 lbs. of tea; but the present premises, which have been enlarged from time to time, are becoming too small for the purpose, and Mr. Hulett intends shortly to erect a factory which shall contain three or four stories, and measure 150ft. x 75ft., so that he may be able when necessary to deal with upwards of a million pounds of manufactured tea per annum. The pioneer of tea-planting in Natal will thus keep pace with the development of the industry, and remain in the forefront of promoters of colonial enterprise.

THE DUTCH MARKET.

Amsterdam, March 9.

The cinchona auctions to be held here on March 23rd will consist of 73 cases and 6,796 bales, or about 577 tons, Java bark divided as follows:—From Government plantation 12 cases and 394 bales (about 37 tons); from private plantation 61 cases and 6,402 bales (about 540 tons). This quantity contains: Of druggists' bark—*Succirubra* quills 9 bales 73 cases; broken quills and chips 640 bales; root; 43 bales. Of manufacturing bark—*Ledgeriana*, broken quills and chips 4,443 bales; root 1,069 bales. *Officinalis*—broken quills and chips 33 bales. *Hybridæ*—broken quills and chips 423 bales; root 124 bales. *Calisaya*—root, 7 bales,—*Chemist and Druggist*.

FOOCHOW TEA NOTES, &c.

March 4.

According to the returns made by the Tepas of the different districts in this prefecture, as many as 600 beggars fell victims to the snow and frost during the severe weather of January and the early part of Feb.

We learn from the tea districts that the late frosts have had the effect of stripping all the tea shrubs of their leaves. In consequence of this, the coming tea crop is expected to be a good one, both in quality and quantity, and it is to be hoped for the sake of the trade that these expectations may be realised. It is said that the crop will be later than usual, but this drawback, if it is one at all, would be a matter of small importance as compared with the distinct benefit that would accrue to the trade from an improvement in quality. The latest home advices hold out the prospect, at this juncture, of a revival of the trade with improved quality.—*Echo*.

THE CHINA TEA TRADE :

DECREASE BY ONE-THIRD IN 10 YEARS.

Shanghai, March 10.—(From Messrs. Welch, Lewis & Co.'s report).—No business has been reported in either Black or Green Tea during the interval. Stock of Black Tea 586 half-chests. The Customs Trade Reports lately published show that China has lost one-third of its trade in Tea during the past five years. In 1888 the exportation direct to Foreign countries was 321,731,000 lb.; in 1892 it was 221,112,000 lb., a decrease of 100,619,000 lb., or nearly equal to the total Indian crop. With the finest raw leaf in the world, this decrease is only to be attributed to excessive taxation and to faults in preparation, which between them are ruining the trade. This decrease has taken place whilst all other Tea producing countries have greatly increased their exports, and whilst the consumption of tea in Foreign countries has been steadily advancing.

VARIOUS AGRICULTURAL NOTES.

PRICE'S PATENT CANDLE COMPANY (Limited) state that the profit for 1892 was about £65,000, to which must be added the balance brought from 1891, making together about £72,100. After deducting the dividend paid in September last, appropriating £12,500 for depreciation, and placing £5,000 to a reserve fund, there will remain about £31,000, out of which the directors recommend a dividend of 12 6d per share, making a distribution of £15s per £16 share for the year, leaving £7,700 to be carried forward.—*Chemical Trade Journal*, Feb. 18.

THE HAWAIIAN ISLANDS are now six days sail from San Francisco, but could be reached in five days by fast steamers. As a place of call for ships, and a naval station, they will be of great value to the United States, as they possess a good harbour in the Bay of Honolulu. They have this advantage over Samoa and the more southern islands of the Pacific, that their varied climate enables most forms of vegetation to flourish, and an American scientific paper points out that a botanic garden unique in the history of the world might be established there.—*Globe*.

DECREASE OF ARABLE LAND.—During the last twenty years England alone appears, from the official agricultural returns, to have diminished the area of land under the plough by very nearly two millions of acres, or over 14 per cent. The amount of arable land in Wales has dwindled during the same period by a trifle more than one-fourth of that amount, or 21 per cent. Scotland, on the contrary, returns 78,000 acres more than before. This, it is thought, may be partly explained by the marked characteristic of the agricultural system of North Britain in contrast with that of England, which appears in the relatively large area retained under clover and rotation grasses. Nearly one-third of the whole cultivated surface of Scotland remains in this category, while in England the proportion of the cultivated area so occupied is very little more than a tenth of the whole.—*Public Opinion*.

THE MANGO CROP in Southern Queensland is now ripe, and in such situations as have not suffered from the floods a good harvest is being reaped. Mr. A. Williams, of the Green Hill Nursery, Eight mile Plains, is one of the fortunate growers who were above high water mark, and some samples of his produce which have reached us show that the unusually wet season has not adversely affected the flavour of the fruit. The samples comprised two varieties, the Maldo and the Kysapatie, and all were of very large size and of excellent flavour. The former especially is notable for a refreshing tartness which is not present in most other varieties. Judging by some of the fruit the peach fly has included the mango in the list of its hatching grounds this season which is a matter for regret, as this is one of the few fruits that have hitherto escaped the attention of this troublesome insect pest.—*Queenslander*.

NATAL: AGRICULTURAL AND INDUSTRIAL PROGRESS.—The year under report has been a fairly prosperous one for stock farmers, and good prices have been generally realized. Sheep farming is increasing, but the abnormally low price of wool has had a depressively effect. According to the returns the yield of sugar for the year was very good, and a large increase upon that for the preceding year. A large proportion of the sugar manufactured is consumed in the colony or sent across the inland borders. In addition to this, the export by sea for 1891-2 was 11,705 cwt, as against 21,962 cwt for 1890-1; 251,940 proof gallons of rum were distilled, as compared with 153,360 gallons in 1890-1.—Tea continues to be largely grown in the coast districts, chiefly in Victoria County and the Lower Umzimkulu Division. The area under cultivation may be put down at about 2,200 acres. The crop for the past season was about 350,000 lb, and that for the ensuing season is expected to reach 500,000 lb. The quantity of tea exported by sea during the year was 43,633 lb. Coffee cultivation is successfully carried on in the coast districts, though not to a large extent. Coffee does not figure conspicuously among the colony's exports, the local demand being greater than the supply. The planting of trees is extending, and attention is being more particularly given to the cultivation of the *acacia molissima*, the bark of which is a valuable tanning product.—*British Assistant Colonial Secretary at Pietermaritzburg*, Oct. 8th, 1892.

AMERICAN RUBBER NOTES.—The Joseph Dixon Crucible Co. (extensive lead pencil manufacturers), give notice that they will henceforth make their own rubber tips. The demand for the best Para by the cycle factories is enormous, and constantly increasing.—*India-Rubber Journal*.

COFFEE IN THE SHEVAROYS.—Yercaud, March 17.—We are having the most extraordinary weather up here, such as the very oldest inhabitant cannot remember the likes of. On 22nd ultimo, we had a few cents of rain, followed by over half an inch on 25th and 2 to 3 inches on 27th idem. From 1st to 16th March we have had rain on 7 days, and the fall has amounted to about 2½ inches, making 5½ inches more or less (the fall varies a good deal and I can only take what I register here, though I invariably hear that some have got more and some less rain than I) in the last 3 weeks! And not merely is the amount extraordinary, but the manner of its fall is equally so. When we do get rain at this time of the year, it is generally in short heavy thunder showers, but this year we might be at the beginning of the monsoon is far as appearance goes. Crops are all practically in now, and those not sent to England are all sold. I am glad to say things are even better than I anticipated; almost every estate up here has not only had a good crop, but a crop considerably over the estimate, and prices have been equally abnormal; high as they have been of late years, this year they are higher than ever.—*Madras Times*.

PLANTING IN KLANG.—On the 9th March the Resident paid a visit to Klang, and drove three miles along the Melegum Road, and was much interested in the very flourishing native cultivation on each side. There are said to be 476 acres under Liberian coffee, 346 under coconuts and 301 under areca-nuts. The road was originally and commenced by the *Datu Dagang* was taken over and extended by the Government; it is now being gravelled at a cost of \$1,200 a mile. The resident then drove to the Tremelby estate, which affords a good example of what can be made of fallang-covered ground. The estate comprises 500 acres, and there are 35 acres under pepper in bearing and 65 under Liberian coffee, all looking very well. The following day the Resident visited the native gardens along the Telok Pulai Road, where are located 81 Javanese, 35 Malays and 25 Chinese engaged in the cultivation of 67 acres of Liberian coffee, 248 acres of coconut, and 34 acres of areca-nut. The Headman of the Javanese is *Haji Latip*, who came over to Selangor from Samarang about 28 years ago, and has been settled at Klang for the last 10 years. The Resident had not time to visit the other European Estates in the District—*Beverlao*, *Enterprise*, and *Glenmarie*.—*Selangor Journal*.

BLUE-GUM OIL.—The Government Quinologist has addressed the local Government strongly recommending that all the blue-gum oil required for the Medical Store Department may be obtained from Mr. S. G. Wallace's Drug Manufactory, Nilgiris. *Eucalyptus globulus* oil manufactured by Mr. S. G. Wallace has been carefully examined on several occasions, and it has been reported to be absolutely pure, being identical with that made in the Government Gardens in its specific gravity and optical properties. Mr. Wallace has recently started a laboratory for the manufacture of several drugs. He is said to be an expert and deserves the encouragement that can be given him by Government. As may be seen from the annual reports of the Botanical Gardens for many years back, it has been the object of Government to induce private persons to take up the manufacture of blue-gum oil on a large scale, and it is gratifying to see that this is being at last accomplished. The price of blue-gum oil sold to the Medical Store Department by the Government Gardens has, it is observed, fluctuated enormously since 1887. Mr. W. Wallace's offer to deliver it at R2-8-0 per pound free of all charges in Madras may therefore be deemed reasonable.—*Madras Mail*.

TROPICAL AGRICULTURE IN JAMAICA.

The Botanical Department of Jamaica would seem to be doing a good work in advancing the agricultural interests of the Colony and developing its resources in addition to its legitimate botanical work. The department supervises six different Experimental Gardens, at which the work carried on is of a very thorough nature, to judge from the details given in the bulletin issued in January last by the Director of Public Gardens and Plantations. Nevertheless, we have no doubt Dr. Trimen was correct in his statement made before the British Association, that "no other British Colony possesses so complete a system of botanical and experimental gardens as Ceylon." The Jamaica report of the botanical work proper does not possess more than a local interest, dealing with the introduction and trial of new foliage and flowering plants, trees of economic value, and food and fodder crops; but the references to regular cultivation and the statistics connected therewith form a specially interesting and valuable record. During the past year 5,485 cwt. 15 lb. of cacao were exported, valued at £12,349 11s. This is rather less than in the previous year, but there is a tendency to a steady increase. We quote as follows:—

The question of curing properly is one of the most serious to the Island, involving in Mr. Morris's opinion (see *Kew Bulletin* No 23) an annual loss of £20,000 or £30,000. If settlers fermented their cocoa they would get better prices, and would soon plant more trees, and increase the amount as well as the value. Messrs. Wilson Smithett and Co. speak of Jamaica cocoa in very disparaging terms.

They say:—"In a small proportion of Jamaica cocoa imported there has undergone fermentation to a greater or less degree, but the bulk is of very ordinary quality, the only West Indian Cocoa taking rank below it being St. Domingo from Jeremie, whilst that from Samana in the same Island is superior to Jamaica. It has, however, all the characteristics of good cocoa—although wanting in size, and if properly harvested, fermented or sweated, and then dried in the sun until the bean becomes crisp to the feel, so that the shell is fairly loose, and the interior dry and of an even chocolate brown not violet brown; when broken, it should command the general attention of the trade. Great care should be taken to protect it from rain whilst curing. It must be noted that manufacturers cannot pay much attention to small parcels, and that to insure a ready sale not much less than a ton weight of even colour and quality should be shipped, the larger the lot the better." The words "small parcels" in the preceding statement point to the main difficulty that lies in the way of improvements. If brokers in London will only deal with shipments of at least a ton in weight, merchants in Kingston must mix all the small parcels brought in by the buyers, and cannot discriminate between good and bad curing, for the proportion of good to bad must be, for some time, at any rate, very small and therefore cannot have any great effect in improving the quality of the whole. If the same price is then paid to the people for their cocoa, whether cured or only washed, it is not to be wondered at if they refuse to take trouble that is not paid for. It would appear that the only way out of this difficulty, inasmuch as it is hopeless to expect a combination amongst shippers, is for the Government by some means to prevent the shipment of inferior quality. The same remark applies to oranges, logwood, &c.

Of coconuts 7,885,656 were exported, of which the value was £26 512 16s 9d. The export was greater during 1891-92 than during any year for the past 10 years in spite of the great mortality among trees at Mont go Bay. 86,926 cwt. 1 qr. 20 lb. of coffee were exported, bringing in £336,839 18s. Here too the prospect is good. Of bananas 3,503,275 bunches valued at £262,745 12s 6d were exported. This is

nearly £2,000,000 less than last year and is accounted for by short crops owing to drought and the large local fruit-crop in America. Of other fruits mangoes brought £203 2s 6d, oranges £23,263 15s (less than half of last year's value), pineapples £1,286 15s 2d, limes £361 1s 6d, strawberries £3,607 2s 3d; lime juice alone was exported to the value of £4,865 4s 2d. Among other exports are ebony, fustic, ginger (£40,682), lancewood spars, lignum-vitæ, log-wood £303,364, nutmegs (£23,264), pimento (£50,984), rum (£256,000), sugar £255,500), tobacco and cigars (£9,430) and jams. Anato (of which nearly £4,000 worth was exported) is recommended as a hedge plant, as cattle do not browse on the leaves. More care given in preparation will it is said be repaid. Arrowroot on the other hand is recommended for men of capital rather than the peasants; for unless great care and skill are expended in the preparation of the starch, and proper appliances used, the price will be scarcely remunerative. Only about £8 value was exported. The cultivation of cassava or manioc by small settlers is suggested, for preparing starch, meal, tapioca, cakes and cassarep. Cinnamon (though growing freely) is not barked; but cacao growers are strongly advised to plant kola in their plantations. The cultivation and preparation of sisal hemp is mentioned as one of the most important among new industries.

The principal imports consist of corn, which cannot be produced as cheaply as in the United States, rice and pulses. The attention of planters and small renters is directed to the cultivation of nutmegs and to the large profits to be made in suitable localities; and it is noted with pleasure that this cultivation is being entered upon with spirit and energy. Liquorice is another plant recommended for small settlers as growing in deep soil such as that in which the orange flourishes.

In one of the Botanical Gardens exists an Industrial School for instruction and practice in general agricultural operations. Some of the boys work in the Garden for two or three hours in the morning, and another set in the afternoon. At other times they are employed in school, or at work round the school-house under a school-master. Among other things the boys are taught how to cultivate and cure cacao.

LETTERS FROM JAMAICA.—No. 35.

(The Editor, "Tropical Agriculturist," Colombo, Ceylon.)

For Packet of Feb. 7.

DEAR SIR,—After my long silence caused by my having really nothing special to write about, I am now able to send you a letter which may be of interest to some of your readers as it gives an account of

MY RECENT VISIT TO MONTSERRAI,

whither I went for a short holiday, after having had no change out of the island for about nine years.

I left Kingston on the 27th Dec. in the royal mail steamer "Para," a most comfortable and well-ordered vessel in every respect. Our first port of call was *Sacmel* in Hayti: it has a very picturesque appearance from the ship, but I am told this illusion is dispelled on landing, because of the dirty streets and bad smells. On Saturday morning at daylight we had arrived at

BARBADOS, OR "LITTLE ENGLAND"

as I believe it is often called, and its description had not been belied, for it is an island thoroughly cultivated with sugar, sweet potatoes and native "grounds," there are only a few acres of forest left in the Scotland district, the highest part of the island which touches an elevation of 1,100 feet. The land

is undulating, and one passes from one property into another without any specially marked boundary, sugar works abound and wind-mills: the latter pump up water from wells, and there appears to be an abundant supply, and I was surprised to find a splendid swimming bath at "Halton," though to all appearances no water or springs were to be seen.

I spent a very pleasant two days at "Halton," the property and home of Colonel and Mrs. Tolson, a most hospitable residence, reminding one of an old English country-house. The crop was not yet on, so I did not see sugar being made, but saw people at work in the fields. The cultivation appeared to be neat and excellent, in fact the whole island is like a sugar garden. Labour is abundant and cheap, as the island is well populated and but few Barbadians care to emigrate; good terms have been offered them to come to Jamaica, but they don't seem to see it. On Sunday, New Year's Day, I attended St. Philip's Church; there was a large congregation, white, coloured and black; so different to ours here, with usually but three Buckras in attendance. I cannot say I liked the singing in that church, for I have never heard more curious *pointing* as it is termed. I was disappointed because of a rainy afternoon from seeing Codrington College and the view from St. John's which I was told is the prettiest and most extensive over the island. On Monday afternoon I was on board the intercolonial royal mail-steamer "Eden" of about 2,000 tons burden, she was slow but sure, as she was going up to St. Thomas to be docked. I was up at 4-30 the next morning as we were then off the Pitons, those celebrated rocks on the coast of

ST. LUCIA,

and I had a grand view of them in bright moonlight, these two most peculiar rocks reach the height of 2,000 feet, and are situated on each side of a little bay, one is in the form of a sugar loaf peak, the other more rounded, they are truly grand and picturesque.

We entered the fine harbour of St. Lucia, destined to be the future Naval and Military Station of that part of the West Indies, at 9 a.m., and after coaling were off for Martinique, which we reached in the afternoon. In these waters famed for the deeds of Benbow, Rodney and other brave and famous British Admirals, we passed the "Diamond" Rock, another piton-shaped elevation rising perpendicularly from the sea on the western side, but habitable on the eastern. St. Lucia and in fact all the islands are very mountainous, the hills are all much in the same steep, pointed piton shapes which are evidently peculiar to these islands, both the large and smaller ones. It was unfortunate that there was no time to land at several of the islands, specially, at the French. As I was naturally curious to see the people and how they compared with our local Jamaicans, but the steamer only remains long enough to land mails and passengers. The boatmen and deck passengers who came off at Martinique and Guadaloupe, as also at St. Lucia and Dominica, spoke a most unintelligible *patois* of which I could only here and there catch a *bona fide* French word.

MARTINIQUE AND GUADALOUPE

are certainly very fine large islands, but Dominica is said to bear the palm for scenery; unfortunately the Government is financially in a bad way; for though there is a large quantity of fine virgin land available for coffee, cacao, and other tropical cultivation, labour is scarce and dear, so that no rapid progress can be made, and moreover the interior where these lands are situated requires opening up by good cart roads, but there is no money to construct them.

The trip coasting along under the lee of the islands is smoothish water, with just enough of the *trade* breeze to make it cool and pleasant is most enjoyable, and a very good view of the coast and mountains, and the cultivation alongshore, chiefly sugar, is obtained.

We arrived at

MONTSERRAT

about 10 a.m. on the 4th January. The friend with

whom I was going to stay is the manager of the Montserrat Company, an old Ceylon planter of 10 years' experience principally in Uva, where he was the friend and employé of the much-lamented R. B. Downall. I refer to

MR. H. DE COURCY HAMILTON

who must be well-known to many of your readers, not only as a good hard-working planter, but as a great sportsman who has slain his many elephants and other big game. Mr. Hamilton was for some time manager of that very fine property *Dambetenne* now I believe owned by Mr. Lipton of "Mazawatee Tea" fame. Mr. Hamilton came off to meet me, and took me to his office at the Depot, which is a large store owned by the Company, where are to be obtained all necessary estate supplies and other goods, the Company also are the Bankers of the island, and Mr. Hamilton has his office there and the Banking business is looked after by a Canny Scot of the name of MacGregor. Little Montserrat is still so charmingly primitive that it boasts neither telegraph, nor newspaper.

After waiting at the office for the home letters, Mr. Hamilton drove me up to his pretty residence "The Cot" situated some eleven hundred feet above the sea, where I did not find it much warmer than it is here at 2,700. The lovely views from and near the house reminded me partly of the Mediterranean, and partly of the Channel Islands. From various points of vantage, St. Kitt's and Nevis, the little island of Rodonda, where nitrate is dug and exported and on a clear day even "Saha" may be seen and from the other side Antigua and Guadaloupe are seen away in the offing: in fact I believe Montserrat must be the gem of the West India Islands as Capri and Sark respectively are of the Mediterranean and Channel Islands. My first walk at Montserrat was to the

COFFEE FIELDS

Those last planted run up to 2,000 feet and will believe be equal to about 3,000 feet in Ceylon. They are certainly steep in parts, but as the soil is stiffer than ours here which so easily breaks away, I do not apprehend any damage from landslips; and as to steep land, were not some of the steepest estates, notably in Badulla and Haputale, some of the finest and most productive in Ceylon? Lower down there are fields from 2 to 3 years old at various elevations down to about 500 feet which have grown and borne marvellously fast, and when I went down to the store I was surprised to see what a very fine sample had been obtained from that elevation. It is to be sent home in parchment and cured in London and will no doubt fetch very remunerative prices. The cacao that is growing among the lower fields is very fine, and I don't remember ever to have seen larger pods; some that Mr. Hamilton sent home lately, cured Ceylon fashion, fetched 9% and thus beat the average of Trinidad "bollow." Then I next day visited the

ARROWROOT FIELDS,

saw the men at work digging at so much a barrel; it is then conveyed by women to the store, where it is washed, sorped and washed again, and then passed through the machinery; the starch is run off into round tanks and after the necessary process has been gone through, it is dug out of the tanks and placed on wire shelves until quite dry, and fit to put into the casks. On the trays arrowroot looks like small blocks of snow; it is so white and powdery. Arrowroot does not need much cultivation, so it must I believe be a paying concern so long as the market is not swamped. But why Bermuda arrowroot, which certainly is not to all appearances better than that of Montserrat and St. Vincent, should fetch much higher prices is a puzzle *no fellow* can unriddle. As to the lime cultivation which I believe is some 600 acres in extent, some of the trees have done their duty for 20 or 30 years, and some are now suffering from blight, but the Company are nothing daunted and are re-planting and supplying, as well as planting out new land.

Besides all the forementioned, the Company are breeding mules and cattle and horses. I saw some

very fine specimens; two fine entire horses were like an immense cart horse to give bone, also two proof asses, and a familiar friend in the shape of a big Bramini bull, appropriately named "Ramen," who is doing his best to improve the breed of cattle. With so many irons in the fire, all doing well, and under such able and experienced management, assisted by two European Superintendents (in fact the Company's employes are all white men) the Company cannot but be prospering, and I consider they are very fortunate in possessing such a manager as Mr. de Courcy Hamilton, for they would find it difficult to find another of so varied experience and capabilities. Mr. Hamilton's work has been thoroughly done Ceylon fashion, and it reminded me of old times so see his well-traced roads, his lining, holing, and planting all after the old familiar sort.

On the Sunday we attended service at the local Parish Church, the Rector is a Welshman, by the name of Evans; the service pleased me much better than that at Barbados, it was hearty, and the singing was good, the sermon practical. I should think Mr. Evans was much liked and esteemed by his parishioners, for he is undoubtedly a sincere, zealous, and hardworking man, who at once wins one's respect and good opinion. As to the people they appeared to me more respectful, less humptious, and not so overdressed as ours in Jamaica; the fact is they are not so well off, and are content with lower wages, and "bread kind" appears to be cheaper than it is here, milk plentiful and sheep mutton not a luxury as it is in these parts.

The last four days of my stay in Montserrat were unfortunately marred by my getting a bad twist, and straining a muscle in my side when riding one of the Company's large American horses, which put an end to all walking and riding. Then a sad accident befell on board the R. M. S. "Esk" which was to have brought the mails and passengers from St. Thomas to Barbados, for when three hours out from the former port, some pipes connected with the boiler burst, killed two stokers, and very badly scalded two of the engineers who went to the rescue; so the "Esk" had to put back. A delay of two days was thus caused, as the little steamer "Tyne" which plies from island to island of the Leeward group had to be requisitioned to take the "Esk's" place and had to be sent up to St. Thomas for the mails, and as there was no telegraph to inform us of her movements, I had to spend not a very pleasant three nights and two days at a local hotel with the sobriquet of "the house that Jack built," as it is owned by one John Smith, an old sailor and boatsman. At last the "Tyne" arrived in the very early hours of the Saturday morning, and being new and fast, indeed quite a yacht of a boat, about 700 tons burden, made a very fast run to St. Lucia, picking up the mails on the way, and made the voyage to Barbados in 48 hours, inclusive of delay in transferring mails and taking in coal and water at St. Lucia. Meanwhile the "Orinoco" had been ordered to meet the "Tyne" at St. Lucia, we arrived first on the Sunday morning, and she soon came in sight, and we transferred the mails and passengers, and thus one day of the delay was saved, and it appears the "Orinoco" saved her time arriving at Plymouth on the contract Wednesday.

The accident to the "Esk" thus spoils my second visit to Barbados. I was to have visited a Mr. Greenidge, of Greenwich, St. James, who is about to try coffee planting in the Scotland district of the Island, and who was desirous of obtaining my opinion on his venture.

The "Atrato" is a noble steamer, over 5,000 tons burden, with a bad name for rolling, and for "had luck," but she gave us no cause of complaint as the weather was perfect, and we arrived at Kingston on Friday morning "all well," after a very enjoyable "jaunt," not exactly a "frolic" which was the word used by the daughter of my nautical landlord at Montserrat when she was recounting to me her travels to Barbados, Trinidad, and the Spanish Main, lamenting she feared such good luck was not again in store for her.

W. S.

NOTES FROM THE OCEAN.

('By Old Colonist.')

R.M.S. "Oroya."

The KANAKA LABOR QUESTION continues to form a subject of warm discussion; the statements and conclusions of that fervid apostle Mr. Paton have been severely handled by a series of articles in the *Argus* written by Mr. Melvin who has made himself better acquainted with the subject than perhaps any other man, and whose perfect honesty of purpose no one who knows him will doubt. Bishop Montgomery of Tasmania agrees with this clever writer and testifies to the eagerness of the islanders to get to Queensland, and the benefit they derive therefrom. Dr. Renton on the other hand, bears out the contention of Mr. Paton that the traffic is, and can only be iniquitous! While the Samoan Missionary, who has an intimate knowledge of, and sympathy with, the islanders, says "the iniquity exists only in the fervid imagination of Mr. Paton." That injustice had been perpetrated by recruiters is undoubted, but that seems a thing of the past, and sugar planters must now be too keenly alive to their own interest to badly use the Kanakas. The labour question in Anstralia is however one of the problems these dog-in-the-manager Colonists have yet to solve and which, until the majority of the people learn to be less selfish, cannot be satisfactorily solved.

"TEA, COFFEE, COCOA, AND MATE ANALYSIS" is the title of a book handed to me on leaving England. "A practical treatise by J. Alfred Wanklyn, M.E.C.S.," from which I make the following curious quotation for the information of planters (page 31):—"Coffee is a seed which grows in a pod like the pea or bean. The plant which produces coffee is a tree, *CAFFEA ARABICA*.—It grows in Arabia, Ceylon, the W. Indies, Brazil and other hot countries. Before it is imported to Europe the coffee is deprived of the pod, and also of another covering."

This beats the pamphlet I read in the last Melbourne Exhibition wherein Queensland is described as being "specially adapted for the growth of the finest variety of coffee called peaberry." Ceylon tea is now used on board the Orient Liner 4 times a day. It is remarkable how few now drink coffee. The very reverse, however, is the case on the Pacific routes. Tea and "cocktails" do not agree.

I have been studying with the greatest interest "THE HANDBOOK OF INFORMATION FOR INTENDING SETTLERS IN BRITISH NEW GUINEA" by Sir William Macgregor; an Aberdeenshire ploughman of whom we are all justly proud. I note, by the way, that one of the principal mountains has been named after our friend Dr. Alexander of the *Free Press*. I am very much disposed to visit New Guinea which is a much more get-at-able and promising subject than Uganda.

TASMANIA I mean to revisit and carefully note the progress it has made during the past five years. Will interview the new members of the Ministry, mean to spend a few weeks in N. S. Wales and hope to visit Mildura, &c. Will endeavour to effect a meeting with our correspondent "Aberdonensis" and by rubbing our heads together something may be got out of them.

IN VISITING THE ANTIPODES I have another object in view, viz. to further study the Chinese Labour Question with a view to advocating their introduction into the Upper Valleys of the Amazon.

COFFEE PLANTING NOTES FROM COORG.

COORG, March 3rd.—In my Notes of the 20th ultimo I alluded to the precautions taken against borer on some of the South Coorg Estates. Catching and destroying the insects in the image stage has been much ridiculed, is looked upon as hopelessly futile to make any impression on their numbers in this way as it would be to bale on, say, the Canvey River at any spot without cutting off the influx of waters from above. The parallel is not strictly

accurate, for whereas the waters of the Canvey would be diminished only by the number of cype laded out of it, the killing of every female fly at least would, having regard to the prolificness of creatures low down in the scale of creation, result in the destruction of many prospective borers, provided the insects were destroyed before any eggs were laid. The chance are in favour of this being done, if operations are commenced early in the season, and the insects captured in the active enjoyment of existence—as it may, I think, be reasonably presumed that laying its eggs is the last act of the female's life preliminary to its hopping the twig. As an auxiliary operation in conjunction with the other measures taken to combat borer, the plan is, I venture to think, not to be despised. Here we are trying rubbing down the stems of the trees with pieces of *gunni* sacks and lime, washing them with brushes in parts that have invariably suffered badly with borer. The effects of this experiment will be watched with the keenest interest. The pest causes such terrible destruction that no means should be left untried to mitigate it is possible. Pruning and manuring are still in hand in several places in the Santikoppa district. Every week sees work completed on one or two places, but it will probably not be till the middle of the month before all the places are done. Fish manure, bones, burnt soil, nitrate of soda and cattle dung have been used largely this season. Each of the different manures has been applied separately to separate pieces. An idea can thus be formed of the effects of the different fertilisers. The pruning which is being done, consists simply in removing old wood, and wood that will not bear. No great efforts are made to preserve the shape and symmetry of the bushes.—*M. Mail.*

"MEING."

Inventions of the 21st January contained the following paragraph:—"Among the Laos, a people inhabiting a district of Siam, the chewing of a preparation called 'Meing' is almost universal, the practice being especially esteemed by those whose labour brings great bodily fatigue. Recent inquiry shows that this delicacy is prepared from the Assam tea-plant of commerce. The leaves, instead of being used for an infused beverage as in other countries, are steamed, tied into bundles, and buried in the ground for about 15 days, after which the product will keep for two years or more. A similar use of tea is not wholly unknown elsewhere. Good authority states that, even in European countries, the ordinary dried leaves are sometimes eaten, a craving being gradually established, as in tobacco-chewing."—*London Cor.*, 3rd March.

THE BURMA RUBY MINES.

ALLAHABAD, March 17.—A stone was discovered at the Burma Ruby Mines last week which has been valued at Rs17,000. This is the most valuable ruby that has come to light for some considerable time past. The story that two rubies had been found in the mines worth 14 lakhs of rupees, was evidently a mere fairy tale.—*M. Mail.*

BRAZIL COFFEE NOTES.

Owing to the high prices ruling for coffee many large planters in Cuba are arranging to replant the lands formerly devoted to coffee. In another five years the West Indian product will be very largely increased.

The Sandwich Islands coffee crop for 1894-95 is estimated at one million pounds, owing to the rapid development of the new industry there. One Company now has 120 acres under cultivation and will plant 50 acres more next year.—*Rio News.*

UNDERWRITERS AND TEA.

Tea has not proved a very good risk for underwriters during the past year, and, in consequence of the casualties that have happened through bad navigation in some of the Indian rivers, the claims have been abnormal, and will probably result in the premiums being raised during this season. The ordinary net rate on tea with average from Calcutta to London by first-class steamers is about 16s per cent. This includes transit from the tea gardens to the port of shipment, thence to the warehouse in London; and the f.p.a. rates from Darjeeling and Colombo to London are respectively 10s per cent and 6s 8d per cent. Of course, the risk on Ceylon tea is not affected in the same way as Indian, because the railway from Kandy to Colombo brings most of the tea from the plantations to the ship, and the risk is reduced to a minimum.—*Financial Times.*

JAVA NEWS.

From Blitar it is reported the prospects for this year's coffee crop are very bad owing to heavy rains. Estates that produced 2,000 and 3,000 pikule of coffee last year estimate their crops for this year at 200 and 300 pikuls. The trees appear to be unusually healthy and full of promise for 1894.

The *serch* disease which has been prevalent on the sugar plantations of East Java for some time seems to be disappearing. The planters are now using their own cane for replanting instead of importing it.

Ponies in Java are known to have degenerated very much in time gone by. Therefore a society, composed chiefly of Preanger tea planters, is now making an attempt to prevent the decline of the Sandalwood variety by importing choice animals to breed from and by keeping a pedigree book.—*S. F. Press.*

KAVA.—While in Samoa, Lady Jersey tasted kava. She writes:—"After the King, the principal Tulafale (talking man), and myself had paid and received all proper compliments, the kava bowl was introduced. Kava is a drink extracted from the root of the *Macropiper methyeticum*, a kind of pepper shrub. The orthodox mode of preparation is for a young girl, or sometimes a youth, to chew the root into a pulp (in these degenerate days a grater is sometimes substituted for teeth); it is then mixed with water, and squeezed through a bunch of long bark-strings till the juice is clear and free from any piece of root. The preparation is thrown backwards and forwards from one vessel to another, and when the maker announces that all is ready the assistants clap their hands, then some of the beverage is lifted out of the tanoa, or large wooden bowl with legs, and carried in a coconut shell to the principal person present. He is supposed to drain it at a draught; if not, the remainder is thrown away and the shell refilled and carried to each of the guests in turn, with the strictest regard to the rules of precedence, a kind of seneschal or herald calling out the name of the next recipient. The Samoans are exceedingly fond of kava; it does not affect the head, but a very great quantity is said to produce temporary paralysis of the limbs. Some newcomers compare the taste to soapy water. I did not think it particularly disagreeable, and can imagine that one might end by liking it, though it would always be difficult to drink the whole cupful without drawing breath. A kava bowl in constant use ultimately acquires a beautiful blue glaze inside, and is then highly valued.—*Australasian.*

PRESERVATION FOR LOCALLY GROWN TIMBER.

A correspondent, who tells us he has read recent remarks we offered as to the very free use of teak by our Railway Department, asks whether it is known if the Ceylon Government has made any attempts to experimentize upon native-grown woods with some of the many methods in use elsewhere for the preservation of timber. It is pointed out to us that all sleepers imported for our railways have been submitted to one or other of the processes indicated, and that but for the result to this, the wood of the fir tree would perish with a rapidity to which our own native-grown timbers would not be exposed. We are quite aware that the hard and close-grained woods of local growth do not lend themselves so readily to certain preservative operations as do the woods of which our imported sleepers mainly consist; but it seems very likely that by careful experimentalizing some means could be found to redress this disability. It appears to us extraordinary that the very hardness and density of our woods, in itself so valuable a quality, should be allowed to remain the chief obstacle to their free use in railway work in this island. It has been asserted that the preservative fluids used cannot be forced throughout the structures of hard woods; but we are somewhat inclined to think that this assertion is of comparatively distant date, and was of a time when boilers were not constructed to resist the pressures now in such common use. Prior to the last ten years or so, the highest pressure used for locomotive engine boilers was about 120 lb. to the square inch. Now, since locomotives have been compounded, we hear of cases where 240 lb. to the square inch have been safely employed. If, therefore, it has been simply a question of pressure that can be safely used to force the preservative fluids throughout the structure of timber, it would seem to be possible that by specially arranged methods, force might now be safely be employed which would be adequate to the effective treatment of the hardest and most dense of the timbers to be found in Ceylon forests. Such is the view taken by the correspondent referred to, and we have only recently alluded to the effect the enormously increased price of teak is likely to have upon its future use, as also to the gradual exhaustion of the sources from which at the present time we draw our main supplies of railway sleepers. It can only be rational, therefore, to consider how it may be possible to utilize in the future the vast supplies of timber which this island affords. We have, above, suggested a course of experiment. This no doubt may prove costly; but it would be economical in the end if it afforded the means of utilizing native woods for purposes for which we now have to import foreign timber. We do not think the Ceylon Government should refuse to incur the expense of doing this, and probably the presence of an expert in such work would be necessary. But first of all let inquiry be made through the Crown Agents as to the progress making in Europe with the different preservative processes, and upon the result might be determined the course to be adopted here.

COFFEE CONSUMPTION IN THE UNITED STATES IN 1892.

This was the largest for any year on record, reaching a total of 691,691 tons for Europe and the United States, a gain over 1891 of 31,835 tons and over 1890 of 81,477 tons. This is a remarkable showing, in view of the high cost of the article. Almost the entire increase is credited to the United States, the gain in Europe being only 2,695 tons. Europe used 422,801 tons of coffee in 1892; the United States, 268,891 tons.

The future Brazil supply is variously estimated, and is thought cannot exceed 5,500,000 bags from Rio and Santos.

The Java crop of 1893-94 will show a heavy decrease; some estimate a falling off of two-thirds. Nicaragua is expected to furnish the largest crop ever grown. The reports from the United States of Columbia indicate a reduced yield; similar accounts come from the Malabar coast and Manila.

There are no indications that the world's production is likely to overlap its requirements to an extent large enough to inaugurate an era of low prices.—*American Grocer*, Feb. 8.

MAURITIUS.

GENERAL SUMMARY, PORT LOUIS, MARCH 11.

THE WEATHER AND THE CROP.—The quantity of rain that has fallen since last month has been insufficient in certain districts. Those to windward of the island have principally felt the want of water. The crop is entirely finished and only a few unimportant lots of syrups of inferior quality now arrive on the market. Up to the 4th inst. we have received in the warehouses in town 557,057 hags less than at the same period last year.

VANILLA.—The market is firm. We have to quote the sale of a few small lots of fine quality at R23 to 24 per kilo above 6 inches. We entirely confirm our last valuation as regards the outturn of the crop which will not exceed 8,000 kilos.

ALOE FIBRE.—The market has resumed a firmer tone. We have to quote the sale of 50 bales fine quality at R270. Good to middling R260 per ton we quote.

COFFEE.—Prices for good quality have considerably advanced owing to a reduced stock and having no importation to report since our last it is worth now from R90 to 100 per 50 kilos. mixed triage qualities are nominal at R40 to 54 per 50 kilos according to quality. Réunion and Madagascar are very scarce.—*Merchants' and Planters' Gazette*.

BRAZIL COFFEE NOTES.

If the people who are trying to make money out of Chinese immigration could be sent into the coffee fields and obliged to work, the outlook for the next coffee crop would be better than it is at present.—An association has been organised here under the title "Sociedade Mutualidade Agricola" for the introduction of Chinese laborers. It promises to send them home at the end of five years, but we are willing to guarantee that the promise will never be kept. The society has induced the octogenarian Councillor Sinimhu to accept it presidency, solely, of course, for the influence of his name.—According to the *Pharol*, of Juiz de Fora, the president of the meeting of planters held there to discuss Chinese labor, announced that he had received a letter from the United States minister recommending Mr. John Lawson, who had undertaken to introduce Chinese laborers for the impoverished agriculture of the country. Mr. Lawson's contract is for the introduction of 50,000 laborers at the rate of 10,000 a year, and the maximum cost will be \$20 per capita. The wages are not specified, but Mr. Lawson suggests that \$7 would probably be the rate.—*Rio News*, Jan. 31.

NOTES ON PRODUCE AND FINANCE.

CEYLON SHIPMENTS OF TEA.—The statement, still made, we believe, in some school books, that tea comes from China is an old and very incomplete story now-a-days. The rapid expansion of the tea trade of India knocked the bottom out of that statement fifteen years since, and Ceylon has upset the idea altogether. The supply of tea from Ceylon is increasing to an astonishing extent. The shipment in January amounted to 3,757,000 lb., and for February will no doubt be in excess of this. One ship in January took 925,850 lb., or over 400 tons, of tea, and since then another ship has exceeded even this record—which was the biggest up to the end of January—by carrying over 1,000,000 lb. of tea from Colombo.

TEA AND COFFEE IN FRANCE.—A discussion is going forward in Paris about the merits of coffee and tea. Just as English people have reached perfection in the brewing of tea, the French are consummate artists in all their dealings with coffee. The English, who try to imitate them in this, and who are not very familiar with the ways of the country, almost invariably blunder. They make the discovery that chicory is used in *café au lait*, and they conclude that the success of all French coffee, however drunk, lies in a judicious admixture of this root. The *café noir*, however, which is drunk after meals, is pure coffee made very strong: at all events, it should be so. Then there is an art in the roasting, and much motive in keeping the berries from the fire until a short time before they are required. That the French should have become great coffee-drinkers is the natural consequence of their own skill in preparing the beverage. They take it for their first breakfast, they take it after their midday meal, and again at night. Black coffee, strong as it should be, has a powerful influence upon the nervous system, which is not moderated by the addition of spirit drunk with it or immediately afterwards. In Paris, where so little is needed to set people's nerves wrong, it is said that coffee is working much mischief. Who knows how far it may not have been responsible for the Panama scandals? It belongs to the category of insidious agents of foreign origin. M. Zola, who now (according to the correspondent of the *St. James's Gazette*) appears to spend most of his time answering questions put to him by journalists of all subjects on which it is possible for opinions to differ, has been prevailed upon to say something about coffee. He tells us that for twenty years he has ceased to drink it, and that, although he takes a little now, it agrees badly with his nerves. He long ago gave up wine entirely and took to tea. He confesses that he is a "great drinker" of this beverage. M. Clémenceau is another; tea is the only fillip he believes in when the brain wants sharpening.

ON TEA.—Under the title "Thoughts on Theine" a pamphlet has been issued by a member of the tea trade in Aberdeen, in which advice is offered on the subject of growing, drying, selling and drinking tea. The chief points suggested by the author are the following: The grower, by closely supervising the coolie labour engaged in plucking, curing, in carefully marking on each individual package an honest tare, and in securing that the same make and quality are in every package of an invoiced lot. The seller, by keeping all his teas in bulk, not in packets, and by having these teas selected with due regard to the water of the district in which they are to be used. The consumer must put himself to the trouble to see that the tea he likes has had fresh water, freshly boiled, and in its first boiled stage, poured upon it. After standing, warmly covered for ten minutes the delicate infusion is ready, and, as our author observes, is "really nectar for the gods." From judiciously prepared blends a second cup of good tea may be had; but, in many cases, only fresh tea, freshly boiled water, and another ten minutes' infusion will yield that desirable consumption.

TEA PROSPECTS AND TEA ESTIMATES.—Discussing this subject the *Grocer* says:—"The firmness and buoyancy which characterised the market during the

closing months of 1892 and in January of this year, chiefly on the strength of the revised estimates issued last autumn having been carried too far, have been succeeded by fitness and depression, and the advance in value then established has since been partly lost. It may, however, be presumed that the total of 113,687,000 lb. in round numbers) fairly represents the extent of the 1892-93 crop, so that the trade may feel pretty sure that no serious discrepancies in the estimates (real or imaginary) will from this time be announced. Both importers and the wholesale dealers will now know better what supply they will have to depend on until the period arrives for the new crops of Indian tea to come forward, and it is possible for the market to exhibit greater steadiness, as arrivals begin to fall off materially, and the quantities in public sales to shrink into smaller dimensions. Still it must not be forgotten that, whilst stocks of Ceylon and China descriptions are much lighter than in 1892, those of Indian teas, equalling 50,000,000 lb. on the 1st instant, are in excess of the weight on hand in 1892, and considerably larger than the average of 40,000,000 lb., or more, that were held in this port at the same period of the two previous years. It is also reckoned that the shipments of tea from Calcutta to all places from May 1st to December 31st, 1892, reached nearly 100,000,000 lb. and allowing 7,000,000 lb. for exportation from thence to the colonies and other ports, there remained close upon 6,700,000 lb. to be afterwards shipped to this country, which would bring the exports hither for the current season up to 107,000,000 lb., or more than sufficient, plus the bonded stock, to satisfy the wants of consumers, who in the United Kingdom, during 1892 took off 109,528,169 lb. of tea of this class, against 98,941,931 lb. in 1891, and 101,961,686 lb. in 1890."—*H. and C. Mail*, March 3.

COFFEE, COCOA AND CARDAMOMS.

(From *I. A. Rucker and Bencraft's Weekly Circular*.)

LONDON, March 2nd, 1893.

COFFEE.—We have received the well known yearly table of statistics issued by the following Rotterdam Brokers. Messrs. G. Duiring and Zoon, Dalen and Plemp, Kolff, and W. A. Kamp, and Leonard Jacobson and Zonen, from which we extract as follows:—

	Imports—Europe and United States:—		
	1893. Bags.	1892. Bags.	1891. Bags.
Mexico & C. America..	1,500,000	1,258,000	1,349,100
Venezuela ..	900,000	859,000	816,700
West Indian Islands ...	200,000	257,000	179,900
Haiti ...	500,000	476,000	454,700
Brazil Exports:—	1892-93.	1891-92.	1890-91.
Rio ..	3,000,000	3,702,000	2,350,000
Santos ...	3,500,000	3,588,000	3,041,000
Bahia ..	250,000	306,200	156,000
Imports—Menado into Holland ...	11,000	3,500	5,100
Exports—Macassar and Timor	80,000	50,000	32,100
Exports—Ceylon ..	42,000	50,000	116,700
Imports—Europe and States of East India and Manilla	250,000	338,000	208,700
Imports—Africa and Moka ..	220,000	215,000	114,000
Java Government and Private ...	950,000	695,600	398,700
Padang ...	83,000	59,800	74,300
Grand Total ..	11,486,000	11,858,100	9,297,000
Imports—Europe and United States:—	1890.	1889.	1888.
Mexico & C. America..	997,200	1,055,200	900,900
Venezuela ...	612,300	701,400	713,900
West Indian Island ..	269,300	296,900	214,600
Haiti ..	463,200	449,700	769,100

Brazil Exports :-			
	1889-90.	1888-89.	1887-88.
Rio ...	2,441,100	3,786,100	1,896,700
Santos ..	2,061,600	2,555,900	1,327,800
Bahia ..	169,500	164,200	106,400
Imports Menado into Holland ..	23,000	8,000	4,000
Exports—Macassar and Timor	86,300	112,300	42,600
Exports—Ceylon ..	100,000	110,000	111,100
Imports—Europe and States of East India and Manilla	299,500	261,600	338,000
Imports—Africa and Moka ..	130,400	118,100	73,800
Java Government and Private ...	918,100	873,300	498,800
Padang ...	86,700	105,500	89,000
Grand Total ..	8,658,200	10,598,200	7,077,000

Of course the figures which are found in the first column, and which total 11,486,000 bags, are estimates. Europe and the United States:—

	1892. Bags.	1891. Bags.	1890. Bags.
Importations	11,898,400	10,386,100	9,701,200
Deliveries	11,378,500	10,570,400	10,127,700
Stock, 31st Dec.	1,653,200	1,134,100	1,320,300
	1889. Bags.	1888. Bags.	1887. Bags.
Importations	10,268,000	9,670,600	9,054,300
Deliveries	10,175,500	10,344,900	9,185,800
Stock, 31st Dec.	1,746,800	1,655,200	2,334,700

These figures confirm the statements issued by us for many months, viz., that this campaign, supply and demand promised to be about on a par. Last year, according to these figures of the Dutch brokers, we delivered 11,378,000 bags, this year estimates of supply total 11,486,000 bags. Some argue that we shall deliver less this year, but on the other hand shall we get 6,500,000 export from Rio and Santos, as per their figures, so far the Brazil receipts do not point to such an export. Markets continue excessively quiet, and the values of spot coffees have given again a little. Terminal markets ruff steady but quiet. Havre appears to be firm, 106 francs having been paid for March.

CINCHONA BARK.

(From C. M. & C. Woodhouse's Monthly Report.)

IMPORTS OF CINCHONA BARK INTO GERMANY—1st JANUARY TO 31st DECEMBER.			
	1892. Kilos.	1891. Kilos.	1890. Kilos.
From Great Britain..	3,616,600	1,952,700	1,875,800

Elsewhere ..	2,694,000		
	6,059,000	5,417,000	4,011,000

IMPORTS INTO THE UNITED STATES—1st JANUARY TO 31st DECEMBER.			
	1892. lb.	1891. lb.	1890. lb.
Cinchona Bark ..	3,144,000	2,861,000	3,274,000
Quinine and Quinine Salts ..	3,486,000	2,527,000	3,800,000
Cinchona Bark ..	1,428,000	2,325,000	4,418,000
Quinine and Quinine Salts ..	2,675,000	2,074,000	2,567,000

In the above statements we are enabled to give statistics of Bark and Quinine in Germany, the largest manufacturing country, and in the United States, the largest consuming country of Quinine. It is somewhat remarkable that in 1892 Germany should have imported the larger portion of its Bark from Great Britain rather than from Holland; but the chief feature of interest is the very large and steady increase in the export of Quinine and other Quinine Salts, which have nearly doubled since 1887. These figures fully confirm the reports of a large increase in consumption during the last two years, owing to influenza. In comparing the exports of Quinine from Germany with the imports of Quinine into the United States it appears that in 1892 and 1889 the United States imported the chief part of its Quinine direct from Germany, whilst in 1890 and 1891 a considerable portion may have been taken from the stocks of German Quinine in this country. No statistics are available showing what are the stocks of Quinine in the United Kingdom, but they are probably much reduced. The stocks of Bark in London are returned in packages, which of course vary in weight, but for the purposes of comparison, if we estimate South American bales, &c., at 100 lb., and Ceylon, East India, &c., at 250 lb. each, the Stocks on 31st Dec. for last 6 years would compare as follows:—

	1892. lb.	1891. lb.	1890. lb.
	6,250,000	8,216,000	8,761,000
	1889. lb.	1888. lb.	1887. lb.
	9,350,000	9,675,000	9,583,000
and the Board of Trade Returns show the Imports and Exports of Bark for the same period to have been—			
	1892. lb.	1891. lb.	1890. lb.
Imports ..	11,917,600	11,934,000	13,083,000
Exports ..	12,356,000	11,879,000	11,848,000
Left for Home Consumption			
	nil	55,000	1,235,000
	—439,000		
	1889. lb.	1888. lb.	1887. lb.
Imports ..	14,515,000	16,264,000	16,109,000
Exports ..	13,506,000	13,865,000	14,714,000
Left for Home Consumption			
	1,009,000	2,399,000	1,395,000

From the above it is evident that for some years past we have had to draw on our stocks of Bark to supply the requirements of the trade as the quantities imported have been insufficient. In Germany also it seems probable that no stocks of Bark or Quinine can have accumulated in the manufacturers' hands at any rate for some years, in fact, in 1892 it appears from the statistics, that the quantity of Quinine, &c., exported considerably exceeded the quantity of Bark imported: this, if the Bark imported is estimated to contain on an average $3\frac{1}{2}$ per cent of Crystallised Sulphate Quinine—the amount of Quinine contents would be as follows, viz. :—

	1892.	1891.	1890.
	(Ozs.)	Ozs.	Ozs.
Imports of			
Bark equivalent to ozs. Quinine	7,315,000	7,421,000	5,994,000
Add Imports of Quinine	262,400	258,000	381,000
	7,577,000	7,679,000	6,375,000
Exports of Quinine and Quinine Salts	7,966,000	6,589,000	5,536,000
Left for Home Consumption and Stock	—	1,090,000	839,000
	—	1889.	1888.
Imports of		Ozs.	Ozs.
Bark equivalent to ozs. Quinine	6,448,000	6,448,000	5,815,000
Add Imports of Quinine	367,000	367,000	215,000
	6,815,000	6,815,000	6,030,000
Exports of Quinine and Quinine Salts	6,059,000	6,059,000	5,417,000
Left for Home Consumption and Stock	756,000	756,000	613,000

On the other hand, the Stock of Bark in Amsterdam on 31st December was estimated at—

1892	11,268 packages.
1891	5,279 "

Increase .. 5,989
At 250 lb. each equivalent to 1,497,250 lb.

As regards the supplies of Bark the shipments from Ceylon, British E. I. and Java from 1st January to 31st December have been as follows:—

	Ceylon lb.	British E. I. lb.	Java. English lb.	Total lb.
1892	6,675,194	2,456,024	7,191,341	16,322,559
1891	5,589,551	3,123,934	8,699,530	17,413,015
1890	8,779,500	2,294,379	7,291,169	18,365,048
1889	9,325,728	2,406,908	5,323,306	17,055,942
1888	12,482,817	2,297,305	4,306,656	19,086,778

The arrivals of Cultivated Calisaya Bark from Bolivia for the past six years have averaged about 7,300 packages, and other South American importations have practically ceased, but it is reported that considerable shipments might be made of Calisaya Bark from the plantations in Bolivia if any material rise in prices took place.

4,300 packages West Coast African Bark were sold at public sale last year against 720 packages in 1891.

Prices at end of each year compare as follows:—

	Value of unit of Quinine.	German Quinine on the spot.
	per lb.	per oz.
1892	.. 1 $\frac{1}{2}$ d	9 $\frac{1}{2}$ d
1891	.. 1 $\frac{1}{2}$ d	9 $\frac{1}{2}$ d
1890	.. 1 $\frac{1}{2}$ d	1/
1889	.. 1 $\frac{1}{2}$ d to 2d	1/2 $\frac{1}{2}$
1888	.. 1 $\frac{1}{2}$ d	1/3 $\frac{1}{2}$

Prices of Bark have declined since end of 1889 from 1 $\frac{1}{2}$ d to 2d per unit to 1d per unit, and of Quinine (German) from 2 $\frac{1}{2}$ d per oz. to 9d per oz. Of course it must be remembered that Bark is not a crop, and increased supplies could be obtained in the course of a few months by planters coppicing or uprooting their trees, and, no doubt, any material advance in prices would soon be followed by larger importations, yet since the price of 1d per unit can hardly pay for the cost of harvesting and bringing the bark to market (at any rate for qualities analysing 3 per cent and under) we see nothing in the present statistical position to justify the late decline in prices.

TEA IN AUSTRALIA.

(From Alfred Harvey & Co.'s Monthly Tea Report.)

MELBOURNE, March 7th, 1893.

GENERAL.—A remarkably quiet month in all branches of trade has to be reported. The few public sales have shown that buyers are so far disinclined to take China leaf in quantity at present rates; and that they have taken freely both Indian and Ceylon leaf at a still further advance in price—particularly marked in the 7d to 8 $\frac{1}{2}$ d grades, and better kinds up to 10d; finer qualities showing no material change. Deliveries, although for the month fairly good, are upon the whole disappointing; the shrinkage for the eight months now reaches 3,000,000 lb., the whole of this being due to a falling-off in the Home Consumption returns, which are mainly affected through old 1d duty paid stocks being larger than generally believed, and the change that is rapidly taking place with the country dealers, who now buy largely from the blending firms, and consequently carry little or no surplus stock.

CHINA.—The "Tsinan," from Foochow, with 154,000 lb., has been the only arrival; this brings the exports up to somewhat over 14 $\frac{1}{2}$ millions for the season. Local trade has been exceptionally quiet, the shortage in supply of common leaf making a firm market for that grade. Everything under 6 $\frac{1}{2}$ d has now passed into dealers' hands; but really good value is still obtainable at 7 $\frac{1}{2}$ d to 9d, with limited demand for finer sorts. S. O. Pekoes continue quiet, with small sales. There is an unhealthy ring about the scented trade, as also with buds, but these fancy lines suffering from the increasing demand for Indians and Ceylons. Public sales were confined to a small catalogue on the 23rd February, when 1,400 packages were sold at 6d for common, 6 $\frac{1}{2}$ d to 7d for clean common, and 8d to 9d for fair to good medium panyougs. For today's sales 700 quarter-chests first-crop buds are printed. Stocks in bond, 3,681,218 lb.

INDIA.—The "Waronga," with 150,000 lb. for Melbourne (sailed on the 1st instant), has been the only departure for the month, bringing the exports up to 3,570,000 lb. The only public sales held locally were on the 23rd February, when 2,600 packages were sold. A small catalogue of 330 chests is printed for today; the "Argus" shipment will not be offered until the 23rd. Public sales confirmed the anticipated advance in value of leaf, which advance can safely be quoted at a full 1d upon broken and whole leaf pekoe souchongs up to 9 $\frac{1}{2}$ d, and $\frac{1}{2}$ d to $\frac{1}{2}$ d upon good pekoes up to 11d; fine kinds unaltered. Sales were affected at 6 $\frac{1}{2}$ d to 7 $\frac{1}{2}$ d for poor fannings; 8d to 9 $\frac{1}{2}$ d for clean to good pekoe souchongs; 9d to 10 $\frac{1}{2}$ d for fair to good pekoes; 10d to 1s 2d for good leaf to fine orange pekoes; up to 1s 6d for fine Assam and Darjeeling orange pekoes. Stocks in bond, 425,883 lb.

CEYLON.—Public sales have been confined to one catalogue, on the 7th February, when 350 packages were sold at 7 $\frac{1}{2}$ d to 8 $\frac{1}{2}$ d for broken; 8 $\frac{1}{2}$ d for clean whole leaf; 9d to 9 $\frac{1}{2}$ d for pekoes; 1s to 1s 2d for broken pekoes. A further catalogue of 1,000 chests is printed for this day's sales. Prices paid showed an advance of $\frac{1}{2}$ d upon broken, with no change from previous full rates for other grades. Private sales, although of fair volume, have been effected with difficulty, holders demanding highest rates. Stocks in bond, 342,278 lb.

COFFEE PLANTING in the Lake District of British Central Africa is thus referred to by the correspondent of a South African paper:—

The coffee planting industry is receiving a large amount of attention, and in some districts will probably prove worthy of the enterprise displayed by the planters. The present produce of the country is shipped down the rivers Shiré and Zambesi by steamers; but the fleet of vessels, which the Rand correspondent would have us infer is now running, is still in the future. Much needed improvement in river transport has been delayed by circumstances and accident, but there is a good time coming.

THE INCINERATION OF TOWN REFUSE.

Mr. B. R. Harrington of Calcutta, civil engineer and architect, has sent us a paper, in which he gives his experience on the above question, acquired during five years' constructing and burning operations in India. The subject of the disposal of the refuse of Colombo, including night soil, has come up for discussion again and again during the past few years, both in the Municipal Council and in the local press but with no satisfactory results. At present, the refuse of Colombo is either buried in the compounds attached to the various houses, or scattered over the water-grass fields which cover large tracts in the outskirts of the town. Both these methods of disposal are objectionable on several grounds, chiefly sanitary; and the late Sanitary Inspector of the Colombo Municipality and his successor have more than once recommended that incineration should be enforced,—the former gentleman inventing a small incinerator which has been adopted successfully by a few persons in Colombo. But the matter should not be left to private individuals: it is one that the Municipal Council should consider it one of its duties to carry out; and what Mr. Harrington has successfully achieved in Calcutta can be done as easily in Colombo. It is worthy of note, in this connection, that the Madras Electric Tramways Co. is to combine the incineration of refuse with the working of its line. Perhaps Mr. Matthew might do the same. Another want in Colombo is a Crematorium for the disposal of the bodies of those who prefer this method to earth burial. Some attempts have been recently made in this direction; but, for some reason or another, without result. This by the way, however. We append some extracts from Mr. Harrington's paper:—

It is essential that an incinerator furnace should burn wet and dry refuse with equal ease. A furnace that would destroy wet refuse might probably run away with dry, leaving the furnace cold for next morning's supply, and when ignited would flare away in a comparatively cold furnace, and thereby be the means of producing volumes of smoke. A large volume of smoke indicates imperfect combustion. A low temperature furnace may produce smoke, or the smoke current may be so rapid that unconsumed matter, such as dust and soot, may escape even through a fierce furnace. * * *

Moisture is another matter requiring consideration when burning refuse. From experiments I find ordinary dry refuse will absorb as much as four gallons of water per cubic foot of the refuse. A Harrington furnace can easily destroy on an average 600 cubic feet refuse daily, and if the refuse is very wet so that water drains therefrom, the 600 cubic feet would probably contain 2,400 gallons of liquid, to evaporate which would be the duty of one ton of best coal or 2½ tons of best straw. Refuse generally contains no coal or cinder residue, and but little straw, the most of it is garbage and sewage garbage, with about ten per cent incombustible. The steam and moisture emitted by evaporation from such large quantities of liquid is of course conveyed in the direction of the smoke current, and this in itself tends to lower the temperature of the current, and also weight the solid particles which it contains, so that at times it would have a tendency to fall on escaping from the chimney. * * *

The success and reputation of the Harrington Incinerator is greatly owing to the combined smoke annihilator. The absence of coal cinder or cinder residue makes Indian refuse difficult to treat perfectly, especially during wet weather when there is so much water to contend against. The refuse burns well enough in the Harrington furnace, but were it not for the annihilator, there would be a tendency to give off large volumes of smoke, and when the volume of smoke is large, its temperature is liable to be low, so that a crematorium of itself would

have but little effect in raising the heat of such large volumes to any appreciable extent; but with the washing process the volume is at once largely reduced by distillation of the vapour which it contains, and again by the removal of soot and other suspended solid particles. The action of the water wheel also neutralises deleterious gases, in as much that the revolutions of the wheel thoroughly mixes or mills the smoke combustion, whilst at the same time the water attacks the acids. * * *

In conclusion, the work or process of destruction or the maintenance of the Incinerator should be simple and in no wise complicated. A Harrington furnace, when full to the top contains a matter of 500 cubic feet of refuse and 200 cubic feet of ashes, and the furnace works best when filled quite full of refuse, and left very much to take care of itself. The work of stoking is simply occasionally to remove ashes from below, to stoke the fire bars and remove clinker therefrom. All parts of an Incinerator, such for instance as the fire-bars and furnace doors, the reverberatory arch and other brick work of the furnace, the refuse shoot and the platform, the flues, baffling chambers and chimney have each separately and all combined a duty to perform, and any one part acting imperfectly militates against combined perfectness of the whole. Simple though the construction of an Incinerator is, to ensure success it is absolutely necessary to have proper plans and to build in exact accordance with them.

Incinerators can be applied to electric lighting, pumping, ejecting night soil and drainage or to any purpose which boiler power may be applied. Particulars upon application.

THE SEA-CARRYING TRADE TO THE EAST.

It was recently stated in our London Letter as the opinion of a good authority that much of the cheapness with which goods are now carried between the United Kingdom and the East is due to the rates charged for passenger traffic,—in other words that it is the passengers who largely pay the freight for exporters from home! So long as passage rates are kept up—and these have just been somewhat increased by all our great steamer lines—so long, it is argued by those in the position to form a judgment, will the rate of freight for goods be kept down. This bears hardly of course upon the private shipowner, who finds himself compelled by competition to accept freights which must to a considerable extent be unremunerative to him, and it can cause no wonder, therefore, to hear of so much tonnage of steamship being laid up in the ports of Great Britain solely because it does not pay the owners to accept freights at the low rates at present prevailing. This result has been the direct consequence we apprehend of the cutting of the Suez Canal. We are all well aware of the position the P. & O. Company, for instance, found itself in when the opening of that highway let through a perfect flood of steamships conveying cargo and passengers at a low rate. Its directors had to face a competition which carried goods outwards at 15s or even less per ton as compared with the £4 or £5 per ton it was then receiving for outward freights. Ruin seemed to stare our great Steam Company in the face. It was Sir Thomas Sutherland who grasped the situation and made arrangements to meet it. What were then, relatively to modern accessions to the fleet of the Company, only toy boats, were rapidly got rid of, and replaced by Goliaths which have now reached the dimensions of those seen constantly in our harbour. The accommodation afforded by these new ships killed off the competition in the passenger trade and deprived private owners of the

aid—their cabin freights afforded to their goods freights. Now these floating palaces must have their holds filled up. Some hundreds of passengers and the stores and water needed for these will not suffice to ensure stability to the vast bulk by which they are transported. It has become cheaper, therefore, to carry cargo in such ships almost for nothing rather than to have to fill up with the ballast required to ensure stability. Passengers may be described as "top-hamper," and their weight must be counteracted by a load well below the centre of a vessel. It was attempted to supply this to some extent by water-ballasting; but a shifting load of this character becomes dangerous when adopted beyond certain narrow limits. These monsters which, week after week, discharge hundreds of passengers upon our shores are therefore the chief factor in keeping down freights. Their receipts being mainly for passengers they can afford to fill up with 2,000 or 3,000 tons of goods at almost nominal rates. We confess we do not see how this influence can ever be got rid of to the extent which may redress the effect that it has upon the vessels of private owners. When we hear that the ships of the P. & O. and Orient Companies are carrying cement from London to Australia for one shilling and sixpence the cask, we may well believe the assertion that the saving to the shipper is made at the cost of every individual passenger on board the ship. But we can only state the point; we can suggest no means for reducing the disabilities which it creates.

COFFEE IN MYSORE.

THE VALUE OF SHADE—NO BURNING OF FOREST—A NEW CROSS SPECIES OF COFFEE.

We had as visitors two leading proprietary planters from Mysore: Mr Middleton, formerly of Ceylon, a friend of many years' standing—an extensive cultivator of cardamoms as well as coffee, and the value of whose main staple has been considerably affected by the large production of cardamoms in Ceylon of recent years. Still coffee is making amends, for Mysore continues to crop well. One of the oldest and most successful coffee planters in Mysore is Mr. Mockett, and he declares that the main reason why their coffee has kept up against fungus, borer, bug and all the other modern enemies of poor coffee in the Eastern hemisphere, is to be found in the selection of the proper shade tree. Mr. Mockett has 25 years' experience, and yet he alleges that only within the past ten years or so have they arrived in Mysore at a proper solution of the "shade" question and they can now point to coffee as healthy and vigorous as they could wish it to be. But we must always remember the rich soil and comparatively dry climate—inimical to fungi—of Mysore with a rainfall not exceeding 70 inches concentrated chiefly into a few months. Still, why should not our coffee in the somewhat similar soil and climate of Uva live as long and do as well as in Mysore? On this point, Messrs. Middleton and Mockett (both old planters) had some further suggestive information to give. Mr. Middleton was the first to introduce (over thirty years ago) the Ceylon system of burning off the forest into Mysore, and he believes it now to be an utterly wrong, mischievous as well as wasteful system. To Mysore at least, it proved quite unsuited. Estates so opened never lasted beyond a limited term of years, no matter how liberally treated; whereas places opened with the forest chopped, piled and allowed to die down gradually, how-

ever untidy for a term, have gone on without manuring, yielding heavily. Next, however, we learn how the original Coorg "chick" coffee proved a failure: it was the discovery of the hardy "Nalkanaad" coffee that made the cultivation, always under proper shade planted and cultivated in the clearing, a success in Mysore. A good deal of manuring is done, but both gentlemen have even more faith in digging and turning over the soil in their fields once a year—in tilth in fact. The returns have been most handsome in heavy crops and high prices of recent years—though the past season has been an unfavourable one for blossoms, &c. A difficulty now is about labour; for with so keen a demand and high price for coffee, the Mysore natives have set to work planting it on their own account in every piece of ground they can command—often most unsuitably. Indeed the greater part of such planting will be complete failure; but meantime the people cannot be got to work for the planters as before. Perhaps, though, the most important fact related by Mr. Middleton and confirmed by Mr. Mockett has reference to a new coffee plant—a cross from natural cross-fertilization between Liberian and Nalkanaad coffee. This plant (and he has a few specimens 6 to 8 years old) is a very vigorous, bushy, free yielding one. It seems to have the good qualities of both the parents with none of their drawbacks. The bushes have never been touched by disease of any kind, though they are in no way treated differently. The crop return from them is extremely heavy, equal to a few tons per acre. It is only within the past three years that Mr. Mockett noted these peculiar bushes in his Liberian-field. He has now a big clearing of seed which he believes similar to what produced these cross-species; for he has already found that there is degeneration if he takes his seed from the crossed species itself. The first generation alone apparently shows the vigour, and heavy cropping capacity referred to. The bushes in their wide-branching luxuriant appearance present a contrast to the tall and rather spindly Liberian and equally to the much smaller Nalkanaad bush. We are promised photographs of the bushes as well as some seed, and further information as to the progress of the new clearing, all of which will be of interest.

SCIENCE TO AID THE TEA PLANTER.

The following Resolution was moved by Mr. T. G. HAYES at the General Meeting of the Dimbula Planters' Association on the 24th March:—"That this Association deems the time has arrived for calling in the aid of the best scientific opinion to determine the means that should be met to retain the quality and quantity in the output of tea from the island." The mover said: Mr. Chairman and Gentlemen.—To save your time, I have written what little I wish to say in bringing forward the motion that stands in my name, and I will ask you to allow me to read it. I am no speaker and my object is to provoke speech from those who can talk and have something to tell first here and then I hope in the other Associations of the island. To commence with, my motion is evidently ambiguous in a way I did not intend. It has been taken to mean that our enterprise is in so risky a condition that steps must be taken to bolster it. To correct this, and to dissociate myself at once from the faction of croakers at heart, who are so ready to take alarm, I will ask leave to amend it as follows:—"That in the opinion of this Association the tea enterprise of Ceylon has reached a position of present success and future promise such as warrants us in taking the best scientific advice etc." The past eight years may fairly be described as years of scares. First, quite early in

the day we were threatened with "overproduction." It was said that when our produce reached forty millions, the limit of consumption would be attained. Our last year's exports are seventy millions. More recently we trembled for exchange; any serious alteration for the worse of the position of that element of our prosperity seems now as far off as ever. There have been giants in the way all along, and ample room for the anxious to despond; but our fears have not hitherto been justified by the result; and now least of all, one would think it is necessary to raise phantoms. Our policy has been to advertise, to court publicity, not to work in the dark, and if under pressure of no panic or pest, or waning fortune, we overhaul the foundation of our prosperity, there is no fear that the motives will be understood. Business men at home, whether friends to Ceylon fortunes or otherwise, watch our career as critically as we can do ourselves. They know the risks of tropical agriculture as well as we do, and have learned them, in common with ourselves, from the fate of coffee, and also from the vicissitudes of tea in India. There are at all events largest and most prosperous concerns now existing that covers the ruin of more than one generation of shareholders. Supposing that after careful enquiry we came to the conclusion that systematic manuring is a necessity in order to maintain the vigour of our tea-bushes, this conclusion would be accepted as no admission of weakness, but rather as an act of prudent self-preservation. One article says in a Money Market Review cutting up our system of cultivation and finding us unprepared with a defence, would do more to destroy confidence and to cause diversion of capital than any amount of enquiry on this side as to how to cultivate so as to secure the permanence of our staple. Depend upon it, men at home ask first "will it pay," and next "will it last." Directors of Indian companies at their annual meetings delight in assuring them that in Ceylon it will not. Our business in Ceylon is to neglect no means for securing the vigour of our bushes—and to see us setting ourselves resolutely to that task will do more to promote confidence than anything else can. The aim of my motion is, of course, examination of our present system of cultivation. Is it in accordance with the scientific knowledge of the day? I say the time has come for this enquiry. (1) Because we have money in our pockets to promote it if money is needed—the result of good yield—fair markets and a very favourable condition of exchange. (2) Because we have found out the virtue of combination to widen our markets, and combination, where money is needed, is easy in prosperous times, and the reverse in times of difficulty. (3) Because this is no season of panic calling for urgent remedies; but we can quietly and dispassionately work at an enquiry which needs time to be effectual. Lastly, there is no time to be lost in getting enquiry on foot. It is easier to strengthen the healthy than to cure the sickly tree. We have brought science to bear upon every branch of our tea industry, on our machinery, our transport, and so on; but we have not applied it to it as a community for help in the cultivation of our bush, nor in the processes of the manufacture of our leaf which are depended upon chemical changes. Our estates are better drained, our bushes better plucked and our factories more roomy than ever they were before; but have we got further and seen if we are retaining in our soil the constituents that have given our bushes their first vigour. We do not want to wait to wait till observation shows us that something is wrong; if we wait for that it may be too late, or we may find that we are told then we must replace them at a heavy, perhaps impossible cost, what, spread over a series of years, would have cost us little and saved our bushes from destruction. This latter has been an accomplished fact in India—but as to quantity and quality of teas. An expert called in to prescribe remedies for red spider told them long ago that their soils were being exhausted by long cropping without manure, and that the pest was the result of their system then. In the Indian Tea Gazette, Dr. Schrottky wrote "The greater portion of the tea

sent out of India for the last fifteen or twenty years, has it not been grown without a particle of manure?" Has not the soil of the majority of tea gardens year after year been deprived of its mineral plant food, which in the very best soils seldom exceeds 10 per cent of the whole? And can one be surprised to find the plants every year growing weaker and weaker? Do the shareholders in tea Companies—happily deluded by the receipt of large dividends know that these dividends are portion of their *capital* of the concern, and that they do not represent their real *interest*, do they know that shares—the real value of which is £100 today must next year be worth a definite amount less paid away in dividends—for do they not sell in every maund of tea a portion of their garden? Indian gardens have mostly possessed large reserves and these are being constantly draw upon?" We can't do that in Ceylon. How do you know what proportion of our success in tea, in the higher districts, we owe to artificial manures already applied in days of coffee, and never drawn out by coffee trees in the shape of crop? I do not think that the failure of artificial manure to save coffee can be quoted against its use in the case of tea. When manure was applied to coffee, leaf disease was already in possession, and its nature was such, that any accession of vigour to the coffee tree, meant accession of vigour, out of all proportion, to the fungus also, even so the best cultivated estates lasted the longest—so that the balance of evidence is in favour of the manure. Applied too, to tea, it is not subject to be baffled in its aim by adverse seasons to anything like the same extent as it was in the case of coffee. Therefore, for the sake of our cultivation, I plead for the appointment of an analyst to *prove* to us that our soils are liable to deterioration, if science asserts they are, and *after* that to tell us *what* to apply to prevent it, and in what quantity, according to the individual requirements of estates—so as to safeguard us from the very real risk of overstimulation. Without scientific direction, experience has already taught us how dangerous artificial manure may be. For the sake of our *manufacture* also urge the same examination. Brewing I suppose, offers a close analogy. It is subject to the same risk of bad material, and deals with the same chemical processes—fermentation and temperature. I am told that science has revolutionized brewing, and that what used to be determined by taste and observation is now determined by analysis, and the thermometer. Perhaps some here can tell us if this is true. At all events, if we do give that science an opportunity we shall satisfy ourselves that we are leaving no stone unturned in the struggle for continued success, and if this subject is sent on to the other Associations by your vote today, we shall have it thoroughly ventilated and a great mass of information, as I hope, added to our general stock of knowledge.

AN AMENDMENT.

Mr. W. CROSS BUCHANAN proposed an amendment:—"That this Association does not consider the services of an analytical chemist are at present required." His reason for moving the above amendment was, that he considered estates at present were well and profitably managed, and to change this comfortable state of affairs by the introduction of an unknown quantity in the shape of "a man of science" was to run the risk of having our estates scientifically mismanaged and worked at a loss.

Mr. RYAN seconded the amendment and spoke at some length on the subject, saying that he had paid considerable sums for analysis *re* tea, but with no practical result.

THE RESOLUTION CARRIED.

Mr. BUCHANAN'S amendment was then put to the meeting and lost.

Mr. HAYES' resolution was then put to the meeting and carried—7 votes to 6.

The meeting closed with a vote of thanks to the Chairman. A. A. BOWIE, Hon. Secy. Dimbula P. A.

CEYLON TEA SALES IN LONDON.

WEEKLY RETURN FOR FOUR YEARS WITH NO. OF PACKAGES SOLD; AVERAGE PRICE PER LB.; AND RATE OF EXCHANGE FOR 1889, 1890, 1891 AND 1892.

We have received the following return in MS. from Messrs. Shand, Haldane & Co., which we reproduce as received, although there are one or two gaps at the end. It cannot fail to be of

interest to tea planters. The biggest sale, so far as number of packages goes, was on August 22nd last year with 2,9,612 packages; the lowest 633 packages on May 23rd, 1891. The highest average price recorded is 1s 2d on October 23rd, 1889; the lowest 8½d in July last year. Exchange was highest (1s 8 15-16th d) on August 22nd, 1890; and lowest (1s 2 11-16 h d) in August last year. With these notes we offer the figures as sent to us by Mr. Shand to our readers:—

1889			1890			1891			1892

London, Feb. 9th, 1893.

SHAND, HALDANE & CO.

COFFEE HUSK CONSOLIDATION MACHINERY.—Since notifying in our December number the opening that exists for plant of this description in Brazil, we have received further inquiries for the names of makers of such apparatus, a firm of engineers having branch houses in London, Liverpool, Newcastle, and Glasgow informing us that they "have had repeated applications for machinery of this class." Surely briquette machine manufacturers should be sufficiently interested in the prospects of

the trade which is foreshadowed, to endeavour to meet the requirements of the planters who desire to utilise coffee husks as fuel.—Independent Review.

SEVERAL PLANTERS in East Sumatra look favourably on cultivation of the so called *Getah Gitang*, a kind of caoutchouc which abounds in the forest there and yields readily within a short time. This getah is said to fetch low prices at Singapore, owing to the careless way in which the Malays prepare it for market.—Straits Times.

THE CAUCASIAN "TEA" INDUSTRY, EXTRAORDINARY REVELATIONS.

A commercial swindle of the most barefaced description has lately been brought to light in Russia. The St. Petersburg correspondent of the *Standard* says that M. Gulishambaroff read an interesting paper on the "Transit of Tea on the Russian Railways," before the Russian Technological Society, in which he showed that various stations sent on a great deal more than they received, though no tea plantations existed in their neighbourhood. A striking example of this was the town of Kutais, on the Transcaucasian Railway, which in the year 1890 received only one thousand five hundred poods, a quantity not more than sufficient for its own consumption. Nevertheless, during the same year it sent out two thousand and thirty poods, a fact which led the lecturer to examine more closely this particular case.

It then appeared that an enterprising merchant of Kutais had applied to the "Caucasian Society of Rural Economy" to give him their enlightened assistance in order to procure special privileges for the manufacture of "Caucasian tea," of which he furnished them with samples. The chemical analyst of the Society discovered, however, that the so-called tea was nothing more than the leaves of the wild plant called "brussnik" (*Vaccinium acrostaphylos*), which grows in profusion in the forests round Kutais, and, in fact, over the greater part of Russia. The secret of the preparation of the leaves proved to be very simple, consisting merely in crumpling them in the hand, or treading them under the naked foot into a lump of "dirty green material," which was afterwards dried in the sun, under whose heat the leaves curled and shrivelled into a resemblance to ordinary tea. An infusion was made, but the taste was so bitter and abominable that nobody could be found to drink off a cup. Consequently, the Society refused its countenance decisively to the manufacture of Caucasian tea, a step which did not prevent the inventor from pursuing his happy idea, which soon found imitators. The extent to which this trade has grown may be guessed from the fact that from one property, near Kutais, three thousand poods were exported, at an average price of six roubles a pood. Considering that the cheapest tea on ordinary price lists is one rouble fifty copecks a pound, or fifty-six roubles a pood, the damage done to honest dealers by those who buy the "Caucasian tea" to mix with their stock can easily be imagined.

The best tea in St. Petersburg is quoted at four roubles, or eight shillings, the pound, and that generally drunk by the middle classes at about five shillings, and the consumption is enormous. It is shown by M. Gulishambaroff that the principal market for "Caucasian tea" is Odessa, from whence it is sent up to Moscow and St. Petersburg, and quite a sensation has been created by his revelation, since nothing of the kind was suspected, and in an elaborate monograph recently published by M. Lubhotin on "Tea and the Tea Trade in Russia and Other Countries" not a word was mentioned with reference to "Caucasian tea."—*Pioneer*.

VARIOUS AGRICULTURAL NOTES.

RUBBER CROPPING IN THE DUMBARA VALLEY.
—We regret to learn from Mr. Vollar that his Rubber cultivation in Dumbara is not likely to be permanent. The Cearas were originally planted as shade trees for the cacao, but they have not proved very suitable for this purpose and will probably have to be cut down. Meantime perhaps 5,000 lb. of rubber will be collected on Pallakelle this season: a coolly by beginning the tapping early in the morning usually gets 3 lb. of rubber in the liquid or soft state, which hardens and dries down to perhaps half that weight. There is no fortune to be made out of this, considering how long the rubber trees have to grow before yielding an appreciable quantity of milk.

COCONUT BUTTER is now being made at Mannheim. The method of manufacture was discovered by Dr. Schlunk, a practical chemist at Ludwigshafen, the butter is said to be very nourishing.—*Indian Agriculturist*, March 11.

COCONUTS AND CACAO OR LIBERIAN COFFEE CULTIVATION.—We call attention to the practical remarks of our correspondent "W. J." in reference to questions raised in our columns—more particularly as regards coffee or cacao being cultivated with coconuts.

BOLIVIAN COCA AND CINCHONA.—From the Peruvian port of Mollendo 123,000 soles' worth of coca-leaves were exported in 1891, the *Chemist and Druggist* tells us. These leaves, with few exceptions, come from Bolivia mostly from the district of Cuzco. The bulk of the leaves were sent to Hamburg. There is a tendency (assisted by the recent civil war in Chile) for Bolivian products more and more to come into trade by way of Mollendo, instead of as formerly via Tacna-Arica. The exports of cinchona-bark from Mollendo reached 217,200 soles' worth in 1891. Most of this also was of Bolivian origin.

SCIENCE AND COFFEE-PLANTING.—Our contemporary of the "Times" is plainly unjust in denying any benefit our coffee-planters ever received from "science" or "scientific men." First of all, he forgets that if the warning of one man of science—the late G. H. K. Thwaites, F.R.S.—had been attended to, Ceylon coffee planters would have saved a great amount of money put into coffee after 1870. Dr. Thwaites foretold correctly—though no one believed him at the time—that *Hemileia vastatrix* had come to stay and to wear out Arabian coffee in Ceylon. Then as regards Mr. D. Morris and Mr. Marshall Ward, each did undoubted good service to the planter, and the latter most fully and accurately worked out the life-history of the fungus pest, making it very apparent how impossible it was to fight it successfully in any large district in Ceylon. Science therefore should not be despised in the present day in regard to tea, though it is open to every planter and man of sense to consider what value should be attached to counsel of a positive as well as of a negative character. To be told what *not* to do, is often as important as it is to learn what ought to be done.

CEYLON TEAS AND KEEPING UP THEIR REPUTATION.—Tea planters will give all due consideration to the letter from Mincing Lane of Mr. Wm. Somerville, our esteemed fellow-colonist, in reference to the importance of keeping up the quality of our teas. There is a good deal in what is urged, and we have no doubt that Ceylon planters,—especially as a swing of the pendulum is about due in favour of fine teas,—will be careful not to abandon their medium plucking. But we should certainly have liked Mr. Somerville (as he was writing with the brokers and tea buyers within reach) to enter into some explanation of the state of the market and the distinct discouragement offered to fine teas since the beginning of the year. Here by this mail, one firm reports,—“Demand principally directed to sorts below 8d per lb.,” while another makes the following comparison:—

	Ceylon	Aug. '92.	March '93.
Pekoe Souchongs		6d	8½d
Broken Pekoe		11d	10½d

There can be no question of the effect of such a turn of the market in discouraging the shipment of souchongs; but we expect to see fine teas very soon in demand, and our planters will no doubt be on their guard.

DATE SUGAR.—The comparatively low price of *gur* and sugar and the scarcity of fuel in Bengal are said to be having a distinct effect in gradually reducing the old native industry of the manufacture of date sugar. An enquiry has recently been made with a view to reviving the industry, but it is found that the estimates that have been made of the profit to be derived from it are very much exaggerated. Date palms only thrive in the light loamy soils of Lower Bengal, where the climate is humid, and the prospect of any extensive growth in this industry does not seem to be at all promising at present.—*Indian Agriculturist*, Feb. 25.

STRAWBERRIES WANT WATER.—Strawberries when in flower and setting their fruit will usually require copious supplies of water, and will generally be benefited by mulching. For this purpose short grass or lawn mowings are very useful. Runners should be removed, if not required for making fresh beds. Bush fruits will also be benefited by mulching, almost anything that will check evaporation of moisture from the surfaces will answer the purpose. Moisture encourages slugs and snails, and these will have to be treated with strong but clear lime water, not whitewash.—*Horticultural Times*.

JUTE MANUFACTURE IN MEXICO.—London *Industries* says:—"An important concession has recently been granted to an American syndicate for the establishment of four extensive jute factories in different parts of Mexico. The concessionaires must invest at least £400,000 in the enterprise, work on the first factory to begin within nine months, and the building to be completed within three years. The construction materials and machinery for each factory will be admitted into the country free of duty. The capital invested, the buildings and the business will be exempt from all taxation, except the stamp tax, for ten years."

COFFEE NOTES FROM COORG. 14th Feb.—Take the case of the owner of a coffee estate who lives at home in England. Say a year's expenditure on his place amounts to Rs2,000 all told and he gets say an average of 35 tons of crop off it. For purposes of easy calculation we will take exchange at Rs15 per £ sterling, and the price realised for the coffee at £100 per ton. It is easy to see how he fares under these circumstances. To meet the expenditure on his estate he has to remit £2,133 $\frac{3}{4}$. He sells the coffee for £3,500, so that his income amounts to £1,366 $\frac{3}{4}$. If exchange went back to par we find his profits would be reduced to only £300 unless he curtailed expenditure which would be a very risky proceeding in these days of leaf disease &c. The above will serve to illustrate how every further drop in the value of the rupee benefits the Planter and how any approach to the par value of the rupee affects him prejudicially. By far the greater number of estates in Coorg have finished picking. Indeed I believe only a few out Somwarpette way are still somewhat backward. I will let you know results in my next. Pruning and manuring are now in hand Suntikoppa way but work in the Bamboo is almost entirely completed.—*Nilgiri News*.

RUBBER FORESTS IN BURMAH.—The Forest Report of Upper Burma says that it is hoped that two Assistant Conservators of Forests, will be employed on settlement duty during the next open season. At present officers can with difficulty be spared from district work for settlement duty. During the year 1,024 square miles of forests were notified as reserved in Upper Burma, and at the end of the year 3,978 were awaiting settlement. The total area of protected forests at the year's close was 16,461. Among the forests examined during the year were the famous rubber forests of the Hukong Valley. Mr. O'Bryen, the visiting officer, found the forests wastefully worked, but it is reported that the Katchin Chiefs, who collect and sell the rubber to Chinese merchants, are beginning to realise the disadvantages of destroying the trees by over-

tapping. Rules have been made on the model of the Assam rules, but these will remain a dead letter until the Hukong Valley is brought under direct administration; a task not likely to be undertaken at present. *Ficus elastica* is reported to extend to the Indawgyi Lake northwards, and northwest into Assam; but rubber does not appear to grow east of the Irrawaddy. A considerable area of rubber forests appears so remote as to be practically unworkable. Countings made in the forest showed a general average of nine trees per 100 acres, but on the jade mines road 50 trees per 100 acres were found.—*Indianrubber Journal*.

BURMESE RUBIES.—A Mandalay correspondent states that the Ruby Mines Company have obtained from their new borings at Kyoatpyin two rubies, one estimated at over five lakhs, and the other considered as one of the most valuable extant.—*Indian Engineer*.

MONSOON AND CROP.—This is a year of short crops generally, the estates that have been well worked and not stinted, are the ones that pay the current expenses and give a profit. An estate should pay its expenses in a short-crop year anyway, or it is a case of going back, and in other years it ought to give a handsome income to its Proprietor, at present exchanges and prices of coffee, which is a great chance for all who own coffee and land. Young plants should have soil pulled up round their roots before the hot weather sets in, after the monsoon, and ferns stuck in round them bring them on rapidly even in the poorest land.—*Nilgiri News*.

NICARAGUA RUBBER OUTLOOK.—The wasteful methods prevalent in many regions as regards the collection of india-rubber and gutta-percha have often been commented on in these pages. Happily, in some parts an improved policy is now adopted as we had occasion to notice last month in our remarks on the Congou rubber supply. But in Nicaragua improvidence as regards this valuable natural product is still rife. The rubber is procured by felling the trees, thus taking no care of the future whatever. Consequently, the yearly output of this valuable substance from Nicaragua is steadily decreasing. The Government attempts no supervision of the forests; anyone may cut down the trees, and great destruction is caused by the saplings being cut down as well as the mature trees. Yet it cannot be that the gutta tree cannot be cultivated in Nicaragua as well as elsewhere; in the district of Managua there are large tracts of lands that could readily be thus utilised. There can be no question that if it be profitable to plant tracts of land with coffee, oranges, &c, and wait years for the crop, that the financial return from a rubber crop would well repay the enterprising planters who turned their attention to it.—*Indianrubber Journal*, Feb. 8.

THE CAOUTCHOUC INDUSTRY OF ASSAM.—The *Calcutta Englishman* states that a change has been recommended in the present regulations affecting the sale of caoutchoac in the Government forests of Assam. Owing partly to the reckless method of working adopted by contractors and their agents, and partly to the depredations of illicit tappers, there has been a serious falling off in production. The unprotected and inaccessible situation of most of the rubber tracts enables the neighbouring hill tribes to illicitly tap the trees and import the rubber into Assam free of duty as foreign produce. It is stated that the Government forests on the frontier are overrun with foreign rubber tappers who come down systematically by night in separate gangs, each under a sardar, and tap nearly all the trees growing within a few miles of the border. The leases to contractors have, however, now expired, and a scheme for the better protection of the forests is now under consideration. On the average about Rs30,000 has been derived annually from this source during the past 10 years, and under an effective system of administration the revenue could doubtless be largely increased.—*Indianrubber Journal*, Feb. 8.

GAMBIR.

(From the *Agricultural Bulletin of the Malay Peninsula*.)
(Concluded from page 634.)

MANUFACTURE.

The leaves and twigs are brought to the factory, as above stated, in large rattan baskets, each of which contains about four cubic feet. Ten of these baskets will produce about 120 pounds of gambir.

After roughly taking out the larger sticks, the leaves and small twigs are thrown into a large iron cauldron of boiling water.

The cauldron is sunk in the clay floor of the shed, which is so raised as to allow of a large fire being built underneath. It is about five feet across and four feet deep and is filled full of the leaves. There are from two to twelve or more cauldrons in the shed, according to the size of the plantation.

While it boils two coolies are employed in stirring it round with large three-pronged stirrers made out of the hard wood of the *Tampinis* tree (*Sloetia sideroxylo*). These implements are about six feet or more in length, with a strong handle ending in a club-shaped portion with three prongs arranged in a circle. They are made from a single piece of wood. This stirring is considered the hardest part of the manufacturer, and the coolies employed in it are paid at a higher rate.

The leaves are boiled for some hours till they are quite broken up and yellow. They are then removed with the aid of a large wooden fork and a kind of rattan racket is also used to collect the bits which escape the fork. They are then thrown into a large trough made out of half a tree-trunk scooped out, about 12 feet in length, and cold water is poured on them. The first two washings are allowed to run back into the cauldron and then a small bamboo trough is put to the end of the large one, and the remaining liquid allowed to run off into the next cauldron. This liquid is used to boil the next lot of fresh leaves in. The broken up leaves while being washed are constantly stirred up with the large fork, and when the water runs off clear it is allowed to run into the second cauldron.

The liquid in the cauldron is still boiled for some time longer after the removal of the leaves, till it becomes of a deep brown colour, during which a perforated coconut shell attached to a rattan is suspended in it in which all the remaining bits are caught as the liquid boils. It is then baled out into little tubs about 13 inches tall and a foot or nine inches across and set to cool. Any remains of sticks, leaves &c. are carefully taken out, or, the Chinese say, it will not set. When the cauldron is used for the first time, it is necessary to boil some other leaves in it for some hours, or the gambir will turn out black owing to the formation of tannate of iron. Bamboo leaves are generally used partly on account of their abundance and partly perhaps on account of the silica which they contain scouring the rust off the new pan.

When the liquid is cool, the coolie commences the operation of setting the gambir. This is done with the aid of small cylindrical sticks of wood about an inch and a half thick and 9 inches in length, a little shorter than the diameter of the tub. These sticks are commonly made of Mahang puth (*Macaranga hypoleuca*), but really any stick of the right size will do, and I have seen even joints of bamboo used. Sticks which have been used several times will make the gambir set faster than newly cut ones. The coolie takes a stick in each hand and squats down by two tubs, and commences by giving the liquid a stir or two. Then holding the stick beneath the liquid in a sloping position away from him he passes his hand down it in a spiral direction, rubbing hard against the stick. This operation takes about a quarter of an hour. The liquid, which is at first of a deep brown chocolate colour, becomes gradually lighter and yellower, and almost suddenly becomes as viscid as treacle. It sbrinks considerably, about an inch in a painful, at the same time. When the hand can no longer move easily in the gambir the operation is complete. In a very few minutes the whole

has set in to a bright yellow claylike mass. It takes some hours to become solid enough to be taken out of the tub, but eventually a knife is passed round the sides of the tub, and the whole is turned out and allowed to dry.

In the bigger plantations it is put into a large hand-press and squeezed to expel the water. It is then cut into small blocks of 2 or 3 inches cube and put out to dry on a frame of rattan. It is dried partly over a fire and partly in the sun. As it dries the outside of the blocks becomes dark brown, the interior remaining yellow, and it is still quite soft like wet clay. It takes about half a month to dry properly, and is then made up into oblong blocks, wrapped in grass mats (Bale gambir), or left in the cube shape (Cube gambir) and sent to town for export. This is the Chinese method of manufacture of bale and cube gambir in Singapore and the Straits generally. In Bangka the method adopted is different, and will be described below. The Malays adopt the Chinese plan, with some variations in the making up of the stuff, as they manufacture gambir for chewing with betel, and have hardly as yet begun to manufacture for export. In Couperus' time the method was slightly different. The cauldrons had at the top a continuation in the form of a cask of staves three feet high and luted with clay, so that it was not burnt by the fire. The advantages of this were that a smaller kettle could be used, the liquid is said to boil better in it, besides offering a smaller surface of iron to the liquid gambir, by which a better coloured product was produced (owing to a smaller formation of tannate of iron). I have seen this arrangement in some boiling sheds. Copper boiling pans would obviate this chemical change to a large extent, as copper is not acted upon by tannic acids.

The liquid was then poured through a sieve into earthen pans and set to cool. When cool enough to put the hand in the planter took a piece of linen in his hand with which he continually stirred the sap, and every now and then wrung the linen in the liquid whereby the sap became speedily thick and stiff. It was then left till quite cold, when it was bundled in a piece of flemish linen and placed under a press to drive out the remaining water. The press consisted of a long beam, one end of which was inserted into a hole in a tree or a post and the other weighted with stones. The gambir was put in the cloth between two boards and the weight of the stones allowed to drop on it so as to squeeze out the water.

This method is not in use now, as far as I know, but the Malays sometimes get the gambir by merely crumbling the liquid as it were in their hands and not using a stick or piece of linen at all.

BANGKA METHOD.

The account of this I take from Dr. Van Romburgh's Report, 1891 (*Korte Berichten uits Lands Plan tenuin*). The leaves and twigs are first gathered and exposed to steam for 15 minutes, the mass still hot is put into a basket made of plaited rattan and placed under a wooden press of most simple construction. The liquid is collected in earthenware dishes and exposed to sunheat until it is sufficiently inspissated, when it is removed on to a flat board, with very low sides, of a height equal to the thickness of the cakes. In this wooden tray the gambir is cut up into cakes by means of threads and is left till it is dry enough to be turned over and still futher dried in the sun.

Here it will be noted that there is no stirring of the liquid or rubbing it with a stick required. It seems to set of itself.

The Bangka gambir, which was analyzed by Dr. Romburgh, consisted of light yellowish brown flat square pieces that floated on water and only sank after long immersion. In fact it is what is known here as *gambir papan*.

The result on analysis of this product is very different from that given by Mr. Evans from gambir exported from Singapore, but I do not quite under-

stand the figures which in all Dr. Romburgh's calculations work out to above 100:—

Water	18.5 %
Catechin	57.0 about
Catechutannic acid (absorbed by hides)	1.6
Matter (organic) insoluble in boiling water	2.5
Matter (organic) insoluble in boiling alcohol	8.5
Matter (organic) insoluble in boiling alcohol	1.8
Ash	2.6
Organic matter other than the above	20.0 about

Total...112.5

Some of this Bangka gambir was sent by the *Factorij der Nederlandsch Handel Mijners* to some experts (merchants) in Singapore, who reported that the gambir was boiled too young and was mixed with *deduk* (rice dust), quite unsuited for export to Europe and only fit for consumption in Java. Dr. Romburgh thinks that this supposed appearance of *deduk*, of which he declares there was not a trace, was possibly due to the product being richer in catechin which separates in larger crystals, either because the product is pure or has been less agitated on settling.

ADULTERATION.

A good deal of complaint has risen lately about the inferiority of the gambir exported now, which has been stated to be much adulterated. I cannot find, however, that, excepting in a certain class of chewing gambir, there is any adulteration properly so called. In chewing gambir, made in Negri Sembilan and elsewhere, rice dust called *deduk*, is often added, rather, I believe, to give a whitish colour than to increase the bulk.*

It is the excess of water that is most complained of. Mr. W. N. Evans, of Bristol, writes that the ordinary block comes over with 30 to 50 per cent. of water in it. This seems an enormous excess and could certainly be reduced. It was reported to me that it was a common practice of the Chinese town *toekay*, who purchases the gambir from the manufacturer, to open the sacks and pour water upon the gambir pounding it in to increase the weight. To test this, I sent Mr. Evans some gambir which I took out of the manufacturers' shed, and which had not passed through the *toekays'* hands at all. This he analysed and I append the analysis of this and one of gambir after it had passed through Singapore.

	Ordinary block gambir from Singapore.		Sample from the field.
Tannin ..	14.63	..	11.48
Organic matter	42.26	..	30.11
Water ..	31.89	..	53.39
Ash ..	6.34	..	4.46
Loss ..	4.88	..	.56
	100.00		100.00

The organic matter contains catechin and other organic acids not precipitated by gelatine. From this it can be seen that there was absolutely more water in the manufacturer's gambir than in that of the *toekay*, and, therefore, it is probable that this adulteration does not, in the general state of things, take place. Mr. Evans then suggested that I should dry a quantity of the leaves in the shade and export them to England in order that the gambir might be extracted from them, and so the heavy loss due to the excess of water might be avoided. I was not so sanguine as to the results of this experiment as he was, for in the first place, a case of dried leaves is very bulky in proportion to the amount of gambir which could naturally be expected to be derived from them, and in the second place, from the taste of the dried leaves and from what the Chinese told me I was convinced that the drug absolutely disappears on drying, and this indeed proved the case. I found it impossible to dry the leaves in this wet climate in the shade, as they merely decomposed, and so had to use artificial heat which, however, I kept very low. The leaves on being tested by Mr. Evans did not contain a trace

* Couperus says that in his time the people of Patabakan mixed a portion of the boiled leaves with the gambir to increase the weight. Those of Kampar (Sumatra) cut the cooked leaves as fine as flour and mixed them in, and the Siak men added sago flour

of gambir. As a matter of fact it is essential to treat the leaves as soon after plucking as possible; after twenty-four hours they become brown and worthless.

This being so, it is obvious that the gambir must be manufactured on the field, and the water should be extracted there. There should be no difficulty about this in ordinary circumstances, but as a rule, little trouble appears to be taken with this matter. Very few of the Singapore plantations possess even as simple a press as that described by Couperus, and the Gambir is, in fact, not pressed at all.

Mr Finlayson tells me that the shrinkage of bale gambir is $7\frac{1}{2}$ per cent by steamer to London. If this shrinkage could be saved a higher price could be paid for gambir here, and certainly it ought to be possible to extract at least this amount of water before shipping it. Some gambir that I have seen which was supposed to be fit for sale in Singapore was so wet that in a day or two it was covered thickly with a dense crop of mildew. This contained nearly 50 per cent of water.

(To be concluded.)

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, March 2.

CINCHONA.—A cable from Java announces that the exports for February have been light:—370,000 Amst. lb. against 420,000 Amst. lb. in February 1892.

CINNAMON.—At the quarterly periodical sales held on Monday; 1,006 packages Ceylon bark were offered. About one-half of this sold with good competition at an advance of about 1d per lb on medium and ordinary, and 2d to 3d per lb on good fine qualities. The following prices were paid:—Ordinary to superior firsts 8d to 1s 7d; ditto seconds $7\frac{1}{2}$ d to 1s 3d; ditto thirds $6\frac{1}{2}$ d to 1s; fourths $5\frac{1}{2}$ d to 10d per lb.

ANNATTO.—Seed is still declining. At today's auctions 2d per lb. was accepted for 12 bags 'good bright seed from Madras, while for another parcel from Colombo 2 $\frac{1}{2}$ d per lb. was the highest bid obtainable. This was rejected.

CALUMBA.—Slightly easier, 25 bags sold today at 29s per cwt. for very very good bright yellow, and 20s for rather dark mixed sorts.

ESSENTIAL OILS.—Lemongrass oil keeps steady at 2d per oz on the spot, or 1 $\frac{1}{2}$ d c.i.f. for Ceylon oil. From Ceylon none is offering at present. Citronella does not move off so well. The spot price is $\frac{3}{4}$ d per oz., and the c.i.f. quotation 10 $\frac{1}{2}$ d per lb. for tins and 10 $\frac{1}{4}$ d per lb for drum.

SILK WORM REARING.—The Calcutta Silk Committee are be congratulated upon the success which has attended their efforts to improve the Bengal silkworms, says a Calcutta paper. Their little silk-rearing establishment in Kidderpore is a picture of neatness, and the big basketwork trays laden as they were a few days ago with golden cocoons from which the moths were expected to appear, make a sight that is calculated to astonish anyone who has been used to the solvent methods of native rearers in the mofussil. What is of most interest, however, is the quality and size of the cocoons, which differ almost as widely from the native product as the studbred horse from the ticca garri tat. The native rearer as is well known, takes an immense amount of trouble, and often travels great distances to obtain good silkworm eggs; but the uncertainty produced by disease combined with the unmethodical habits of the Bengali, when working for himself have hitherto been fatal to any proper system of selection such as is generally pursued elsewhere. In the Kidderpore establishment, the element of disease has been to a great extent eradicated by the treatment which has proved so successful in Europe, and this has enabled the selective system to be followed which in the hands of the horse breeder has produced the thoroughbred and in those of the market gardener has turned the sloe into the plum and more than doubled the amount of sugar stored up in the beetroot.—*Pioneer*

TEA AND SCIENCE.

It is impossible to get ignorant critics like this Mr. Peter Keeveney of Manchester—whose vapourings, reproduced by the *Home and Colonial Mail*, will be found on page 690—to listen to any reply from Ceylon. He maintains after the most authoritative fashion that “the tea gardens in Ceylon have been forced to a point of exhaustion that is now telling against the quality, and if we give him a flat contradiction and some of the evidence at our command, he simply turns round and declares “Oh you are interested—you are a Ceylon resident and of course desire to maintain the credit of your Colony, &c.” Now it seems to us, that here is just a case in which an agricultural and analytical authority from home, furnishing a Report after some months spent in our Tea Districts, could be called on to reply as an impartial and all-sufficient referee, to such slanders. In fact Mr. Peter Keeveney and his tribe could from time to time, be confounded and shut up with a copy of the Report itself probably.

CINCHONA REPORT.

(From the *Chemist and Druggist*.)
LONDON, March 9th,

CINCHONA.—The fortnightly auctions held on Tuesday were unusually heavy, no less than 3,781 bales of bark being catalogued, of which, however, 118 bales were withdrawn. The remainder was composed as follows:—

	Pkgs.	of which	Pkgs.
Ceylon cinchona ...	773	1758	were sold
East Indian cinchona ...	2,295	do	2,115 do
Java cinchona ...	63	do	68 do
South American cinchona ...	527	do	527 do
	3,663		3,463

The quantity actually offered fell considerably below what had been expected, as the manufacturers had received samples of over 5,000 bales. The assortment was a fairly good one, Indian barks, especially grey and yellow varieties, being very plentiful, considering the extent of the sales, and the fact that it is known that the next Amsterdam auctions will again be very large ones. Tuesday's sale was not altogether unfavourable. All the German works competed very well, and the average unit was scarcely notably lower than that of the previous sale. It may be put at from 15-16ths d. to 1d per lb.

The following are the approximate quantities purchased by the various buyers:—

	Lb.
Agents for the Auerbach factory ...	198,972
Agents for the Brunswick factory ...	174,646
Agents for the Mannheim and Amsterdam works...	121,347
Agents for the Frankfurt o/M and Stuttgart works	71,015
Agents for the Paris works ...	46,910
Messrs. Howards & Sons ...	34,620
Mr. Thos. Whiffen ...	15,520
Agents for the American and Italian works ...	2,000
Sundry druggists..	78,312

Total quantity of bark sold ...	743,342
Bought in or withdrawn...	81,710
Total quantity offered ...	825,052

CEYLON CINNAMON.

It will have been seen from the information which we published in last Tuesday's issue, that only a very small quantity of cinnamon was offered at the last quarterly sales held in London on the 27th ultimo. The falling off in the quantity of the spice catalogued—itsself explained by the failure of the South-West and North-East rains and the consequent difficulty of harvesting the two crops—is sufficient to explain the rise in prices. Only 967 bales were brought under the hammer, as compared with 2,495 bales at the previous auction in November, and with 1,487 bales at the corresponding February sales of 1892. Naturally, competition was keen for this reduced quantity, and specially so for fine sorts, in which only three marks were represented. The

coarser sorts advanced only ½d to 1d per lb.—some marks made no advance at all while fine quills fetched from ¾d to 2d per lb. more. This difference affords gratifying evidence to the leading Marks that there is a demand yet for fine spice; and that the apprehensions felt and expressed in London, and re-echoed here last year, that the day for fine spice had passed, were not well-founded. True, the catalogues contained an exceptionally small quantity of fine spice; but the fact of a demand remains. The lesson to be learnt seems to be that it is not over-production generally which alone has had a disturbing effect, but over-production of the finer sorts as well. As usual, A. S. G. P.—the Mark of the Goula Pokuna spice which is maintaining its reputation under its new Superintendent, Mr. Gerald Nicholas—topped the list with 1s 7d for its firsts, and correspondingly high prices for the other qualities. J. D. S. R. and F. B. Franklands followed with small quantities; but the Wester Seaton and Kimbulapitiya Marks were not represented. Not the least interesting feature in the sale was the large quantity of unworked Cinnamon which changed hands—that is, spice which had not incurred the heavy cost of unpacking, brushing and repacking in the Dock Warehouses. Nearly one-half of the quantity offered was “unworked”; and that about 300 Bales of it were cleared at from 6½. to 8d. per lb. is a hopeful sign. If buyers find that there has been no adulteration, and that the Bales as landed contained what they purported to contain, there may be a chance for the demand put forward often from this side, that shipments be sold on average samples drawn from the various qualities, without any superfluous and expensive manipulation in London. If the trade once accepts this reasonable request; for it is absurd to suppose, either that the leading Marks will expose themselves to the loss inevitable from the certain detection of attempts at deception, or that the spice can improve by unpacking and exposure in the damp and unsavoury atmosphere of the London Docks—the small profits which Cinnamon yields to the grower need not be reduced by a needless addition to the big London charges.

Since the Sales, we are glad to note prices have been maintained and have even advanced. The rains we have had since the middle of February have favoured harvesting operations, and a good deal of spice which would have coarsened against the big crop, has been harvested within the last few weeks. Still, the quantity cannot be very large; and although the May Sales might show a rarer Catalogue than the February one, the falling off in the Exports of last year cannot be made good at once. Indeed the shipments up to date are less than those for the corresponding period of the last three years, so that there is every prospect of the advance in prices already recorded being maintained, at the next Sales.—Local “Examiner.”

SCIENTIFIC NOTES.

More than a quarter of a century ago a remarkable book was written by Mr. Marsh, United States Consul at Florence, entitled *Physical Geography as Influenced by Human Action*. It gave a long list of instances in which the indiscriminate cutting down of forests had affected the rainfall of countries. Climate is an exceedingly sensitive thing, and every leaf on every tree, shrub, and plant influence it. Vegetation is a marvellous regulator of climatic conditions—particularly of rainfall. Cut down the forests of a country, and the rainfall becomes irregular; so, of course, does the volume and velocity of rivers, floods, and torrents. Such altered conditions bring about extremes of dryness and wetness. Let all the vegetation be cleared away, and perhaps general aridity, and therefore sterility, are the results. It is within the province of man thus so to influence the dryness of the country for

better or for worse. There was something more than appears at first sight in the remark of the laird in Sir Walter Scott's novel who recommended people to be "aye sticking in a tree."

In the last number of the *Kew Bulletin*, a periodical devoted to practical and economic botany, we have a remarkable illustration of the influence of mankind upon local climates. In Africa, the country between the Nile and the Red Sea is notable for its general barrenness. It is a desert, and the effects of wandering in this region upon the minds of Englishmen—as I can personally testify—are very depressing. But the *Bulletin* shows that this physical condition of things has very probably been brought about by human agency. This is largely proved by the names of localities. Thus the Arabic names of the valleys are those denoting the names of trees, although now not a single tree is to be met with. There can be little doubt these valleys abounded with arboreal vegetation 1,200 years ago—about the period when the Arabs began to extend over these regions. The Arab and his camel have been the means of converting a wooded country into a desert, and also of bringing about the climatic changes following upon such a physical revolution. The camels ate the leaves of the trees, and the Arabs converted the trunks, branches, and roots into charcoal. Similar vegetable destruction, it is believed, brought about the semi-desert-like physical appearance of Palestine, which so strongly contrasts now a-days with the description of the country in the Old Testament as a land flowing with "milk and honey," and whose tribal wars show that it was capable of supporting thousands of horses, chariots, and horsemen.—*Australasian*.

NOTES ON PRODUCE AND FINANCE.

BIMETALLISM AND TEA.—Some correspondence under this head has been published in the *Manchester Guardian*. A correspondent, signing himself "Disappointed," writes:—"I enclose reports on the tea market in London for 1st and 2nd inst. Indian and Ceylon tea show a falling off in consumption in the United Kingdom, of nearly 2,000,000 lb. in February, 1893, as compared with February, 1892, and the demand has been running for weeks past on common qualities at low prices, to almost the utter neglect of the higher grades. This state of matters corresponds so entirely with the state of the Manchester market for Indian makes of shirtings, the lower qualities only having been in request for many weeks past, that I beg to call attention to the matter. Whether tea and cotton goods are being over-produced may be a matter of controversy, but surely there cannot be two opinions with respect to the demand being now confined to the lower qualities of both, *i.e.*, of tea in England and of cotton goods in India. Both would seem to prove that it is inability to buy the better articles rather than choice that has brought about this state of things. Common China Congous, once so neglected, are now owing to their extreme cheapness, being taken readily by the trade. From this point of view the figures may prove interesting to your readers, but they are the reverse of encouraging. Anyone who attentively reads the instructions given by the Government to their representatives at the Brussels Monetary Conference will see that it was never intended that they should concur in any measure whatever. They erred egregiously in not following out their instructions to listen attentively, and make notes, and this brought the Conference to an abrupt termination, which, to say the least, was bad diplomacy on their part, for even without the assistance of England the other nations might have elaborated a scheme for their mutual benefit if England had not so stupidly displayed so hostile an attitude."

FINE TEAS IN GREAT DEMAND.—In answer to this, a letter appears, signed "Peter Keeney," in which the writer says:—"There cannot be two opinions

with respect to the demand being now confined to the lower qualities of both—that is, of tea in England and cotton goods in India. I know nothing of cotton goods, but fancy I understand tea, and I venture to assert that the finer teas have not been in greater demand for many years than they are today. Admitting that 2,000,000 lb. less of Indian and Ceylon have been taken by the trade last month as compared with February, 1892, that does not prove a greater consumption of common tea than usual; it simply points to a falling off in consumption from the great depression in trade generally. This season's Ceylons are unusually poor, but the Indians are exceptionally satisfactory, and hence it follows that the falling off is in the Ceylons. For reasons best known to Ceylon planters the gardens have been forced to a point of exhaustion that is now telling against the quality. The teas are flat and badly made, and in point of value are fully 12 per cent. dearer than Indians. The great bulk of common teas sold in London are for the Russian market, and never find their way into the channels of home consumption. Those people unacquainted with the movement of tea naturally conclude that the low priced congous sold in London find their way into English homes, but such is not the case. China will have to improve her quality of tea very much indeed before she regains her lost reputation. Bad as Ceylons are this season, they are infinitely superior to Chinns. Whatever effect bimetalism may have on trade and trade prices, nothing will force the people of these islands to drink low priced congous."

THE RESPECTIVE MERITS OF INDIAN AND CEYLON TEAS.—"Disappointed" replies to Mr. Peter Keeney as follows:—"In reply to his letter of the 6th inst. allow me to point out to Mr. Peter Keeney that he has introduced a question which I did not touch upon, *viz.*, the respective merits of Indian and Ceylon teas. The proof of the pudding is said to be in the eating thereof. The average prices for the above-named teas realised at public sale for the past two weeks were respectively as follows:—Indian, 9³/₄d and 9³/₄d; Ceylon, 9³/₄d and 9³/₄d. During the past nine months bonded stocks of Indian tea have increased by 2,600,000 lb., and Ceylon stocks have decreased 2,700,000 lb. London deliveries of both teas during February last were unsatisfactory as compared with the same month in 1892, *viz.*—Indian, 8,689,410 lb., as against 9,899,400 lb.; Ceylon, 4,104,000 lb., as against 4,769,000 lb.; total, 12,793,410 lb., as against 14,659,400 lb., or a falling off of nearly 2,000,000 lb. as previously stated by me. It is not clear whether the large sales effected of cheap China Congous have been for home consumption or for export. If they have been principally exported, then the lessened figures for strong Indian and Ceylon tea go to prove that the masses are extracting more from them in the form of liquid tea than is good for their health. All the tea broker's reports mention that the demand lately has been principally for the lower and cheaper qualities, while high-class teas have been neglected and are relatively now very cheap."

ON THE INFUSING OF TEA.—Writing on the subject of tea infusing and "Thoughts on Theine," a correspondent points out the absurdity of calling tea that has been infusing ten minutes "delicate" or "nectar for the gods." He is of opinion that tea should remain in the pot about a minute and a half, or at most three minutes, and he argues that if the consumer would abandon the absurd and harmful practice of stewing tea, or, as they do in some poor households, using the leaves a second time, the popularity of tea would increase enormously, and both the planter, the dealer, and the customer would benefit. He quotes the opinion of Dr. Hutchinson, in proof of his contention that tea infused for a minute and a half may be taken as often as possible without injury. It would certainly be a great boon to the consumer of tea, who likes it mild doses, if at the various hotels, tea-shops, and restaurants they would simply infuse for a very short time and not stew tea. The awful stuff sold as tea in the cup, in some public places, is enough to prejudice the public mind against tea for ever.—*H. & C. Mail*, March 10.

COFFEE AND TEA IN QUEENSLAND.

The colonists of North Queensland are very fond of dabbling in experiments in our Ceylon staples, but without making much progress. We notice from our exchanges last to hand that Mr. R. V. Webster (formerly of Opalgalla, Rattota) has been writing to the press on "Tea—how it is grown and prepared in Ceylon"; while on Coffee there is rather a long letter signed "W. J. Thompson, Cairns," in which some rather curious statements and calculations appear. We quote as follows:—

COFFEE IN QUEENSLAND.

To the Editor of the *Queenslander*.

Sir,—There are scattered along the whole coast of Queensland, specimens of both varieties of coffee (Arabian and Liberian) flourishing without attention or care, and giving an annual crop per tree that would make them the show trees on any of the Southern Indian coffee estates. Some of these trees are as much as 12 years of age. It is easy to see that for some years they have been allowed to grow at "their own sweet will," then some one has attempted to prune them into shape, but still they crop heavily. In any other country they would resent such treatment by either dying out or refusing to crop.

With all the experience of Southern India and Ceylon coffee planters to be had for the asking, it is astonishing to hear of men who are looked upon as competent advisers still advocating the hillside system of planting. The fault evidently lies in the form in which the question is put. If we ask, "How do you plant coffee?" we get for answer "On newly felled jungle (scrub) at an elevation of from 2000 feet to 5000 feet; pot holes are made 6 feet apart among the stumps and logs; and the plants set in them; the weeding is done once a month by a gang of coolies." Now, in this answer which is a truthful one, there are two things that we do not possess in any quantity—that is elevation and coolies, so we had better refer to the coffee trees that have already told us so much. They, we shall find, are flourishing best on flat land with good natural drainage (nearly every sugar planter has a few in his private garden), and they are giving an annual crop of from 3 lb to 5 lb of clean coffee per tree at from 3 to 5 years of age. If we ask the experienced planter what he was told by the experts and scientists he called in to report on leaf disease in the years 1878-9, or still better refer to their printed reports, we shall find that they attribute the appearance of *hemilia vestatrix* to (1) Want of deep cultivation; (2) the proximity of half-rotten roots and logs; (3) the excessive use of the hoe and half burying weeds in so-called renovating pits. This then is the pernicious system that those asking for information are told to adopt! Fortunately the few trees that can be distributed by the Acclimatisation Society will be too isolated to incur any great risk, but should this system be carried out on a large acreage the result cannot but be disastrous. Apart from this the old system is both expensive and slovenly compared with that advocated by me in my last article on the subject. Let us compare the estimate of cost of upkeep only with the two systems on 50 acres at the lowest cost of labour:—Old System: One man to every 3 acres equal to 16 kanakas at 15s per week equal to £12; 52 weeks at £12 per week, £624. New System: Two ploughmen at £1 per week, £104; rations, £52; 2 small ploughs £11; 2 harrows or scarifiers £9; 4 horses at £10, equal to £40; total £216. Here at once in the first year we have a saving of £408, with the highest state of cultivation, under which treatment the coffee tree will sit up and show what it really can do in a new country. If we put the whole £408 against cost of stamping the land we still have the saving in future years, which will go beyond the cost of picking the heaviest crop with outside labour.

Some two years ago the system I am now advocating thrust itself upon me, through seeing about ten

coffee trees planted in one row, and all had just borne a heavy crop, and were withstanding a drought from which orange and other fruit trees were suffering. The sum I worked out upon the spot was something like this—10 trees, bearing 5lb. each=50lb.; 1 acre, planted 8ft. x 8ft.=646 trees; 646 multiplied by 5=3,230lb., or 1 ton 8cwt. 2qr. 24lb., or at 1s. per lb.=£161 10s. per acre. As I knew that figures could not always be trusted I halved it, and still felt quite satisfied with the result—namely, £80 per acre per annum. The next thing that struck me was the ease with which a large acreage could be "kept in hand" by the use of implements and horses, and thus, as far as coffee was concerned, do away with the labour question. Any one with the least knowledge of the use of field implements will at once see that by planting on ploughed land the space between the plants when planted 8ft. x 8ft. can be kept clean by a horse-hoe or scarifier, not a weed need be allowed to seed, and grass will be entirely eradicated in hot weather. In the case of sugar on stumped land the rows can only be kept clean with implements while the cane is young and the hoe is required to clean among the cane, but in the matter of coffee there will be a free passage for horses across and across the field. Acting upon these figures and the settlement of the labour difficulty by the adoption of this system I obtained the lease with the right of purchase, at a stated figure, of this selection, and have now some 20,000 plants of the best variety of coffee, known in Southern India as Cooy [*sic*—Goorg] coffee, ready for the field. I anticipate a great success in this industry, more especially if the capital is forthcoming to enable me to double my acreage next year.

NORTH BORNEO DEVELOPMENT CORPORATION.

A report, dated Jan. 8th, has been received from Mr. W. B. Pryer, manager of the above corporation, in which he reports the operations undertaken during the six months ending Dec. 31 last. The total land planted with various products approximates 1,000 acres, which may be considered good for the time operations have been in progress. With regard to coffee, the Byte estate has received the most attention, the total area planted there being about 170 acres. The total acreage of coffee planted on the three estates is 215 acres, with 75 acres more in course of being planted. Mr. Pryer states:—I venture to hope that the area planted up this year will be considered satisfactory. The acreage under coffee vies in size with most other British-owned estates, with one exception, in the Far East; a large number of Manila hemp plants are growing well; the acreage under coconuts and sago will show a yearly advance in value out of proportion to the money spent on their upkeep; the sugar cane promises well, and various other products have been tried with result with but one or two exceptions, that would seem to be worth while following up. We have a settled population, small at present, but giving signs of considerable increase in the future, to draw a supply of cheap and reliable labour from, and who are also, without expense to us, putting a value upon the land; we have large nurseries of coffee seedlings, many thousands of Manila hemp suckers ready to plant out, and a large supply of sugar cane ready to afford tops for the future extension of this industry, and we are daily advancing in our knowledge of our land, and the purposes for which it is best adapted.—*L. and C. Express*, March 10.

PEARL FISHERIES.—The Government of India has referred the question of the Mergui pearl fisheries to the Secretary of State for India. His decision is awaited with interest in the East, as the local Government claim the right of territorial jurisdiction, which is at variance with the position of the British Government in the Behring Sea controversy.—*Colonies and India*.

THE REGULATION OF HOME TEA IMPORTS.

When last writing on this topic we noticed a suggestion from home that it might be possible for our Planters' Association to negotiate arrangements by which its members should bind themselves to prepare a certain preparation of tea of different grades for shipment according to the requirements of the home tea trade. This suggestion was the outcome of complaints made by Mr. Peek, the Chairman of the London Wholesale Tea Dealers' Association. We have little faith in anything of the kind being practicable. We are now informed as to the further proposal discussed at a meeting of the same London Tea Association summoned to consider Mr. Peek's letter. Unfortunately we are without details of the discussion that followed the bringing forward of Mr. Peek's proposal; but the main facts of it are known, and sure at least to warrant consideration from those who are interested in the prosperity of our tea planting industry. Those who appear as yet to have chiefly interested themselves in this matter apart from the Wholesale Tea Dealers' Association are the Indian tea planters, and we are told that Mr. Wallace, of the Johore Tea Company, has taken the foremost lead in bringing Mr. Peek's suggestion to active discussion. The scheme most in favour at the meeting seems to be that a union of the chief importers should be formed with the object of binding themselves to limit their orders to certain proportions of each grade of tea; and it must be admitted, that the formation of such a union affords the prospect of at least some degree of controlling action. Certainly, more so than would any course that might be followed by a single tea-growing country. It seems likely that the importers would be able, did they all work in unison, to influence the proceedings of planters in nearly every locality wherein tea is grown. But at the same time, while admitting so much, it must be recognised that in many directions they will fail to present independent action, and their best calculations would be liable to be upset and the effect of their action to be materially impaired. Many planters are their own exporters, and some proprietors are even their own importers, direct their own sales, and act with full independence of the professional importers who simply buy the produce of estates as it is brought forward, and who can exercise no control whatever upon the producers. While such independent action may be possible, the question must remain how far the professional importers can direct the course followed by planters who may remain unfettered by any accepted obligations? So long as the latter choose to stand outside of any combination, so long will they follow their own judgment, and it may well be that these may deem that their private interests could be best served by proceedings directly at variance with the conclusions arrived at by an Importers' Union. Notwithstanding these difficulties it may be accepted as a fact that all, whether producers or simply dealers, are injuriously affected by the severe fluctuations in the price of tea to which Mr. Peek's letter directed attention. What that gentleman wrote as to this fluctuation and its most leading cause cannot be gainsaid. If an Importers' Union should be formed, we should hope to see it receive the co-operation of tea planters as far as possible, for it would be to their interest to do anything to aid the object it would have in view.

PLANTING IN EAST AFRICA.

AN ASSISTANT WANTED.

In directing attention to the advertisement by Mr. W. H. Cowley for an assistant in East Africa we make the following extract from a letter from Mr. Cowley:—

You will note I state the assistant "must be in sound health," and I am taking the precaution to state this, not because this is a bad climate, but because anyone with a weak constitution, and therefore more susceptible to any malaria knocking about, has no business to apply; and medical certificates will be called for from the eligible applicants. Of course at certain seasons when land is being cleared, and whilst the rotting vegetation lies on the ground, it is feverish more or less, but it is the same in almost every tropical country, and as the land gets opened up the chances of getting fever rapidly diminish.

The free copy of your *Overland* and the *T. A.* came to hand a few days ago and very many thanks for both. Sinclair's letters are most interesting and when reading them I was wishing myself in Peru. There is lots of work yet for Ceylon planters to do.

The Chief Engineer of the railway line has come out, and others, I fancy, will soon follow to begin work in earnest, I hope. Every steamer coming here now brings railway material of all kinds.

BRAZIL COFFEE NOTES.

The price of ground coffee has risen to 2\$ per kilo. The Lamport and Holt steamer "J. W. Taylor" left Santos for New York on the 8th inst. with a cargo of 52,110 bags of coffee, one of the largest cargoes which ever left that port.

From the *Gazeta de Noticias*:—"Your coffee has one very good feature and one very bad one." "How so?"—"Its good feature is that it contains no *carnauba*; its bad feature, that it contains no coffee."

Incredible! On the 8th some police and sanitary officials "raided" an establishment in Rua Barao de S. Felix where coffee is roasted and ground for the retail trade, where they found a large quantity of coffee mixed with Indian corn. And this in Rio, the greatest coffee market of the world!—*Rio News*, Feb. 14.

A CUP OF TEA.

BY CLEMENT SCOTT.

"Tea or coffee, sir?" The question is asked countless thousands of times all over England every single day of the year. But few at home are aware how very important is the answer to it to the industrious planter of Ceylon, the cheery, open-hearted fellow who by pluck and determination has turned the once most productive coffee-ground in the world into the best tea-bearing island that is blest with burning rays of tropical sun and almost daily tempests of tropical rain. This is what the sturdy little tea-plant lover, and so she has flourished exceedingly on the highlands of India, and has indeed "flourished like a green bay tree" both in the lowlands and the highlands of Ceylon. Tea, and tea alone, has become the salvation of this sunny land, where you can be in a moist, muggy, and truly West Indian climate at Colombo, and in a few hours as braced and invigorated on the green uplands as if you were on a summer holiday in the Swiss Engadine, basking at St. Moritz or Pontresina, or "dreaming the happy hours away" in the hill-country of our own Scotland and North Wales. Since I arrived at Ceylon I have been transported in imagination to one and all the places I have mentioned, so exactly does Upper Ceylon, smiling with vegetation, well watered and full of roaring cataracts, cultivated and recultivated in every available inch, correspond to the best and most popular holiday grounds of England and Western Europe.

And here, before I proceed to show you how the failure of coffee in its stronghold has become the salvation of tea, I may be permitted to digress for a minute in order to point out, or rather to suggest, how the lovely island of Ceylon might be made, with a little capital and a fresh infusion of English energy, the great sanatorium of the world. In my travels so far I have not met with one single individual who has not voted enthusiastically for Ceylon as one of the most charming spots on earth. Egypt and Ceylon run a very good race for supremacy in the matter of climate. You may remember how I basked on the terrace of Sheppard's Hotel, at Cairo, and saw the sunset between the old Pyramids, walking round the Citadel where Tommy Atkins protects our British interests. You may recall a journey up the Nile, and a donkey-ride across the desert to Sahara. You cannot have forgotten how I told you how the invalids chased out of Torquay and Bournemouth, driven by one doctor to the Cape and another to Australia, exposed to all the many discomforts as well as the so-called rest of a long sea journey, found themselves ultimately banished to Luxor, there to recover or to be laid to rest with the mummies in the Egyptian sand. It was of these same invalids that I thought one lovely January morning as I sat, after breakfast, under a tree glorious in blossom, in the garden of the mountain hotel at Nuwara Eliya, in an atmosphere as pure and soothing as any sick person could desire. In a very few hours you can be transported by the mountain railway from the heat of the plains, to the cool of the hills, and it would cost no considerable exhaustion to the invalid to breakfast in the bright morning at Colombo and dine in the delicious evening at Nuwara Eliya. Kandy has its many advantages, and so have countless hill stations; but the enterprising folk who are always ready to build hotels for the strong and the sick should think seriously of Nuwara Eliya as the spot for a mountain sanatorium at Ceylon. The climate there is equable, never too hot and seldom too cold. The mountain ranges are superb, the whole district grand in flower and foliage. Already this favored paradise has its club, its racecourse, and its tree-sheltered hungalows. Here are walks and drives and mountain excursions without number, and if a fashionable doctor or so in London could be induced to write a pamphlet on "Ceylon as a Health Resort," I doubt not that there would be plenty of visitors every winter to sip tea in the very heart of its own tea bushes, with cinnamon on the one hand for their invalid puddings, and as much quinine on the other as they could conveniently consume. And then think how comparatively easy it is to reach Ceylon by innumerable popular lines of steamers. The P. & O. and the Orient lines make for Ceylon direct on their way to Australia, so that the "passenger" could embark in the fogs of the Thames, and arrive in the sunshine and gaiety of Ceylon Harbour.

And now I must get back to my tea bushes and try to explain how they supplanted the far prettier growth of the ruby-berried coffee. Some mysterious fungus, or blight, or insect, or parasite suddenly descended on Ceylon and threatened the commercial interest and the planters with ruin. Despair stared them in the face. There was no resisting the baleful disease. They tried to wash it out and smoke it out; they treated the soil chemically and tenderly, but all to no purpose. Acre after acre was devastated, and in far worse fashion than in the vineyards of France. But the bold planter held on. First he tried spices, and then he tried quinine, till at last one fine day an ingenious person suggested the obvious alternative to coffee—tea. Now, your tea plant is a most extraordinary little shrub. The more you ill-treat it the better it appears to thrive. When it begins to "flush" you pick the very life out of it. When it is determined to flourish into verdure you hack it down with a pruning-knife. When it wants to blossom you give it up in despair. All that the tea-plant needs is plenty of moisture, plenty of rain, and plenty of sun, and then it will grow before your very eyes. Tea is a most accommodating little

plant. It will grow anywhere—down in the plains or up on the hills. You send up an army of coolies into the mountain forests untraversed yet by human foot, and these expert natives cut away at the trees and shrubs, and in a few days the trees come crashing down into the valley, the hillside is a desolation, only to be studded with transplanted tea-bushes a few months after. Out of the nursery come the young plants; they are arranged in lines and rows and "quincunxes" in true Virgilian fashion, under the keen eye and direction of the planter, and then all the baby plant asks is a deluge of rain and a blaze of sun to make it sprout and flush, to the great joy of the planter and the picker. Never was a thriving infant more mercilessly mauled and picked about. Up comes the fresh young shoot, or, as the planters call it, "two leaves and a bud"; pick, pick go the black fingers, be they of men, women, and children, in goes the tender leaf into the basket; from there on it passes into the canvass bag; in a few minutes more it is whizzing down the telegraph-wire shoot thousands of feet below, into the valley miles beyond, to arrive at the factory, there to be sorted, dried by machinery, washed, curled, and made into what we call tea, and ready to be packed and sent home for the breakfast table next morning.

It was, thanks to the great kindness of the Ceylon agent to one of Mr. Lipton's gigantic tea estates far away on the hills, that I was able, when spending a few days in the island, to become more practically acquainted with the growth and manufacture of tea. In the course of a busy life I have again and again been compelled with my will and against my will to be taken over huge manufacturing. I have been down coal mines and salt mines and copper mines by means of a hideous invention known as a "mau engine," which nearly cost me my life and whose ghastly refrain of "chaug" will ring in my ears till I die. I have seen how cloth is made and pens are shaped and razors are manufactured and linen is woven, and have submitted, as all must do, to the tyranny of your guide and counsellor. They never let you off half-way when you are dropping down with fatigue, are maddened with wheels and cogs and ropes and wires and the roar and scream of machinery that makes your brain ready to burst. No, on you must go and see every detail of the industry, from the door into which the workmen enter down to the very stacks of wood from which the packing cases are made. It is considered an insult if you pass by one room or one ear-piercing loom. I remember once that I visited some manufactory in the North with my dear old friend J. L. Toole, the most cheery of companions and amiable of men, but a perfect victim to the provincial manufacturer, who considers that to be taken over one of these houses of direful din is the greatest treat in the world to the novice. I could see that my companion was breaking down under the weight of commercial knowledge, but I was not prepared for the sudden revolt. "Now," said our guide, "you must come to the room where thousands of artisans are employed on ten thousands of cases, where they turn out so many hundreds of thousands of articles in so many seconds." Judge of my surprise when the cheerful J. L. Toole answered, "No; I am hothered if I do. I won't move a step further, and wild horses shall not drag me another yard. I don't care if I never see another pen nibbed or razor ground for the rest of my life. I may possibly go over a brewery or a wine-cellar on a hot day when there is a little tasting to be done; but I don't want to write any letters or to get shaved, and—besides, we want to go to lunch!" We struck, and I was never happier to get free from the din and also fresh air again.

But there are none of these discomforts of disagreeables in visiting a tea estate at Ceylon. In fact, it is an Alpine excursion on a small scale, and it is necessary to map out your progress with great care, with a view to getting sleeping accommodation at the various mountain "rest-houses" and the neces-

sary portorage for your haggage on the way. You are soon far from the haunts of men, of road and coaches, and are wandering over the hills and far away, where elephants trumpet in the jungle, and monkeys chatter in the trees, and great black snakes glide across the path into the bushes, and gorgeous birds scream over your head, and the wayside is as brilliant with rhododendron and wild snrflower and mountain lily as it is fruitful with lime and banana. They sent down from the Dambatenne estate to meet us at the cross roads, near the supremely lovely Hakgalla botanical gardens, our convoy. It consisted of a couple of horses, with three horse attendants, and a dozen active coolies to carry our luggage on their heads, and as on exploring party consisted of three, we thought it advisable to supplement the expedition with the "rickshaw," so that we might take it in turn to ride, walk, or be wheeled over the ruts and culverts and stony places by this perambulator, dragged and pushed by perspiring natives. But I am bound to own that the "jinricksha" proved a failure. It was irritating in the highest degree to get in and out of this "go-cart" every dozen yards or so in order to ford streams or mount stony places, so that as my companions were not, on the whole, favourable to walking, I elected to start ahead, with a coolie for a guide, and to trust my mountain welfare to my old Swiss friend Shanks's pony. So on and on we plodded, amidst scenery of indescribable beauty, until at sunset we arrived at one of the mountain "rest-houses" provided for the planters and their families going back and fro to their distant estates.

These "rest-houses" in Ceylon vary in size and comfortable order. In some I have eaten and slept as well as in the best-conducted Eastern hotels. In others I have gone quite superfluous to bed, there to have my bones broken on sparsely covered iron frames, and my head jarred with pillows hard as stone, and such slumber as weariness might insist on, disturbed by coolies chattering all night on the verandah and rats gambolling over the dirty counterpane. But it is a long road that has no turning. If we are parched with thirst on the way, the coolies hunt for limes or passion-flower fruit and make a goodly drink out of them from the pure mountain torrents. If we are footsore and dust-stained, the exhilaration of the mountain atmosphere hears us along, with the additional charm of convivial companionship. At last the coolies quicken their pace, for they see perched on a high crest of the neighbouring hill the bungalow of the Dambatenne estate. The lawn in front of this mountain gorge slopes to the edge of a perilous ravine, down which the tea bags are sent careering into space. But how, will you ask, was wire ever connected with the factory miles away as the crow flies, high over forest lands never trodden yet by man and across inaccessible rocks and ravines? Simply by rocket-firing. In the old days the tea bags were taken down to the factory by armies of coolies down rough and rugged mountain paths, heart-breaking work at the best. Now the "shoot," as it is called, takes the leaf to the manufacturer in a few seconds. We sit out on the verandah after dinner in the cool evening, and I almost envy the peace of a planter's life. He has hard work to be sure daily and incessant toil. He has to be up and about at daybreak to command and discipline the little army on the estate, for whose duties and lives he is responsible. He has to be guide, counsellor, doctor, and friend. At one minute a master, next a magistrate, now a doctor, now a soldier, he knows that his own life and that of his companions depends on his fairness and determination. If there is fever on the estate he has to cure it; if there is insubordination he has to put it down; if there is a spirit of revolt he has to smelt it out. There are no police or any power to depend on. Yet here the planter lives, sometimes, but not often, married, with a small staff of servants and a "chum" to direct the household, the responsible manager of an estate that may mean a little fortune to the lucky owner of it. The best colonists all the world over are Scotchmen, and it is needless to say that half the success of Ceylon tea planting is due to the thrift, energy, and resistless determination of

the Scotch character. You cannot go a mile in Ceylon without finding what a Buchanan, or a Morrison, or a Stuart has done for this magnificently-prosperous industry. But though the night is lovely, and the stars and moon are out, and the Dambatenne ravine exquisite in its majesty and its silence, we must turn in soon, for the morrow is crowded with hard work. This is one of the few estates that grows the best of coffees and teas. It is the envy of Upper Ceylon. At five o'clock we are among the pickers; but the deputy-manager has been ahead of us before daylight to assemble the coolies and dismiss them to their work. Prettier, even, than the gathering of the grapes on either side of the dividing river at Bordeaux; gayer than the coloured army that goes out in the morning from Rheims and its adjacent villages to collect the fruit to be pressed into sparkling champagne, is the system of tea-gathering in Ceylon. These dark-skinned coolies are cheerful in heart and facile in hand. Every man, woman, and child knows how to pick, and woe-betide the clumsy wretch who misses the flush and the young green shoot. By breakfast-time the gathered bags are weighed and sent whizzing into space, and as we cannot perform a Blondin feat on the taut tight-rope to follow them, we must put out best foot forward and descend the interminable zig-zag path down to the tea factory miles away in the valley. Now a tea factory is, as other factories are in this business-like world, eminently useful but unpicturesque. There it stands, all windows, doors, and chimneys, a mass of black and white against a background of verdure. The process is simple enough. The tea leaves, or, rather, sprouts, are laid upon wire shelves, and are thus artificially dried, curled, and cured. The three classes of tea or pekoes are easily assorted, and in a very few hours that which was young sprouting leaf is dry tea fit for the chest and the market. And you may be quite sure that it is not very long in getting there, or arriving, through countless hands, and at every conceivable price, into the British teapot. As you well know, at home, you can have "golden tips" at fancy and sensation prices or an ounce of "blend" that will not be discarded by the proverbial washerwoman, to whom a dish of tea is not so much a luxury as a necessity.

I candidly own that I was vastly sorry when the news went round that the good ship "Rohilla" was in sight, and that once more traps had to be packed up in order to make a fresh start with new companions for distant Penang and Singapore, and the long looked-for countries of China and Japan. However, as good luck would have it, there was no chance of sailing until midnight, so there was ample time for one more dinner at Mount Lavinia and a last farewell to one of the most romantic spots on earth. So we bring our glasses out to the seaside garden, and toast our new-found friends in Ceylon, not forgetting absent friends at home. Once more, and for the last time, we drive back along the dark coconut avenue, illumined by the moon, and find at midnight Colombo as cheery as ever, as busy and bright by night as it was by day. All the shops and hotels are open, for the Australian-bound "Himalaya" and the China-bound "Rohilla" are to sail at the witching hour of night. The sapphires that were not to be purchased for sovereigns are now forced upon us for a few rupees. Prices go down 200 per cent just before the steamer sails, and the wary passenger lays in a cheap stock of laces and cat's-eyes. Farewells are given and re-given on every side. Scarcely a week in Ceylon, and yet courtesy and good fellowship suggest a "send off" ere the "Rohilla" steams out of harbour. The little smoking room on deck is the scene of the parting symposium, and humpers of champagne "speed the parting guest." When the cabin steward comes in with "chota hazree," or early breakfast, next morning we are well on our way to the typhoon-haunted China Sea, and to the land of the chrysanthemum. Farewell, Ceylon! It does not seem like an everlasting parting. Perhaps some day I may be in peaceful retirement in one of the mountain bungalows of those evergreen and distant hills!—*Daily Telegraph.*

KITUL FIBRE IN NEW YORK.

A new substance has been imported and classified by the name of "kitool." The appraisers find:—1—"That Messrs. Lewisohn & Co. imported into New York, November 24th, 1891, certain fibre invoiced as kitool, upon which duty was assessed at 20 per cent ad valorem, under section 4, act of October 1st, 1890, as a non-enumerated manufactured article. 2—"That said merchandise is a vegetable fibre and is not crude fibre, but has been dyed and prepared fit for use in brushes and other like articles. The same is not cocoa fibre. "The importers claim that the same is entitled to free entry under paragraph 597 N. T. as a fibrous vegetable substance unmanufactured and undressed. "This claim we cannot sustain, and the protest is overruled." The dictionary will have to be enlarged to that extent.—*Boston Commercial Bulletin.*

COFFEE AND TEA STEALING PREVENTION ACT.

The following Petition of the Nilgiri Planter's Association has been presented to H. E. the Governor of Madras in Council:—

The attention of your Petitioners has been forcibly drawn of late to the disadvantageous working of Section 9, of The Coffee Stealing Prevention Act XIII of 1878 which runs as follows:—"Any cooly maistry or other labourer employed on a Coffee Estate found with green-gathered Coffee in possession and failing to account satisfactorily for such possession shall be liable on conviction by a Magistrate to pay a fine not exceeding five hundred rupees. That the words "labourer employed on a Coffee Estate" absolutely restrict the application of the Act as far as this Section is concerned, to cases of theft by persons so employed. All other cases of theft of Coffee, *e. g.* by Carriers, Vagrants, or even by road or railway-coolies employed by Government or by a Company and living in or near Coffee, have to be taken under the Indian Penal Code, which throws the *onus probandi* on the prosecution, and thus renders a conviction impossible except in those very rare cases where the offender is actually caught in the act of stealing. Your Petitioners respectfully submit that the Act was originally intended to be capable of dealing with all cases of coffee pilfering, and that the altered and developed conditions which now obtain, such as the construction of railways and roads, and increased traffic generally, call for the alteration of this Section by the use of the word "person" instead of "labourer," and by the omission of the words "employed on a coffee estate," thus making the Section commence—"Any cooly maistry or other person found, with" &c. In a recent case where a railway cooly, camped on the edge of a field of coffee, was detected with some freshly-gathered coffee in his possession, the Court ruled that the case could not be dealt with under this Act, as the accused was not actually "employed on a coffee estate." It is hardly necessary to add that the cooly was acquitted in consequence. That, in this same Section 9, the words "green-gathered" be omitted before "coffee," leaving "coffee" to stand as it is explained in the Act. Your Petitioners submit that a strictly technical rendering of the expression "green-gathered coffee" would prevent the other and much more abundant forms of the produce, such as red cherry coffee, dry cherry, parchment coffee, &c., from inclusion under this Section. The loss from thieving continually sustained by planters, and the great difficulty that is experienced in first detecting the offenders, and then in obtaining a conviction, are, in the opinion of this Association, more than sufficient grounds for requesting the favourable consideration of Your Excellency in Council to remedy the above serious drawbacks in this Act. Your petitioners would further pray that tea, which has now come into common use among the local tribes as well as among natives generally, who have not before indulged in the beverage, may be protected by a special legislation, similarly to coffee. Cases of theft of tea

have of late become alarmingly common, and as the tea of any one estate is practically the same as that from other properties in the same district, the identification on oath of stolen produce is all but impossible. Tea therefore now labours under the same disadvantage in this respect as coffee did formerly. It would seem, therefore only equitable that tea which grows along side of, and often even among coffee, should enjoy the privilege of protection which the latter to a great extent does under the Act.—*M. Mail, March 25.*

COFFEE PLANTING IN JAVA.

Sir,—In your issue of the 27th of January last appears an extract from a letter from Mr. Donald Mackay, Perak, comparing coffee planting in Perak with the same culture in Java. Mr. Mackay writes:—

"Why do Ceylon planters go to Java when they can get as good a soil, and perhaps a more suitable climate, here?"

In commenting on above you say:—"We are quite at one with Mr. Mackay as to the superior advantages of Perak as a field for British enterprise. Java labours under many disadvantages:—a Dutch Government, heavy taxation, and a gold coinage, whereas Perak is very much favored in every way. Labor is the only difficulty, and that, as Mr. Mackay shows, is gradually being overcome."

May I request you kindly to allow me space in your paper to make a few criticisms on Mr. Mackay's letter and on your own remarks thereon? I may preface my remarks by saying that my Java experience extends over a period of upwards of 18 years. With Perak I am not acquainted. I have, however, resided for several months in the State of Selangor, which adjoins Perak, and where, so far as I know, conditions as to soil, labour, climate, &c., are very much the same as those of Perak. I venture, therefore, to assert that, neither in point of soil nor in that of climate, can the Malay Peninsula compare with Java. From Mr. Mackay's remarks, therefore, I can only conclude that that gentleman has never visited Java. As regards labor, Java is immeasurably ahead of the Malay Peninsula in every respect. Java possesses a rich and productive volcanic soil, a fine climate for coffee, while indigenous native labor of a good class is everywhere obtainable. Coolie hire is about tenpence per diem. The disadvantages which you refer to of coffee-planting in Java are three in number, viz.:—(1) A Dutch Government. (2) Heavy taxation. (3) A gold coinage.

I shall proceed to deal with these in detail.

(1) A Dutch Government.—Well, I must confess that to British the slow and lethargic lines adopted by Dutch officials are not pleasant. On the other hand the Government, when it grants lands to planters, does so on very fair conditions.

(2) Heavy Taxation.—The taxes which a coffee planter has to pay are the following, viz.:—

(a) Grounds are granted on a 75 years' tenure on payment of a tax called "erfpacht." This is at the rate of one guilder (1s. 8d.) per bouw (1 bouw equals 1½ acres) per annum. The lessee, however, is free of this tax during the first five years of tenure. (b) "Verpanding."—A tax of ⅓ per cent. per annum on assessed value of the estate. This tax, however, is not levied till the sixth year of the estate's existence. (c) An income tax of 2 per cent. per annum on nett income. (d) A house and furniture tax, amounting to about 7 per cent. on house rent. (e) A horse tax of about ten shillings per annum per horse.

I come now to the third and last disadvantage alluded to by you, "A gold coinage." Now, I don't profess to be an authority on "mono," "bi," or any other kind of metallism. I do, however, profess to represent Java opinion when I say that we here are very satisfied with our gold coinage, and have not the slightest desire to exchange it for the experience of Ceylon and other places in the East, who are now struggling with all the difficulties and fluctuations of a silver standard. The reasons of our

satisfaction with our present standard are not far to seek. Our course of exchange with home keeps very steady and has done so for years. Our importers, when ordering their goods from Europe, do not require to trouble themselves with conjectures as to how exchange will fluctuate between the time they order their supplies and the date when they will be drawn upon for cost of same. The export merchant, too, sells his produce for forward delivery without requiring to rack his brains with regard to rates of exchange, which he is likely to get when selling his drafts against cost of his produce. I assure you, sir, you are welcome to your silver standard so long as you leave us with our gold one. One disadvantage to newly arrived British here which you have not enumerated is want of knowledge of the Dutch language. Absence of this knowledge to a British planter (especially in the interior of Java, where but little English is spoken) is certainly a great disadvantage. However, in this respect, an experienced Dutch tea planter with no knowledge of English would be equally at a disadvantage in Ceylon as an English planter of experience in Java with no knowledge of Dutch. A non-Dutch speaking English planter, if starting in Java, would require a mentor in the shape of an English-speaking Dutch coffee planter associated with him during the first few years of his Java life.

I don't intend to enter here into a long "puff" as to what coffee in Java can do. If any of your readers, however, are interested in knowing what Java coffee has done, let me advise them to procure and study the book published annually by Mr. J. H. de Bussy, Amsterdam, entitled "Handbook von Cultum en Handelsoememingen in Nedelansch India." The book is well worth perusal.

Before I close, let me give you the experience of one of our young lands in East Java. It was started in 1887, and, at end of 1889, 350 bouws were under coffee. In 1891 the dividend declared was 13 per cent, and in 1892 82 per cent, or 95 per cent within two years. If I tell of older lands which paid dividends of over 300 per cent, I shall probably not be believed by your readers. However, to all sceptics about coffee cultivation in Java, I can only say "come and see for yourself." I think most strangers who have visited this part of the world will confirm my statement that Dutch planters are most hospitable, and will gladly give an enquiring brother planter, albeit he comes from another land, all the information and statistics at their command.

Mind you, I do not say that all the tickets in the Java coffee lottery gain Prizes. I think, however, it will be found that the prizes outnumber the blanks. The first two or three years of coffee planting on a new land are hard and anxious ones, no matter in what part of the world that land be. I feel sure, however, that, taking both advantages and disadvantages into account, Java coffee planting will hold its own against coffee cultivation in any part of the world, whether north or south of the equator.

Sourabaya, March 9th. LOCHABER:
—Local "Times."

FOREST PRODUCTS OF BRITISH GUIANA.

In 1890, the exports of timber from British Guiana amounted to 332,098 cubic feet, valued at 110,000 dollars, and, in 1891, to 312,801 cubic feet, valued at 96,330 dollars. The United States Consul at Demerara says that this industry could be developed to almost any extent, if the difficulty of the rapids were overcome, so that timber could be easily brought down from the interior. At present, little or nothing can be done beyond the rapids, so that only a very small portion of the country can be profitably worked. Another product of the forest is ballata, a kind of gutta-percha, which was exported in 1890 to the amount of 226,809 pounds. Shingles, firewood, and charcoal are also exported to a small extent, principally to Barbados. The forests embrace a great many species of trees. The varieties of timber are, as a result, numerous in colour—from dark red to almost pure white—and, in specific gravity, from nearly double that of water to less than half that of the

standard liquid. The principal building woods are green heart, mora, and wallaba. The first is a most valuable wood, being classed with teak, either one of which may be exclusively used in shipbuilding, while its durable qualities are placed on a level with oak, only teak coming before it. It is heavy, very close grained, grey, with a greenish cast, and may be obtained 50 or more feet in length. Under water and in the tropics it is superior to all other woods, house frames, made of green heart which are 100 years old, having been found still unperforated by worms. The mora is not so close-grained as green heart, but it is almost equally durable. Its colour is reddish, and it may be obtained in as large dimensions as green heart. Wallaba is a dark red wood, with an unpleasant odour when new, very durable, but not obtainable in such large sized logs as those referred to above. Being easily split, it is commonly used for making shingles, palings, cask and vat staves, &c. On account of its colour and smell, it cannot be used for rum puncheons, but, after a little use, water makes no impression upon it. Other timbers are particularly suited for special purposes, such as that of the bullet tree, which was formerly considered the only timber fit to be used for the arms and shafts of windmills. The silverbally is light, and suitable for boat building, from its containing a bitter element obnoxious to worms and barnacles. As to the woods suitable for furniture, these, it is said, will no doubt be better appreciated in other parts of the world, when they are known a little better than at present. The native cedar (*cedrela*), which is quite different from the timber of trees of the pine family, is very useful for wardrobes and cabinets, where its scent tends to keep away insects. Mahogany is not native to the colony, but the wood called Guiana mahogany is that of the *carapa*, commonly known as crab wood. It is not so dark in colour or so hard in texture as mahogany, and, being more easily worked, is used for all kinds of furniture. Letterwood is one of the prettiest, but, as the peculiar dark marks are only found in the heart, only small logs can be obtained, rarely exceeding six inches in diameter. Purple heart is unique, being of a pretty violet colour, when fresh or new, which, however, turns to a dark brown after being worked up. There are many different varieties of furniture woods produced in British Guiana, and a list, enumerating 63 distinct kinds, was prepared for the Paris Exhibition of 1878. In the various woods every colour known is represented, from almost black, through browns and reds to deep and pale yellow, to almost white. They are, however, curiously free from irregular veining and knots, the marks being almost uniform and in parallel lines, but they are not wanting in beauty. For panelling, nothing can excel the nearly black wamara, contrasted with the pale green heart or the lighter and more easily worked sinarupa, which is almost white. At present, the demand is so limited that many of the fancy woods are difficult to procure, the woodcutters looking only for such timber as they know will command a market. If, however, says Consul Carrol a market were opened, these could be collected as easily as green heart, mora, and wallaba are at present.—*Journal of the Society of Arts.*

The use of tea is yearly increasing at Venice. The inferior qualities of Russian teas sold by many retailers at high prices cannot compare with the finest China, India, and Ceylon teas now supplied direct to customers here, at very moderate prices, by the United Kingdom Tea Company, Limited, of London.—British Vice-Consul at Venice, January 4th, 1893.—*British Trade Journal.*

ELEPHANT TUSKS.—It is difficult to obtain from an elephant's tusk a perfect slab of ivory more than six inches in diameter, as the upper end of the tusk, which is the thickest, is hollow, and the material is coarser than that in the solid part of the tusk. Every part of the tusk is put to use. Even the chips and sawdust are converted into ivory black by burning.—*Echo*, March 17.

OUR STAPLE PLANTING INDUSTRY:
POSITION AND PROSPECT; ENEMIES;
PRICES AND CROPS.

We are not quite ready yet to sum up the exact statistical position of our Planting Industry: further returns have to come in from several districts, and the whole has to be brought together, analyzed and arranged in tabular form. But no one can travel through the heart of our tea country at the present time or spend even a few Easter holidays "on the hills" without hearing and noting a great deal about the Enterprise with which the continued prosperity of this Colony is so closely bound up. No one also who has passed through the scathing fire of adversity which passed over Ceylon and her chief planting industry between 1877 and 1885 can ever ignore or forget the lesson which was, as it were, then burnt into the experience of planter, merchant, chetty, labourer and journalist alike. It is impossible in viewing the fresh vigorous appearance of our upland districts in the present day, not to recall the same green pristine vigour which marked the show of coffee bushes twenty or even fewer years ago. And then, there comes the inevitable questioning as to whether tea is secure in its universal cultivation throughout the same planting country against the appearance and ravages of an insidious enemy such as devastated coffee? Newcomers, in the face of the splendid appearance of our plantations, are not troubled with such thoughts; but they go a long way in the minds of the English capitalists, and these are still numerous, whose connection with the island extends back to the sixties and seventies. We do not believe therefore in shirking any doubts raised by past experience. We believe it is far better to put and answer critical or even sceptical questionings in the bluntest form as to,—

the common though the hidden thought

of most old Colonists. It is, of course, absurd to suppose that any great agricultural, and especially tropical, industry can exist without enemies. The Old Book is still true in its teaching:—"In the sweat of thy face shalt thou earn thy bread." The latest issue of "The Indian Museum Notes" published by authority of the Government of India in the Agricultural Department, presents quite a formidable "Conspectus of the insects which affects crops in India." The total in number is no less than 240 and the proportion affecting tea and coffee is considerable. Personally, we have no such dread in Ceylon of insect enemies as we have of those of a fungoid character. There need be no great wonder at this after the coffee experience of *Hemileia vastatrix* and the realization of the fact that a great part of Ceylon with its moist hot climate is a perfect paradise for fungi. The late Dr. Thwaites, F.R.S., was in his element here! It is always a relief, therefore, to learn as we have on the present occasion that no sign whatever of a fungoid enemy has appeared in our tea at low, medium or high elevations. But there is surely a warning to be given here to Ceylon tea planters about not needlessly courting danger, especially in the hotter and moister districts. All agricultural and horticultural authorities agree as to the risk attending the decay of vegetable matter above ground in reference to the fostering and development of fungi. If we had the power, we would make it incumbent on every tea plantation proprietor in the island to bury his prinnings, and for segregation, as much as anything else, to plant a certain proportion of timber and fuel trees on his tea-fields, more or less according to the forest reserve he had to show.

We need not say that tea in Ceylon is no more free from insect enemies than it is in India; but in the cultivation of trees we encourage the location of birds, often very efficient enemies of troublesome insect pests. A planter with large experience in a district of medium elevation told us yesterday how he has encouraged with success, the small black ants often found in swarms on estates, to eat up scale insects. In this way he has seen partial developments of green bug on tea as well as coffee (it attacks everything in fact with a white flower: cinchona, lime, orange, guava, jasmine and gardenia) stopped and cleared off by the advance of the minute black ants which eagerly feed on the enemy! That insect pests can even now prove troublesome and seriously injurious to our tea in Ceylon, is undoubted. We do not hear so much of red spider as of the other insect pest so well described by Mr. E. E. Green and which is so partial to the young buds coming on after a pruning. In this it shows a strange peculiarity,—attacking young vigorous tea, while never seen on bushes which might be said to be temporarily exhausted through a too long continuance of plucking without pruning. The contrast given to us the other day of two fields in a high district, was a striking one:—the one of tea just "coming away" after pruning, but devastated by the mite; while the other adjacent although it looked almost neglected, through the bushes having "run" too long, was without a sign of the pest. The effectual cure so far for this enemy and other insect troubles has been a good shower or at least a steady downpour of rain, no uncommon occurrence fortunately in most of our tea districts.

Heavy rain it appears has hitherto been sufficient to sweep away the most persistent of our insect enemies on tea. Will it always be so? is the question of the doubter, who may be on the same platform as the friend who observed to us the other day that he noticed Tea Companies afforded a convenient means to many of our oldest and shrewdest tea planters for arranging that all their "eggs should not be in one basket." We can only think well of the planter, or any other man, who does all in his power to guard against such an arrangement of his eggs, that is his capital! Tea under favourable circumstances, is undoubtedly a good—a splendid—investment; but to prevent the eggs being in one basket, and to ensure the stability of the Planting Industry and the continuance of even moderate prosperity for the Colony, local capitalists should endeavour to have an interest in cacao, in Liberian coffee, in cardamoms, and also in coconuts.

Nevertheless, we fear there is still more land being opened with tea in the island than in all the other products put together. We cannot point this time to any new district carved out of forest or chena or patana land, nor to any very extensive clearings; but we suspect when we come to sum up the total of the different additions,—corner clearings, or fields to round off ("is it not a little one?")—made both up and down country to existing plantations, that the area planted since our last tabulating of the figures will be very considerable—more so perhaps than most planters or merchants imagine.

And this naturally brings us to the question of tea crops and prices. We were asked the other day, how it came about that the prices and averages for the teas of a certain favorite upland division, had been falling off of late? We understood that the fall was out of proportion even to the general disfavour in which our fine teas have been held in London. We do not know if the answer is to be found in the fact that our present trip has clearly

revealed to us, namely, that the "plucking" of tea-leaf on the fields of not a few of our larger "tea concerns (to use an Anglo-Indian business term) is guided or influenced, by telegraph from London. For instance, plucking on not a few places has become a little freer if not coarser ever since it became clear that the home trade were determined to have cheap teas. It can be seen how important it is for large Companies or the owners of plantations of 500 or more acres, to have early and accurate information of this kind; for there can be no doubt that even a little change in the plucking may materially influence profits when "Pekoe Souchongs" are within 2d a lb. of "Broken Pekoes" or when, as happened the other day "broken tea" described by the London Agents as mere stuff, sold for 7½d a lb. This was equal to 42 cents in Colombo for a tea that would not have realized here more than 20 to 22 cents! Without saying that "coarse" has superseded "medium" plucking upcountry, we believe the tendency, and very naturally, has of late been to freer plucking in correspondence with the tone of the home market and that this fact, as well as the favourable flushing weather, will influence the large quantities of tea which April and May will see pass through Colombo. It is already asked upcountry as well as in Colombo, how the "official" estimate, looks in the face of the facts already realized as well as the prospect thus described. With a comparative increase of 4 millions lb. on the first quarter, we have met no one who anticipates a less proportionate increase in the second quarter. What then about the third and fourth quarters? Without looking ahead so far, it is quite evident that we must now count on a total export in excess of 80 million lb. in 1893, unless something very unusual occur; and our special desire at present is that our friends, the buyers already flocking out to China, would bear this fact in mind and be guided in their operations on behalf of the London market by it, to some extent at least. In over-production, or rather low prices, at present lies the risk before our tea-planters, far more than in any enemy or drawback incidental to local cultivation. As has been said again and again, we can offer such a fight to even the minutest enemy that may develop in the hardy, deep-rooted tea bush, as we never could to the fungus or bug on coffee, and what therefore we have occasion to be anxious about is the extent to which Australia, and especially America, is likely to relieve the London market of our Ceylon tea exports during the current and coming years. This, certainly, then, is not the time for a contemporary, to indulge in abuse of the Americans who—after a fashion, perhaps, peculiar to themselves and the style of business in their country—have been undoubtedly advertising and distributing our teas to an extent which, *malgré* the Chicago Exhibition, could not have been accomplished by any other agency that Ceylon planters could possibly compass, for many years to come.

TROUT IN NEW ZEALAND.—"I have caught this year," says Mr. Shury, of Ashburton (N. Z.), "213 trout, weighing 750 lb. 8 ozs.—one fish 14 lb. one 12 lb., two of 10 lb., six of 9 lb., six of 8 lb., and thirteen of 7 lb., and any quantity from 3 lb. to 6 lb." This appears to be the outcome of under twenty days' fishing. On November 21 he took nineteen fish, weighing 169 lb. 4 ozs.; and on the two days (January 2 and 3, 1893) thirty-five fish, weighing 140 lb. The fish were taken from the Rakaiia and Ashburton rivers.—*Colonies and India.*

DARJEELING: ITS TEA AND SANITARIUM.

There is a marked improvement for the better in the weather and the temperature as the days are decidedly clearer, better and warmer, and the genial soft breath of summer is already with us. The summer birds are beginning to return from below and new faces are to be met every day and ere the end of the month the season will be in full swing. Every house has been taken up and Darjeeling promises to be fuller than ever this year.

Thanks to the intelligent energy of Mr. Cary, the General Manager of the Darjeeling-Himalayan Railway, a way has been discovered by which ample light can be obtained for working the local trains up and down hill with perfect safety on the darkest nights.

The good people of Darjeeling are always alive to the requirements of their beautiful sanitarium to increase its comforts, conveniences, popularity and attraction as a summer resort. The Municipality has done much of late years to improve things and have just spent Rs30,000, borrowed from Government, in perfecting the latrines and drains and are now tackling the water question; not that the water needs improvement, as it is the best and purest in India, but only that more has to be brought in from the supply head at Senehell to thoroughly flush the new and improved drains and to meet the needs of the new Military Cantonment to be established on the Lebong Spur.—*Indian Planters' Gazette*, March 11.

JAMAICA DRUG AND OTHER CULTURES.

The annual report of the Director of the Jamaica Botanical Department contains a few interesting bits of information on the Drugs exported from the island. The production of annatto is falling off, and this the writer of the report considers strange, though, in the light of the prices which the product realises, the fact does not appear so very extraordinary. As cattle do not eat the annatto-leaves, the plant can very easily be grown along the fences of pastures. Arrowroot is not a Jamaican industry; only a few hundredweights of it are exported yearly. The main reason of this is that it is an unsuitable crop for the small farmer, as its manufacture requires, the use of more expensive appliances than he can afford and of greater skill than he possesses. The shipments of quassia-wood are increasing very quickly. They have multiplied tenfold within five years.

The growing and curing of ginger is a work well suited to small settlers, and the exports of the drug have increased considerably of late years. The lime-juice industry might be made more flourishing if the essential oil of the limes were extracted from the peel and the "first quality of lime-juice made from the drainings of the fruit when cut before being pressed to make the "concentrated juice." The cultivation of liquorice is strongly recommended to settlers.

The attention of planters and small settlers has been directed to the large profits to be made in the cultivation of nutmegs, hence this industry is entered upon with spirit and energy, as many as 20,978 plants having been sold by the Department during the year. All the nutmegs used as seed are most carefully selected on one of the best estates in Grenada. Subjoined are the figures relating to the export of the principal Jamaican drugs. No statistics are given for the year 1890:—

	1892	1891	1890	1888	1887

COFFEE CULTIVATION IN MEXICO.

E. P. Allen contributes to the *American Agriculturist* the following interesting article regarding the growing of coffee in Mexico:—

The planter who makes coffee growing a business, will select a somewhat shaded recess somewhere between the ridges of the giant mountains which stretch their huge lengths from Guatemala along the Pacific to Sinaloa, or upon the Gulf coast from Yucatan to Tamaulipas. Or, he may turn to some of the numerous fertile valleys which lie in deep dents on the great Central tableland. The height at which he will naturally locate his field will be from 1,000 to 4,000 feet above the sea, but he may even go 1,000 feet higher and not go beyond success, as he may also seek a lower level, since in some places, coffee is produced at the very seaside. Off the eastern coast of Yucatan, on the island of Cozumel, coffee trees of prolific yield are growing nearly at a sea level as well as in many other localities on both the Pacific and Gulf coasts. Indeed, the objection to the sea lands for this purpose is probably not on account of the effect of the climate upon the plants, but upon the planter, the tierra caliente being everywhere unhealthful.

As in Brazil the plants are started in a nursery. At the age of one year or eighteen months the infant shrubs are transplanted to the open fields, or coffee field, which has been thoroughly cleaned of all undergrowth and the soil well prepared. To protect the young plants from the sun, open forests are used and more gradually shade must be created, which is most easily attained by planting bananas between the coffee plants. But some more intelligent planters set out their fields with cecropia trees for shade, and these yield quinine, and some use oak and walnut trees for the purpose. A rich sandy soil is desirable for coffee, and manuring pays well, often increasing the yield to three pounds. In exceptional cases it has risen to twenty-five pounds for one tree, under favourable conditions.

Plants are set out about three yards apart, although often planted closer. Sometimes irrigation is necessary, but not often when the plants are once well started. Pruning a tree back to six or eight feet in height is thought to improve its yield. The coffee shrub has a curious habit of blooming three times a year, sometimes as early as December, then along in February and then in April. This makes the gathering of the crop a tedious task, as each tree must be gone over by hand, and must be done carefully, which requires an extra number of laborers, but women and children can be employed at low wages. After picking by hand, the next process is to dry the berries, which is done in the sun, beneath which they shrivel and change to a black color. They are then put into a mortar and the grains hulled or beaten out with a pestle and then separated from the husks by the crude old-fashioned method of fanning them out by hand, or winnowing, though sometimes a fan mill is used. It is then carefully picked over by hand, put into sacks, and is ready for market. So far, in its cultivation, no disease of plant or berry has been developed and no insects have attacked it. It is also clean and comparatively easy to cultivate. Only at the picking season is there much urgency required. Once gathered the crop can be prepared for market at the planter's convenience.

The greatest difficulty lies in the fact that the planter must wait at least five years from the seed sowing before he obtains a return upon his investment, and the first year's crop barely pays the cost of cultivation and curing. But, as compensation for this, a plantation once established yields a never-failing crop without renewal, anxiety, or uncertainty, for a lifetime. An intelligent American planter in the valley of Cordova claims, that with attention and care, plants ought to continue bearing vigorously for fifty years. The profit upon well-grown plantations is not less than 100 per cent. over the cost of cultivation. An attractive feature of coffee planting in Mexico is that its habitat is usually a locality both healthy and pleasing, high enough to

escape the diseases of the tropics, and over in the midst of the most beautiful scenery. The great possibility of expansion of this industry can be estimated by comparing its present out-put with that of Brazil, not more favourably situated as to climate or people than Mexico. With the degree of peace and safety, now assured to the immigrant, this branch of agriculture offers great attractions to the farmer.

COFFEE ADULTERATION.

There never was a more iniquitous system than that which has so long ruled the sale of coffee in the United Kingdom, and the veteran ex-Ceylon Colonist, Mr. Thomas Dickson, senior, is quite right in asserting that the policy he advocates is simply "the path of common honesty." We call attention to the Correspondence with which Mr. Dickson has favoured us. He is acting not merely in the interests of what remains of Ceylon coffee—and we trust Liberian will yet add to our exports—but in those of the coffee planters of Southern India, and we trust success will crown his efforts to the fullest extent. We shall be interested in seeing how Mr. Gladstone will act in reference to this Bill of Dr. Cameron of Glasgow, one of his own staunchest supporters; because, we regret to say, that Mr. Gladstone has hitherto been the great obstacle in the way of a stringent measure passing to prevent the adulteration of coffee. We will remember a gathering of gentlemen interested in coffee from all parts of the world—Ceylon, India, Natal, Guatemala, Jamaica, &c.—held at the residence of Mr. C. Tottenham in London, in 1870 at which we were present, when Mr. Rucker, senior, related to us the fate of a very influentially signed City Memorial of which he took charge some years before, begging for the most ordinary protection for coffee. A deputation with the Memorial waited on Mr. Gladstone, then Chancellor of the Exchequer, and he (Mr. Rucker) was able to show the hon. gentleman samples of so-called "coffee and chicory" sold by grocers in London and throughout the country containing from 60 to, in some cases, 90 per cent of chicory against 40 to 10 of coffee! All the Deputation asked was that retailers should be bound to specify the proportions of each article on their packets; but Mr. Gladstone declined to support the request.

Of course the proper way would be to buy coffee in the berry and have it ground; but to the working-classes the convenience of buying it ready ground in packets can well be understood, and thus by degrees their tastes through insidious, adulterated compounds have become corrupted; so that they would not appreciate pure coffee now if they got it. The difference is seen in America, where the regulations against the sale of unspecified mixtures being very strict, wholesome pure coffee is the rule and Americans prefer buying the product in the bean. True, we have heard of imitation coffee beans as of "wooden nutmegs," but these are readily detected. We trust then that Dr. Cameron will be fully successful with his present measure: it is headed and backed as we learn from a copy forwarded to us by Mr. Dickson as follows:—

A Bill to amend the Sale of Food and Drugs Act, 1875, and the Margarine Act, 1887, (Prepared and brought in by Dr. Cameron, Mr. Channing, Dr. Farquharson, Mr. Frederick Frye, and Mr. Kearley.

SCHEDULE. A.D. 1893

Coffee Mixture Containing—
Form of Label.

Coffee.—Four-fifths, or three-fourths, or one-half, or one-fourth. Chicory.—One-fifth, or one-fourth, or one-half, or three-fourths.

And so on, as the case may be, specifying in equal parts on each label the respective proportions of coffee and chicory contained in the mixture sold.

NEWS FROM JOHORE: PLANTING &c.

The Malay Peninsula ought to be opened up by railway as soon as possible to unite Australia and India and help on the consolidation of our Colonial Empire. It is just over 2,000 miles from here to Calcutta, and it is just under 2,000 miles from Adelaide to Port Darwin; from there to Singapore six days steam or less. I suppose the Australians have made about 600 miles from South to North and from Port Darwin South about 130. Every mile would be taken up in the Johore territory as soon as made. I mean the land on both sides. Gambier planters are hungering and thirsting for new lands whereon to grow gambier and it grows nowhere better than in Johore—it is a leaf crop and the frequent rains suit its nature well. Here the Chinese are welcomed. Our good Sultan gives them every encouragement and leaves them to themselves as much as possible.—I mean by this he does not harass them by unnecessary rules, laws and regulations and they being guaranteed security for life and property thrive wonderfully in Johore cultivating gambier and pepper. Many come and go to and fro—passage \$4 to China; by steamer it is only \$5 to \$7. The coolies at the saw mills constantly visit their native place in the Amoy Province. Singapore would be nothing without the Chinese. Malacca is their paradise. They are a wonderful people, can live where the European would starve—it will become a great problem what we are to do with them or as it has been said what they will do with us! Our policy is to be friendly with them, they are great in point of numbers—led by a Gordon they would go anywhere and do anything.

SALE OF A COCONUT ESTATE.

Mattekelle Estate situated at Wellariwadia in Pitigal Korale, South Chilaw District, containing in extent 139 acres, partly planted with coconut, belonging to the estate of the late A. R. W. Evaris Perera, was put up for sale by public auction this afternoon by Mr. A. Y. Daniel at his rooms in Baillie Street. It is said that there is a dispute as to a part of the property, and consequently very few put in an appearance. There were present Messrs. Arnold Dias, Proctors Muttu Oumar, Arthur Alwis and J. Koerts, J. D. Vanderstraaten, Dadhaboy, Simon Silva, Malleappa and some natives. After the reading of the conditions the sale commenced with a bid of R1,000 by Mr. Malleappa and within a few minutes Messrs. Dadhaboy and Vanderstraaten raised the bid to R2,000. At this moment Mr. Simon Silva put in a bid at once for R5,000. The bidding was then continued between Messrs. S. Silva, Dadhaboy and Vanderstraaten until it was knocked down to Mr. Simon Silva for R7,500. It is said that Mr. Silva bought the property for Mr. N. D. Paulus Silva, the famous plum-bago merchant, and if the title is safe he has made a very good bargain, as it has cost him only R54 an acre, for which price even good waste land cannot be purchased now.

INDIAN PATENTS.

Specifications of the undermentioned inventions have been filed, under the provisions of Act V. of 1883, in the Office of the Secretary appointed under the Inventions and Designs Act, 1888. Copies have been sent to the Governments of Port St. George and Bombay, the Chief Commissioner of Burma, and the Director, Department of Land Records and Agriculture, North-Western Provinces and Oudh. A copy of every specification is open to public inspection from 11 a.m. to 4 p.m. at the Office of the Secretary appointed under the Inventions and Designs Act, 1888, in the Imperial Secretariat Buildings, Government Place, West, Calcutta, upon payment of a fee of one rupee. A certified copy of any specification will be given to any person requiring the same on payment of the expense of copying:—

No. 347 of 1891.—Eugen Reverdy, of No. 14 am Markt, Bremen, in the Empire of Germany, Factory Manager, for a new improved machine for sorting hulled grain from unhulled grain and chaff. (Filed 7th March 1893.)

No. 73 of 1892.—Edward Lennon Cantwell, Civil Engineer and Patent Agent, 5 Old Post Office Street, Calcutta, for an improved huller for rice, coffee and grain, and for scouring and cleaning rice, wheat, and every description of grain. (Filed 1st March 1893.)

The fees prescribed in Schedule 4 of Act V. of 1888 have been paid for the continuance of exclusive privilege in respect of the undermentioned inventions for the periods shown against each:—

No. 16 of 1888.—John Charles William Stanley, of 5 Dewhurst Road, West Kensington Park, Gentleman, and Leonard Butler Wrightson of John Street, E.C., Merchant both in the County of Middlesex, England, for improvements in tea chests, boxes or the like, applicable for containing other goods or articles. (From 1st March 1893 to 28th February 1894.)—*Indian Engineer*, March 25.

VARIOUS AGRICULTURAL NOTES.

A NEW MISSION has been started in the Shiré Highlands, under the title of the Zambesi Industrial Mission. The moving spirit is a Mr. Joseph Booth, an Australian colonist, who has obtained the support of the well-known Messrs. John and Richard Cory and others. A large tract of land has been purchased, to be laid out in coffee-plantations, for it is intended that the Mission eventually become self-supporting. Several Volunteers are already proposing to join Mr. Booth.—*C. M. S. Gleaner*.

WET BOOTS.—When the boots are taken off, fill them quite full with dry oats. This grain has a great fondness for damp, and will rapidly absorb the least vestige of it from the wet leather. As it quickly and completely takes up the moisture, it swells and fills the boot with a tightly-fitting last, keeping its form good, and drying the leather without hardening it. In the morning, shake out the oats and hang them in a bag near the fire to dry, ready for the next wet night.—*Notes on Tea*.

LARGE SPIDER.—The *Nephila Madagascariensis* is a large "orb-weaving" spider of very industrious habits apparently, for the Rev. P. Cambone writes from Madagascar to the *Revue des Sciences Naturelles Appliquées* to say that in 27 days one of the species spun 4,000 metres, or over three miles of golden yellow silk. He also sends a drawing of an apparatus for winding it. But if spider silk is to become a commercial commodity, how are the spiders to be bred and kept? A vast colony of *Nephila Madagascariensis* is rather an eerie notion.—*Colonies and India*.

CHARCOAL IN SIKKIM FOR TEA DRYING.—Mr. J. C. White, Political Agent of Sikkim, recently made an inspection of the sal forests on the banks of the great Runjeet and Rumman rivers and reported to Government that the timber of late years in the sal forests on the north bank of the great Runjeet, above the oane bridge and the North bank of the Rumman, had been used to make charcoal for the tea gardens near Darjeeling. No system what ever had been followed, and the charcoal burners had been allowed to cut any trees within reach of their kiln. The consequence was that the forests had been all but ruined. This year the Durbar stopped this reckless cutting, and allowed no trees to be cut without permission. Mr. White suggests that a notice should be given now to the Darjeeling planters, stating that from next year no charcoal will be available from the forests named and the proposal has been recommended by Mr. Paul, Deputy Commissioner of Darjeeling, who adds that if timely notice be given to the planters they will have ample time to make other arrangements for obtaining charcoal or to import the latest improved machinery for making tea without the use of open fireplaces and charcoal.—*Statesman*.

THE QUININE-FACTORY AT NADU-

VATAM.

An Indian subscriber to the *Chemist and Druggist* has been visiting the Government quinine-factory at Naduvatam [or "Neddiwuttum," as he calls it—unity of spelling, is sadly required in Indian geographical designations], and sends us the following account of the establishment:—"The factory at Neddiwuttum is a building 70 feet long, constructed on the site where convicts were housed when the plantation was in process of formation. One new shed was added for the scalper, and another (heated by steam) for the drying process. Water is obtained from a well 25 feet deep, attached to which is a reservoir connected with a 6-horse power turbine, working a Carter's disintegrator, that pulverises the bark at the rate of about 25,150 lb. a month. An engine, also nominally 6-horse power, does the boiling and works a still for recovering the fusel oil from the bark-refuse. The disintegrator turns out the bark in impalpable powder, about 200 lb. of which is put at a time into a cylindrical vat 6 feet by 3, fitted with revolving winged-stirrers. A mixture of water (100 gallons), paraffin (96 gallons), fusel oil (24 gallons), and caustic soda (14 lb.) is then placed into the vat and beaten up for three hours. This is allowed to stand undisturbed overnight, and in the morning the oil is drawn off into another cask, called an agitator, in which water acidulated with sulphuric acid is worked up with it for ten minutes to dissolve the alkaloids held in suspension in the oil. The acidulated water is then drawn off by a tap at the bottom of the vat. More acidulated water is added, and the washing of the oil twice repeated to exhaust it of the alkaloids. The acidulated mixture with the alkaloids in solution is then filtered through charcoal and stored in a separator or conical tub, till a sufficiency is collected to fill the three boiling-pans of 50-gallon capacity, in which it is made to boil for fifteen minutes, when a handful of animal charcoal is thrown in with caustic soda to neutralise the liquor. After filtration into cooling-pans quinine crystallises out, leaving the other alkaloids in the solution; but the crystals are only a crude product, with an admixture of 16½ per cent of cinchoidine, requiring further treatment the next day. After drying, the crystals are powdered, dissolved in boiling water slightly acidulated, and boiled for another fifteen minutes with charcoal, then double filtered into cooling-pans, where the pure quinine is again crystallised, this time containing only 4 per cent of cinchonidine. Mr. Hooper recently worked out the acid-sulphate process as employed in Germany and Holland, by which on the second crystallisation the whole of the cinchonidine is eliminated, thus rendering the quinine absolutely pure. The pure crystals obtained are now drained and dried by being placed on blotting-paper spread on blocks of plaster of Paris which absorbs the moisture, and a final drying is given them on filtering-paper spread on calico trays placed in the hot-room, where a temperature is maintained of 15 deg. to 20 deg. above that of the atmosphere, by means of hot-water pipes. When dry the quinine is ready for packing after the crystals are broken up. That supplied to the Bombay Government is coloured with a rose anilin, which gives it a beautiful and attractive appearance."

The initial outlay on machinery, buildings, &c., in Naduvatam was between 15,000r. and 16,000r.—*Chemist and Druggist*, March 18.

A NEW RAIN COMPELLER.—Mr. H. W. Allen, formerly of the Nizam's Public Works Department, is, says a contemporary, the inventor of another spray rocket rain-producer capable of rising to a height of one mile or more and then descending slowly, like a parachute. "It has been admitted by learned scientists that intense cold must cause a cloud to discharge rain, but as to its continuing to rain for any prolonged period, there are still different opinions expressed on this point."—*Indian Engineer*, April 1.

GREEN AND BLACK TEAS.

BY ROBERT O. FIELDING.

It is not my intention to enter into an account of the different processes of manufacturing black and green teas, but to find a reason for their chemical differences. By *green tea* I do not mean the highly colored article which is sold in this country, but the pure green teas of the Northern tea-growing districts of China, to the Namuna* teas of India, very little of which, if any, are ever seen here. I may also state that the finer grades of Formosa Oolongs are really green teas, and they are often spoken of in the trade as "a black tea with a green tea flavour." It is a curious fact that the tea bushes grown in the colder and higher altitudes produce the finest green teas. The word *green*, to the Chinese and tea growers of India, has no reference to color, but means "immature," "not of full growth," and is used in some what the same sense as we say "green corn."

The characteristic differences between green and black teas—the differences of color and flavor, and the effect produced on some constitutions by green tea, such as nervous irritability, sleeplessness, etc., which are distinct from those produced by black teas—are so marked that they need no comment, but they possess peculiar chemical properties which have always been attributed to the effect of high heat in the process of manufacture.

From whence do these distinguishing peculiarities arise, and to what are they to be attributed? It is found that many medical herbs, principally those of a nitrogenous nature, such as *atropabelladonna*, *hyoscyamus niger*, etc., when brought in fresh and cool by the grower or collector, dry a bright green color, but if they have been delayed in transit, or remain in a confined state for any length of time, they become heated from a species of spontaneous fermentation, and when loosened and spread open emit vapors and are sensibly warm to the hand. When such plants are dried, the whole of the green color is found to have been destroyed, and a red-brown, and sometimes a blackish brown, result is obtained. When a clear infusion of such leaves is evaporated to dryness, it is not all indissolved by water, but there is left a quantity of brown oxidized extractive matter, which is denominated *apothene*. A similar result is obtained by the evaporation of a clear infusion of black tea. The same action takes place in the infusions of other vegetable substances when exposed to the oxidizing influence of the atmosphere. They become darkened

* To those who may not be acquainted with the term "Namuna" used in the above article I wish to offer a few words of explanation. The word "Namuna" means in Hindustani "sample," and its application to the peculiar description of teas which now go by this name happened in the following manner: a planter sent to England some boxes of this tea ticketed "Namuna," and the London brokers being unacquainted with the meaning of the term, have always since applied the same "Namuna" to this class of tea. They are made from the unfermented leaf, as is the case with Oolongs and Greens. The leaf is generally of a dark olive-green, though some incline to a greyish-black tinge. The liquor is very pale and slim looking, but its quality is stronger by far than ordinary Pekoe (Indian or Ceylon); in flavour, it is between a Flowery Pekoe and a green tea, quite distinct from Flowery Pekoe, possessing somewhat of the rasping catching of the green tea class, with the flavour a little refined. The out-turn is generally green, sometimes with brownish leaves mixed. These teas are often called "Indian Oolongs" or "Indian Mandami Pekoes." They are chiefly produced in the Darjeeling and Kumaon districts. The indigenous plant of India is unsuited for the production of Namuna, nor is the hybrid suitable, but the pure Chinese plants which have been transplanted to India make fine Namunas, and with this variety of the tea bush are the estates of Darjeeling and Kumaon chiefly planted, the original having been brought there by Messrs. Bruce and Fortune in the "Fifties." These teas are invaluable for blending purposes,

on the surface. This gradually spreads through solution, and on evaporation an oxidized extractive matter remains which is insoluble in water. If green tea is wetted and redried with exposure to the air, it will be found to be nearly as dark in color to ordinary black tea. The conclusion then is, that the peculiar characteristics and chemical differences which distinguish black tea from green tea are to be attributed to a species of heating or fermentation, accompanied with oxidation by exposure to the air, and not to being submitted to a higher temperature in the process of manufacture, as has generally been thought. Those who have seen tea manufactured, I think, will agree that this is the rational result of the process. For the purpose of black tea the leaves are allowed to remain in bulk exposed to the air for some little time before being fired; whereas, for green tea, the freshly picked leaves are fired at once, without delay, at a high temperature, fired and rolled again and again, assisted sometimes by a fanning operation to drive off the moisture, and always with brisk agitation until the drying is completed. It is during this firing that the green powder is added that produces the green color of the so-called *green teas* sold in the European and American markets, about one pound of coloring matter being required for every hundred pounds of tea leaves. That the color of black tea is not owing to the fire is evident from the following facts: When the leaves are dried in the sun the same color is obtained, and on the other side, if roasted by fire, without the process of fermentation or withering, and then finished in the Poy-long, a kind of green tea is produced.—*American Grocer.*

THE TEA TABLE.

'Tis there all meet.

The downright clown, and perfectly well-bred.

Blair's Grave.

Though all unknown to Greek and Roman song
The paler Hyson, and the dark Souchong;
Though Black nor Green the warbled praises share
Of knightly Troubadour or gay Trouv er,
Yet scorn not thou, as alien quite to numbers,
That friend to prattle, and that foe to slumbers,
Which Kien Long, imperial poet, praised
So high, that cent per cent its price was raised;
Which Pope himself would sometimes condescend
To place commodious at a couplet's end:
Which the sweet bard of Olney did not spurn,
Who sung the music of the "hissing urn":
Let her, who bade me write, enact the Muse,
Inspire my genius, and my Tea infuse:
So shall my verse the hovering Sylphs delight,
And critic Gnomes relinquish half their spite.
Clear, warm, and flowing as my liquid theme,
As sweet as sugar, and as soft as cream.
May it awhile engage the gentle fair,
Then gambol gaily in the morning air,
Twined in the tendrils of her nut-brown hair!

Who has not read in chronicle or fable,
Of good King Arthur and his famous Table,
Where Kay and Tristrem talk'd by fits and starts,
Of love and murder, broken heads and hearts?
Like this the modern talk at time of tea,
Of the Round Table and its chivalry,
Who speak with even voice and equal zest,
Of hearts ensnared, and heads absurdly drest.
'Tis true a softer race the board environ,
Who corslets wear indeed, but not of iron;
Who play—but seldom combat by the card,
And drink—but drink not through the helmet barr'd.
The fair alone with Chalybean proof,
Support their busts, their lovers keep aloof.
The Muse is female, and may dare reveal
What I have heard, and some, perhaps, may feel.

King Arthur kept his Court in Camelot,
But the Round Table graces every cot.
Palace and farm enjoy the gentle feast
That blends the products of the West and East.
Where'er a British ground, our footsteps roam,

We find is still, and find it too at home.

Whether t'leight the formal guests delay,
Or meet at seven in a friendly way:

Sooner or later, till the board is crown'd—
The lacquer'd tray and argent spoon resound—

The homely delft or far-sought porcelain,
In circling ranks are marshall'd on the plain.

The polished chest with curions art inlaid,
Or quaintly wrought by some ingenious maid,

Displays the lawful spoils of venturous trade.
But not alike in every place and time,

The social banquet that provokes my rhyme;
Not social there, where law or logic lovers,

At inns of court, or academic bowers:

In silent sip the solitary tribes

Of lank-jaw'd students, and of sallow scribes.

Pot after pot is drain'd, yet not a word

From lady's lip in those confines is heard;

Nought save the knell of "midnight's dreary noon,"

And the dull jingle of the circling spoon.

Hie we from thence, nor shall we long delay.

About the homely meal of every day:

For the dear comforts of domestic tea

Are sung too well to stand in need of me,

By Cowper and the Bard of Rimini.

Besides, I hold it for a special grace

That such a theme is rather common-place.

The joyous blazing of the new-stirr'd fire,

The mother's summons to the dozing sire;

The whispers audible, that oft intrude

On the forced silence of the younger brood:

The blooming daughter's ever-ready smile,

So full of meaning and so void of guile;

With all the little mighty things that cheer

The closing day from quiet year to year,

I leave to those whom more benignant fate

Or merit destines to the wedded state.

A stranger I, a wanderer upon earth,

A thriftless prodigal of tears and mirth,

Must learn, without a cherish'd hope, to see

The loving looks that look not love to me;

Happy, if time at length shall teach me this,

To find my proper joy in o'er's bliss:

But ne'er be mine the selfish heart forlorn,

The tear of envy, or the laugh of scorn.

I grow too grave, and must in haste return

To the frail China, and resplendent Urn.

Behold the Table spread, the lady set;

Matrons and spinsters, all are duly met:

The younger belles dispos'd in scatter'd troops.

In rows demure, or gaily whispering groups;

The female elders chat the time away,

(I often wonder what they find to say),

Or sort the pearly fish in painted pools,

(Their light exchequers), while their coffee cools.

What various tones from female organs flow,

How briskly smooth, or languishingly slow;

The pretty creatures laugh, and weep, and rail,

In all gradations of the vocal scale,

From fell Xantippe's emphasis of brass

To the soft murmur of the melting lass;

The smoking board sets all their tongues in motion,

Like many billows of the voiceful ocean;

From note to note the keen remark descends,

In squalls begins, and in a whisper ends.

For loud and shrill the bulky bourgeoisie

Accosts the beauty of departed days—

With accents tuned with unavailing skill,

The Vestal answers to the Matron shrill;

With temper'd melody of cautious speech

The Hostess doubts, and yet accords with each;

Then round and round the breezy murmurs glide,

And every absent Miss is named a Bride.

Yon rosy lassy, just arriv'd from school,

Where all must look, and think, and feel by rule

Uneasy novice of an order strict,

That on her tongue has laid an interdiction,

With her small hands the weighty secret spells

And weaves her fingers into syllables.

Of things like these my infant mind took note

Ere yet my limbs had left the strait collette;

Ill could I else by human wit divine

What Ladies do, when Gents are at their Wine.

At length the summons of the simpering maid,

Or bold-fac'd footman, tardily obey'd,
 Calls Lords, and Knights, and Squires and Priests and
 From white and red, to coffee, tea, and cards. [Bards,
 When the rude North comes roaring up the vale,
 To silence sinks the lily-bending gale:
 So sinks the converse of the soft-robed clan
 At the hard step of heavy-tramping man.
 Lost is the tale, adjourn'd the cutting jest,
 The secret kept, the sly charade unguessed.
 With many a smother'd laugh, and many a flush,
 The buzzing watch-word passes—hush—hush—hush—
 'Tis but the Parson—perhaps it is but I—
 Then wherefore, Ladies, all this mystery?
 The Parson, sure, cannot excite your fears,
 And I, you know, have neither eyes nor ears,—
 Then let the tale, the jest, the laugh revive,
 As if there were not such a quiz alive.
 Oh! let me hear your sweetness; and I'm stunn'd
 With thine, Ricardo, and the Sinking Fund.

As when victorious troops to pillage bound,
 In scatter'd bands, obey'd the bugle's sound,
 So one by one, the jovial swains repair
 To the soft standard of the muster'd fair.
 First, the prim Dangler, complaisant and sleek,
 With frill that flutters, and with shoes that creek,
 Tells all the news to every aged she,
 And points each slander with a low congee;
 Pays for each morsel that the Lady gives
 With parasitical superlatives:
 Whate'er he tastes—'tis excellent—divine—
 Above the coffee—as below the wine.
 Next comes a thing, I know not how to name,
 Of doubtful sex, which neither sex will claim—
 So rank with Bergamot and Attargul,
 That every nose will wind him for a fool—
 A thing so fine, so exquisitely nice,
 It has no *gout* for virtue,—no, nor vice.
 Its waspish waist, elaborately thin,
 Its heartless leer, and apathetic grin,—
 That arching eyebrow of inane pretence,
 That eye of unimpassion'd impudence—
 Are these permitted at a lady's side?
 Forbid it, Modesty, and Maiden pride.
 Shall he your soft embosom'd thoughts engage,
 That joins the negatives of youth and age?
 Boyish in brain, in heart as well as cold
 As a French Courtier fifty winters old,
 Yet of the feeling heart, the thinking brain,
 Attempt to ape him, but attempt in vain:
 For let kind Nature do the best she can,
 'Tis woman still that makes or mars the Man.
 And so it is—the creature can beguile
 The fairest faces of the readiest smile.

The next that comes the Hyson to inhale,
 If not a Man, at least we own a Male
 His worst offences are against your ears,
 For, though he laughs too loud, he seldom sneers.
 He knows the Coachman's craft, the Hunter's hollo,
 The Fancy phrase, that might confound Apollo.
 Right well he loves, in *Row*, or *Lark*, or *Spree*,
 To "sound the base string of humanity."
 His rural friends are Nimrod's genuine seed,
 The best among them are his Hog and Steed.
 His town acquaintance, form'd on midnight bulks,
 Adorn the Nabbing Cheat, or man the Hulks.
 With iron grasp—with face and voice of Brass,
 He shouts loud greeting to each bonny lass—
 Then bolts his tea—and straight begins a story
 Of Hunters' perils, or of Bruisers' glory.
 Talks in an unknown tongue of *Max* and *Milling*,
 And doubtless fancies he is mighty killing.
 Now, up the stairs, disputing all the way,
 Two keen logicians urge their wordy fray:
 Abrupt they enter, voluble and loud,
 But soon remember that they have not bowed;
 That error mended both at once relate
 To some fair maid the subject of debate:
 To her kind judgment both at once refer—
 For each expects a judgment kind from her.
 But she too meek, too witty, and too wise,
 To judge between the vassals of her eyes,
 To each Polkio seeming to incline—
 Allots to each the happy chance—to shine,
 Through four full cups their nice distinctions run,

And all suppose them just where they begun:

Till a gruff senior and his copper nose,
 Arrive to part the Dialectic Foes.

"Yong men," says he, "be sure you both are wrong
 And all your Theories are not worth a song:
 The point is one that elder heads has puzzled:
 Presumptuous boys like you should all be muzzled."
 And to the Maid he turns his solemn face,
 And gravely tells her he has judg'd the case.

But now the ling'ring votaries of port
 Make to the fair—their long-delay'd resort.
 What bulky forms around the table press!
 D. D. and D. L. I. and A. S. S.
 The China rings, the urn is nigh o'erret,
 By such a Bacchannalian Alphabet.
 With glowing faces and with watery eyes,
 They pass about their pury gallantries.
 What beauties they in every dame behold—
 Inspired adorers of the plain and old:
 If men were still so happy and so blind,
 Could men or women call their fate unkind?
 They not remark the glance—the laugh suppress,—
 In the pert virgin's newly-budded breast;
 Nor see their wives' contracted brow severe,
 Their daughter's blush, that moves the Dandy's sneer.
 Nsy, scarce young Nimrod's merry roar can hear,
 Hark, like the rumble of a coming storm,
 Without we hear the dreadful word, Reform—
 Last of the rout, and dogg'd with public cares,
 The politician stumbles up the stairs:
 Whose dusky soul not beauty can illumine,
 Nor wine dispel his patriotic gloom.

From guest to guest in turbid ire he goes,
 And ranks us all among our country's foes.
 Says 'tis a shame that we should take our tea,
 Till wrongs are righted, and the notion free;
 That priests and poets are a venal race,
 Who preach for patronage, and rhyme for place;
 That boys and girls are crazy to be cooing,
 When England's hope is bankrupt and ruin
 That wiser 'twere the coming wrath to fly,
 And that old women should make haste to die.
 As froward infants cry themselves to sleep,
 If unregarded they are left to weep,
 So patriot zeal, if unopposed, destroys,
 Its strength with fervour, and its breath with noise,
 Allow'd resistless as the Son of Ammon,
 Behold the great Reformer at Backgammon:
 Debt, taxes, boroughs, and decline of price,
 Forgotten all, he only damns the dice.

But pause,—the urn that sweetly sung before,
 Like a crack'd lute, is vocal now no more;
 Dry as the footsteps of the ebbing sea,
 Effete and flaccid lie the leaves of tea.
 And I, who always keep the golden mean,
 Have just declined a seventh cup of green.
 The noise, the tumult of that hour is flown;
 Lost in quadrille, whist, commerce, or Pope Joan,
 With eager haste my theme is clear'd away
 And Tea concluded, shall conclude my lay.

 p. 503.

DRUGS, ETC. IN LONDON.

(From the *Chemist and Druggist*.)

London, March 15.

CINCHONA.—The value of the cinchona exports from the U. S. of Colombia has receded from £13,919 in 1888 to £4,610 in 1889, £188 in 1890, and £225 in 1891.

ESSENTIAL OILS.—Lemongrass oil keeps steady at the recent advance to 2d per oz. for native brands. Sales have been made privately at that figure. Citronella is held at 3d per oz. for fair quality on the spot.

QUININE.—Lower. On Friday last 5,000 oz. Brunswick quinine on the spot, in second-hand, sold at 8½d per oz. It is pointed out by a New York house that the imports of quinine (as sulphate and in the bark) into the United States in 1892 amount to at least 4,500,000 oz. or half the estimated output of all the factories in the world. As it is said to be "a well-known fact" that stocks in the States are lighter than usual, it is argued that the consumption of quinine in America must be on the increase; also that, generally, all over the world the consumption is ahead of the production, and that

the deficiency is supplied by the surplus stocks of former years.

ANNATTO.—Quite neglected. Good to fine bright Ceylon seed was bought in today at 2½d to 3¼d per lb.

ARECA-NETS.—For 20 bags of fair quality from Ceylon 25s was refused, and the parcel bought in at 30s per cwt. Another lot was bought in at the same figure.

CALUMBA.—Very little offering; only 3 bags brown and dark mixed sorts sold today at the full price of 20s per cwt.

CROTON-SEED advanced in price at today's auctions by nearly 100 per cent, 36s being paid for a parcel of 52 bags fair quality Ceylon; similar seed was previously worth 20s per cwt.

NUX VOMICA.—A parcel of 76 bags bold grey and pale mixed silky seed, from Colombo, was bought in at 10s to 10s 6d per cwt.

VARIOUS AGRICULTURAL NOTES.

THE INDIAN "TEA EXHIBIT" for Chicago comprises tea and photographs relating to the tea industry, besides the ten khitmutgare previously mentioned.—*M. Times.*

A DODO'S BONES.—Rear Admiral W. R. Kennedy (says the *Madras Mail*) has presented the Bombay Natural History Society with the bones of a dodo which he obtained last year when his flagship visited the Island of Rodriguez. The dodo was a huge ungainly bird belonging to the order of *Columba* incapable of flight and weighing between forty and fifty pounds. It was quite abundant in the Islands of Rodriguez, Bourbon and Mauritius in the commencement of the 17th century, and a live specimen was taken to London in 1638. The Dutch introduced dogs and hogs into the islands in 1644 and these by destroying the young of the dodo probably contributed greatly towards its extermination. In 1693 (thereabouts these curious birds became extinct, but their bones are occasionally found in caverns and swamps.

THE ACME TEA CHEST—we learn is coming rapidly into favour in India, especially for the fine Darjeeling teas—a proof that there is no loss of flavour or depreciation in quality through their use. Nothing can be neater or more convenient in appearance and it is no wonder that grocers are so fond of these boxes at home. The Acme is bound to be the tea box of the future, though for a time many of the Ceylon planters may go on with wooden boxes on account of cheapness of first cost. It is a question however, whether taking ocean freight, safety of the tea, regularity of tare and popularity with the retailers if not the dealers, into account, the "Acme" is not even now as economical as the cheapest wooden box? The fact that the Managing Director, Ceylon Tea Plantations Company, thinks well of the Acme boxes and uses them freely is a strong recommendation.

GAMBLING IN TEA SHARES.—We are very pleased to see our contemporary of the Ceylon "Times" raise a note of warning on a subject to which we specially referred on our return to the island as well as once or twice since. His note is as follows:—

TOO MANY COMPANIES: A WARNING.—A business man writes to us in the following terms:—I hear that no less than four new tea estate companies are shortly to be launched, and, I think, it is a great pity if true. Too much gambling is going on in shares, and many apply for shares in a company simply in order to sell out at a premium to those who were not allowed any. Again, many on hearing of a new company sell out the shares they already possess below last quotations simply to get into one of the new concerns going. Altogether this state of affairs is not very healthy, and I hope the story about the new companies is not true. Mark my words, the present condition of things, if continued, will lead to a number of "wild cat" schemes being floated to the loss of many innocent investors, and the detriment of good concerns.

FARMING IN MADRAS.—A writer in the *Madras Mail* describes the successful farming of a colony of Roman Catholic Christians at Kelacheri in Obingleput through deep ploughing, better manuring and better cattle, and he adds:—It is confidently asserted by many that our ryots are thoroughly alive to their own interests; that all that is needed for their improvement is to show them practically that the adoption of a certain system will pay them and they will readily take to it. What answer will these apologists give me when I show them that the ryots of Perambakam, a village within two miles of Kelacheri, have not to the slightest extent been influenced by the everyday practice in Kelacheri carried on for the last one hundred years? Really there is something rotten in the State of Denmark.—*Pioneer*, March 16.

THE FLOWERING STALK OF "FOURCROYA SELLOA."—At the meeting of the Royal Botanic Society on Saturday, one of the branches of the flowering stalk of *Fourcroya selloa* was shown from the Society's conservatory. This is a Mexican plant allied to the aloes, and like them it flowers only once during its life. The plant, which has been in the conservatory for upwards of twenty years, late last autumn threw up a flower spike, which in a very short time grew to a height of 30 feet, and, passing through the glass roof, rose for some feet into the open air. It could not, of course, resist the frosts and fogs of winter. The flower-buds dropped unopened, when immediately from each node a number of young plants appeared. This mode of reproduction is found in only a few varieties of plants, and is especially valuable in relation to the cultivation of *Fourcroyas* as a source of commercial vegetable fibre.—*Nature*.

A EUCALYPTUS "TROPHY" FOR CHICAGO.—Mr. T. Ingham, of Rockhampton, Queensland, has prepared for exhibition at the World's Fair a trophy illustrative of his eucalyptus-oil manufacture. The central piece is a huge wart or excrescence, 20 feet in circumference, which was found growing on a citron-scented eucalyptus in the neighbourhood. It has been highly polished and embellished with the national arms. Round the wart are arranged with good effect native quadrupeds and birds, and in front of the trophy is a railing made of citron-scented wood, the panels of which are relieved with photographs of the works. When erected at the Chicago Exhibition the trophy will be fitted with a fountain from which the citron-scented oil will be sprayed. Mr. Ingham has secured 100 feet in the very centre of the British section. His exhibit is the only one going to Chicago under the direct supervision of the Queensland Government.—*Chemist and Druggist*, March 18.

THE ORDINARY LIFE of unprotected timber structures is not more than twelve or fifteen years, timber exposed to moisture in the presence of air, especially if in a warm place, or to alternate wetting and drying, will decay rapidly. Sap and moisture retained in timber, by painting or closing in the sticks before they are seasoned through, will cause decay of a very insidious kind, as it works in the interior, leaving an apparently sound exterior or skin, which is the layer that had an opportunity to season. Paint on unseasoned timber is, therefore, more hurtful than serviceable. Large sticks of timber dry so slowly that, before they are seasoned throughout, decay may begin; and hence pieces of small scantling are preferable to large ones. Dampness and a lack of ventilation combined will hasten decay. The best seasoned timber will not withstand the effects of exposure to the weather for much over twenty-five years.—*Nilgiri News*.

Correspondence.

To the Editor.

THE CEYLON PLANTERS' TEA COMPANY
AND MR. ELWOOD MAY'S WORK IN
AMERICA.

New York City, Feb. 21.

DEAR SIR,—At the request of the President of the Company, Mr. S. Elwood May, I send four "menus," as used on "The Wagner Palace Car Company's" system, which system is owned by the Vanderbilt (considered the richest in the world, as well as the largest owners of railways) family.

Competent judges here considered this stroke of President May's as likely to accomplish far more for Ceylon than will the Chicago Exposition, although you may spend the very large sum that Mr. Grinlinton has at his disposal and which he says he will expend.

Notwithstanding every voice to the contrary, I claim and maintain that Mr. May has done, is doing, and will do more for the Tea Industry of Ceylon in America than has ever been accomplished for any product where it WAS WANTED. In this country Ceylon Tea is NOT, to put it mildly, at first liked by the consumer, and it is positively NOT wanted by the Trade Houses. Mr. May is entitled to greater credit for finding and permanently locating in the United States a house for Ceylon tea. The shareholders and those here who know the *zeal* and *skill* with which he has grappled with and surmounted what, to others, would appear insuperable difficulties are amazed at the ingratitude of some of those directly interested in the Tea Planting Industry of Ceylon. Apparently they have worked against him and this Company. Mr. May and I feel that such is not so; but that they have been misled, and did not nor do not understand the situation. I happen to know that if the planters would at once acknowledge his great work through some trivial mark of their appreciation of it, he could enlist the proper capital. Mr. May, as you know, is a well-bred and an exceptionally mentally strong man, and he would not, nor will not open *his* mouth to ask for anything like an endorsement. Hence, I throw out a hint for the planters to embrace and act upon *forthwith*. It is my *first* as it will prove to be my last hint to a misguided, deluded body of intelligent (?) men.—Believe me, yours sincerely,

R. E. PINEO.

[The menus can only be described as "prodigious"; and 17,000 people are every week fed on the cars working on the "Wagner" system. We extract the items which concern the Ceylon tea planters most:—

BREAKFAST.

(A long Menu and then) Lanka Coffee. Bhud Tea.
(From The Ceylon Planters' Tea Co.)

LUNCHEON.

(Long Menu and) Lanka Coffee. Bhud Tea
(From The Ceylon Planters' Tea Co.)

DINNER.

(Long Menu and) Lanka Coffee. Bhud Tea.
(From The Ceylon Planters' Tea Co.)

WAGNER PALACE CAR CO. BUFFET CAR SERVICE.
(Long Menu and) Lanka Coffee, 10c. Bhud Tea
10c. Ised Tea, 15c.

(From The Ceylon Planters' Tea Co.)

—ED. T.A.]

CEYLON AND CHINA TEAS:
A WARNING TO CEYLON TEA
PLANTERS.

London, E.C., March 3.

SIR,—I am glad to see by your *Overland* to hand this week that the rumoured resort to coarser plucking in Ceylon is without foundation. I agree with the opinion of a Ceylon friend I met the other day that if our planters generally resorted to coarser plucking the effect would be an extremely low average in June or July. It is, perhaps, tempting to see these comparatively high prices paid for the lower grades, but it is the average price that producers are interested in, and coarser plucking would reduce it more than the increased quantity would make up for.

Not only would the average price—the principal point for producers—decline considerably but the result would be most prejudicial to Ceylon interests. Ceylon has beaten China by sending a good sound tea at a price which she can't—at any rate hasn't—and she has tried at the expense of many pockets. China's efforts are now principally confined to supplying the very lowest qualities at about 4d per lb. Ceylon should leave her this dirty work, for in the end it will complete the ruin of her tea trade. Already some of the blenders are finding that it does not pay to have any poor China teas in their blends, and the number will increase. No: let Ceylon keep up the fire which has proved so fatal by continuing to send a good sound tea, of distinct Ceylon character—the results of good medium plucking—and continued success is certain. If she condescend to follow her beaten antagonist in supplying poor "fusionless" teas, her enemies alone would rejoice; but I believe our planters are too shrewd to play this poor game.—I am, sir, yours respectfully, W. SOMERVILLE.

COCONUT CULTIVATION IN CEYLON:
ANSWERS TO PRACTICAL QUESTIONS—
COCONUTS AND CACAO.

Pamban, March 15.

DEAR SIR,—In reply to queries of your correspondent "Coconut" in the issue of the *Observer* of the 8th instant:

1.—Yes; it is a fact that Kurunegala coconuts are smaller than those of the Negombo and Chilaw districts. Taken the whole year round I do not think that they are smaller than the Mahaoya Valley nuts, as the latter fall away greatly in size during the dry months. The reason of the Negombo and Chilaw nuts being larger is I fancy that soil is lighter and the roots of the trees can forage more easily for nourishment; and also that water is nearer the surface. Kurunegala and Mahaoya Valley soils are rather stiff, and would benefit greatly by ploughing.

2.—Good seed nuts can be got from Veyangoda where the trees are not grown on hilly land, and if a dependable person can be got to select them. Selected nuts from Goluwa Pokuna are as fine as any that can be procured in Ceylon, and may be relied upon, as being what they profess to be.

3. If your correspondent had ever seen a coconut estate ploughed or dug up with mamoties, and observed that every inch was occupied with roots, he would hardly have asked the question "Does it harm coconuts to plant coffee and cacao among them?" The coconut being the hardier plant would suffer least, but neither would be as

vigorous as if the other were absent. Coconuts do not adversely affect coffee or cacao, and the three products may be grown together, without much harm to each other, provided sufficient manure is returned to the land to replace what is removed in the shape of crop; but if it is expected that all three will grow and yield as much crop as if each were grown apart, great disappointment will follow, and all the products suffer.

W. J.

INDIAN AGRICULTURAL EXPERIENCE.

DEAR SIR,—You should copy into the *Tropical Agriculturist* the article in the *Madras Mail* of the 11th March, headed "Indian Agricultural Notes." The first part may not be of much interest to Ceylonese, but certainly the second part is; for besides showing how good crops of dry grain can be successfully grown on flat lands; it also illustrates how hard it is to get conservative people to adopt new ways though the benefit may be demonstrated before their eyes, for even one hundred years!—Yours truly,

OLD PLANTING RESIDENT.

[See page 715—ED. T. A.]

TEA CULTIVATION AND MR. HUGHES'S IDEA OF A LEAF CROP BEING MORE EXHAUSTIVE THAN ONE OF COFFEE. BERRIES.

DEAR SIR,—I was much interested in reading your article "PROPOSED TEA ANALYSES," as well as your London Correspondent's letter giving Mr. Hughes's views with regard to the manuring of tea estates, in your issue of the 8th instant; but must confess that I was not a little surprised to read:—"Now we have full evidence that a leaf crop is far more exhausting to the soil than is a seed crop," and "It is manifest from this that the plucking of the tea leaf is more exhausting to the soil than the gathering of the coffee berry." I always thought it was the other way about. Of course I cannot refute Mr. Hughes' statement as he must have a scientific reason for saying so, and I can't prove that he is wrong.

However, I fancy he arrived at this conclusion, more from his experience of the crops of hay wheat &c. grown on farms in England, than from his actual knowledge of the manner in which the tea bush is plucked, and the almost microscopic quantity of green leaf that the bush is deprived of at each plucking. I cannot quite see the analogy between the annual farm crops of England which amount to tons and tons per acre, where the entire produce of the soil—straw, seed and roots—is carried off bodily, and the perennial,—tea plant of the tropics with its minute yield of leaf,—not removed, mind you, at one fell swoop, but little by little, a handful at a time, as I shall proceed to show.

400 lb. of tea an acre is considered a good crop in the "high districts," without manuring. Roughly speaking, an acre contains 3,000 to 4,000 trees—say 3,200. Now 2 ounces made tea per tree per annum is equal to 400 lb. per acre exactly; and 2 oz. made tea is equal to 8 z3 green leaf. If you divide 8 oz. by 36—the number of pluckings in the year—that is, three rounds a month, the result is .22—say $\frac{1}{4}$ oz. of green leaf from each tree every ten days. There you have the whole produce of the tree for the

year, in green leaf, viz. 8 oz., which you could very comfortably put in your coat pocket; and the result in made tea, 2 oz., in your waistcoat pocket. In cwt., the above comes to $3\frac{1}{2}$ as against 10 cwt of coffee which was considered a good crop. I leave your readers to judge which is the most exhausting to the soil.

It might appear from what I have written that I do not believe in manuring; on the contrary I am a strong advocate in favour of it, although I cannot speak of its effects on tea from my own experience. Still, I know an estate where a field doubled its yield from one application of poonac and bones; and all to whom I have spoken on the subject strongly recommend it. I believe the crops of the well-known K. A. W. Group have been increased about 50 per cent by the judicious application of castor cake and bones. The worthy Manager of that group would confer a great boon on his fellow planters were he to give them the benefit of his experience with manure—the quantity applied, the cost and the increase in crop compared with unmanured fields. It is almost unnecessary to say that we have no choice as to the kind of manure that should be applied to tea on a large scale. It is "Hobson's Choice"—poonac and bones or nothing, and from all accounts it suits admirably. It would no doubt be very interesting to get scientific opinion as to the ingredients which the tea plant extracts from the soil, and what should be returned to restore its fertility, but would it be profitable? In my opinion, the quantity of tea and increase in yield can be improved only by fine plucking and manuring and we can do both the one and the other without the aid of agricultural chemists.

BROKEN PEKOE.

COCONUT CULTIVATION IN CEYLON: BY AN EXPERIENCED PLANTER.

Pamban, March 24.

DEAR SIR,—After the recent discussion on the bearing capabilities of the coconut tree, perhaps a few remarks upon its cultivation may not be out of place. The soils upon which coconuts grow vary greatly; and upon the quality of the soil depends the future of the estate. I would arrange coconut soils in the following order:—

1st. A light friable soil mixed with sand and humus, which impacts but little in the driest weather.

2nd. A dark chocolate friable soil.

3rd. A thoroughly disintegrated laterite soil mixed with small stones or gravel.

4th. White sand with a very little admixture of good soil.

5th. Hard cakook and stiff sandy clays.

The first in my experience is the best suited for the successful growth of coconuts, and responds the most readily to good treatment.

Nos. 2 and 3 follow, and are benefited even more than No. 1 by deep ploughing and digging.

No. 4 will not derive much good from these operations, as there would be very little in such a soil to be acted upon by atmospheric influences.

Nos. 5 and 6. The outlay in bringing even a foot depth of surface into a fit condition for the roots to travel freely through it would be great, and the result would hardly justify the expenditure; while the subsoil would still remain cold and wet and impervious to the roots. I would warn all against venturing to plant upon such lands, even if given as a gift! Where however estates upon lands of this kind already exist I would, before spending money on surface digging or manuring, advise that drains be dug one chain apart

(across the slope if there is one) three feet deep and two feet wide, and opening out into a cross drain so that excess of moisture may drain away. These drains should be cleaned out before the beginning of each monsoon. The good effect of this treatment would soon be apparent, and any subsequent tillage would not be thrown away. To satisfy the doubting mind an acre or two might be tried as an experiment. Where an estate has been neglected it would be necessary, before venturing upon manuring, to clear and burn all jungle growth, weeds and fallen branches; and to dig over or plough the surface to a depth of at least one foot. Drains should be cut where the soil is at all inclined to be swampy, or where the land is very level and water does not flow off readily. Stagnant water is poison to a coconut tree, while it revels by the side of a running stream. I know of many estates and gardens that would benefit greatly by having some drains cut in them, though the owners do not seem to see it.

It is not to be expected that the first application of manure to a neglected or partially exhausted estate will raise the yield from say 15 or 20 nuts up to 35 or 40 in the second year. There will be an appreciable increase in the yield, but the bulk of the manure applied will go to build up the trees and fit them for heavy bearing after the second application. The first dressing to a neglected estate should consist largely of nitrogenous matters so as to give the trees good heads of leaves: a very necessary thing if the trees are to do their duty by the tillage they receive afterwards. To all who are inclined to manure their estates I would give this advice: do not begin unless you intend to carry on the work systematically and at regular stated intervals. To adopt the Irishman's method of procuring streaky bacon, by fattening his animals at one time and starving them at another, will never do. To permit the first application of manure to be completely exhausted before giving a second is wasteful in the extreme; the vigour of the trees decline, and a large part of the second application is consumed in again bringing the trees into good condition to enable them to bear—and I have learned by experience that this is a harder thing to do than might be supposed—while a second application before the first is exhausted, keeps the trees in continuous vigour, and enables them to yield the maximum crop possible from the food available. I have found that manuring once in two years is a good plan; that is doing one half the estate in alternate years. This is preferable to doing the whole estate each year, as there is a saving in application and the roots are not cut too often. While to apply sufficient to last three years ties up too much capital, and increases the risk of some of the manure being washed away beyond the reach of the roots. With these remarks I will now state what I consider the best manures, and the method of their application.

Foremost comes cattle droppings; then bones or fish; white castor cake; wood ashes. These contain the elements most largely removed from the soil by crops, and which if not restored soon causes "exhaustion"; namely nitrogen, phosphoric acid and potash. To obtain the greatest benefit from cattle manure the animals should be tied to the trees during the night, as by this method no ammonia is lost. If cattle are housed during inclement weather they take no harm from exposure at other times. Proceed thus: let two head of cattle be tied to each tree for seven nights, then spread the droppings evenly in a circle of 12 feet diameter—the tree being the centre;—

over this scatter a mixture of 4 lb. finely ground bone dust and 6 lb. ground white castor cake. Dig and thoroughly mix all these to a depth of 9 or 10 inches; after levelling; sprinkle 10 lb. wood ashes, and lightly rake in. The object of applying the ashes on the surface is to prevent, as far as possible, the soluble potash from being carried down too quickly, by heavy rains, beyond the reach of the roots. As over the dug surface grass and weeds are sure to grow rank, and appropriate a share of the manure, I would recommend that it be covered over with the leafy portion of the dry coconut leaves too deep; this will prevent the growth of weeds, and somewhat retard evaporation; and if the land is at all on a slope will prevent wash, while it will not interfere with aeration or prevent access of rain. Some people like to see nothing but a green sward under the trees, and object to this semi-mulching as detracting from the appearance of the estate. Such may dispense with it, but the manured spaces will need to be mamoty weeded once in three months and the grass and weeds buried. A manuring of the above description will last for two years; and where the trees are already in good heart, should yield from 60 to 80 nuts per tree according to the season, and at the end leave them in full vigour. It is very seldom however that any considerable extent of an estate can be manured in this way, as one head of cattle would only do 26 trees in a year; and to treat 100 acres of say 7,000 trees would require 270 cattle. As very few estates are so fortunately situated as to have grazing ground for such a herd it becomes necessary to rely mainly on bones, castor cake and wood ashes, supplemented with whatever manure can be purchased from the roadside cattle sheds and chekku yards, whose owners either do not know the value of it, or have no gardens of their own in which to utilize it. On the first three descriptions of soil, bones, castor cake and wood ashes do well; but on the fourth it is necessary to have some bulky substance, say vegetable, tank soil, or burnt clay, to mix with them. I would recommend the following as fair proportions for a good mixture which would last two years and yield satisfactory results.

12 lb. white castor cake.

4 lb. finely ground bone dust.

12 lb. wood ashes.

If cattle manure is available one imperial bushel to each tree would be a very great addition; but it is not absolutely necessary. These are to be applied in the same manure as directed above for cattle manure &c. Steamed bones are more expensive than the ground article; but where a speedy result is desired they are preferable.* Coconut husks and leaves contain a large percentage of potash; and if those are burned in small heaps in the squares between the trees much of the potash removed from the soil will thus be restored. When purchasing ashes from villagers they should be tested by washing a few lb; pure ashes will nearly all float away with the water, and the residue will show how much sand is mixed with it. Fancying I was getting pure ashes I for one entire week paid for what on testing turned out two-thirds to three-fourths earth and sand! Where there is difficulty in procuring ashes, a trial might be made of kainit, an impure potash salt from Germany; Light soils would be greatly improved by growing a crop of some legume and ploughing it in just about the time it shows signs of blossoming. W. J.

* If fish manure is used 8 lb. should be applied to each tree with the other ingredient.

SCIENTIFIC INVESTIGATIONS TOUCHING THE CULTIVATION OF TEA.

Hatton, April 3rd.

DEAR SIR,—I have marked with pleasure the passage of the resolution of the Dimbula planters in the above connection. We have lately heard a great many complaints respecting the falling off in quality of Ceylon tea. Many will not admit this, and such may have been their experience, but as far as I have been able to observe. I have noted that I have obtained more aromatic and nicer flavoured teas from trees which have aged from 3 to 10 years than from trees aged beyond the period named. Especially so has this been the case in new land. This decay, we can only attribute to the exhaustion of some material in the soil which supplied this fine flavour. We have noted further, that there are certain tea estates in Ceylon, which produce a very finely flavoured tea, but at present are unable to determine whether this result comes about through the tea being grown in better soil or at a higher altitude or both. Portswood for instance and some other estates at higher altitudes must contain some property in the soil which imparts such fine flavour to the leaf grown on these estates, and the matter to determine is, whether or not a man of science could tell us what properties those soils contain, that others do not possess; and having found out the characteristic that they possess and that poor estates lack proprietors will at once (if possible) supply the needful nourishment and improve the quality of their teas. A field of tea was manured on Strathdon; and it is stated by the manager (Mr. Blacklaw) that the yield was greatly increased, but what is more significant, that the teas had a very peculiar flavour, which was not relished, so if manuring can bring about such a result, is it not possible that some other kind of manure (containing more of the properties of the soil of the estates which obtain good yields and good prices) could be supplied, and the same favourable results obtained. If such were possible, we should not only double the value of poorish properties, but would maintain the high opinion formed in the Lane, as to the excellence of our teas. The process of manufacture of our teas calls for investigation also, and we could not do better than undertake to solve both matters at the same time. The brewing of beer has been brought within a scientific sphere; and seeing that tea undergoes a process something similar to hops, there is no reason to think otherwise than that tea manufacture could be brought within the same sphere and results infinitely better.—Yours truly,

W. A. T.

PERTINENT QUERIES FOR TEA ESTIMATORS.

Upcountry, April 1.

DEAR SIR,—Your *Overland* of March 30th gives an export of over 4 million lb. of tea more than last season at same date. The rainfall here to date is 30 inches, having fallen on 43 days, this is ahead of last year by 10 inches falling on exactly the same number of days 43. Last year we were told our outturn of tea was short, owing to the want of sun-heat and too much rain. How are we now going to account for the excess?—another chance for the P. A.—Yours truly,

AN OLD COFFEE STUMP.

BRITISH NORTH BORNEO.

Kandy, April 3rd.

DEAR SIR,—Incorrect reports having got about, I have been requested to give publicity to the following facts regarding reductions of the Staff there. The total number of Officers who have left amount to four, viz. three from Sandakan and one from the West Coast. Of these one went home on leave and may or may not return. A second resigned the service so that there are only two remaining officers to make up the so-called reductions. The tobacco crop for 1892 will be shipped shortly; it is reported as satisfactory in almost every district. Attention is now being drawn to planting it by natives. Mr. Cottah, an experienced planter, is about to start operations on the Sabah river. Much attention is drawn to Liberian Coffee and Manila Hemp and both of these valuable products promise a valuable return to the investor.

British North Borneo expects shortly to be placed in telegraphic communication with Singapore and Europe, the Eastern Extension Telegraphic Co. having undertaken to lay down a cable from Singapore to Manila touching at Labuan from where a land line can be made to Sandakan.

Labuan and North Borneo have just been visited by Admiral Sir Edmond Fremantle with H.M.S. *Imperieuse* and *Archer*.

The settlement of the Dutch Boundary question has enabled the Government to open a new Station at Tawar which is attracting much attention and already applications are being made for town lots and village sites.

W. D. GIBBON, *Agent*.

THE ACCLIMATISATION OF TROUT.

SIR,—May I, through your columns, inform those who are interested in the acclimatisation of trout how the matter stands at present, and in doing so, reply to numerous letters addressed to me on the subject.

The first experiments in trout-breeding were made in 1880 by the late Mr. H. L. Hubbard, of St. John's, Udapussellawa, who was greatly interested in the subject, and to his efforts is due the knowledge that trout could be easily reared in Ceylon waters. He was assisted by Mr. Le Mesurier and Mr. Hearn, but no record, so far as I can learn, was kept by him of the number of ova imported. About twenty fish were turned into the Nuwara Eliya stream in 1882 by Mr. Hubbard, and he continued to import ova, but I cannot learn the results of his later experiments.

In 1886 Mr. Hubbard's efforts were energetically and successfully followed up by Mr. C. J. R. Le Mesurier, then Assistant Government Agent of Nuwara Eliya, who, as Chairman of the Local Board, invited public support, and began operations on a larger scale. In 1886 and 1888 the public subscribed liberally, and an equal amount was contributed by the Local Board, making a total of considerably over £3,000.

Ova were imported in 1886, 1887, 1888, and 1890, but it is to be regretted that no record was kept of the results, nor of the localities in which trout fry were turned out. I believe that several streams were stocked by others, Mr. Wilson of Drayton, especially, besides the lake and river in Nuwara Eliya; but the trout seem to have entirely disappeared from them. Mr. Le Mesurier devoted a great deal of care and attention to attempts at artificial spawning; but without success. In 1890 and 1891 hardly any fry were turned out, and

though no fishing had been allowed, the trout had decreased deplorably, and are now rarely to be seen, except in November and December, when they ascend the stream to spawn.

Unfortunately it is beyond all doubt that few of these, if any, ever return to the lake. It is impossible effectually to protect the stream from poachers of all kinds, and it is hopeless to expect the lake and stream ever to become stocked with trout by natural increase, as this stream, the only spawning ground, is unsuitable for the purpose. But there are numerous other streams which ought to have a better chance, and, as for Nuwara Eliya lake and stream, a very small amount is sufficient to stock it annually with sufficient trout to afford excellent fishing.

In 1892 I imported 10,000 ova merely to obtain an exact account of the cost of fry turned out into the streams. Half the ova unfortunately proved infertile, and of the remainder only about 390 reached an age when they could take care of themselves. These cost, however, under R300 and, with ordinary luck, three or four times the number would be turned out for the same amount. As I was dissatisfied with this result I imported another lot of 12,000 ova this year, which have hatched well, and I hope to be able to prove that R400 per annum is sufficient to provide for annually stocking Nuwara Eliya lake and stream with trout enough to afford excellent sport, whether they breed locally or not. Surely there are enough disciples of Izaak Walton in Ceylon to provide the necessary amount.

In future the only funds available will be those realised by the issue of licenses to fish, and, if a sufficient number is not taken out to enable the Local Board to import ova annually, fishermen will have only themselves to blame.

Nuwara Eliya.

GEORGE M. FOWLER.

CEYLON TEA IN AMERICA.

SIR,—Your contemporary of the "Ceylon Times" makes a solemn appeal in the following words:—

We entreat planters to remember that the American Company is not the only organisation trying to sell Ceylon tea in America, and, if rumour is to be trusted, more than one other syndicate will shortly take up the work. Why, therefore, should they be placed at an unfair disadvantage with the Elwood May combination by the teas of the latter alone being pushed at Chicago?

Now, sir, I would ask where is the evidence that any other "Organization" or "Syndicate" has spent a cent on advertising Ceylon Tea in America?

I can quite believe, however, that Lipton or a syndicate may desire to enter now on a field which Elwood May and Pineo and others of the Company have prepared for them. But to throw E. May over at this time would be the shabbiest thing ever done in the name of Ceylon planters is the opinion of—Yours truly,
A TEA PLANTER.

THE MAHOGANY TREE is found to thrive at Bangalore, and a plantation has been raised there, and handed over for maintenance to the Forest Conservancy Department.—*Indian Agriculturist*, March 11.

GREEN TEAS.—We call attention to a paper on this subject by an American gentleman, given in our *Tropical Agriculturist*. It is interesting to find this authority drawing a wide distinction between "pure green teas" and the "highly-coloured" (and we may add impure) article so much in vogue with his countrymen,

CHEMISTRY OF TEA.

At a time when the advantage of calling in "science," in the person of an Analytical Chemist, to the aid of the Ceylon tea planter is being discussed, it is well to call attention to the following notes written some years ago by Mr. A. J. Dowling, Tea-planter, of Chittagong. It is possible that some of his remarks may prove usefully suggestive here:—

There is scarcely an industry of importance that does not call in the aid of the analytical chemist. There are laboratories in most smelting, dyeing, bleaching, mining and other large works, but tea ignores the chemist entirely, and yet it is an article of manufacture which gets, perhaps more than any other price for quality. An anna per pound more or less represents a fair profit or a serious loss. Tea is at present entirely dependent on the Broker, who, although qualified to pass an opinion on the appearance of the leaf, the color of the outturn, the flavor and the strength, never ventures a remark as to what important constituent the tea is deficient in, or of what objectionable substance it has an excess. He will possibly tell you that your defect is a dull outturn. You send him the finest outturn he could wish to see, and he reports your tea "soft" and "wanting in quality." Tea is not manufactured to be looked at, but to be consumed, and although appearance goes some way, strength and body will ever command most attention, and what we want to know in a Report is not only how the teas look and how they taste, but of what they should have a little more, and of what they would be the better to have a little less.

From the moment pressure is brought to bear on the succulent leaves in the Rolling Machines through the silent process of fermentation or coloring, to the time when the fragrant smelling tea leaves the fires, a variety of chemical changes occur in the Dextrine, Glucose, Gum, the Tannin, Nitrogen, Potash, Ammonia, Chlorine and Sulphuric Acids, and Essential Oil, which are found in the extract or "Liquor." Is it too much to expect that in the course of time to the monotonous report of "greyish, fair tip, brisk little flavor," may be added the more desirable information of "fairly gummy, potash 2-13 per cent only, good trace of Essential Oil"? We could then with our knowledge of manures, supply after a while the lacking Potash, and do our best to keep up the desired proportion of Essential Oil.

Referring to "Soils and Manures" for the constituents of tea leaves and manufactured tea, I add the following particulars from my note-book:—

Acids redden blue litmus paper.

Alkalies or bases give a blue color to red paper.

Acids and Alkalies have thus a kind of antagonistic function, and neutralize one another.

Acids acting on bases form salts which commonly have no action on either blue or red litmus paper.

Theine gives tea its bitter taste—it is very nitrogenous; although a base, it does not, as other bases, neutralize an acid. It does not exist in the leaf in a free state, but as *Tannate* of *Theine*.

Tannin gives astringency and color to the tea—it is partially destroyed during fermentation.

Tan consists of nitric acid and resins. It can be manufactured from nitric acid and charcoal. A solution of *Gelatin* gives a white flocculent precipitate showing the tannin in tea, and ferric acid, which can be made from iron filings dissolved in warm dilute nitric acid, gives a blue-black precipitate.

Certain combinations of *Tannin* absorb oxygen from the air and turn black, and all substances containing tannic acid turn black when brought in contact with iron.

The following experiments may be of interest :—
Added to roll :

	Makes the outturn and	the liquor:
Chlorate of Potash ...dulls the tips,	bright,	pungent
Carbonate of Ammonia...improves ,,	dark green,	soft thin
Tannic Acid... ,, ,,	dirty,	thin
Carbonate of Soda ...dulls ,,	fair	dark
Hydrochloric Acid ...ordinary ,,	ordinary,	weak thick
Gum Arabic. ,, ,,	good,	thick
Hydrochloric Acid and Gum ... ,, ,,	good,	weak
Nitrate of Soda ... ,, ,,	good,	full
Tincture of Steel ...dulls the ,,	black,	very bad
Nitrate of Potash ...ordinary ,,	good,	cloudy

taste of the liquor being injured in every instance. The last experiment but one shows how necessary it is to ensure that no iron comes in contact with the moist roll, or the appearance of leaf, color of outturn and the liquor will be prejudicially affected.

IN DEFENCE OF ELWOOD MAY AND THE AMERICAN METHOD.

Sir,—Without going into the question of the dispute between Messrs. Elwood May and Grinlinton, and your remarks thereon, which latter I do not consider justified, I would like to point out the great difference there is in many respects between English and American methods of conducting business, and that which might strike us as peculiar or even "outrageous" in the latter would certainly not be considered so in America. Unless an Englishman has been to America it is simply impossible for him to properly understand the difference there is.

The Ceylon Planters' Tea Company was formed, and the money entrusted to the Ceylon Commissioner at the Chicago Exhibition was subscribed, with, I take it, one and the same object, viz., that of pushing the sale of Ceylon teas in America.

The Company, in pursuance of this object, has very largely advertised our teas, has established agencies for the sale of these teas, under certain brands, in most of the leading cities of the States, and within the last few months were getting more orders for tea than could be supplied with the limited funds at the disposal of the Company.

And I say without hesitation that if the Ceylon Court at Chicago is not going to be worked in co-operation with the Ceylon Planters' Tea Company, the former will, as regards the object for which the money to run it was given, be a ghastly failure.

Mr. Elwood May—who is not a shopkeeper, as you sneeringly term him—has, as Managing Director of the Company in America, done more in my opinion to make our teas known in America than any other man could have done, and this in spite of want of funds, little or no support from this side, and distrust, culminating, in some instances, in virulent abuse.

If, as you anticipate, the collapse of the Company takes place, those persons in Ceylon who will be largely responsible for bringing it to that end are not to be congratulated.

So far from newspaper proprietors clamouring to know if Mr. Elwood May's promises will receive fulfilment, I saw, when in New York, letters intimating that contracts for advertisements of the Ceylon Planters' Tea Company were drawing to a close, and offering to renew them on the same terms, viz., by payment in shares of the Company!

I send you a copy of the illustrated paper *The South*, which you have doubtless seen before, also photo, of

a small exhibit of Ceylon teas made by the Company at one of the large stores in New York. These will give you an idea of two different ways by which the Company is pushing our teas. C. O. M.
Colombo, April 7th.—Local "Times."

THE DOWNDRAFT SIROCCO.

IMPORTANT IMPROVEMENTS IN THIS YEAR'S MACHINE.

Messrs. Davidson & Co. have made a small but very important alteration in these machines whereby the quality of the tea turned out is very much improved, and the drying capacity of the machine considerably increased. The alteration consists in the insertion of an intermediate tray port and set of resting pawls in the drying box, about midway between the inlet doors for the trays containing wet leaf and the top outlet for the dried tea.

The advantage of this is that the trays on reaching this stage of the drying operation can be taken out, the leaf well shaken up and turned over, and the tray re-inserted. If an increase in the outturn is desired the contents of two of the trays thus treated can be put on one, as the leaf after being shaken up will allow the air to pass through this larger quantity perfectly satisfactorily. This will make room for the insertion of an extra tray of wet leaf at the lower inlet door every time the operation is performed. The shaking up of the leaf in this way gives it a more curly appearance when fully dried, and we are convinced that the users of this new type of Sirocco will find an appreciable increase in the market value of their tea. The operation is very simple, and does not necessitate any increase in the labour employed. The machine can also be worked as hitherto if so desired. A perforated plate has also been inserted in these new machines at the top of the drying box immediately above the trays to effect an even distribution of the hot air on all sides of the drying chamber. We understand the existing machines can be altered to the new style at a very trifling cost.

A LONDON COFFEE MART.

THE WHOLE-BERRY COFFEE COMPANY (LIMITED).

For years past it has been a chronic complaint on the part of successive Chancellors of the Exchequer that the consumption of coffee either decreases or that it maintains a character of dull uniformity. And, strange to relate, we are in the United Kingdom consuming less coffee per head of the population than we did forty years ago; in addition to which it may be said that we use less than any other civilised country in the world. We intend in this article to show the "why and the wherefore" of so unsatisfactory a state of affairs, which, after all, is not creditable to us as a nation, for whilst this delightful and refreshing beverage has consistently been diminishing in quantity—and too often in quality—the consumption of alcoholic liquors has more than correspondingly increased. Still, one cannot overlook the fact that the coffee trade forms one of the great staples of British commerce.

The honour of introducing the aromatic berry into European civilisation is claimed by both English and Italians. But so early as 1652 we find that an English merchant from Turkey brought over a Greek servant with him who knew how to roast coffee, and he forthwith opened a coffee-house, a record of which has been preserved. The merchant in question issued a handbill drawing attention to "The virtue of the coffee-drink, first publicly made and sold in England by Pasqua Rosee, in St. Michael's Alley, Cornhill, at the sign of his own head." Its introduction was not, however, received with any particular amount of favour, for it excited antipathy from a domestic point of view, and incurred the odium of the medicos of that day and generation. An English pamphlet was printed at Oxford in 1659 on "The Nature of the Drink Kawi or Coffee," and about that time Purchas wrote respecting coffee,

which, he said, was "drunk as hot as they can endure it; it is as black as soot, and tastes not much unlike it; good, they say, for digestion and mirth." The fair sex were particularly disinclined to favour the new concoction, and to such lengths did prejudice go that in 1674 they drew up "The Women's Petition against Coffee." It was alleged as cause of complaint that "it made men unfruitful as the deserts whence that unhappy berry is said to be brought; that the offspring of our mighty ancestors would dwindle into a succession of apes and pigmies; and (most unpardonable offence) on a domestic message a husband would stop by the way to drink a couple of cups of coffee." On its subsequent growth in public favour—though it became more popular from the first on the Continent—and its influence on the manners, morals, and politics of the people, has shown in the history of the coffee-houses which were afterwards established in all directions, space forbids us to dwell. Of late years, however, as we have already said, there is a marked declension in the consumption of coffee in England, and perhaps the primary reason for this is to be found in the fact that coffee admits of so much adulteration, and the trade has also been hampered by loose and costly methods of distribution.

It was with a full realisation of these two drawbacks that several years ago some enterprising merchants and coffee brokers in the City determined to form the Whole-Berry Coffee Company (Limited), with an idea of replacing the old elaborate and costly system by a simple organisation, which should embrace the importer, broker, dealer, and distributor all in one, and by touching everything at first hand it was hoped to afford some exceptional facilities to customers such as could be obtained in no other way. Whether they have succeeded in that task the many large customers of the company can best judge; but in a recent interview with the able and energetic secretary of the Whole-Berry Coffee Company he stated to a representative of *Money and Trade* (who went over the premises at 3 Jewry Street E.C.) that there were as many as 3,000 names on their books at the present moment the *clientèle* including many of the largest hotel proprietors and restaurateurs in the United Kingdom, in addition a number of firms in the British colonies and abroad.

"The object of our company," continued the secretary, "has been to supply families with pure coffee roasted on the premises every day and packed in air-tight tins, and dispatched the same evening. We send out packages of two pounds and upwards, and during the last two years business has increased largely, and the export trade has been also very encouraging. We often consign a quantity of 7-lb. and 14-lb. export tins to India, Australia, New Zealand, and South Africa."

In the course of subsequent conversation we were informed that the best coffee comes from Mysore, though the Central American coffee from Costa Rica, &c., it appears, runs it very closely. The Abyssinian coffee from Mocha, however, has a flavour peculiar to itself, and this coffee is enjoyed by a limited few.

Showing us some samples of various berries, which certainly differed both in colour and flavour, the secretary said that in Abyssinia the natives let the berry hang until it is dead ripe, hence its yellow appearance; whereas in other places, more especially in European colonies, the berries were quite green when picked.

"Look at these," he continued, sampling a canister of bright green coffee berries from the island of Ceylon; "this coffee used to be considered the very best grown, but now the quantity produced has fallen off considerably. The flavour of Mocha coffee," he continued, "is very different to that—in fact, so marked is it that after roasting one might almost compare it to the difference in flavour between mutton and venison, for the Abyssinian coffee berry has a peculiarly 'gamey' flavour. If buyers found their Ceylon coffee to taste like that called Mocha they would say it was vile, and refuse to touch it."

"Whilst you are referring to the differences of

quality in coffee, can you say why it is we find that on the Continent—in Paris, for instance—the coffee served is often so superior to that obtained in England?"

"That is to be accounted for by the method of preparation; but I maintain that the very finest coffee in the world comes to England, and if the public only get coffee pure, freshly roasted, and grind it 'only when required,' it will be found equal to and much better than any beverage of the kind on the Continent. It is, however, essential that the greatest care is taken in roasting the berries."

This, it was explained, is performed in different ways. In Arabia, America, and some other places it is done in an open pan over the fire. In this country we usually roast the berries in a cylinder. The greatest skill having been displayed in selecting the best grown berries, it is imperative that the "roasting" should be properly performed, and the Whole-Berry Company provides for this by the particular attention which is paid to that process. When roasted, the properties of the berries—whether these berries have come from South or Central America, Jamaica, India, Ceylon, or Java—are quite transformed; and if one only touches or smells a single berry this will be observed, and one may detect the fine aromatic flavour which characterises fresh coffee. After being roasted the coffee should be used as soon as possible, or it will spoil, for the least damp affects it, and it readily absorbs moisture from the air. If, therefore, coffee is not wanted for immediate use it requires to be securely packed in air-tight tins.

Turning to the subject of adulteration, the secretary spoke warmly in condemnation of the pernicious system which so often obtains in mixing large quantities of chicory with coffee, and palming it off on the purchaser as a *bona fide* pure article. Some idea of the magnitude of this fraudulent dealing may be gathered from the fact that, whereas it is estimated that the weight of the coffee annually sold in packets and tins throughout the United Kingdom amounts to more than 42,000 tons, the actual weight of coffee upon which duty is paid for home consumption is only about 14,000 tons a year. Again, analysis of 43 samples of coffee obtained some time ago, and tested by the analyst, Dr. B. H. Paul, F.C.S., showed that "13 contained from 62 to 93 per cent of adulteration, mostly chicory; 27 contained from 30 to 59 per cent, and three about 25 per cent of adulteration; 22 of the number being labelled 'French coffee'!"

The Whole-Berry Coffee Company is strongly in favour of Parliamentary enactment in regard to the placing of labels on packages of coffee mixed with chicory, and they urge that the exact proportion of each article should be clearly stated on the label, so that the purchaser may see that adulterations are marked thus:—"This mixture is guaranteed to contain 50 per cent of coffee and 50 per cent of chicory;" or that "This mixture is warranted to consist of 75 per cent of coffee and 25 per cent of chicory," as the case may be. Also, the Company strongly approves of all the items in Dr. Cameron's Food and Drugs Act (1875) Amendment Bill. There has lately been a great agitation on the subject both in the trade and in Parliament, and a little time ago the matter was brought directly before the notice of Mr. H. Fowler, as President of the Local Government Board.

"There is no fear of the purchaser getting adulterated coffee," remarked the Secretary, "if he will only buy the berries. One cannot then be cheated, for, although there has been talk about artificial berries being made, depend upon it there is really nothing in such a suggestion. The coffee which we sell, and which we are prepared to grind for consumers, varies in price from 1s 3d to 1s 10d per lb., and the parcels are made up every day and dispatched free of charge, not only to consumers in London, but throughout the United Kingdom."

With a view to securing only the best and purest article the Whole-Berry Company is specially organised so that it either imports its coffee direct or buys the produce from the importers on the London market in Mincing Lane. In the rear of this company's clerical

offices in Jewry Street special machinery, driven by gas power, has been set up for roasting and grinding the berries, and this machinery is kept for the convenience of customers who may not have mills of their own, and who are guaranteed to be supplied with an unadulterated article. After the coffee has been properly roasted (a process taking from 20 to 30 minutes) it is placed in bins, and goes downstairs to be packed. In the basement is the packing department and as we passed through it we noticed several cases were being prepared for shipment to Adelaide, and busy hands in another part of the building were engaged in weighing and packing in air-tight tins smaller packages for ordinary consumption.

Having therefore investigated for ourselves the system upon which the Whole Berry Coffee is supplied and further submitted samples to a practical test, all we can say is that if the general public wishes to procure the best and purest coffee there is no difficulty in finding out where it is to be obtained.—*Money and Trade.*

VARIOUS AGRICULTURAL NOTES.

CENTRAL ASIAN COTTON.—The export of cotton from Central Asia during 1892, the Odessa correspondent of the *Daily Chronicle* says, reached nearly 50,000 tons. During 1891 it was a trifle over 42,000 tons, and in 1888, when the Transcaspien line was first opened to Samarkand, only 18,800 tons. This cotton is almost entirely consumed in Russia, being shipped from the eastern Caspian ports to Astrakhan, and thence up the Volga. American long staple cotton is gradually taking the place of native cotton all over the Central Asian provinces.—*Indian Engineer.*

LONG LIVED TREES.—How vast are the periods of life allotted to the long-lived trees may be judged from the following list of ages known to have been reached by patriarchs of the respective kinds:—

Elm ..	300	years	Walnut ..	900	years.
Ivy ..	335	do	Oriental Plane	1000	do
Maple ..	516	do	Lime ..	1100	do
Larch ..	576	do	Spruce ..	1200	do
Orange..	630	do	Oak ..	1500	do
Cypress	800	do	Cedar ..	2000	do
Olive ..	800	do	Yew ..	3200	do

—*Nilgiri News*, March 22.

PROGRESS IN NEW GUINEA.—Says the *Australasian*:—

It is stated in the last annual report on British New Guinea by the Administrator, Sir W. MacGregor, that the yield of gold has fallen off for last year. The output was 1,235oz., as against 2,426oz. in 1891. The alluvial washing is now apparently at an end. The beche-de-mer fishery has also decreased in value, the exports for 1892 being 49 tons, as against 64 tons in the preceding year. Copra will undoubtedly now become the principal export. At present this industry is in its infancy, but in a few years it will be of great importance. and Sir W. MacGregor points out that it will have the advantage over gold, pearl-shell, and beche-de-mer of giving a perennial yield which will increase with time. Last year 340 tons were exported, as against 198 in 1891. In a number of districts the natives are now settling down to more systematic work in preparing exports for the trader. In some districts they have planted out very considerable quantities of coconuts for their own use and profit. During the year a greater tendency has been manifested on the part of the few European residents in the possession to form plantations of coconut trees, &c. Every possible facility is given to them to plant. There is, however, a great want of men with some capital and a sufficient knowledge of the different branches of tropical agriculture to introduce new industries, and to show the natives the beneficial results of steady application.

FOOCHOW FLOWERY TEA.—Reports reach us from the country that the scented flower plants suffered severely in the late frost, and that the flower this year will be very scarce in consequence.—*H. D. Press.*

THE FOLLOWING WRINKLE may be of use to planters who have jungles adjoining their coffee. A piece of jungle is cut down and leaves are allowed to decay; in a few months the stumps of the trees grow vigorously again. The jungle is cut down again, and after it has decayed somewhat, coolies are allowed to help themselves to the twigs for firewood and then after the whole surface had been strewn over with lime, put to collect the leaves and top soil into heaps. These heaps after a time are mixed with lime and fish and applied to the coffee, and the effect it is said lasts for 3 years. A piece of jungle treated in this way, will yield manure periodically.—*Nilgiri News.*

QUININE FACTORY ON THE NILGIRIS.—An account of a visit to this factory will be found in the *Tropical Agriculturist*; it will be observed that Mr. Hooper supplies quinine to the Bombay as well as Madras Governments, and that he has greatly improved the manufacture. Has the Ceylon Government tried to get a cheap supply of quinine from the Nilgiris, we would ask? One interesting fact mentioned is that the initial cost of the Factory was only between R15,000 and R16,000. Surely it would pay Uva planters with appreciable clearings of cinchona trees (if such still exist) to form a Company, start a factory and turn their bark into quinine, saving transport, commissions freight, &c., and perhaps getting a profitable local sale!

A NEW RUST PREVENTIVE.—It is reported that a new compound, which is said to be an excellent preventive of rust on bright iron and steel articles, was accidentally discovered some time ago by Messrs. Edmund Mueller & Mann, Charlottenburg, Germany. The compound, which consists of a mixture of the essential oils and grease, is now being largely made use of in several of the German Government departments, and has been called "Mannocitin." The composition is a thin fluid, which may be readily applied by means of a brush. In a short time after application the oils evaporate and the grease remains behind, forming a coating which protects the metal against atmospheric influences and sea water. The absence of acid in the composition is alluded to as an important feature. It is claimed that the composition does not turn rancid, and that it can be readily removed by rubbing with cotton waste saturated with turpentine.—*Electrical Trades Journal*, March 8.

COTTON MILLS AND THE COTTON SEED TRADE.—Last year there were at work in India 127 cotton mills containing 24,670 looms and 3,272,988 spindles, employing a daily average of 681,330 men, and 48,500 women and children. Eighty-seven of the mills are in the Bombay Presidency, 65 being in the City of Bombay. There are 8 in Bengal and 10 in Madras, and in the North-West Provinces. These figures must be taken into account in connection with the continuous falling-off in our exports of cotton yarns and cloth; for how is it to be expected that our exports will keep up to their former normal condition, when we are sending countries that used to buy largely of our productions such quantities of machinery to enable them to make the same articles themselves. The wonder is that we have not lost much more ground. Australia opened her first cotton mill near Brisbane at the beginning of the year and Japan is manufacturing largely; but notwithstanding this, she has imported from India and England manufactured cotton goods of an average value of nearly £1,000,000 per annum during the last three years. In the face of these facts, it cannot be said that the world's consumption of cotton goods is decreasing.—*Indian Engineer*, April 2.

EXPERIMENTS IN TEA MANURING
IN SOUTH INDIA.

A correspondent writes us ("Madras Times") :—
In the bad times of coffee some 100 acres of laud, which had only had coffee for 3 years were planted with tea 4 x 4 with cinchona 10 ft. apart. They were left to grow together, the tea being only cut down in its second year, giving about 60lb. an acre; in its third to fourth year only 120lb. The cinchona was then dug up, which besides removing the shade, was like digging up or trenching the soil, and the tea jumped to 290lb. next year, the year after to 310 about; then it was manured in plots with the following: (1) Lime refuse and cattle dung mixed, (2) "ashes," (3) "jungle soil alone," (4) "jungle soil and bones," (5) "ditto and poonac" (coconut), (6) "ditto and castor poonac," and (7) "nothing but pits dug above each tree and left to fill in with the showers." This was done in January and February. About May the whole place came on, but all about the same, no distinct difference could be seen, and the heavy rain and wind of the monsoon, for the estate is very high, about 4,500 average, kept the flush back; still the trees looked more ready to flush and in better heart than before, especially where the cowdung and lime refuse had been put. In September the flush began again, and now, just two years from the application, the results are still distinctly visible. The ashes, after the first few months, did absolutely nothing; the part pitted but not manured, and that pitted and with jungle soil only applied did well till after the rains, in May and September and October put on very large flushes, an increase of 60 to 70 in the year, but went off after January, and I could see no difference between what was only pitted and left and what had jungle soil alone applied. That part manured with the two poonacs gave an average increase yield of about 90lb. in the year in excess of what it did previous to application, and is still going on at a lesser rate, but still improved from what it was before manuring. That with lime, refuse and cattle manure went ahead earliest and put on about 120 lb. increase the first year, and about 70lb. this, whilst the jungle soil and bone, which was on the most exposed part of the place, gave an increase of 90 to 100 in the May following and has now if anything increased on that, certainly shows no signs of falling off. Even the jungle soil gives about 30lb. per tree with $\frac{1}{2}$ a lb. of poonac and $\frac{1}{4}$ lb. of bone to each tree. The trees are manured by having pits 1 foot long, 1 foot wide, 6 inches deep cut a foot above each tree. I have no hesitation in saying that leaving out the part manured with ashes, the value of the tea is increased £5 an acre, as the trees have spread and thickened very greatly, and that it is due to the high cultivation is evident, as there is some not manured, which compares but badly with it. The place will, I believe, this year give 400 lb. an acre, and this is a very excellent yield for the elevation. I was much astonished at the effect the bone dust had; it did not force on a huge flush of leaf; in fact, acted slowly; but it benefited the trees most of all, and bone is, of course, generally supposed to be a fruit-producing manure. The cost of artificial manure may be put at R40 an acre, with jungle soil at any distance it costs R60, and I should doubt it being wise to put it by itself. Cattle manure, of course, depends much on carriage, but putting it as you always can, by having movable cattle sheds at a distance of not over 200 yards, including cost of cattle keep, it should not be more than R25 to R30 an acre. Putting, say $\frac{1}{4}$ cwt. to each tree, I believe every third or fourth year is quite sufficient to back the trees up to their full vigour. Failing this, renovation pits between every four trees 2 feet square by 9 inches deep could be cut for R7 an acre easily, and would repay amply. Even stirring up the ground round trees with crow-bars has a good effect. But I believe it will pay proprietors over and over again to go in for a thorough system of manuring; and on account of the difficulty of getting to soil within an easy carriage. We have no hesitation in saying cattle manure well torted and kept in covered pits till it cuts like a

cheese is *facile princeps*. It is, I think, however an open question whether swamp soil well dried, mixed in a compost with a little cattle manure and, say, an ounce or $1\frac{1}{2}$ oz. of fine bone powder would not be as cheap and nearly as effective as manure. For this a few cattle would suffice.

ON THE SAME.

There appears to be a great diversity of opinion as regards the manuring of tea, and many planters of experience seem to think it better left alone, the general reason being, that if once begun it must be continued, and also that though it increases the yield, it in a corresponding manner reduces the quality. Now as to the first reason, it may be laid down as an axiom, that any given plant, giving and having crops either of fruit or leaf, must consume a large amount of the chemical ingredients on which it lives. Again, the harder a tea plant is picked, the greater will be its endeavours to throw out new leaf to supply itself with air, and therefore the more food will its roots require, to balance the artificial state produced by plucking. Of course, especially in virgin forest soil, there is a sufficiency of leaf-mould, the deposits of ages, to last for many years. And provided the soil has a strata of clay or stiff soil below (at not too great a depth) which will hold damp enough during the hot months to feed the huge top root the tea plant sends down, there is no doubt manuring is not necessary. In old coffee land where the soil has been exhausted by plants, and moreover by the weeder with his hoe scraping down all the best top soil into the nullahs, tea takes twice as long to come on as a young plant, and we have never yet heard of even one authentic case of tea in old land not manured by hand, or by the silt of overflowing rivers, ever equalling its brethren in new land. Of course, there is a good deal in tea being a sub-soil feeder. But that only means that manure after the first few months filters slowly down and acts more gradually. The tea plant is by no means deficient in surface roots; digging up the ground alone will show this very quickly. But after this is over, it takes longer for the manure to get down, and it is absorbed far more gradually than is the case with coffee and cinchona, which use it up by their surface roots almost entirely.

Is it reasonable to expect a plant to grow in the same place giving crops of leaf every 8 days for 10 months in a year, for an infinity of time, without giving it extra nourishment to enable it to go on yielding the same or more? And why are places like the Gorthie flats in Dikoya, which are subjected to annual overflows of rivers, leaving behind that richest of manures, the silt, famous throughout Ceylon for their yield and prices? No doubt it is an error to manure too early. But the moment yield becomes stationary before it begins to exhaust itself is the time. Probably new tea land would bear for five or six years after arriving at a plucking age, whilst old land barely runs three; that is to say, to give satisfactory yields. To wait, however, till tea exhausts itself, and then have to bring it back to its primary vigour, is an error in a financial way of the worst kind, as with tea in a vigorous state, a small amount applied every 2 years would keep up the average. To bring it back would cost a vast amount more and would never recompense the trees for the shock their system had sustained. It is not necessary to manure to get excessive yields, because, if with the present competition a planter puts into cultivation inferior land, which naturally will only yield, say, 250lb. an acre, he must work at a loss or only a low margin of profit; the average of his neighbour's is, say, 350 lb., and if to increase that yield artificial means have to be used, he must go under, for there is plenty of land going quite capable of giving big yields; and the lines of supply and demand are now almost merged, so small profits must be put up with. But it is against all lessons high farming has taught us, to let good laud wear itself out, for want of a little expenditure.

As to manuring deteriorating the quality of tea we are very sceptical. We have yet to hear of any experiment being carried out with breaks of tea from similar jats of tea, at similar elevations and made in the same factory, and put up at the same auction. It is impossible to see what case there is for non-manuring on these grounds. Has anyone ever noticed he got better prices the year before he manured than the year after? Allowing for any difference there might be in the price of tea generally, as shown by the Broker's account, do not people manure for fruit, and does not fruit take more out of trees than leaf? Are there not chemical properties required to make it? Do not people manure their grass fields in England for hay, and did ever anyone hear of the hay from manured fields being less nutritious than the hay from unmanured land? Yet hay is made up from innumerable leaves of plants and grasses. The very fact of the tree throwing out a superabundance of leaves seems to point out that it has extra vitality, and extra vitality ought not to mean diminution of strength in the leaf. Leaf from newly-pruned tea is inferior, but that is no reason that manured tea should be so. The young shoots from the pruned tea are left to grow up; if not, the plant would die, from being unable to breathe, and the first pluckings are invariably coarser than the later ones, as the tree itself is struggling to get over the shock it has sustained from the knife. As we said before, there is probably much more assertion than proof in this theory, and we quite fail to understand why tea alone, amongst agricultural products should not be benefited by high cultivation. We give on another page an account of experiments in tea manuring which may be of interest. It tells of what has been done in South Travancore, and the correspondent to whom we are indebted for the account states that leaving out the part manured with ashes, the value of the tea is increased £5 an acre, as the trees have spread and thickened very greatly. He gives details as to the result of application of various kinds of manure, and what he says strongly supports his conclusion that it will pay proprietors over and over again to go in for a thorough system of manuring. It must be borne in mind that the bulk added to an acre putting in $\frac{1}{4}$ cwt. to a tree is very great, equalling with trees planted 4 \times 4 35 tons of bulk. For our part we feel sure that manuring must soon be recognised as one of the necessities of tea cultivation, and we feel equally sure that those who take time by the forelock and apply it whilst their trees are still in good heart, will be amply repaid. To starve land has always been recognised as the most shortsighted policy, and has probably ruined more English farmers than anything else; and to our mind this principle applies here with equal force.—*Madras Times*.

We have heard it said that if planters begin to discuss manuring their tea fields, capitalists will begin to think the end is at hand. The effect of a movement in favour of systematic manuring might, some planters fear, be to create distrust of the Tea enterprise. On the contrary, sensible capitalists would recognise in such a movement the best guarantee for the permanence of the industry.

The first step towards scientific cultivation is to keep the surface soil from waste and wash, by thoroughly efficient surface drainage, and the next is to maintain the fertility of the soil by suitable feeding. The two principal sources of waste and exhaustion will thus be eliminated and all practicable permanence may be secured. Inasmuch as the soils of different districts, and even in parts of the same district, vary in character and composition, the manures required for each may, and almost certainly will differ, perhaps considerably. Hence, a course of experiments should be pursued, and the effect of available manures should be undertaken in all localities to test the effect of each in different situations. Scientific aid would be of great value in directing experiments, and would probably save expense and disappointment, by proceeding more directly and certainly to the attainment of the object by the light

of science. The proposal recently suggested, to obtain the services of an agricultural chemist, is deserving of serious consideration, and as all planters would be ultimately benefited by the services of an expert, the cost of them should be borne by the planting community as generally as possible.

In the meantime, much may be done by judiciously conducted experiments, based on the knowledge which most planters possess of the general nature of soils and manures. We have alluded already to waste, and it is needless to point out that the prunings should be assiduously preserved in every case. They contain the very essence of the bushes, and their preservation, therefore, is essential wherever any pretension is made to regular economic cultivation. It is an open question, and one of great importance, to determine whether the function they may fulfil in protecting the soil from the sun, or that of their decomposition by gradual decay by being buried fresh in the soil yields the best results. The difference is considerable. When exposed on the ground they speedily shrivel up and are reduced to little more than their ash. They are thus liable to be washed or blown away and wasted. If buried, on the other hand, their decomposition results in the production of ulmic and humic acids, that have a powerful and beneficial effect on subsoils. Wherever these are clayey, these acids tend to mellow them, and to break them up.

We have more than once alluded to the action of decaying vegetable matter in breaking up and fertilising obdurate subsoils, as the writer witnessed the process systematically pursued in Italy, where soils that were utterly barren in their natural state were brought into a fertile condition, by means of vegetable matter buried in holes dug to receive it. Prunings of Tea may be employed in either of the ways mentioned, and we should conceive that the latter is much the better, both in point of economy and fertilising effect. For the same reason, we should think that vegetable matter from the jungles, especially if buried green and fresh, with a slight admixture of manure to aid in their decomposition, would prove a valuable resource. A common chena shrub, *kepitiya*, (*croton laccifera*) has highly fertilising properties, being rich in potash, and is extensively used in some parts of the country by the Sinhalese.

It is a common mistake to suppose that leaf produce is necessarily less exhaustive than fruit. Whatever part of a plant constitutes the value of its produce is the part which, when harvested, takes most out of the soil. Tobacco leaf, for instance, is extremely exhausting, far more so than coffee and many other fruits. The fact that tea is a leaf does not, therefore, prevent its being an exhaustive crop. The theme contained in the tea leaf is closely allied to the caffeine which gives its chief value to the coffee bean. For this, and other reasons it is unreasonable to expect tea bushes to go on yielding leaf for an indefinite length of time without receiving artificial aid. The form in which the necessary support may be most economically given is therefore a principal part of a tea planter's duty and interest to discover, either by experiments, suggested by his own observation and experience, or by the light of science, under the guidance of an expert.

The objection frequently urged against the manuring of Tea fields, that once begun, it must be pursued, is generally based on a mistake of practice. When economic plants have become weak and in want of support, they are generally overdosed with manure, which has the effect of stimulating them to an unnatural degree, and hence they collapse unless the action be kept up. This is a main objection against allowing the bushes to run down and become exhausted before giving them artificial aid. To avoid that violent oscillation between extremes of excitement and relapse, the proper course is to give the necessary support betimes in *small measure*, such that the bushes may receive the requisite support without being stimulated into such unnatural effort, as cannot be sustained without the repeated use of stimulants. We regard this objection as containing its own refutation. The fact that a stimulating as distinguished from a feeding system of

manuring necessitates the perpetuation of an unnatural action, is one of the strongest arguments against allowing the bushes to run down into a weak and exhausted state; and is equally against administering stimulating doses of manure to bushes in any condition whatever. Manures that operate slowly and feed without exciting the bushes to abnormal effort are those which a judicious planter will endeavour to select, and he will apply them in feeding volume, and not by trying to do several years' manuring by a single act. The action to be imitated is that of a pendulum, which receives at each beat a gentle tap, just sufficient to maintain its proper swing and *no more*. An occasional heavy blow to set it swinging for some time would destroy its proper function.—Local "Independent."

TEA AND SCIENCE.

The *Madras Times*, referring to the discussion in the Dimbula Planters' Association, in a short article which we quote elsewhere, stigmatises the absurdity of the idea that the employing of an expert by the Ceylon Tea Planters would be regarded as an indication of decline in the planting enterprise, and urges, as the *Ceylon Observer*, and we ourselves have done, the importance of systematic scientific investigation into the processes of cultivation and manufacture of Tea by an expert. It is very doubtful whether any scientist would effect important improvements until after considerable research; and it is quite certain that he would not produce any sudden revolution in the system at present pursued. The probability is, that his first suggestions in regard to cultivation of the plant would concern the condition of the soils in which it is growing, and that its component ingredients would be reserved for after consideration. The physical condition of a soil may be of greater importance than its composition, and would be scrutinised carefully before any analysis were attempted. The processes of manufacture would be studied, in the first instance, with reference to the qualities that are sacrificed by unsuitable treatment, prior to any attempt to impart fresh qualities to the Tea.

The disclosures that the light of science might make would probably be slow, but they would be certain in the end to improve the practice of both the cultivation and manufacture of Tea, and to give the enterprise more permanence, by means of saving what may now be unwittingly sacrificed or lost, and by supplying what is either wanting or wasted under existing conditions. A good deal has been and still more may be done by means of experiment, but it is important that the end sought to be attained should be itself a real desideratum. A coffee planter, who conceived that the soaking of coffee in the cisterns, after pulping, must be injurious, constructed a machine to remove the slime mechanically, instead of fermenting and washing it off the beans. The machine succeeded perfectly. The coffee beans, fresh from the pulper, were cleansed completely by the new operation, and in less than half an hour after emerging from the pulper, the beans were beautifully clean, and, so far as external moisture was concerned, also perfectly dry. In this condition, and having not been soaked and saturated with water in the cisterns, the beans were easily cured, and they presented a most satisfactory appearance. The experiment appeared, at that stage, to have been a thorough success.

A quantity of coffee so prepared was sent home to be reported upon, and great expectations were indulged. The report, however, was disappointing, for the coffee was said to be raw, wanting in flavour, and altogether deficient of the highest qualities. The simple fact was that these qualities depended on the fermentation, which had been so sedulously avoided. Such was the result of a very costly experiment. An expert chemist would probably have suggested the result; but, whether or not, experiments directed by an expert would be aimed more directly to their specific ends than others conducted without the light of science.

We have already, in our issue of the 23rd of March, strongly recommended the employing of an expert chemist to investigate the soils that are being cultivated and the processes of manufacture that are being employed, with a view to their improvement by the light of science. It might be some time before any important results would be attained, but it is certain that in the end well directed research would suggest improvements in both cultivation and manufacture, which would tend to the economical production of Tea, the improvement of its flavour, and the permanence of the enterprise.

There are many suggestive facts in the short history of Tea production in Ceylon for which an expert would be able to assign a cause. In more than one instance, within our own knowledge, qualities that had been lost were afterwards restored, showing that, in those particular cases, the processes employed, and not the soils or capabilities of the estates, were at fault. Tea is a delicate product, and is easily affected by neglect, for want of a thorough knowledge of the chemistry of the processes employed, and is peculiarly in want of scientific examination.

One defect, common to all Ceylon teas, is that they do not keep. This is a serious disadvantage, and one that will tell against them more hereafter than in the past. Till now the demand for Ceylon Tea has been so active that none has had to be kept long unconsumed; but, as the production increases, and the consumption ceases to keep pace with it, its lack of keeping quality will be more and more felt. We have noticed, in some of the latest advices, since the recent run on the lower qualities set in, a preference having been given to China teas in blending, because of their superior keeping qualities. We have several times brought this property of keeping into notice in our columns, and it is now of greater importance than ever it was.

The problem is not how to impart a new quality, which might be a very difficult or impossible matter, but how to fix in our Teas those they naturally possess. This is a much simpler problem, of which an expert would probably discover the remedy easily. We have ventured to express the opinion, based on experience with coffee, that the lack of fixity of the aroma of Tea is due to too great rapidity in the firing processes. It is in these that the fixing of the properties of the Tea consists. Col. Money, in his book on tea, says that the Chinese pan their teas, that is: fire them several times, and not by the short and rapid process used in our factories. He reports that frequent experiments satisfied him that there was no advantage gained by these repeated firings, and he, therefore, does not advise planters to adopt them. It does not appear, however, that he tried the effect of frequent pannings on the keeping qualities of the Tea, as this could only be known by a comparison of Teas made by the two methods a year or more afterwards, and we do not see that he made any such comparison. Possibly, some of our planters may have tried the experiment. Be that as it may, the keeping quality of Ceylon Tea is a great desideratum, and worthy of crucial experiment and consideration.—Local "Independent."

INDIAN AGRICULTURAL NOTES.

(By a Practical Agriculturist.)

THE IMPORTANCE OF DRY LANDS.

In my last Notes I pointed out some of the main defects in the management of wet lands in Chingleput. In these I propose to give a succinct account of the cultivation of dry lands. But before I do so I wish to point out that, with the Mirasidars of the Tamil Districts, there is an impression prevalent that the management of dry lands ought to be relegated to the poorer classes of tenant-farmers on account of the uncertainty and poverty of the yield in general. Good farming is, with most of them, identical with the cultivation of wet lands, which give a fair return

without much labour. This view is certainly to be regretted, because out of 25 million acres of cultivated area in the Presidency, nearly 20 millions are dry lands. The extension of our irrigation system will not go far enough to solve the agricultural problem of the day, how to give sufficient food for the ever increasing population, for the irrigable provinces have nearly all been tapped. Our faith and hope must therefore be centered in developing the resources of our dry lands, which depend for their productiveness on the seasonal rains, which are often precarious and irregular in their distribution. Bearing these facts in mind, let us see how far the ryots of Chingleput have succeeded in managing their dry lands. The dry lands of Chingleput are, no doubt, poor. They belong to the arenaceous group characterised by their dryness and looseness of texture. But they readily respond to good cultivation on account of the facilities for natural drainage, ploughing, &c. In Chingleput we have very nearly 260,000 acres under dry cultivation. Among the dry cereals *varagu* occupies a prominent position. More than 43,000 acres are annually under *varagu*, a cereal which is classed as an inferior food-grain but which, withal, is a very exhaustive crop. The ryots are so fully aware of the exhaustive nature of *varagu* that they leave the land cultivated with that crop fallow sometimes even for two years. This practice gave occasion for Mr. Justice Holloway to write a very trenchant judgment in a suit brought by Government for the recovery of rent from *varagu* lands during the periods of fallow. Mr. Justice Holloway characterised the practice as highly detrimental to the cause of good husbandry, and remarked that any mercy shown to the ryots in this line would be a premium paid to bad cultivation and idleness. The practice of growing pulse crops such as horse gram either for green-manuring, for fodder, or even for seed on *varagu* lands, is not pretty well known. Dr. Voelcker mentions it and Dewan Bahadur Streenuvasa Ragava Aiyangar has made capital out of it, that the exhaustive nature of Indian farming in certain lines is compensated for by the cultivation of pulse crops annually over large areas. The Doctor's remarks are academical, but carry less weight when seen through the light of statistics, at any rate with regard to a District like Chingleput which, with its 120,000 acres of dry cereals, without taking into account the land left fallow, has only about 5,800 acres, or less than one-twentieth of the area, under pulse crops! Certainly this is not restorative farming. Cholum ought to receive greater attention than it does now. There are only about 7,000 acres under this crop, and this is cultivated chiefly by the Telugu ryots on Chingleput,—the Reddies and the Kammavars. Ragi occupies a considerable area, nearly 62,000 acres. The area under well irrigation is not large, and consequently the yield is less, as ragi, of all other dry cereals, requires water, and the rainfall is often insufficient for the dry lands of Chingleput.

HOW CHRISTIAN COLONISTS FARM.

In what direction, then, should we work so as to make the dry lands of Chingleput more productive and less liable to the effects of periodical droughts? Certainly by deep ploughing and good manuring. These are no doubt very true sayings, but they are nevertheless true. I will not ask my readers to go to the Saidapet Farm to convince themselves of the results of deep-ploughing, for I know they have very little faith in Robertson and his followers. I shall ask them to go to some of the villages in Chingleput inhabited by a very sturdy class of peasantry who carry on a system of husbandry in which the principles of deep ploughing, thorough pulverisation of the soil, and good manuring, have been to a certain extent recognised. Their history is interesting. More than a hundred years ago a terrible famine swept over Guntur, in the Kistna District, and many families migrated to neighbouring Districts. A colony of Roman Catholic Christians of the Kammavar caste came all the way down to Chingleput. Collector Place was then in charge of the administration of the District, and with his characteristic enthusiasm for agricultural improve-

ments encouraged these Christian peasants to settle down as farmers. They occupied the poorer uplands in the Conjeeveram Taluq. They had brought with them the talent for dry land cultivation so much in vogue in the Ceded Districts and the Northern Circars. The heavy plough for stirring the soil deep, the *guntaka*, or grubber, for scarifying the surface soil, the *goru* for sowing, and the *Papatam* or bullock-hoe for interculturing were all duly introduced. And above all, splendid stocks of Nellore bulls were worked on the poor soil. At the village of Kelacheri, near Streperambudur, there is an important settlement of these Christian farmers. The village is situated on a low laterite eminence indicative of extreme barrenness. On the waste lands not even a dried up blade of grass can be seen in the dry weather. The District was, when I was last at Kelacheri passing through a severe drought. And yet, I was astonished to find splendid crops of cholum, horse-gram, *cumbu* and paddy growing on those poor lands, while in the village of Coovum, under the Coovum tank, the paddy crops cultivated by the Tamulians were withering. That the success of the cultivation of the poorer lands by the Christians was due to better ploughing, better manuring, and better cattle, will be found in the following short account of the management of a farm by one of the Christian settlers.

A. has 70 cawnies, or about 93 acres, under cultivation, of which 30 cawnies are wet and 40 cawnies dry. He keeps 7 pairs of working cattle, each pair costing on an average R150, besides 20 cows and 2 buffaloes. The whole of the straw, both paddy and cholum, and the horse-gram produced in the farm are consumed by his stock. There are, in addition, 15 acres of grazing ground. The working cattle are given cake and paddy bran in addition, which cost him about R150 per annum. The dead stock consists of 7 ploughs (much bigger than the ordinary plough), 5 *guntakas* or grubbers, 7 *papaddms* or bullock-hoes, 4 seed-drills, 6 carts, 6 mamoties, &c. The carts are engaged in bringing tank-mud and other manures from distant places, and carting the produce to the farmstead. The preparation of the land both for the dry and wet is somewhat similar; for these Christians generally carry on the dry system of paddy-cultivation recommended by me in my last article. With the early showers of rain, the heavy plough is worked in the land deep about four times; then the land is grubbed by means of the *goru* twice, and then the *guntaka* is worked twice. When the time for sowing comes, the *goru* is again worked, and seeds sown in regular lines by means of the *goru* which is convertible into a seed-drill. After sowing the *guntaka* is worked to consolidate the soil and level the field. During the growth of the crop the bullock-hoe is worked between the rows of plants. Thus at the very outset of life the young plants get all opportunities of striking their roots deep into the soil so as to get nourishment from the moist sub-soil. The plants are thus able to withstand drought and bear good crops.

Now, this system is certainly in advance of the usual practice in Chingleput and elsewhere. The Christian cultivators have not grown poorer by investing more money in cattle and implements. On the contrary, they are comparatively richer. The fine crops of cholum and paddy raised year after year on very poor soils have not taught a lesson to the neighbouring ryots. For more than one hundred years these Christians have been carrying on a system of high farming which has no parallel elsewhere in Chingleput. Though they differ from their neighbours in religion they are of the ryot class; share the same prejudices and superstitions, and yet with more than 100 years' contract have not been able to produce any impression in the minds of the Tamil population regarding their system of cultivation. It is confidently asserted by many that our ryots are thoroughly averse to their own interests; that all that is needed for their improvement is to show them practically that the adoption of a certain system will pay them, and they will readily take to it. What answer will these apologists give me when I show them that the ryots of Peram-

bakam, a village within two miles of Kelacheri, have not to the slightest extent been influenced by the every day practice in Kelacheri carried on for the last one hundred years? Really there is something rotten in the State of Denmark.—*Madras Mail.*

THE KELANI VALLEY TEA ASSOCIATION (LIMITED).

REPORT OF THE BOARD OF DIRECTORS.

The Directors feel much satisfaction in submitting to the Shareholders the Report and accounts of the Company for the past year (1892).

The Estimate of Tea for 1892 was, including the produce from Dover, 302,000 lb; but owing to a continuance of abnormally unfavourable weather, the quantity actually secured was only 260,085 lb. shewing a deficiency of 41,915 lb. on the estimate, and, gratifying as present results are, they would have been still more favourable but for this short fall.

Although the Factory and Machinery are new, and thoroughly efficient, the Directors have decided to commence writing down their cost, and 10 per cent, amounting to £581 19s 7d, has accordingly been written off for depreciation.

Including the small balance of £28 10s 9d brought forward from last account, the Company's net profits for the year amount to £3,245 5s 5d, which it is proposed to appropriate as follows:—

Interim dividend of 5 per cent paid in September, 1892, absorbed ...	£503 14 0	
It is now proposed to pay a final dividend of 15 per cent (free of Income Tax) making 20 per cent for the year ...	1,511 2 0	
To place to Reserve Fund, (bringing it up to £1,000) ...	345 10 0	
		£3,245 5 5
		2,360 6 0

Leaving a balance to carry forward of ... £884 19 0

The Directors, in the interests of the Company and under the advice of Mr. Porter, have acquired the Estate of Wereagalla, almost adjoining Degalessa. It consists of 230 acres under Tea, and 64 " under Forest, &c. In all 294 acres.

This property is taken over as from 1st January last, the price paid is £8,250, and the estimate of produce from Wereagalla for the current year is 115,000 lb. of Tea. The buildings on the property are substantial, and the factory and machinery amply sufficient. It is not the present intention to create fresh Capital, but, towards providing for the purchase of Wereagalla, a call of £2 per share has been made on the last issue of 397 shares, and a further call of £1 per share will be made almost immediately, bringing up the amount paid on these shares to that of the previous issues.

The Company's acreage now consists of:—
864 acres under Tea Cultivation.
370 " Forest, &c.
3 " Grass.

1,237 acres in all.

ESTATE ACCOUNT, for the Year to 31st Dec. 1892.

A NEW QUININE SALT.

Chemistry has just enriched medicine with a new product, having quinine as a base. If such authorities as MM. Grimaux, professor of chemistry at the Ecole Polytechnique, and Laborde, chief of the physiological laboratory at the Paris Faculty of Medicine, are to be credited, their experiments tend to show that it is capable of rendering real service to therapeutics. The chemical in question is chlorhydro-sulphate of quinine. The following are according to MM. Grimaux and Laborde. The advantages of this new salt:—The salt which is represented by the formula (C₂₀H₂₄N₂O₂)₂HCl, H₂SO₄·3H₂O, is very soluble in water; it dissolves in its own weight of water at an ordinary temperature. Under these conditions it can be easily absorbed by the digestive organs, while medicinal sulphate requires more than 700 parts of water, and only, apparently, dissolves in the stomach by the aid of the acid gastric juice. This case of solubility renders it very useful for hypodermic injections. A solution prepared with 5 grams of salt and 6 cc. of water contains 50 centigrams of salt per cc. A further advantage is that it contains for the same weight the same quantity of quinine as crystallized medicinal sulphate; with 7 molecules of water it contains 74·2 per cent. of quinine, while medicinal sulphate at 7H₂O contains 74·3 per cent.—*Oil, Paint and Drug Reporter.*

PRICES PAID FOR JAVA TEA IN LONDON AND AMSTERDAM.—Messrs. J. Peet & Co. of Batavia last month addressed a letter to the Secretary of the Soekaboemi Agricultural Association pointing out an apparent error in the Association's report for 1892, where the results of the Java tea sales in London and Amsterdam for 1891 are quoted as for 18 2. Messrs. Peet & Co. appended to their letter an elaborate table, compiled by Messrs. John Pryce & Co., giving the figures for Java tea sold during the years 1886-91 in London and Java respectively, and the prices paid. The average prices compare as follows:—

	1886	1887	1888	1889	1890	1891
	c	o	c	o	c	c
London ..	43-05	37-12	37-52	31-94	37-05	35-68
Java ..	41-33	31-75	29-99	30-96	33-81	36-01

the averages of the totals being respectively 37·3510 and 33·5550 per half-kilogram, the total amounts sold in the six years being 11,967,328 half-kilos at London, and 2,827,809 half-kilos at Amsterdam. In accordance with the expressed wish of Messrs. Peet & Co., the Secretary of the Soekaboemi Association has had their letter with the appended table and his reply printed and circulated. In his letter of reply he combats the contention that better prices are obtainable for Java tea in London than in Amsterdam; pointing out that the reverse was the case in 1891; and that, although the figures for 1892 are not yet available, there are undoubted proofs that last year also the prices fetched in Amsterdam were higher than those realized in the London market.

TROPICAL AGRICULTURE.*

This is the title of a volume of about 300 pages by Dr. H. A. Alford Nicholls, and published by Messrs. Macmillan & Co. as a "text-book" in their series of manuals for students. The book is dedicated by the author to Dr. Joseph Hooker in addressing whom Dr. Nicholls says:—"If there is anything useful in the following pages the credit is due in a great measure to you." We are told in the preface that the idea of the book originated with the Jamaica Government having offered a premium for the best text-book of tropical agriculture specially adapted for the use of the colleges and higher schools in that colony. The author's manuscripts having been adjudged the best, the same Government undertook to publish it after having been added to and revised. "It is not a mere compilation," says Dr. Nicholls, "but the record of experience that has been gained by study, observation, and experimental cultivations."

The work under review is divided into two parts: Part I Elementary Agriculture, and Part II Agricultural Products. The first part treats of soils, their origin, distribution, constituents, classification and properties; of the plant in general, the functions of its different organs, fertilization, germination; nutrition, and the different modes of propagating plants; climate; manures; rotation of crops; drainage; irrigation; tillage operations; pruning; budding and grafting.

The author thus explains the general principle of pruning: "When a branch of a tree is cut off much of the sap or nourishment that would have been used by it goes to the branches that remain, and more especially to those in the vicinity of the part taken away. Besides by removing useless branches, or as it is called 'thinning them out,' more air and light are allowed to reach the remaining portions of the plant, and thus their assimilation of food from the atmosphere is increased. The removal of one portion of a plant, whether it be the branches, leaves, flowers, or fruit, is always followed by extra development sooner or later. If for instance all the first flowers of young cacao trees be taken away, as they should be, there will be increased fruitfulness at the next season: And if all the young fruit be taken off an orange tree, flowers will break out again and the crops will be reaped at a much later time." This means of altering the crop time to some extent in the case of fruit trees is, as the author remarks, a very important one to fruit growers who will thus be enabled to take advantage of the fact that prices are high at some seasons when the late crops can be brought into the market. In pruning to increase fruitfulness, it is remarked that one has to observe first on what portion of the tree or plant the fruit is borne. Where it is borne by the wood of the same season, it will be necessary to prune out branches that are backward in growth, and that have little or no fresh wood on them. Where the fruit is borne by the wood of the second season, the young wood must be cut back so as to allow the strength of the plant to be put forth in pushing out flowers instead of continuing to increase the new wood. Lastly, where the fruit is borne on the wood of the stem or the mature branches, the small branches and the young wood not required to increase the spread of the tree must fall to the pruning knife.

In all cases, however, it is advised, that *suckers* or "robber-stems" must be removed from trees

or bushes grown for their crops, as they appropriate the sap or food necessary for the production of flowers and fruit. "Pruning," we are told, "does not simply mean chopping at a tree with a cutlass so as to decrease its bulk, but it means an important operation that should not be undertaken without forethought, or without some knowledge of its principles. We are cautioned in cutting a branch not to injure the bark of the tree which will grow and in time heal up the wound. In case the bark is torn or ragged, a longer time is taken for the work of repair, and the wood of the tree itself may become decayed and there might thus be permanent injury. In order to prevent decay by the action of the air and moisture, or by insects, painting the wound with tar or some such substance is recommended, where the branch pruned off is a large one. In cutting away small shoots it is advised that a sloping cut should be made coming out just in front of the bud, forming a wound at half a right angle with the branch. The reason given for this is that as soon as the bud develops, the increased vigour of growth will quickly heal up the wound, while if any considerable portion of the stem is left beyond the bud, it will die and produce decay in the branch or cause the necessity of another pruning operation to remove it. Pruners are cautioned not to operate on trees or shrubs when they are full of sap, as they will then "bleed" so much as to injure the plants. "The circulation of the sap," says the author, in conclusion, "is not the same in regard to time in all plants or in the same plants growing in different places and in different climates. Observation and experiment are therefore necessary to determine the proper time for pruning, and a small cut into the stem of a plant will always show if bleeding is likely to take place."

The last chapter in the first part of the book treats of budding and grafting; and the various methods of grafting, such as whip or tongue grafting, wedge grafting, saddle grafting, crown grafting, and grafting by approach are all fully explained and illustrated by means of diagrams.

What we have said about the book so far sufficiently indicates what the author was led to believe, namely, that his work "will prove serviceable to present proprietors, owners of small estates, and intending settlers in tropical countries," and that "it has supplied a distinct want." With the more practical and perhaps the more useful part of the book, that treating of plants cultivated in the tropics, we shall deal in another issue.

JAMAICA AT THE WORLD'S FAIR.—Exhibits, consisting of the various productions of the island of Jamaica, which will make an exceptionally interesting court at Chicago, will leave during this month. Coffee, sugar, rum, and cocoa, and the woods of the colony are well represented. A guide-book will be issued shortly, and it will be well illustrated by photogravures.—*Daily Chronicle*.

THE JAVA EXHIBITION.—The exhibition of industrial and natural products of the Dutch East Indies, which is to be held at Batavia in the course of this year promises to be a decided success. The agricultural section will include extensive exhibits of cinchona, including flowering branches as well as dried bark, indigo and other dyestuffs, spices, gums and resins, essential oils and medicinal drugs, of native as well as European use. Prizes are offered for the best treatises on the cultivation of and commerce in cinchona, pepper, cubebs, vanilla, cloves, and cinnamon, and for the best project for the establishment of a cinchona-factory in Java.—*Electrical Trades Journal*, March 8,

* A Text-book of Tropical Agriculture. By H. A. Alford Nicholls, M.D., F.L.S., &c. With illustrations. (Macmillan & Co.)

COFFEE TRADE OF 1892 AND PROSPECTS FOR 1893.

The position of coffee has become of great interest, and is engaging the attention of the trade in this country and abroad to an unusual degree. As bearing upon the situation, we present some facts throwing light on the movement of 1892-93 and the outlook for 1893-94.

The following table exhibits the imports, exports and net imports or consumption of coffee in the United States for four years:—

	Quantity, Pounds.	Value, Dollars.
1889—Imports	491,441,003	84,378,649
Exports	9,866,742	1,687,314
Net imports	481,574,261	82,691,335
1890—Imports	548,008,838	77,938,131
Exports	13,927,467	2,274,411
Net imports	534,081,371	75,663,720
1891—Imports	580,995,965	110,444,817
Exports	6,620,488	1,119,297
Net imports	574,375,477	109,325,520
1892—Imports	595,903,228	136,557,692
Exports	11,540,115	1,799,011
Net imports	584,363,113	134,758,681

From the above group of figures and from stock as reported by Smith and Schipper and the coffee exchange, for the six Atlantic ports, and by R. Hocklofer and C. E. Bickford, for the Pacific coast, we have the following statement:—

	Tons.
Stocks, Dec. 31, 1888.....	17,013
Imports in 1889.....	214,988
" " 1890.....	238,429
" " 1891.....	256,418
" " 1892.....	260,876
Total supply, four years.....	987,724
Less stocks, Dec. 31 1892.....	25,057
Consumption, four years....	962,667
Average per year.....	240,667
For the year 1892 the movement was as follows:—	
Stocks Jan. 1st 1892.....	19,878
Imports, 1892.....	260,876
Total supply, 1892.....	280,754
Less stocks, Jan. 1st 1893.....	25,057
Consumption in 1892.....	255,697

The above shows a consumption in 1892 largely in excess of 1891, and 15,030 tons above the annual average of four years, and that in spite of high cost. Messrs. James Cook & Co. report the deliveries for consumption, in Europe, as follows:—

1889 ...	399,204
1890 ...	400,757
1891 ...	420,106
1892 ...	422,801
Total four years	1,642,868
Average per year	410,717
" " United States (our figures)	240,667
Average Europe and United States	651,384

The above, on the basis of seventeen bags to the ton, shows an average annual consumption in Europe and the United States, of 11,073,528 bags, and this is fairly correct. Last year the consumption, based on our table for 1892 and Cook & Co.'s for Europe, absorbed 11,534,466 bags; according to James Cook & Co.'s tables for Europe and the United States, 11,758,747 bags. We may fairly estimate from the above group of figures, which include the Pacific coast movement, that Europe and the United States must have not less than 11,500,000 to 11,750,000 bags

to meet 1893 requirements, and this forbids any increase in consumption over 1892. This ought to be considerable, in view of the World's Columbian Exposition and the unequalled prosperity of the country. The fear of cholera, prevalence of strikes and a drawback to trade and commerce from changing political conditions, may tend to hold consumption steady or reduce its volume. These factors make coffee a good article for speculation and bring into prominence all information as to the position and condition of crops.

In 1892 the Empire of Brazil cleared 7,014,000 bags of Rio and Santos coffee to Europe and the United States, which quantity represents nearly two-thirds of the actual consumption, or 63½ per cent of 11,500,000 bags actually consumed.

In March, 1892, W. Schoffer & Co. gave it as their opinion that Rio, Santos and Pabai would give a maximum export of 7,000,000 bags; others estimated 7,425,000 bags. An official statement from the Minister of Finance to the Bureau of American Republics makes the exports from Rio, Santos and Victoria, for the year ending June 30, 1892, 7,337,122 bags. This shows pretty fair estimates by the Rotterdam brokers. With the huge Brazil crop of 1892, the visible supply of the world Jan. 1, 1893, was only 405,000 bags larger than Jan. 1, 1892. Europe shows a trifling gain in consumption, a paltry 2,700 tons, while the United States shows an increase of about 15,000 tons or more than one-half the increase reported in the world's visible supply.

The next Brazil crop is estimated at 5,500,000 bags. The Java 1893-94 crops are reported as showing a large falling off. Reports of a decreased yield come from the Malabar coast, Manila and Colombia. There has been an extension of the industry in Mexico and Central America, but the new plantations are not far enough advanced to warrant counting upon them as likely to largely exceed last year's crop. Porto Rico and Jamaica will have a good crop.

These facts are sufficient to awaken unusual interests in the Rotterdam estimates of this spring and to cause the bears considerable anxiety. Definite information about coffee is not at command and at all times the returns are imperfect.

At present the prospects are that the world's crops are not likely to yield a supply equal to last year's consumption of 11,500,000 bags, if present estimates of the Brazil crop are anywhere near correct. If the Brazil crop turns out as some figure, 4,750,000 bags, then the supply will be largely below last year's absorption. To make it look like another year of high prices and big consumption.

Since writing the above, we have received the London Grocer of Feb. 11th, and take therefrom the following, bearing upon the prospects for coffee:

COFFEE AS VIEWED BY THE LONDON "GROCER."

"Much as a return to lower prices is to be desired in the interests of the home trade, it is feared that prices of coffee will continue to range high for some time to come, and buyers must be prepared for the worst if they do not wish to be placed altogether in a disadvantageous position. Although stocks in Europe are believed to be much heavier than they were in February last, a circumstance like this is of little moment when weighed against the probability—yea, almost certainty—of failing supplies through a deficiency in the world's crops, and while the disparity between the quantities produced and those consumed exists, no relief from the present strained situation of the article can reasonably be expected. What renders the maintenance of stiff rates for coffee an almost foregone conclusion, is the fact that the production generally is contracting rather than expanding and the scarcity complained of is more the result of a prolonged absence of supply than of any sudden or marked increase of demand. The latter, if too brisk or extensive, might be kept under efficient control, and so moderated as to bring it within necessary bounds; but over the aggregate supplies from different countries no influence can be exercised beyond that of repeatedly advancing quota-

tion for the berry, and, when these fail to attract the requisite shipments hither, there is no help for it but to pay the utmost money for the best assortment that can be got. In times of dearth, great inconvenience and difficulty are experienced, and that, too, for a whole season or more, as the coffee plant requires several years before it is fairly matured and capable of bearing any amount of berries; and let it be as eagerly and urgently wanted as may be, its cultivation is one that is always tardy, and which cannot in the least be hurried."—*American Grocer*.

COFFEE IN NORTH BORNEO.

The Commissioner of Lands in British North Borneo says that about 330 acres were planted with Litterian Coffee by Europeans during 1892 and that preparations are in progress for planting other 330 acres in 1893. This gives a total of 660 acres for the two years not including land planted by Chinese and Natives. The present appearance of the young coffee is, we understand, very encouraging.

Coffee planting is being pushed on the West Coast of British North Borneo by Mr. R. M. Little the Resident and by Mr. P. F. Wise who are distributing Liberian seeds and seedlings among the natives. The system adopted in Java ensures the planting by each man of at least fifty coffee trees, the produce of which must be sold to the Government at a fixed price.—*Straits Times*, April 5.

SCIENCE IN PLANTING.

The question which is just now agitating the planting community of Ceylon is whether or no it would be advisable for the Planters Association to engage the services of an Agricultural Chemist, in order to see if an improvement cannot be effected in the quality of the tea and the yield per acre by applying fertilisers on a scientific plan. It has been very noticeable in Ceylon, as it also has been in Travancore, and we believe in every other tea district, that the leaf plucked for the first year or two off bushes grown on soil that had not before known tea, contained some high quality which it subsequently lost, and which no cultivation, however high, has yet been able to restore. The planter not naturally considers that science ought to be able to step in here and to say just what constituent in the soil has been exhausted and how it is possible to renew it. Unfortunately, agricultural science, in so far as tropical products are concerned, is yet in its earliest infancy.

A Ceylon planter at a recent Association Meeting held in Ceylon concluded a speech strongly in favour of employing the services of an agricultural chemist thus:—"For the sake of our cultivation, I plead for the appointment of an analyst to prove to us that our soils are liable to deterioration, if science asserts they are, and after that to tell us what to apply to prevent it, and in what quantity, according to the individual requirements of estates, so as to safeguard us from the very real risk of over stimulation. Without scientific direction, experience has already taught us how dangerous artificial manure may be." We do not question that an analyst would be able to tell whether the soil had deteriorated or not, and after that he might be able to say what fertiliser ought to be applied—theoretically; but it would not need many experiments to prove that the effect produced by artificial manure, in theory and practice, are by no means one and the same. "Without scientific direction experience has taught us how dangerous artificial manure may be"; but experience has so taught us that with scientific direction it may be equally if not more dangerous. If a man, feeling seedy and out of sorts, were to consult a chemist and to be told that he could soon be cured, only that he must give up all solid food and take nothing but tablets and lozenges, he would look on that chemist as a lunatic, and yet this is practically the advice that

the agricultural chemist, fresh out from home tenders to planters. He forgets that coffee estates cannot be allowed to lie fallow every few years, or that change of crops cannot be practised on teafields, and because he has doubled the yield of some acres of turnips, he considers that similar treatment will give a similar result with tea and coffee, which is much the same as arguing that one and the same treatment will cure bay fever and malaria. As a matter of fact, at the present time the practical knowledge of planters is much more valuable than any information agricultural science can give. But it should not be so. If a young fellow, blest with common sense, were brought out now either to Southern India or Ceylon, who thoroughly understood the theories of agricultural chemistry, and if he were allowed to experiment here and there, at the end of ten years he would probably have killed a few acres of tea or coffee and injured a few more, but his advice would then be most valuable and he would be able to furnish without hesitation that information about fertilisers which the planting industry needs so badly at the present day.—*Madras Mail*, April 6.

VARIOUS AGRICULTURAL NOTES.

To have bright lamp-light, soak the wicks in vinegar before using them in a lamp. Wash smoke-stained chimneys in warm water and soap, and rub while wet with vinegar or dry salt. They can also be cleaned in warm water and soda, and then in warm water and ammonia.—*Progress*.

The medical qualities of nutmegs are worthy of considerable attention, on account of their value in the treatment of diarrhoea, many cases quickly yielding to the administration of half a drachm in milk. Sleeplessness may be effectually relieved by them when opium fails and chloral is not advisable. They are also a sedative in *delirium tremens*, and can be given with safety and marked benefit.—*Progress*.

TEA FREIGHTS.—The arrangement sanctioned at Tuesday's meeting of tea shippers is as follows: Agreement with the Conference liners to be for three years certain, terminating at the end of that period on six months' notice from shippers wishing to withdraw; failing such notice the agreement to continue until six months' notice is given on either side. The rate of freight to be 15s per ton as customary, above the rate for wheat insured, and jute ruling during the previous month, subject to a return of 5s per ton payable as heretofore to those shippers who confine their shipments during the period of the agreement exclusively to Conference liners. The minimum rate to be 35s gross. All returns to be payable up to the termination of the agreement. All rets earned up to 31st July, 1892, to paid in full.—*Statesman*.

TEA IN RUSSIA.—In a paper read before the Society of Arts on 28th February, on "Russia as a Field for Tourists," Sir Edward Braddon, K.C.M.G., thus referred to tea in Russia:—

Russian tea, as it is drunk by prince and peer, and peasant, is, in my opinion, a dismal substitute for the cheering cup as it is known in England; and herein was one of my few disappointments; I expected great things of that tea which is transported overland, in brick or otherwise, from Kumaon, manufactured with the aid of a samovar, and served with a slice of lemon instead of cream—I realised so little of my anticipated joy, that I abstained from tea altogether after the first day or two. Nor can I consider it a success, as tea, with the Russians themselves; it is only an excuse for the hot-water cure recommended for dyspepsias, the infusion, made in a small tea-pot of a pint measure, being diluted again and again with a gallon or two of hot water, without any thought of adding fresh tea. The tea at the railway restaurants is one of the worst features of Russian railway journeys; indeed, it is the only unfavourable feature that was impressed upon us.

MUTURAJAWELA LANDS.

We learn that Mrs. J. P. Obyseskere bought a couple of days ago the (1,326) acres of Muturajawela which some time ago belonged to Mr. J. W. Home. Originally, it belonged to Baron Delmar, thsn to Baroness Rochefoucault, next to the Oavandishes, then to Mr. Home, next to Mr. Akbar, from him Mr. Tambyah, Shroff of the Mercantile Bank bought it and sold it to Mrs. J. P. Obyseskere. This enterprising lady—an example to Sinhalese ladies in high life and one who should receive royal recognition by-and-by—intends to cultivate it with paddy if possible. We think Government should help Mrs. Obyseskere to do this by preventing salt water flowing from the canal and by having the flood outlets in that part of the country restored. When the seat of the Sinhalese kings was in Cotta the whole tract of fields extending to Pamunugama was successfully cultivated with paddy, and it was so fertile as to deserve the name Muturajawela, which is rendered by some as the "pearl of royal fields." The conditions necessary for the successful cultivation of these fields are outlets to drain away the superfluous water that flood them after rains, and dams to keep out the flow of salt water from the canal to them. In this connection, the completion of the Flood Outlets cannot be too strongly pressed on Government. The Dutch had several canals in different parts of the country cut to prevent the floods. Their traces are still to be found and if only these canals were restored some of the fields in the Western Province that are now abandoned might be cultivated with success.

DELGOLLA ESTATE CO., LD.

Report of proceedings at the extraordinary general meeting of the Delgolla Estates Co., Ltd. held at Hatton on the 11th day of April 1893.

Present.—Messrs. W. D. Gibbon (in the chair), Thomas Mackie, Buxton Laurie, O. C. Shepard and A. P. Waldoek. Messrs. A. E. Wright and W. Forbes Laurie were represented by their Attorneys and Messrs. G. W. Sulren and W. W. Sevier by proxy.

Notice calling the meeting was read.

Minutes of the general meeting held on the 20th January 1893 were read and confirmed.

The report and balance-sheet for season ending 28th February 1893 were taken as read and passed. Commenting on these the Chairman pointed out that the sum subsequently realized for the cacao and coffee in store at 28th February was nearly R900 in excess of the sum estimated.

DECLARATION OF DIVIDEND.

Mr. SHEPARD proposed:—"That in view of the produce in store having realized more than was anticipated a dividend of 9 per cent be paid instead of 8 per cent as recommended in the report." This was seconded by Mr. WRIGHT and carried.

ELECTION OF DIRECTORS.

Mr. WALDOCK proposed the re-election of Messrs. Mackie and Buxton Laurie, the retiring Directors. Seconded by Mr. SHEPARD and carried.

ELECTION OF AUDITOR FOR THE CURRENT SEASON.

Mr. GIBBON proposed and Mr. MACKIE seconded:—"That Mr. John Guthrie be appointed Auditor."—Carried.

DATE OF ANNUAL GENERAL MEETING.

Mr. LAURIE proposed:—"That the ordinary general meeting of the Company be fixed for the 21st day of April in each year," seconded by Mr. MACKIE and carried.

The CHAIRMAN, who had just returned from a visit to the Company's properties, gave a short general report. He said that he had been most favourably impressed with their present appearance and future prospects. The young coconuts on Delgolla were

coming on very well and promised in a few years to become a valuable adjunct to the profits of the Company. Last year's clearing of 29 acres planted with cacao, Liberian coffee, and coconuts was looking healthy, and a further clearing of about 60 acres had been felled and burnt off preparatory to being similarly planted. The new bungalow was approaching completion and would be finished by about July.

As regards Isabel, an estate of 160 acres, of which about 150 acres are planted with cacao and a few coconuts—the Chairman stated that the property had for many years given a good return and with liberal cultivation and the attention that would be devoted to supplies and shade trees, should do still better in the future, and prove a valuable addition to the Company. He strongly recommended the further extension of this estate by the acquisition, if possible, of land in the vicinity. Summing up he said that he had been well pleased with the property on his first visit previous to the inception of the Company, but now on his second visit he had been much struck with the improvement in general appearance, and considered that the shareholders had reason to congratulate themselves on their property, which he thought was a valuable and steadily improving investment. There being no further business before the meeting it was closed with a vote of thanks to the Chairman.

A. P. WALDOCK, Secretary.

FROM THE REPORT OF THE DIRECTORS.

The amount at credit of profit and loss account leaves a balance of R13,324'44 to be dealt with, and out of this sum the Directors now propose to pay a dividend of 8 per cent on the original capital of R144,000, leaving a balance of R804'44 to be carried forward.

The Directors are of opinion that this is a satisfactory result, considering the very dry season that has been experienced, and which materially affected the yield of the various products in which the Company is interested. It will be seen from the Profit and Loss Statement that a considerable sum was incurred under the head of interest, owing to the estate having been purchased as from a date about three months before all the capital was subscribed.

Owing to the lateness of the cacao crop, and in view of the fact that shareholders were not called upon to pay for their shares till March 1892, the Directors deemed it advisable to carry on the season till the end of February 1893, and February will in future be the terminal month of each financial year. This will also accord with the date of the acquisition of Isabel estate referred to below.

CACAO.—The original estimate for the season was 300 cwt., while the total secured was 355 cwt. The trees have evidently carried their crop well, for the estate superintendent reports that the cacao has improved in appearance since the late rains, and there is a good blossom on the trees. He estimates the spring crop at about 100 cwt. Those interested in cacao cultivation have reason to be pleased with the satisfactory prices now ruling for the product.

LIBERIAN COFFEE was estimated at 80 cwt., while the actual yield was 75 cwt. On this also a good blossom is reported.

COCONUTS.—The number of nuts plucked was 83,311, as against an estimate of 80,000, of which some of the best were selected for nurseries. The area in full bearing is only about 25 acres, so that the shareholders will see that this cultivation is but in its infancy. A considerable extent is, however, planted, and the trees are coming on well. Each year will therefore increase the value of the property and the profit therefrom.

CLEARINGS.—Thirty acres of new land have been planted with cacao, Liberian coffee, and coconuts, and the clearing is reported to be doing well by the Company's Visiting Agent. A further sixty acres have been felled and will be similarly planted.

CAPITAL.—In accordance with resolution passed in general meeting, the Company's nominal capital has been increased to R220,000. The Directors

decided to call up R60,000, making the total subscribed capital R204,000. This sum it will be seen appears in the balance sheet, although only the original 360 shares participate in dividend.

ISABEL ESTATE.—With the addition to the capital this promising property has been purchased at a cost of R45,000. The directors have every confidence that this will prove a valuable acquisition to the Company. The balance of called-up capital is to provide for expenditure on opening clearings, &c.

NOTES ON PRODUCE AND FINANCE.

DIGESTIVE TEA BY ELECTRICITY.—Of the wonders of the electric belt, all those familiar with advertisements are acquainted, but a new application of electricity is announced. The Universal Digestive Tea Company, Limited, of Manchester, are anxious to make known the fact that tea dried by their new electric process is "freed entirely from injurious tannin. The flavour of the tea is more delightful, and the theine—the refreshing property—remains unaltered. The tea has already been tested and approved by over seven hundred medical men, many of whom speak of it as the *only safe tea*." We are quoting from the circular of the company. The electric process is, of course, the secret of the company at present, and we have no desire to penetrate its mysteries. This much is made known, however, and the italics which follow later on are not ours, viz., that there is a cylinder which, doubtless, is as important a factor in an electric process as the drum to a Salvation Army band.

MAY QUICK DIGESTION WAIT ON APETITE.—The following (says the circular) "speaks for itself":—At the suggestion of a doctor a sample pound of tea was divided into two half-pounds. One half-pound was put into the cylinder for twenty-five minutes and treated by the electric process; at the end of that time an ordinary strength infusion was made from each of the half-pounds, and tested to show the action on the digestion of starchy food. In the tea that had been treated by the electric process digestion was complete in eight minutes; but the same tea, not so treated, delayed digestion three hours and twelve minutes.

THE NEW PROCESS IMPROVES THE TEA.—Any tea can be treated by this process it appears. "The company treats all kinds of tea—Indian, China, or Ceylon tea. We think" (says the circular) "that few will run the risk of drinking tea that has not been dried by the electric process, when the new process improves the tea, makes it perfectly safe, and does not increase the price. In order that the fullest investigation may be made by those who are interested and desire to procure the best and safest tea, the Universal Digestive Tea Company, Limited, will exhibit the tea while it is undergoing the process, and also show several tests with the tea both before and after it has been in the cylinder." The experience of the Manchester Company should give a stimulus to the experiments of those ingenious inventors who are endeavouring to apply electricity to the drying of tea during manufacture.

COFFEE IN AMERICA.—Messrs. W. D. Barnett & Co. report:—The coffee markets at New York for more than a week past have been feverish and unsettled, there being a number of sudden declines and recoveries, in which fluctuations were generally confined to the narrow limit of ten and fifteen points. Very little in the way of new speculative business was drawn in, and since the 1st inst. the trading in contracts for future delivery was almost no larger than cash sales from warehouses to the regular trade. It is worthy of notice that, while the market for several months past has been controlled by speculative influences, the actual volume of speculative transactions has been all the time growing smaller and smaller in both Europe and America. Apparently, the temper of operators has been undergoing some change, and, whereas it was in accordance with the general craze some months ago to be bullish, there is now an inclination towards the bear side. Prices at the close were lower than at any time since early in the year,

with local traders working for a further decline, and the professional bears selling moderately. The reaction seems due to the discovery that the discounting of the deficiency in the present crop yield had been carried too far, and that, at the lowest yield estimated, the world's large visible supply, with the enormous invisible stock carried over from last year, will be more than sufficient to meet ordinary consumption until the next crop becomes available. Had it not been for this surplus stock, which is always invisible and impossible to estimate, the shortage of the present crop would have been felt more severely. —*H. and C. Mail*, March 24.

REMARKABLE EXPERIENCE OF A CEYLON PLANTER; HIS GUN STRUCK BY LIGHTNING.

A gentleman resident on a tea plantation between 2,000 and 3,000 feet above sea-level writes to us:—

April 11.—I do not wish my name published with the following, but if you think it has any interest to your readers by all means publish it. I'd like a scientific opinion on the subject. One afternoon lately I was in the jungle with 2 coolies superintending the cutting of a path. We got to the edge of the jungle into light chena just as a thunderstorm came on. Rain did not fall till later on. I was carrying a gun on my right shoulder, when suddenly my gun was knocked out of my hand and thrown about 4 feet in front of me, and I saw very red lightning under the rim of my hat and found myself knocked down and sitting with my legs straight out in front of me, my gun being 4 feet away from my feet. I had on a very thick pith hat and tweed clothes, and there was a smell of singeing either from the cover of the hat or from my clothes I suppose. A cooly about 3 feet from me who had a billhook in his hand remained standing; and when I spoke to him he remarked that my gun had been struck by lightning. I suppose this was really the case, and that the gun being knocked out of my hand instantaneously, the electric fluid hit the ground instead of hitting me. The above may seem rather like a yarn, but if I had collapsed from fright when the clap of thunder came I should have gone to earth in a heap gun and all. The gun has only two small dents in it from its fall, and I had no bruise of any kind or any feeling that anything unusual had happened, except of course a momentary fright and a feeling of gratitude for what seemed to me a most providential escape.

The only parallel case we can recall is that of the Ceylon Rifle soldiers who were struck down in their barracks just as they were about to mount guard, a good many years ago. The event is recorded as follows:—

1854.—22nd May. Awful thunderstorm bringing in monsoon from 3 to 9 a.m., Rifle Barrack struck by lightning in Colombo, 29 men accoutred struck down and more or less injured, rifles twisted, 40 men knocked down by shock. (On 16th May, storm at Galle, lightning made hole near Fort wall 3 feet diameter by 20 feet deep.)

PLANTING IN EAST AND WEST AFRICA.

(From the letter of a Ceylon Planter in East Africa.)

Civilization is fast catching us up—hand over fist, for the Chief Engineer and Surveyor of our Railway line is out, and hard at work getting ready to begin operations, so sometime between this and Christmas next I hope to see the cutting of the first "sod" of the Tanga-Koroague line. It is just possible I shall be opening close to the line soon, some 20-25 miles from this. However can't tell till I pitch my tent there. I've done a good deal, but

fancy opening in our orthodox way 400 acres with cacao! It's possible in Ceylon, but here without a large and well-trained labour force it would be foolish to attempt it. No, I'm steadily going on planting as weather permits, besides continuing to extend, and roading the place, besides having several buildings in hand and all done by the coolies. I've been successful beyond anything I thought it would turn out to be with the planting. Exceedingly few vacancies and all plants "all abloom and agrowing," and looking so healthy. All coffee.

My assistant when he does come I guess will be rather surprised.

Lots of visitors come up here. To tell the truth quite becoming a nuisance. One day, botanists looking out for weeds, another, a geologist "quite nuts" on brickbats of all sorts. Then a Government doctor fully impressed with the idea that the Heathen Chinese is far more subject to disease than the generality of mankind. Then some blueblooded Prince wanting the black man's medicine—Whisky or Brandy, but "Cham-pagne" is better; or another member of Royalty to borrow money. In fact at times quite a series of "Durbars" here, so much so that I am going to "debar" them by putting up a Visitors' Bungalow, where they can contemplate "Ceylon transplanted into Africa" at a respectable distance.

Ah! by the way, never lend Royalty any money! I did so to a member of the "House of Africa," rather a big sum to lose, and it took a lot of diplomacy to get it back. Knowing that silver was of little value I suppose, this mighty hero of a hundred fights (fits I should say after a hoot of the bottle) tried on payment in kind—Indian corn and a sheep, but as it was a question of cash, I told him I wanted to see the colour of my money, in the politest Ki-swahili of course, and about a week after I got back the 6 rupees. They're a beggarly lot some of them. This man did he choose to exert his authority without abusing it, and had he more respect for himself, his influence would be great, but I fancy he'll lose it entirely one of these days, and he has splendid land all round him, but too lazy to see it decently cultivated. Just sufficient and no more; should a famine occur he'd be up in "gum" tree, though I haven't noticed any growing here. Such is life.

By-the-bye I hear Van der Poorten is very much disgusted with the aspect of affairs in the Congo. At any rate, at the time of writing to me he was far from elated. I fancy, Greenwood must have seemed a "Paradise lost" to him, when he was penning his experiences out West: we say out West here, it's just at the other end of the equator, passing through like a "skewer." He was great on oil palms and had recommended 12,000 acres to be planted up gradually (a nice little hillet that lasting at rate of printer's devil's estimate of 400 acres per annum—30 years), and the only place where they could plant was on an island, about this extent, after exterminating the natives!! Guerra al cuchillo. Coffee and pistols for two! That's the way to do it. I can fancy Van der Poorten, leading his 20 soldiers (he was going to ask for 20) on to victory, "Death or Glory boys!" style, and then, when they had driven off "these brutes who would not work until slavery was re-established," he would commence to plant up the 12,000 acres with the 20 soldiers I suppose. A Ceylon planter can do anything! I really think that Ceylon planters must belong to an entirely superior and different race of men after this!

EFFECTS OF TEA-TASTING.—It is well known that the abuse of alcohol, tobacco, opium and quinine seriously affects the sight but, generally speaking tea has not been considered liable to have such influence. Cases are on record, however, where professional tea-tasters have had to seek treatment for weakness of vision, induced by the prolonged practice of tea-tasting.—*Nilgiri News.*

ROYAL GEOGRAPHICAL SOCIETY OF AUSTRALASIA.

COFFEE-GROWING IN THE NEW HEBRIDES: TEMPTING PROSPECTS.

SIR JOHN FRANKLIN AS A "MIDSHIPMAN": ONE OF "THE BRAVE DEEDS OF OLD."

We have to acknowledge with thanks from Mr. Macdonald, F.R.G.S., &c., the Secretary, the receipt of Vol. X (issued March 1893) of the Transactions of the above Society—an interesting number with a variety of papers more or less referring to the Australasian or South Pacific world. We have a progress report from the Antarctic Committee, valuable notes on volcanic mountains in New Zealand, a progress report of the Elder Exploring (Australasian) Expedition, notes of a long-forgotten Antarctic voyage in 1833, synopsis of a paper upon "The Astronomical Theory of an Ice Age," Baron Mueller on "The Columbus Jubilee," &c.,—showing the variety of the subjects treated. But we are more especially interested in an incident related in an account of the Life and Works of Sir John Franklin by the Secretary, and in Mr. Lindt's paper on the Resources and Capabilities of the New Hebrides particularly with reference to coffee-growing.

But to turn to something more immediately practical. Mr. Lindt's paper on the New Hebrides really deals with "a pioneer coffee plantation" and from the following headings it will be seen that it is comprehensive enough:—

1. How to get to New Hebrides; 2. How to choose land; 3. How to purchase it; 4. How to settle on it; 5. How to start a nursery; 6. How to clear the land; 7. The planting out. Shelter trees; 8. Maiden crop; 9. Storehouses, pulping plant and their situation; 10. Pulping, fermenting, washing and drying; 11. Pounding, milling and final drying for market; 12. Topping and pruning the coffee bushes; 13. How to procure labor; 14. Rates of labor and cost of maintenance.

Of course no Ceylon planters need half the instruction afforded; but the rest we must place on record for reference in detail in our *Tropical Agriculturist*, merely stating here that the islands referred to are now within five days of Sydney by a regular monthly steamer. The best coffee land is between 500 and 1,000 feet above sea-level and is covered with luxuriant forest; but the larger trees are left as shelter and only the low jungle or scrub cleared. As to purchase of land £50 cash will buy outright from 200 to 500 acres from a Chief, according to situation. Then as to labour, there seems to be no difficulty in getting men on a three years' engagement at £6 wages per annum (paid at the end of the term), the passages to and from their homes (in other islands) in all about £12 a head, being also paid by the planter. That is a total cost of £10 a year for able-bodied men; but then the cost of "keep" has to be added. This Mr. Lindt says is however merely nominal. Here is an extract:—

The cost of their keep is merely nominal on established plantations. Yams, taro, bananas, maize and sweet potatoes are planted. Breadfruit, tomaka, manioc, arr-wroot, naiap, papua-apple, coconuts, numapi and many other native fruits grow wild in the jungle. When establishing an estate, coconuts should be planted by the thousand, as they become a source of revenue in the course of six or eight years. Besides the many uses coconuts are put to while growing, the kernels of the matured nuts are dried, either by sun or artificial heat, and thus converted into the article called copra. It takes about seven thousand nuts to make one ton of copra, which is worth in the islands about £7 at the present time. Bananas, oranges, grenadillas, and in fact all tropical fruits grow to perfection, and will no doubt find a

ready market in the future. Yams and other native food can be bought at the rate of ten pounds for one penny, or its equivalent in tobacco. Of wild animals there are none but pigs. The few tree snakes are all of the non-venomous kind. There is an abundance of wild pigeons and jungle fowl, and also brush turkeys (*megapodiac*). There are no cockatoos, and only one or two kinds of parrots. The flying fox is found, but not in such numbers as in the northern parts of Australia or New Guinea.

We confess the New Hebrides would seem to us to be more favourable for the practical Ceylon coffee planter-capitalist than either East Africa or Java. The Australasian market with a good demand for coffee is near at hand, and as yet apparently only one coffee plantation worthy of the name (that of Messrs. Roche Brothers; Rathmoy estate on the island of Efate) has been established.

In concluding our notice we have to acknowledge the courtesy of the Australasian Geographical Society in nominating both our late senior and ourselves Hon. Corresponding Member; the death of the former as well as of Sir James McBain is noted in this number. We must endeavour by-and-bye, to give the Society a paper on the close connection (trading, business, social &c.) which ought to be established between Ceylon and Australasia; our tea, cocoa, cinnamon &c. supplying their market and their frozen meat, wines, fruit and potatoes being welcome to Colombo.

POTTERY IN EGYPT.

In the early part of the year we mentioned that the Government had lent its sanction and support to a project for the investigation of the question as to whether it was possible to revive in this country the manufacture of pottery as it existed in years gone by. Mr. de Morgan, an English gentleman connected with the Staffordshire potteries, has been for some weeks making experiments with clays collected from different parts of Egypt, for the above purpose. A report is now being drawn up by him embodying the results of his work and the opinion that he has formed as to the chance of the success of the scheme. Until the report is submitted to the Government we are unable to publish Mr. de Morgan's decision. Generally speaking, however, he is of opinion that a development of the pottery industry can be brought about, especially in the ruder articles of manufacture, where a high degree of skill is not required in the finish, and in the heavier goods, such as large jars and open vessels, the freight of which from Europe adds greatly to their cost in Egypt. In the case of highly finished and lighter ware the competition of the Italian supply renders the success of its manufacture in this country very problematical. What is chiefly needed is a series of further experiments with native clays baked in native kilns under proper supervision and direction, and for this purpose a further expenditure of time and money will be necessary. Mr. de Morgan leaves Cairo to return to England at the end of the week. He will take with him a collection of clays brought from different parts of the country, with which he will make further experiments in England.—*Egyptian Gazette*, March 28.

BADULLA PLANTING REPORT.

BADULLA, April 11.

MARCH has been an exceedingly wet month, no less than 14.35 inches of rain in 18 days having fallen in what is usually one of our driest months. This has been very favourable for TEA, but it has entirely ruined all chance of the big crops of COFFEE on low places, that at one time seemed probable. A very fine COFFEE BLOSSOM burst on the

6th of March, and prospects were then excellent, but we have had no regular blossom since and the spike has mostly gone to wood, while now it is too late to expect any, with the little monsoon fully on. What an outcry these March rains would have caused a few years back!

TEA however was very glad to get them, and since they set in, has done very well indeed: some fields; especially fields pruned within the twelve months, have had some extraordinary flushes, and I have heard of as much as one hundred pounds made tea per acre being plucked in the month off a considerable acreage. The weather is now quite perfection for tea,—warm, very hot mornings with plenty of rain and showers in the afternoons. A good deal of supplying and planting has been done in the past month; and if the rains last well into May as they usually do, clearings planted last season will not be as irregular as they promised in many instances to be. The tea market is not very encouraging, but the Uva teas have sold well,—the factories in the district being all well up in the list of averages.

TOBACCO IN SOUTHERN INDIA.

We have had a call today from Mr. G. Jahn-Mengel of Dindigul, who has had a good many years of experience now as a tobacco-grower in Southern India and who was over here some years ago. He is surprised to learn of the failure of the European Company's experiment in Ceylon, but is to call on Mr. Ingleton to learn all about it. Mr. Mengel has been lately making an interesting experiment with seed from different parts of the world, and has found some from Pennsylvania the best, some samples of the leaf being very fine. Mr. Mengel may visit the tobacco districts of the Central Province.

THE RATWATTA COCOA COMPANY, LIMITED.

The above is the latest addition to local Plantation Companies. It is established primarily to purchase or otherwise acquire the Ratwatta Estate, situate at Matale, containing in extent three hundred and twenty (320) acres or thereabouts.

The nominal capital of the Company is one hundred thousand rupees (100,000) divided into two hundred shares of rupees five hundred (R500) each, with power to increase or reduce the capital. The signatories are F. M. Mackwood, Colombo, George J. Jameson, Colombo, H. Drummond Deane, James R. Fairweather, Edmund J. Friles, Gangarua, Kandy, T. O. Huxley, Peradeniya, and A. Collingwood Smal, Galaha, Kandy.

OIL OF CINNAMON.

The chemistry of this oil has not been touched for some time, the latest investigator being J. Weber, who reports in *Arch. Pharm.* that the oil from Seychelles Islands has the colour and odour of oil of cloves and a burning taste (sp. gr. 1.0552 at 18.5°), and consists of eugenol principally, with small quantities of cinnamaldehyde and of terpenes. Attempts to identify pinene and cineole among the latter were unsuccessful. Benzoic acid, also, could not be detected. The root-oil procured from Schimmel had the colour and odour of oil of cloves, (sp. gr. at 19.0 1.0411), and consisted mainly of eugenol, but contained also safrole, small quantities of benzaldehyde, and a considerably larger amount of terpenes than the bark-oil first mentioned. But Schimmel suspects that this second sample was really a leaf-oil.—*Chemist and Druggist* March 25.

TASMANIA REVISITED.

By Old Colonist.

I have an intense dislike to the gentleman who says "I told you so," and I am not going to commit the contemptible offence of bantering people in their adversity. Tasmania like the rest of Australia has fallen upon bad times, and deserves our sympathy in its present effort to surmount the calamity. Owing to the labour difficulties capitalists have been frightened away with their money and confidence the consequence being a bad falling-off in the trade returns. The public revenue has fallen by 1/5th—a very serious matter in itself; and all officials from the Governor downwards—in this somewhat over-governed colony—are submitting with the best grace they can to a considerable reduction of salary. All public works, not absolutely necessary for present requirements, have been stopped, and the strictest economy is being enforced in all departments. Fortunately at this juncture, as Sir Robert Hamilton remarked the other day in Edinburgh, the colony has now at the helm of the Treasury a more than ordinarily competent and clear-headed man in the Hon. John Henry, whose faith in its recuperative powers continues unabated. Though no one more regrets the ridicule that has been brought upon the island by part mismanagement, and the absurd booming by unscrupulous adventurers at home. We had a good laugh over a recent article in *Blackwood* (for Oct.) so outrageously inaccurate as to be harmless.

HOBART has changed but little during the last six years, but what little change there is, is for the better. The streets are decidedly clean, and one or two fine buildings add much to the beauty of the city, particularly a corner building on Collins St. and the grand Coffee Palace.

The general business of the place is sick as sick can be, but one or two new ventures form a pleasing exception. Ceylon Tea is being pushed with marked success; and the

DISTILLING OF EUCALYPTUS OIL,

by Gould, is a most promising industry. The former is ruining the Cascades Brewery very hard, while the oil is beating 'Jacob's' out of the market. Not only is it found to be a powerful disinfectant but taken inwardly or outwardly it is said to be a specific for numerous ills. Old Homœopathy with his petit pills still drives his wretched round, sitting erect as ever, but finds the sturdy folks of Hobart so seldom getting ill, that he has had to take to other occupations, such as the supplying of "undiluted" milk and the growing of fruit for the market. I am specially interested in his orchard, having seen it when newly planted some 7 or 8 years ago when I had many interviews with the very intelligent gardener then in charge. Needless to say he is no longer there, but 1/4th part of the garden is still fairly flourishing; the rest, I am sorry to say, as Billy Rudd said of Saffragam, is all "wind, weeds, and walking-sticks."

Passing out the Augusta Road I was interested in seeing the effect of seven years upon

THE ORCHARDS

familiar to me in 1836. Trees then in their prime are unquestionably now in the ere and yellow leaf, confirming my previous formed notion that 16 or 20 years will sum up the profitable life of an average apple tree here. Young trees are however taking the place of the old, and on the whole the industry is advancing. New gardens have been planted, and some really beautiful villas erected in this most delightful suburb of Hobart, with views of the Derwent valley unsurpassed by anything of the kind in this isle of beauty. Travelling onwards we enter the Kangaroo Valley, the larger portion of which is still in the same condition as when Captain Cook landed on the island, or when Lady Franklin loved to ramble amongst its fern-trees; but there is one little fairy-like spot that has a peculiar interest for me. Here the apple, pear and plum trees seem to rejoice under their enormous loads; the freshly blown flowers,

like the rosy children; run wild with joy, while around this little paradise ripples as pretty a burnie as ever "wimpled through a clachan." Here I once more visited my friend frae Kirriemuir—a veritable native of "Thrums," happier than ever an "Auld Licht Minister" could have made him yonder. Here, too, I met one who was long a resident in Ceylon, whose father was one of the most energetic, but ill-requited of men, that dare fortune ever tantalized in your island. Poor J. W. H., it seems but yesterday—though well-nigh 30 years—since I saw him land, at Galle, full of feasible schemes.—a Grand Hotel at Buona Vista, then Paradua, after which, Saw-mills in Colombo—a submerged. Then contracts for irrigation works, ditto for hotels, auctioneering, &c., &c., always on the very brink of rivers of wealth, but as often did the mirage vanish from his sight. 'Tis passing strange that the same fatality seems to attend the family. As far as I can gather, the only daughter married an immensely rich squatter, who soon after died, settling however £70,000 upon her, with which she promised to endow her brother liberally, and upon the heads of this he married a sister-in-law of my "Thrums" friend. The lady, however, took a trip to England, followed by a clever man of business who got her to make her will all in his favour, and then suddenly died. There the matter rests, the poor brother baving got nothing.

Another gentleman I met in Hobart will long be remembered in Ceylon as the valued henchman of Mr. FAVIELL, who out of 27 Assistants to start with was the only one who survived to see the train enter Kandy, his own brother being the first to be swung over the "Sensation Rock," and was fatally injured thereby.

Mr. ALAN STEWART, who now looks the picture of robust health, came to Tasmania seven years ago, and has done some admirable survey work in a country where surveying and road-tracing has ever been the weakest point of the most deplorably incompetent Works Department ever a poor colony was cursed with. But a fiat went lately forth that all unconvenanted surveyors must pass an examination, and quite characteristically, they would begin upon Mr. Stewart! Well might he ask—"But who is to examine me in Tasmania?" It is simply another example of pandering to the cry "TASMANIA FOR THE TASMANIANS" which I fully hope the present adversity will cure. Meanwhile Mr. and Mrs. Stewart go home by the "Oceana" will visit Ceylon *en route*, and if your Government do not give them a free pass over the railway, he helped so ably to construct, then I shall once more blush for shame!

COTTONSEED OIL PRICES.

The *Baltimore Manufacturers' Record* says: "The present position of cottonseed oil is no less interesting than the phenomenally short cotton crop. The small yield of cotton and the unusual demand for oil to supplement the scanty supply of lard have given to cotton seed products an importance never before reached. Last summer cottonseed sold at \$7 per ton and less in some localities, but now the mills are buying all they can get at upward of \$20 per ton, \$22 being about the ruling figure. Refined oil is now selling at 60c. and upward per gallon, as compared with 20c. a year or two ago."—*Bradstreet's*.

THE BIGGEST CARGO OF CEYLON PRODUCE,

From the Chamber of Commerce Circular we find that the largest cargo in a Liner taken from Colombo was that by the s.s. "Oshshire" (Bibby Line), which cleared on Feb. 3rd last, viz., 2,397 tons, 120 tons of which was steel tyres, 964,000 tea, and the balance 1,313 tons Ceylon produce.

The "Capella" (Harrison) comes second in tea, 925,000 lb.

CINCHONA REPORT.

(From the *Chemist and Druggist*.)

London, March 23.

CINCHONA.—The sales of cinchona-bark which were held here on Tuesday were again rather large, the twelve catalogues containing over 3,000 packages of Bark, divided as follows:—

	800 of which	656 were sold
Ceylon cinchona	1,659	1,505
East Indian cinchona	85	85
Java cinchona	265	265
West African cinchona	292	254
South American cinchona	3,101	2,765

The assortment of bark was hardly up to the average, although the poorer Ceylon kinds were but sparingly represented. There was a smaller proportion than usual of grey bark, but East Indian Ledgers (of rather low average quality) were plentiful. A feature of this sale as it has been of the two or three previous auctions, was the inclusion in it of a considerable proportion of old stock, imported in 1886 and 1889, part of which was now worked off at figures that can hardly have paid more than the warehousing expenses. At the beginning the tone was rather dull, but it speedily improved and kept moderately active throughout the greater part of the sales. The average unit was quite as high as that of the preceding sales—say 1d per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Auerbach works	172,010
Agents for the Mannheim and Amsterdam works	146,719
Agents for the Brunswick works	96,472
Agents for the Paris works	75,215
Agents for the Frankfurt-on/Main and Stuttgart works	47,531
Messrs. Howard & Sons	22,860
Agents for the American and Italian works	13,430
Sundry druggists	54,827
Total quantity of bark sold	628,887
Bought in or withdrawn	69,342
Total quantity offered	698,229

It should be remembered that the weight of bark purchased is no criterion as to the quantity of quinine acquired by the buyer.

COFFEE IN THE STRAITS.

Coffee planting in the Straits Settlements may be said to date from the arrival of the first Ceylon planter in the Colony, who, on the failure of the industry in Ceylon, came over and settled chiefly in Johore and Singapore.

The results of those early ventures induced Mr. T. H. Hill, one of the first and most enterprising of the Ceylon planters, to prospect the other Native States with a view to planting operations, the Government granting him large concessions of land in Sungei Ujong, Selangor and Perak as a Pioneer Planter, a title which he well deserves, having been the first to successfully cultivate Liberian coffee in these three States.

In 1882 Mr. Hill, then managing the Ampang Tin Mines, selected and took up some land near Kuala Lumpur which he planted up with Liberian coffee, pepper, tea and other tropical trees. Mr. Evans, who died some years after of cholera in Perak, was the first Superintendent on this the first coffee estate in Selangor, which was appropriately named "Weld's Hill," after the late Sir Frederick Weld, then Governor of the Straits Settlements. This estate is now almost entirely under Liberian coffee, there being only a few acres of pepper left, which is being gradually worked out as the proprietors evidently find coffee at \$35 a pikul pays very much better than pepper at \$10.

Messrs. Hill and Rathborne next selected and planted "Ginting Bedai" and "Batu Caves" Estates. Ginting Bedai, situated above the pass of that name on the main mountain range, at an elevation of between two and three thousand feet, was planted with coffee (Arabica), but had to be quite

abandoned before any results could be obtained, as it was found impossible in the absence of roads to maintain a labour force some 23 miles from Kuala Lumpur in the heart of the jungle. Some trees that were then planted may even now be seen struggling for life amongst the native jungle.

Batu Caves Estate is a stretch of some 2,850 acres of flat land lying round the base of the Batu Caves, from which it takes its name. At first there were only some 12 acres of coffee (Liberian) planted and a few trees of cocoa, but within the last three years the proprietors have considerably increased their planting operations. In 1883 Stephenson opened the estate of "Beverlac" at Klang. This estate—along with "Tremelbye," "Enterprise" and "Glenmarie," which are situated in the same District and all opened about the same time—was planted with pepper, but the later clearings have been planted with Liberian coffee. From 1884 to 1889 no new estates were opened, but a few Javanese and Kuantan Malays settled in different parts of the State and planted up an acre or two round their houses, the most extensive of these perhaps being the group lying between the Racecourse and Lincoln Estate. Towards the end of 1888 the late Mr. William Douglas, Manager of the Chartered Bank in Singapore, Mr. Sword of the Straits Trading Company. Mr. Currie of the Borneo Company and myself obtained a grant of 1,500 acres of land in the Setapak Valley, in three blocks of 500 acres each, named, respectively, "Hawthornden," "Roslin" and "Lincoln" after these places at home.

This was immediately followed by the opening of "Wardieburn" by Messrs. O. and R. Meikle in 1889. This estate is thoroughly Scottish, as its name would lead one to expect. Named after the proprietors' beautiful home near Edinburgh, it is kept in the highest state of cultivation for which Scottish farmers are everywhere famed, and the good old Scottish title of "Laird" has been bestowed by his brother planters on one of the proprietors.

At the end of 1889 Mr. H. Huttenbach acquired two small patches of coffee near Kuala Lumpur, one of some 10 acres, about half a mile out of town, from Mr. Bristowe, late of the Land Office, which he has called "Selangor Coffee Garden," the other, some three miles along the Selangor Railway from some Javanese which he named "Batu" Estate, both these properties he has, with his usual enterprise very much improved and extended. Towards the end of 1890 another estate was opened in the Setapak Valley by the Messrs. Glassford, who had had some experience of coffee planting in Southern India, and they named their estate "The Mount," after a property of that name in Fifeshire. A few months later Mr. M. A. Stonor opened "Klang Gates" Estate near the rocky gorge through which the waters of the Sungei Klang flow. About this time Mr. G. Murray Campbell of Messrs. Campbell & Co. at that time engaged on the Railway Extensions in this State applied for land from Government, and finally selected a block to the east of Lincoln Estate, but which was not opened until some months later. This was named "Abercrombie" Estate after the place where Mr. Campbell first saw the light and where his forefathers lived before the history of Scotland began. This estate has been largely extended since the first opening. The next block taken up was by Mr. E. V. Carey, acting on behalf of some influential Ceylon gentlemen and himself, early in 1892. The land selected was in the Gombak Valley, opening out of the Setapak Valley, and amounted to 1,000 acres, to which he gave the name of "New Amherst," after his old Ceylon estate. The last estate opened in Selangor, "Kent," the property of Mr. A. B. Luke, is on the Batu Road, and originally this land formed part of Messrs. Hill and Rathborne's concession at Batu Caves.

The steady increase in the number of coffee estates argues well for the future of Selangor as a coffee-producing country.

The estates in the Kuala Lumpur District alone now represent an area of some 7,000 acres of which over 1,500 acres are planted with Liberian coffee.

F. A. TOYNBEE.

VARIOUS AGRICULTURAL NOTES

PEARL FISHERIES.—A Company has been registered by J. M. Mitchell, 110, Cannon-street, E.C., with a capital of £1,200 in £10 shares. Object, to explore and examine certain mines and pearl and shell fisheries in West Africa.—*Financial News*, March 27.

ADVANCE AMAZONIA!—Brazilian politics and Brazilian Finance have of late attracted considerable attention in various quarters. Some writers take a very gloomy view of the national prospects. Fortunately,—says the *India-Rubber Journal*,—the rubber provinces are a long way off the capital, with its intrigues and cabale. Amazonia possesses in itself vast resources, great powers and opportunities for development, and a more general spirit of individual and mercantile enterprise than many would suppose possible in these tropical regions. Whatever revolutionary changes, or whatever processes of disintegration Brazil may yet have to experience, the provinces of the Amazon valley have undoubtedly a great future before them. In spite of the assertions of pessimists, the sources of supply are practically inexhaustible, and on the other hand customers from Europe and America are always waiting with gold in their hands ready to purchase all the rubber that can be produced.

THE LARGEST FARM IN ENGLAND.—The Apethorpe farms, near Wansford, in Northamptonshire, tenanted by Mr. Andrew Montagu, contains 4350 acres, of which 2250 acres are arable, and 1800 acres pasture. Some ninety-four men and boys are employed in winter, and about double this number of people in harvest. There are ten sets of farm buildings, with steam chaffing and corn grinding machinery. An 8-h.p. traction engine, by Fowler & Co., and a threshing machine, by Clayton & Co., are regularly employed from October to June also about nine-months of the year a double set of Fowler's 16-h.p. compound engines and cultivating tackle. The live stock consists of about 300 sheep, 500 cattle, 95 horses, and 350 pigs. The labour is supplied from the adjoining villages, and the work is principally done by piecework, even to cutting with sheaf binders and reapers in harvest. The cost per acre for labour alone runs from 15s. to 16s. 6d. per acre on the 4350 acres.—*N. B. Agriculturist*.

FARMING TO PAY.—An animated discussion is going on concerning the true cause of the existing agricultural depression and the proper remedies for restoring that great industry to a flourishing condition. Everybody imagines himself capable of teaching the British farmer how to conduct his business profitably. He is contrasted—very much to his disadvantage—with his agricultural ancestors who worked so hard, lived so frugally and accumulated so much money. We (*Sala's Journal*) would point out that the indictment of extravagance and the habit of referring to the good old time when things were so different, is of no recent growth. Here is a cutting—very cutting—from the *Times* about seventy years ago:—

FARMERS IN 1772.

Man to the plough;
 Wife to the cow;
 Girl to the sow;
 Boy to the mow;
 And your rents will be netted.

In 1822.

Man, tally-ho;
 Miss piano;
 Wife silk and satin;
 Boy Greek and Latin;
 And you'll all be gazetted.

TECHNICAL EDUCATION IN MALTA.—Amongst the many important improvements which Dr. A. A. Caruana has introduced into the department of Education since he has been placed as its head, says the *Malta Standard*,—a new Technical School—has been started under the superintendence of Mr. Cardona, where young men are taught the art of carpentering, carving, plastering, modelling and other useful works. This is a step in the right way. Some time must elapse before we will see the fruits of this school, but, as Dr. Caruana has taken the thing bodily by the hand, the time is not far off when we shall see our young men competing and holding their own in the industrial race with other nations. This will also be a great boon to our commerce, for it will open a vast field to our young men, and instead of seeing numbers of them with strength, sinews and muscles, standing idle and loitering about the streets, we shall see them engaged in useful and profitable employment; moreover, instead of spending their money abroad the people will be able to purchase the same objects at a lower price, and with less trouble at home, and thus the money will be circulated in Malta among the Maltese.

CEYLON MANUAL OF CHEMICAL ANALYSES.

A HANDBOOK OF ANALYSES CONNECTED WITH THE INDUSTRIES AND PUBLIC HEALTH OF CEYLON FOR PLANTERS, COMMERCIAL MEN, AGRICULTURAL STUDENTS, AND MEMBERS OF LOCAL BOARDS.
By M. COCHRAN, M.A., F.C.S.

(Continued from page 669.)

CHAPTER IV.—TEA.

PREPARATION OF TEA—ANALYSES OF BLACK AND GREEN TEAS—CHIEF CONSTITUENTS OF TEA—UNPREPARED TEA LEAVES—RELATION BETWEEN CHEMICAL COMPOSITION OF TEA AND ITS MARKET VALUE—ANALYSES OF TEAS BY BATTERSHALL AND DAVIS—ANALYSIS OF CEYLON TEA, MEDIUM PLUCKING AND FINE PLUCKING—ANALYSES OF INDIAN TEAS BY AMERICAN CHEMISTS—DETERMINATIONS OF THEINE IN INDIAN AND CEYLON TEAS—TANNIN IN TEAS—TEA PRUNINGS—CALCULATION OF THE AMOUNT OF FERTILIZING MATERIAL REMOVED PER ANNUM FROM ONE ACRE OF SOIL BY THE TEA CROP—MANURING OF TEA—TABLES OF USEFUL DATA FOR MANURING EXPERIMENTS—ANALYSIS OF LEAVES OF GREVILLEA ROBUSTA—COMPARISON OF THE IMPORTANT CONSTITUENTS OF PLANT FOOD IN TEA LEAVES AND GREVILLEA LEAVES.

TEA is the prepared leaf of *Thea sinensis*. Its use appears to have been first known in China, where it was, according to some authorities, a general article of diet as early as 600 A.D. It was not till the 17th century that tea was introduced into Europe.

The tea plant is a hardy shrub which flourishes in latitudes between the equator and 40°.

In the preparation of the teas of commerce the treatment varies to a considerable extent. In China there are four pluckings during the year, one in spring, the next in May, the third in June, and the fourth in August. In Ceylon, tea plucking goes on continuously throughout the year, so long as the bushes continue to flush freely. The flushing usually extends over a period of about eighteen months. The bushes are then pruned down, and after an interval of from six weeks to three months according to weather, the bushes again begin to yield crop, and undergo another series of regular pluckings at intervals of about ten days.

The leaf, after having been withered, is rolled for a shorter or a longer time, and then allowed to ferment. The time allowed for fermentation varies. It may continue for three hours, or no fermentation may be allowed to take place other than what goes on while the tea is being rolled. Finally the rolled tea is dried over charcoal fires, or, as is now almost universal, in specially constructed hot air driers. The made tea is separated by sieves into sizes known as broken pekoe, pekoe, pekoe souchong and coarse leaf. The processes which are productive of chemical changes in the leaf are the withering, the rolling and fermenting, and the firing or drying.

Green tea differs from black in the treatment the leaves receive at the factory. In the case of green tea, the leaves a few hours after being plucked are roasted for a short time. They are then rolled and quickly dried. Under this treatment the leaves do not become black but of an olive green tint.

The following analyses according to Dr. James Bell, Director of the Somerset House Chemical Laboratories, may be taken as fairly representing the composition of black and green teas as imported into London. The black is represented by a Congou Tea at 2s. 10d. per pound, and the green by a Young Hyson at 3s. per pound.

Analyses of Black and Green Teas. (BELL.)

	Black Tea.	Green Tea.
	Congou.	Young Hyson.
Moisture	8.20	5.96
Theine	3.24	2.33
Albumin, insoluble	17.20	16.83
Do soluble70	.80
Extractive by alcohol containing nitrogenous matter	6.79	7.05
Dextrin or Gum	—	.50
Pectin and Pectic Acid	2.60	3.22
Tannin	16.40	27.14
Chlorophyll and Resin	4.60	4.20
Cellulose	34.00	25.90
Ash	6.27	6.07
	100.00	100.00

According to Professor Church good average black tea as imported may be fairly represented by the following figures:—

Analysis of good average Black Tea.

	In 100 parts.
Water	8.0
Albumenoids	17.5
Theine	3.2
Tannin	17.5
Chlorophyll and Resin ..	4.5
Essential Oil4
Minor extractives	8.6
Cellulose, &c....	34.0
Mineral matter	6.3

The following table of analyses shows the composition of the ash of seven descriptions of tea. The table is quoted from Dr. Bell's work on "The Chemistry of Foods."

Constituents of the Ash of Tea.	Gun-powder. (Fine.)		Assam.		Moning.		Son-chong.		Hyson.		Congou (Fine).		Congou (Low).

Percentage of Total Ash in Dry Tea.	6.67	5.66	6.49	3.72	8.29	5.99	6.46	6.94	6.10	6.94	6.10	6.10	6.10	6.10

The constituents of tea already enumerated may be divided into substances soluble and substances insoluble in water. Of these, the former only are of dietetic importance to tea drinkers. The soluble substance or extractive matter contains most of the tannin, a large portion of the theine, and of the essential oil. It contains also pectin, mineral matter, and a small fraction of the albumenoids present in the leaf. On account of the insolubility of the greater part of the albumenoids, infusion of tea has a low nutritive value, but it possesses important stimulative properties on account of the essential oil and theine that are present.

Tannin.—The tannin of tea is commonly regarded as identical with gallo-tannic acid. Dr. Bell is of opinion, however, that while in its reactions it exhibits a close relation to this substance, yet, from its comparative instability, and the modifications it undergoes under chemical treatment, the tannin of tea differs in some important respects from gallo-tannic acid. Tannin is the most abundant of the soluble ingredients of tea, and it is to it that tea owes its astringency or strength. Analysis usually shews a higher percentage of tannin in green than in black tea.

Essential Oil of Tea.—This ingredient of tea appears for the most part to be developed by the process of manufacture. It is present in very small proportion, yet the characteristic taste and smell of tea is very largely due to this ingredient. When tea is distilled with water, the colorless distillate which passes over possesses the characteristic odour of tea to a marked degree, although no oil whatever is visible. By saturating the distillate with a salt such as chloride of calcium, shaking the solution with ether, and then allowing the separated ethereal solution to evaporate, a portion of the oil may be obtained as a residue. It is an oil of a yellowish colour, and passes into a resinoid state by exposure to the air.

Theine.—This alkaloid of tea is a highly nitrogenous substance, containing about 29 per cent of nitrogen, whereas albumen, the most abundant nitrogenous constituent of plants, contains somewhat less than 16 per cent. The tea leaf contains nitrogen in both forms, and the Japanese take advantage both of the stimulating theine and the nutritive albumen by powdering their finest teas and consuming this along with the infusion. The alkaloid theine, like the alkaloid quinine in some of the cinchonas, appears to be increased by the exclusion of light for a time from the growing plant, the total nitrogen being also thereby

increased—thus B. Kozai (Journal Chem. Soc. quoted from Bied. Centr. 1892) found, that, if the tea shrub, for three weeks before plucking be encased so as to exclude the light, the leaves are etiolated and vary in composition from those in full light as follows:—

	Grown in dark.	Grown in light.
Theine ...	p.c. 4.532	p.c. 3.784
Total nitrogen ...	7.835	6.945
Nitrogen in theine	1.311	1.094
Percentage of theine nitrogen on total nitrogen ...	16.72	15.75

In both of these analyses the percentage of total nitrogen is very high. The proportion of nitrogen in tea grown under natural conditions appears to range from about 2.6 to 7 per cent. There is usually a somewhat larger proportion of nitrogen in tea than is accounted for by the theine and albumenoids present. This nitrogen exists as an amide. In Japan tea, at different times of the year, Kellner found amido-nitrogen to vary from nil to .66 per cent.

Unprepared Tea Leaves.

Comparatively few analyses of unprepared tea leaves (with the exception of Japan tea leaves) have been made; but the following determinations of certain constituents in Assam, China and Ceylon tea leaves are interesting. In the case of the Assam and China plants the determinations were made in London with unprepared leaves received direct from India by Dr. Bell. In the case of the Ceylon plant the determinations were made by the author in green leaves received a day or so after they had been plucked. The Ceylon samples were all from the same estate.

Amounts of extractive, of soluble and insoluble Ash in the unprepared leaves of the Assam, China, and Ceylon Tea plant.

	Percentage.			
	Ex-tractive.	Total ash.	Ash soluble in water.	Ash insoluble in water.
Assam plant:				
Pekoe leaves ...	54.0	5.87	3.49	2.38

" coarser leaves than used in manufacture	50.9	8.50	2.63	5.87
China plant:				
Pekoe leaves ...	48.9	5.45	3.36	2.09
" souchong ...	49.3	6.16	3.39	2.77
" coarser leaves than used in manufacture	39.9	7.57	2.75	4.82
Ceylon plant:				
Unassorted 16th Apl.	49.91	5.25	3.59	1.66
" 3rd May	47.77	5.45	3.62	1.83
" 16th May	47.71	5.26	3.48	1.78
" 2nd June	44.89	5.32	3.70	1.62

One hundred parts of the ash of the Ceylon tea leaves contained potash 41.96 lime 10.24; and phosphoric acid 16.04.

I quote from the Journal of the Chemical Society the following elaborate analyses of green tea leaves. These are the more interesting as they form almost the only case in which systematic analyses have been made of an evergreen plant at intervals during a large portion of the year, including the whole time during which the leaves are harvested. The analyses are by Professor O. Kellner of Tokio. The leaves were from 50 nine-year old trees on the estate of the Minister of State, the Marquis of Nabeshima, near Tokio.

	Percentage in dry matter.

It will be observed from these tables of analyses that, in the case of young leaves, there is a remarkable decrease from May to November in the amount of theine, the proportion in May being 2.85 times as much as in November, while old leaves in May contain less than young leaves in November. The tannin in young leaves gradually increases with slight fluctuations from May to November, while the tannin in old leaves in May is only a little above the average of the young leaves. The considerable decrease in the young leaves in the amount of crude protein and cellulose &c. and the considerable increase in the ethereal extract as the year advances shew that the composition of the tea is affected to a considerable degree by season.

It will also be observed that the three most important elements of plant food, i.e., those that

are most readily exhausted from the soil, and which therefore constitute the most valuable ingredients of manures, viz., nitrogen, phosphoric acid and potash all decrease from May to November, while most of the less important or more abundant constituents soda, lime, magnesia, oxide of manganese, peroxide of iron and sulphuric acid all increase. Silica and chlorine, however, fluctuate in an indefinite manner.

In Ceylon, where the seasons are not so marked as in Japan, at least in respect of temperature, it is probable that tea leaves, plucked in different months, would exhibit greater uniformity of composition.

Relation between Chemical Composition and Market value of Tea.

Various attempts have been made to discover a relation between the chemical composition of tea and its market value, but with only partial success, one reason for this comparative failure being that the flavour and probably also the stimulating effect are in no inconsiderable degree due to the very small quantity of essential oil present, which, moreover, is an ingredient, the amount of which it is very difficult, if not impossible, to determine with accuracy.

The following table of analyses from Dr. Jesse P. Battershall's work on "Food Adulteration," that writer says, "exhibits the results obtained by the examination of various grades of Formosa, Congou, Young Hyson, Gunpowder and Japan teas, made under the supervision of the writer, by Dr. J. F. Davis. It will be noticed, if the same varieties of tea be compared, that, with some exceptions, their commercial value is directly proportional to the percentage of soluble ash, extract, tannin and theine compounds".

Following the table of American analyses by Battershall and Davis is a table of analyses by the author, of young tea grown in Ceylon at medium elevation, about 2,400 feet.

These analyses were undertaken partly to ascertain if the market value of Ceylon tea bore any relation to the amount of extract, tannin, theine and soluble ash present, and partly to ascertain if there were any marked difference in the chemical composition of tea on account of its having been harvested after the methods known as medium plucking and fine plucking respectively. By "medium plucking" is understood the removal from the tree-branches of two leaves and one leaf bud. By "fine plucking" is understood taking only one leaf and one leaf-bud. The six samples of tea were all from the same estate, which was land that had been previously thirty years under coffee. The tea bushes were exactly five years old. The samples were valued in the usual way by tasting by Mr. James A. Henderson of the firm of Messrs. Whittall & Co., Colombo, who had not seen the analyses before making his valuation.

London value 18th July 1889	7 ¹ / ₂ d.	9 ¹ / ₂ d.	10 ¹ / ₂ d.	1/1 ¹ / ₂	1/1 ¹ / ₂	1/1 ¹ / ₂	1/1	1/8

If the values of these six samples of tea were to be estimated as directly proportional to their respective amounts of extract, soluble ash, tannin and theine added together, the three qualities of medium plucking would be in the proportions 53.06, 57.92 and 58.2, and the three qualities of fine plucking in the proportions 59.45, 59.82 and 60.92. The average figures then would be for medium plucking 56.33 and for fine plucking 60.06. If we take the figures for extract only which really includes the tannin, theine, and soluble ash, the average would be for medium plucking 40.57 and for fine plucking 42.5. The average market value on the other hand was for medium plucking 10¹/₂d. and for fine plucking 1/1¹/₂d. Analysis, thus, indicates a much smaller difference in the qualities of the teas than is indicated by the market values. It will be observed, however, that with one exception the market value of the six samples rises or falls with the amount of extract. It is therefore probable that if the same method of preparation agreeing in all details were followed in every factory, the amount of extract might be made a measure of the market value. A certain amount of extract, say e.g., 39 per cent being taken as standard, each unit and fraction of a unit above or below this amount could have its corresponding money value to be added to or subtracted from the standard as the case might be. At present the market value of tea as determined by the tea taster depends on the age of the leaf, and the flavor, astringency and bouquet developed by infusing or "drawing"

a certain weight of tea for a given time with a given quantity of boiling water. The bouquet is mainly due to the presence of a volatile oil very appreciable to the senses of smell and taste, but for the estimation of which the chemical processes at present in use are unsatisfactory.

The six analyses last given were of teas grown at medium elevation 2,400 feet. I now give determinations of total extract tannin and theine on other six samples of teas grown at a high elevation about 4,200 feet on land that was for a number of years previously under coffee.

Partial Analysis of Ceylon high-grown Tea.	In 100 Parts.	Pekoe Souehong fermented 2 to 2½ hours.	37.2	9.98	1.06	Average.
		Pekoe Souehong Bulkied.	37.2	10.05	.70	
		Pekoe Bulkied.	38.7	10.5	1.22	
		Pekoe fermented 2 to 2½ hours.	40.8	11.23	1.32	
		Broken Pekoe	39.5	10.57	2.00	
		Broken Pekoe fermented 2½ hours.	38.8	10.11	1.57	
		Total extract ...	38.7	10.41	1.31	
		Tannin in aqueous extract	
		Theine in aqueous extract	

The average results of the above table might be compared with the corresponding average results of the previous table taking the "medium" and "fine plucking" averages separately.

Comparison of total Extract, Tannin, and Theine (in aqueous extract) in high-grown tea and in tea grown at medium elevation.

	In 100 parts.		
	High elevation.	Medium elevation. Medium plucking.	Fine plucking.
Total extract ...	38.71	40.5	42.5
Tannin in aqueous extract	10.41	10.56	12.16
*Theine in aqueous extract	1.31	1.78	1.88

When the first and second columns are compared, the difference in the proportion of tannin is but small; while in the total extract and theine the difference is tolerably marked. When the first and third column are compared, there are marked differences in the amounts of all three items.

* By ether process.
(To be continued.)

"STALK" IN MANUFACTURED TEA.

We doubt very much if it would be generally admitted by planters that the teas sent home from Ceylon contain any appreciable amount of "stalk;" but the results obtained by Mr. Hughes according to his recent analyses, and since shown to our London correspondent, seem to indicate that, at all events in the case of the samples operated on, there was no inconsiderable admixture. Of course it may be conceded that it must be almost impossible to altogether avoid the presence of some "stalk" Probably the most careful and expert pluckers could not altogether avoid breaking off some trifling portion of stalk when taking off the leaf, and perhaps there must be a greater liability when the plucking is done at an advanced stage of maturity in the leaf. Nevertheless, while admitting this liability, we would urge a greater degree of strictness being exercised over pluckers and the punishment of coolies guilty of such careless plucking. It seems certain that when an undue amount of stalk is detected in tea samples, the price is affected. Mr. Hughes, during the course of the analyses lately made by him, appears to have been struck by the amount of stalk that he discovered to be present in the small samples operated upon; so much so, indeed, that he mentioned the fact to the dealers from whom he obtained them. These gentlemen were so incredulous of Mr. Hughes' statement as to this, that the latter went to the trouble of separating the dried stalk by hand, and then swelling it by hot infusion. The result was evidently a surprise to the vendors of the tea, and Mr. Hughes pointed out by reference to drawings of the tea plant how liable the position of the leaf upon the stem was to cause the breakage off of a part of the latter in the plucking. In less than an ounce weight of tea a large number of pieces of stalk about half an inch in length were discovered. This substance is not likely to improve either the infusing strength or the flavour of the tea, for Mr. Hughes tells us that the stalk contains none of the valued theine, though it probably—as does all bark—contains a very material proportion of tannin. We should think it to be very difficult to separate stalk from the leaf at the Factory, and therefore that the only remedy must be to insist on more careful manipulation by the coolies when plucking.

Perhaps, however, some of our upcountry friends have had their attention directed to this matter before, and could tell us what measures they have adopted to ensure the absence of any considerable admixture of stalk in the teas they have sent home? In any case the opinion of practical planters on this question of "stalk" would be very acceptable. Mr. Cochran, to whom we referred the matter in the first instance, writes very sensibly as follows:—"I am of course of opinion that the presence of stalk other than the mere petiole of the leaf which in tea is very short, the leaf being almost sessile, must deteriorate its value. It is not a new thing to find some stalk in tea as after infusion everyone is familiar with the appearance of a small piece of stalk floating on the surface of the tea occasionally. I should think where tea is plucked by hand there should be no difficulty in keeping down the amount of stalk to a minimum: but when patent clippers are used, I could easily understand an undesirable amount of stalk being taken along with the leaves." We may put the question as to whether the tea samples operated on by Mr. Hughes could possibly have been prepared from "leaf" cut by a "patent plucker"?

MR. JOHN HUGHES' ANALYSES OF TEAS.

LONDON, April 14,

Although I know that Mr. John Hughes had sent you a full report of the several analyses recently made by him of different samples of teas, I responded this week to an invitation sent me by him to see him on the subject. Doubtless you will have given to your readers the particulars Mr. Hughes sent you; but as I found some difficulty in fully comprehending them until he gave me fuller explanations, it may not prove to be superogatory if a few remarks of my own on this topic are offered you here. What seems to be of special interest in the results obtained by these analyses is that the quantity of soluble ash and nitrogen ascertained, closely varies in accordance with the price of the teas. This would seem to indicate that it is these residuals which mark the absolute values of the teas, other constituents varying out of proportion to the prices given. The nominal value of the samples as opposed to the prices at which they were selling, were fixed by the dealers (or brokers) from whom Mr. Hughes obtained them. Another noteworthy fact is that nearly all the tannin and theine was extracted during the first five minutes of infusion, the further quantity resulting from thirty minutes of boiling being relatively very small. The question thereupon arises as to whether even five minutes infusion may not be too long for ordinary domestic purposes, and whether it would not be advisable to strictly limit this to three minutes at the outside. I did not at first understand what Mr. Hughes intended to convey by the words "soluble extract (dried)." He explained to me that, having infused the tea and strained it off from the leaf, he evaporated the whole of the liquor and so obtained what was really the body of the infusion, that which, in other words, would be really consumed by the drinker. You will see that by this test the Ceylon tea valued at 1/1 possessed but little more nourishment than did that valued at sixpence, and upon this ground Mr. Hughes thinks that for the supply of the bulk of teadrinkers your planters would find the cheaper teas as well suited as the more expensive; while it would be the better economy to themselves to devote their attention to the preparation of the second class of teas, in spite of the demand of the home brokers that now attention should be given to quality. You will also notice that the Ceylon teas valued at 1/1, selling at 11^d, yielded the soluble extract almost to the same amount as did the Indian teas valued at 1/5 to 1/6 and selling at 1/3, whilst it largely surpassed the yield from the China teas selling at 1/7. The figures could more clearly show the relative value for money of your teas over those both of India and China.

But probably the greatest interest attaches to remarks made to me by Mr. Hughes on the subject of stalk found in the teas he experimented upon; you will see that in this respect both the Indian and Ceylon teas gave a larger proportion than did those of China, and that, singularly enough, it was among the more expensive teas that the greater proportion of stalk was found. Mr. Hughes told me he had felt much surprize at the amount of stalk he found. On his mentioning this to the brokers from whom he bought the teas, those gentlemen would not believe that so large a quantity of stalk could be found. Mr. Hughes therefore invited them to attend at his laboratory, and in their presence he had the stalk carefully separated out by hand. He then placed the quantity obtained in hot water so as to swell it, and the result was shown to

me in that state, and there could be no denying that what I saw was veritable stalk and not leaf fibre. I am hardly competent to judge on such a matter, but it appeared to me that out of some fifty or sixty grains weight of tea there had been obtained some hundred or so of pieces of stalk about half an inch in length. This is no inconsiderable proportion, and Mr. Hughes said that the stalk would not yield any theine, though it probably—as do most barks—contained a large proportion of tannin. It occurs to me to suggest whether the larger amount of the latter which China merchants charge the Indian and Ceylon teas with containing, may not be due to the larger amount of stalk which those teas undoubtedly contain as compared with those of China. As to this the suspicion must naturally arise whether the coolies of Ceylon and Indian tea estates are as expert pluckers as are those of China, and it might be worth while to insist on more caution being exercised as to cleanly plucking of the leaf. Of course these remarks are written on the assumption that you have the tabulated results of Mr. Hughes' analyses before you, and that your readers have also had an opportunity of perusing them. I am not aware if Mr. Hughes has specifically drawn your attention to the several points mentioned by me, but from what he said to me it may be concluded that they have occurred to him since he wrote you on the subject, and they may therefore be novel to you.—London Cor.

SALE OF A BADULLA ESTATE.

It is rumoured that the well known old estate of Nahavilla, Badulla, so long held by Hormusjee Bomanjee Jeejeebhoy of Bombay, has been sold and that the purchasers are Messrs. Alfred Brown (Colombo Commercial Coy.) W. H. Figg and Capper. Nahavilla includes 597 acres, of which 552 have been or are in cultivation in coffee, cinchona or tea. Uva properties should certainly rise in value to correspond with the advantages of Railway communication so soon to be made available to them.

THE BRITISH WEST INDIAN PLANTATION SYNDICATE (Limited) has just been registered by Torr, Janeway & Co., 38 Bedford Row, W. C., with a capital of 12,000^{l.}, in 10^{l.} shares. The object is to adopt an agreement, made March 18, between J. H. Hall of the one part, and the company of the other part, for the acquisition of the Hatton Hall and Mount Jewel Estates, Prince Rupert's Bay, near Portsmouth (Dominica), and to carry on business as cultivators and dealers in colonial produce. The first directors are to be nominated by the signatories to the memorandum of association, the qualification being 20 shares.—*Colonies and India.*

"REPORT ON INSECTS AND FUNGI INJURIOUS TO CROPS, 1892."—We note the publication by the Board of Agriculture of this report with great pleasure. We have so often called attention to our lamentable deficiencies as compared with the energy shown in the United States and some European countries, that it is a great pleasure to welcome a report on the insects which have been noted as specially injurious during the year to our farm and garden crops. The insects are described, their life-history given, and excellent coloured illustrations afforded. Among them our old acquaintance the red-spider finds a place. An article also illustrated, on the club in Cabbages follows. In each case the appropriate means of prevention, palliation, or cure are given.—*Gardeners' Chronicle*, April 29.

CEYLON TEA IN AMERICA.

Writes a business man:—

"If Lipton should start in America it will be a very good thing for Ceylon, for he cannot be approached even by *Elwood May* for advertising. The latter get to my mind thinks more of advertising himself."

In the advertisement *per se*, the name of E. May never occurs of course; but in other notices no doubt his personality is put well forward—and what harm, so long as he bases his claims to notoriety on Ceylon tea?

LABOUR IN BRITISH NORTH BORNEO.

(*British North Borneo Herald*, 1st April.)

During the past fortnight the Superintendent of Immigration informs us he has engaged about one hundred and seventy-six Chinese coolies who have signed contracts for work on estates in Marudu Bay, Darvel Bay, and Banguay Islands. Nearly the whole of these men, originally engaged in China, have been working on estates in this country for three, and some for four years, have made money, and have without exception re-engaged entirely of their own free will, instead of going back to China. The coolie returns, again, all show a constant and steady improvement—in many instances most marked—in the health of the coolies on the tobacco estates. Desertion is nearly unknown, and the reward for the capture of run-away coolies is hardly ever applied for. With the extension of the clearings, the greatly improved health on the estates, the abolition of the broker system as it originally obtained, and more than all, the fact that a coolie who means work can make money, all these causes have quite revolutionized the state of the labour market in North Borneo during the past two or three years.

MAURITIUS.

Port-Louis, April 10th.

THE WEATHER AND THE CROP.—Since last month the plantations have been well watered and the fields in general look satisfactory. Now that we may consider the season of cyclones to be over, we can rely on a very fair crop for 1893-94.

ALOE FIBRE.—Since our last the market has resumed a finer tone. We have to quote the sale of 150 bales of good quality at R275 per ton. The following quotations are nominal:—

1st quality... R275 to 280 per ton
2nd " " " 225 to 235

COFFEE.—Market is still bare of good quality which is worth from R90 to 100 per 50 kilos. Mixed triage qualities continue to sell at R40 to 54 per 50 kilos according to quality. No Madagascar and Reunion on the market. —*Merchants' and Planters' Gazette*, April 11th.

THE AMSTERDAM MARKET.

AMSTERDAM, April 12th.—The cinchona auctions to be held here in Amsterdam on April 27th will consist of 421 cases and 4,829 bales, about 430 tons, divided as follows:—From the Government plantations, 12 cases and 353 bales, about 31 tons; from private plantations 409 cases and 4,476 bales, about 399 tons. This quantity contains:—Of druggists' bark—*Succiruba*, quills, 372 cases; broken quills and chips, 386 bales and 49 cases; root, 59 bales. Of manufacturing bark *Ledgeriana*, broken quills and chips, 3,573 bales; root 415 bales. Hybrids, broken quills and chips 298 bales; 48 bales. Official; broken quills and chips, 50 bales root.—*Chemist and Druggist*, April 15th.

UPCOUNTRY NOTES AND QUERIES.

At last the WHIPPING ORDINANCE has been introduced into the districts of Dumbara and Matale! And this, too, just at a time when men's minds began to be exercised about the Commission that was at one time so imminent, that the name of the Commissioner became pabulum for the news-monger. The 19th century discoverer of the Oiceronian *sic vos, non nobis* ought now to rest on his oars and be thankful.

Let not the enthusiasm of the CACAO-GROWERS subside with this concession. A great deal has yet to be done! The receiver of our stolen produce must be reached; for so long as he flourishes, and his name is Legion,—the temptations to thieving will not abate. We must have some such provision of the law as came to the rescue of the planter in the old coffee days. Surely, "there is something rotten in the state of Denmark," if the man who vends cacao seeds without a single cacao tree that he can call his own, cannot be made to account for his possession of that produce? Our Magistrates are perfectly helpless here. Why should the possessor of *unripe* produce be asked to account for such possession and not the possessor of *ripe* produce? Why deal severely with the man who steals valueless fruit, and tenderly with the man who steals valuable? Is this not an anomaly that requires to be dealt with promptly? Let our Planters' Association be up and doing, and the remedy will come.

Let all the native *kaddies* where COCOA is bought and sold be registered; and let every *kaddie*-keeper have a book showing the dates of purchase and the quantities purchased and the names of the sellers; and let there be a stringent prohibition of purchase after nightfall and before daybreak. The *Tambies* are the principal offenders in the matter of purchasing stolen produce,—and they must be carefully looked after.

Does the WHIPPING ORDINANCE touch the Receiver? It is worth knowing this: for otherwise, the fat oily Moorman and the sleek Chetty trader will escape.

When COCOA-STEALING has been banished from the island—and the receiver of stolen produce has become a character in past history; then we shall be ready to pass from our position as a Crown Colony, to a dependency of the Indian Empire; at all events with all the irritating present-day questions at rest, we shall be in that state of delectable composure, as would enable us with good grace to face the question of absorption into India.

Certainly if that day should ever come, our Railway system will be considerably benefited. At present every thing that can ensure discomfort to the passengers and gain to the Government, is in the ascendant. This is not a crying but a piercing shame!

Is it true that such a lot of goods traffic is sent on by the mail train leaving Colombo at 7 p.m. that the draught-power of the locomotive is not equal to the task of pulling the heavily laden waggons up the incline? A few days ago some of the first-class passengers going upcountry were heard pouring their benediction on the driver and the guard. No wonder; when they found the train nearly an hour late. India is the remedy for this.

And other departments will be similarly benefited. What a scope for our budding lawyers and civilian judges India will afford! One comfort will be that the *law of Agency* under which the country is groaning at present will come to an end; and a more healthy Administration take its place.

But what about Indian tea then? Shall we have divided interests in respect of that, or will there be one grand Indian blend. **QUERIST.**

COCONUTS.—There seems to be a real mania for the purchase of Coconut properties in Jaffna. Every one is anxious to invest his capital in Coconut estates. The two leading Tamil Brokers of Colombo who are now on a visit to Jaffna are prepared, we understand, to purchase coconut estates here even at a fancy price; but unfortunately for them there are none in the market just now.—*Ibid.*

MR. TOM. GRAY'S REPORT ON UPCOUNTRY TEA,—

that is in the districts of Maskeliya, Dikoya and Dimbula—is, we are glad to learn, entirely favourable. Mr. Gray has been resident for some weeks in the first-named district and has visited the others, and he says that tea everywhere is looking very vigorous. He is well-pleased with his own properties which are the oldest in his district,—they have been in full bearing for about a dozen years perhaps and have done exceedingly well. Mr. Gray has been clearing away a bambu-and-silt obstruction in the river which was of no benefit to his and the other adjacent properties. He speaks favourably of the 1,000 acres of crown forest land to be put up for sale shortly: tea already planted up to 5,000 feet is quite as high as most of this forest and £100 an acre is likely to be the minimum price! Mr. Gray returns home by the Orient s.s. "Oroya" tonight, or tomorrow morning, and he promises to look after the interests of his brother planters in the Lane and to report to us when there is anything worthy of the *Observer's* criticism.

CEYLON TEA FUND.

Kandy, April 17.

DEAR SIR,—I enclose for publication copy of the minutes of proceedings of a meeting of the Standing Committee of the "Ceylon Tea Fund" held on Friday, the 14th instant.—I am, dear sir, yours faithfully,

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

Minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Nuwara Eliya on Friday, the 14th day of April 1893 at four o'clock (4 p.m.) in the afternoon.

Present:—Messrs. Giles F. Walker (Chairman, Planters' Association of Ceylon), Hugh B. Roberts (Dikoya), Chas. Young (Kandy), Walter Agar (Chairman, Dikoya Association), John H. Starey (Kandy), and A. Philip (Secretary, Planters' Association of Ceylon, Kandy).

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on Thursday, the 16th February 1893, were taken as read, and were confirmed.

Resolved:—"That the names of Messrs. H. B. Roberts and A. P. Crawley-Boevey be added to the Standing Committee of the Tea Fund."

Read letter from the Yataderia Tea Company of Ceylon, Limited. Resolved:—"That the proposal made be accepted."

Read letter from Mr. Wm. Cameron intimating that Ythanside estate would contribute to the Tea Fund from 1st January 1893.

Read letter from Captain Toller intimating that Annandale estate would contribute to the Tea Fund from 1st January 1893.

CEYLON TEA KIOSK.

Submitted memorandum on the subject of accounts for supplementary construction in connection with the Tea Kiosk which up to date had not been disposed of in terms of the following Resolution passed at a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy on the 8th April 1892 that subject to the amounts already voted with interest thereon not being exceeded, the additional claims be referred to the sub-Committee appointed for the purpose of establishing a Tea Kiosk at Colombo. Resolved that consideration of the matter be disposed of next meeting of the Standing Committee of the Tea Fund.

Submitted letter to the Syndicate Boat Company, Limited regarding the fire recently reported in the

newspapers. Resolved that the attention of the Syndicate Boat Company, Limited, be drawn to the provisions of their lease with special reference to the storage of dangerous or obnoxious materials or manufacture in the neighbourhood and be warned that they will be held responsible for any consequences that may ensue thereon.

CEYLON TEA AT THE WORLD'S EXPOSITION AT CHICAGO IN 1893.

Read letter from the Agent of the Commissioner annexing copy of telegram intimating the safe arrival at Chicago of the Exhibition Staff; also sending notice of an official dinner given at Chicago by the President of the Brazilian Commission in which favourable notice is made of Ceylon.

Read letter from the Colonial Secretary sending a copy of a letter from Mr. J. J. Grinlinton reporting the safe arrival of the Ceylon Staff at Chicago.

CEYLON PLANTERS' TEA COMPANY OF NEW YORK.

Read letter from Messrs. Darley, Butler & Co. (1) enclosing invoice of 50 packages Tea weighing nett 2,800 lb. shipped to New York on account of the Ceylon Planters' Tea Company completing the grant of 9,000 lb. (the actual amount shipped being 9,084 lb.); (2) acknowledging receipt of cheque for £2,381-26 in payment of the abovementioned invoice. Read letter from the Ceylon Planters' Tea Company of New York giving information regarding the progress of the Company. Read letter from Mr. A. E. Wright.

CEYLON GREEN TEAS.

Read letters from Messrs. Darley, Butler & Co. advising having forwarded the various samples of Green Teas made up in ½ lb. packets as instructed. Submitted advertisement notice on the subject. Resolved that the advertisement amended as indicated be again inserted in the newspapers.

CEYLON TEA IN GERMANY.

Read letters from Messrs. Kroning & Schrader reporting on the efforts made by them in the introduction of Ceylon Tea into Germany. Resolved:—"That Messrs. Kroning & Schrader be thanked for their letters and informed that the Standing Committee of the Tea Fund will give as early consideration as possible to their further suggestions."

Read letter from Mr. Frederick H. Corbet making a suggestion on the subject of distributing presents of Ceylon Tea in Munich and Erlangen.

CEYLON TEA IN FRANCE.

Read letter from Colonel Byrde with extract of letter from General La Touche on the subject of pushing the sale of Ceylon Tea in the South of France. Resolved:—"That consideration of the matter be deferred to next meeting."

CEYLON TEA IN RUSSIA.

Read letter from the Ceylon Tea Company Limited (under the patronage of the Planters' Association of Ceylon advising having arranged for the shipment of 9,000 lb Ceylon Tea for Mr. M. Rogivue Moscow in terms of the resolution passed by the Standing Committee of the Tea Fund at a meeting held on the 16th February 1893. Resolved:—"That the course adopted by the Ceylon Tea Company be confirmed."

CEYLON TEA IN CAPE COLONY.

Read letter from Messrs Bossanquet & Co., Agents for the Ceylon Co-Operative Tea gardens Co. on the subject of the proposed grant of tea samples for free distribution in Cape Colony, and pointing out that Ceylon Tea is well-known in South Africa.

Read letter from Mr. A. E. Wright on the subject. Resolved:—"That the resolution passed by the Standing Committee of the Tea Fund at its meeting on the 16th February be cancelled."

The Standing Committee of the Ceylon tea fund then adjourned.

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

THE PAPAWE TREE.

This tree generally finds a place amongst other cultivated products in Zanzibar, the fruit, both green and when ripe, being much esteemed as an article of diet. The tree is more easily and quickly raised from seed, attaining a thickness of one foot by the third year, and commencing to decay during the fourth or fifth year. The straight and unknotted stem is herbaceous and soft, though it develops an external layer of fibrous tissue; as might be expected from the rapidity with which it grows, the trunk is hollow, though it has more or less dense, imperfect septa. "The newer parts of the stem are green, but as they age become greyish; towards the top it also bears the scars formed by the falling-off of leaves, which are arranged in a kind of umbellate canopy." It grows to about 20 feet in height. (*Consular Report, 266 1892.*)—*Pharmaceutical Journal.*

THE INDIAN TEA SEASON.

The *Indian Agriculturalist* writes:—Now that the tea season for 1892 has closed and all assets realised, we can form a pretty good idea of the present position of the trade, which leaves little to be desired, though its future prospects must depend greatly upon the efforts of the Indian representative at Chicago, and the moderation of planters here in the way of extensions. Of course, fine plucking and decreased outturn have led to the high prices of the past season, and though the greater portion of the dividends are not derived from sound commercial sources every one seems tolerably satisfied. The recent four or five years of depression in the trade has been due undoubtedly to over production, and although efforts have been made to open new marts, the tendency on the part of the producer has been to provide tea for such marts, without troubling his head as to whether these new openings would absorb his surplus or not. The mere despatch of three or four travellers to Australia and New Zealand certainly did not justify the expectations anticipated, but though words of caution were not wanting, from time to time, a trade was rashly anticipated, with the result of ruinously low prices and accumulated stocks. Now, though we look forward to the Chicago Exhibition aiding in materially increasing the demand for Indian tea in the course of time, we are equally certain that any sudden demand for large quantities is unlikely to arise. We have to oust China from the America markets, and introduce our own article, which the past history of the trade shows, relies for success upon our creating a taste; and as this is in all cases a matter of time, are our planters justified in adding to their planted area additional acreage, the produce of which may not be required for some half-dozen years to come? The new extensions may, perhaps, be the means of pressing down prices to the 6 anna average of two years ago ere the new markets have been established. The Tea Association should look into these matters, and bestir themselves, sending forth the "bagman" throughout the length and breadth of the States, as we suggested should be done in the United Kingdom ten years ago. The London representative of the Tea Association at the time, harped on the hopelessness of competing with people like Moore and Horniman; in fact, he was not, as he should have been a tradesman. So Mr. Lipton took the matter in hand, and is now in the position the Association should have occupied from the outset. If India tea were properly pushed, the future prospects of the trade are assured; but the work must be undertaken by tradesmen who know their business, and we think this must now be patent to all members of the Association.—*Madras Times, April 7.*

A MONSTER ESTATE IN JOHORE: LIBERIAN COFFEE.

A recent visitor to the large estate known as Ayer Syn, at Cocob, in the Johore territory, states that this property or plantation belongs to Syed

Mahomed bin 'Ahmed Alsagoff, and is under the management of Syed Abdulla and a Javanese assistant, under whom are several Javanese mandors and about 170 coolies of the same nationality. The extent under cultivation is some 16 square miles, or about 10,000 acres, of which area some 5,700 acres are under mature sago palms, 350,000 having been planted out; the balance, leaving out what is under coconut, areca palms, and Liberian coffee, is planted with still very young sago palms. The roads and drains have been laid out with great care, and the drainage especially has been well done, at no small expense. The soil consists for the most part of a vegetable humus from two to four feet deep, of a very dark brown colour, much resembling coffee-grounds, overlying a fatty clay subsoil. In dry weather the top crust burns just as readily as peat. The one advantage about it is that it retains moisture more than any other class of land, hence its great adaptability to sago culture. From the 350,000 plants that were originally planted there are now more than double that number of big sago palms, varying in length of trunk from 30 to 42ft. Some of these trunks have a girth of from 6 to 7ft. 6in. The trees are felled, cut into lengths, and removed by Chinese coolies to the sago factory, consisting of some very primitive attap huts. The bark is half an inch thick, and is then removed, and the pith is rasped or grated by simple graters like the coconut *parut* or rasp, but somewhat coarser. The desiccated pith is then soaked in water, and after some few hours pressed through coarse sieves, the residue or *ampas* being piled up in heaps to be eventually buried as a future manure supply. The milky residue or sago water after repeated washing in very primitive troughs is allowed to settle, and the sediment is stored in vats ready for shipment to Singapore by tongkang in bulk, where it is refined into flour and pearled. This work is all done by Chinese, who contract to divide half the result of the sago produced with the owner of the estate. Some idea of the immense extent of this estate may be formed from the monthly shipments which are made under sago, which range from 2,500 to 3,000 piculs a month, selling at 1.75dols. per picul, while there are yet some 300,000 stools not yet touched, ready for cutting down. These trees vary in the amount of sago they yield, as under:—No. 1, 8 trees to a koyan of 40 piculs; No. 2, 10 do do.; No. 3, 12 do. do. It is proposed to introduce a Decauville 18-inch tramway to facilitate the removal of the cut-up trees to the factory. The yield of Liberian coffee, according to figures courteously supplied by the manager, show the output to be about 40 piculs monthly, selling at an average of 32 dols.—*Globe.*

THE PROSPECTS OF TEA IN AMERICA.—The editor of the *American Grocer* thus expresses himself in answer to a correspondent:—

The question of climate has much to do with the beverages of a people. It is a matter of record that the per capita consumption of tea in this country is not as large as it was years ago, nor does it increase from year to year. On the other hand the use of beer and coffee has increased largely, particularly the former. We think the point well-taken that low grade tea is largely responsible for the non-increase in the use of tea as a beverage. The American people have not been educated to appreciate the delicacy of flavor resident in certain growths and blends of tea. We doubt, if the popular taste in this country will ever take the direction of the prevailing taste in England. Our people do not like heavy-bodied, red-liquored tea, with the sweetish flavor so pronounced in many sorts of fermented teas, particularly those of Ceylon and India. There is more hope if fine China blacks are urged upon the attention of consumers, or, as suggested by Mr. Fielding, fine blended teas. Mr. Elwood May and Mr. Pineo should make a point of calling on the Editor and inviting him to judge for himself that high-grown Ceylon teas are as delicate as any "fine China blacks."

SALT IN THE HOUSEHOLD.

A little rubbed on the cups will take off tea stains, says *Hall's Journal of Health*. Put into whitewash, it will make it stick better. As a tooth powder it will keep the teeth white and the gums hard and rosy. It is one of the best gargles for sore throat, and a preventive of diphtheria, if taken in time. Use salt and water to clean willow furniture; apply with brush, and rub dry. Salt and water held in the mouth after having a tooth pulled will stop the bleeding. Prints rinsed with it in the water will hold their colour and look brighter. Two teaspoonfuls in half a pint of tepid water is an emetic always on hand, and is an antidote for poisoning from nitrate of silver. Neuralgia of the feet and limbs can be cured by bathing night and morning with salt and water as hot as can be borne. When taken out rub the feet briskly with a coarse towel. Salt and water is one of the best remedies for sore eyes, and if applied in time will scatter the inflammation. Silk handkerchiefs and ribbons should be washed in salt and water, and ironed wet, to obtain the best results. Food would be insipid and tasteless without it. Hemorrhages of the lungs or stomach are promptly checked by small doses of salt.—*Sydney Mail*.

PARA INDIARUBBER.

Owing to the great fluctuation in the price of india-rubber, the trade is described as being very uncertain. According to the last official report, two-thirds of the State revenues of Para are derived from the export duty on indiarubber, which is said to contribute 25 per cent. of its value. Owing to the fact that Para possesses almost a monopoly of this valuable article, the report alleges that this high rate of duty may be maintained for many years to come without destroying the trade. Favours are, however, conceded to the indiarubber produced in the State, as also to that coming from the entire Amazon region if exported from Para (*Consular Report*, 1136, 1892).—*Pharmaceutical Journal*, March 25.

ZANZIBAR ARROWROOT.

A variety of arrowroot is to be found in most native gardens in Zanzibar, and named "uwanga," but do not think it is the true arrowroot (*Maranta arundinacea*), the shape of the leaves differing, though the preparation of the roots appears to be the same; "uwanga" bearing a fleshy knotty root, which is ground and washed in repeated waters, and finally sun-dried. This preparation, mixed with sugar, forms a favourite sweetmeat with the Arabs. I see no reason why arrowroot should not be more extensively cultivated on the island, and form an article of export. The cultivation is easy, and immediate returns are obtained:—"The plants are propagated by parting the roots. A light loamy soil is the most favourable for their growth. When they are a year old the roots are in a fit state for use" (*Consular Report*, 266, 1892).—*Pharmaceutical Journal*, March 25.

NOTES ON PRODUCE AND FINANCE.

THE TEA INDUSTRY IN 1891.—The Government of India has issued a statement from which it appears that the total number of tea gardens throughout British India in the year 1891 was 4,293, with an aggregate of 362,130 acres actually under tea. Besides this area, some 450,000 acres had been taken up, but had not, up to date, been planted. The total approximate yield was 123,712,825 lb., of which by far the greater part was black tea. The average yield per acre of mature plants was 399 lb. In future returns, the total number of labourers employed will be shown.

INDIAN TEA GARDEN AT THE CRYSTAL PALACE.—The following is taken from the "Crystal Palace Hand-book"—"A model of a tea garden in Assam—which was appropriately called 'the Eden of India,' by the late Lord Napier of Magdala—has been arranged in a building on the North Lawns. Indian tea plants may here be seen in a healthy state of growth, and the preparation of the tea is carried on in all its stages of withering, fermenting, rolling, drying, &c., by natives of India. The model has been arranged by Mr. Patrick Macgregor, an old tea planter of Assam."

CEYLON TEA IN AMERICA.—We continue to receive copies of papers referring to Ceylon tea in America, and these show that Mr. Elwood May and those interested with him in Ceylon tea are very busily engaged in pushing the sale, and that they know how to do it.

TEA AND COCOA.—The croakers maintain that tea has had its day, although, when they read statistics on the subject, they find it difficult to prove this. They persist, however, and point to coffee by way of moral. It is quite true that the medical faculty have, as a rule, objected to the increasing consumption of tea, although if it leads, as they say, to so much indigestion, and, consequently, more frequent consultations, it is remarkable that they regard it as an evil. There is no sign that we can see of the decreasing popularity of tea, although it may be noted that cocoa and chocolate are now introduced at numerous functions where tea and coffee only were admitted. Even after dinner cocoa is frequently taken, and in America this is more common than on this side. There is no doubt that cocoa is received with favour by dietetic and medical authorities, which helps its popularity.—*H. and C. Mail*, March 31.

COFFEE AND TEA PILFERING.

A leading article, signed "P. H.," appears in the *Indian Planter's Gazette*, under the above heading. The writer supports the memorial of the Nilgiri planters upon the disadvantageous working of the Coffee Stealing Prevention Act, XIII. of 1878, and the suggestion that Tea should be protected as well as Coffee. It is undoubtedly the case that petty thefts of Tea and Coffee are numerous, and there are circumstances quite distinct from considerations of the intrinsic value of the plunder which give importance to the demand of planters that these pilferings should be put a stop to. In Assam as well as on the Nilgiri planters suffer from deprivations of this sort. It is well known to all Managers, says our Calcutta contemporary, that most garden coolies drink tea as regularly as any Europeans. Ramaswami in our homes prefers Coffee, but he takes tea if he cannot get anything else; and the planters' cooly probably makes a similar virtue of necessity and practically gives a preference to that which can be obtained most easily. Our contemporary remarks, rightly enough, as regards tea thefts, that "it is often less in actual dried tea that the loss is suffered, than in green leaf, which the women pluck on the garden, carry to their houses in their aprons, to be hand rolled, and dried over the *chula*." Calcutta experience coincides with that of Southern India in regard to convictions, too, for we read:—"We have known many instances of cases, instituted by Tea planters against Natives, in which there was no moral doubt of the accused's guilt, fall through, to the loss of European prestige which a court defeat always inflicts, simply on account of the absence of such a provision as the Neigherry planters are now trying to obtain." And the objections that have been raised in the North are similar to those that have been put forward in the South when the planter has urged his claim to protection. Our Calcutta contemporary has heard it said, "Imprison a poor cooly for taking a few tea leaves to his house! Why, you will want to put coolies in prison for bad plucking next?" and has reasoned in vain that a practice which makes a difference on the wrong side of many

maunds on a garden crop can only be stopped by making examples in "petty individual instances," and that "in those absolutely maddening cases, which so often happen about the present time of year, when plucking women stoop and pick buds off the bark of heavy pruned lower growth, knowing every bit as well as the manager knows how intensely bad it is for the bush, 'why then we would prosecute them.'" So would any planter; and the provoking custom of breaking off stems of the new wood to make tooth-cleaners merits the indignation of the *I. P. G.* and punishment at the hands of the law. The complete list of pilferings and of petty damages would be very long, but the Nilgiri planters have, we trust, made out a sufficiently clear case to convince Government that their complaints are in no way exaggerated, and that there is urgent need of a revision of the law in regard to coffee-stealing, and the extension of a similar law to tea.

ORANGES AND LEMONS.

17th April.

To the Editor,—

Sir,—Those with any experience in the growth of Oranges and Lemons know how disheartening it is to find trees gradually die off after bearing for a few seasons. In the absence of proof positive of how death is caused, each one assigns a theory for it. My theory always has been that decay and death are due to the roots reaching the subsoil; and I have always suggested manure to be heaped in a circle round the trees within a space enclosed by coconut husks, stones or logs of wood, so as to bring all the roots to the surface.

The Sinhalese have a practice of paving the holes in which they plant oranges. Whether the idea was suggested to them by anyone experienced in horticulture or was "evolved out of their inner consciousness" I know not; but I am inclined to think the practice is the result of experience, for unlike those who think the ordinary villager knows nothing of agricultural principles, I have always found him in many respects well acquainted with them as the result of observation and experience. Well, however he may have learnt the practice of paving the holes for orange plants, it is very interesting to find he has "Antiquarian" sanction for it. In Sir Walter Scott's "Antiquary" occurs this passage. "The planters of those days possessed of the modern secret of preventing the roots of the fruit trees from penetrating the till, and compelling them to spread in a lateral direction, by placing paving stones beneath the trees when first planted, so as to interpose between their fibres and the sub-soil.—Truly yours, B.

TROUT OVA ON THE NILGIRIS.

The trout ova recently imported have not hatched out so successfully as had been hoped. This appears to have been due to their not being sent out quite soon enough, as, not arriving in Ooty until March 4th the water in the hatching boxes was already of too high a temperature, 67°, and although ice was used it was not found practicable to keep the temperature below 60°. It should be about 45°. From this cause the daily loss of ova was about 200. until March 24th when they began to hatch out. For a few days previous to that date a succession of storms caused a fall in the temperature of the water to about 55°, but occasioned some trouble by the amount of silt brought down. On the 24th and 25th March, just as the ova was beginning to hatch out, there was a sudden rise in the temperature which proved most disastrous. A large number of the fry died immediately, some when only half out of the egg. On the 2nd April only 293 fry were left and some 70 ova, and these decreased until, on the 8th instant, only 201 healthy fry remained. These so far appear to be getting on well, but the ova sacs have not yet been completely absorbed. This is not a very encouraging result from a batch of 20,000 ova.

It is intended to import Rainbow trout ova and Loch Loven trout ova in November next, and it is hoped that the valuable experience which past experiments have afforded will obviate all chance of failure. It will be willingly conceded that the perseverance of the Nilgiri Game Association and its most energetic and painstaking Honorary Secretary, Mr. Rhodes Morgan, thoroughly deserves to be rewarded by success, and all sportsmen owe them a debt of gratitude.

A brief description of the mode of packing and transporting will be of interest. The first batch sent out by Mr. Silk was packed in a case too large to be taken out of the ice house, and it had to be unscrewed and lifted in and subsequently out sideways. This caused the ova, although packed with cotton wool to run together and they became a frozen mass. On being thawed when put into the hatching boxes all the ova immediately turned opaque. With the batch sent by the "Manora," care was taken to pack in a suitable sized box, which was slung in the cool room—not the ice house—and the ova were packed in Irish water moss. For transport from Madras, Mr. Rhodes Morgan had a box made just three inches wider every way than the case in which the ova were packed, and this space was filled with ice kept constantly renewed, and the outer case well wrapped in blankets. In this way, as we stated at the time, the ova were received in Ootacamund in excellent condition.—*South of India Observer*, March 12.

THE "LITTLE MONSOON."

All doubts about the "little monsoon" having burst have now been set at rest. The rainfall in Colombo for the 24 hours ended at 9 30 a.m. today was 2½ inches, and more is likely to fall ere nightfall. On Monday Galle had 2 30 inches of rain; and yesterday Chilaw had .66 inch, Ratnapura getting .30 inch. Most of the other outstations, however, report fine weather. We append reports that have reached us regarding the monsoon burst:—

GALLE, April 18.—Between 6 and 9 last night there was heavy rain with vivid lightning and loud peals of thunder. The showers this morning and in the afternoon have been from the south-west with a pleasant sea-breeze. The wet weather has tended to cool the atmosphere considerably.

LOWER MASKELIYA, April 18.—This morning every appearance of burst of little monsoon. Temperature has risen from 42½ yesterday morning to 45½ this morning. We have not had it so high since 3rd Dec. 1892. The clouds are passing slowly over from S.W., also wind from there. The sky has a regular S.W. appearance, and the feel of the air is very different to what we have had for a long time, viz. close and muggy. Tightening last night to S.W.

THE PANAWAL TEA COMPANY, LD.

The Company has been formed principally for the purpose of acquiring the two adjoining Tea estates, known as "Gassel" and "Ernan," situated in the Kelani Valley, Ceylon, as from 31st March, 1893, for which estates the Vendors have agreed to accept the sum of £20,000 payable £10,000 in shares and £10,000 in cash.

The properties are held under Crown titles. Mr. William Mackenzie, Manager of the Castlereagh Tea Company, Dikoya, in his valuation of the properties, writes:—"In valuing these properties I take the yield as 600 lb. per acre, cost of production as 22 cents, upkeep of machinery and buildings 2 cents; profit 16 cents. Value of tea 40 cents in Colombo or R96 profit per acre, which at six (6) years' purchase amounts to R576 for tea in bearing." The following

particulars as to the acreage of the respective estates are taken from his valuation:—

	In Bearing.	Partial.	Young.	Avail- able Land.	Timber.	Total.
Glassel..	230	8	75	100	78½	491½
Ernan ..	182	—	13	70	160	425
	412	8	88	170	238½	916½

and he values—

"Glassel" at	R176,250
"Ernan" at	R123,700
						R299,950

The following is extracted from a report by Mr. Mackenzie, dated 15th September last—"Of the strength and vigour of the Tea Bushes I can speak in the very highest terms as well as of the general order and condition of each estate in every particular. The tea (by which I mean the bushes not the manufactured article) is far above the level of the average of the Kelani Valley. The estimated yield of 600 lb. per acre seems quite safe up to an age equal to the oldest tea of which we know anything in Ceylon. Buildings—The factories and machinery are new, capacious and durable. Beyond ordinary repairs these should give little trouble for many years. On Ernan a new bungalow has just been erected. On Glassel one is in course of construction. There is sufficient accommodation for all the labour required in the 'Lines' on each estate. Water carriage to Colombo—say 40 miles—by river makes transport an easy item on these properties."

Mr. A. Mansfield Forbes, one of the vendors, in a letter to the directors, of the 14th March, 1893, states, "I estimate the crops for the nine months, from 1st April to 31st December, to be 200,000 lb. made tea, which at present market rates should produce a profit of at least 2½d per lb." No promotion money has been or will be paid.

CEYLON TEA COMPANIES.

The following is a list of all the Tea Companies of which, at present, we have particulars for our "Directory." We shall be much obliged by receiving the useful information as to any others that may be in existence, to go into the register:—

- 1 Castlereagh Tea Co. of Ceylon, Ld.
- 2 Ceylon Co-operative Tea Gardens Co., Ld.
- 3 Ceylon Tea Co., Ld.
- 4 Ceylon Tea Plantations Co., Ld.
- 5 Yatideria Tea Co. of Ceylon, Ld.
- 6 Scottish Ceylon Tea Co., Ld.
- 7 Tagaswela Tea Co. of Ceylon, Ld.
- 8 Yatiyantota Tea Co., Ld.
- 9 Wé-Oya Tea Co., Ld.
- 10 Dunkeld Estate Co., Ld.
- 11 Kelani Valley Tea Association, Ld.
- 12 Agraouyah Estate Co. Ld.
- 13 Upper Maskeliya Estates Co., Ld.
- 14 Glasgow Estate Co., Ld.
- 15 Hunasgeria Tea Co., Ld.
- 16 New Ceylon Plantation Co., Ld.
- 17 Ceylon and Oriental Investment Corporation, Ld.
- 18 United Planters of Ceylon Co., Ld.
- 19 Lauderdale Tea Estate Co., Ld.
- 20 Standard Tea Co., of Ceylon, Ld.
- 21 Mahauva Estate Co., Ld.
- 22 St. Helier's Tea Co., Ld.
- 23 Wanarajah Tea Co., Ld.
- 24 Mocha Tea Co., Ld.
- 25 Great Western Tea Co., of Ceylon, Ld.
- 26 Eadella Estate Co., Ld.
- 27 New Dimbula Co., Ld.
- 28 Clunes Estate Co., Ld.
- 29 Panawal Tea Co., Ld.
- 30 Ceylon Planters' Tea Co., Ld.
- 31 Lanka Plantations Co., Ld.
- 32 Ceylon Lowcountry Products Co., Ld.
- 33 Eastern Produce and Estates Co., Ld.

- 34 Ceylon Estates Investment Association, Ld.
- 35 Ceylon Land and Produce Co., Ld.
- 36 Oriental Bank Estates Co., Ld.

Tea Companies of which no particulars have been received:—

- 1 Ceylon Estates Association, Ld.
- 2 Delgolla Estate Co., Ld.
- 3 Battagalla Estate Co., Ld.
- 4 Asiatic Produce Co.
- 5 Ceylon Tea Growers' Co., Ld.
- 6 Consolidated Estates Co., Ld.
- 7 Duckwari Tea Co., Ld.
- 8 East Matale Co., Ld.
- 9 Eila Tea Co., of Ceylon, Ld.
- 10 Galella Tea Estates Co., Ld.
- 11 Gona Adika Tea Co., Ld.
- 12 Gongalla Tea Plantations Co., Ld.
- 13 Mahaousa Tea Co., Ld.
- 14 Narangalla Estates Co., Ld.
- 15 North of Scotland Co., Ld.
- 17 Strathellie Tea Co., Ld.
- 18 Taprobane Tea Co., Ld.

The particulars required are the names of Directors and Secretary and the names and address of London or Colombo Agents as the case may be.

VARIOUS AGRICULTURAL NOTES.

TECHNICAL SCHOOLS SANCTIONED.—The Lieutenant-Governor of Bengal has sanctioned the opening of a Technical School at Burdwan and "agrees to present the school with a lathe costing not more than R500." The school for the present will take the form of a good artizan class with a little instruction in drawing and mensuration, and will be started with the following staff:—Superintendent from the Sibpur College, at R60 rising to R75; smith and assistant, R35; carpenter at R15; durwan at R7. The cost with R3 for contingencies will thus be R120 (rising to R125) per mensem, towards the payment of which the Municipality will give R20 per month, the District Board providing the balance. The Government of India has sanctioned the establishment of a Technical School for Engineering in connection with Rangoon College for training Burmans for service in the Upper and Lower Sub-ordinate grade of the Public Works Department.—*Indian Engineer*, April 1.

COFFEE IN THE WYNAAD.—The coffee is certainly looking better than I have seen it for very many years. There is a tremendous flush of young leaf all over our estates, and no signs of disease, this will follow of course, but the trees, must benefit by so long a rest from their enemy. As far as we can judge at this early stage, the fine blossom has set well. As for the Liberians, not content with one amazing blossom, they have contrived a second, nearly as good, and the mystery will be, if it all sets, where the fruit will find room for itself! My fifteen years old trees are a mass of crop. These particular trees have never had an ounce of manure since they were planted, and are still bearing heavily on their first branches. If your correspondent who wished for particulars about the planting, etc., of Liberian will communicate with me, I will with pleasure give him all the information I can tell on the subject. I presume that we can be introduced to each other, through the kind agency of our Editor. Faith in the advantages of Liberian strengthens every year in Wynaad, and large quantities are being planted. Of course, our great difficulty still lies in the future, *i. e.*, the curing and pulping. No doubt the efficient machinery will be available, but you cannot pulp without water, and these indiscreet berries will ripen in the hot season when our nullahs are particularly low. However, I have no doubt our ingenuity will find out a way of storing water for pulping purposes. If tea is well started, there should, with it and Liberian, be a regular revolution in our planting arrangements, and there will be very little getting away in the hot months for our coming superintendents!—*Cor., M. Times*,

BORNEO TOBACCO.

We are told by a friend writing to us from England that cigars received from Borneo and locally manufactured there from leaf produced in the country, are finding much appreciation with home smokers. Dealers who may be supposed to be judges of what constitutes a good "smoke" strongly recommend these to their customers and they also declare the tobacco to be second only in every desirable attribute to that obtained from Havana. Our correspondent adds his own testimony in support of this professional verdict, and states that, price especially being considered, he has never yet obtained any cigars which have afforded him greater satisfaction in every respect than do these cigars from Borneo. Our own experience of failure in Ceylon is but of too recent occurrence not to make us feel somewhat envious of the reputation. Borneo now seems likely to achieve in England. It is one which may tend towards stimulating progress in that settlement and to reversing, to some extent, the adverse opinions of late current as to its future prospects. We are told that the cigars upon which has been founded the judgment referred to, were purchased of the Civil Service Stores, which have just reported a large and increasing sale for the various brands kept by them. These are sold at the Stores at a very moderate price, 8s 9d for boxes containing 50 cigars, or little more than twopence each. They are said to be exceedingly well made, and to so closely resemble in appearance the coveted cigars from Havana that they could not be distinguished from these by any passer-by, and we learn that this is regarded by smokers as a great desideratum. The statement is also made that large quantities of tobacco leaf are sent from Sumatra and Manilla—the latter island more especially—to Havana for the purpose of covering the cigars manufactured there,—it being the fact, as we are told, that the native leaf of the last-mentioned place is so full of rib and fibre that it does not afford the smooth and sightly surface desired by smokers. A ribbed outer covering, also, is said to tend to much inequality in burning, and probably much of the high cost of Havana cigars is due to the labour necessary for extracting this rib and fibre from the tobacco used for the interior of them. It will be remembered that one shipment of Dumbara tobacco some years ago, was thought so suitable for outside coverings, that it fetched a high price in Amsterdam and sent Deli planters to explore the island for land with a result which they and the local Tobacco Company have reason to regret. But we should like to know whether the Ceylon-grown tobacco, which has in later years been so thoroughly experimented with, had lost the smoothness referred to, and was possessed of the disability of rib and fibre; and if so, whether any attempt was made to get rid of it before using it in the local manufacture of cigars, or to import a Sumatra leaf for the purpose of obtaining a finished external appearance. We believe Mr. Ingleton does use carefully selected foreign, as well as Ceylon, grown leaf for his wrappers, and there can be no question of the importance of care in the finish. For, apart from appearance, it is certain that no cigars can give satisfaction if their burning is likely to be variable, and we hear that nothing is more likely to cause this latter annoyance than coarseness or roughness in the leaf in which the internal packing is rolled. If Havana has to resort to importation to overcome this difficulty, with

regard to its own growth, there could be no reason why the same thing should not be done by the makers of Eastern cigars. In any case, it is satisfactory to know that the Tobacco and Cigar industry of Borneo appears to be in a fair way of achieving success for what is now, apparently, to be its most important cultivation. On this we heartily congratulate the planters of the island, who have up till now had to struggle against so many difficulties, as also the shareholders who have invested in the capital of the several Companies working there, without, as yet, having received the least return for their money. There is much need for encouragement in North Borneo, and this news of the popularity in London of its cigars, may cheer the despondent.

ANNUAL TEA REPORTS OF LONDON BROKERS.

In a special *Supplement* to last issue of the *Tropical Agriculturist*, we placed the interesting and valuable Annual Reports of Messrs. Geo. White & Co. and Wilson, Smithett & Co., Tea Brokers, for 1892. We gave both nearly in full and we trust exactly as received, save that errors pointed out by the Broker compilers, have been corrected by us, as also others discovered by local planters and ourselves, more particularly in reference to the elevation of certain plantations. We must confess, however, that a number of names included in Messrs. Wilson, Smithett & Co.'s list are unfamiliar to us, notwithstanding all the information collected for our Directory and we shall be glad to have, as early as possible, particulars of the following places to embody in our District lists:—

1. Valamaly	11. Kelso
2. Elangapitiya	12. Amawatura
3. Dinastow	13. Sumtravalle
4. Devanella & Deemally	14. Sapitiyagodde
5. Braintree	15. O'Galla
6. Come Away	16. Lokamanda
7. Angalla	17. Saidevatta
8. Gona	18. Akuressa
9. Ambragalla	19. M. K. Oya
10. Mataza Oya	20. Fairfield

[It is possible that some of these may be in our Directory list under different names?] Turning now to Messrs. Geo. White & Co.'s very interesting Report, we are arrested by the explanations offered as to the low prices of tea prevalent for some time back. These are: large deliveries previous to the close of the year; recent depression in trade; and as we ventured to anticipate ourselves, an expectation that the duty on tea might be lowered again by the Chancellor of the Exchequer—perhaps from 4d to 2d per lb. The reference to Ceylons, and the scarcity of fine teas, reads to us just now like a bit of satire, in view of the small encouragement offered in the Lane all this year to send home fine Ceylon teas.

It is interesting to see that the quantity of Ceylon tea re-exported from the United Kingdom last year was 2,448,000 or within 314,000 lb. of the quantity of Indian so distributed, and still more satisfactory this trade in the case of Ceylon shows an increase of 1,341,000 lb. over that for 1891. But one fact that arrests attention in the statistics afforded, is that while Indian and Ceylon teas have so largely ousted "Chinas" in the home market, yet in regard to the re-export trade from London, China has still the great advantage—the export of the latter tea being three times that of the former last year. This means, of course, that China still commands the Continental market so far as the London export trade is concerned; but surely there is room for a great change here

during the present year in view of the low range of Ceylon prices.

As respects Java teas, we call attention to the letter of "Planter" elsewhere: we do not think, however, that the choice of seed has no effect on the quality of the tea. We know what vigorous bushes are grown from a good jat judiciously selected with reference to soil, climate and elevation, and it stands to experience that a vigorous bush produces the leaf from which good teas can be prepared. There can be no doubt that Java teas have greatly improved in quality since the planters there discarded their China jat, introducing instead Assam seed and at the same time, *proper preparing machinery for their factories* which have so great an influence in turning out good teas. Of course the London market is open to the Java tea planters, but we hold very strongly that they ought to make much more of their Amsterdam market and that, following the example of Ceylon planters, they ought to institute a regular campaign with a view to get their teas drunk throughout Holland, Belgium and especially North-Western Germany where, at present, inferior China teas are very largely consumed. Of course, London Brokers do not care to see trade even in "Javas" go past them; but the sooner Java planters do their duty in making an extending market for their teas (to the supercession of China) on the Continent of Europe, the better for Dutch as well as British grown teas.

As usual Messrs. Geo. White & Co. give some useful hints in reference to "size of breaks," packages, warehouse charges, &c.

It is interesting to refer to their tables of monthly averages for the different Indian districts separately, as well as for India, Ceylon and Java as a whole. It will be seen that Darjiling comes in an easy first and we may indeed tabulate the results as follows according to merit:—

District.	Packages.	Average for 1892.
Darjiling	.. 58,113	1s 0½d
Assam	... 297,809	11½d
Ceylon	... 503,700	9½d
Cacher and Sylhet...	161,089	9½d
Dooars	... 69,256	9½d
Kangra Valley	... 2,158	9d
Travancore and S.		
India	... 19,770	8½d
Java	... 35,900	7½d
[All India	... 608,185	10½d]

The Estimate of the requirements of the London market for the home trade as well as re-export, during the present year, has attracted a good deal of attention and so far as we can judge in the case of Ceylon, the figures for the supply of the same may be taken as very reliable, though we should not be sorry to see China's share drop to 40 to 45 million lb. (not at all likely, however, in view of moderate estimates and expectations from India and Ceylon):—

Indian	... 116,000,000 lb.
Ceylon	... 74,500,000 "
Java	... 4,500,000 "
China	... 50,000,000 "

245,000,000 "

We now return again to the Report of Messrs. Wilson, Smithott & Co., and first in point of local interest is the analysis of Ceylon Districts with their crop yield and average in price. As usual "Bogawantalawa" heads the list; but as Mr. R. W. Wickham fairly points out to a contemporary, there is no reason why Dimbula should be treated as a whole, if Dikoya and Bogawantalawa are to be separated. He therefore separates Agradatana (the division of Dimbula parallel

to Bogawantalawa) with the result that it becomes the premier one in respect of highest average price for its teas last year, as the following figures show, based on Messrs. Wilson, Smithett & Co.'s memoranda:—

	Average price per lb. in 1892
Agradatana	... alone 11½
Bogawantalawa	... " 11
Dimbula	... " 10
Dikoya	... " 9½
Dimbula including Agradatana	... " 10½
Dikoya including Bogawantalawa	... " 10½

The detailed summary in the Report itself may be repeated here for convenience of reference:—

Estimated relative yield and average price realised for the different Ceylon Tea Districts, compiled from the Public Auctions held in London between January 1st and December 31st, 1892:—

	lb. about	Av. price £ lb. about in 1891.	
Bogawantalawa	... 3,000,000	0/11	0/11½
Nuwara Eliya, Maturata and Uda Pussellawa	... 2,500,000	0/10½	0/11½
Dimbula	... 10,500,000	0/10½	0/10½
Dikoya	... 4,500,000	0/9	0/10½
Uva	... 2,500,000	0/9½	0/10½
Maskeliya	... 4,000,000	0/9	0/10½
Hewaheta	... 1,500,000	0/9½	0/10
Pussellawa, Kotmale, Pndaloya, and Ramboda,	... 6,000,000	0/9	0/10
Ambagamuwa and Lower Dikoya	... 3,000,000	0/9	0/9½
Dolosbage and Yakdessa	3,500,000	0/8½	0/9½
Knuckles, Kallebokka, Rangalla, &c.	... 2,500,000	0/8½	0/9½
Nilambe and Hantane...	2,000,000	0/8½	0/9½
Kalutara	... 2,000,000	0/8½	0/9½
Matale and Hnnasgeri...	3,000,000	0/8½	0/9½
Kaduganawa and Alagalla	1,500,000	0/8½	0/9½
Kelani Valley	... 5,000,000	0/8	0/9
Sabaragamwa	... 1,500,000	0/8	0/9
Galle	... 305,000	0/7	0/8½

N. B.—Untraceable marks to the extent of about 5,000,000 lb. averaging 7½d per lb. are not included in the above estimate.

We do see why the district represented by the Nuwara Eliya Planters' Association should not be in the first rank; and we suspect that that would be the case if the portions of Maturata and Uda-pussellawa which run down comparatively, to quite a medium elevation, were omitted. The Nuwara Eliya Association must try to establish the reputation of what ought to be regarded as the district representing Darjiling in Ceylon.

We must call attention to the extraordinary discrepancy, as it seems to us, between description and facts in the early portion of the Report before us. Messrs. Wilson, Smithett & Co. refer to the "sanguine estimates" of Ceylon crop early last year as "hanging like a cloud over the market till the autumn." [Not a word as to their effect in checking the purchases of China tea at the opening of the season.] But when we come to the actual facts of the market as described by themselves, what do we find? Why that the year opened well with brisk competition at hardening rates; that subsequently heavier auctions (not estimates) checked rising prices; but the better teas commanded "firm rates" and these continued through February, March and April, only common teas falling or tending lower. In May (not in autumn) they recognised the Ceylon over-estimate and the average improved. But look at the contrast this year: the Ceylon crop has been most carefully (probably under)

estimated, and yet where are the satisfactory prices which were got for good tea all through the spring of last year?—while now China buyers are generally busy expecting a good season and larger shipments.

We have spoken of premier tea districts as respects prices; and in regard to plantations, the palm for 1892 belongs to Messrs. Macfarlane's fine plantation Ormidale in Maskeliya, which gained an average of 1s 4½d for some 40,000 lb. of tea, thus taking the place of Fortswood which fell from an average of 1s 4½d to 1s 1½d.

FISHING AT DEHRA DUN.

Mr. A. Smythies, the Honorary Secretary of the Dehra Dun Fishing Association, has written a Report on the work of the Committee of the Association during the past year, in which there is much of interest to fishermen and naturalists. The efforts were chiefly directed to building a fishing lodge in the Western Dun, and to the introduction of English trout into the streams of the valley. The experiment of introducing trout ova with a view to acclimatising English trout in the Dun streams was undertaken in the cold weather, but like the attempts made in the Nilgiris and Ceylon, has resulted in failure. Mr. Thomas Andrews of Guildford sent out 10,000 eyed ova of *Salmo Fario* in layers of moss placed in perforated zinc trays, and packed in a foreign transport case surrounded by ice; the case left Liverpool early in December last, and was two months on its way to Dehra. When opened on the 6th February, it was found that half the ova were dead, the remainder was at once placed in the hatching trays on a canal made from the Be Nadi, and about 900 fry were hatched and turned into the trough prepared for their reception; of this number only 4 survived and were put into the stream. It is much regretted that this expensive venture was not more prosperous, and very disappointing, for Mr. Smythies, who closely followed the instructions drawn up by Mr. LeMesurier of Ceylon (based on his experience in hatching trout ova in that island) and took every precaution to ensure success. The result of the experiment is very disheartening; the causes of failure may lie in the water which came from the Natranada swamp springs, and was very largely impregnated with carbon. The temperature of the water was high, while in February, when the hatching was going on, the cold in Dehra was unusually severe; either or both of these causes may have killed the young fry shortly after they were hatched.

The cost of the experiment will be of interest to those who are desirous of introducing trout into other streams in India:—

10,000 ova, packing case, hatching boxes	£17	...	280
Freight, carriage, agency charges, ice, &c		...	470
Filters, sheds, canal, watching &c.		...	150

Total... 900

A plan is now being formulated for introducing trout into the Kumaon lakes, where climatic conditions are more favourable, and among the weeds the young trout will find shelter until large enough to hold their own against their numerous enemies.

The Dun Association are endeavouring to get the Government of India to legislate to prevent the destruction of stock in the rivers of India, a point so strongly advocated by Sir Francis Day in his preliminary Report on the *Fishes of India*. A new set of fishing rules are likely to be shortly brought out by the Forest Department which will assist in preventing unfair fishing in Government forests, it is hoped that fish will then seek the protection of Government streams from poachers, just as deer and feathered game now seek repose, by instinct as it were, in closed Government forests. Expenditure is being incurred by the Committee in keeping the minor streams of the valley, that are the hatching grounds of trout and mahseer, in their proper channels, and preventing pools from drying up.—*Civil and Military Gazette*:

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

London, March 29.

CINCHONA.—At last Thursday's bark-auctions in Amsterdam 6,869 packages Java bark total weight 565,994-kilos were offered. The manufacturing barks represented 22,472, and the druggists' barks 1,021 kilos sulphate of quinine, an average for the manufacturing barks of 4.23 per cent. The tone throughout the auctions was flat, and only 4,631 packages sold at a unit ranging from 4½c to 5½c (equal to ½d to 1½-16ths d.) per lb. according to the quantity of bark. The following were the principal buyers:—

	Sulphate of Quinine.
	Kilos.
Mr. Gust. Briegleb bought 4,891
The Amsterdam and Mannheim Works do 3,703
Mr. H. A. C. Wischerhoff do 2,416
Mr. J. Louet Feisser do 1,911
Messrs. Matthes & Bornmeester do 1,289
Messrs. Hoppert & Heyse do 526
Mr. J. de Ligt do 483
Smaller buyers do 406

The general quality of pharmaceutical barks was exceedingly poor, and the total supplies of this kind were small. What was sold of this bark brought unsatisfactory prices. The best parcel of bark in the sale was one of 45 bales crushed Ledger stem, containing the equivalent of 7.83 per cent of S.Q. This sold at 4½c per half-kilo (equal to about 8d per lb. net.)

COCA-LEAVES.—There has just been an arrival of 27 cases coca-leaves from Ceylon.

ESSENTIAL OIL.—Lemongrass has made a further advance, business having been done at 2½d per lb: there are now further buyers at that figure.

VARIOUS AGRICULTURAL NOTES

COFFEE prospects in Coorg are, we learn, moderate. The "bloesom shower" has been partial and not altogether seasonable; on many estates the rain fell too soon when the wood was still green and required hardening. According to present estimate the coming season will be a moderate one.—*M. Mail*, April 15.

TROUT OVA.—We call attention to an interesting reference in the *Tropical Agriculturist* to recent experiences at Ootacamund in the hatching of Trout Ova. Messrs. Le Mesurier and Fowler cannot fail to be interested in what is doing on the Nilgiris and the detailed experience gained there ought to be of value to experimentalists in Ceylon.

TREE-PLANTING IN PUSSELLAWA.—One of the pioneers of tree-planting on plantations in the island is Mr. Gabriel Rose, the well-known Manager of the Le Vallon group of estates. Thirteen years ago, he went in very freely for grevilleas which suit his average elevation exceedingly well, and now Le Vallon can show as large specimens as are to be found in the island of this tree. Mr. Rose has also a large number of "toone" and of *Albizzia moluccana*; while *E. robusta* does well in his top fields which run up to 5,000 feet above sea level.

LORD KELVIN, says the London Correspondent of the *Indian Engineer*, has made very careful calculations to ascertain the best method of obtaining power, whether it is better to use one or more steam-engines, and then whether to transmit the power by shafting and belting by ropes, or by electricity. The results being that with electricity he can confidently count on 70 per cent. of the indicated horse-power at the machine; but with shafting he can only get about 60 to 63 per cent. In Mr. Alexander Siemens' view, the ideal way of applying electricity as a motive power in factories is to provide each machine tool with a separate motor, and thereby avoid the use of shafting, and counter-shafting, pulleys and belts, besides dispensing with the heavy columns necessary to carry these.

THE CAUSES OF THE FALL IN PRICES OF GOOD CEYLON TEAS.

From an authority well able to discuss the subject, we have information which we lay before our readers with the prominence it deserves. The price of Ceylon Tea and especially of good Teas has steadily declined since the commencement of the year owing to direct and indirect causes. The direct causes are the strikes in Lancashire and elsewhere, and the serious agricultural depression caused by the failure of last harvest and the great suffering entailed on the great tea-drinking classes by the failure of the Liberator and many kindred Building Societies—suffering, which will be further increased by the stoppage of the Commercial Bank of Australia and Australian Joint Stock Bank in both of which several millions of Scotch money are said to be deposited.

The indirect causes are the political uncertainty and the feeling that a General Election may be imminent and the unsettlement of all Irish trade. This last specially affects broken and orange pekoes, a very large proportion of which go to Ireland. Added to all this there was a vague feeling in the City when the mail left, that the Pandarus who holds the public purse-string may try to get a few more voters into the already much-tangled-web by a reduction of the tea duty.

The direct causes affect the market not by reduced consumption, but by the increased consumption of low-priced teas, because those who used to pay 1s 6d per pound are driven to the 1s canister. The indirect causes affect the market by a general shrinkage of credit which causes the trade of the country to be carried on in a restricted and hand-to-mouth manner.

Added to these causes many brokers who have to give reasons, will say quality has been poor; but there has been no demand for good teas and broken pekoes have been selling from 10l to 11d which in October and November would have sold for 1s 2d to 1s 3d. The statistical position should be a very strong one: total stocks are 4,700,000 lb. less than at the same date last year, the supply from India will rapidly fall off now and though there is the usual uncertainty about the quantity which may come from China, there is every prospect of a good demand for Ceylon medium teas though there is very little inducement to planters to go out of their way to make good teas. Steadily it becomes more and more apparent that the market for good teas is a limited one. Formerly if there was a strong demand for pekoe souchongs, there was a proportionately strong demand for pekoes and broken pekoes; but so much of the retail trade is now in the hands of the great Packet Companies and prices are cut down so that if they pay much for their pekoe souchongs they cannot afford to pay high for their broken pekoes and consequently use less of them. In giving advice from the "City" side, brokers and others are rather apt to eliminate "weather" and to consider that planters have the regulation of quantity and quality entirely in their own hands. "In medio tutius est" will, in the long run, be found the planters' safest course both for plucking and manufacturing. Is there any one again drawing planters' attention to the necessity for reducing the number of small breaks.

For Tuesday, 11th April, there were, when the mail left, catalogues out for about 2,000 packages Ceylon tea in more than 800 breaks of which more than 150 were small breaks; many of one or two chests only. It takes on an average a minute to sell three breaks, that is at the rate of 180 per hour, so it will

be nearly 5 o'clock on that particular Tuesday before the sales which began at noon were over. In this connection it may be remarked that after fighting hard to have Ceylon sales held independently of Indian on Thursdays, sellers are availing themselves but little of the concession. The trade is said to prefer Tuesday, but what the buyer likes is not always good for the seller if there is a large Tuesday sale say 20,000 packages and a small Thursday sale say 1,000 packages, naturally the latter falls very flatly, but if the 21,000 were divided somewhat more evenly between the two days, the overcrowding of Tuesday would be prevented and would almost certainly tell in the buyers' favour. As the large importers of Ceylon tea are or should be all represented in the Ceylon Association in London, and considerably more than half the Ceylon tea brought to the hammer in London is sold by four firms of brokers, this should be a matter easy of adjustment.

CONSUMPTION OF TEA IN GREAT BRITAIN.

Messrs. Gow, Wilson & Stanton append some interesting figures to their circular which we issued on Saturday. They show how the consumption of Indian tea has progressed since 1866 when the total consumed in Great Britain was little more than 4½ million lb. against nearly 98 millions China &c., and the gradual change year by year until 1885 when Ceylon first appears with about 3¼ million lb. in consumption against nearly 66 millions Indian and 113½ millions of China. It is from this year that China steadily declined, and not only did Ceylon go ahead in favour of the people, but it seems to have carried Indian with it far more freely than it had been taken off for some years previously. Thus in 1892 we had the consumption distributed as follows:—109½ millions Indian, over 63 millions of Ceylon and less than 34½ for China &c. The amount shown of tea consumed per head of population for the series of 27 years is even more interesting; in 1866 the rate was 3.42 lb.; in 1876 it rose to 4.49; in 1886 only to 4.87; but in 1892 it was 5.43 lb. Curiously enough so far back as 1885 it was 5.02 lb. a rate which was not reached again till 1890. That there is room for much further increase can be judged from the Australian Colonies where the rate is between 7 and 8 lb. per head.

COMPARATIVE ANALYSES OF INDIAN, CEYLON AND CHINA TEA.

We append a very interesting not to say valuable series of tabular analyses, with explanatory remarks by Mr. John Hughes. In forwarding the same to us, Mr. Hughes remarks:—

"I enclose you a paper which contains the results of some weeks' investigation into the composition of Indian, Ceylon and China teas. You will notice that it opens out some new points, and I believe it will be appreciated. It is on these lines that I wished the Planters' Association to take up the chemical investigation, but apparently no money can be spared for the purpose.

We feel sure that the perusal of the paper will enable our tea planters to see how much practical service could be rendered to them by a competent Analytical Chemist after the stamp of Mr. Hughes. This gentleman points out so clearly the various inferences and lessons to be derived from his figures, that there is no need for us to add any words of our own. But the all-important information has yet to be afforded, namely, how is the planter to secure in the tea the properties most

valued by the expert as shown by the prices paid. Only by experimenting on the spot and especially in the Tea Factory can the Chemist tell us this. Meantime here is Mr. Hughes' paper:—

So much has been said and written of late in reference to the respective qualities of Indian, Ceylon and China tea, more particularly in regard to the tannin contained in each, that some Comparative Analyses will probably be of interest. Accordingly samples fairly representative of these teas were furnished the writer by Messrs. Elliot, Lack & Porter, a firm of brokers dealing in the three kinds of tea abovenamed and therefore quite impartial in the matter. The analytical results, which have occupied some time and trouble, are arranged in the following tabulated form. The names and description of the specimens are first given, followed by the market price at which they were sold, to which has been added the normal value of each tea by way of comparison.

This was desirable, because of late there has been a poor demand for tea of high quality and a large demand for tea of a comparatively low quality; the consequence being that at public sales the latter have commanded unusually high figures and the former unusually low ones. How far these market prices have agreed with the practical results, a careful examination of the analytical details will show. In order to assist in this examination it may be useful to take the various items as they present themselves in the table and offer a few remarks by way of explanation.

1. The Percentage of Water expelled at a temperature of 212° F. varies from 5.63 in No. 3 to 8.86 in No. 5. The China teas are evidently not so highly dried as the Indian and Ceylon specimens.

2. The Proportions of Oil and Chlorophyll show considerable variations. No. 3 which fetched 11½d containing the least 1.10 per cent, while No. 2 which fetched only 7½d. contained the most 3.23. These results however must be considered as rather exceptional, for No. 1 containing 2.47 sold for 1s 3d and No. 5 containing 2.70 sold for 1s 7d. A high percentage being generally associated with a good market price.

3. The amount of Tannin is expected under two headings, first the percentage yielded to the usual 5 minutes' infusion made by pouring a definite quantity of boiling water upon a definite quantity of tea; secondly, the total amount of tannin yielded after boiling for 30 minutes.

In each case Assam yielded the most, Ceylon next and China the least, but the differences are by no means large and certainly do not justify all the fuss that has been made about the respective quantities of tannin. At least so far as these analyses indicate, the total tannin varies from 9.40 in No. 5 China to 14.76 in No. 1 Assam, the former being sold at 1s 7d and the latter at 1s 3d, both being relatively high priced and the normal value put down at 1s 5d in each case. In No. 2 there is 11.80 while No. 3 4 and 6 practically contain very similar quantities of tannin. Comparing these results with the figures giving the proportion of tannin yielded by 5 minutes' infusion with boiling water, we observe that of the 14.76 present in No. 1 there is 10.35 dissolved out or 70 per cent of the whole; while in No. 5 of the total 9.40 there is dissolved out as much as 7.80 or 83 per cent of the total tannin present in the China Tea. Tannin therefore being soluble inversely according to the percentage present. Assam tea contains more tannin, but yields it to an infusion more gradually, in other words if we use Indian Tea and wish to avoid an excessive quantity of tannin we should allow it to infuse for a shorter time than China Tea. Consequently for obtaining a cup of tea quickly Indian and Ceylon Tea are more efficacious than China Tea.

4.—Theine has also been arranged under two headings; namely the amount yielded by the usual 5 minutes' infusion with boiling water, and the total amount yielded by treatment with slaked lime and hot water with subsequent extraction by chloroform and evaporation. It will be noticed that the variations of the total Theine are inconsiderable, the

Assam specimens containing the most, also that of the total 3.86 in No. 1, 3.33 was yielded in the 5 minutes' infusion, or nearly 87 per cent of the total quantity.

On the other hand No. 3 which contained 3.36 only yielded 2.13 or 63 per cent of the whole, but this No. 3 specimen is evidently somewhat abnormal as will appear more clearly presently. The alkaloid Theine containing as it does a high proportion of soluble nitrogen no doubt exerts an important medicinal effect but any variation in the quantity present cannot be detected by the tea expert, for the simple reason that it possesses no distinctive taste or smell whereby its presence in large or small quantity can be detected, and consequently it can in no way affect the valuation for market purposes.

5.—The figures for woody fibre (cellulose) are very similar in all the samples with the exception of No. 3 in which instead of the usual 8.20 or 8.50 per cent there is as much as 10.40 or an increase of upwards of 20 per cent.

6.—The figures for soluble ash are very interesting because they appear more than anything else to agree with the actual market price:—

Thus No. 5 with:	4.01 soluble ash sold at	1s 7d
No. 1 "	3.75 "	1s 3d
No. 3 "	3.46 "	0s 11½d
No. 2 "	3.06 "	0s 7½d
No. 4 "	3.06 "	0s 7½d
No. 6 "	3.06 "	0s 6½d

7.—The figures for insoluble ash show also a wonderful agreement with the market price, inversely with the quantity found.

Thus No. 5 which contains	1.92 sold for	1s 7d
No. 1 "	2.27 "	1s 3d
No. 3 "	2.47 "	0s 11½d
No. 4 "	2.64 "	0s 7½d
No. 6 "	2.70 "	0s 6½d
No. 2 "	2.94 "	0s 7½d

The samples 2, 4 and 6 contained the same quantity of soluble ash and very similar quantities of insoluble ash while the market price only varied from 6½d to 7½d.

8.—The variation in nitrogen is very slight. No. 3 containing the least 3.80 and No. 5 the most 4.08. Taken with the ash determinations, a high percentage of nitrogen may be regarded as indicative of a superior quality of tea.

9.—The weight of the dried residue left on evaporation of a portion of the water extract obtained by the five minutes infusion gives a practical illustration of the difference between Indian and Ceylon taken together and China tea. The former yield a larger quantity and more highly coloured liquor. The dried water extract only varies in the former from 24.13 in No. 3 to 25.06 in No. 1, a very slight variation. In the two China teas, however, there is only 23.20 in the best quality and only 20.40 in the inferior quality. Consequently more China tea would have to be used in order to produce the same quantity of the same coloured liquor. The question of flavour is of course another matter; at present it is only the few who desire flavour.

The public care more for quantity and colour than for quality, and hence the extended demand for Assam and Ceylon tea and for a coarser, but more leafy quality provided it yields a good deep coloured liquor. It is this demand that has so affected the market of late and these analyses so far as they go, help to explain why such a demand has arisen.

In table II. a comparison of these six samples has been made with a view of ascertaining the extent to which variation occurs in the proportions of leaf, stalk and total water extract. A definite quantity of tea was taken in each case and thoroughly exhausted by continued boiling with fresh quantities of water. After pouring off the final exhaustion, the stalks were carefully separated from the leafy portion, both were then dried separately at 212° F and weighed. The results will be interesting to planters as well as tea experts and suggests further investigation.

JOHN HUGHES.

Analytical Laboratory, 79 Mark Lane, London, E.C.

JAFFNA: GRAIN AND PRODUCE IN THE NORTH.

OUR MARKET.—A number of native vessels arrived recently with large supplies of paddy and rice for Jaffna. The cargo has been landed and has found its way to the consignees, who are mostly Chetties. The price of paddy and rice has however not declined, but continues steady with a tendency to increase. It is feared that our Chetties who control the market are in combination and are not disposed to slip the opportunity of "making hay when the sun shines." It has always been a matter of surprise and regret to us that not a single native or Tamil of Jaffna from among the well-to-do class in our midst has started in the rice trade. Not only is it the most remunerative trade, but it is one of the few trades in which there is hardly any risk or loss. Paddy or rice will always get its price and the idle capital now in the hands of men like Messrs. Mannepillai and Assaipillai may well be employed in the rice trade. A local or native trader will not only be a check on combination but will, what is very important to the poor, keep the market always in tone.

TOBACCO.—There is a brisk demand for this article especially the kind, which is used in the manufacture of cigars for the Colombo market. The crop already gathered is very small and the price is steadily advancing. The recent rains have not been a benefit to tobacco cultivation at large and the high price now required is one of the results.

COPPERAH.—Jaffna is no doubt a centre of coconut cultivation. Our coconut estates cover a large extent of ground and compare very favorably with the estates in other parts of the island. The Jaffna copperah, as is well-known, commands a higher price than copperah from other places, chiefly in view of its size and substantial contents. The "boom" in the price of copperah reported some time ago in our Colombo contemporaries, has produced a marked effect in Jaffna. A good business is being done and men and carts are unceasingly at work. Prices are steady, with an upward tendency. The latest quotation is Rs56 per candy, but we will not be surprised to hear that it has gone up higher still.

In another column appears a notice inviting offers for the sale of a coconut estate. It will be a good investment for one of limited means.

FIBRE.—The market for this article is dull and there is an impression abroad that the business would not revive. Work however continues, but it is a question that it is worth the trouble at all. We do not however regret the present lull, but hope it will be long enough to enable the palmyrah plants which have been badly treated, to revive and put forth a new set of stalks before the knife is again laid on them by the ruthless fibre trader.—"Jaffna Patriot," April 14.

CEYLON PLANTERS IN EAST AFRICA.

Melangi, B. C. Africa, 14th Feb. 1893.

It is quite evident you don't get all my letters; at all events they don't appear in your paper.*

We are now in the middle of our

PLANTING SEASON.

and so far it has been a favourable one, plenty of rain which makes the weeds as well as coffee grow like mushrooms. I got a fair blossom upon 13 months' old coffee in November, which set well and is now showing up to the tune of about 7 cwt per acre on some especially fine trees. Coffee is decidedly a success here and the climate and rainfall seems to suit it admirably. It is not without enemies; although no bug or leaf disease appears, we have borer and grubs of every description, and last enemy I observe is a fly who sends his little proboscis into the young primary and presumably lays his egg there, resulting in a small borer grub as thick as a pin, about an inch long who works his way along the pith till the stem of the tree is reached; the

* We shall begin numbering. This is No. 1 for the present year.—Ed. T.A.

he emerges from his hole and attacks another primary; of course they wither and die. Grub galore attack the roots and ring the plants just the same as Ceylon fellows do; resulting in some fields of about 50 per cent of failures. It's to be hoped as the trees become stronger they will resist and get over all those pests.

There is still much to complain of against the B. C. A. A., and the whole European population are vowing vengeance against the actions of their employees who have at last roused the natives into a general revolt.

The latest news is

A GREAT RISING OF NATIVES

on the upper Shiré, midnight scares and great excitement at Blantyre the immediate cause of which it appears. About a fortnight ago Capt. Johnstone released a slave caravan on the Upper Shiré at "Luondis;" as he was returning to Inyanga's the natives attacked him, and although he had only 20 armed men he kept his ground and brought away the slave dealers prisoners. Soon after this one of the

AFRICAN LAKES CO. BOATS

was proceeding up the Shiré and was attacked by the natives, who killed one of the boatmen, the others jumped into the river and swam for it thus escaping. The A. L. Co. Agent at Matapé has left his station and run into Blantyre, others who could escape have also left the Upper River.

The A. L. Co. steamer took up Major Wisnmann and party by last trip, she has now stuck on the rocks on her return trip at Mysapa's.

Wisnmann who was camped on shore at Leopold's Bay saw one of Makauera's dhows making straight for his Camping ground, so he fixed up his Hotchkiss gun and sent a lb shell into her, sinking her on the spot.

It was rumoured that Capt. Weatherly and Mr. Coe, sportsmen, were killed, but it turns out that Capt. Weatherly is safe in Fort Johnstone and Mr. Coe, who was attacked and his carriers all bolted and left him reporting his death, turned up safe and well.

This opportunity has been seized upon for a general rising of the native chiefs against the B. C. A. A. who have disturbed as I said before the whole country not, as would appear, by their endeavours to put down slavery (although in this case it was so) but other causes which the British Government does not seem disposed to listen to or believe.

Rumour has it that many of the Chiefs round here are rising.

THE COMMISSIONER, MR. SHARP

Vice-Consul, Capt. Johnstone, with the gun-boats crews and 150 soldiers have gone up to try and negotiate for peace or fight. The new gun-boats for the lake are expected to reach their destination soon and he ready for service. H. B.

DURBAN BOTANIC SOCIETY.

REPORT on Natal Botanic Gardens for the year 1892. In this document which has reached us, it is stated:—

During the year it was brought to my notice that two insect pests had appeared, and were doing considerable damage to certain cultivated plants. I obtained specimens of each and forwarded them to Mr. R. Trimen, F.R.S., of the South African Museum, Capetown. The first one, which had attacked the "Umondi" (*Chlorocodon Whitei*), proved to be a rather rare beetle *Chrysomela Clarki*, baby, a near relation of the destructive "Colorado beetle"; and Mr. Trimen states that members of this group have a habit of suddenly multiplying to an immense extent. So far as I am aware, this pest has confined its attentions to the "Umondi," and should it increase alarmingly the best way to get rid of it would probably be to get rid of the "Umondi" plant together. In case, however, it should attack other and more valuable plants, it will be well to bear in mind Mr. Trimen's suggestion, viz., spraying the plants with a mixture of "Paris green"

(*Arsenite of Copper*), a tablespoonful to a bucket of water, to be kept in constant agitation when applied. This appears to have been successful in the case of the Colorado beetle. Specimens of *Chrysomela Clarki*, with instructions as to spraying the plants, were sent to the Durban Museum, Museum of Natal Society, and Botanic Gardens, Maritzburg. The other insect, which had attacked the mealy plant, proved to be a species not so rare, and is called *Epilochna similis*, Thunberg, and belongs to the family of "Ladybirds." Mr. Trimen states that he has often found it on mealy leaves, and that it is also destructive to the potato plant. Very probably the treatment recommended by Mr. Trimen for destruction of *Chrysomela Clarki* would be effective in this case also. Samples of Banana and Cassava flour were obtained by Mr. R. Jameson from the Government of Jamaica, and landed over to me. A specimen of each was forwarded to the Botanic Gardens, Maritzburg, and also to the stores of Messrs. Jameson & Co., the remainder being retained at my office. Both of these articles could be produced here in quantity, but there appears to be considerable doubt both as to the value of the Banana flour as an article of food, and also as to the permanence of the demand. The Cassava plant will be alluded to later on in this report. A sample of extract of Mangrove bark was also obtained from the same source by Mr. R. Jameson; but as the true "Mangrove" is not at all common in Natal the trees on our Bay side being chiefly *Avicenna officinalis* and not *Rhizophora sp.*, there is little chance of our being able to supply this extract, and I find also that it has not been favourably reported on at home. The Right Hon. W. L. Jackson says of it: "I have examined the sample of Mangrove bark extract, and I regret that I am not able to report very favourably upon it. Gambier at present is much cheaper as a tanner, and I do not think buyers could be found who would pay a proportionate price for it." Two brokers say that they have been unable to induce tanners to even try it.

AN EX-CYLON PLANTER IN AUSTRALIA.

AUSTRALIA AND CEYLON: A CONTRAST—SCARCITY OF WATER—MR. HENRY POETT AND THEMILDURA SCHEME.—MISS SHAW'S LETTERS ON AUSTRALIA—GENERAL ITEMS.

The Barrier, New South Wales, March 1893.

In three days will have completed my twelve months here and I have not been once outside the boundary fence of the Run during all that time. It has been a very pleasant time altogether, but the chief pleasure has been the magnificence of the climate and the keen enjoyment of robust health.

It sometimes strikes me as being wonderful to realize the difference between these present surroundings and those of the Central Province in Ceylon. On the one hand in your humid island you have constant downpours of rain; you have two monsoons vying with each other in soaking your land; you have rippling streams and raging torrents;—murmuring rivers and roaring waterfalls. The whole country is green and succulent, and the ever-present water accompanies you wherever you go. You see the rice fields glistening with this much prized element, along the side-drains of the road the happy streams plunge merrily and disappear beneath culverts. But here man has made it possible to exist where the very blacks in days of yore found it well nigh impossible. All this country was considered an impracticable desert save after heavy rains when the water-holes became filled with water, thus enabling the travellers to cross with safety. But here in this desert you find a luxurious home, a happy community of men, a thriving industry, a sharing of the luxuries of civilization. As you sit in the comfortable buggy of the Boss, and watch the sombre stunted timber swiftly whirl by—and the great spread of level plain unroll itself before the rapid wheels of the carriage.—You find it hard to realize that but for these large artificial tanks—not only the sheep—but the occupants of the buggy

would find existence impossible. It makes one serious to think of the perils of a stranger here. Those familiar paddocks round the very homestead are deathtraps indeed to the stranger where the boundary rider steers his course almost unconsciously. I often stroll away into the silent bush and try to realize the frenzied agony of a lost man in these terrible thirsty solitudes, I picture the various stories I have heard lately. That one of the parson and his friend, both New Chnms, whose horses both jibbed with them and refused to proceed further because they had been ridden too rapidly and too far without water. They were reduced to such straits that although they were on a coach track and near (comparatively) stations. Yet they were so far reduced that one man lay down half unconscious, while the parson cut the shoulder of his horse and drank the blood. By the time the coach came along a few days had reduced them almost to maniacs solely by the want of water. Then the story of old Dan who was paralyzed by a kick from a horse so that his legs were useless. Dan had been left in charge of part of a contractors team and camp while the contractor, his men, and the rest of the team had gone for supplies. He had dismounted about three miles from the camp and somehow had been viciously kicked by the horse which deprived him of the use of his legs. Then the tough old fellow started for the camp on his belly—the only means of locomotion being his arms and hands. Four days later he arrived at the camp. It was no easy stroll though but three miles. It was no light stepping Marco, but the toes of his boots worn through and part of the flesh from his feet, the clothes on his stomach were matted with blood and torn flesh, and clay,—while his arms from the elbow down and the palms of his hands were raw and bleeding. What a wonder of determination. The instinct of self-preservation is strong, but how many persons would have foot by foot, inch by inch steeled for three miles, without food or drink—yes he had water at the place where he was kicked—but during the journey he was without food or drink. The men in search came across a curious trail was it a sheep with a broken leg, was it a lame kangaroo?—Such a trail had never before been in the bush. Let my readers try to make progress across the carpet of the dining-room entirely by means of the fore-arms and elbows, and they will realize in some manner how these four days were spent. Old Dan only made progress during the night—guiding himself by the stars. Had he attempted to do so by day the excursion would have created a thirst that would have killed him. Think of him lying under a mulga bush his body deadened not only by paralysis, but by scraping over sticks and stones and yielding sand. What patience, what enduring to the end. Then there was the balmy swagsman who stripped naked and ran round the horse-paddock. This casting away of not only the swag but also the very clothes themselves is a very common symptom of this madness. He was seen afterwards at an abandoned camp. Then he turned up at a camp away on the other side of the run. Then his hat was found far away from track, or tank, camp or hut, and farther on the overseer declared that he and the man with him whiffed a ghastly odour. They looked, but not too closely. They reached, but none too narrowly, and to this day it is believed that there lies a skeleton in that far outlying corner. Thirst, whether on those boundless plains, or in the trackless ocean, it overcomes all the natural instincts of the animal. It makes a man hanker after the life-blood of his mate, it makes a ewe leave her lamb. It is getting time again for rain. We have had none since November, and there is the lambing to consider. It is to be hoped it will not be like last year. Already rain is banking up and threatening.

By the coach which has just left I have received another letter from Mr. Henry Poett. I sent him a copy of my Mildura Report feeling sure that he would say I had over coloured it though I honestly tried not to do so—But so many have accused me of that that I

heard Poett would do so also. His testimony is more valuable in that he has seen the place as a permanent resident not as a visitor of a few hours like myself. He says "I was very pleased with your report. It is a very able drawn up document and does not in any way over rate Mildura which is a very decided success although the settlers through following utterly bad and unprincipled advice are doing their level best to wreck the place and themselves too." I am glad I am supported by Mr. Poett; because I felt it a responsibility to write and advise people to come to a place which might not turn out the success I foretold.

Your readers should read Miss Shaw's letters to the (London) Times about Australia, and I would be glad if any of them would send me copies of the Times containing same. (You have my address) Miss Shaw's opinions would be crystallized concise opinion intelligible and to the point;—and, what is more perfectly reliable. Of course a mere visitor misses a great deal and is apt to generalize too greatly. Witness the M.P.'s and globe trotters who visit India; But Australia is an easier problem for the globe trotter or a newspaper correspondent than India.

ABERDONENSIS.

P.S.—A camp was robbed in the absence of the Boundary rider and the sheep overseer and a station hand started on horseback to follow up the trail. Some dastardly sandowner, some pitiful thriving sneak. The meanest trick to rob a lovely boundary rider of his tobacco and molasses &c.! But nemesis was on his track. They found the footmarks go away to the South and hit a fence a few miles off, but parallel with the coach track showing that the man knew the country. Right along for many a mile the footprints were outside this fence and then crossed the fence and travelled in the direction of the next station home stead and near the Coach Track. After a while in the wide plain they sighted their quarry "humping his drum" and raising a long line of dust. They spurred their horses and rapidly neared him. As they rode up he threw his swag on the ground and stood over it. This action alone had a guilty look. The overseer said they were in search of a thief who had robbed the Camp and they wanted to look at his swag. If they were mistaken he would pay his fare by the coach to the terminus if necessary. All that was wanted was that the swag should be examined. The man eyed the two as they sat on their horses. "What the — do you mean stopping a traveller and wanting to look in his swag for?" "Well, in the 1st place we have tracked you from the hut where the robbery took place and in the 2nd place you are off the track in a suspicious manner. What more could you want to make us answer to do to examine your swag? However whether you will or no we mean to do it. Murphy, open his swag. Murphy open his swag. Murphy alighted and sent his horse off out of reach and presently he and the thief were at it hammer and tongs. Murphy soon proved his superiority and the swagsman, seeing he had no chance, suddenly drew knife and rushed at the overseer. "Ah!" shouted the overseer, as he dexterously wheeled his horse, "Ah! that's just what I was waiting for," Whack! went the stock whip, a truly formidable weapon. It is quite awe inspiring to hear a bushman wielding a stockwhip near to you. Reports like rifle shots and the hissing of the long lash like a huge snake. There's "the Sydney Flash" three cracks like thunder in three turns of the arm. There's the flogging cut, and the up and down cut &c. &c. A very few moments of the full weight of the stockwhips made the thief lie down and my like a child. Then the swag was opened and didn't the overseer swear. There was everything even down to a few coppers that the beast stole. You bound you deserve to be lynched. "You blasted wretch! Down went the full force of the stockwhip, hang" bag! crack! crack! till the Overseer was weary and the setting sun warned him to desist. "Go! you brute. It is a pity we haven't more time or I would give you another dose when I have rested," and off the two started for home at a handgallop very satisfied with their days' work.

ABERDONENSIS.

COMPARATIVE ANALYSES OF TEA:

FLAVOUR *vs.* QUANTITY.

LONDON, April 7.

In my communication on the above by last mail I find an error was made in the figures for dried soluble extract in Table II. specimen No. 3—the figures should be 38·04 instead of 28·04 as stated.

The corrected results should stand as follows:—

No. 3	
Ceylon Pekoe sold at 1½d	
Water originally present	.. 5·63
Dried exhausted leaf	.. 32·53
Dried exhausted stalk	.. 23·80
Soluble extract (dried)	.. 38·04
	100·00
Proportion of leaf	.. 57·74
Proportion of stalk	.. 42·26

These results agree very well with those for No. 1 representing Assam Orange Pekoe with 40·57 of soluble extract. It will be noticed that Indian and Ceylon tea yield a larger proportion of extract than China tea. Possibly some objection may be taken to the term *stalk* as opposed to *leaf*. Specimens of each are therefore enclosed, and if some hot water be added and time allowed for the necessary expansion, planters and tea experts will see how far the application of the term *stalk* is justified. The enclosed rough sketch of the tea leaf as it grows naturally on the tree is taken from *Blyth's Food Analysis* and will indicate that a considerable quantity of stalk may be plucked with the leaf unless proper care be taken.

Instead of picking the fine tips or undeveloped leaf the writer thinks it would be more profitable to allow the leaf to mature and open out into full blossom. In fact to give up fine flavour and go in for quantity and a large soluble extract.

These analyses have certainly proved that it is the *quantity* and *colour* of the soluble extract that commands the markets and not fine flavour. If these results are deemed of practical use they may suggest future work in a larger and more extended scale.

JOHN HUGHES.

I hope the correction will be carefully made in the figures for No. 3 Table II before the MS. appears in the *T. A.* [Yes—this correction is in time for *T. A.* and *Overland Observer*.—Ed. *T. A.*]

TASMANIA REVISITED.

(By *Old Colonist*.)

When three and thirty years ago, a man who even now I only partially know, wrote a series of "objectionable" letters to the *Observer* signed "Young Scotchman" the planters of the day were up in arms, and a meeting was held in Kandy at which I was present, when it was resolved that should the offending scribe ever become known he must be horse-whipped. And to this I agreed.

But the planters of the past generation were better than their word, for after the culprit became known he was punished with such lavish kindness that to this day he has the tenderest affection for all and sundry in Ceylon.

In the same way Tasmania has had its revenge. I had forgotten that in writing to the *Observer* from South America, I had compared Tasmanian hospitality rather disparagingly with the spontaneous entertainment we received from the *hill* tribes of Peru. But if I had forgotten my friends in Hobart very soon reminded me of the fact. Though instead of tarring and feathering me as I doubtless deserved, they proceeded to pile coals of fire upon my head. For five nights in succession I have dined out, declining several invitations with grateful thanks.

THE GREAT TIPPLE HERE IS TEA—invariably the best Ceylon, and "brewed" to such perfection as we seldom get it in Colombo, where the anti-tannin craze is carried to an absurd length. Here the majority like a little taste of the tannin and I much prefer it to the mere hasty washing-off of the tea leaves remorselessly offered to a jaded man in Ceylon. The tea may, and doubtless is the finest in the world but as the Buchan farmer said of "Wandering Willies" neck "it wad be a the better to be drawn a little longer."

But to return to the

TEA DRINKING IN HOBART.

It is in the good old style only to be seen at perfection in Hobart and Aberdeen. It is late in the afternoon the table is laid with Artistic taste, and here literally trembles under the weight of flowers tempting meats, fishes, cakes, fruits and sweets of the most digestive and indigestive discretion. The grand prologue is the pouring out of the tea. Not dished on the sideboard and apathetically handed round by the appoos as in Colombo, but at the end of the table surrounded by her precious hand painted Carlsbad, sits the lady of the house, or if the family be up the prettiest of the pretty daughters presides. And here let me say that Lima may well look out for her laurels when Hobartina enter the field—the first act viz:—the pouring out of the tea is accomplished with a grace that leaves nothing to be desired and if the unvarying queries as to whether you take milk and sugar are apt to prove a trifle tedious—they break the ice, and pave the way for the brilliant chatter which follows. Mountains of cake disappear and cup after cup, passes round; the aroma so excellent and the effect so exhilarating that we no longer wonder why the Cascade Brewery shares have gone down 20 per cent. since the introduction of Ceylon tea!

Such a tea—in 3 acts, usually takes a full hour to accomplish, is equivalent to a dinner in other parts of the world, and the fact that I am fit to tell the tale on the morning after five such outings is a sufficient guarantee of their wholesomeness.

While in Hobart I visited the Training School for boys under the able supervision of Mr. Longmore himself a born and trained teacher, having had much experience in the management of similar institutions in Scotland.

THE SCHOOL AT HOBART

is one of the most creditable things ever the Government of Tasmania undertook, and is being carried on with a tact and perseverance truly admirable. Here are a number of previously neglected boys of the genus larrikan from 12 to 18 years of age whose only crime is that they were badly brought up by their parents, or it may be orphan outcasts. It requires only a cursory glance at the majority of the faces to see that the 'loons' are amenable to kind, firm and methodical treatment, and will yet prove useful men. A minority of course, there are—the formation of whose heads indicate that there is something hopelessly wrong, and we wonder how far such boys are responsible, and how far the doctrine of free will applies to them. Beside being taught the three Rs. These boys are trained in many useful occupations such as gardening, ploughing, carpentering &c., and unquestionably much tact and patience is required in dealing with them, the result shows that this is not a wanting on the part of their foster father Mr. Longmore who is more than a parent had ever been to them. I had the pleasure of listening to the rehearsal of sundry songs and recitations prepared to celebrate the 9th anniversary of the school. All the pieces were admirably rendered with good musical voices, and particularly was I gratified to hear them sum up with what I would call the *Federal Anthem of the great English speaking race*, for I have often seen Yankees, Irish or other malcontents leave a meeting with their noses in the air when the *English National Anthem* was sung, but never once did I come across an English speaking soul that did not lustily join in

'AULD LANG SYNE.'

One of the most interesting duties Mr. Longmore delights in attending to, is the keeping up correspondence with the boys who have left the institution, who now write him affectionately from all parts of Australasia. In a letter received during my visit the writer spoke of the "dear old training school" with evident gratitude and pride, "my master" he says told me this morning he heard I had been in "jail in Hobart. No sir, I said I never was in jail but for three years in the Training School under Mr. Longmore and I shall always feel proud and thankful to acknowledge it"

Tasmania has been the scene of many blunders and some very inhuman wrongs, but this institution goes far to make atonement for the past and cannot fail to bring its own reward.

At a little distance from the "Boys Training School" is another institution inaugurated and supported by Lady Hamilton during her residence in Hobart, this is for,

THE REFORMATION OF "LAFSED" GIRLS.

It is satisfactory to hear that a number of benevolent ladies are carrying on the work, and that substantial good is being effected, I cannot give particulars, but the "poor soiled doves" are comfortably quartered. In a pretty cottage surrounded by a neglected garden where the lovely flowers—like the inmates of the cottage have grown up in a wild and wilful way. Yet they are none the less heaven-sent flowers, and as I cull a handful I hear some recent arrivals singing "Ta-ra-ra boom deay"

We have got no rent to pay." The weak point in Tasmania is undoubtedly

THE NEGLECT OF CHILDREN

the consequent marked absence of respect for parents or old age. A contempt for honest industry and a hatred of poor John Chinaman. This last is still instilled into youth in a manner to shock our northern notions of civilization and fair play

This very day, (21st March) poor Ah Kap one of the most inoffensive and industrious of men—watering his plants after all Hobart had gone to bed - and heaving them long before the larrikin is awake. Today he was working busily at noon when from a board school hard by, the boys began pelting him with stones. This becoming uncomfortably annoying, A. K. went round to the street expostulating with the youngsters when by came two big cowardly ruffians of men, who seized the meek and fragile Chinaman, and holding him firmly, invited the boys to make a target of his face. Nothing loth one boy soon smashed the nose while another bunged up both eyes, finally running away and leaving poor John lying bleeding on the ground.

Tomorrow morning a brief para headed "a Chinaman's grievance" is all that is ever likely to be heard in Hobart of this diabolical outrage.

LEAF MOULD.

A very useful little pamphlet has recently issued from the pen of M. Georges Traffaut,* on the chemical and physical properties of leaf-mould in the cultivation of *Vriesia splendens*, *Anthurium Scherzerianum*, and *Latania borbonica*. The author, while calling attention to the increasing importance of artificial manures in horticultural practice, deprecates the neglect too frequently shown by the gardener to avail himself fully of the investigations brought to light by the agricultural chemists during recent years. The experiments of the last twenty years in this department show conclusively how necessary it is that the manure employed should be suitable both to the soil used, and to the requirements of the plants we cultivate. Of all the various soils employed for horticultural and greenhouse purposes, the author considers the soil derived from decomposing leaves, humus, or leaf-mould the most effective.

There are two kinds of leaf-mould in use among the French gardeners, called *La terre de bruyere* and *Le terreau de feuilles*. It is known that these two kinds of mould are formed from decomposing plant-leaves and roots mixed with ordinary soil or sand and ferric oxide (irony matter), and that these moulds have a peculiar acid property from the humic acid which they contain.

The first description of leaf mould, *La terre de bruyere* (peat), is formed on sandy heaths by the decay of the leaves and roots of *Erica tetralix*, *E. scoparia*, *E. vagans*, and frequently also from *E. cinerea*, which flourishes there, the soil being held together in such a manner by the roots of the growing plants as to allow of its being cut into square blocks, and so dispatched for market. To prepare the material for use, it must be broken up and sifted, removing the larger undecomposed roots which hold the mass together.

The second description of soil, *La terreau de feuilles* (leaf-soil), is different from the former, being obtained from the forests, and is the result of the decomposition of the fallen leaves mixed with the earth upon which they rest; that obtained from under the Oak trees is considered the best. These soils are light in character, and peculiarly suited for the growth of most greenhouse plants. The peculiar properties of the leaf-mould is, that it facilitates drainage and aëration, causing a quick and active plant-growth, with a free development of root. The partial decomposing leaves and roots forming the mould require a free passage of air, to allow of the nitrification of the organic matter, and given this, the roots of the growing plants develop rapidly. As both the drainage and evaporation are great, frequent waterings become necessary. The mould has also a large absorptive power: one hundred parts, by weight, of the mould will take up one hundred and ninety parts, by weight, of water.

As it is known that the fertility of all soil is nearly connected with its powers of retaining plant-food, several experiments have been tried of the retentive properties of leaf-mould for different manurial substances, which have shown that it has a great absorbent power for potash and phosphoric acid, but that nitrate of soda is retained in a much less powerful manner. These facts agree with what has been found in ordinary agriculture.

The following table shows the amount of selected chemical constituents in 100 parts of the finely sifted leaf-mould obtained from the neighbourhood of Rambouillet (Seine-et-Oise).

Selected Constituents in Parts per hundred.

Nitrogen	0.587
Phosphoric acid	0.116
Lime	0.260
Silica (sand)	83.600
Humus (organic matter)	9.530

It is known that soils containing humus will absorb ammonia from the atmosphere, and thus increase their store of nitrogen. The organic remains of former crops or plants are also oxidised, the nitrogen being converted into nitric-acid. The fragments of silica or limestone will at the same time be more or less disintegrated by the combined action of water and air, assisted by the carbonic acid and humic acids arising from the oxidation of vegetable matter, and a portion of the insoluble plant-food be thus brought into a state suited for assimilation by the roots of growing plants.

From several carefully-conducted experiments, it has been found that the leaf-mould on being passed through a sieve, yielded 80 parts per 100 of fine soil, and that the weight of fine dry earth in one hectolitre, which is equal to about 3½ cubic feet, or 2½ bushels, was 143 lb. The sifted-out portion was composed mainly of leaves in an early stage of decomposition, which would act on the soil to which it was added by virtue of its physical properties.

The following table shows the weight of each fertilising element in one hectolitre of leaf-mould, and its degree of assimilability.

* *Extrait des Documents presentes au Congres Horticole de 1892.*

Elements in one Hectolitre of Sifted Leaf-mould.

Total nitrogen	0.59 lb.
Lime	0.34 "
Phosphoric acid	0.15 "
Potash	0.46 "
Silica sand.. .. .	108.68 "
Humus	12.39 "

Assimilable Elements:—

Nitric nitrogen provided in 6 months by nitrification	34.45 grammes
Phosphoric acid (soluble).. .. .	2.60
Potash (soluble)	47.45

Knowing, therefore, what are the substances directly assimilable by plants in one hectolitre of leaf-mould; it is important to enquire the best means of applying to the soil the elements that are wanting, or are not present in sufficient quantity.

Nitrogen.—Although the nitrification in the leaf-mould may be sufficiently active for us to be able to dispense with nitrogenous manures in most cases, yet there are certain species of plants which rapidly develop a large mass of foliage, and these cause a rapid and extensive draught on the nitrogen. For such, it will always be advisable to use nitrate of soda in solution when watering, and to supply it frequently and in small quantities. The presence of crystalline nitrate of soda in direct contact with plant-roots is sometimes hurtful, and the plants do not get the full benefit of the supply.

Nitrate of soda should be given in doses of 1 gramme per litre of water, that is about a quarter ounce for two gallons.

To calculate the quantity to be applied, we rely on the fact that nitrate of soda of commerce contains 15 per cent. of nitrogen. For cultivation removing 30 grammes of nitrogen, there must be applied 200 grammes of nitrate soda. The mould containing so much humus, absorbs and strongly retains ammonia.

It might, therefore, be thought advisable to use ammonium sulphate as a nitrogenous manure. But for this to be fixed the soil must contain a certain proportion of lime. This will take the acid from the sulphate and be changed into ammonia carbonate. For this salt to get assimilated by plants, it must be changed into nitric nitrogen by nitrification.

Phosphoric Manures.—Assimilable phosphoric acid is in very small quantity in leaf-mould; it is therefore necessary to add it in manure. The best form is that of pulverised bone-phosphate. Phosphate of potash is also excellent. Superphosphates yield a certain proportion of phosphoric acid soluble in water, but in leaf-mould culture they are not to be recommended, being almost always acid, and this introduction of sulphuric acid into soils poor in lime would be certainly hurtful.

We recommend precipitated bone phosphates which may contain as much as 45° per cent. of soluble phosphoric acid. Basic slag is also strongly recommended. This product, having no acidity is very good for soils poor in lime; it must be used finely ground, and mixed with the earth. The quantity of the phosphates to be applied will vary according to their percentage of phosphoric acid.

If we have need of more rapid assimilation, phosphates of soda and potash are to be recommended. The former contains one-half its weight of directly assimilable phosphoric acid. It may be dissolved in water, and use for watering the soil we wish to enrich.

Phosphate of ammonia is sometimes recommended. This gives excellent results; it furnishes both phosphoric acid and nitrogen, but it is too costly for general purposes.

To sum up, we shall apply bone phosphates or precipitated phosphates according to the duration of the cultivation.

For plants of rapid growth, phosphates of potash, soda, or ammonia.

Potash Manures.—Leaf-mould contains a considerable proportion of potash, which is only slowly available for vegetation. For certain cultivations, especially that of Ferns, potash manures have a very

beneficial effect. The most rational method is to use carbonate of potash, and to apply it dissolved in water on to the soil to be manured; this salt is retained by the soil, and the plants are able to absorb it as they need. The proportions to be used vary according to the requirements of the plants cultivated. Commercial carbonate of potash contains from 52 to 63 per cent. of potash.

Nitrate of potash will serve both as a nitrogenous and a potash manure. It is directly assimilable by plants; it is very soluble in water, and must be used for watering in the same proportions as nitrate of soda. It is an excellent manure, containing 45 per cent. of potash and 13 per cent. of nitrogen. It is thus valuable when we wish to associate nitrogen and potash together.

A salt likely to become of great importance to horticulture is sulpho-carbonate of potash, which acts as a manure and as an insecticide.—J. J. WILLIS, Harpenden.—*Gardeners' Chronicle.*

TEA CULTIVATION: PRACTICAL EXPERIENCE.

(By a Tea Planter.)

TILTH—BURYING PRUNINGS—CATTLE MANURE.

"Tilth" or tillage.—My experience here quite agrees with a correspondent you quoted that on poor soil tilth without manure does no good, in fact in my case I thought it did harm as it tended to harden the wood and encourage seeding. They had the same experience on the adjoining estate. At the same time I remember digging in stable manure factory and line sweepings on a young field in the lowcountry, and the supply running short before time to knock off, the coolies went on digging away till muster time; this had quite a marked effect, but then the case was different, this was young land with lots of roots to tare up and cause to rot more readily.

Last week I saw you writing strongly on *burying prunings*. Well; I have done a great deal at that, considering my acreages. It is beneficial certainly, but considering cost and the number of coolies required for the work, especially at a busy time I question if it has any advantage (that's strong! you'll say).

But let us reason it out. Prunings left on the ground act as thatch or shade and prevent the ground from being washed and baked. Ultimately a percentage of the prunings get carried away; but it is principally dry twigs, and one can see a layer of mould being formed from the prunings which must act as a barrier between the atmosphere and soil.

In the lowcountry prunings disappear from white-ants after a few months, but there no one can doubt the beneficial effect they have in protecting the soil from being baked by the fierce rays of the sun, and also shading young rootlets near the surface as well as collecting and retaining dew at night.

Were it not that the expense is prohibitive there is nothing except cattle manure that has so marked or so lasting effects as *thatching with mana grass* where procurable. I am not writing about what I have not tried and more than experimented with. I agree with I think all you have written in favour of, but I certainly differ about burying prunings.

THE DRAYTON (CEYLON) ESTATE Co.—A Company has been formed under the above title to take over the Drayton and Yuill field estates. The capital is to be R750,000 in 7,500 shares of R100; but the shares are all privately held, chiefly by the proprietors of the two estates mentioned. In future they will be worked together as one estate. The two contain 1,120 acres, of which 920 acres are now planted in tea. The vendors take the whole of the purchase money (R671,000) in fully paid up shares in the company, and the estates are taken over as from 1st of July next.

THUNDERSTORMS:—THEIR CAUSE AND EFFECT:

DURATION OF A LIGHTNING FLASH 'ONE-MILLIONTH OF A SECOND'!

With reference to recent experiences in Colombo, the following account of the development of Thunderstorms from the latest *Encyclopædia Britannica* affords a good many points of interest. It will be observed that our experience on Galle Face the other day of a special and sudden increase in the rainfall—a perfect torrent in fact it became—following on the flash and crash—accords with the scientific explanation. Very interesting is it to learn that the duration of a lightning-flash is only about "one-millionth of a second"! If it could be made to last one tenth of a second, it "would give near objects an illumination 100,000 times more brilliant than that of moonlight"! And once more that the so-called "flash" is really "a column of intensely heated air driven outwards from the track of the discharge at a rate initially far greater than that of sound." The rate at which sound travels, it will be remembered is roughly speaking, about a mile in five seconds. We quote as follows:—

There can be little doubt that atmospheric electricity, at least in the great developments which characterize a thunderstorm, is due in some way to water. Before a great thunderstorm the lower air is usually at an abnormally high temperature, and fully saturated with water vapour, so that it is in a thoroughly unstable condition. Immense cloud masses, often miles in vertical thickness, which produce almost midnight darkness by day in the region of the storm, and which appear, when seen from a distance, as if boiling upwards, are always a notable feature of great thunderstorms. These are usually accompanied by torrents of rain, or by violent hail-showers. And it is commonly observed that each flash of lightning is followed, after a brief interval, by a sudden but temporary increase in the rate of rainfall. At what stage of its transformations the electrification is developed by water-substance is, as yet, only guessed at,—though it seems most reasonable to conclude that it is anterior to the formation of cloud, *i.e.*, to the condensation of vapour. And, though the idea was at one time very generally held and still has many upholders, it seems unlikely to be the direct result of evaporation. For, were it due directly either to evaporation or to condensation, it is almost impossible to doubt that proof would long since have been furnished by careful experiment, even if made on a scale so limited as that afforded by our laboratories. No trace of electrical effect has been found to attend the precipitation of moisture; and the electrical effects, sometimes considerable, which have been found associated with evaporation have always been accompanied by relatively violent physical and mechanical actions which are not observed in conjunction with atmospheric electricity. It has been suggested by some authorities that the electricity of a thunderstorm is developed during the formation of hail, by others that it is due to the molecular actions which accompany the diminution of total surface when two or more drops of water coalesce into a single one. It has been ascribed to the friction of moist against dry air, and to the dust-particles which appear to be necessary for the condensation of vapour. Again, it has been suggested that it may be a mere phenomenon of contact electricity due to the impact of uncondensed vapour particles

on particles of air. It is almost unnecessary to observe that, whatever hypothesis we adopt, some explanation must be given of two important points:—(1) What becomes of the electricity equal and opposite to that in each drop, which must be produced simultaneously with it? (2) By what means is the attraction between the drops and the recipient of the opposite charge of electricity overcome so that the drops may be enabled to part with their charge? It is to be presumed that gravity satisfies the second of these questions. As to the first, it seems to necessitate the presence of something besides water, in order that the electric separation may be commenced, and thus appears to be fatal to the capillary theory indicated above. Whatever be the true source of the charge, it is easy to see, by known properties of electricity, that even an exceedingly small charge on each vapour particle would lead to a very high potential as soon as a visible drop is formed, and that as a drop increases in size its potential is proportional to its surface. That drops of rain are often individually electrified to a very high potential is proved by the frequent occurrence of "luminous rain," when the ground is feebly lit up by the multitude of tiny sparks given out by the drops as they come near it. The flakes of falling snow, also, are often strongly electrified, so that smart sparks have been drawn from an umbrella on which the snow was falling. But the law of electric repulsion shows us at once that, as soon as the drops in a cloud are sufficiently electrified, at least the greater part of their charge must pass to the boundary of the cloud. When this occurs, the nature of the further behaviour of the charge presents no difficulty. The reason for our singularly complete ignorance of the source of atmospheric electricity seems to lie in the fact that it can only be discovered by means of experiments made on a scale very much larger than is attainable with the ordinary resources of a laboratory. The difficulties will probably be easily overcome by the first nation which will go to the expense of providing the necessary means.

Numberless other explanations of the origin of thunderstorms have been suggested; but the more reasonable of these do little more than shift the difficulty, for they begin by assuming (without any hint as to its source) an electrification of the earth as a whole, or of the lower (sometimes the upper) layers of the atmosphere. Induction, convection, &c., are then supposed to effect the rest. Another and much less reasonable class of explanations depends upon magneto-electricity. Some of these introduce the so-called "unipolar" induction supposed to be due to the rotation of the earth, which behaves like a gigantic magnet. Of this nature is the suggestion of Edlund, which was recently crowned by the Academy of Sciences of Paris. That rapid variations in the earth's magnetic elements, such as often occur on a large scale as in a "magnetic storm," have at least a share in the production of the aurora is a perfectly reasonable and even plausible hypothesis, long ago brought forward by Balfour Stewart. But we have yet to seek the source of these variations.

The brightness of a flash of lightning is usually much underrated. It is true that it rarely gives even at night an illumination greater than that due to moonlight. But it must be remembered that Swan has proved that the impression of a flash on the eye depends upon the duration, being nearly proportional to it, and steadily increasing for about a tenth of a second. Now the duration of a lightning-flash (roughly speaking) is only about one-millionth of a second. This is proved by the fact that the most rapidly rotating bodies appear to be absolutely steady when illuminated by it. Hence, if it could be made to last for a tenth of a second, it would give near objects an illumination one hundred thousand times more brilliant than that of moonlight. It must be remembered that the flash is not a mere line, but a column, of intensely heated air, driven outwards from the track of the discharge at a rate initially far greater than that of sound.

"TROPICAL AGRICULTURE."*

We are told in the preface to this little book that twelve years ago, when the author directed his attention to Tropical Agriculture, there was no practical book that he could refer to for help in all the difficulties that were constantly cropping up in his path. Knowing by practical experience therefore the obstacles that generally beset the inexperienced planter who is not content to follow the old grooves of unscientific agriculture, the author has so written the second part of his book as to afford the information he needed greatly in his own planting noviciate. This has, he says by way of apology, rendered it necessary to enter into details which to the experienced tropical agriculturist may appear superfluous. In the introduction to the second part of his work, the author inveighs against what he calls the great fault hitherto committed by so many tropical planters, namely, the confining of their attention to one product or one kind of cultivation on their land: "It," he says, "several different crops were taken off alternately as in a system of rotation, or grown in different parts, if the soil and climate prove suitable, the planter would be in a much better position than he is in now, for he would not as it were have all his eggs in 'one basket.'" This is advice—varied according to the different circumstances of the case in Ceylon and India—that is worthy the attention of every planter, and our own Director of Botanic Gardens in Ceylon, has not been backward in insisting upon its importance. The crops and cultivation treated in this second part of the book include:—Coffee, cacao, tea, sugar cane, fruits, spices, tobacco, drugs, dyes, tropical cereals and food plants.

While speaking of the necessity of shade for young Coffee the author refers to the pigeon pea (*cajanus indicus*) or "dhall" as making an excellent shade plant, and fertilising the soil by throwing down large quantities of leaves rich in nitrogen. Besides this, its roots penetrate to a considerable distance, and thus when the tree is cut down, the soil is improved by the decaying roots and by the free entry of the atmosphere into the channels formed in the ground by such decay. The importance of growing accessory leguminous crops or even the encouragement of leguminous weeds, as a means of enriching the soil has often been insisted on in the *Magazine of the School of Agriculture* (given as a Supplement to the *Tropical Agriculturist*) and in the light of recent research into the question of the fixation of free nitrogen by the *Leguminosæ*, the adoption of such means would constitute an enlightened and economic phase of husbandry. We have heard of one Ceylon planter who is making the experiment of growing the pigeon pea pretty freely on his upcountry estate. Now that the much advertised *lathyrus sylvestris* of Professor Wagner has been proved to be totally unsuited to the tropics, it will be better wisdom for cultivators in localities which have their special characters of temperature, elevation and rainfall, to choose their own nitrogen-fixing crops.—The latest deliverance on this subject is by Dr. Taylor in his science notes as follows:—

The fact that leguminous plants have their minute roots occupied by nodules which harbour hosts of nitrogen-secreting bacteria is now established. Several distinguished German chemists, however, have shown that it is the young roots possessing susceptible hairs which are most likely to be affected, although the age

of the plant, provided that the roots are normal, has nothing to do with the formation of nodules.

The subject of Cacao, as might be expected, since the writer's experience of tropical agriculture is mainly derived from the West Indies, is fully treated of under the headings (1) varieties, (2) soil, (3) climate, (4) propagation, (5) preparation of the land, (6) lining, (7) holing, (8) planting out, (9) shade, (10) weeding, (11) pruning, (12) manuring, (13) catch crops, (14) enemies of the cacao tree, (15) crops, (16) fermenting, (17) curing, (18) claying. It is difficult to make any selections from the treatise on this subject, but it will interest Ceylon cacao-growers to find Dr. Nicholl's saying, while speaking of claying cacao seed to improve their colour: "It is not recommended in English colonies to clay any cacao. If improvement is sought it should be in the direction of Ceylon cacao." Mr. Hart's Manual is, of course a fuller guide to the Cacao Planter.

With regard to Tea, there is as might be expected nothing new that the author has to tell Ceylon planters, the vexed question of manuring not even being touched upon. Sugar cane as an important West Indian crop is treated of at length. Then follow the fruits: orange, lime, banana, plantain, coconut (on this part we should like to have a review from our correspondent "W.T.") and pineapple. With regard to the yield of coconuts we quote as follows: "In Ceylon it is said that the general average returns of coconut estates is not over 30 nuts per tree; but individual trees have been known to give over 300 nuts every year for a period of 10 years. This enormous yield, however is most exceptional; but, with a good climate, a fair average soil, and judicious cultivation, the return ought to be at least 50 nuts per tree, and at 25 feet distance, this would give a yield of 3,500 nuts per acre. By the application of suitable manure the returns may be increased to 80 nuts a tree or over 5,000 per acre. but such a yield cannot be expected from the light sand soils of the coast line."

Under Spices we have the nutmeg, clove, pimento, cinnamon, ginger, cardamoms, pepper, vanilla. Tobacco occupies a fair space by itself, while cinchona, castor seeds, coca, jalap, and sarsaparilla, represent the Drugs. The dyes include anatto, turmeric, logwood and indigo. Tropical cereals are represented by maize, rice, guinea corn (sorghum), and the "food-plants" by cassava or manioc, arrowroot, tous-les-mois (varieties of the "Indian shot," used as substitutes for arrow-root), jam, sweet-potato, and the tania (colocasia).

As a Text-book for Students Dr. Nicholl's work is admirably adapted, and it certainly supplies a want, in that there is no book available at present, on agriculture as applied to the cultivation of crops in the tropics for use in our higher schools and colleges where the subject is taught. Again although rather too sketchy in some parts, to the intending settler in tropical countries this little volume may prove a useful introduction to the several *Manuals* dealing more particularly and fully with the staples of his cultivation.

TEA PROSPECTS IN CHINA.

A letter from Hankow to a Northern paper states that a larger number of tea-buyers than usual have lately arrived at that port from Shanghai, Foochow and Canton, which may mean a prosperous season for the Tea trade this year, although the disheartening news has been received from the interior that the severe weather of last winter destroyed about one-third of the crop, so that it is to be feared the out-turn will not be so great as in preceding years.—*China Mail*.

* A Text book of Tropical Agriculture by Dr. H. A. A. Nicholls.—With Illustrations. Macmillan & Co.

GAMBIR.

(From the Agricultural Bulletin of the Malay Peninsula.)

(Concluded from page 688.)

CHEMICAL COMPOSITION.

Flückiger and Hanbury (*Pharmacographia*, p. 337) state that gambir in composition agrees with cutch (*Acacia catechu*), and especially with the pale variety made in Northern India. Both consist mainly of catechin, and the yellowish colouring matter was determined by Hlasiwetz and Lowe to be quercetin, also occurring in cutch.

The results of quantitative analyses vary to a certain extent according to the method used. In the analysis of Messrs. Evans and Dr. Romburgh the methods employed are not given, so it is difficult to compare these analyses. The latter gives also an analysis of Singapore gambir, cube No. 1 in bags, which may be compared with Mr. Evans' analysis of Singapore gambir:—

Water	16.2 per cent.
Ash	3.9 "
Catechin	42.0 "
Catechu tannic acid	5.9 "
Other organic matter	32.0 about.
" " insoluble in alcohol	16.1
" " " in water	5.5
	121.6

The water here is much less than in Mr. Evans' two samples. Dr. Romburgh says the water in commercial gambir seems to vary from 9.5 to 16 %/o, but it is certainly too often more than this. The question of the water I have, however, dealt with.

The ash varies, says Dr. Romburgh, from 2.5 to 5.4 %/o, and he suggests it is influenced by the amount of water used in contact with the gambir. Thus in Singapore gambir made by boiling the leaves in water (as described above), he found 3.9 ash, while in Bangka gambir made by steaming he got 2.6 ash only. In Mr. Evans' analysis the ash is given as very much more than this, viz, 6.34 and 4.46.

Flückiger (1. c.) got 2.6 ash from some cube gambir, and this he says consisted mainly of carbonates of calcium and magnesium, but there must be some error in this, as these salts are not stable under heat.

The catechin and catechu-tannic acids are, of course, the important factors in the gambir. In Dr. Romburgh's samples Singapore gambir contained less catechin and more catechu-tannic acid than that of Bangka. This difference, he says, is most likely mainly due to different modes of preparation. According to the Bangka method one would obtain less extractive matter and owing to the much shorter exposure to boiling heat, the amount of catechu-tannic acid produced by decomposition of catechin (which change appears to be produced on protracted boiling) would be less.

Catechu-tannic acid is an anhydride of catechin which can be obtained by gently heating the latter. It is soluble in water and capable of decided tanning properties, precipitating alkaloids and albumen. It must, therefore, be remembered by manufacturers that if a product rich in catechin is required, excessive heating must not be resorted to.

Dr. Romburgh mentions an instance published (but where he does not say) in which a sample consisting of round pressed cakes of 2.5 to 3 grams each, gave catechin only (40 %/o) and no catechu-tannic acid. This sample was said to have come from China. If so it was probably not gambir at all, as gambir is not made in China.

If a leaf of gambir be rubbed in the hand, as described before, a soapy looking substance is exuded, of a white colour. This put under the microscope can be seen to be composed of innumerable white crystals, very minute, acicular, much resembling those of prepared gambir, only smaller. These are crystals of catechin. They are not visible in the leaf itself, nor can they be obtained by cutting the leaf across

and expressing the little juice obtained on a glass slide. From this, I gather that the catechin in the living leaf is in a state of solution, and is crystallized only on friction.

The leaves, which are very rich in chlorophyll, become brown very rapidly when bruised. A transverse section shows that this is not due to the alteration of chlorophyll, but to the alteration, probably oxidation of the other cell contents, probably the liquid containing the catechin, which becoming brown masks the green chlorophyll.

When the leaf is brown, no catechin remains, so that I gathered that the catechin is only stable in the form of crystals, and that the liquid containing the catechin is rapidly destroyed by oxidation.

In conclusion, I may state that the chemical investigation of gambir during the various stages of the growth of the plant and preparation of the extract, has been taken up by Dr. Bott, Government Analyst of the Straits Settlements. We may, therefore, look forward before very long to a paper dealing fully with the chemistry of gambir, the knowledge of which at present must be considered incomplete and in some respects even indefinite.

At present I am able to append the results of analyses by Dr. Bott of a number of samples of gambir, and to add a few general remarks as to gambir considered chemically.

ANALYSES.

No. 1.—Malacca Finger Gambir (Gambir paku) No. 1 quality.		No. 2.—Malacca Finger Gambir No. 2 quality.	
Water	14.50	..	13.35
Ash	2.92	..	3.50
Catechin	43.00	..	42.00
Catechu-tannic acid	3.00	..	5.20
Organic matter other than tanning principles	36.58	..	35.95
	100.00		100.00

No. 3.—Malacca Finger Gambir. (No. 3 quality.)		No. 4.—Malacca Flake Gambir (Gambir papan).	
Water	19.99	..	14.25
Ash	3.65	..	2.80
Catechin	42.20	..	44.00
Catechu-tannic	7.80	..	2.80
Organic matter	26.86	..	36.16
	100.00		100.00

Bale Gambir as received in Singapore.

	No. 5.		No. 6.	
Water	36.65	..	44.02
Ash	3.50	..	3.54
Catechin	26.10	..	20.50
Catechu-tannic	9.20	..	11.00
Organic	24.55	..	20.94
		100.00		100.00

From the above it appears that No. 3 is really the richest in tanning principles, though containing more water than the rest, except the very wet bale gambir. The low percentage of tanning principles in bale gambir should be considered, together with the large percentage of water. Referring the percentages of tanning principles to the samples free from water we get the following:—

Contains total tanning principles.

Dry No. 1	52.60
" " 2	54.60
" " 3	61.90
" " 4	54.46
" " 5	55.50
" " 6	53.30

It will be seen that, but for the large amount of water, Nos. 5 and 6 are not bad gambir for tanning purposes, although for dyeing they might not be suitable on account of their bad and uneven colour

Regarding the two principal constituents of gambir, viz., catechin and catechu-tannic acid, it still remains to be proved that they are identical with the homonym extract from Catechu (*Acacia Catechu*), even the formulæ of both bodies are not definitely fixed. It has generally been assumed that catechu-tannic acid, essentially differs from catechin in being directly absorbable by hides, but from the experiments made both catechin and catechu-tannic acid combine with isingless, gelatine, etc. The ordinary method of separating catechin and catechu-tannic acid is therefore, obviously inapplicable, and the same applies *mutatis mutandis* to the usual method of estimating tanning principles (in the case of gambir) by means of permanganate.

Before we can determine the value of gambir for tanning purposes, it has to be settled which of the two constituents—catechin and catechu-tannic acid—is “physiologically active,” that is, produces good leather, and which is merely pathological, and we shall then know whether in the manufacture of gambir we should aim at production of much catechin and little catechu-tannic acid or *vice versa*.

CULTIVATION FOR PROFIT.

Now I will give some observations on the culture of gambir for profit, and again will remark that, with improved methods, a larger output of better material would doubtless result.

The best plantation I have seen was that of a Chinaman, Kee Ann, in Malacca.

The owner cultivated other plants besides gambir, but possessed eight hundred acres of the latter and was opening up more land for the same cultivation. He made a large profit on pepper and tapioca apparently, and did not care much for the gambir, though he evidently spared no pains to grow and manufacture it well, according to the Chinese method.

I got the following details as to expenditure and profit from him.

The estate, 800 acres, produces 6 pikuls a day, which, taking a year at 350 working days, gives 2,100 pikuls a year. This selling at \$5 a pikul gives a sum of \$10,500 a year. The expense of making a pikul including cooly-labour, firing, &c., amounts to \$3.75, so that 2,100 pikuls cost \$7,875 to turn out. This works out to:—

Sale of Gambir ...	\$10,500
Expenses of making	7,875
	<hr/>
	\$2,625 dollars a year profit.

This does not appear a very high profit, but I believe he was really under-estimating it. For while he was assuring me that this did not pay him sufficiently, he was yet opening up fresh gambir fields.

The gambir he produced was block gambir No. 1 which is priced in Singapore at \$6 a pikul. If, therefore, he could get full price, the net profits should be \$4,725 a year on an estate of 800 acres.

Kee Ann was, as I have said, using the ordinary rough machinery of the Chinese method. With improved apparatus, such as copper cauldrons instead of iron, a better form of press than an old wooden one which he used for pressing out the water of the drug, and more rapid drying apparatus, he would be able to get a greater out-turn, while manning the plants and increasing the growth of leaf, by removing the flower heads, except where wanted for seed, would give a greater production of leaf, though adding a little to the expenses.

I then examined some Malays, who were manufacturing gambir at Pangkalan Balak in Malacca, as to their profits. The Malays have only small holdings of about 20 to 30 acres, and manufacture only chewing gambir. They adopt the Chinese method of manufacture, but turn out only the forms described above as *Gambir bulat*, *papan*, *paku* and *dukur*. No Chinese are employed on the estates.

Twenty acres of land covered with jungle costs \$80 to clear, weeding costs \$4 a year, coolies, 20 required at 25 cents a day, cost \$150 a year. The annual out-put of gambir is 120 pikuls amounting to \$720.

The carriage of this amount of gambir to Malacca cost \$36 as the plantation was a long way off and the roads not very good for part of the way.

Now to tabulate this:—

Preliminary expenses, clearing ground, etc.	\$80
Coolies for second year	2,150
Coolies for third year	150
Weeding for two years	8
Carriage of gambir	70
	<hr/>
Expenses	\$438
	<hr/>
Produce, second year after planting half-crop	60 pikuls.
Produce, third year, full crop	120
	<hr/>
	180 pikuls.
	<hr/>
At \$6 a pikul	= \$1,080
Expenses of produce	438
	<hr/>
Nett Profit	\$642

But the profit should be much more than this. In the first place the cooly labour is far too highly paid. In most places coolies can be got for six dollars a month or less. Again, with so small an estate, the coolies could not be employed all the year round, but only at the time when the gambir was being planted and prepared.

The gambir I estimate at \$6 a pikul, but the finer class of gambir, which indeed these Malays were turning out, was fetching as much as \$8 a pikul.

Lastly, the price of transport was exorbitant. The Malays possess no means of transport themselves and had to hire bullock-carts of the Chinese, and they, of course, put on a very high price for their use.

It is indeed always a difficulty to get any native to tell you how much profit he makes on any business. The Chinaman gives false information partly at least because he has some idea that the enquirer's object is connected with some tax on the produce which may be imposed. The Malay probably has no idea what he makes or loses on the business.

I consider it likely that under careful European management, with improved appliances, a good profit could be made out of gambir. Indeed there are a number of wealthy Chinese in the Straits who have derived a large part at least of their wealth from this source, and there is no reason why Europeans should not do the same. Planting has not as yet been thoroughly established in the Straits Settlements, and the few Europeans who have commenced planting have chiefly devoted themselves to coffee, tea, sugar and coconuts. There is, however, a Company in Johor which is cultivating gambir on a large scale under the management of Mr. M. Lorken, who has also a large coffee estate in the same district. Gambir has several advantages which these products do not possess. The demand for it is large, and its cultivation are at present very restricted. The climate, in which it thrives is a peculiar one. It requires constant rain, and yet plenty of sun; dry seasons are injurious, and, if prolonged fatal to it. Another advantage it has is that it begins to bring a return in a year and a half after planting, and, if necessary, within six months, though this is not advisable. Furthermore, it requires a comparatively simple plant, and thus the preliminary expenses would be less than those of most other products.

H. N. RIDLEY.

INDIAN TEA CROP IN 1893.

(From William Moran & Co.'s Market Report.)

CALCUTTA, April 19th, 1893.

Advices from the districts are generally favourable. A few hail-forms are reported, but as far as we can gather no serious damage has resulted.

A few musters have come to hand which show fair quality for early manufacture.

We have been favoured by the General Committee of the Indian Tea Association with the following estimate of the crop of the coming season:—

ORIGINAL ESTIMATE OF CROP OF 1893.

	lb.
Assam	50,326,320
Cochin	18,216,560
Sylhet	20,387,680
Darjeeling	7,330,430
Terai	3,427,200
Doon	16,085,055
Chittagong	1,008,000
Chota-Nagpore	267,000
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native Gardens ...	4,000,000

125,543,245

being 11,861,363 lb. over the actual output of the crop of 1892, but 3½ million lb. less than original estimate of that crop. Estimating shipments to the Colonies and other Ports with local consumption at 9 millions, there will remain about 116½ million lb. for export to Great Britain.

TEA FREIGHTS.

As has been already announced terms have been substantially settled between the Calcutta Tea Shippers and the Conference Liners. The arrangement sanctioned at Tuesday's meeting of tea shippers is as follows:—Agreement to be for three years certain, terminating at the end of that period on six months' notice from shippers wishing to withdraw; failing such notice the agreement to continue until six months' notice is given on either side. The rate of freight to be 15s per ton, as customary, above the rate for wheat, linseed, and jute ruling during the previous month, subject to a return of 5s per ton payable as heretofore to those shippers who confine their shipments during the period of the agreement exclusively to Conference Liners. The minimum rate to be 35s gross. All returns to be payable up to the termination of the agreement. All rebates earned up to 31st July 1892 to be paid in full.—*Pioneer*, April 15.

PLANTING AND THE GERMAN EAST AFRICA COMPANY.

RETURNED FROM EAST AFRICA.

Our readers will doubtless remember the attempt made by Mr. Percy Braine, the local Agent of this Company, some time ago, to obtain Sinhalese labourers to work on the company's estates near Tanga. The project, however, had to be abandoned, as the Government, when it heard of the matter, informed Mr. Braine that his proceedings were illegal. In view of these circumstances, the following facts which we have gleaned from a young gentleman just returned from East Africa with whose health the place did not agree, may not be uninteresting or out of place.

THE COMPANY'S ESTATES,

said our informant, are from 50 to 60 miles from the coast. They have opened out only two estates at present—one of which (the one I was on) was planted with coffee, and a sprinkling of tea, the other being also a thriving coffee plantation. The first is about 250 acres in extent and is under the management and control of Mr. W. H. Cowley, the other being managed by a German. There is no proper road to the estates at present—no line of march—only a little path bordered by jungle and forest. It took us about a month to travel from the coast to the estate, which is named 'Derema' after the river which rises in it and later joins the River Zegi. We had suffered considerably from the scarcity of good water during the journey, but when we got to the estate we found an abundance of pure drinkable water. The labourers on the Estate were all

CHINESE AND JAVANESE,

about 150 in number, with an equal number on the adjoining plantation. But somehow, I don't exactly know why, attempts were being made, as we learnt, to procure labourers from Ceylon—Sinhalese labourers then, one day, we heard that the plan had been prevented by the Ceylon Government. There were originally eight of us Ceylonese there—but sickness compelled some to return. There are now only five there—2 Tamils, 1 Malay and 2 Sinhalese. It seems hard at first to believe that though the water is pure and drinkable,

THE HEALTH OF THE ESTATE IS BAD.

There are many swamps round about, and thick black forests through which the sun never penetrates, and from underneath rise the demons of malaria, and fell vapours, the attacks of which none can long withstand. Mr. Cowley keeps his health splendidly—though this is accounted for, by the fact that he has been, if I mistake not, in several malarial districts here in Ceylon. I believe our Sinhalese labourers, had they gone there, would have been compelled to return—almost all of them—with a year, at most. The attacks of fever are something unbearable and carry one off within eight to ten days. To add to the hardship, there is a scarcity of good and nutritive food, and what little there was, we had to cook ourselves, as our African servants were woefully ignorant in the culinary art—and didn't even understand how to fry an egg!

THE WORK ON THE ESTATES

is still in its infancy, and with the malaria-proof Chinese and Javanese, the Estates will thrive and flourish and be a source of wealth to the company, in time. But as I said before, the Sinhalese labourer cannot stand the fever. It is malaria *par excellence*, and even some few of the Chinese, with their tough and sinewy frames, succumbed to it. The worst part of it is that there is no proper medical attendance in cases of sickness, as there is on our Estates. Once you're in for malaria there, it is a toss up between life and death, what with the incompetent dispenser (Doctor he called himself!) to attend to our physical ills.

AN ENCOUNTER WITH A LION.

It is not an every-day experience, to come within twelve feet of a real, live, growling African lion, but such was what I actually experienced one day, having ventured a little too far away from the Estate, —and without my gun, too! Talk of Lord Randolph Churchill! Why, his case was child's play compared to mine! I was walking leisurely along admiring the mighty forest trees, when all of a sudden my eyes beheld, about twelve feet away from me, underneath a bush, a shaggy maned king of the forest. I trembled like an aspen leaf, but kept looking at him fixedly, and retiring slowly step by step. When I had gone a considerable distance in this manner, I plunged into some brushwood and fled for life, reaching the Estate in safety. The dreaded beast had not pursued me, or even risen from his lair—perhaps he was after a good meal! Whatever may have been the cause of my deliverance, I shall always regard it as providential.

I mean to go back to Africa, if possible, but certainly not to the same place. This time I have been promised, by a friend, an appointment in Central Africa—which is healthy and nice. More anon.—Local "Examiner," April 25.

KELANI VALLEY TEA ASSOCIATION.

The seventh ordinary general meeting of the Kelani Valley Tea Association, Limited, was held yesterday, at the offices, 16, Philpot-lane, E.C., under the presidency of Mr. George W. Paine (the chairman of the company).

The Secretary (Mr. John Anderson) having read the formal notice of meeting,

The CHAIRMAN said:—Gentlemen, your directors regret the diminution in the quantity of the crop, it being 3,412 lb. less than last year; but this has arisen from two causes—one the more careful plucking, and the other from the very unseasonable and dry weather in the latter end of the year. Unfortunately, this unseasonable weather has continued in the beginning of this year; but our letters for March state that there is an improvement, there having been some rain, and the flush is increasing in quantity. You will notice that in this report we have given you no estimate of the quantity of tea for the coming year. The reason was that in the preceding years the crops have varied so greatly that we thought an estimate rather delusive. In 1891 the crop was 46,797 lb. more than the estimate, while last year it was 41,915 lb. less; so that we have given no estimate for the present year, but we hope the crop will be, at all events, as much as last year. Against this deficiency for last year your directors wish to point out to you the improvement in the manufacture of our tea. This is entirely due to the excellent advice of our superintendent, Mr. Porter, and also to Mr. Mitchell, our manager, for the careful manner in which this advice has been carried out. I think we stand in the proud position of obtaining the best prices for our tea of any estate in the Kelani Valley district. On one special occasion our broken orange pekoe realised 1s 10½d per lb. You will, no doubt, notice the rather large amount carried forward to next year—sufficient, with the amount placed to the reserve fund, to have paid another good 10 per cent dividend; but this amount is liable for the manager's commission, not yet paid—about £160—and your directors, also recognising the old proverb that "one swallow does not make a summer," prefer not to divide up to the hilt, as tea-planting, like all other industrial occupations is liable to fluctuation arising from a fall in the market, short crops, &c. It will, no doubt, occur to you that the purchase of Wereagalla, mentioned in the report (which has taken a long time to accomplish, and was a source of much anxious thought on the part of your directors and officers), will materially add to our revenue without increasing our expenses to any considerable extent. The estate is within three miles of Degalassa, and will be managed by Mr. Mitchell, our manager there, with the aid of an English assistant. The time having expired last January for which the first portion of our debentures at 6 per cent. were issued, we have had the satisfaction of reissuing the whole of them at 5 per cent., and, had we more at our disposal, could have issued twice the quantity. That has been done without any commission or other expense to the company. In referring back to our first report, 1887, I notice we had then 10 acres of tea in full bearing; now we have 864 acres in bearing, 373 acres in forest and grass, and our factories and bungalows, in all, are worth, at a low estimate, £6,000, and I think it is a very moderate estimate to say your property is now worth between £38,000 and £40,000. (Applause.) I do not think there is anything further I can add, and I now move "That the report and accounts, as presented to the shareholders, be received and adopted."

Mr. Leopold F. Davies seconded the motion.

Mr. H. T. Mennell said he saw, with satisfaction, from the report that there was no intention to issue fresh capital, and that there would be a call made on the last issue of 397 shares.

The motion was unanimously agreed to.

The Chairman moved:—"That a dividend of 15 per cent., free of income-tax, be declared, making in all 20 per cent. for the year, payable forthwith."

Mr. Donald Andrew seconded the motion, which was passed.

The Chairman proposed and Mr. Dudley A. C. Scott seconded:—"That the reserve fund be increased by the transfer of a sum of £345 10s, bringing the amount up to £1,000."

The motion was carried.

The Chairman proposed the re-election of the retiring director, Mr. Andrew, who, he remarked, had served on the board since the commencement of the company, and had always given his best attention to the affairs of the undertaking.

The motion was seconded by Mr. Davies, and carried.

The Chairman proposed a vote of thanks to Mr. Porter, Mr. Mitchell, and the Ceylon and London staff for their efficient working of the company's property. The best illustration he could give the shareholders of the work the staff had done was in the report, which he thought had been satisfactory to all. (Hear, hear.)

Mr. Andrew seconded the motion.

Mr. Mennell remarked that there was no more pleasing feature in the history of the company during the past year than the vast improvement in the quality of the tea sent to market and the increase in the price, that must be largely due to the managers, and he thought some of the shareholders contributed to the result in drawing attention, at the meeting last year, to the importance of that subject. The quality had now gone up wonderfully, and the thanks of the shareholders were due to the managers for having brought that about.

The motion was then unanimously agreed to.

The auditor (Mr. James B. Laurie) having been re-appointed, on the motion of Mr. Mennell, seconded by Mr. C. J. Scott,

Mr. G. W. Dodds moved a vote of thanks to the chairman and directors. He thought that presented was one of the most satisfactory balance-sheets he had ever had in his hand. They had not simply had a lucky year, but the cost of cultivation being £5,000 and the net proceeds of the tea sold £9,170, showed bona-fide business, and they were greatly indebted to the management for their care. He noticed that the general charges, including London office expenses, directors' fees, audit fee, income tax, stationery &c., only amounted to £316 which he thought was extremely small, and he should be glad to move that the directors receive a small honorarium of £100. He thought special credit was due to them for the way in which they had effected the purchase of the Wereagalla Estate. (Hear, hear.)

The motion with the addition, was seconded by Mr. Moss and carried unanimously.

The Chairman briefly acknowledged the vote, and the proceedings terminated—*Financial News*, April 7.

NEWS FROM THE CENTRAL PROVINCE: PLANTING AND OTHERWISE.

(Notes by "Wanderer.")

April 24.

PLANTERS' ASSOCIATION.—The proceedings of the Committee at their last meeting in Nuwara Eliya deserve notice, especially the reply of Government to the letter forwarding the resolution to reduce the railway rates on cocoa. The Governor requires "that some reasons should be given for asking that the railway freight on cocoa be reduced to the same rate per tea as that charged on coffee, tea." Really H. E. ought to have one of his superfluous Civil Servants, now that the paddy tax is abolished, employed to read the daily papers and thus be saved from asking silly questions.

VOLUNTEERING IN CEYLON.—If the Ceylon Government really wish the "mounted fut" to be a success, let the Governor pass an Ordinance to the effect

that all planters under 40 years of age be exempted from serving on the jury if they are all reported to be efficient members of that Corps.

PRICES OF TEA.—Especially of the finest sort will not be better till Home Rule is either granted or knocked on the head, is the opinion of *knowing ones* in the Lane. It is also considered by some that dealers lie low at home when they can buy cheaper in Colombo, and that they play the one market against the other.

CEYLON EXPORT TO DATE—Being reported to be less than at same date last season is most extra ordinary :
 1893 17th April, lb. tea 21,331,794
 1892 21,660,717

Deficiency, this season 268,923
 Who has been bottling up their tea? "The London market" Messrs. Somerville & Co. may well say "is wired firm and prices a shade better" under such circumstances as these.

COFFEE.—Blossoms are reported so far to have set most indifferently, so the export of this product will be a very sad one to chronicle this year. To date however the export is a shade better than last year.

CAAO.—The exports of this high-priced article to date are much higher than at same date in 1892, and even top the export in 1891.

Exports 17th April	1893	cwt.	13,926
	1892		9,230
	1891		10,295

One hears that there is a great deal of native grown cacao in the Kurungala, Matale and Dumbura districts, and that respectable natives are now alive to its value. Thieves of course have been for some time aware of this fact.

CINCHONA—Is going steadily down in our exports and prices follow suit. Planters therefore may congratulate themselves on having so little of it on their hands.

WEATHER.—You seem to be having a high old time of it in Colombo, and the little monsoon is coming in like a "Lion." We ought to have it up here about the 24th. In the middle part of Dimbula it is rather dry than otherwise. Nothing could have been better for the Kurungala, Matale and Dumbura districts than the sunny weather they have had lately.

CEYLON TEA IN AMERICA.—I do think Mr. Pineo piles on the agony on Ceylon men for their indifference to his hero, Elwood May. As a private planter I have dropped \$1,000, for I never expect to see a rupee-cent of it again, on the American Tea Company. Why I should be called apathetic for doing so, I should like Mr. Pineo to explain. All the same I believe Mr. Grinlinton is too 'cute a man to show temper needlessly even though Mr. Elwood May was not ready to meet him, hat in hand when he landed on the shores of the country of the star-spangled banner, &c., &c. It is a case of Greek meeting Greek when Elwood May and our own Joseph have an encounter.

ELECTRIC TEA CURING—"Electricity is being applied to the drying of tea in Ceylon, the process having proved to be more economical than the old method."—Extract from Home Paper. Who is this dark horse? and why does he not give us the result.

CEYLON HOTELS have certainly much improved within the last few years, but they are very deficient in the matter of "early tea." In an otherwise good hotel in Colombo what is served out at that meal consists of highly tanned tea, tinned margarine butter, decaying plantains and toast so tough and unpalatable that we can hardly eat it. In this hotel cautions are freely printed on the walls against the inmates making noises to disturb other inmates. I confess to stamping my feet and using other strong methods of showing displeasure when I get this sort of stuff forced on me in the early morning.

TEA IN JAPAN.—The latest *Japan Weekly Mail* reports—Nothing heard of tea prospects, the cold weather retarding the budding and planters are praying for warm showers. Exchange has again declined, and rates are weak and uncertain.

TEA DRINKING: A FRAGMENT.

Let others relate each heroical deed,
 Of the mad Macedonian, or foolhardy Swede;
 No god I'll invoke, no patron will chuse,
 Nor ask I the aid of a splenetic muse.

—Anony.

DUBLIN. Printed in the Year MDCCLII.

- 1 Sparkling, with youth's gay pride, like mirthful May
 In the Sedan enclosed by slaves up-borne;
 See the love-darting dame, swing 'long the way,
 Or to present the visit, or return.
- 2 The sleek-comb'd valet trimly trips before,
 Loud, thro' the gazing crowd, commanding place;
 With well-tim'd raps he strikes the sounding door
 Thunders in taste, and rattles with a grace.
- 3 Along the pavement grates the swift-stopt'd chair
 Back on its well-oil'd hinges flies the gate.
 Behind the high-held hoop, upspring the fair,
 Rustling in rich array, and silken state.
- 4 The how'd' ye ended, the contest of place,
 And all the fashionable fluttering toils,
 Down, curtsying, sink the laughter-loving race,
 And undisturb'd one moment silence smiles.
- 5 Behold the beau-complexion'd porcelain,
 As bell turn'd tulips variegated show,
 In order set amidst the tittering train,
 Replete with spoils which from Cathaya flow.
- 6 The leading fair the word harmonious gives,
 Betty around attends with bending knee,
 Each white-arm'd fair, the painted cup receives,
 Pours the rich cream or stirs the sweeten'd Tea.
- 7 The chrystal sweets in sparkling fragments view,
 As glittering pebbles in disorder lie;
 Ah! what avails its spangle-candy'd hue
 Like fate-fall'n snow, it must dissolving die.
- 8 Thus when black scandal taints the fair-form'd toast
 Heedlessly fall'n to ap, ette a prize;
 Drown'd by despair she drops, her lustre's lost
 Sinking in shame, and mourning melting dies.
- 9 With verdant Hysou fill'd, Libation rare,
 The flow'ry figur'd-fair enamel fume:
 The odour-spread'ng s'cams regale the fair,
 And breezy fragrance fills the rich-spread room.
- 10 Within the circ'd smooth transparent brim,
 How prettily the fair-ones prattling sip:
 While rising bubbles o'er the surfac skim,
 Mantling with joy to meet each lovely lip.
- 11 Not so the sons of Riot, sickly Train,
 Dos'd mid-t Circian cups they waste the day:
 The silent hours of night with noise prophane
 And dawn inglorious, cool reflection's ray.
- 12 Ye sons of thirst; ye health-aborbing race,
 Shan the insidious glass, rich reason's bane,
 Ere purpl'd poisons scorch the pimpl'd face,
 And boil the blood in each pulse-waiting vein.
- 13 Bloat the bloom'd cheek, the sparking eyeballs bear
 Make pale the healthy, and unnerve the strong,
 Swell the small waist, the memory impair,
 And steal each secret from the stammering tongue.
- 14 Free from disease the active, temperate feast,
 Each dainty meal by exercise they prove
 What courts may envy thy unsated taste,
 The joys of health, of liberty, and love.
- 5 While taper fingers tend the spiral blaze
 The shiuing lamp on the firm tripod flames,
 The sacred fire thus on the altar plays,
 Thus stood around the spotless vestal dames.
- 16 Thus they prepared the sacrificing feast,
 While fragrant clouds involv'd the massy shrine,
 Thus fell the victim by the blood-flush'd priest,
 To bribe success, or satiate wrath divine.
- 17 Improv'd these rites our British-fair retain,
 Lodge there in finest forms such fierce designs,
 The ancients only offer'd up the slain,
 But living victims glut the modern shrines.
- 18 O'er the rich incense-breathing fumes, preside,
 How'ring on harpy wings, the traffic show,
 Envy, self-plu'd, suspiou yellow-eyed,
 And venom-breathing sea-dal, merif's foe.
- 19 Ill-nature, like an antiquated maid,
 Cluts her foul spleen with headless beauty's fate,
 Thus Casar at the foot of Pompey laid,
 Became a prey to each pale coward's hate.

- 20 The veteran fair in chastity grown grey,
Are cruel, crabbl'd, bitter, base and wroge:
A's! the finest vines as well as they,
Will turn to vinegar if kept too long.
- 21 Chance can, like death, the fairest forms confound,
Thus sobb'd th' unhappy, poor unthinking maid,
As from her hand a saucer slip'd to ground,
In many-colour'd shining fragments laid.
- 22 Tho' sweetly shows the snow-complexion'd toast,
In pearly pride, and flowry bloom full blown,
In one sad moment thus her beauty's lost,
If careless crabb'd, or craftily o'erthrown.
- 23 Be warn'd ye fair, around ye dangers wait,
Let caution guide your steps where'er you go,
Like China, ladies' charms submit to fate,
As pure, as bright, but yet as brittle too.
- 24 Do not, ye lovely, love's fond laws despise,
Mark on each cheek the scars of time,
Examples fear—obey him and be wise,
Accept the hint—be happy in your prime.
- 25 See the bright planet of the new-born day,
Dart on the virgin rose-bud's leaves,
Unfolding fragrant to his powerful ray,
His genial heat white-spreading, she receives.
(Cetera desunt.—The rest is wanting)
FINIS.

INDIAN PATENTS.

Calcutta, the 23rd March 1893.

Applications in respect of the undermentioned inventions have been filed, during the week ending the 18th March 1893, under the provisions of Act V. of 1888, in the Office of the Secretary appointed under the Inventions and Designs Act, 1888:—

No. 81 of 1893.—Thomas Cattell Jones, M.R.C.S., Eng., L.R.C.P. and L.M., Edin., and George Winter, Tea Planter, both of Shumshernugger Tea Estate, Shumshernugger, Sylhet in Assam, British India, for a new or improved mixture for preserving tea bushes, trees and the like from the attacks of insects, to be called "Red Spider and Blight Destroyer."

No. 86 of 1893.—T. Drewet, Jr., and Palouji D. Chowna, both Engineers and Contractors of 17, Elphinstone Circle, Bombay, for improvements in fibre beling machinery.

Specifications of the undermentioned inventions have been filed, under the provisions of Act V of 1888, in the Office of the Secretary appointed under the Inventions and Designs Act, 1888. Copies have been sent to the Governments of Fort St. George and Bombay, the Chief Commissioner of Burma, and the Director, Department of Land Records and Agriculture, North-Western Provinces and Oudh. A copy of every specification is open to public inspection from 11 a.m. to 4 p.m. at the Office of the Secretary appointed under the Inventions and Designs Act, 1888, in the Imperial Secretariat Buildings, Government Place, West, Calcutta, upon payment of a fee of one rupee. A certified copy of any specification will be given to any person requiring the same on payment of the expense of copying:—

No. 89 of 1892.—David Rowell, Engineer, of 5 Victoria Street, in the City of Westminster, for improvements in apparatus for withering or drying tea. (Filed 9th March 1893.)

No. 152 of 1892.—Henry Thompson of Gainsborough in the County of Lincoln, Engineer, but now residing at Ipswich in the County of Suffolk, for improvements in the method of and apparatus for drying tea leaf and the like. (Filed 10th March 1893.)

No. 208 of 1892.—Beaumont Richard Harrington, Civil Engineer, of No. 1, Wood Street, Calcutta, for an improved refuse and excrement incinerator. (Filed 25th February 1893.)

The 29th March 1893.

No. 88 of 1893.—Luis Jose Pinto, Licentiate of Medicine and Surgery, residing in Cavel, Bombay, for a machine for husking and paring rice and other cereals.

No. 100 of 1892.—Samuel Cleland Davidson, of Sirocco Works, Belfast, Ireland, Merchant, for improvements in apparatus for drying tea or other substances. (Filed 7th January 1893.)

No. 300 of 1892.—Samuel Cleland Davidson, of Sirocco Works, Belfast, Ireland, Merchant, for improvements in air-heating stoves. (Filed 25th March 1893.)

No. 13 of 1893.—William Bull, Civil Engineer, at present residing in Calcutta, for an improvement in the burning of bricks and tiles. (Filed 13th March 1893.)

CALCUTTA, the 13th April 1893.

Applications in respect of the undermentioned inventions have been filed during the week ending the 8th April 1893, under the provisions of Act V. of 1888, in the Office of the Secretary appointed under the Inventions and Designs Act, 1888:—

No. 101 of 1893.—Albert Angelo Lacey, of 116, Ripon Street, Calcutta, for extracting fibre from the agave or aloe, pineapple, and other fibrous plants.

Specifications of the undermentioned inventions have been filed, under the provisions of Act V. of 1888, in the Office of the Secretary appointed under the Inventions and Designs Act, 1888.

No. 105 of 1892.—Syed Anir Ali, Coffee Planter, at present an inhabitant of Hassan in the Province of Mysore, in the Madras Presidency, for certain improvements and alterations in his invention called the "Hussani Coffee Peeler." (Filed 30th March 1893.)

No. 250 of 1892.—Humphry Aram Hole, Tea Planter, of Atrgram, Sylhet, for an improved tea-drying machine which can also be used for withering fresh tea leaf. (Filed 4th April 1893.)—*Indian Engineer*, April 22.

TEA AT FOOCHOW : NOTES.

Heavy rains are reported to have fallen upcountry at the end of last week and the commencement of this, to the great satisfaction of the farmers, as they were much needed by the land. It is impossible to say what the natives have to go on, but it is predicted by them that the river will be swollen to an extraordinary extent at the commencement of the 3rd moon (middle of April) and that big floods may be expected.

A coming war with Russia is freely talked about as the latest news at the tea-house in the city and in the streets. Without any known, real foundation for this, we can only account for its having arisen from a paragraph which appeared lately in the *Shenpao*, stating that a number of trained officers, and fifty men from the Viceregal troops, with 40 field guns, and 2,000 rifles, are to be despatched shortly to the frontier province.—*China Mail*, April 13.

THE FUTURE OF TEA.—There was a great gathering of Ceylon men at a residence at Guilford a night or two ago at which were present Messrs. Sparkes, Mr. Forbes, of Inverly, and Mr. Robertson, a former planter in your Island, now of the Mincing Laue fraternity. Ceylon topics were, of course, freely discussed, and amongst other subjects that of tea and its future was to the fore. The opinion which is gaining ground on all sides, and which certainly was held by the Guilford gathering, is that the days of high priced teas are numbered amongst the things of the past. At the same time I incline to the belief that there will always be a certain demand for really fine grade teas: look, for instance, at what I am writing you about the figure at which the Imperial Institute contractor is prepared to take Ceylon Tea for use in the Refreshment department of this new Exhibition, which promises to be patronised by the "Upper Ten" on South Kensington, especially if, as reported, the Prince of Wales gives the tone to the *al fresco* gatherings in the open, brightened as they will be by good music and illuminations—a sort of West End Tivoli!—London *Cor.*, local "Times."

THE TECHNICAL INSTITUTE.

In an interview with the representative of a contemporary Mr. Human, the Instructor of the Technical Institute which will be temporarily carried on in the Old St. Sebastian Mills is reported to have said with regard to the curriculum:—

"In the wood-work shop we shall teach the principles of working in wood, with no regard to any particular branch of trade. The training we shall give will be such as will fit a pupil for beginning any kind of woodwork, and it will also fit him for handicraft in other directions. We shall teach him how to handle and use tools, how to make joints, how to use the plane, and the use of tools generally, and in illustrating these, more or less useful ends are looked to. We shall have lathes for wood-working also. In the metals workshop there will be training in the uses of the lathe and planing and drilling machines, and the students will have to do a certain amount of smith's work. The training is of a very thorough nature, and before a student makes a thing he has to draw it, after which he makes it according to the drawing, and this he will be taught to do in the drawing school; while the lectures will further increase his knowledge of fundamental principles and their applications, and when the pupil has acquired this knowledge, higher work can be undertaken under the auspices of the school, and he will be able to draw more complicated objects—which he need not make, although there will be a chance for him to make them. Suppose a complete machine is undertaken, I mean, he will work on parts of this machine; also he will undergo a training in the laboratory for mechanics and physics, and get a grounding in the general laws which govern the motions of bodies, the stability and equilibrium of structures, and the strength of materials, and similarly in Physics, by means of handling the apparatus which exhibits them. In the physical laboratory the first thing a student will be required to do will be to make a thermometer.

With regard to the cost of the school he said:—

"I cannot say even approximately yet what the cost of the school is likely to be. In the larger schools in England the deficiency that has to be made up is about £2 a head every year. These are very large schools, however; in smaller schools the deficiency is greater. Here, with the low fees that prevail, the deficiency would of course be larger. Suppose, say, the cost of the school were about £600 and we had 50 students, I do not suppose we would get much more than £1 a year from each out of the students, which would leave a deficiency of £550, or £11 a head. I hope, however, we will be able to get more than a pound a head in the way of fees. We shall not make articles for sale. The objection to that is that, instead of pupils learning, it makes the school more of a factory, and the school must not take the place of a factory in any sense.

IMITATIONS OF PRECIOUS STONES.

A recent writer in a Washington technical journal describes the methods employed for producing imitations of precious stones. He says that in manufacturing glass for this purpose the processes employed have to be conducted with the utmost nicety. For making even the best mirrors the necessary silica is obtained from ordinary white quartz, while common window panes are produced from sea sand to a large extent; but in this case rock crystal is substituted, composing about 50 per cent of the ingredients of the paste. To it must be added 22 per cent of carbonate of soda, and due proportions of calcined borax, saltpetre, and red lead. All of these things are reduced to the finest powder, mixed, fused together by heat in a crucible and cooled slowly. The density, transparency, and beauty of the plate depend upon the care taken in these processes. Thus, made it is ready to be cut into diamonds and prepared for market. It may be, however, that the manufacturer desires to produce counterfeit gems of all

sorts. If he wants rubies he fuses with the paste a small quantity of peroxide of manganese and a trace of Cassius purple, which will give the proper colour. For emeralds he employs in like manner oxide of iron, and for sapphires oxide of cobalt. Topaz is easily formed in the crucible by mixing with 1,000 parts of paste, 40 parts of glass of antimony, and 1 part of Cassius purple. For manufacturing other kinds of gems there are methods equally simple. Of course these imitation precious stones have not the chemical construction, hardness, specific gravity, or optical properties of real ones. Accordingly their spurious character is readily perceived by an expert. Inasmuch as the elements of which various gems are composed are well-known, synthetic chemistry has attempted to reproduce them by putting the ingredients together and effecting crystallisation in the laboratory. In this way large masses of what might be termed true rubies and sapphires are turned out artificially, such gem-like material having some usefulness for industrial purposes, although lacking the brilliancy of nature's products.

THE COMING JAVA CINCHONA CROP.

From a return just to hand which has been compiled by the Java Planters' Association, a Commission of which has collected statistics from all the plantations on the island, (with a very few unimportant exceptions), it appears that the exports for the year 1893 are likely to amount to 3,783,899 kilos. of bark (against 3,232,922 kilos. in 1892), representing 169,761 kilos. sulphate of quinine, as compared with 138,315 kilos. last year. The average percentage of the bark this season (quin. sulph.) is estimated at 4.48; last year it was 4.27. If these figures prove approximately correct (as the statistics for the last four seasons have done), the present year's exports will exceed by about 10 per cent, those of 1891, when they were the highest on record, and will surpass those of 1892 by 17 per cent. in weight and by 23 per cent. in quinine value. "This increased production (the Commission report) is in some degree due to the total or partial uprooting of a few plantations, and in some degree to the fact that younger plantations of a higher standard are gradually being brought into exploitation." "Java, they add, "till remains on the wrong edge of over-production, and caution should be exercised in harvesting and in laying down new plantations." Out of ninety-seven plantations now in existence on the island, five are not yet harvesting anything, six will produce a crop for the first time this season, three have been wholly or partially uprooted, and six are temporarily suspending their bark shipments.—*Chemist and Druggist*, April 8.

PROSPECTS OF THE TEA SEASON AT FOOCHOW.

The departure of many of the teamen this week for what are known as the high districts, with treasure, opium and lead for the purchase of the new season's leaf, leads to the consideration of what the prospects are for season 1893-94. The information given us at this time last year by certain teamen of our acquaintance regarding the prospects last season proved to be so correct that we are quite willing to give credence to what we have learned from the same source within the last few days. The general impression is that foreign buyers have done well in the past season. Much importance is attached to the traditional belief that a tea crop following a heavy fall of snow must be a good one; and on the strength of these premises more men and more money are going up country than last year. This means more competition and consequently higher prices; for, contrary to the general experience that a good crop will be a large one, this year, is, according to accounts from the country, to prove a singular exception. The reason given for this is that the ends of the branches of the plants were so frost-bitten that they had to be cut back to such an extent that the points

of flushing were lessened considerably; and so the weight of production will necessarily be greatly reduced. On this account, the growers estimate that they will be able to pick no more than they did last season under the most favorable conditions of weather. Our informants, interviewed separately, who by the way are all natives of this province, are unanimous in their belief that the foregoing sketch of how matters stand at the present moment is substantially correct. The crop is expected to be better in quality than last season, but the yield will be smaller—of the first crop, at any rate. There is no doubt in our informants' minds about the prospective greater competition up-country as compared with last year; not only by the local and Chiu-chew men, but the Cantonese. This is thought so seriously of by one or two of our friends that they intend to stand aside until the first crop is picked; they fear that prices may be run up too high, and that they will lose their money; they will watch the course of events with a view to getting in on more favorable terms with the second crop.

It will be a great thing for the trade if the new crop shows a marked improvement in quality; but foreign buyers cannot afford to pay any higher prices than they did last season—indeed, to act on lines of safety, they should lay down their teas lower. Although the first crop last season was laid down at 20 to 25 per cent. cheaper than the previous season, the small profit which was obtained on the average (for many of the teas lost), was really only realised through the outside circumstance of the bulk of the Hankow crop being in "weathery" condition. If the Hankow crop is a good one next season, and in good condition, Foochow Congou can scarcely be expected to sell as well as they did last season. The Canton men are full of there being no stock of China Congou left in London on the 1st June. Certainly it will be small. It may be estimated at 5 to 6 millions lb. against 12 millions at the same date in 1892, but this will be ample considering the further falling-off there has been in deliveries. From the 1st June 1891 to 31st May 1892, these were 51,192,000 lb. or 4,266,000 lb. per month, while those for the current twelve months ending 31st May may be estimated, at the outside, at 43,648,500 lb. or 3,637,875 lb. per month. So that 5 to 6 millions lb. stock, is in our view, ample. Those of the Canton men who think that this stock will justify them in being bolder than they were last year will assuredly lose their money. Letters of caution, not to be led away by the results of last year, are already beginning to arrive from London; while all the foreign buyers will, of their own accord, only act on lines of safety, so that those tea-men who are reckoning on higher prices being paid in this market than last year, and buy in the country accordingly, will find themselves greatly mistaken. Of course statistically the trade generally is in a very sound position. And there is also a talk of China tea returning into public favour at home; but the alarming continuance of the falling-off in the deliveries of Congous must, or should, be taken as a better guide to shippers than talk; then they improve, then there will be grounds for hope of better times. Shipper's have fortunately made money in the past season but it has been made as it were by accident, that is to say, in the early part of the season through the had condition of the Hankow crop, and during the last few months through a partial failure of the Indian and Ceylon crops which prevented the estimates of supply being reached. By way of emphasising our point, we would ask how would Foochow ventures have fared in the past season, even at their first low cost had the Hankow crop been in good condition and the estimates of supply from India and Ceylon been realised? We repeat, that if the tea-men expect a higher range of prices to rule in this market for first crop teas than were current last year they are labouring, in our opinion, under a very great mistake. Although we have made no mention of the Australian colonies being large buyers in this market, the tea-men may rest assured that they will pay no higher prices than the buyers for the London market.—*Etc.*

NOTES ABOUT COFFEE.

We quote the following from our Upper Chatham Street contemporary:—

LIBERIAN COFFEE IN THE STRAITS.

The M. M. Steamer "Salazie" sailed today (Monday) for Marseilles with several Ceylon friends. Amongst others who left by her was Mr. V. R. Wickwar (brother of Mr. J. Wickwar of Nuwara Eliya), who has been spending a month of his leave in Ceylon. He left here about 11 years ago for the Straits, since when he has been planting, and is now Manager of one of the finest Liberian coffee estates in the Peninsula. Mr. Wickwar speaks in terms of the highest confidence of the future of Liberian coffee in the Straits. Linsim estate, of which he has charge, is one of the show places of Snajei Ujong, where it is situated. It bears about 8 owt. an acre regularly, and the difficulty concerning labor, which used to trouble estates in that part of the world, is not now anything like so prominent. Tamils are coming over in fair number, and although R20 per head has to be paid for freight, labor is fairly abundant, if somewhat dearer, than in Ceylon. Mr. Wickwar has a railway station within 4 miles of his estate; so that he is in quite civilized and get-at-able quarters. The climate, he says, is good as soon as the jungle is cleared, and he is of opinion that a very prosperous future is before the planting industry in the Straits' so far as Liberian coffee is concerned. Mr. Wickwar, goes home on nine months' leave, and we hope he will have an enjoyable holiday.

COFFEE IN NYASSALAND.—Mr. J. W. Moir, formerly manager of the Lakes Company, has purchased one of their properties, and is adding a 40-acre clearing to the 200 already planted. One of the sons of the late James Imlah of Hapntale has given up his work as marine engineer, and is hard at work planting in Nyassaland. The weather six weeks ago is described as similar to that of Uva or Lower Udapusselawa. A nicer climate could not be wished for. There is a good deal of fever at times, but it is of a mild type. It would seem to be of no use young men going there without money; but a few hundreds might be very well invested with every prospect of a good return.—Local "Times."

CEYLON TEA IN LONDON.

About the selling of our teas by a Ceylon Tea Company which until very recently, had confined its entire attention to Ceylon teas pure and simple; and that the change had been decided upon in self-defence. To confirm these words of your correspondent, let me quote from the *Grocer's Review* the prices offered by the United Kingdom Tea Company, Limited, which, with every other tea-trading company, is scrambling for all sorts of business, and appeals to the grocer for orders at the same time that it is advertising in the daily papers for the grocers' customers. The advertisement above referred to runs as follows:—

" UNALTERED

By the market either in
QUALITY OR PRICE.

There is no occasion for grocers to do with a fraction less profit on the teas they retail; on the contrary, they can make more money provided they place their orders in the right direction:

	O	at	9d	Duty paid.
OO	"	10	do	
A	"	11	do	
B	"	11½	do	
C	"	1s 1d	do	
D	"	1s 2½d	do	
E	"	1s 4d	do	
F	"	1s 5½d	do	

Tea bags, attractive window hills, and window tickets gratis."

There is also a line about "Orders of £3 and upwards carriage paid." As it is not quite certain whether this refers to the above blends or packed Ceylon teas in same advertisement, I do not remark further on the item of carriage.

This advertisement of the United Kingdom Tea Company on a par with that of all the other great firms. The tea trade is "out" like every other trade, and the middleman, as can be seen from the prices of the U. K. T. Co., is not having that good time that he is popularly supposed to enjoy. To sell teas at 9d and 10d, duty paid, is simply to conduct business at a loss which has to be re-couped out of the higher grades, and the cut-throat competition, which is a feature of this end-of-the-century trading, must make the older firms, like Peek, Winch & Co., Hanson, and others, long for the good old days never to come back again. The Ceylon specialist is rather given to make little of Indian teas. The firm which attempts to send out travellers to sell Ceylon alone will find out by hard experience that the traveller wants to sell what the trader asks for. He will not long encounter being shown the door by being unable to offer any other sort of tea than Ceylon without objection. Whilst the packet trade was in full swing he had the whip hand of other travellers, because he was offering what every other traveller was offering, with the advantage of his Ceylon being plainly the genuine article. But the packet trade is salt and blends are up, and the traveller worth his salt must have blends or go to the firm who will do them.

What has become of Ceylon green tea. "In self-defence," tea wholesalers in London have to go back to "good old China" for this article, which has a very strong hold abroad in many parts. Over and over again opportunities of foreign trade have been missed by me, because I could not supply what was wanted, viz., green tea. Only this week I have executed an order for green tea for Rio de Janeiro, and would gladly have sent Ceylon, as it would have saved a special label. Price would not have stopped Ceylon being used, as a fine tea was required for which I paid 1s 5d. I should imagine that it ought to pay to produce green tea to compete with the China article. It is useless to say let them drink black. I lately attempted this for Morocco, and to this day I have not sent a pound of tea to that market, though I had excellent chances of an established trade, although I live in hopes of doing so. Ceylon first by all manner of means is my motto; but if they won't have Ceylon don't throw them up, but peg away with what they will take, and eventually get the thin end of the Ceylon wedge in and then drive it home.—A London Cor., local "Times."

ARTIFICIAL INDIARUBBER.

One of the most important events in the history of chemistry during the past year was the discovery by an English professor that a substance corresponding in every respect to indiarubber may be produced from oil of turpentine. Dr. W. A. Tilden began a series of experiments last spring with a liquid hydrocarbon substance, known to chemists as isoprene, a product of the destructive distillation of indiarubber. In 1884 Dr. Tilden discovered that an identical substance was among the more volatile compounds obtained by the action of moderate heat upon oil of turpentine and other vegetable oils, such as rape seed oil, linseed oil and castor oil. Isoprene is a very volatile liquid, boiling at a temperature of about 36 degrees Fahrenheit. Chemical analysis shows it to be composed of carbon and hydrogen in the proportions from five to eight. In the course of his experiment, Dr. Tilden found that when isoprene is brought into contact with strong acids, such as aqueous hydrochloric acid, for example, it is converted into a tough elastic solid, which is, to all appearances, true indiarubber.

Specimens of isoprene were made from several vegetable oils in the course of Dr. Tilden's work on those compounds. He preserved several of them and stowed the bottles containing them away upon an unused shelf in his laboratory. After some months had elapsed he was surprised at finding the contents of the bottles containing the substance derived from the turpentine entirely changed in appearance. In place of a limpid, colorless liquid the bottles contained a dense syrup, in which were floating several large masses of a solid of a yellowish color. Upon examination this turned

out to be indiarubber. This is the first instance on record of the spontaneous change of isoprene into indiarubber. According to the doctor's hypothesis this spontaneous change can only be accounted for by supposing that a small quantity of acetic or forenic acid had been produced by the oxidizing action of the air, and that the presence of this compound had been the means of transforming the rest. Upon inserting the ordinary chemical test paper the liquid was found to be slightly acid. It yielded a small portion of unchanged isoprene. The artificial indiarubber found floating in the liquid upon analysis showed all the constituents of natural rubber. Like the latter it consisted of two substances, one of which was more soluble in benzine or in carbon bisulphide than the other. A solution of the artificial rubber in benzine left on evaporation a residue which agreed in all characteristics with the residuum of the best Para rubber similarly dissolved and evaporated. The artificial rubber was found to unite with natural rubber in the same way as two pieces of ordinary pure rubber, forming a tough, elastic compound.

Although the discovery is very interesting from a chemical point of view, it has not as yet any commercial importance. It is from such beginnings as these, however, that cheap chemical substitutes for many natural products have been developed. Few persons outside of those directly connected with rubber industries realize the vast quantities imported yearly into this country. Last year there were brought into United States ports, as shown by the reports of the customs officers, no less than 84,348,000 pounds of indiarubber. The industry has been steadily progressive since the invention of machinery for manufacturing it into the various articles of every-day use. The wonderful growth of the indiarubber interests in this country will be seen from the statistics compiled in the tenth census.

In 1870 there were imported 5,132,000 pounds at an average rate of \$1 per pound; in 1880 the imports were 17,835,000 pounds, at an average price of 85 cents per pound; in 1890, 31,949,000 pounds were imported, at an average price of 75 cents per pound. The present price of Indiarubber varies from 75 cents per pound for the Para rubber to 45 cents per pound for the cheapest grade. It will be seen that notwithstanding the increase in importations the price of the raw material remains at a comparatively high figure. Many experiments have been made to find a substance possessing the same properties as indiarubber, but which could be produced at a cheaper rate.

Many of the compositions which have been invented have been well adapted for use for certain purposes and have been used to adulterate the pure rubber, but no substance has been produced which could even approach indiarubber in several of its important characteristics. There has never been a substance yet recommended as a substitute for rubber which possessed the extraordinary elasticity which makes it indispensable in the manufacture of so many articles of common use. Great hopes were at one time placed in a product prepared from linseed oil. It was found that a material could be produced from it which would to a certain extent equal indiarubber compositions in elasticity and toughness. It was argued that linseed oil varnish, when correctly prepared, should be clear, and dry in a few hours into a transparent glossy mass of great tenacity. By changing the mode of preparing linseed oil varnish in so far as to boil the oil until it became a very thick fluid and spun threads, when it was taken from the boiler, a mass was obtained which in drying assumed a character resembling that of a thick, congealed solution of glue.

Rosin was added to the mass while hot, in a quantity depending upon the product designed to be made, and requiring a greater or less degree of elasticity.

Many other recipes have been advocated at different times to make a product resembling caoutchouc out of linseed oil in combination with other substances, but all have failed to give satisfaction, save as adulterants to pure rubber.

Among the best compounds in use in rubber factories at present is one made by boiling linseed oil to the consistency of thick glue, Unbleached shellac and

a small quantity of lampblack is then stirred in. The mass is boiled and stirred until thoroughly mixed. It is then placed in flat vessels exposed to the air to congeal. While still warm the blocks formed in the flat vessels are passed between rollers to mix it as closely as possible. This compound was asserted by its inventor to be a perfect substitute for caoutchouc. It was also stated that it could be vulcanized. This was found to be an error, however. The compound upon the addition of from 15 to 25 per cent of pure rubber may be vulcanized and used as a substitute for vulcanized rubber. Compounds of coal tar, asphalt, &c., with caoutchouc have been frequently tested, but they can only be used for very inferior goods. The need for a substitute for guttapercha is even more acute than for artificial indiarubber. A compound used in its stead for many purposes is known as French guttapercha. This possesses nearly all the properties of guttapercha. It may be frequently used for the same purposes and has the advantage of not cracking when exposed to the air. Its inventors claim that it was a perfect substitute for indiarubber and guttapercha, fully as elastic and tough and not susceptible to injury from great pressure of high temperature. The composition of this ambitious substance is as follows: one part by weight, of equal parts of wood, tar, oil and coal tar oil, or of the latter alone, is heated for several hours at a temperature of from 252 to 270 deg. Fah., with two parts, by weight, of hemp oil, until the mass can be drawn into threads. Then one-half part, by weight, of linseed oil, thickened by boiling, is added. To each 100 parts of the compound one-twentieth to one-tenth part of zokerie and the same quantity of spermaceti are added. The entire mixture is then again heated to 252 deg. Fah., and one-fifteenth to one-twelfth part of sulphur is added. The substance thus obtained upon cooling is worked up in a similar manner to natural indiarubber. It has not been successfully used, however, without the addition of a quantity of pure rubber to give it the requisite elasticity. A substitute for guttapercha is obtained by boiling the bark of the breh tree, especially the outer part, in water over an open fire. This produces a black fluid mass which quickly becomes solid and compact upon exposure to air.

Each guttapercha and indiarubber factory has a formula of its own for making up substances as nearly identical with the natural products as possible, which are used to adulterate the rubber and guttapercha used in the factory. No one has as yet, however, succeeded in discovering a perfect substitute for either rubber or guttapercha.

Isoprene, from which Dr. Tilden produced indiarubber, is comparatively a new product, as derived from oil of turpentine. It yet remains to be seen whether rubber can be synthetically produced certainly and cheaply. The result of farther experiments will be awaited with interest, as the production of artificial rubber at moderate cost would be an event of enormous importance.—*Oil, Paint and Drug Reporter.*

COFFEE-PLANTING is being pushed on the West Coast of British North Borneo by Mr. R.M. Little, the Resident, and by Mr. P.F. Wise, who are distributing Liberian seeds and seedlings among the natives. The system adopted in Java ensures the planting by each man of at least fifty coffee trees, the produce of which must be sold to the Government at a fixed price.—*Indian Agriculturist*, April 22.

PENANG.—A small plantation of economics at the end of the garden includes Camphor, Nam-Nam, a native fruit; Cola Nut, like Cocoa, from Kew; Chinese Leeches, Jack and Bread Fruits. This has been made too recently for any results, but in time the experience gained in this garden will doubtless prove useful to the planters in the island. Opposite this, near a Poinciana regia and young Grevillea robusta are different kinds of rubber plants, and some Liberian Coffee; a curious rubber is Landolphia Kirki, a climber from Africa.—A TRAVELLER'S NOTES,—*Gardeners' Chronicle.*

CEYLON TEA PLANTATION COMPANY, LTD.

THE PREMIER CEYLON COY.—TOTAL DIVIDEND FOR
1892 EQUAL TO 15 PER CENT.

We are very pleased to learn from Mr. Talbot, the Ceylon Manager of the above Company, that he has received a telegram advising that the directors have declared a final dividend of 8 per cent making the total for the past year equal to 15 per cent. As a considerable portion of the development of the young estates has been charged to upkeep during 1892, and the sum of £6,275 written off for depreciation, as well as £5,000 added to the Reserve Fund, (making the latter up to £25,000),—the results of last year's working may be looked upon as very satisfactory. We heartily congratulate the Directors, Mr. Talbot and the local Staff generally, on the good results to their labours.

A NEW TEA BREAKER.

A patent has just been taken out in the names of Mr. Wm. Cameron, planter, Ythanside, and Mr. Jas. Brown of Messrs. Brown & Co., Hatton, for a new tea breaker called the "Equalizer." A model of it and samples of tea broken by it have been on exhibition at the premises of Messrs. Brown & Co. and they have so commended themselves to men of experience in tea manufacture that quite a number of orders has already been placed with the firm. The "Equalizer" differs from other breakers in this respect that it breaks the tea longitudinally instead of across. It is of very simple construction consisting chiefly of two plates with fingers or batons which come together and crush the tea between them, the pressure being regulated by an adjustable weight. The novelty of course consists of the action of the two plates and the incisions on the face of them. The machine can be worked either by hand or by power and can be supplied with or without sifters. It is somewhat like Sutor's roll breaker and sifter made by the same firm, and, as we have already stated, has caught the fancy of many. The principal credit for the invention is due we believe to Mr. Cameron who has devoted his attention for a number of years to the improvement of tea machinery, and we cordially congratulate him upon this latest development of his inventive genius. The manufacturers are also to be complimented upon the manner in which they have carried out the idea of the inventor.

TEA CULTIVATION AND PROSPECTS IN CEYLON.

(By a Planter of experience.)

MR. JOHN HUGHES' CONCLUSIONS: QUALITY V. QUANTITY.
HOW "ASSAM" BEAT "CEYLON" IN 1892.

ECONOMY OF LABOUR AND THE NEW PATENT TEA
PLUCKERS.

I don't know what to say about Hughes' conclusion. But I do know, that unless in very small quantities fine teas do not pay. While only a few estates make them, their stand-out price may be worth getting. But some of the large pick-t distributors make their 'finest tea in the world' out of very cheap material. And until they raise their retail price, they must do so, as one way or another profit and expenses, they make 4-1 per lb.

Yes, Assam beat us in price in 1892; but I also know, some of those interested, regret they went for quality instead of quantity.

Some one ridiculed my figures a few months ago when I said 2-7ths of our labour might be saved by using patent clippers, instead of Coropy's deft and agile fingers.

Since then I have been looking closely into the matter, and have seen many times, the fields on which the machines have been used, in the Dikoya district, as well as tried them myself. Throwing out *weeding* which is almost roughly done by contracts, I find that of 22,000 coolies working in 6 months 14,000 were plucking.

Taking 15 lb. as the average by hand plucking and 30 lb. by machine (much under what is really the case) I would have saved half my plucking force, or 7,000 coolies—or rather more than 2-7ths—Q. E. D.

The "clippers" in use are about as clumsy, flimsy and expensive as patents generally are at first. But the principle once established, a cheap, handy, well-made tool will follow. Already women work them as well as men, and a large wide-mouthed basket hanging at its side, has displaced its awkward and troublesome cradle which was attached to the cooly's back.

TROUT ACCLIMATISATION IN THE EAST.

We are indebted to the courtesy of the Honorary Secretary of the Nilgiri Game Association for some interesting information relating to the latest attempt to introduce trout into the rivers and lakes of the Blue Mountains. It will be remembered that last December the Association had the bad luck to lose a batch of ova imported in the "Golconda" owing to their being frozen to death in the ice house. Undeterred by this misfortune, as by many previous pieces of ill luck—evidently in the lexicon of N. G. A. there is no such word as *fail*, and if continued effort in the face of frequent disappointments merit success, then the Association certainly deserves it—a telegram was despatched to Mr. Silk, the Superintendent of the Marquis of Exeter's Fish Hatcheries at Burgleigh Park, Stamford, to despatch immediately 20,000 more ova on the 24th December. Unfortunately Mr. Silk delayed despatching the ova till the 27th January, when a case was shipped by the "Manora." To meet her, the Honorary Secretary went to Madras, where the case of ova on 2nd March, and arrived with it at Ootacamund on 4th. When the case was unpacked the ova were found to be in splendid order, the percentage of dead ova being very small. Unfortunately the temperature of the water in the hatching boxes had risen to 67 degrees and ice had to be put in to reduce it, but it was not found practicable to keep the temperature below 60 degrees even with ice. The daily loss of ova from this cause amounted to about 200 till the 24th March when they began to hatch out. Previous to hatching out the temperature of the water fell for several days to 55 degrees on an average, owing to thunderstorms which brought down a considerable amount of silt. A sudden rise of temperature on the 24th and 25th March was most prejudicial, and the loss of ova great. A large number of the fry hatched out died immediately, some when only half out of the eggs. On the 2nd April only 293 fry were left and some 70 ova. The number of fry and ova gradually decreased till on the 8th April only 201 healthy fry had survived. These so far appear to be getting on well, though the ova sacs have not yet been completely absorbed.

A few particulars regarding the packing of the ova, their transport, and subsequent treatment may be of interest to others engaged in similar enterprises, such as our Ceylon friends and the Dehra Dun Fishing Association, which has been somewhat unsuccessful of late in its expensive experiments dealing with the "Golconda first—the ova sent out in that

vessel were packed in a case so large that it could not be got out of the ice house without first unscrewing it and lifting it out sideways. The ova were packed in cloth with cotton wool above them. When the case was taken into the ice house and out of it sideways, the ova all collected in a mass on the lower side of the trays, where they were subsequently frozen. When these ova were removed from the trays it was found necessary to thaw the frozen cotton and ova by pouring cold water over them, and when the ova were put into the hatching boxes, the temperature of the water of which was then 46 degrees, they all immediately turned opaque, due to their being thawed.

To avoid any such misfortune with the shipment by the "Manora" Mr. Silk was given clear instructions to pack the ova in a box which could be conveniently removed out of the cool house upright, and instead of the ice tray being screwed on to the ova box it was arranged to fix it on with hooks. The ova were to be packed in Irish water moss and the case slung in the cool room. The result was that these directions having been carefully attended to, and the butcher of the ship having daily filled the ice tray with fresh ice the ova, as already mentioned, arrived in excellent condition. The exact dimensions of the ova box being previously known, the Honorary Secretary was provided with a deal box exactly three inches wider every way. The ova case was placed in the deal box, crushed ice filled in all round it, and the whole covered up with blankets, it was slung up and removed to the deck and then ashore. The box was then kept in a hotel, the temperature being taken every half hour, and kept at 38 degrees. At 5 p.m., the case was removed to the Railway station, and slung to the roof of a third class compartment, two attendants being employed the whole night in renewing the ice, of which a supply of 400 lb. was taken. From Mettapolinn the case was carried by relays of coolies to Coonoor where it arrived at 7 p.m. The next morning the case was carried into Ootacamund, and the ova placed in the hatching boxes.

Next year it is proposed to import Rainbow trout ova, and Loch Leven trout ova in November so as to obviate all chances of failure.—*Asian*.

NOTES ON PRODUCE AND FINANCE.

INDIAN TEA AT CHICAGO.—Mr. Blechynden and those who have charge of Indian tea interests at Chicago are not to be outdone by their Ceylon rivals. From an American paper just received we find that there are the usual sensational headlines to a notice of the Indian tea exhibits at the "World's Fair." Then follows an account of the tea industry. It will not be the fault of Indian and Ceylon tea planters and their representatives in the United States if the reproach once urged against Americans that they drank the worst tea in the world is not wiped out altogether. The following are some of the headlines referred to:—"From Old Bombay," "Indian Merchants Prepare an Exhibit of Tea," "Looking for New Markets," "They wish to Establish Trade with America," "A Structure of Oriental Architecture to be Erected at Jackson Park," "Queen Victoria's Asiatic domain, the Empire of India, will be represented at the fair with a comprehensive exhibit, which will be housed in a special building of distinctively Eastern architecture."

COFFEE FOR MEMBERS OF PARLIAMENT.—On Thursday afternoon the Post Office authorities at the House of Commons were alarmed, the *Daily News* says, by the arrival of an unprecedentedly large consignment of parcels. They looked like tins of dynamite, and were found to exceed 700 in number. Each of the 670 members of the House had a packet addressed to him by name and style, an additional half-hundred being directed to officials and others connected with the House. On investigation it appeared that this access of business was due to the enterprise of a firm in the City who, as they wrote, "in view of the great debate of tomorrow, beg your kind acceptance of a half-pound tin of our freshly-roasted pure coffee."—*H. and C. Mail*, April 4.

VARIOUS AGRICULTURAL NOTES.

ELECTRIC LIGHT IN TEA FACTORIES.—The other day—write a correspondent—I was shown over Mr. T. N. Christie's factory, which was brilliantly illuminated by electric light (five acres in each room) the whole of which was put up by Mr. Christie himself, and is a great success. Mr. Christie is about to introduce it into his bungalow, which has already got electric bells in every room.—Local "Independent."

THE AGRICULTURAL SOCIETY OF MADRAS.—From the Annual Report which has reached us we quote as follows:—

The season of 1892, was unfortunately a continuance, more or less, of the drought of the preceding two years, only 42 inches being registered at the Madras observatory. The season however commenced favourably and gave us 22 inches, and enabled us to finish the planting out of many Palms which were not before represented by living specimens in the garden grounds; many other kinds of trees, shrubs, and more lowly perennials were planted, where space existed, or where it was found desirable to throw more colour into the landscape, some very choice and showy varieties of Hibiscus lending themselves admirably to the purpose.

PREPARING BONES FOR MANURE.—The fineness to which bones are ground is an important consideration as to their value. The finer the meal so much the more readily will it putrefy and dissolve in the soil and so much sooner will the crops be fed. There is some difficulty in grinding fresh, raw bones. To obviate this difficulty, they are generally steamed or carried through some process whereby the fat is extracted. Steamed or desiccated bones if not very strongly steamed, are better for fertilizers than raw bones. This is contrary to the general belief but raw bones contain the fat, which is not only useless to the plant, but adds weight and clogs the meal, and hinders decomposition of the bone in the soil. Of course the steaming process must not be carried on to such an extent as to extract the nitrogenous portions of the bone.—*Indian Agriculturist.*

ERYTHROXYLON COCA IN FIJI.—Mr. Keppel having handed to the Agricultural Society for distribution some packets of seeds of the above plant, we give some particulars of it with which he has furnished us. [Extracts from the *T. A. & C.* then follow and finally the editor says:—After this it is to be hoped that everyone receiving seed will do his very best to make them successful plants, for it is a good commercial crop, as will be seen when so little preparation is necessary, while the yield is over £50 (\$300) per acre. It is entirely an experiment in bringing it here, for while the temperature will suit the soil and climate are altogether different to that it meets with in its home; ours may improve it or the reverse may happen; intelligent and painstaking experiment is the only way to decide.—*Samoa Times.*

TEA FROM NATAL.—We duly chronicled the fact at the time when last season South African tea was offered at Mincing Lane, that some 12,000 lb. from Natal had found purchasers at what we supposed was a remunerative price. Whatever the net receipts by the producers, it has given encouragement sufficient to warrant a more heroic effort for the season now coming on, for we learn, on the highest authority, that over half a million—500,000—pounds of tea will be offered in London for public competition. We do not hear that any improvement has been effected in curing the leaf, the necessity for which was pointed out at the time, and as this is stated to have affected the price paid at the sale, one would have thought the experience paid for would have had a different result. They are easy-going folks in the colony—whose jubilee will be celebrated next year—but things might be made even more easy than they are if just a trifle more enterprise were shown in these early days of tea making.—*Gardeners' Chronicle.*

LIGHTNING KILLING TEA.—Such is the report from a Kelani Valley correspondent we gave yesterday (April 26th): 60 bushes of tea killed out by lightning on the top of a hill; a large rock close by, being also split up. We do not remember hearing of tea or coffee being killed by lightning in Ceylon before this?

QUININE IN AMERICA.—Judging from a recent report of the quinine market, it seems (says the *Gardeners' Chronicle* of April 22nd) that the consumption of this all-important medicine, though still realising low prices, is on the increase. Brunswick manufactured quinine was fetching last month only a trifle over 8d per oz. It was stated by a New York house that the imports of quinine (as sulphate and in the bark) into the United States in 1892 amounted at least to 4,500,000 oz., or half the estimated output of all the factories in the world. As it is said to be a well-known fact that stocks in the States are lighter than usual, it is argued that the consumption of quinine in America must be on the increase; also that generally all over the world the consumption is ahead of the production, and that the deficiency is supplied by the surplus stocks of former years. If this is true, it is good news for Cinchona planters.

TEA DUTIES IN CHINA.—The annual discussion on this subject has commenced in the China papers, the *N. C. Herald* of 10th March leading off with two letters under the heading of "The Ruinous Imposts on Tea." The writer of the first letter refers to the great falling-off in the exports of black tea from China to the United Kingdom, equal to 116½ millions in the past twelve years; and adds that "at this rate it will take only four years more to entirely extinguish the China trade in Black Tea to England." This enormous decrease and the consequent loss and distress in China he attributes to the crushing taxation of the article, amounting to from 30 to 80 per cent on the cost; and he complains bitterly of the action (or rather inaction) of the authorities in the matter. He then goes on to show that in the case of other markets, such as Australia, North America, and Russia, the state of affairs is very little better. He concludes by saying:—

As the period at which we are entitled to Treaty Revision does not recur until 1898 I fear that nothing can be done as regards the export duty, but surely the tariff taxation can be dealt with, and it is to be hoped that the able British Minister now at Peking will grapple with this pressing question, so long neglected.

The other writer supports the contention of the first, and states that a petition on the subject, to the Viceroy Li, is being drawn up. He concludes his letter as follows:—

London advices for a year or more past have pointed to a desire on the part of many consumers to revert to the use of China tea, and there are evidences that if cheapness and quality could be combined an impetus would be given to the rehabilitation of China congon, but at present, in spite of the unsatisfactory result to growers, middlemen and exporters alike, there is no doubt that, quality considered, China congon is about the dearest kind of tea in use in England. With the exception of the negative quality of possessing less tannin than British-grown tea, there are no points of fragrance, strength, or palatableness in it of which an energetic grocer could brag to attract customers. The London dealers require a sounder, better, more cleanly article than the China congon of today presents before they can take hold of it and laud its excellence. More attention would undoubtedly be given to these points if the taxation were not so ruinously exhaustive, and as the Chinese are universally acknowledged to have by far the finest raw material to work on in the leaf of their tea plant, we still hope to again see it take the front rank in the Tea Trade for its manufactured article.

SCARCITY OF CATTLE.—There is evidently a scarcity of cattle and especially of milch cows at present in Ceylon from the demand and inquiry we hear on every side. And yet this being a time of scarce and dear food in Southern India, cattle ought to be readily purchased at moderate rates there and the present should be a good time to make a suitable selection and importation. A sale of draught cattle took place today (April 29th).

INLAND TRANSPORT OF TEA.—Carts, it seems continue to beat the railway in some directions: tea from Bogawantalawa for instance, we are told, cost 1½ cents (by cart and rail) to Colombo. From the Balangoda estates over the range, it can be delivered in Colombo at 1½ cent. But then the difference in time,—especially in wet weather,—is surely worth something even in such a comparison as this.—We learn that while planters in the Kalutara district near the river send their produce by boat to the capital utilising the canal, those farther back, prefer to cart to Kalutara and thence despatch by rail.

THE BALANGODA TEA DISTRICT has evidently by no means attained its full limits: we have information of quite a number of extensions, new clearings &c. in the district and fear there is going to be a considerable addition to the tea area there, so favorable are the prospects. If only there was encouragement in the tea market, and consequent justification for the Government to sell land,—a splendid new district could be carved out of the 30,000 to 40,000 acres of Crown forest available between Maskeliya and Balangoda, and the Maskeliya road could be prolonged on an easy gradient, to open up such a district. But we must all wait until the Australian and American markets are fully won for Ceylon teas, before encouraging so big a planting order.

SALE OF APPLES AND PEARS.—Messrs. Venn & Co. of York Street held a brisk sale of the apples and pears the firm received on from Australia by the P. & O. s.s. "Oceana." There was a large attendance of bidders, the Moormen predominating and as usual endeavoured to keep down prices. Mr. Foster was too cunning for them and disposed of the fruits in a very quick manner, so that the majority of the cases of apples especially went to the gentlemen present. During the progress of the sale telephone messages poured into the office from several gentlemen in the Fort who asked that cases of the fruit might be reserved, but this was useless as the consignment received for sale went under the hammer. Good prices were realised and the manner in which the sale passed off has acted as an inducement to Auctioneers to get up a large consignment. Shortly after the sale it was a pleasing sight to see the apples hawked about for sale by Moormen—and at fabulous prices!

POTATOES AND ELECTRICITY.—The Scientific writer to the London *Globe* has the following which ought to interest Mr. Nock:—

In order to test the conclusions of M. Spechnew, director of the Botanical Gardens at Kew, a French horticulturist, M. E. Lagrange, has cultivated potatoes in a field divided into three parts, all of the same soil and exposure. One section was cultivated after the manner of Spechnew, the potatoes being planted between plates of zinc and copper connected above the soil by wires so as to form earth batteries with a current through the ground where the potatoes were growing. The second section was cultivated in the ordinary way without electricity. The third section was provided with small lightning rods thrust into the soil between the potatoes until their ends were on a level with the tubers. The yield of the third section was much better than that of the other two sections, and was obtained 15 days sooner. The ratio of the crops in the different sections were as 78, 80, and 103. The first section, although poor in roots gave an exceptionally vigorous foliage.

THE INCOME FROM LAND.—Lord Carrington stated in a recent speech that his spending income from his land rents now was only half of what it was when he inherited his 21,000 or 22,000 acres property twenty five years ago.

RED SPIDER AND BLIGHT.—It will be seen that among the list of recent Indian Patent detailed elsewhere, there is one for a remedy for the above well-known enemy of tea. We must hear, however, how far it may be successful from practical men in the Indian tea districts.

Prof. Stewart's receipt for killing lice on cattle is as follows: Mix one part of liquid carbolic acid with ten parts of rain water. The carbolic acid being heavier, thorough mixing should be had. Then slice up thin some castile soap, and mix this diluted carbolic acid well with the soap. This will make a plastic substance which can be rubbed in the hair, and Professor Stewart says it is quite effective.—*Southern Planter*.

CEYLON TEA.—With reference to growls about our teas falling away in quality on properties as years go by, a planter who sees much of the country writes:—"I know places that have gone off, and others that have improved in quality during the last year. I fancy *plucking* and the *weather* have a lot to do with the quality, but no doubt tea is a subject we have all a great deal to learn about yet, if we ever do master it, which I much doubt."

COFFEE IN THE PHILIPPINES.—The *Comercio* bewails the heavy decline in coffee-growing in the Philippine islands, where formerly it was a leading export article. In the provinces of Batangas and Cavite, the crops of the berry, so abundant in years gone by, have shrunk to miserably low figures, owing to canker having seized upon the roots of the plants. Ruin has fallen upon many families who earned their living by this line of cultivation. The canker arises from a worm and has defied every effort to trace out its cause. The natural history and habits of the worm are now well known, but not one investigator has found out any remedy for the canker.—*Straits Times*.

CINCHONA BARK.—Messrs. C. M. and C. Woodhouse published statistics in a recent circular of the Bark exports from Ceylon, India and Java, and in making a comparison they double the weight of Java, because Java bark is, on an average, twice as rich that of Ceylon or India. With this allowance, the total for the past four years compares as follows:—

1889	22,379,243 lb.
1890	25,656,217 do.
1891	26,112,544 do.
1892	23,685,447 do.

The falling-off of the last year was in India and Java bark, the latter showing a decrease from 1891 of 1,500,000 lb. and India of about 670,000 lb., while Ceylon shows an increase of 1,300,000. The totals for 1892 were as follows:—

Ceylon	6,846,741 lb.
India	2,456,024 do.
Java	7,191,341 do.

As regards 1893, Messrs. Woodhouse incline to our estimate of about 5,000,000 lb. for the export of this year. India is not expected to ship more than 2½ million lb. while it is unlikely also that Java will exceed the export of last year, unless there should come especial encouragement through a rise in prices. Meantime the demand for quinine goes on increasing, the export from Germany alone, which was about 250,000 lb. in 1887 having risen to very nearly 500,000 lb. in 1892, 190,000 lb. of this going direct to the United States, against only 56,000 lb. in 1887. There is a good prospect therefore before the cinchona bark market.

A KINCARDINESHIRE HOUSEWIFE purchased a hen from a farmer in the Gartly district of Aberdeenshire, and after killing it (says *Poultry*) she found the following extraordinary collection inside:—One sleeve link, one three-quarter-inch button, a top of a small cartridge, a flattened lead bullet, two pins, a brass nail, and a pipe of a watch-key. The whole collection weighed nearly 2 oz. Despite the fact that the hen had swallowed such a quantity of odds and ends, it was in quite a healthy condition at the time of its death.—*Echo*.

INDIAN MUSEUM NOTES.—Volume III. No. I.—has come to hand and is full of useful reading as the contents show:—

Miscellaneous Notes by E. C. Cotes, Notes on Scolytidae by W. F. H. Blandford, F.E.S., F.Z.S., Notes on Coconut Palm Coccidæ by W. M. Maskell, F.R.M.S., The Silk Cotton Pod Moth by F. More, F.Z.S., A New Gall-making Aphid by G. B. Bnckton, F.R.S., A New Wood Borer by O. E. Janson, F.E.S. The following extracts will indicate the great value of these notes:—

SCALE INSECTS ON TEA.—In Dec. 1891 information was received through Messrs. Mitchell, Reid & Co., of the presence in small numbers of the Coccid *Chionaspis theæ* Maskell (= *Aspidiotus theæ* Green M.S.) on tea (*Camellia Thea*) in the Kangra Valley. The curious little fluted scales of the male insect of this species were represented in considerable numbers upon the leaves that were sent to the Museum for examination. No particular harm seems to have been done as yet by this insect, but it is one to be watched carefully as it has now established itself upon tea both in the Himalayas and in Ceylon, and may at any time prove destructive. It is satisfactory to learn that the kerosine and soap emulsion which have been recommended for use against this insect have been used successfully in the Kangra Valley.

ACRIDIDÆ ATTACKING TEA.—In February 1892 information was received through Messrs. Jardine, Skinner & Co., of considerable injury to young tea (*Camellia theifera*) bushes in the Western Doars by Acrididæ. Of the insects forwarded to the Agents, some were identical with specimens in the Museum collection determined by Dr. De Saussure as his *Catantops indicus* while others seemed to be a variety of the same species characterized by the absence of striped markings on the posterior femora. Two specimens of the species *Acridium flavicornis* Fabr. were afterwards forwarded as associated with the insect first reported. In the end of February the manager wrote that he had been to a great extent successful in destroying the insects, and that he had not heard of their appearing on any of the neighbouring gardens. The method adopted was hand-collecting by children and coolies, were paid two annas per hundred insects. Up to the date of his letter, the manager estimated that he had destroyed 31,770 insects in this way, with the result that they were getting so much scarcer that, at the time he wrote, the coolies were only bringing in about 25 per cent of the daily number they had been able to obtain when hand-collecting was first started.

SULPHUR vs. RED SPIDER.—A very complete and interesting series of reports by Mr. G. F. Playfair, on the results of experiments conducted in Cachar upon the subject of the sulphur treatment for red spider, have been furnished by Messrs. Barry & Co. Five tons of refined flowers of sulphur were sent up to the garden for application as a remedy against red spider (*Tetranychus bioculatus* W. M.), which is one of the tea planters' most inveterate enemies. The sulphur was applied over an area of 138 acres, and the results appear to be so successful that the treatment seems likely to prove of the very greatest value. Gas lime and lime has long been recommended against root-feeding insects, and in a recent Bulletin of the New Jersey Agricultural College Experiment Station, Mr. J. B. Smith advocates kainit and muriate of potash for a similar purpose.

THE PRICE of Coffee has risen from thirty or thirty-five cents a catty about two months ago to fifty cents at present. At this rate things ought to be looking rosy with coffee planters.—*Pinang Gazette*.

CEYLON TEA does not compare favourably with that of India in respect of the average prices for last year as quoted by us on April 21st. The time is not so far back, when we were accustomed to speak of the superiority of our teas to those of Assam; but it will have been observed that while our average for 1892 was only 9½d, that for Assam (11½d) was not only far above ours, but equal to the average for the very best district—Agrapatana—in all Ceylon. We must never again therefore think that Ceylon can as a whole rival Assam in the home tea market.

COFFEE IN BRAZIL.—The following circular says the *Rio News* of March 14th, has been recently published:—

"The committee of coffee factors of Rio de Janeiro appointed to estimate the coffee crops available for exportation from this market, ratifies the estimate it handed to the press on the 22nd of last November. Up to the end of January the season was unfavourable, and the long drought in the coffee districts injured the crop and at the same time caused its rapid ripening. This circumstance will lead to receipts at this market in advance of the usual time and will increase the figures for the present crop year, which had been reduced to 2,700,000 bags. In some districts in the month of Feb. there was abundant flowering and if the coffee resulting therefrom should mature, it may compensate for the loss in the early flowering. Under these circumstances the committee deems advisable to maintain for the present its estimate of 2,700,000 bags as the maximum quantity available for exportation. The want of laborers and the lack of discipline among the few who seek employment and the rise in wages are difficulties with which the planters still have to contend. The transportation service should be improved so that planters may promptly market their crops and receive supplies.—Joaquim Mello Franco.—Miranda Jordão & Co.—Herman Joppert.—Cesar Duque-Estrada & Co.—Araujo Maia & Co."

MANUFACTURE OF SULPHATE OF CINCHONIDINE.—Discussing the relative advantages of sulphate of cinchonidine and cinchona febrifuge, the Government of India, in a letter addressed to the Bengal Government, suggested that before attempts to manufacture the former drug on the Government plantations were finally abandoned, the impossibility of preparing cinchonidine at a reasonable price should be fully demonstrated. Brigade-Surgeon-Lieutenant-Colonel G. King now reports that a process, which has been under trial for some time, and which seems more hopeful than any other, is to treat the precipitate from the mother liquors with sulphuric acid and Rochelle salt, by which means the quinine and cinchonidine are converted into tartrates, and the cinchonidine and amorphous alkaloids are left behind. The tartrates thus obtained are treated with a weak solution of caustic soda, and the quinine is then separated by adding oxalic acid, the residue (combined with sulphuric acid) forming sulphate of cinchonidine. He is not without hope that some modification of this process may yet be found which may be profitably worked; but hitherto it has not proved a success. He is, however, of opinion that, instead of trying to make cinchonidine sulphate at Mungpo, it would be more economical, and quite practicable, to crystallise as sulphates the whole of the crystallisable alkaloids which are contained in the precipitates, which are obtained during the present process of making both quinine and cinchona febrifuge. An alternative, and still cheaper plan, would be to convert the quinine and cinchonidine into tartrates without attempting to separate them from each other, and to issue the product as a mixed tartrate of quinine and cinchonidine. One objection to this drug is, however, that it would be less soluble than either sulphate or quinine or cinchonidine.—*Pioneer*, April 4.

THE ORIGINS OF INDIAN TRADE.

Sir George Birdwood, K.C.I.E., has written a lengthy and very interesting introduction to "The first letter book of the East India Company, 1,600 to 1619," which is published by Mr. Bernard Quaritch. It deals very exhaustively with the subject, as may be judged from the following extract:—

The highest value of the book, he says, is the withful record it has preserved of the character and conditions of the great secular trade between Europe and Asia at the very instant when England first entered on her now fulfilled possession of it; and its highest interest in reference to the consequences of the dexterous measures then taken by the East India Company to obtain a footing in it, involving as these did the whole future of the United Kingdom. The current of this trade, at first, and for four millenniums, through Mesopotamia and Egypt, and then round the Cape of Good Hope, and, after nearly four centuries, once again through Egypt, has, from its forgotten beginnings, determined the destinies of the historical nations, of the Old World; and now we find it dominated by the United Kingdom, not only along both its competing courses, but at all its perennial head springs, in the tropical fertility of India, Farther India, the Indian Archipelago, and the East Indies generally, from Abyssinia or "Middle India," to China, or "Superior India." The history of the Old World has, in brief, been the history of its commerce in the dye-stuffs, cloth, and spice, and gold of India; and it was the fame of the East Indies for their fresh spices, deep-toned dyes, bright cloths, and precious stones, and wrought gold and silver, and sumptuary arms, that led Columbus on to the unexpected discovery of the New world of the American.

BLAMELESS ETHIOPIANS.

The elaborately broken coast line stretching obliquely from the British Isles gradually southward through a distance, as the crow flies, of from 8,000 to 9,000 miles, until it ends in the Indian Archipelago, naturally invited the population along its entire length to mutual commerce, not simply by the facilities it affords for intercommunication, but also by the infinite variety in the productions of the temperate and tropical zones they have to offer each other. Once settled by the human race, it was inevitable that a great commerce, having its inexhaustible sources in "the world's green end" of Homer's "blameless Ethiopians," should grow up everywhere along this remarkable coast line. The renown of the riches of the trade with India and the Indian Archipelago was propagated from the earliest date all over Asia and Europe in the Legends of the Earthly Paradise, the Sea of Riches, the Land of Gold, &c. and the geographical, mercantile, technical, and other myths of universal fable and folk lore are the vague broken traditions of the immemorial trade, in his prehistoric origins, pursued for countless generations along all these shores of old romance. For centuries this commerce was carried on, not directly between one country and another, but through innumerable intermediate agencies, so that distant countries knew each other only by their productions and the strange "travellers' tales," that grew in wonder as they passed from mouth to mouth between the East and West. The very name of India remained unknown among the nations of the Mediterranean Sea for centuries after its costly perfumes had been in daily use in the service of the Tabernacle at Shiloh, and afterward of the

Temple at Jerusalem, and for millenniums after their earliest use for embalming the dead in Egypt.

A RETROSPECT.

This southern coast line of the continent we arbitrarily divide into Europe and Asia is interrupted between the Mediterranean Sea and the Indian Ocean by the Isthmus of Suez; and as the peninsula of Arabia extends from this point about 1,500 miles southward, the Isthmus of Suez really presents the length and breadth of Arabia as an obstruction to the direct transit of the trade between the Mediterranean Sea and the Indian Ocean; and as it is twice as long from Suez to Aden as from the Mediterranean Sea to the head of the Persian Gulf, the commercial advantages of the Red Sea route, even after the discovery of sailing to India by the monsoons, have always been nearly equalled by the comparative shortness of the route by the Persian Gulf and Euphrates Valley. Thus from "the deep backward and abyss of time" these two lines have competed on almost equal terms for the commerce of India, and the competition between them is the true key to the history of the successive states and empires that rose and fell along their course; rose as they gained the trade of India, and fell when they lost it. So important are the positions in connection with the Red Sea and Persian Gulf, that not only was there always a rivalry between the nations on the Persian Gulf and those on the Red Sea, but it was a vital question among the latter whether the trade should go by the Gulf of Akba, or the Gulf of Suez. The rivalry successively of Assyria and Babylonia with Phœnicia on the one hand, and Egypt on the other, and again between Jerusalem and Tyre, and Jerusalem and Petra, that finds such startling expression in the prophetic denunciations and lamentations of Isaiah, Jeremiah, and Ezekiel, had largely for its origin the competition for the monopoly, or at least a share of the profits of the commerce between the Indian Ocean and the Mediterranean Sea.

EARLY TRADING.

The overwhelming advantage of the Semitic races, and particularly of the Arabians and Phœnicians (for the Hebrews were unfortunately placed between the Idumæans and Phœnicians) was that from the dawn of history they were already in occupation of all the lands separating the Mediterranean Sea, from the Indian Ocean. This gave them their start in the civilisation of the world. The Phœnicians in the Mediterranean Sea, and the Arabians in the Indian Ocean, at once engrossed in their own hands the whole of the trade between the countries of the Mediterranean Sea and the countries of the Indian Ocean; the Arabians keeping possession of their share of it without interruption until Vasco Da Gama (A.D. 1497) opened up the trade to India by the Cape of Good Hope. Ultimately the Phœnicians and their colonies were forced to succumb to the rivalry of Assyria and Greece and Rome. Yet Tyre was not finally destroyed until taken by the Crusaders, who behind their religious professions, were chiefly influenced in their operations by the sordid interests of the commercial Italian States of the twelfth century.

A FATEFUL DISCOVERY.

During the 300 years subsequent to Da Gama's enterprise the Red Sea and Persian Gulf routes gradually fell into disuse, but are now regaining their former importance; and to safeguard them against all danger as the future channels of the rapidly increasing commerce of Europe and America with Asia and Australasia has become one

of the highest political obligations of the British Empire. Commerce always sets steadily toward the shortest routes, and under the pressure of the competition of the modern world, Egypt and Mesopotamia will become the chief commercial high-ways between the East and West. Commercial supremacy, the only sure foundation of political supremacy, is absolutely dependent on the opportunity of roads and markets, or on strategical points and communications, as military men call them. Indeed, war is only another form of commercial antagonism, seeking by violence the same advantages commerce often more surely secures by its slower, deadlier sap. It was of comparatively little consequence that the three successive Egyptian empires, and the Assyrian and Babylonian monarchies were overthrown, or that ancient Tyre was twice razed to the ground, for while the commence of India still went by the Red Sea and the Persian Gulf the people prospered; but when the Portuguese outflanked these routes by doubling the Cape of Good Hope, then Egypt became indeed "a base kingdom," and "great Babylon" "a refuge for the wild heasts of the desert," and Nineveh "a desolation," and Tyre "a place to spread nets upon." If

"Peace hath her victories
No less renowned than war,"

her defeats also are not less terrible and crushing and are far more enduring in their disastrous results. The discovery of Da Gama made the whole of Anterior Asia a desert, and impoverished all the countries of the Mediterranean Sea, for more than 300 years. Their revival, already rotatable in the instances of Italy, Greece, and Egypt, may be formally dated from the reopening of the overland route between India and Europe by Lieutenant Wagorn in 1845, and was placed beyond all future hazards by the successful opening of the Suez Canal on Nov. 17, 1869, and the insurance of its freedom and neutrality by the British settlement of Egypt in 1882-83.—*Overland Mail.*

BARK AND DRUG REPORT.

(From the *Chemist and Druggist.*)

London, April 13.

ANNATTO.—Slow of sale. Of 51 packages Madras seed offered today 30 sold at the rate of 2½d per lb for good bright, and 1½d per lb for fair quality.

CARDAMOMS.—At the sales disposed of today only 89 packages were reached, of which 82 sold at a fresh advance in price, contrary to the general expectation. The quantity of the fruit offered was of very high average, and competition was good. The following prices were paid:—Ceylon-Mysore, fine medium to bold pale 3s 5d; very good ditto 3s 1d to 3s 3d; medium ditto from 2s 6d to 2s 10d; small to medium pale, full 2s to 2s 3d; very small pale 1s 8d to 1s 9d; mixed sizes, partly yellow 1s 6d to 1s 11d; ordinary seed brought 1s 4d. Tellicherry fair sound palish 1s 10d; common to medium brown, from 1s 7d down to 1s 2d per lb.

CINCHONA.—Of South American Guayaquil, bark 2½ bales were advertised, but the bulk of this was withdrawn or bought in. Six packages fair broken brown quill sold at 7½d per lb. A rather mixed collection, described as Carthagena, &c., bark, imported in the years 1879 and 1880 was offered today; it consisted of 66 packages, out of which 43 sold subject to approval at 2½d to 1½d for Carthagena character 1½d to 2½d for Colombian character; and 1d for Cuprea character. A newly imported parcel of 31 packages (aggregating 3,171 lb.) Red bark from Guayaquil was also offered; the quality upon the whole was anything but good. A few bales of rather pale coloured split bark brought 5s 9d to 6s 2d; thinner quill, rather dusty mixed 2s 6d; and common chips and brownish quill from 9½d upwards.

COCA-LEAVES.—For 6 bales fine bright, but very broken green ruxillo, a bid of 1s 9d per lb was rejected today. Of three other bales bright Truxillo leaves 2 sold at 1s 6d per lb.

QUININE.—In the early part of the week no further business was reported, holders generally being reluctant to sell below 9½d per oz. On Wednesday, however, a strong demand again set in, several American buyers again appearing upon the scene, and some 40,000 oz German bulk, in secondhand, were disposed of at rising prices from 9½d to 11½d per oz, on the spot, and at 9½d per oz. for May delivery.

TRAVANCORE TEA.

The market this week opened after the Easter holidays with a large supply of common and medium kinds. There was very free bidding for all common classes, which in most instances went at an advance of ¼d per lb., pekoes generally attracting most attention. Broken pekoes were difficult to dispose of at previous quotations.

TRAVANCORE.—The general quality of the 1,170 packages offered in sale this week was fairly good, although rather too light in flavour to suit the present requirements of the market. Prices were firm, and in the case of teas for price showed an advance upon late sales. Broken pekoes, although unchanged, are difficult of sale, owing to the cheap rates current for this grade in Ceylon and Indian.

	Bro. Pek.	Pekoe.	Pek. Sou.	Souchong.	Dust	Quantity.	Av. about.	
Brigton	10½d	7½d	26 pkgs.	8½d

THE GRASSE FLOWER-CROPS.

April 12.

The violet crop in Southern France is now at an end, and has given a mediocre result, the output being not quite sufficient to satisfy the requirements of the local manufacturers. The prices have advanced considerably in consequence, up to 4f. per kilo being now freely paid for the flowers by perfumers. This price is a very remunerative one, and may possibly cause an extension of the plantations. Jouquils are now being gathered; but the prices of these flowers are low, and they are gradually going out of use for perfumery purposes. The prospects of the neroly crop which will shortly commence, remain excellent, and if nothing unforeseen occurs the production will be above the average. The roses do not look so well, but it is hardly yet time to say for certain how this crop is going to turn out. Taking things all round the Grasse manufacturers are fairly well satisfied. After a long period of bad trade, especially in the export department, orders are now again coming in more freely.—*Chemist and Druggist.*

GUATEMALA produces one of the most sought after descriptions of coffee in large quantities which realize high prices, so that the estate owners earn from it a larger profit than any of their colleagues do from grain, beetroot or cotton, in Europe or the United States.—*London Chamber of Journal.*

THE AGRICULTURAL PARADOX.

The modern land question is the most perplexing that was ever raised, though land questions have vexed the world ever since the days of ancient Rome and probably before the great city came into existence. In all parts of the world the cry is going up that the farmer cannot live by the working of the land—that absolutely he is bound to starve with plenty before his eyes. He is the modern Tantalus, who sees over-flowing streams which fly from his parched lips when he attempts to reach them, so that in the midst of all that he needs he perishes for lack of what he requires. The paradox is a strange one, and yet the trouble grows more intense day by day, and seems to be spreading in all parts of the world. In the United States the farmers are said to be little better than bondmen of the money-lenders, for they are mortgaged so that they work for others rather than themselves. In France there is an ever-renewed demand for increased protection, because the farmer declares that he cannot live, and must have help from the state. In Great Britain, we are told on the most excellent authority, unless the price of wheat can be raised considerably and permanently farming cannot be made to pay. Prices there, alike of stock and of grain, are so low that the farmers are ruined by the very abundance that exists. In Germany there is a new Agrarian rising, which threatens to become a power of obstruction in the state, for the farmers declare that they cannot live, and will impede all legislation unless they are helped by heavy protective duties. In Australia, as we know, the farmers want various things for their special benefit in the different colonies, ranging from a bonus in Victoria to the fixing of a minimum price in Tasmania. In Italy, Scandinavia, and other places, the agriculturists, formerly the most stable and conservative of all the classes are full of projects for the re-distribution of land, combined with schemes for the Governments to pay off the mortgages, and give the farmers a bonus for stopping on their farms. In the United States there are organisations having for their objects some of the wildest proposals ever made, and we are told, on good authority, that the Asiatic and Russian populations "go on cultivating, though half of them get nothing out of their labour except bare bread, and often bad bread, and in Asia scarcely any clothes." The ownership of land, it is broadly stated, once the very acme of security, is now the least secure of all forms of property, as revolution is stalking on, even in the United States, demanding the settlement of a whole host of agrarian questions, any one of which may be said to involve a change in the actual state of society. When protection is found to fail—as it has been found everywhere—the next demand is for the fixing of rents by law or their abolition; and that failing, too, as it has failed, the farmer demands some new régime, which is, somehow, to make something out of nothing. We read that "a new class of questions will come up for settlement, at least as difficult as those raised by the artisans, and they may not be settled anywhere without revolution."—*Australasian*.

ADULTERATION OF COFFEE.

Mr. Thomas Dickson sends us the following correspondence as of interest to coffee planters and others:—

THOMAS DICKSON, ESQ.,

Dear Sir,—With reference to the meeting held at the Chamber of Commerce yesterday, we beg to enclose you a copy of a letter we recently sent out to members of Parliament, and others, with the enclosed draft Bill.—We are, dear sir, yours faithfully,

J. W. ROGERS, Chairman.

119, Cannon Street, London, E.C., 5th April 1893.

DEAR SIR,—The adulteration laws have been long in a very unsatisfactory condition, for they do not materially interfere with the practices they are directed against, while as a rule, the real offenders escape

the punishment which should fall upon them, but which, too often, falls on innocent individuals.

A Bill has been brought into the House of Commons by Dr. Cameron, and others, with a view to amend the Sale of Food and Drugs Act of 1875. This Bill contains several very valuable proposals, as to the extension of liability for adulteration to wholesale dealers and manufacturers; new conditions as to warranties; margarine; chicory and coffee; and the proportions of water in butter.

All these provisions are excellent, so far as they go, but any warranty which may be arranged for, should certainly bind importers, brokers and others, as well as wholesale dealers. The question of a warranty with goods sold in bulk is a very intricate one, for it is difficult, without facilitating adulteration, to safe-guard the interests of innocent retailers. With a proper system of access by the public analysts to wholesale warehouses, etc., it is questionable whether a warranty for goods sold in bulk would be desirable in the public interest. At any rate, any such warranty should have a time limit; which limit, however, should not apply in the case of goods originally sold in small packets, where the warranty might fairly be permanent. Further, the giver of a warranty should surely have notice to be present at any action where his warranty is to be pleaded as a defence to a charge of adulteration. With alterations on these points, and one or two minor detail objections, Dr. Cameron's Bill would be a valuable one, but it only goes a short way in the direction which should be taken.

Indeed, Dr. Cameron's Bill, while it affords some proper relief to the retailer, in no way attempts to put down adulteration, which is, after all, the main object the law should have in view in such matters. It is questionable whether it is worth while taking up the matter at all unless the following, among other points, are really grappled with,—

(1) The opening of wholesale warehouses, sale-rooms, etc. to the access of officers who carry out the Adulteration Acts, with full power to obtain samples, to institute prosecutions, and to seize adulterated goods.

(2) The creation of a Government analytical department, with large discretionary powers, to supervise and assist the public analysts, and to give them a better and more defined position than they now enjoy.

(3) A comprehensive treatment of all admixed goods (for instance, mustard and cocoa) not confining the amendment in the law to coffee, as proposed in Dr. Cameron's Bill.

(4) Amendments to the existing law more closely dealing with detail forms of current adulteration.

We have enclosed in something like Bill shape, our idea of the general direction that any new adulteration law should take in order to effectually cope with an evil that is not only injurious to the public interests, but is, at the present moment, threatening to destroy the business of honourable traders in several important branches of business. The present Adulteration Acts, for instance, give practically no protection in one branch of our own trade, that of wholesale spice grinding, where adulteration and chicanery are more rampant than at any time in our experience.—We are, dear sir, yours faithfully,

(Sgd.) for JOSEPH TRAVERS & Sons, Ltd.

April 11.

J. W. Rogers, Esq., Chairman, Joseph Travers & Sons, Ltd., 119, Cannon Street, E.C.

DEAR SIR,—I am obliged by your letter with copy of proposed draft of bill re Sale of Food and Drugs Act.

I thoroughly endorse your proposals and regret my arguments based upon the lines you have adopted were not accepted by the majority of the Chamber of Commerce to (10 6) yesterday, owing, no doubt, to the constitution of the majority of the members present.

I have supported Dr. Cameron with petitions from myself as representing the Planters' Association of Ceylon, The Ceylon Association in London, and the various Ceylon Companies I represent.—I am, dear sir, yours faithfully,

THOMAS DICKSON,

TASMANIA REVISITED.

(By Old Colonist.)

But a truce to tea-drinking and Hobart gossip. Let us forth to the fields to note what progress Tasmania has made in

AGRICULTURE

during the past seven years; for well I wot the always-about-to-retire Ceylon planter wants to know what prospect there really is, of making a comfortable home for the evening of life in "the best climate in the world."

Around Hobart the progress is so characteristically slow, that there may be said to be no change. The best land at the base of Mount Wellington is still in the primitive hush, "belonging" it is said to a big Brewing Syndicate and to other dogs in the manger who are always ready to snarl at the approach of any intending settler. The few orchards there are in the creeks, have not however, fallen off in productiveness, while acreage has been somewhat extended.

About 5 miles out from Hobart or half way to Glenorchy there is a very successful

APPLE ORCHARD

now in full bearing which I saw planted seven years ago. At Glenorchy itself there are considerable additions, though the father of the district—good Mr. Shoobridge is no more. He was really a good orchardist and so admirable an example of the strict teetotaler, that the grief of his life was the fact that his own brother should cultivate such a wicked weed as *hops*. It seems strange to think that while the erratic Ebenezer is still flourishing, the altogether pure, the careful and industrious husbandman has himself been garnered.

At Bridgewater there are a few more houses, but there is still an absence of anything worthy the name of cultivation, and beyond this for many miles matters remain in *statu quo*.

Near Jerusalem I see a field of late OATS being harvested, the outturn of which my travelling companion—a farmer—helps me to estimate at 10 bushels to the acre; this I believe is a fair average for the district.

Beyond this the country gets bleaker and more neglected. On the left is the

"LAKE OF IBERIAS"

a filthy swamp of some 1,500 acres, belonging to a Mr. Harrison and we wonder if it ever occurs to Mr. Harrison what a valuable property he is here neglecting. To drain it would evidently be a simple matter, and to turn the accumulated deposits of ages to good account could not fail to be very profitable.

There is little worthy of remark as we pass on towards Launceston. On the right the hearty erection called Mona Vale—built to entertain the Duke of Edinburgh in—and since a white elephant, still stands in striking contrast to its surroundings. On the other side is

HORTON COLLEGE

an educational establishment which looks like "a lodge in a vast wilderness." Then come the decaying villages of Ross and Campbell town, after which the more promising valley of the Esk, a pretty river almost equal to its namesake.

THE VALLEY OF EVANDALE

is to the agriculturist one of the most interesting in Tasmania, closely cultivated in neat little fields extending for many miles eastward. The hardy farmer has here made a cosy home, and plods along in a quiet industrious—albeit in a very primitive way. We pass an eight oxen plough at work, similar to what our grandfathers held 100 years ago and doing about half the work a pair of horses have to do in Aberdeenshire today. The crops raised here are not equal in bulk, to what we grow in Scotland and the markets are decidedly more uncertain. Yet, here there are greater possibilities. The climate is in-

initely more agreeable and although the soil is not rich it could readily be made so by labour and water.

IRRIGATION in short is what Tasmania most needs. Without irrigation it is still found impossible to grow sufficient food for the scanty population that vegetate upon the island. *With water*, judiciously applied, the island might well support its millions.

But successful irrigation means abundant labour at a moderate cost; this is not to be had in—and under present conditions would not be admitted into—Tasmania. Therefore, and to be brief, *profitable farming in this island is an utter impossibility for those who have to employ and pay for labour*. I have not come across a single instance to the contrary, though I regret to say scores of disheartening failures may be enumerated. The matter being of some public importance it may be well to give one example which will be well understood in Ceylon.

Ten years ago during the memorable depression

TWO CEYLON PLANTERS

left their blighted coffee behind and took passage for Tasmania, in the full determination of forming a home for themselves and families in this favoured island, for had they not read as many others have done of its perfect climate and prodigiously productive land? And yet, they had no foolish notions of fortune-making, believing that much hard and unremunerative work lay before them.

Probably no fitter or more likely colonists ever entered the bush. The one cautious, plodding and easily contented; the other physically capable and energetic beyond the average of men.

They took up land in the favorite district of Scotsdale, literally put their heads and shoulders together and lost no time in starting work. Perhaps they were a little taken aback when they first looked at the monarchs they had to cut down before a home could be made, and after a few days of toil would sometimes exclaim "appa"! as they tried in vain to see each other across the prostrate trunks; but they were not daunted, and soon began to plant their little plots of potatoes and sow patches of wheat. True, the value of the whole produce,—supposing it had been all profit,—did not seem much to old planters—barely equal to kangany pay. Yet they plodded on contented and healthy, albeit thinking occasionally of the society they left behind them and often regretting they could not entertain the old Ceylon man who came out of his way to call at their door.

The time came, however, when it dawned upon our friends H. and U. that life was too short in which to make the home they hoped to do, and meanwhile their families were growing up and needed change of scene and society.

For 9½ years the two had worked together as men have rarely been known to work in Tasmania, and the net result was that financially they were worse off than when they felled the first tree. H. at length gave in; U. determining to carry on the struggle yet a while.

"Then don't let me stand in the way" was the parting salute of H. as he left the result of *nine and a half years' hard work* behind him, and wended his way to Hobart where I was glad to find him the other day usefully employed in an office.

This is by no means an exceptional experience, and it is well it should be made known in these days when an Agent General is again "hooming" the colony as a Paradise for old Anglo-Indians.

Cleverly embellished as Sir E. Braddon's pictures of Tasmanian life are, nothing can possibly be more inaccurate than his deductions—except perhaps his figures, a fair sample of which may be seen in a recent number of "Blackwood" in which he pictures the Silver City Zeehan with a population in 1893 of some 50,000—the unadorned and indisputable fact being that Zeehan today is a struggling little township of between 700 and 800 souls!

It is but right to say that no one is more ashamed of the Agent General's misstatements than the Tasmanian ministers themselves.

(New South Wales in my next).

PLANTING IN THE CENTRAL PROVINCE OF CEYLON.

(Notes by "Wanderer.")

May 6th.

PRICES OF CEYLON TEA.—They say any stick does to beat a dog, so all advices from London and Tea Circulars bark on the same string and try to apologise for the apathy of the Tea Buyers at the expense of the Producer. Formerly it was the agitation on the Home Rule question that prevented the Belfast Tea Dealer from going in for our Broken Pekoe, now we have the dread that the Chancellor of the Exchequer was to take off the Tea Duty, or reduce it. This last question has been settled, and still 9d or 9½d continue to be our average. That the Tea is going more slowly into consumption than last year is manifest for the increase of duty paid tea in England to end of April was only 2 per cent. on Ceylon and Indian tea and a reduction of 4 per cent. on China. Java Tea seems to be coming to the front. I suppose the Bushes from Assam tea seed imported there, are now coming into bearing.

TEA FREIGHT has certainly been low and your yesterday's issue shows that the usual reaction is setting in and that Freights will now go higher.

EXCHANGE and its upward flight have surprised us, and must worry the Banker and tea buyers in Colombo.

COFFEE.—The blossoms have been a perfect fiasco and now green bug is showing up. Planters who have tea over two years old are now rooting what coffee they had left interspersed, as they find that the bug finds its way from the coffee to the tea.

WEATHER was settled fine but today it is cloudy and rain is not far away.

PLANTERS ought to be much obliged to you for laying before them in such a handy form the annual tables of Messrs George White & Co., and Wilson, Smithett & Co. What strikes the Planting reader unfavourably is the tumble down in the price of tea in the last three years. 10d½ in 1890, 10½d in 1891, and only 9½d in 1892. However, the comforting thought comes to mind that we never expected the tea to net more than 50 cents f. o. b., and thanks to exchange I fancy we have realised that figure. Messrs. Wilson, Smithett & Co. give the following reasons for poor prices. 1st Stock-taking, but one would suppose that this occurs every year. 2nd. General election and political anxiety. 3rd Quality was sometimes of a most undesirable quality. Portsworld tea is pilloried for its terrible fall 1s 4½d to 1s 1½d; but this is the result of three poor shipments, for the teas, with these exceptions, were during the year as fine as ever. This knocks on the head the croaker who often tells you "Ceylon tea is steadily becoming weaker." Bogawantalawa catches it. "The inferiority of the teas from this district was very noticeable towards the close of the year." I hope the lively proprietor of Holmwood did not chuckle over this sentence! He was quite right to show the public that the Agra Patana tea is quite as good as Bogawantalawa. Who is responsible for this cutting in two of the Dikoya district? Wilson, Smithett & Co. paraphrase the old saying "with all thy faults I love thee still" by patting Ceylon on the back and concluding "Ceylon continues not merely to hold its own, but to beat its rivals in these days of keen competition." Let us hope Ceylon planters will send them large and numerous invoices of tea as a reward for that last "pick 'em up."

In looking over the averages one is surprised that Kalutara beats Kelany Valley. How is this. Is there not a lot of ironstone in the Kalutara district as compared with the latter? Why should the fine old districts of Kelebokka, Knuckles and Rangalla allow Dolosbage and Yakdessa to "take the cake."

Let us now see what Messrs. George White & Co. say.—Unfavourable climatic influences, (good sounding sentence that) and moderate plucking prevented our getting worse prices than at one time were apprehended. These worthy brokers go on the tack

of making us thankful for small mercies. Oh George White! George White! what is this I see you write about Ceylon. "After the turn of the year, however business slackened" (no objection to that remark) "owing partly to many of the teas lacking strength and fullness"—the same old whine, and from thee Tu Brute!! Did the recording Angel of George White's publishing department drop a tear when he wrote that 1,000,000 lb. of tea found a good market in the Hooley? This excellent firm tell us that 75,000,000 lb. of Ceylon tea are wanted in London. If therefore we ship 5,000,000 lb. tea to Australia, Ceylon will thus accommodate him if we export 80,000,000 lb. this season. Let us devoutly hope that the banking trouble will not affect for long the trade direct with the Colonies.

Mr. Hughes has done the Planting community good service by his careful attention being given to our Tea Agriculture. His latest talk with your London Correspondent *re* tea leaf stalk being so much to the front in Ceylon teas, is interesting. Is not the whole leaf plucking responsible for this state of matters? The coolies have a much easier task in plucking on the whole leaf system, but no doubt we get more stalk thereby. Mr. Hughes has found out in theory what some of us found out in practice that fine plucking punished our bushes more than medium plucking. It is time we went in for finding out what manure will keep up our trees. Cattle manure is out of the question, except to a very limited extent, and it is ridiculous to expect that our tea, mostly grown on old coffee soils, can go on yielding 300 to 400 lb of tea yearly without any return to the soil of what is taken out of it.

OUR EXPORTS OF TEA TO DATE.—Two millions ahead of same date last year means 6,000,000 lb. of an increase to our last year's exports. That can be taken off easily.

THE COCONUT OIL SITUATION IN AMERICA.

In spite of the fact that the large break in the price of tallow has caused a stoppage of the demand for all competing materials, including coconut oil, the position of the last named commodity is a peculiarly strong one. The predictions, made in the article in our issue of January 23rd, have been closely fulfilled, and many of the conditions which then prevailed, are still to be numbered among the influences controlling the market for Ceylon coconut oil today. We referred then to the scarcity of supplies in the primary market and to the fact that no considerable quantity of the oil would be available for shipment until the end of March. This is proved by the very small shipments made of late, the vessels that have recently sailed bringing only from 50 to 200 tons each. The largest shipment so far reported is some hundred tons on the Glen Morag, which cannot get here much before the middle of July. There is very little available stock here at present, and as no additions, and then only very small ones, are expected for the next ninety days, and improvement in the demand is very likely to cause a material advance in prices, and this is the more probable because of the very strong cable advices received of late from the primary source of supply. According to these reports there is very little stock, and that little is being constantly drawn upon to satisfy a demand from India, where the use of this oil appears to be rapidly extending. The effect of these conditions is shown by the advancing prices in Colombo, the last quotation from there being fully equal to the inside quotation for spot stock. But for the slump in tallow, there is no doubt that the spot market for Ceylon coconut oil would have promptly responded to the advance on the other side. As it is, buyers, who are still pretty well supplied by deliveries made earlier in the year, are holding off, awaiting further developments in the tallow market and any improvement in prices, is consequently out of the question at present. However, the outlook is highly encouraging to sellers of the oil. The present indifference of buyers cannot long continue, and when they are forced into the market by actual necessity the present strong

features of the situation are bound to make themselves felt. As I have stated, there is very little stock on the way, and most of that is far off. The first vessel to arrive is the "Saerimner" with about three hundred tons, but as she did not sail until February 10th she cannot get here much before May. Following come two or three vessels, with from fifty to one hundred tons each, and following them is the "Glen Morag," which will bring the first voice of consequence, and she is not expected to arrive much before the middle of July. The "Harriet S. Jackson" is to bring the cargo of the wrecked "Neach IV.," but it is uncertain when she will get here.—*Drug Reporter New York, April*

AUSTRALIAN AGRICULTURAL INDUSTRIES.

(FROM THE LONDON "TIMES" SPECIAL CORRESPONDENT.)

The use of the refrigerating chamber, which is giving us the benefit of the Australian meat supply, has alone made the dairy export trade of Australia possible. If it were not for the long winter of some of the most densely inhabited portions of our northern hemisphere, such a trade ought hardly to be needed, but the Australian summer begins just as ours is coming to an end, and their sweet grass-fed butter begins to overstock the local market at the very moment of the year in which our butter supply runs short. The export season begins in Australia in September, and ends in February—that is, consignments arrive in London from October until March. Australian Dairy farmers count upon this natural fact as the basis of a stable trade, and this reversal of the seasons is evidently the great fact to be considered in our entire food trade with the Antipodes. It gives South Africa the advantage which her colonies have been a little backward to profit by in the fresh fruit market, and there can be little doubt that there are still many mutual benefits to be developed between England and Australia. The carrying trade in refrigerating ships, and under the rapid conditions of modern locomotion, is still relatively in its infancy. The producers of the southern hemisphere and the consumers of the northern have everything to gain from further development and application of its uses, and in becoming acquainted with the immensely productive powers of the Australian Continent. It is difficult to avoid the conclusion that the constantly increasing importance of the export trade must some day lead colonial public opinion to appreciate the advantages of throwing Australian markets more freely open to the world. Compared with the magnificent results which are to be obtained from her soil, the manufactures of Australia take the place of a child's game. Yet, to protect them, life is made difficult and expensive for the cultivator of the land, and production is proportionately diminished. In the mallee country I found, as among the sugar planters of Queensland, that the current of opinion was strongly in favour of free trade. As the country party grows, this opinion is likely enough to spread, and to become more representatively efficient. It is more than possible, therefore, that even in protectionist Victoria the last word has not been said upon this subject.

Before quitting the subject of the wealth now being produced in Victoria by bringing the mallee country under cultivation and irrigating already cultivated districts, I would like to point out that, while crops grown under irrigation are so heavy as to double and treble the value of the land, and to make it capable of supporting a proportionately larger population, cultivation, especially where the old system of dry farming is abandoned for the intense culture of Mildura and the Goulburn Valley, demands more constant and elaborate care. A mallee farm of a thousand acres will employ three men. Fifty acres of vines or fruit will employ four men and give them rather more than they can do. The average of labour required for this kind of cultivation is usually fixed at about one man to ten or twelve acres. If, therefore, improved methods are rendering the land capable of supporting an almost

indefinitely increased population, they are at the same time creating a demand for population. The area of thirteen of the largest shares in Victoria taken together and representing an important agricultural district, comprises something over 16,000,000 acres, and in 1890 it was estimated that they had between them a population of 72,000 people. Even if a fourth of these were adult labourers, which they probably were not, there would still be little more than one man to every 1,000 acres. This being so, it is evident that the natural resources of Victoria are still far ahead of her capability to make use of them. I have scarcely touched upon her wine industry, because, when I come to speak of the wine industry of South Australia, the two can be more advantageously treated together. There are, however, many thousands of acres in Victoria devoted to this lucrative form of small farming, and there might be many thousands more if the necessary labour and capital could be found. Neither is it possible to speak here of the mineral wealth, which is amply demonstrated in its principal centres by the flourishing condition of the towns of Bendigo and Ballarat. Both of these towns grow daily larger, and furnish always more important markets to the surrounding country. The gold mines of Bendigo are the deepest, not only in Australia, but in the world, and in one which I descended for 2,900 feet gold indications of a satisfactory nature were declaring themselves at that depth.

A colony which possesses all this wealth in its back country, combined with the energy and enterprise that is already, as I have shown, engaged in the work of even partial development, cannot possibly be regarded as suffering from any inextricable financial embarrassment. What I have had to say has, I hope, made it clear, not only that the country districts are perfectly sound, but that they offer an outlet for English as well as for Victorian enterprise. In travelling through them the conclusion which must, I believe, be forced upon any impartial observer is that Victoria suffers from exactly the same want as Queensland and New South Wales, and that from Cape York to Port Phillip the supreme need of Australia is not money, but population.

HINTS FOR PRUNING FRUIT TREES.

(From a Planter.)

"Young trees should be regularly weeded (*monthly*) and all *gormandizer* like suckers taken off every three months at least. Peaches need light pruning every year and once in four or five years a heavy one. Pears, light pruning regularly seems to be enough. Plums, light every one or two years and then a heavy pruning but of this you must judge by the look of the tree. Oranges when young trimmed up; *very lightly* pruned; only taking out young branches, which run across and would be likely to get matted, and as they get older, only take out *dead or dying* wood; heavy pruning won't suit them. Calcutta guavas give finer fruit if trimmed up when young and lightly pruned afterwards. Apples never gave me enough wood to prune: all I did was cut off any dying branch or tipped those that were hide-bound and scarified the bark. This I have done to other trees as well, but when doing so find a liberal dose of manure gives extra good results. Figs need pruning; you cannot hurt them much by cutting; extra pruning gives smaller crop that year, but larger fruits, and the next year a heavy crop. For all these I find farmyard manure, cattle manure, the best; a little bone dust will not do any harm, but stimulating manure I think shortens the life of the tree.

A TOPAZ-BEARING tract of country has, we hear, been found in this Presidency, and that gem gives promise of being in sufficient quantity to render the exploitation of the tract a commercial success *Madras Mail*.

VARIOUS AGRICULTURAL NOTES.

THE TRANSVAAL AND FRUIT IMPORTS.—The reports from the upper districts of Natal are to the effect that large crops of Apples, Pears, Plums, &c., have been gathered, which would have been sent to the Transvaal, but for the prohibitive duty of 15s. per 100 lb. load on fruit. This also affects the fruit grown at the Cape; and thus producers in both colonies are severely hit by this heavy and surely injudicious duty.—*Gardeners' Chronicle*.

TECHNICAL EDUCATION.—On the 19th ult. evening, Mr. R. Cock, County Council lecturer on cottage gardening, gave an interesting lecture in the school-room at Sandon (Staffs.). Mr. Cock spoke first on bees and bee-keeping, illustrating his remarks with magic-lantern views. He strongly recommended cottagers to try bee-keeping as a profitable business. He afterwards dealt with winter work in the garden, discussing insect-pests among other things, and recommending fruit-growing, which, with care, could be made to pay well.—*Ibid*.

FRUIT CULTIVATION IN ENGLAND, AND IMPORTED FRUIT.—The following interesting statement as to the cultivation of fruit in England was made by Mr. H. R. Williams (the acting Master) at the dinner of the Fruiterers' Company lately:—"The following was the area under small fruit cultivation in England and Wales in each of the following years:—1888, 36,700 acres; 1890, 46,200 acres; 1891, 58,700 acres. Compared with 1888, there is an increase in 1891 of no fewer than 22,000 acres. Of this increase, 1760 acres were added to the small fruit area in Kent, the area for that county for the year 1890 being 10,061 acres, and for 1891, 19,821 acres. From these figures it will be seen that Kent maintains its pre-eminence in fruit-growing. Orchards also show a gradual and not inconsiderable increase in area. In 1881 the returns show 185,000 acres, while in 1891 the total was 210,000 acres, an increase in ten years of 25,000 acres. Market gardens also show a considerable advance in area. In 1881 there were under cultivation 46,604 acres, while in 1891 there were 81,368 acres, an increase in ten years of 34,764 acres. In 1882 the raw fruit imported, exclusive of Oranges and Lemons, amounted to 5,000,861 bushels, while the quantity in 1892 was 7,387,670 bushels. The Oranges and Lemons imported in 1890 represented a quantity of 5,746,135 bushels of the value of £1,756,£52, while in 1892 the imports came to 6,763,276 bushels, of the value of £2,052,561. *City Press*.—*Ibid*.

MOISTURE AND VEGETATION.—M. E. Gain has been conducting some comparative experiments, with a view of ascertaining the effect of a moist soil and of a moist atmosphere on the development of plants. M. Gain finds the action of moist soil very variable according to different circumstances, especially the physical conditions of the soil. The period of flowering is retarded either by dryness of soil, or by moist atmosphere, and it is hastened either by dry air or by moist soil. Under ordinary circumstances, in practice the conditions are combined or mixed. The two factors which retard flowering are a dry soil and a moist atmosphere. These conditions only occur in a foggy or clouded country where the soil is very porous. A combination (1) of moist air and moist soil is very common in wet seasons on a retentive soil; an analogous combination (2) of dry soil and dry air is common in some hot countries. In the first case, the delay caused by the moist air deprives the plant of the advantages derivable from the moist soil, and the period of flowering is very much retarded. In the second case, the advantage consequent on the dry air brings about an earlier flowering. The two favourable conditions may be realised in southern countries by irrigation, the results of which are as every one knows very remarkable. To sum up, it may be said that dry air is very favourable to the production of flowers; moist soil is favourable; dry soil is unfavourable, moist air very unfavourable to flowering. The full details may be read in a recent number of the *Comptes Rendus*, p. 890.—*Gardeners' Chronicle*.

TREE PLANTING IN IRELAND.—The Irish Land Commission, encouraged by the success of their operations in this direction last year on the west coast of Ireland, have been introduced to extend the woods in the exposed district, and are importing large quantities of forest trees from the principal nurseries of the country.—*Gardeners' Chronicle*.

CION, OR SCION?—"The difference between "cion" and "scion" is not generally known. Cion, refers to the cutting of a tree, and scion to the animal kingdom, no matter what *Webster's Dictionary* may say about it. This difference was recognised by all of the early English scholars, Bacon included." Andrew S. Fuller, in *Gardening*. [It is true that Bacon's *Sylva Sylvarum* has "cions" (ed. 10, 1676). Evelyn's *Sylva* (1678), has grafts (French, greffes), Insitions (Latin), and cions; Parkinson, who wrote more genuine English than Evelyn (1629) has "grafts," and does not use the word cion or scion at all. Miller (*Dictionary*) writes cion. Littré's *Dictionary* gives "scion" in the sense of shoot or graft, but not "cion," which latter, accordingly, is the truer English.—*Er.*]—*Ibid*.

LECTURE ON HORTICULTURE AT BECKENHAM, S.E.—Professor Cheshire, in the course of a lecture at Beckenham on Tuesday, November 22, alluded to the subject of the deficiencies of the soil in regard to certain items of plant food. Mr. Cheshire said he was trying to find ideal manures, which would be more perfect in their character than anything they had hitherto used. The three principal ingredients of which the soil was likely to be deficient were nitrogen, potash, and phosphorus, and for the purpose of testing which of those were required, he advised them to take four flower pots, and representing these elements as one, two, and three, to put some mould into the pots, and mix the manures one and three, one and two, two and three, and so on, and then plant half a dozen Barley seeds or some other, and see in which pot they grew best, and by this process they would be able to tell what the soils wanted most.—*Ibid*.

TASMANIAN FRUIT EXPORTS.—Growers of fruit in this colony are at present apprehensive about the success of the oncoming Apple crop, owing to unfavourable weather, and the probable value of the fruit when placed on the London market—if it should be ample enough to justify a large shipment. New orchards it is supposed will make up for failures through unfavourable meteorological conditions, and greater care in picking, choice, and packing will this season be looked to, last year's experience on these lines having been costly—not everything will do for the English market, it is found. Should the Australian crops prove short, of which there is some prospect, then a local demand will be experienced, and shipments for England be restricted—but a short time will settle these matters. It would appear that much more attention is being paid to the cultivation of sorts best suited to the English market, and altogether, recent bad fortune would appear to have been looked at in the proper light.—*Ibid*.

FROZEN FLOWERS FROM NEW ZEALAND.—On Friday, February 24, there was an exhibition at the Ipswich Fine Arts Club of flowers grown within 12 miles of Wellington. These flowers were procured by Mr. E. Herbert Fison, of Ipswich, a director of the Bank of New Zealand, preserved in ice, and were placed by him at the disposal of the Ipswich Scientific Society. The flowers were almost all those of European garden plants. It would have been much more interesting to have sent New Zealand flowers. New Zealand has flowers which are fit rivals to any the world produces, and yet we see that, as in other colonies, Christmas-themum and other European fancies are preferred at flower-shows. That is a matter of taste; but when our colonial friends send flowers to this country, they would do well to remember that native flowers would be more novel and more appreciated. Alas! the beauty of the flowers fades as the ice melts—fit subject for the moralist. A *Dendrobium* we saw lately at Messrs. Saunders', presented but a sorry spectacle, even though the ice was only partially melted.—*Ibid*.

COCONUTS in North Borneo, we are told, can only be had at twenty cents each for household purposes! In Colombo the people are grumbling because they cost five and six cents.

NORTH BORNEO, so far from being deserted, seems to have a long roll of officers still on its active list. There are 31, we are told, each drawing over 100 dollars a month salary: while the number of subordinate officers drawing less than this standard is very large. It would almost seem as if the Settlement known to some as "New Ceylon," had copied some of the faults of old Ceylon in getting over-officed in proportion to the work to be done.

THE "BURNING TREE" OF INDIA.—At a late meeting of the Royal Botanic Society of London, among the orchids and other plants in flower shown was a specimen of *Laportea*—the "burning tree" of India: both leaves and stems of this plant are covered with stinging hairs after the manner of our own nettle, but of a far more virulent nature. It is stated that when touched the sensation felt is as of being burnt with red hot iron, the pain extending over other parts of the body, and lasting for a fortnight. Little or no mark is to be seen on the skin, but, for some time after, should cold water touch the part, the pain returns with all its original intensity. —*Pioneer*.

STAPLE EXPORTS FROM JAVA—Are recorded in the following figures. It will be found that of cocoa the export last year was about 6,500 cwt.; of coffee a total of about 875,000 cwt. We quote:—

Cocoa	exported in 1892...	330,000 kilos.
Indigo	" 1891...	720,000 "
"	" 1892...	691,000 "
Pepper	" 1891...	3,000,000 "
"	" 1892...	6,000,000 "
Sugar	" 1891...	463,500,000 "
"	" 1892...	425,000,000 "

The sugar is exported as follows:—One-third to England, one-fourth to America, one-eighth to Australia, and one-sixth to China. Coffee shows an export of 28,500,000 kilos. in 1891 against 23,000,900 kilos. in 1892 from private undertakings. The Government crop amounted to 350,000 piculs in 1892 against 325,000 piculs in 1891. The total production of Java cinchona bark in 1892 was 3,232,922 kilos. bark of 4 27/100 per cent quinine, and 1,383,148 kilos. cinchona. The crop of 1893 will be 3,783,839 kilos. bark of 4 48/100 per cent quinine and 1,697,605 kilos cinchona. The estimate of the private coffee crop in Java for 1893 is about 159,408 piculs against 402,495 piculs in 1892.

Cutch is an important article in the trade of Burmah, the exports averaging from twenty to twenty-five lakhs annually in value: but of late John Chinaman has been doing his best to discredit the trade in the markets of Europe by wholesale adulteration. Cutch is mainly used (outside Burmah, where the native takes it medicinally or eats it in *pan*) for tanning purposes, and the Chinaman found that it could be adulterated, greatly to the profit of his pocket, by extracts from the barks of *leintokayan* and *panya*, which contain a considerable amount of tannin, but nevertheless render the cutch exported spurious and utterly worthless. The adulteration is easily recognised by local merchants thoroughly accustomed to the article, but it has been successfully passed on to consumers in other countries by unscrupulous vendors. The Forest Department and the Chamber of Commerce in Rangoon are both highly interested that the purity and good fame of Burmah cutch shall be beyond question, and the Chief Commissioner has now, on their earnest recommendation, proposed to levy a heavy tax on the manufacture of extracts used for adulteration.—*Indian Agriculturist*, April 22.

THE FIBRE TRADE IN JAFFNA, we understand is on the decline. The cause is attributed to the difficulty of procuring palmyrah stalks in large quantities.—*Hindu Organ*.

THE CURING OF TOBACCO is going on in all parts of the country. The crop is believed to be below the average. On account of the high price demanded by the cultivators, an attempt is being made by the traders to combine together and to purchase the article at fixed rate. It is very much doubted that the traders would succeed in their attempt.—*Ibid*.

INDIAN CATTLE.—Notwithstanding that there are complaints regarding the difficulty of maintaining cattle in many places in the Presidency owing to scarcity of fodder, neither milch cows nor draught cattle appear to find their way to Ceylon in any numbers, though there should be a ready market for them in Colombo, where there is demand and inquiry for them on every side.—*Maaras Times*, May 8.

CURING OF FISH.—In Jaffna fish curing is carried on extensively. It is a pity that there is no separate locality or enclosure for drying salted fish. The people of Karayoor utilize the space between the sea and the beach road for this purpose. A very bad smell emanates from the fish during the process of drying up. And as this is injurious to public health the authorities should take notice of the matter and set apart a proper locality for the curing of fish.—*Cor.*, Jaffna "Catholic Guardian."

NATIVE TEA COMPANIES are paying well in Cachar. What a commentary upon the old fashioned belief that everything must be personally overlooked by a European, and the large staffs of European assistants, who were often supposed to have "no time" for anything but toil, sometimes even on Sunday, and who are now largely done away with altogether, Not that the native Companies would not pay even better under the advice of skilled European gentleman, who understood that to labour like tramway horse does not bring about *pro rata* profit. In Assam, certainly in the late seventies, native tea gardens or companies did not pay at all, and many Englishmen made handsome profits by buying up and amalgamating blocks put out by natives (usually with stolen seed).—*Indian Planters' Gazette*, April 29.

JAFFNA TOBACCO.—The local traders have already begun to make purchases. The demand seems to be greater than the supply; and this is owing to the very large number of cigar traders that have sprung up of late years. There are two varieties of tobacco grown in the peninsula, one is used for chewing and the other for smoking. The chewing variety is grown in the Waligamo district and finds a market in Galle and South India. There are also certain inferior kinds of smoking tobacco grown in Waligamo. A large quantity of these inferior kinds is now bought and removed to Pachhillapalli to be cured with the better varieties grown there and the whole is passed off on the unwary traders as genuine stuff. It is only when the tobacco is manufactured into cigars for the Colombo market that the inexperienced and unsuspecting trader detects the fraud of which he has been made the victim.—*Cor.*, Jaffna "Catholic Guardiank."

TEA PLUCKERS: ARE THEY TO WORK A REVOLUTION.—This is the question we ventured to put to the experienced planter who recently addressed us on the subject, and here is his reply which will be read with interest by all concerned with our tea planting industry:—

"With regard to your questions about tea pluckers, I do not pretend to say they have yet been proved a success. The machine, I am glad to know, is being strengthened and improved. But that is a secondary consideration, as if the principle of machine plucking is once established, the tools will come,—perhaps many of them. Some of the men who first tried them are still much in favor of the principle;—while again I know two instances, where it was condemned after a short trial. By the end of this year, I we shall know more of the result upon the trees."

THE COCONUT INDUSTRY OF CEYLON.

A contemporary headed some information the other day about coconuts in a way which described this branch of planting, as "the largest commercial enterprize" of the island. But this is a mistake. (Coconut cultivation can be rightly described as the largest or most extensive agricultural or planting enterprize, seeing that at least 500,000—perhaps 550,000—acres are covered, if not cultivated with this palm. But a very large if not the greater proportion of the produce, is consumed locally in the food and the personal and household requirements of the people, so that the proportion which enters into our commerce, manufactures or export trade though very considerable in all its various branches of cocorut oil; copra, punack; coir fibre, yarn, rope; coconuts and desiccated coconuts—do not in the aggregate make up nearly so important a total as does our ono product tea. We shewed this in reviewing the Customs Accounts for 1892 a few weeks ago; but the information may be repeated here as of more than passing interest:—

We sent away in value in 1892:—

Coconut oil 564,450 cwt., or 7,025,512 gallons valued at R1 per gallon (chiefly sent to India, U. Kingdom, U S. A., & Con. Europe)	R7,025,512
Coconuts, sent to U. K. (India, Suez and Port Said, &c) 384 bags and No. 367,043	423,591	
Coconuts, Desiccated	369,778	
Coconut shells (to India)	29,743	
Copperah 169,073 cwt. (to France, U. K. India America &c.)	1,625,085	
Poonack to (U. K., C. n. Europe and India)	857,761	
Arrack, cocorut spirits (to India) 88,874 gal.	100,236	
Cocorut rafters and laths	195	
Coconut Husks	45	
Coir (U.K., Australia, India, & Con. Europe) 45,404 cwt.	340,530	
Coir rope (Straits, U. K., India Australia and other countries) 8,907 cwt.	111,338	
Coir yarn (U. K., India, U. States, France, Australia, &c.) 105,673 cwt.	634,067	
Coir manufactures	6,309	
Cadjan	60	
Total	R11,524,755	

The value here, it is true is taken from the Customs Accounts which are probably far below the market prices. But allowing for this, there can be no comparison with tea, the value of which exported in the same year was not less in the same return, than R32,525,993. Here then, we must find our largest commercial enterprise. But the export trade in coconuts, in all its branches, undoubtedly comes second and gives employment to a very large number of people. This may be partially judged from an interesting statement supplied to a contemporary by a Colombo manufacturer of desiccated coconut, showing the wonderful increase in the export trade last year over 1891 and giving the equivalent of oil, copra, 'desiccated,' &c. in nuts:—

STATEMENTS SHOWING NUMBER OF COCONUTS SHIPPED OR SHIPPED IN MANUFACTURED FORM FOR TWO YEARS.

	1891.	Nuts.
Oil shipped	409,521 cwt equal to	163,806,400
Copperah shipped	45,660 cwt do	11,415,000
Coconuts shipped		6,899,403
Desiccated cocorut shpd.	1,416,330 lb do	4,248,990
Total nuts		186,171,793
	1892.	Nuts.
Oil shipped	550,977 cwt equal to	220,390,800
Copperah shipped	134,590 cwt do	33,647,500
Coconuts shipped		9,719,386
Desiccated coconuts shpd.	3,849,724 lb do	11,549,172
Total nuts		275,306,858

The shipments are taken from the Chamber of Commerce figures, and the calculations made as follows:—Oil 6½ candies of copperah to one ton; 1,250 coconuts to a candy equal to 400 to a cwt. of oil. Copperah 1,250 nuts to a candy equal to 250 nuts to a cwt of copperah. Desiccated Coconuts 30 lb to a 100 nuts, say 3 nuts to 1 lb. The aggregate it will be observed is over 275 millions of nuts. This calculation has come under the notice of the gentleman who is generally regarded as perhaps the very first planting authority on coconuts in the island, and he has been good enough to favour us with the following statement of his view of the cocorut industry as it stands at present. Our correspondent first takes up the question as to whether the manufacture of desiccated cocorut, started within the past few years, has had much to do with raising the price of coconuts. He does not think so, save in the districts where the mills are located. He then goes on to make very interesting calculations as to the total area under coconuts and the total production in the island; but it is time we quoted what he says:—

The recent and present high price of coconuts has nothing to do with the desiccating business, but is due to the great demand for oil consequent upon the deficient supply of tallow, and to the anticipated short crop of coconuts expected during this year. The desiccating industry cannot have affected the price of nuts generally throughout the island; but that it has raised the price from one to three rmpes per thousand within a radius of say 25 miles from Colombo I am strongly inclined to believe. The farther those mills go afield for the nuts they require the higher will be the cost of transport, and hence within the distance I have named there is keen competition between them and the copra driers; and prices have in consequence ruled higher than they would have done had there not been this competition. But then this only affects the small number of nuts required for desiccating purposes and for export, altogether about 20,000,000. Mr. Figg's figures are interesting as showing the number of nuts utilised for manufacturing into oil, &c. If we take the population of Ceylon at three millions, and allow five persons to a family we get 600,000 families. It is safe to say that each family will use at least one nut per day, this for one year will give 219 millions. To this can be safely added 25 millions for drinking purposes. We then got

Used in manufactures	..	275,000,000
Used in households	..	219,000,000
Used for drinking	..	25,000,000
Total		519,000,000

or to be within the mark say 500,000,000 nuts are yielded annually by the bearing cocorut trees in Ceylon. Allowing 20 nuts per tree we get 25 million trees; but to them have to be added the trees not yet in bearing, and those set apart for toddy drawing. What their number is it would be rather difficult to ascertain, but I should think that for the former 7 million trees and for the latter 4 millions would be within the mark. This would give a grand total of 36 million trees which at 70 trees to the acre would give say 514,000 acres. These figures I believe to be rather under than over the correct number, and am inclined to think that 40 million trees are about the number now growing in Ceylon.

It is extremely satisfactory to us to have such a reckoning as the above independently worked out, and for this reason. Up to 1860, the highest estimate ventured on was 250,000 acres under coconuts in Ceylon. Feeling sure this was below the mark, we offered a much higher estimate and about 1887 put the total at 500,000 acres, raising the same in our latest "Handbook" to 550,000 acres. Then as regards the annual production in nuts, we wrote in August 1891:—"We believe that the number of coconuts produced in a good

average season in Ceylon is not much above five hundred millions (this was in contrast with Blue Book returns which gave 954 millions for 1890) the greater portion being used for the food of the people." Where we slightly differ from our esteemed correspondent is in the number of trees; he gives 36 millions; we estimated 45 millions as an approximative number, because of the very large total in crowded native gardens which scarcely bear at all and so reduce the average for the island, much below, we fear, the 20 nuts per tree. Indeed, it will be seen that comparing the total area and average crop of nuts, it works out to less than 1,000 nuts per acre which at 70 trees to the acre would only give an average of 14 nuts per tree all over; but knowing how natives crowd in trees, we should be inclined to count 75 trees per acre. These, we believe are the best approximations that can be made for the present:—

THE COCONUT PALM INDUSTRY OF CEYLON.

Total area cultivated	= 550,000 acres.
Total number of palms	
old, full bearing, young &c.	= 42,000,000 trees.
Total yield of nuts in a	
good average year	= 550,000,000 No.
Used for Manufacturing	
and Export purposes	= 275,000,000 No.
,, for local food and	
drinking purposes	= 275,000,000 No.

TEA AND COFFEE CROPS:—AND THE SOIL.

Mr. John Hughes sends us the further long instalment of his valuable and interesting investigations into the constituents of tea with reference to the requirements of the soil, which we print today. It will be observed that he also institutes comparisons between analyses of tea, coffee and sugar; and though the last-mentioned is in an entirely different category, yet the comparative results obtained in respect of our old and new staples are so startling as to call for, in our opinion, the special attention of our planting community. Mr. Hughes himself in forwarding the paper, modestly writes:—

"I enclose you my concluding paper on the comparative analyses of Indian, Ceylon and China tea, and hope your readers will be interested in the results which I think open up new views in regard to the production and relative market value of the different qualities of tea.

"Some Ceylon men to whom I have shown the tabulated results, appeared to be much interested and think that they suggest future research as being of real practical use especially to the planter, for the London broker has simply to sell what has been manufactured and shipped home."

It will be observed that Mr. Hughes insists, as the result of his analyses, on the fact that, taking the same quantity of made tea as of marketable coffee, the former (*tea*) removes from the soil nearly three times as much nitrogen and nearly twice as much mineral matter as does coffee! This is very extraordinary in view of what some of our older tea gardens have continued to do for a long series of years without the aid of manure. We have quoted Loole Condera before as one of the oldest of tea estates, and one which we suppose has had very little, if any, manuring for the twenty-five years of its existence and yet we have not heard that its crop bearing has fallen off in quantity or quality. There are some other illustrations

which might be adduced. True Mr. Hughes supplies part of the explanation by telling us how the requisite supply of nitrogen may be got from the air and from rain; but this does not apply to the equally, or more, important mineral matter.

On the other hand, there is no question of the great benefit that tea fields in different districts—in Matale as the Damto Lagalle experiments show, in Mariawatte, in the K. A. W. group and elsewhere—have derived from judicious and even liberal manuring. Surely then, the time has come for the Planters' Association to cause some systematic inquiry to be made into what has already been done in this direction, and to what more may be done in view of Mr. Hughes' investigations. We give Mr. Hughes' paper as follows:—

COMPARATIVE ANALYSES OF INDIAN,
CEYLON AND CHINA TEA.

In order to make these Analyses more complete, as well as for the purpose of showing to what extent tea may be regarded as an exhausting crop if continuously plucked, the composition of the mineral matters including the figures for soluble and insoluble ash are fully extended in table 3.

In preparing this table, it may be useful to mention that instead of giving the percentage composition of the ash which is rather likely to confuse the general reader, it has been thought more satisfactory to state the results obtained from the analysis of a 100 parts of the tea itself.

By this arrangement anyone can see at a glance how much is organic matter (or matter destructible by heat) and how much is mineral matter (or matter which remains after incineration).

The proportion of nitrogen is also stated so that the nitrogenous character of the organic matter may be noted. Of the various constituents which comprise the ash or mineral portion, potash is by far the most important, and occurs it will be noticed in pretty equal quantity in all six specimens, in round numbers more than $\frac{1}{3}$ of the total ash consists of potash; indeed if the carbonic acid of the ash be deducted, the potash amounts to quite $\frac{1}{2}$ of the total mineral matters.

This fact naturally suggests the immense importance of a good supply of potash in an available form suitable for rapid assimilation, and it may therefore be fairly predicted that the permanence of a tea estate will largely depend upon the natural richness of the soil in available potash.

Indeed, these analyses have suggested to the writer the possible explanation of patana soils being incapable of producing forest, namely their poverty in potash and phosphoric acid.

In these results it will be noticed that phosphoric acid occurs in the largest proportion in samples 1, 3 and 5 which respectively were sold for 1s 3d, 11½d and 1s 7d; and no doubt the relatively large quantity of soluble ash which it will be remembered was referred to in the earlier part of this paper is made up by the presence of increased proportions of potash and phosphoric acid.

At the same time it is practically important to observe that lime is less abundant in 1, 3 and 5, and more abundant in 2, 4 and 6, the samples which were sold for 7½d, 7½d and 6½d respectively.

Sulphuric acid occurs in very uniform quantity in all six samples and as regards the figures for sand, it will be interesting to notice that the two Ceylon teas are decidedly freer from this gritty constituent than the Indian and China specimens.

Manganese was present in appreciable quantity in all the samples, being largest in the Indian and Ceylon and least noticeable in the China lots.

In order that planters may compare the composition of Ceylon tea with that of Ceylon coffee, table IV. has been added which gives in a manner allowing of easy comparison, the composition of some parchment coffee sent to the writer from Badulla during his residence in Colombo in 1878 and the original analysis of which appears on page 110 of his official Report.

With the aid of Table V. this comparison is easily made and it will be at once seen that 500 lb. of made tea removes nearly three times as much nitrogen and nearly twice as much mineral matter as 500 lb. of coffee.

Of the mineral matters it may be pointed out that tea removes 11 lb. of potash as compared to 6½ lb. in the case of coffee; also 4 of Phosphoric acid against 1½, and 3 of lime as against 1 in Coffee.

If to these facts we add the exhaustion caused to the Tea bush and the damage through exposure of the surface soil to the effects of rain and sun which severe pruning every two or three years must produce, it will probably be admitted by practical planters that tea is decidedly more exhausting than Coffee; further that both in the cultivation and in the manufacture, more care, skill and constant attention is required on the part of the Superintendent and his assistants than were necessary in the days of Coffee.

Admitting however that Tea is more exhausting than Coffee and that under negligent management it may become increasingly so, still it cannot be considered to be exhausting in the same manner or to anything like the same extent as for instance a crop like Sugar which except in land specially rich cannot be profitably grown continuously without the assistance of substantial dressing of manure.

In table VI the composition of an average crop of Sugar is given for the sake of comparison.

It will be only necessary to compare the results in this table with those in table V to see that Tea and Coffee are both of them only very slightly exhausting as compared with a tropical crop like Sugar.

In his official Report, as well as in many private Reports since 1878, the writer has repeatedly pointed out that Coffee could not be considered an exhausting crop *in itself*, and that it was only the conditions under which it was cultivated that rendered manuring necessary or even desirable.

It was the exposure to wind and wash or the occurrence of slab rock in too close proximity to the surface to admit of the trees getting an extensive hold on the subsoil, that led planters to believe in the efficacy of manuring on certain estates.

If, therefore, it was necessary in the old days of Coffee to apply manure on certain estates, and this is only an assumption for the sake of illustration, it certainly would appear necessary on such estates, when replanted in Tea, either to continue manuring or else not to expect that tea plucking could go on continuously with any large margin for profit.

The conditions of situation, soil and season which were unfavourable to Coffee on certain estates apply with equal force to Tea, with however the additional exhaustion to soil and shrub due to severe pruning.

The Ceylon Tea industry has been favoured with a rapid and most remarkable success and the hill districts of the Island are undoubtedly specially suitable to the production of frequent flushes of leaf; but the industry is still in its infancy and it is just as well to look ahead and as far as possible endeavour to improve the cultivation and to avoid undue exhaustion.

Also in selecting new estates to get soils as rich in potash and phosphoric acid as can be conveniently obtained for the preceding analytical results appear to show in a very definite manner that the market value of tea is largely associated with its richness in soluble ash constituents such as potash and phosphoric acid.

Nitrogen, according to recent researches, is undoubtedly largely obtained both from the air and from rain by natural absorption either through the leaf or the root; but as regards the mineral portion of made Tea that must come from the soil, and if the soil cannot supply a sufficient quantity then we must either supply artificially the mineral constituents that are requisite, or else be prepared to take a lower price for what the estate will produce naturally and without the aid of manure.

JOHN HUGHES,

Analytical Laboratory, 79 Mark Lane, London, E.C.,
April 21st 1893.

322

CEYLON TEA PLANTATIONS COMPANY, LIMITED.

Report of the Directors to be submitted at the Sixth Annual Ordinary General Meeting of Shareholders to be held at Winchester House, Old Broad Street, E. O., on Friday, 28th April, 1893, at 2-30 p.m.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1892, duly audited.

£ s. d. £ s. d.

The net amount at credit of Profit and Loss Account, including Balance brought forward at 31st December, 1891, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is	38,350	10	1
An <i>interim</i> Dividend of 7 per cent on the Ordinary Shares was paid 26th of October, 1892 amounting to	10,299	16	0
It is proposed to pay a final Dividend of 8 per cent on the Ordinary Shares (making 15 per cent in all, free of Income Tax) which will absorb	11,771	4	0
A Dividend on the 7 per cent Preference Shares was paid on 30th of June, 1892, amounting to	2,506	2	
A Dividend on the 7 per cent Preference Shares was paid on 31st of December, 1892, amounting to	2,506	2	8
It is proposed to add to Reserve Fund	10,781	12	0
And to carry forward to next year a balance of	494	12	8

38,359 10 1

The Directors have pleasure in again recommending the distribution of a dividend of fifteen per cent for the past year, on the Ordinary Shares of the Company.

Owing to unseasonable weather the yield of tea per acre fell short of that of the previous year, the out-turn being at the rate of 376 lb. as against 414 lb. per acre for 1891. This deficiency in crop was, however, compensated for by the fall in exchange, and the low freights which rule during the year.

It is proposed to write off for depreciation the sum of £6,275 7s 3d which stands at credit of "Reserve from Premiums," and to add the sum of £10,781 12s 0d to the "Reserve from Surplus Profits," bringing this Fund up to £25,000, the whole of which amount will now be available for the equalization of Dividends.

The gross price realised for the Company's teas sold in London was 9-38d per lb., as against 9-27d. for 1891.

The following statements show the Tea Crop for

the past year, and the Acreage of Company's properties at date:—

Estate	Bought		Tea Manufactured for others.	Total
	Tea.	Leaf Tea.		
lb.	lb.	lb.	lb.	lb.
2,481,938	796,766	1,387,995	4,666,699	

ACREAGES.

Description.	Company's Held on		Total
	Estate acres.	Lease acres.	
Acreage of tea in bearing, 1892 ..	6,503	90	6,593
„ not in bearing..	1,595	—	1,595
Acreage for seed ..	25	—	25
„ to be planted with tea in 1893 ..	38	—	38
Jungle and timber reserves ..	1,926	—	1,926

Totals ..	10,376	110	10,486

The Ceylon Manager reports that all the estates are in good order, and, with a favourable season, he estimates a considerable increase on last year's crop.

The Directors have pleasure in again acknowledging the excellent services rendered by the Staff both in Ceylon and London.

Under Clause No. 69 of the Articles of Association, Mr. H. K. Rutherford, the Chairman of the Company, retires on this occasion from the Board, and, being eligible, offers himself for re-election.

W. JOHNSTON, Secretary.

London, 19th April 1893.

CEYLON COCOA PLANTING.

(To the Editor, "The Field")

Ceylon, March 9th.

SIR,—It may interest some of your readers to know that there is a "boom" in cocoa in this island. A great deal of money is being made by the few who are "in the know," and will be made for many years. Only a little land is available for cocoa planting, and that is being quietly bought up.

The cultivation of cocoa is very simple, the first two years being the only period of anxiety. To put 100 acres of land into bearing costs about £1,200 sterling. Good land is worth about £3 an acre, and is getting scarce. Of course, cocoa will grow on most land under an elevation of 2,000-f., but to bear well the land must be suitable.

It bears in some places as early as the third year, but the fifth is as early as you can reckon on a crop of any importance. After seven years it gives about 2 cwt. to 3 cwt an acre, rising to 5 cwt. The present price is about £6 a cwt for the best. It is undoubtedly a very paying form of planting, and I wonder more people do not go in for it.

"Creepers," as they are called, are constantly coming out to learn tea, but one never hears of anyone coming out to learn cocoa. The former will probably suffer from over-production; the latter cannot, as the land available for it is so small that the supply must always be a small one from Ceylon.

In all respects it is well worth the attention of the small capitalist seeking investment and employment.

—Field, April 8.

INVESTMENT.

[See pages 781 and 784 for corrections of above information.—Ed. T.A.]

THE EASTERN PRODUCE AND ESTATES COMPANY, LIMITED.

Report to be presented at the sixth ordinary general meeting, to be held at Winchester House, Old Broad Street, at 12 o'clock noon on the 27th April 1893:—

The directors herewith submit report and balance sheet for the year ending 31st December 1892. The profit for the year (including £690 15s 4d, the balance from last account, after payment of debentures for £7,000), amounts to £21,993 6s 8d. After providing

for interest on debentures, there remains a sum of £11,090 6s 2d, which it is proposed to appropriate as follows, viz:—

Dividend on Preferred Shares ..	£37 13 0
Payment of Debentures ..	3,000 0 0
Dividend at the rate of 2½ per cent per annum, free from Income Tax, for the year 1892, on the Ordinary Share Capital ..	6,730 10 9
Balance to be applied in further redemption of Debentures ..	1,322 2 5

£11,090 6 2

The debenture debt, as per annexed accounts, has been reduced since the date of issue by £20,010. As shown in the accompanying schedule, the extent of the Company's property now under tea amounts to 9,532 acres, of which about 8,000 acres are over four years old. The yield of tea in 1892 was 2,020,780 lb. being short of the estimate, in consequence of the unfavourable weather that prevailed generally in Ceylon during part of the year. The average gross price obtained was approximately 9½d. per lb. The crop for 1893 is estimated at 2,338,000 lb. During the past year the directors have sold Woodslee estate, and have bought 429 acres of land, which can be worked in advantageously with some of the Company's other properties.

In accordance with the Company's Articles of Association, two of the directors, Mr. O. J. Lindsay Nicholson and Mr. Ralph A. Cameron retire by rotation, and being eligible, offer themselves for re-election. The retiring Auditors, Messrs. Welton, Jones & Co. offer themselves for re-election—C. J. LINDSAY NICHOLSON, Chairman, 41, Eastcheap, E. C. 17th April, 1892.

BADULLA PLANTING REPORT.

BADULLA, May 8th.

During April, WEATHER has been most seasonable. Hot mornings with heavy showers in the afternoons. 13'54 in. rain fell on nineteen days. Everything growing and it has been a capital season for supplying and planting. It is now very hot and in the town it is most trying in the middle of the day.

COFFEE is making wood and looking better again with a good blossoming season; most high coffee will blossom fairly for spring. There will be no large crops however in coming year; and autumn crops are short. Spring crop is now ripening up, but the sample is small and as a rule is turning out short of estimate.

TEA is looking wonderfully well and is flushing splendidly; some fields are giving very heavy yields and all estates are doing well; every one has as much as he can do to keep up with his flush; fortunately coolies are plentiful. Factories are of course busy and prices continue good.

CINCHONA has almost entirely disappeared from the district, a few of the higher estates only having any quantity left.

EARTH WORKS on new road are progressing apace but the completion is being delayed by the want of

blasters and masons. It is to be hoped that all will be completed before the north-east rains to permit of the metal being laid and consolidated during the wet months.

A RESTHOUSE is very much wanted at Coombawatta on the Badulla-Haputala road. The traffic will be heavy as soon as the railway is opened, and the eighteen miles between Badulla and Bandarawella is too far for one stage. Passengers between Passara and Bandarawella will require some resthouse accommodation about the end of the new road at Namina-cooly Gap, and the Provincial Road Committee should at once take steps to provide these resthouses.

A VERY SUCCESSFUL MEETING of the Passara Planters' Association was held last Saturday, there was a large attendance of planters from all parts of the district. Particulars of the meeting will no doubt be sent to you in due course—there are now 54 votes registered and the new Association must be one of the largest in the country next to Dimbula and Dikoya, if not the largest.

INDIAN PATENTS.

Calcutta, April 20th.

The fee prescribed in Schedule 4 of Act V of 1888 have been paid for the continuance of exclusive privilege in respect to the under-mentioned inventions for the periods shown against each:—

No. 7. of 1889.—Edmund Burke of Dublin, Ireland, Tea Merchant, for an improved apparatus for mixing or bulking tea or other similar substances. (From 11th April 1893 to 10th April 1894.)

No. 37 of 1889.—Samuel Cleland Davidson of Sirocco Works, Belfast, Ireland, Merchant, for improvements in rotary fans. (From 25th April 1894. 3 to 26th April 1894.)

No. 50 of 1889.—Charles Dixon Aria of 175, Piccadilly, London, England, Lamp Manufacturer, for improvements in oil-lamps. (From 16th May 1893 to 15th May 1894.)—*Indian Engineer.*

TEA PROPERTIES AND GOOD SECURITY.

We call attention to the interesting information afforded under this head in another column. Hapugahalanda is undoubtedly one of the brilliantly successful tea gardens of Ceylon—and the list of such, we are glad to think is not a limited one; while that of places which might be catalogued as more than moderately successful, would be a pretty long one.

Our esteemed correspondent "Another Planter" should now give us his opinion of the analysis of profits offered the other day by "Planter," as also of the comparison between high and low estates. It is well to have both sides of the shield presented; and of course of the great value of many Ceylon tea properties there can be no doubt; but if we have 250,000—or to be safe, say 240,000 acres of tea in bearing this year and if we are to ship 80,000,000 lb. on an average of 333 lb. an acre what about the properties which must necessarily be yielding less than 250 lb. an acre with the average price at 9½d? Are they to be considered good security or as tending to the stability of the enterprise?

COCOA-PLANTING IN CEYLON.—We call attention to a letter taken from *The Field* in which "Investment" (apparently a Ceylon Planter) speaks of cocoa bearing in some places as early as the third year. We should like to know where? We never heard of cocoa bearing in Ceylon under five years.

Correspondence.

To the Editor.

THE LARGEST CARGO OF CEYLON
PRODUCE : 2,200 TONS (850,000 LB. TEA)
WELL DONE!

Colombo, 15th April.

DEAR SIR,—The Brocklebank Line s.s. "Maharatta," which left for London at 2 p.m. today, took away from Colombo 2,200 tons cargo consisting entirely of Ceylon produce, including 850 tons tea, say 850,000 lb. This is we think the largest cargo of Ceylon produce ever taken away by any one liner.—Yours faithfully,

per pro. DELMEGE, REID & CO.,
F. M. SIMPSON, Agents.

THOMPSON'S PATENT TEA PLUCKERS.

DEAR SIR,—With reference to the notes in your last night's paper by a planter of experience regarding Thompson's Patent Tea Pluckers, it is satisfactory to know that their capabilities are being steadily and carefully developed, and that Mr. Thompson's claims which were at first laughed at are being largely realized. Before long they will no doubt be fully realized, but it takes several months' careful and patient working before the full benefits of the pluckers are comprehended.

With regard to the clippers being clumsy, I do not see how such a machine can be made more sightly, but this is a matter which is of very little importance. As to the charge of finisness, this has been rectified to a considerable extent and the pluckers now sold are much stronger than those which were first received and further improvements are now being made by the manufacturers from instructions given by Mr. Thompson, the patentor and inventor, so that before long I think there will be very little to complain about on the score of stability.

As to their being expensive, the machines necessarily carry a royalty, and in view of the great benefits the invention gives to all tea planters who use the pluckers, and the very large saving they effect I cannot suppose that the royalty will be grudged to the inventor. [Then follows a sentence which is too much of an advertisement altogether.—(Ed. T.A.)] Yours faithfully,
E. B. CREAMY,
Sole Agents in Ceylon for Thompson's Patent Tea Pluckers.

TROUT IN NUWARA ELIYA.

Nuwara Eliya, April 18.

DEAR SIR,—I was glad to see by Mr. Fowler's letter and the advertisement in the papers that something is now likely to be done to stock the waters about here with trout, and I trust all sportsmen will take a R30 season ticket from the Local Board; for undoubtedly large sums will be required to properly stock the lakes and streams about Nuwara Eliya; for, to put in 2,000 or 3,000 fish, is simply pottering, and will afford real sport to no one unless a few native poachers.

We have now known for several years that trout thrive well in these high waters, and take the fly greedily, though from some unknown cause they won't breed; so if we only put a proper stock in, and keep it up by annual importations from England, good sport could regularly be afforded for a number of rods.

With so many keen fishermen in the island, it seems to me astonishing that the matter has not been taken properly in hand long ago, and if Mr. Fowler cannot get the Local Board to take over his fish, and make arrangements for getting out very much larger quantities next season, then he should start a regular Fishing Club, and I will be surprised if he does not receive ample support throughout the island, to enable him to thoroughly stock the surrounding waters with river and Loch Leven trout.

If this were done I need scarcely say how it would add to the already numerous attractions of Nuwara Eliya.—Yours truly,
CHAS. YOUNG.

"JAVA" TEAS AND WHAT THEY ARE
LIKE: CORRECT INFORMATION.

April 23rd.

DEAR SIR,—I wonder where your correspondent "Planter" got the impression that Java teas were allied to high-fired Japans or low Chinas. Such is not by any means the case. Some years ago Javas were very fishy in flavor and got a very bad name in consequence, but they have improved vastly since then, and Messrs. Geo. White are quite right in saying they nearly approach Indians in character—especially in leaf which is made after Indian and Ceylon style and not like China leaf. Some Javas have an Indian character in liquor and some a China character. About five years ago a Java tea was sold in London with such a fine China kintuck flavor that several brokers could not say from the liquor only whether it was Java or China. As China, it was valued at 2s, as Java at 1s 3d, simply because buyers were prejudiced against the name of Java. Early Javas were rather thin, but since more Indian jat was planted they are thicker—due to jat of course. If many buyers were not afraid of purchasing Javas in quantity, the price would be higher, but probably even then lower than Ceylon, as we have unusually good flavor here.

As for Ceylons being compared to Indian Assams, which they often are—Assamy-Ceylons they are called, *i. e.* Ceylons with an Assam character. Putapaula used always to be called Assamy, and very similar it was, and heaps of other gardens had a similar character. I don't see that Messrs. Geo. White have made an error in any single statement of theirs. They certainly are not puffing up Javas in particular—they echo what the general opinion of the trade is.—Yours truly,
M. C.

PASSENGERS, PLANTERS AND
SHIPOWNERS.

Ceylon, April 27th.

SIR,—Having read in your journal about tea-freights by s.s. "Marathon," as well as seeing in other Ceylon papers letters relative to the combination of Indian steamshipowners who have formed themselves into a 'ring,' or Conference, and have fixed in an arbitrary manner a minimum rate of passage-money to England, and minimum rate for planters' produce; in excess, as I submit, of the intrinsic value of the services rendered, and vastly above that prevailing in all other quarters of the globe when we consider the type of ships employed in the trade, their speed, age, and the mileage distance covered,—I think a letter showing what co operation can bring about, this current year will be of interest.

Over three years ago, when tea from Calcutta to London was about 100 per cent more than it is now carried for, I was asked to form one of the Committee in a purely defensive counter-combination of passengers, planters and shippers to checkmate the conference 'ring,' by inducing independent shipowners to run 1st class modern steamers regularly to Bombay and Calcutta, at a speed equal to that of the mail line contract (12 knots only), and to carry tea

and passengers at rates very considerably below those which the autocrats of "the city" thought they were able to fix immutably.

That this could be done without a subsidy is clear from what the Chairman of the 'P. & O.' has put down in his handbook page 58, "without the mail contract the capital of the Company would have much greater earning power."

The B. I. S. N. Company, which has no share in the homeward mail subsidy, has paid 12 per cent to shares are at 100 per cent premium: much of this revenue has been derived from freight on planter's produce.

To Australia, China, etc., several independent lines compete with the 'P. & O.' London to Brisbane and back is 26,000 miles; London to Bombay and back is 12,550 miles; the fares by 'P. & O. are nearly the same, but the Australian is carried 13,500 miles further for almost nothing more!

Comment is needless; the old stalking horse of a 'slack passenger season' cannot be urged in comparing Bombay with Brisbane passengers; nor have we touched on the speed and class of boats on the Australian and Indian run, respectively; some of the latter are entering their 22nd year, and the Indian mail subsidy is very heavy. It will be some time before the new contract falls in, which builders should look to.

The Committee which planters and passengers in India formed were at first ignorant of the wide ramifications of the shipping combination, and met with much opposition; however, it plodded on determined then, as it is now, to succeed in the end, and finding that the matter was one which could not be concluded by correspondence from India, 3 of our working members went to Europe taking with them lists of some 3,500 supporters, which with ladies, children and servants represented some 5,000 adult 1st class fares, who were all pledged to support an independent line which would come to our aid in breaking down an unfair monopoly.

I may fairly state the principle of the movement had the sympathy of H. E. the Commander-in-Chief in India, and the support of H. E. the Commander-in-Chief of Bombay who did not approve of officers travelling 2nd class by sea, where they are brought frequently into the close contact of board ship life with warrant and N. C. O.'s, privates etc., not to mention valets and ladies-maids. *Noblesse oblige*, and the position of an officer should carry certain responsibilities as to upholding it.

The lists which were taken home included 10 Generals commanding in India or heads of departments, Commissioners, Judges of the High Court, members of the Secretariats, Editors, Bankers, Private Secretaries, Colonels commanding corps, with some 500 field officers and leading members of the Indian Civil Service, as well as every individual officer in many corps; but the chief strength of the movement lay in the fact that numerous tea, indigo and coffee Planters, Merchants, Contractors, Exporters and Importers who has registered their names and pledged their support and influence.

What passengers, or any ONE class of planters could not accomplish singly, becomes an easy task when all defensively co-operate for their mutual good: our strength lies in union, and is a modern application of the old story; the faggot and the bundle of sticks, and shipowners at home clearly saw this.

The idea was that the Shipping Line which should take up the business would extend its Board of Directors to admit selected representatives from each of the various industries named above; and further that it should create a new class of shares, (value £5 each, (to be within reach of the smallest income,) so that those who would invest in them, and who shipped or travelled by the line, would receive back part of their payments, as dividends; instead of some 10 per cent going into English shareholders' pockets, who do nothing to support the Companies which form the present "Conference," and many do not even know to what ports the steamers trade. It was partly owing to the advocacy of our friends, and coming to the support of the official community in India, that an

old established co-operative store opened branches out here; the business has prospered wonderfully, having done some £120,000 sterling its second year in India, and caused a reduction in prices all round, as well as a fall of 100 per cent in the shares of certain old-established shops, which do not recognise the co-operative system. The same would happen in shipping shares: what this purely official co-operative society has effected could be far more easily and profitably done by a mutual combination among passengers, shippers and planters, and with much more profit to the two latter classes. A case in point is the steady growth of the China Mutual Shippers Co.

Of course all old established interests would be respected, as far as was compatible with taking care of number 1; but with exchange where it is, and keen competition on the increase, each of us should strive to see where our own best interests lie, and to work out our own emancipation, independent of all monopolies; and even of Associations where these evince too much partiality for the latter. As the Tailor said: "We don't come out here for our health's sake;" we spend during our service in the East some £400 per family and servants in steamer fares on an average, and our wives and children at any rate, deserve better than the mixed company in the second saloon of a steamer; but now, with this combined rise in fares and drop in exchange, many cannot afford more, and separations must be for longer periods until we have a line running in our own interests, and controlled by our leading shippers.

The result of the negotiations at Home was that a provisional arrangement was entered into with certain independent shipowners, when what we anticipated would happen occurred [of course our opponents will say it was a pure coincidence]. Just as the Company was about to commence operations, two lines withdrew from the "Conference": passenger fares fell 25, and tea freights dropped about 100 per cent!

We pointed out, in the *Pioneer, Indian Planters' Gazette, etc.*, that this was only a temporary movement. However, it was very profitable to shippers and travellers while it lasted: still, it had the effect of delaying our project for an Indian Cooperation Steamship Company, which had to remain in abeyance until February of this year, when the 'Conference' again formed themselves into a happy family, to "take tea" with the planter and passenger, in the old sweet way; only more so, rates being raised. Our friends at home again took up the matter, and suggestions were made to the Indian Tea Associations, as well as to independent planters, merchants and shippers. In many cases these were well received, especially when it became known that the proposed mutual or cooperative line would have power to advance money to shippers at moderate rates, so as to give them a free hand in making shipments.

But lo! another peculiar coincidence occurred, the conference again climbed down, and has made a *minimum* offer of 35s per ton for tea.—Which is in excess of our friends' proposals. It is probable that this proposal will be rushed through, but there are also numerous strong indications that many will adopt an independent attitude, and will bear in mind that for the last number of years they have been unduly mulcted by the action of the union.

To accept these terms, for a period of three years only (after which rates might be put up to 50s) should be detrimental to planters' best interests, which would seem to lie in shipping by the cheapest and selling in the dearest market. Shippers have been patient long enough if it pays the "conference" to carry tea now and for the next three years, at 30s, planters might claim a very large rebate on the 50s freights they have been regularly paying, for years back; moreover, they are entitled to representation on the Boards of Direction, and to be allowed to participate, as shareholders, in the profits their shipments enable steamer lines to declare; their share is the shell of the Ceylon oyster. It is as well never to forget that the present concessions seem only wrung from the

conference by fear of open, healthy, competition from shipowners of standing not in the list. A co-operative line, such as we suggest, could afford to take its supporters at least R160 cheaper to England, than the mail line. The vessels would not be extravagantly decorated and upholstered, and management expenses would be reduced to a minimum. One of the Indian S. S. Companies charged £148,500 for its office expenses per annum! When this, and the sums put by to reserve, renewals, insurance and depreciation are deducted no wonder the dividends do not appear large; yet the fleet grows. Similarly tea, indigo and coffee could all be carried cheaper by co-operation. To turn to local conditions; probably the Ceylon exports for the current year would amount to forty million rupees, or 400 lakhs; why should not the shipper, or producer, be able to share in the dividends which this amount, or its part will pay to the steamer Companies and shareholders? I can only express my belief, which is not one hastily formed at any rate, and is based on the deliberate opinion of many leading merchants and shipowners at home, and by numerous financial papers, that the Indian planter and passenger is like the Indian elephant, ignorant of his own vast strength and importance.

In December 1889 vide the *Indian Planters' Gazette* we first proposed the outlines of this scheme, and were told we could not bring down the shipping "ring" in its rates. Had our plan been at once acted on, passengers, exporters and importers would have been saved several million rupees up to now.

If Ceylon Planters and Passengers consider their interests lie in the direction we have indicated they should do a little organisation, (independently of any fine old crusted interests if necessary) and if they write to.—The Hon. Secretary Indian Passage Co-operation, Sanawar, Kasauli, Punjab,—he will see that their communications and suggestions are forwarded to the shipowners referred to. Letters should state the support, in freight, which the writer could give, and to what ports it should be shipped, so as to enable the Company to determine whether sufficient cargo, passages etc., was offered from Ceylon plus Calcutta and Burmah, to enable them to take the business up.

It is only in the Crown dependencies like Ceylon and India, where there is a large travelling military and official element always on the move, that such a shipping co-operation is fully practicable, on account of our facilities for defensive counter-combination, afforded by clubs, assembly rooms, Associations and Regimental messes.

I am certain that the matter is one fraught with much pecuniary benefit to the passenger, but with more to the shipper, and it is within measurable distance of success; witness tea freights today and those 18 months back which we three years ago predicted, and were scoffed at. Every effort was made to come to an amicable arrangement with the "Conference" on the entire question, but in vain. It has failed, however, to shut out unimportant 'Tramp' steamers; much more will it be unsuccessful against a powerful organisation such as is indicated above, which those interested in Ceylon are invited to join individually and to elect three members to represent the island, in a great Federation of Shippers and Passengers.

BUNDLE OF STICKS.

MR. HUGHES' ADVICE OF NO USE TO CEYLON PLANTERS?

Upcountry, April 27.

DEAR SIR,—Mr. Hughes' advice to let the tea leaves develop more would have been of use to us some time ago. Now I fear it is too late. We have a strong and powerful foe in front of us, in North India, and a weak but numerous one behind us, in China &c. We are not strong enough to advance on the former and it will be death

to retreat to the latter. To follow Mr. Hughes' advice would be to increase our output by at least 25 per cent, and we have already too much.

We are now living on Exchange—neither a healthy nor safe means of profit—and if science can give us no better advice than the above, then indeed we are in a bad way.—Yours truly,

AN OLD COFFEE STUMP.

CEYLON COCOA PLANTING.

SIR—The letter you published today taken from *The Field* signed "Investment," is as misleading and *couleur de rose* a puff about cocoa as ever startled the cocoa planters of Ceylon. The cocoa tree that bears in three years is the swallow that does not make the summer.

The cultivation of cocoa is by no means simple and the planting out is not limited to two years; since supplying goes on for years after the first planting of the clearing, owing to the many enemies that overtake the plant when young. The mere possession of capital will not suffice, except for the purpose of dropping it in Ceylon and blaming the country afterwards.

Long experience in Ceylon, a mature judgment, patience and a long purse are needed to be a successful cocoa planter. X.

THE GERMAN EAST AFRICA CO.

April 28th, 1893.

DEAR SIR,—I enclose copy of a letter I have addressed to the Editor "Ceylon Examiner" with reference to the article you quoted in your issue of 26th instant.

As regards the emigration of Sinhalese, the statement made in the "Examiner" that the project had to be abandoned is incorrect: the matter has been referred to the Secretary of State. If Lord Ripon should decline to sanction emigration, all the correspondence that has passed on the subject will be sent to you for publication, with other details explaining the action of the local Government. I see no reason for supposing that this will be necessary.—Yours faithfully, B.

(Copy of a letter referred to.)

Galagedara, 28th April 1893.

The Editor "Ceylon Examiner."
DEAR SIR,—The account you published in your issue of 25th inst. contains so many mis-statements, that I cannot leave it unnoticed:

(1.) It does not take a month to travel 40 or 50 miles to the estate: the usual allowance for men carrying loads is *four days*.

(2.) The estate is not unhealthy. The elevation is about 3,000 feet, with a climate resembling Dik-o-ya. Your informant contracted fever probably on the coast by drinking bad water, when soda-water was easily procurable.

(3.) As regards good supplies, all necessaries can be obtained on the estate. Your informant was supplied with rice, whisky, brandy, sugar, fowls, milk, curry-powder, mutton and other stores he might surely have taught his African servants to make hoppers.

Fourthly, the wild statements made as to the malaria carry their own reputation. There is always fever, more or less, in every tropical country when land is being newly opened. You state that "the attacks of fever carry one off within eight or ten days," and "when you're once in for malaria, it is a toss-up between life and death," but though your informant had fever on several occasions, he still lives and with light-headed recklessness libels the medical man to whose care and skill, if he was at any time seriously ill, he probably owes his recovery.—Yours faithfully,

PERCY N. BRAINE,

THE TEA PLANTING ENTERPRISE IN
1892: NO. 1.

March 6th.

DEAR SIR,—Your leader of the 4th inst., in regard to the position of the tea industry is calculated to fill one with grave anxiety supported as it is by figures of the yield of tea and prices realized for the last eight years. The area under tea today is about 250,000 acres and if we take 220,000 acres as being in full bearing in 1892, the yield of 71,133,657 lb. is equal to 323 or say 325 lb. per acre all over.

Let us assume that exchange has been constant at 1s 4d for the last three years for the sake of calculation, and that it costs 6½d sterling to land tea in London or say 5½d nett in Ceylon (= 31½ cents) the results work out as follows:—

In 1890 the Ceylon crop averaged... 11d
Less cost of production 6½d
Balance being profit 4½d
4½d at 1s 4d exchange = 27 cents × 325 lb. and acre = an average profit per acre of R87.75 for the whole island.
But for 1892 the crop averaged 9½
Less cost of production 6½

Balance being profit 3d. and as 3d. at 1s 4d. = exchange 18 cents × 325 lb. per acre = R58.50 per acre profit. In other words for every £100 profit netted on the enterprise in 1890 there has only been £66 netted in 1892,—a rather startling result! Assuming that exchange went up to par where should we be? Of the 6½d cost of production at least 5d. is spent in silver payments *i.e.*, gets the benefit of the low exchange—so to the 6½d we would require to add 2½d for rise in exchange; which would mean that with exchange at par the whole Ceylon crop for 1892 would have cost 9d. to produce and as it only realized 9½d, where would the interest on the capital invested come from?

To come to another point and eliminate possibilities; taking only what actually occurred in 1892, Estates.

	Total crop.	Average price.	Profit per acre say
	gave lb.	at	R
36	3,062,000	7½d	24.37
39	3,070,500	7½	19.50
26	2,069,000	7½	14.62
22	1,083,500	7	9.75
21	799,500	5½ to 6½	0

144 lb. 10,084,500
Note.—The crop is calculated at 325 lb. per acre being the Ceylon average yield.
The figures are taken from Wilson, Smithett's Sale Lists for 1892.

No doubt the low prices in some of the above instances were partly counterbalanced by a larger yield, but this would not affect the total profit for the island as R58.50 per acre.

The above 144 estates produced about 1-7th of the total crop of the island and made a nett profit of about R16.75 per acre on an average; and if during 1893 tea drops another ½d per lb., on an average they will actually make their tea at a loss!

Does not this indicate a coming crisis in the history of the industry?

The capital invested in the 250,000 acres of tea is probably not less than £8,000,000 sterling or £32 per acre and even now it cannot on an average be paying much over 10 per cent (if it is doing so) on this amount. 10 per cent on £32 would = R48 per acre, and the nett profit in 1892 was R58.50 against which has to go wear and tear of machinery and of bushes and buildings.

Two other points that definitely settle the fact that a number of gardens have reached the stage

where they have ceased to yield profit, are (1) several gardens have been abandoned within the last few months; (2) a number of gardens have given very heavy yields and profits as for instance one garden in Dimbula gave £18 sterling per acre last year of profit, and two gardens in Kalutara and Kelani Valley gave about R180 an acre and as these gardens far more than made their share of profit, so others less fortunate must have been working with a fractional profit or even at a loss as the total amount of profit was only R58.50 per acre all over the island.—Yours truly PLANTER.

No. II.

UPCOUNTRY vs. LOW-COUNTRY PLANTATIONS.

DEAR SIR,—I have trespassed far more on your space than I intended and it is with the hope that you, and other abler pens than mine, will criticise my figures and place their views before your readers as the importance of the subject warrants its full discussion.

There is only one point I want to touch on and I've done, and that is, why are hill gardens valued at so much more than lowcountry gardens by the majority of people? Led by Mr. Rutherford several years ago, a school of men arose who condemned the lowcountry and at that time judging by Mr. Rutherford's ability, there must have been facts and figures to support their views; but I venture to opine that not only do the low country gardens on an average today give a profit acre for acre much greater than the hill gardens do, but as their capital account is much lower on the invested capital, their profits per cent are far more than on hill gardens.

To begin with, crop is far heavier, say 500 lb. per acre all round, compared with 350 or less per acre upcountry. Then the cost of production is much less, averaging say 22 cents compared with 32 upcountry.

Take a lowcountry garden giving 500 lb per acre; costing to produce 22 cents plus 8 cents for shipping and sale charges = 30 cents in London and selling for 8d exchange at 1s 4d = 50 cents showing profit 20 cents per lb on 500 lb = R100 per acre. Now take a hill garden giving 350 lb per acre and cost of production 32 cents plus 8 cents shipping and sale charges = 40 cts in London selling for 9½d, exchange 1s 4d = 58 cents = profit per lb 18 cents on 350 lb per acre = R63 per acre. The above I believe to be rather in favour of the hill garden than otherwise. Take last week's sale list and you find Yataderiya and Castlereagh side by side, both one agency: work out the crops and which is better? Or take Clyde (Kalutara) broken pekoe 61, pekoe 41 pekoe souchong 38, against broken pekoe 59, pekoe 51 pekoe souchong 42 for Court Lodge, Nuwara Eliya. I mention this last place as it is one of the crack upcountry estates in the best district of Ceylon.

Will any sane man on the face of those actual figures deny that lowcountry tea is paying far better than upcountry tea on an average?—And the last figures I adduce in support of my statement are again from Wilson Smithett's list:—

Kalutara (which sold a large quantity of its best teas in Colombo in the last six months of 1892 which were bought for Australia and Russia largely) averaged in London in 1892 8½d per lb., actually as much or more than Dolosbage and Yakdezza, Nilambe and Hantane, Matale and Hunasgeriya, Kadugannawa, and Alagalla, Sabaragamuwa, Knuckles, Kelebocka and Rangala, which are all hill districts and produced 14 million or 1-5th of the Ceylon crop. Nobody will deny they were "out of it" in the matter of comparative profits per acre.

Then Dikoya, Uva, Maskeliya, Hewaheta, Kotmale, Pussellawa, Ambagamua which jointly produced 2½ million lb. of tea at an average of 9½ or 1d more than Kalutara got, or = 7 cents say, against a far heavier average yield and lower expenditure.

Then take the three districts whose teas topped the market—Bogawantalawa, Udapussellawa and Dimbula—which produced collectively 16 million lb. of tea at 10½d per lb., and here we have only a difference of 2½d or under 15 cents remember, in the very choice districts, which I maintain is more than made up for by cheaper production, and larger crops in the low country.

I find in conclusion that the Hill gardens sold in London last year 5½ millions of pounds tea, at an average of 9½d per lb., while the low country gardens averaged over 8d per lb. leaving an average of 10 cents in favour of upcountry teas in value against which has to go about 10 cents extra cost of production, and a far smaller crop per acre.—Yours truly,
PLANTER.

COFFEE PLANTING IN CENTRAL AND SOUTH AMERICA.

Kansas City, April 7.

DEAR SIR,—Under separate cover I send you prospectus of Coffee Company and also prospectus of another Company in Bogota. Knowing the deep interest you have always taken in everything pertaining to coffee and coffee planting, I feel sure these papers will be interesting to you. To old Ceylon planters the figures, estimates and statements made in the Bogota paper will be rather startling; to me they certainly are, and I gained my experience in coffee-planting on the Ouvah and Spring Valley Company estates, and I rather think the pioneer and founder of those estates would also be rather astonished with the Bogota prospectus if one were handed to him.

I am interested in the Guatamela Company and purpose going there shortly. Evidently the methods used by South American and Central American planters are very different to our Ceylon methods. Of course I believe in Ceylon methods, and would like to see our style adopted on this property. I would write more fully were I sure that this letter would reach you. Possibly you remember some portions of my career in Ceylon. Geo. Morice, Wood, Bayley, Irvine were my intimate friends and I was manager for Glenny & Co. in Badulla in the last years of my stay in Ceylon.

The last I heard from Ceylon was from my old friend Jas. H. Sproule formerly of Badulla now in Kandy, and he sent me copies of the *Observer*. I trust the island is once more financially prosperous.—Yours very respectfully, W. CARIWRIGHT.

[We are very glad to hear from Mr. Cartwright whose name as an Uva resident, we remember well; we hope his own undertakings will be successful. The prospectuses have not come to hand, but perhaps Mr. Cartwright will be good enough to send us duplicates, as we should like to notice the same for our *Tropical Agriculturist*.—Ed. T. A.]

COCONUT CULTIVATION IN THE WEST INDIES.*

REVIEWED BY A CEYLON COCONUT PLANTER.

Pamban, May 8.

DEAR SIR,—In one of your appreciative reviews of "Nicholl's Tropical Agriculture" you say you would like my views on the chapter on the coconut palm. I am not much of a hand at reviewing, but all the same send you a few notes. The chapter on coconuts is well written and evidently by one conversant with the subject. The different

* The chapter on Coconuts in "Nicholl's Tropical Agriculture," (Macmillan, Publishers.)

uses of the tree and its products are well described; and the directions with reference to soil, climate, cultivation, &c., are good. The writer's views with regard to the best soils coincide with mine; and no doubt whenever coconuts are grown the same kind of soil in each locality will yield pretty much the same result, rainfall being equal. Whatever the practice may be in the West Indies when planting inland, putting salt into the hole, before planting is not resorted to in the East with the idea of supplying the absence of a saline atmosphere. For though no doubt coconuts grow best in a maritime climate, yet they flourish well inland, and do not seem to feel the absence of the salt air. Better grown and more prolific trees than those I saw in the town of Badulla years ago I could not have desired, and they grow quite 50 miles from the sea. Salt is often put into the holes before planting in land badly infested with white ants, as it gives the plants a chance of fixing their roots in the soil before the termites can do harm. I have begun to think that too much stress has been placed upon the necessity of salt for coconut palms. If the trees are grown upon good land in a good condition of tilth, they thrive well without salt; but if the land is not in good mechanical condition the application of salt then, by its action on the soil and its affinity for moisture, improves it, and sets free and makes assimilable ingredients, which without the action of the salt would have lain dormant; poor soils, however much salt is applied to them will not benefit much by the applications. The circumstance that trees nearest the shore bend their heads towards the sea is not proof that it is because they love the sea breezes. The fact is that the coconut palm loves the light, and will always make towards it; and to effect this will, when it has grown sufficiently tall and pliable grow at almost any angle. Trees bordering any open space will behave in the same way as those bordering the sea.

It is recommended by Dr. Nicholls, in laying down a nursery that 50 per cent more nuts than the number of plants required should be laid down in the nursery; this seems much too great a margin, for if good ripe and well selected nuts are sown, there will seldom be more than 10 to 15 per cent failures. It is evident that greater liberality in the allotment of space to each plant is sometimes shown in the West Indies than in the East, where it is too often the other way; 33 feet between each plant sounds extravagant; but 25 feet the distance recommended by the writer, is a very good average distance. The warning not to allow cattle into a young estate is a very necessary one, as their bite is poisonous to coconut plants; and if badly bitten the only remedy is to pull them up and put in others; cattle should not be allowed in till the plants are from 5 to 6 years old. In almost every country where coconuts are grown catch crops seem to be considered a fair and legitimate thing to grow till the trees require all the space for themselves; and no doubt the profits from these often materially help the man with limited capital, who would otherwise not be able to hold out till the trees came into bearing; but the writer's injunction should in all cases be carried out in after years if the estate is to yield profitably. He says "catch-crops, such as maize, cassava, potatoes, and such like may be taken off the land when alluvial loams are planted with coconuts, but it must be remembered that these crops tend to impoverish the soil, and an effort should be made to return in manure what has been taken away by the catch crops." If this is so necessary where rich soils are concerned, how much

more so must it not be in the case of poor soils? The writer asserts that the coconut palm has fewer enemies to contend with in the West Indies, than it has in the East, but in the next paragraph, he mentions a scale insect or *coccus* by which the trees there are attacked. "Little scales are seen closely applied to the leaves; after a time the leaves attacked turn brown and die, and eventually the plant may be killed. Such blights are prone to attack weakly trees planted in unsuitable elevations and badly cultivated; but sometimes they invade healthy trees properly cultivated, in the best soils and climates." It is consolatory to believe that we have no such disease in Ceylon, or if there is something like it that it is of such a mild character as to be practically harmless. When the so-called coconut leaf disease was discussed two to three years ago, the almost unanimous opinion was that though a few trees here and there in good soil and under good cultivation showed some signs of the disease, yet wherever it occurred in an aggravated form the soil was poor, unsuitable for coconuts, and differently cultivated. Where it occurs in well cultivated land it may be owing to the absence of some one necessary ingredient in the soil, and when that is supplied the disease may disappear. I hold that as a rule where parasitic pests attack animals or plants, and are injurious to them, there is something wrong with the conditions under which they are nourished or grown. We all know that where a water famine occurs in a district, and grass fails, cattle become thin, with staring coats, and are covered with vermin; but so soon as rain falls and grass grows they become plump, recover their smooth and sleek coats and the vermin disappear. In one case the vitiated and impoverished blood favoured the multiplication of vermin, while in the other the pure and wholesome blood repelled them. So it seems to be with plant life; and so long as we will grow plants under unfavourable conditions to thrive, we need not be surprised that there will be a certain proportion of parasitic life causing more or less harm to them; yet we can by improving the condition of the soil, and by liberal cultivation, so contract them that they shall be of little or no harm. In Ceylon the red beetle is the only real pest to be dreaded, and wherever a tree is attacked by them it should be destroyed at once by burning the leaves and that portion of the trunk that is infected. It is rarely that a tree is attacked by this beetle after it is about 10 years old, and this I think is accounted for by the fact that by that time it is out of the way of harm by having its branches torn off before they are quite matured and the stem underneath exposed in a tender condition or wounded. It is when these conditions occur that the beetle has its chance and avails of it to lay its egg in the wounds or fissures. To syringe trees for blight could only be done on a very small scale and when the trees are young; just fancy any one undertaking to spray even a few thousand palms say 50 feet high, not to speak of those taller! Rats no doubt commit great havoc where they are in any number, but to circle each tree with a 12 inch wide band of tin or galvanized iron would be costly. Surely arsenic and phosphorus would soon rid an estate of them. They seldom do much mischief in Ceylon. To allow the nuts to ripen fully and fall from the tree is no doubt economical, and for such nuts oil manufacturers would give something appreciable over the ordinary rate per 1,000; but the practice has its drawbacks and no well-regulated estate would tolerate it.

W. J.

"STALK" IN MANUFACTURED TEA, THE PRACTICAL PLANTING VIEW.

May 9.

DEAR SIR,—Of course there has always been stalk in tea. What else connects the bud and two leaves, when plucked together in the ordinary way? "Good tips" are always acceptable in theory as well as in the factory; but are we to believe that your correspondent would have us throw away or leave on the bush all stalk and pick separately each leaf? In this case he would require three times the amount of labour, or thrice the time, or perhaps a new race of coolies with three hands apiece.

Probably you are correct in supposing that the stalk objected to by Mr. Hughes, is the result of the use of plucking scissors. "MULU PER."

NATIVE OILS.

Fort, May 10th.

SIR,—With reference to other oils for lamps, used by the natives outside the Municipality, are Kekuna Etta, Mee Etta, and Domba Etta, largely I should say in the Matara district, and many places in Galle district too.

MATARA.

[We are quite aware of native oils being used in certain rural districts; but the supply of these we believe to be far too limited to extend to the towns and we question if any appreciable quantity of any oil save kerosine, or coconut is used for lighting purposes in Colombo.—Ed. T.A.]

"PLANTER'S" LETTERS ON OUR "TEA ENTERPRISE."

DEAR SIR,—The letters of your correspondent "Planter" are suggestive, if not altogether called for. Leaving many points in his letters to others, I would remark on a few.

He says, "assuming that exchange went up to par where should we be? Assuming that the heavens fell and smothered the larks, where should we be? He says for every £100 netted in 1890—there has only been £66 netted in 1892. But do the dividend declared by Companies bear him out in these figures? Take the Ceylon Tea Plantations for instance—or many others which could be named. The fall in exchange, larger proportions of area in full bearing, and cheaper working, so far compensate for low prices. Were exchange to go up, as Bimetallists pray, is "Planter" prepared to disprove their contention, that prices would go up also?"

That many places yield only very small profits, and that some cannot be worked without loss, I concede. These should never have been planted; and as "Planter" says, "several have been abandoned within the last few months;—this canker in our industry is working its own remedy."

As to the respective merits of low and high estates, you Mr. Editor will admit, that I am quite competent to speak from long and varied experience, and ownership of both kind of properties.

I think it must be admitted that the average of lowcountry profits is greater than that of upcountry estates, but chiefly because the lowcountry was not for many years in coffee. New land or land only a short time under coffee upcountry is doing better (making larger profits) on the average, than lowcountry land. If the profits were known of the twenty estates which gave largest returns during the last three years, perhaps fifteen of them would be found to be estates which had coffee for some years. Where in the lowcountry have such yields been got as from the new land in New Peacock, or from some of the patanas in Bogawantalawa? Or where the profits of Lippakelle, Gorthie, or Chapelton? Yet I could name owners in the lowcountry, whose capital has been returned 2½ times in the last four years!

But really a discussion on such points is of no real value. Those who have the best estates are to be congratulated; those whose lot has not been so

happy, must do the best they can, and we need no bring it home to them, that they are not of the "favored."

But I would ask "Planter" to revise his Estimates for working an Upcountry Estate. He says the local cost of producing 350 lb. per acre is 32 cts. I certainly think it need not be—provided the factory is completely equipped.

I send you an Estimate which I know can be worked to:—

<i>Estimate for working 400 acres giving 350 lb. per acre.</i>	
Supervision and allowances	.. R6,360
Tools	.. 200
Roads and drains	.. 600
Pruning say 170 acres yearly, all to be pruned in 18 months	.. 1,500
Weeding	.. 4,800
Bungalow lines and Tea-house upkeep	1,000
Boundaries, watchmen, &c.	.. 400
Manure, clearing lines, &c.	.. 600
Crop charges 140,000 lb. at 15 cts., Plucking 9 cts., all other charges to shipboard 6 cts.	.. 21,000
Contingencies, repairs to machinery	.. 1,500

R37,960

140,000 lb. say at 27 cts. leaving a profit greater by R7,000, than "Planter's" figures show. That the plucking can be done for 9 cts. I can prove by several instances. The remaining 6 cts. of crop charges are ample, when Agents do not enforce or extort their own charges. If Agency and Brokerage cost $\frac{3}{4}$ per cent instead of the 1 or $\frac{1}{2}$ they need cost, then it is not the fault, but the misfortune of the planter. A V. A. or a proprietor can easily see how a cent can be saved per lb. from above Estimate. X. Y. Z.

STALKS IN TEA.

DEAR SIR,—I do not think the stalks in tea "discovered" by Mr. Hughes have any connection with "Patent Tea Pluckers"; but simply are what have always existed and always will. This illustrates the objection I have always had to scientific interference with tea planting. Here we have our adviser and friend, who might also become our paid adviser, crying "stinking-fish," that is inviting attention to points our enemies the Mincing Lane Buyers and Dealers generally would, if they could, be glad to take advantage of. Sometime ago I examined some small leaf tea a traveller to Japan had brought with him. After infusion on a plate a large proportion was about stalk. But of course tea-experts know all about this new "discovery"; only brokers, *et hoc genus omne*. will keep dark whenever anything can be said to depreciate the produce they live by snapping up.

PRODUCER.

[But surely, "Producer" would like to have all the information which science can afford him; and especially when, as in Mr. Hughes' report, the teas were tabulated according to the prices realized, showing the properties, &c. which were apparently valued by experts. If there is too much "stalk," is it not possible by careful plucking to do something to reduce it?—ED. T. A.]

"ECONOMY ALL ALONG THE LINE?"

Upcountry, May 13.

DEAR SIR,—If you have not seen the extracts on other side, they may be of interest at the present time, the notes, of course, apply to a temperate climate, but how much more exhausting must a tropical climate be.—Yours truly,

AN OLD COFFEE STUMP.

P.S.—"Economy" all along the line is the latest from "the City":—

"In every case the produce of a field and the duration of its fertility bear a fixed relation to the sum of

the mineral substances in the soil. The abundance of the crop is proportional to the rapidity of the action of the mineral matters in a given time, the total produce of a field over a given time is not increased, but only the quantity obtained in a given time."

"The deduction is that agriculture, as at present pursued, tends to a present quickening and increase of produce at the cost of the future exhaustion of soils."

Thus Liebig says:—"The prevailing system of agriculture for half-a-century has been one of spoliation, and that if persisted in, the inevitable result will be, at no distant date, the ruin of the fields of agriculturist."

Again:—"The apparently remunerative employment of these means on many fields may last for a long time, ere the agriculturist becomes aware of the injury he is doing himself by neglecting to return the mineral substances removed by his crops; but the longer he continues by them to obtain larger crops, he is approaching nearer and nearer the limits at which they must cease."

A DISASTROUS COFFEE SPECULATION.

The record of another disastrous speculation has been added to the history of coffee. This had a strong basis of support in the prospective short crop of coffee in 1893-94. The statistical position and outlook warranted a belief in high prices for coffee. Working upon this, one Kaltenbach, an operator, resident in Europe, became the head of a clique which carried an enormous quantity of coffee. Kaltenbach was reputed as having made in his venture over \$1,000,000. As usual with bull speculators, he accumulated a heavy holding and advanced the price of coffee by his own operations. The visible supply kept increasing and Kaltenbach was unable to market his coffee at ruling high prices. The market steadily receded, and as Kaltenbach's paper profits faded, he was pressed for margins on a rapidly declining market. Down, down, down, went prices for the past few days, and down went Kaltenbach, carrying with him the large and well-known firm of Thomas M. Barr & Co., his American brokers. The closing prices of No. 7 coffee, Exchange standard, on the evening before the Good Friday holidays, compare with the closing prices Tuesday night, April 18, as follows:—

	March 30.	April 18.
May	16.35 at 16.40	13.05 at 13.10
June	16.25 at 16.30	13.05 at 13.10
July	16.20 at 16.25	13.05 at 13.10
August	16.15 at 16.20	13.05 at 13.10
September	16.15 at 16.20	13.05 at 13.10

During Tuesday, May sold at 12.75c; June at 12.70c; July at 12.65c; August at 12.70c; September, the most extensively traded in, at 12.60c. After these figures the market closed steady at the recovery shown above.

The above comparative figures show a decline of 3.10 at 3.30c, or over \$4 per bag. If, as reported, the clique carried 750,000 bags, it is evident that in closing the deal, the loss wiped out all the reputed profits of the members and their original capital.

All of this does not destroy the fact that the statistical position of coffee is strong and that now, liquidation having been forced, prices are more likely to advance than decline.—*American Grocer*.

TROPICAL FRUITS AND FLOWERS.—The Editor of the "Horticultural Times" in his issue of April 22nd, pays a high compliment to our correspondent "Old Colonist." He writes:—

"In a very interesting series of articles from the pen of Arthur Sinclair, now appearing in the *Tropical Agriculturist*, we call the following which cannot fail to be of interest to the horticultural world. The subject treats on travels in Peru and the Upper Valley of the Amazon, and a perusal of the writer's description of the luxuriant vegetation is sufficient to make any enthusiastic representative of 'the art that doth mend nature' yearn for a trip to the home of the graceful palm." Then follows a reproduction of the paper referred to.

PLANT PESTS AND INSECTICIDES.

One of the most costly and unprofitable of all the operations in a garden up to less than a score of years ago, and one still too frequent, was the never-ending round of washing, scrubbing, and cleaning insect-infested plants." The costliness mainly arose from the high price of the "insecticides," or the inefficiency of those commonly employed, and the great amount of labour expended in applying them; and the unprofitableness, chiefly because of the severe treatment the plants received under the frequent scrubbing and rubbing to which they were subjected, and the general want of care and thoroughness in carrying out the cleaning process. More money was often spent in futile attempts to free plants from insect pests than would have bought clean, healthy stock of the same size in the open market. Unless the rarity or value of a plant will justify the cost of carefully cleaning it, when plants from any cause get into such a disreputable state of filth and insects, they should be promptly placed in the nearest furnace, and burned along with their dirt and vermin.

At the present time, when the depression in trade and rural affairs makes it a necessity in most gardens to keep down expenditure to the lowest limits consistent with efficiency, the strictest economy has to be practised in all departments. In few garden operations can more economy be generally carried out than in the timely prevention or arrest of insect and fungoid attacks. From want of forethought in applying simple and effective remedies, these pests are too often allowed to get a firm hold upon plants, and even permitted to overrun a house and sometimes a whole range of houses, before a serious thought is given to them, or a finger lifted to repel their attack. By promptly applying a remedy, the outbreak might nevertheless have been stamped out in its infancy in a few minutes. Effective means and prompt action comprise the whole secret of success and economy in dealing with insect as well as fungoid pests.

It is now well-known to many gardeners, and should be known by all horticulturists, that petroleum is one of the best and cheapest of all insecticides; but its liability to abuse by the ignorant or careless makes the general use of it rather risky in unskilled hands, in which it is always dangerous, and sometimes deadly in its effect upon plants. To avoid this, the strength of the petroleum must be carefully reduced to the point at which it will kill the insects without injuring the plant on which they live. It is a curious but most important fact in Nature, that petroleum may be so graduated in strength that it will kill every insect it reaches which infests or preys upon plant life, without injury to the plant, or part of a plant, on which the insect lives. Thus, a very weak admixture of the oil applied to aphids—say green-fly on a Rose shoot, or any other tender young growth which aphides affect, will kill the fly, and not injure the growth. About $\frac{1}{4}$ gill of paraffin oil thoroughly blended with 1 gallon of soft water will destroy all aphides; but even half that quantity of paraffin in a gallon of liquid will do the same, if it is perfectly amalgamated with the water and properly applied in the form of spray. As a rule, red-spider and thrips do not appear on younger growth, although, if not prevented, they quickly overrun it. Older growth, such as fresh full-grown foliage of Vines, Peaches, and the like, are apt to be infested with them, and may be treated with $\frac{1}{2}$ gill of paraffin in the gallon of liquid without fear of injury to the growth, but with deadly consequence to the spider and thrips. For eradicating mealy-bug, scale, and similar pests, which chiefly infest the tough, leathery foliage, and firm woody parts of a host of stove and greenhouse plants, 1 gill of paraffin in the gallon of liquid may be safely employed, and if regularly and judiciously applied it will effectually keep them clear of every insect pest.

Among the various methods, most of which are failures, in vogue for reducing the strength of paraffin to make it safe for use as an insecticide, one of the

safest and handiest is the method, now pretty well known among horticulturists, of boiling black soap and water, in the proportion of one of soap to eight of water, till the soap is wholly dissolved; and then, while the liquid is as near the boiling point as possible, pouring it into bottles, and at the same time adding the paraffin. The nearer the liquid is to the boiling point at the moment the paraffin is poured into it, the better will the whole amalgamate. A fixed quantity of the oil is put into each bottle, so that the exact strength is known. Corked, and set aside in a safe place, it is ready when required to be reduced to a proper strength for use. In preparing for application, it is simply poured into a pail, watering-can, or garden-engine, as may be required, and with soft water it is reduced to the desired strength. If, say, a bottle contains two gills of paraffin, it is enough for making four gallons of water sufficiently strong for spraying plants to clear them of aphids; or two gallons for clearing off red-spider and thrips; and one gallon for eradicating mealy bug and scale insects. With a little practice, this simple and effective method of reducing the strength of paraffin may be safely performed by any intelligent person, although entirely ignorant of chemistry. In these days, however, of evening classes and technical education, every young gardener ought to acquire a sufficient knowledge of chemistry to enable him to clearly understand the nature of the process by which paraffin amalgamates with water, when combined with black soap at a high temperature.

All liquid insecticides of a caustic nature are best applied in the form of spray; either through a garden engine, syringe, sprayer, or other similar appliance. One of the most effective of all the appliances for this purpose is the Stott spraying-nozzle, which can be screwed on to any form of sprayer, syringe, or garden engine, and which distributes the liquid evenly, safely, and economically, wherever it is required. In particular, paraffin, of whatever strength, as an insecticide, should always be applied in a spray, and never, if it possibly can be avoided, in any other way, because all dipping or washing of plants with it, is extremely liable to injure them. A slight film of paraffin may be floating on the surface of the most perfectly blended liquid, or some crude sediment may fall to the bottom, and in either case dipping or washing with it is dangerous, especially so to downy or hairy-leaved plants. Numerous mishaps of this kind have occurred which it is safe to say would never have happened if the insecticide had been applied in fine spray, even by the ordinary method of using the forefinger as a "sprayer" on the jet-nozzle of a common syringe. Still, a careless person with a jet-nozzle may easily play mischief, but with a "Stott" nozzle for spraying the liquid paraffin mixture, the risk of a mistake is rendered as near as possible an impossibility. Many plants, when in a dormant state, absorb this oil like a sponge! While, when growing, and full of sap, it cannot penetrate to the living parts, because the sap or moisture repels it. Hence Vines, and all such open, porous-wooded plants, are easily injured by paraffin, even of a weak strength, when dormant, while a much stronger solution may be safely applied to them when they are growing and full of sap. By bearing these simple facts in mind, any intelligent person may keep plants of all kinds free from insect pests at a minimum cost.—*Gardeners' Chronicle.*

CONSUMPTION OF COCONUTS.

A writer in the "Times" while taking over the interesting information on this subject afforded in Wednesday's *Observer*, thinks the estimate of 219 million nuts consumed in households in Ceylon every year as far too high and continuus:—

We cannot believe that every single inhabitant of this Island uses 73 coconuts per annum! Why, large numbers of the inhabitants hardly use any at all. In the North-Central Province and in parts of Uva the inhabitants hardly know what coconuts are, and to believe that the one million inhabitants of the

Island who are always pictured to us as in a state of semi-starvation use as many per head (including children)—as 73 nuts per annum is more than we can bring ourselves to do. Large numbers of the inhabitants hardly use rice as a diet at all, and we should be inclined to think 70 millions a liberal estimate of the quantity locally consumed in households. We cannot understand how our contemporary passed such an excessive estimate, except that he loves excessive estimates.

Now this criticism reads very plausibly, especially when one is inclined to agree that the consumption of coconuts in the Uva and North-Central Provinces and in other large districts of the interior must be very limited. A few coconut palms do grow about Badulla town and the cultivation we are glad to know is increasing between Kalawewa and Anuradhapura; but still it is the day of small things there, and the coconuts consumed in the interior of Ceylon have to be transported from the Western districts or seaboard. We do not know if there is much trade as yet in coconuts between Batticaloa and Uva, or between the Jaffna coconut-growing regions and the North-Central and Central Provinces. There are a good many coconuts grown and consumed in the Matale district however. But of course the large supply for our hill-country is carried by the railway—a goodly portion besides going by cart, especially up the Ratnapura-Haputale road. Now last year, the railway carried about 5,106 tons of coconuts and we suppose all but a very small proportion were "husked." The tonnage then would mean about 8 millions of separate nuts. This result and the indication we have given of the trade otherwise with the interior may be supposed to tell against our argument; but we have merely referred to the matter so far, to clear the way. For we do not mind giving up Uva and the interior altogether to the "Times" critic and yet showing that our correspondent's calculation may not be so far out. It must be remembered that it is in the heart of our coconut growing regions that our population is densest in Ceylon. From Puttalam all round to Matara with a great portion of the interior of the Western Province is a coconut growing region, and it may surprise our critic to learn that in the large majority of native households from Puttalam, or at any rate Chilaw, right along the sea-coast road down to Matara—a distance of about 150 miles—which has been described as one long village—the daily consumption of coconuts is nearer two or three nuts than one per household. So far as our information goes, we are inclined to think that we should be safe in taking two as an average. In the long road referred to, it may be safely said the traveller is never out of sight of a hut or a coconut palm. If then we take the natives of the Western, North-Western and Southern Provinces with the Batticaloa and Jaffna districts, leaving out the rest of the island, we have two-thirds of the population of the island or on the very fair reckoning adopted by our correspondent, 400,000 households and if we credit these not with the consumption of two nuts as above, but on an average of $1\frac{1}{2}$ nut, we fully justify the estimate of a consumption of 219 millions nuts a year. It looks, of course, very startling to say that on an average each man, woman and child in Ceylon consumes 73 coconuts per annum; but when we put it the other way and mention that there are probably not fewer than 400,000 households in the coconut-growing districts of the island and that it is the habit in such households to use never less than one coconut per diem, in a large number of them probably two nuts, and in a certain number not fewer than three nuts per diem, the case, we submit

looks different. At any rate our estimate of an average of $1\frac{1}{2}$ nut per household per diem when confined to 400,000 households must work out a safe total for the island, if we bear in mind the consumption in the Central, Sabaragamuwa, Uva and North-Central provinces, and the Trincomalee and Wannai districts of which no account is taken.

PLANTING EXPERIMENTS AND EXPERIENCE IN NORTH BORNEO.

HIGH PRICE OF COCONUTS—EXPERIMENTS WITH RICE, GAMBIR, PEPPER, COFFEE—TIMBER—SAGO.

We are indebted to a friend who sends us a letter of Mr. Henry Walker, so well known as Planter and Surveyor in Ceylon, from which we are permitted to quote the passages respecting his rice, gambier and pepper growing experiments in Borneo; as well as an account of what is being done in coffee—all of much interest to Ceylon planters. We quote as follows:—

Sandakan, 11th April 1893.

I see the Ceylon people have lately been very much taken up with the price paid for coconuts and coconut-plantations. Rupees forty-seven per 1,000 nuts seems high when I remember the time when twenty-rupees was a good price. What would you say to twenty (*rupee*) cents per nut which is the price we often have to pay for household purposes. In the town here the Government owns eleven coconut-trees which are leased out annually by auction. In 1892 they realized nineteen dollars, and for 1893 have realized twenty-four and half dollars *cash down*. They always have a number of fruits on them and doubtless bear heavily, but even then two dollars a year rent (four and half rupees) per tree paid in advance is a high price compared with your Ceylon figures. Owing to the want of population in Borneo wild pigs are usually very numerous and coconut planting is always difficult. About two years ago we had pleuro-pneumonia which carried off a lot of cattle and then the pigs suddenly disappeared; the natives say they died in the jungle, but *why* is a mystery as the deer and wild cattle are just as numerous as before. Any way there are no pigs now and so a few people are planting coconuts. We have to import all our nuts so that the food plantation should be able to obtain a good price.

I can tell you something about Gambir which is rather new ground for Ceylon men. When I returned in September 1891 the Government had opened a small garden near Sandakan which was handed over to me. About 200 gambir plants and 100 pepper plants had just been put in, and by 8th December I raised the numbers to 3,253 and 587. I had to import my pepper cuttings from Singapore and the West Coast: they usually arrived dead; I did not grow 5 per cent. out of them. The Gambir was more difficult; it is a finer and more delicate seed than cinchona. I think the watering kills it and that only the finest spray should be thrown on the seed and the water should not be chilling. The sheds used for cinchona will do, but the Chinese do not make the roof so high. One bed I saw last night, which seems a success, had the seed bulbs thrown on the bed with the seed, after being crushed in the hand. Your planters will have to worry out the seed beds for themselves. The Chinese say the seed dies twenty-four hours after it is ripe, but that is nonsense; it is however very susceptible and delicate. In Singapore, gambir is said to be ready to cut when it is eighteen months old. My first plants were so well grown at twelve months that I was able to cut them in October 1892. The matured leaves yield the drug which runs freely out of the green leaf when it is rubbed between the finger and thumb. The leaves are taken off the branches (which are thrown away) and boiled in water in a pan; and when the liquid has been concentrated and the leaves taken out, it is allowed to cool in a tub. While cooling it is rubbed with a stick, not very unlike the way that hot sugar is teased for its crystallises which is said

to be necessary to produce Gambir in the form accepted by commerce. I was obliged to use an iron pan and the Chinese say that in time the iron becomes encrusted and ceases to blacken the drug, but my samples suffered. Each boiling certainly became better in color, but the first samples that went home were damaged in appearance. The first sample was taken without my knowledge by an over-zealous friend who sent it to London and this is the report:—Date of letter 27th January 1893: "Your sample was analysed by Messrs. G. H. Ogston and Moore and we are happy to inform you that in spite of its being very mouldy and dirty the result of the test is eminently satisfactory. In its present moist condition it shows 19.86 per cent of Tannin, but when properly dried and prepared as we should expect it to be delivered when shipped in the ordinary way the test shows as much as 27.85 per cent of Tannin. To show the importance and value of this result we have obtained from the above gentlemen a further analysis of a fair sample of No. 1, Rhio Cubes, such is at present selling on this market at 30s to 31s per cwt., and the following is the result, viz:—

1st Test	Borneo sample.	No. 1 Rhio sample.
Wet	Tannin 19.86 per cent	20.00 per cent.
	Moisture 28.70 "	13.72 "
2nd Test		
Dry	Tannin 27.83 "	23.23 "

Which proves conclusively that on the ground of strength the Borneo sample is all that can be desired." Since that sample went home I have dispatched a sample parcel of 5 cwt. 2q. 21 lb. of black gambir for transmission to London through agents in Singapore who write:—Date 25th March 1893. "The quality we are pleased to say is pronounced by locals to be good and not inferior in any way to Singapore gambir and we have been offered for this small parcel \$7 per picul, while the market price was only \$6.60; however the higher price is explained by the unusual dryness of the parcel which, of course, enhances its value." In another letter they say "if compared with Singapore gambir it is a little too dark coloured and too dry, but you will no doubt be able to improve the next production in these respects." Now that is not a bad beginning when planting a new product. I could easily improve the working in the boiling house and turn out Cube Gambir of a light colour, which would be worth 30s. as compared with 19s. per cwt. of Black Gambir. Sandakan seems to be the natural home of the Gambir plant which grows wild all round this country, but the wild variety does not appear to yield the drug.

The Pepper I planted is doing well and has been turned down and will be allowed to fruit. Both pepper and gambir have been handed over to a Chinaman who is enlarging the garden—a comparatively easy task now that he has stook to draw from.

I told you Coffee does well; in 1892, 330 acres were planted and I believe as much more will be this year. Manila Hemp has been planted by one Company who report well of it and our great staple Tobacco seems to be asserting itself as accounts of last year's crop, which on some of the estates was large, point to a high quality and we hear that prices are going up. This is very much required if the cultivation is to be continued as it is an expensive one.

Trade is looking up and the China steamer which left on the 8th April took away more Timber and rattans than she ever took, previously! On the West Coast exports of Sago, &c., have been steadily rising and will show up in our published returns of last year and this. The title of New Ceylon was bestowed upon us some years ago, but I expect it will be "Bigger Ceylon" before long. Coffee can be planted over an enormous area and so near the sea that the expense of transport will be slight and I expect to see North Borneo King of Coffee as you are King of Tea. We can grow tea too; a Chinaman at Kudat has planted a few acres but unless the Chinese come down upon us in large numbers and grow it, I do not see how we can obtain suitable labor, but

the immigration of Indian coolies to Singapore is increasing each year and before long they will reach North Borneo and when they do they will find work on the Coffee estates.

INDIA TEA NOTES AND NEWS.

Our Selang Correspondent writes on 16th April 1893, as follows:—Had some hot weather at last. Leaf coming away strong.

Our Lallamook Correspondent writes on 16th April 1893:—Two violent storms occurred—one early on the 9th and the other at 9-30 o'clock at night of the same day. Red spider is spreading fast. Last year thermometer was up to 92 deg. during the day, but this year it has only got up to 86 deg. The highest at night has been 68 deg. as against 74 deg. for the corresponding week of last year. The Baboo in charge of a small garden has reported to his Manager that the place was so badly cut up by hail on the 9th that no leaf could be plucked for a month.

Our Dam Dim Correspondent writes on the 16th instant:—We have had a lot of nice showers lately, as the weather continues favourable leaf prospects look fair.—*Indian Planters' Gazette.*

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Vol. IV.]

AUGUST, 1892.

[No. 2.

BANDAKAI FIBRE.

It will be remembered that in a recent issue reference was made to specimens of bandakai fibre prepared by the agricultural instructor at Madampe, Sabaragamuwa Province, and also of rope made from it. Some interest in the subject was aroused at the time and the question of the economic value of the fibre was discussed. The Kew Bulletin referring to Bandakai or okra fibre describes it as "long and silky, with a breaking strain, according to Roxburgh of 79 lb. dry and 95 lb. wet; evidently well adapted for making ropes, twine, and sacking, while the residual portions could be utilised for paper-making." The preparation and use of this fibre is said to have been revived recently in the Southern United States, where the plant is largely grown during the summer months, and also in Cuba. In the report of Consul Ramsden on the trade, commerce, and agriculture of the Province of St. Iago de Cuba for the year 1890, the following information is supplied respecting the fibre of okra known in Cuba as quimbombo (other names for the plant being okro, gobbo, and gombo): "The fruit of the quimbombo (*Hibiscus esculentus*) is well known in the English West Indies under the name of okra, and is used as a vegetable, but although Pichardo, in his Diccionario de Voces Cubanas, mentions the plant as being applicable to rope making, I am unaware that it has been used as fibre, and, therefore, refer to it here. Last year Messrs. Bosch and Company, of this city, made an experiment with some, and sent 400 pounds of the dried fibre to London, where they say it was much liked, and found to be worth £40 per ton. Three crops are obtained in the year, and its preparation by maceration gave very little trouble. The stem produces fibre of fine quality, and about 4 ft. in length,

and apparently strong. Further trials will probably be made here. I send a sample of it with this report."

The sample of fibre above mentioned has been forwarded to Kew by the Foreign Office, and is now in the Museum of Economic Botany.

With regard to the commercial value of this Cuban fibre, Messrs. Ide and Christie, of 72, Mark Lane, E. C., to whom it was referred, report as follows:—"Hibiscus esculentus. The sample shows the fibre to be only moderately stronger than jute, imperfectly cleaned, and very yellow in colour. We value it at £18 to £20 per ton today in London. It is possible that the colour could be greatly improved by more careful preparation, and that in that case its value might be increased by £4 or £5 per ton. We cannot imagine it possible that fibre of this type could have been found worth £40 per ton last year in London as stated to the Consul and mentioned in his Report."

Watt, in his Dictionary of Economic Products of India says referring to the Bandakai plant: The bark yields a strong useful fibre of a white colour, which is long and silky, generally strong and pliant, and composed of very fine individual fibres. It is employed economically in some parts of India....It is undoubtedly valuable and seems to possess qualities specially fitting it for the purpose of paper-making. It contains 74 per cent of cellulose, and in Messrs. Cross, Bevan and King's experiments it was found to lose 9.8 and 14.2 per cent of its weight, when boiled in 1 per cent solution of caustic soda for 5 minutes and 1 hour respectively. The average acre yield of fibre by Deeth and Ellwood's process was only 84½ lb., while by retting, even from this poor crop, it amounted to 6 maunds and 17 seers. Liotard in his *Paper-making materials of India* notices the fibre, mentioning that it is very fine and well suited for paper-making, and in another passage says that paper has been made with it, though only on a small scale, in the Lucknow central jail. In France the manufacture of paper from this fibre is the subject of a patent; it receives only mechanical treatment and affords a paper called *banda*, equal to that obtained from pure rags. This valuable fibre, concludes Dr. Watt, does not appear to have attracted the attention it merits.

There is no direct export of the fibre from India, nor is it sold at all, except either as an adulterant of jute, or under the name of hemp. In Dacca and Mymensingh it is said to be exported under the latter appellation to the extent of a few thousand ewts. yearly.

OCCASIONAL NOTES.

We have been requested to experiment and cultivate some seeds sent to us as Jowari and Bajri, by a gentleman residing in Colombo. The former we find is the arisi-cholum of South India, which is grown to a small extent by the natives of Madampe and other places, and used in the same way as Indian-corn in Ceylon. Jowari is one of the varieties of *Sorghum Vulgare*, and is known here as walu or karal eringu. Bajri is identical with cumbu (*Pennisetum typhoidium*) and is also found in native gardens. Some years ago both these millets were raised successfully in the School grounds, and if the seeds supplied us are good, we have no doubt they will come up well again.

Two other packets of seed labelled *Sorghum vulgare* and *S. saccharatum* have also reached us from Messrs. Sutton & Sons of Reading. We are, however, led to believe that both are varieties of *Sorghum vulgare* (cholum), one, the black variety, (labelled as *S. saccharatum*) being known as karapu-cholum; the other, the reddish variety, (labelled as *S. vulgare*) being known as songu-cholum. *Sorghum saccharatum* or the sugar sorghum is known among the natives here as edal-eringu. All these varieties are we learn found to a small extent cultivated in the Island, and have been experimentally grown before from seed imported by Mr. A. W. Jayawardene of this School.

We are in receipt of an interesting publication (dated June 1892) containing memoranda of the origin, plan, and results of the field and other experiments conducted on the farm and in the laboratory of Sir John Bennet Lawes at Rothamsted, Herts. It forms a valuable work of reference.

A course of lectures for students will be delivered by several well-known gentlemen at the School of Agriculture in the fall of the year. Mr. J. H. Marsh, M.A., late Principal of the Royal College is offering a prize for the best collection of notes on the lectures.

The contents of the last Journal of the Royal Agricultural Society of England (June 30th) are: Vermin of the Farm, The Evolution of Agricultural Implements, Desirable Agricultural Experiments, Contagious Foot Rot in Sheep, Variation of the Four-Course System, The Trials of Ploughs at Warwick, Wild Birds in Relation to Agriculture, Official Reports, and Notes, Communications, and Reviews.

The Agricultural Instructor has lately been the subject of some criticism. In the administrative report of one official he is put down a failure in his role of reformer of the native system of

paddy-cultivation, and is advised to turn his attention to fruit-culture. A writer in the *Ceylon Patriot* considers that the character and duties of the Agricultural Instructor himself require a good deal of reforming. "I look upon agricultural instruction as a peculiarly knotty social problem," he says, "and it would be worth while our putting our heads together to rectify the present defective system."

Mr. Lye, the Colonial Veterinary Surgeon, has begun his course of lectures to the students of the School of Agriculture. Mr. Lye can also be privately consulted any morning in the week at his offices at the School.

The students of the School are busy cultivating special plots allotted to them. Trials are being made with certain English and Indian seeds, with the object of ascertaining the possibility of increasing our supply of cattle fodder.

Musk plants—which produce the musk seed referred to in an extract among our General Items—grow without much trouble and produce large crops of seed. We believe the seeds were exported to some extent by one of our local planters, but it is now of little value owing it is said to the fragrant principle having been produced artificially and more cheaply by the aid of chemistry.

TREE PLANTING.

In the suggestions for teachers and others interested in the planting of trees, issued by the Brisbane Department of Agriculture, Prof. Shelton says that the first objection to the method of pot-hole planting is that the holes are too small. Make them say 8 or 10 feet in diameter, and see that the soil replaced has been properly enriched, and the hole itself thoroughly drained, and an excellent start in tree planting has been made. The great cost of the large hole in labour is the chief and a very serious objection to it. A hole of smaller size fills more or less with water, and retains it for the most part until removed by evaporation. This to the roots of the growing trees means great extremes of cold and heat, and ultimately rapid exhaustion and decay. The small hole again does not afford room for the outward growth and spread of the roots of the tree; the growing tree from the first finds itself imprisoned within the walls of undisturbed earth which surround it on every side. Better far to dig deeply or thoroughly trench the whole area to be planted.

The operation of trenching is variously conducted. Essentially it consists in thoroughly breaking up soil and subsoil to the depth of 18 to 24 inches, and mixing with the broken earth substances likely to act as fertilisers, or substances which serve simply to ameliorate the subsoil. Ordinarily work is begun at one side of the area to be treated, by digging a trench a full spade or fork deep the entire length of the side, throwing the earth on that side of the furrow which is to remain undisturbed. Let the bottom of the trench thus formed then be thoroughly spaded or forked over a full spade deep, mixing with the soil thus broken up the refuse

substances to be added. The surface furrow taken from the second trench will then find a resting place on the broken subsoil of the first trench, and thus the work will go on till the entire area is broken up or trenched. The surface earth taken from the first trench, which so far has not been disposed of, should in the end be carried over to the last trench, which otherwise will be unoccupied. In this manner the ground is thoroughly broken up without transporting soil and subsoil. The labour of this operation is great, but not tedious provided the work be done heartily, and ample time be taken over it. Once done there will be satisfaction that the results are substantial, lasting, and of the best character. If such a system be adopted it will be seen that the need for breaking up the soil about the trees will be absent for an indefinite period.

FROM HAPUTALE TO HAKGALA.

The Uva paddy-fields present a pleasing sight, and the goiya is sanguine of a pretty good harvest, although complaints are made here and there of damages by floods. It is very difficult to convince the Uva villager of the advantage of planting out paddy. When you refer to this method being practised by his Kandyan brethren, and try to expostulate with him, the usual reply is "no doubt it suits the Kandyan districts, but our soil is so poor that we have to sow very thick; and any thin sowing or planting will simply ruin us." He argues that a rich soil responds to transplanting by growing stout healthy plants which 'tiller' or send forth several shoots from underground, and yield heavily; but that his soil is too poor to grow any shoots from the transplanted seedlings. This belief in the infertility of the soil is, however, unfounded in many cases; and I am glad I have succeeded in persuading Mr. J. B. Medekinda, a young and intelligent farmer of Uva, to try planting out paddy, although on a small scale. I should be glad if such leading and influential landowners as the Dambewinne Ratamahatmaya would try 'planting out' seedlings at least in a few lieddas of their vast tracts of paddy-fields.

Passing the red soil spangled with small plates of talc, and proceeding towards Welimada, I found tobacco plants growing luxuriantly in the dark soil of the hollows and ravines where tall mana bushes and brackens once held sway, undisturbed by the goiya's mamoty. This deep, rich soil, where the manurial matter from the highlands has accumulated for years is fit for growing almost anything.

In the dark moist lands near Wilson's Bungalow, onions and garlic are grown by the native villagers and Moormen, and are gently irrigated by streams. Dwarf beans, horsegram, kurakkan and native vegetables of various kinds are grown higher up on the dry soil.

Extensive fields of potatoes and small cabbage plantations thriving at Pálugama (Wilson's)

and Pádinawela speak well of the enterprising spirit of the villagers of Uva, and of their capability of taking kindly to the cultivation of new products.

The Hakgala Gardens, about six miles from Nuwara Eliya, have spread throughout the neighbourhood, some very useful and easily-grown plants of great economic value, such as the chou chou gourd and the tree tomato which were introduced by the able Superintendent, Mr. W. Nock. These plants have now become very common in the villages of Uva. There are, however, to be found growing in the Hakgala Gardens, other useful plants which have not yet become half so popular as they deserve. I might give as instances the *Aracacha Esculenta* (South American parsnip) and the *Ullucus Tuberosus* (the "oca-quina" of Peru), which would grow well in the upcountry villages, and yield excellent food for the people.

E. T. HOOLE.

INDIAN NOTES.

It is unfortunate that grafting in fruit culture is not carried on in Ceylon at all, for by grafting the productive power and the produce of many fruit trees could be improved to a great extent. There are several methods of grafting which requires not only a good deal of practice, but also an exact knowledge of the time and season suitable for the operation, so that their adoption with success is no easy matter.

The grafting of mangoes is done very successfully. I was at first surprised at the manner in which it was done, but the people here were more surprised than I was when I told them that we never grafted mangoes in Ceylon. Their first inquiry was whether we had mangoes at all in the Island. I am inclined to think that we could export mangoes to Bombay with good profit, considering the high prices the fruit fetch here.

The first thing that is done in grafting mangoes as carried on here is to collect any kind of mango plants without any regard to their character or qualities. These plants should be about three to four feet in height, and are planted in pots filled with fine earth mixed with a large quantity of black loam or leaf mould. The pots employed are spherical, about a foot in depth and a foot in diameter at the middle, while the mouth is about 6 inches in diameter. In shape they resemble the pots which are used by toddy drawers in Ceylon.

The plants are allowed to remain in the pots from one to three months, or till they thoroughly establish themselves and begin to grow. They should be perfectly healthy with the full complement of leaves.

Now the plants, as they stand in the pots, are taken to a mango tree which is known to produce a good variety of mangoes, as well as to be a prolific bearer, and they are grafted on to branches (twigs) which are of the same size as the plants, about the size of the small finger of the hand. Just about the middle of the

plant the stem is sliced and a portion removed about three to four inches in length. The same is done to the selected twig, and the two stems are brought together at their cut surfaces and well tied with a piece of twine. Before doing this, pieces of plantain bark or more properly sheath about four inches in length and half an inch or less in breadth are placed on the two sides to prevent the pressure of the twine affecting the bark of the grafted parts.

Nothing else is applied so far as I have seen, but I was told it was advisable to rub a little black potter's clay over the grafted parts. I should have mentioned that the pots containing the plants are suspended by a string to a strong branch of the tree, and are allowed to remain till the two branches grow together. The grafting is generally done just before the rains, so that the plant might get a plentiful supply of moisture, and in order that the sap might not dry off and retard growth.

When the graft and its host are properly welded together, the plant is separated from the tree and the pot is then removed and the plant put into the ground in a prepared hole.

The plant not only produces a tree having the desired properties, but bears fruit very early, and it is not uncommon to see mangoes on plants hardly six feet in height. But the cultivators here prefer to allow the plants to grow to a much larger size before getting a crop, and for this purpose they nip off the flowers during the first few seasons.

The paragraph which appears under the General Items column in the June issue of the establishment of a Veterinary Institution in Bengal has evidently been written by an interested party to the *Indian Agriculturist*, for it says that "the Bombay Veterinary College fell into the error of turning a hospital for animals into an infirmary for horses, almost to the exclusion of oxen which are the beasts of burden and of agricultural work in the East." Without contradicting the last part of the statement, regarding the importance of cattle in the East, the Bengal writer might be referred to the following from the last monthly report of the Bombay Hospital:—"On the first of June last there were 103 bullocks, 17 horses and 5 dogs at the Hospital for animals; during the month of June 109 bullocks, 30 horses and 21 dogs were admitted, and during the same month 82 bullocks, 18 horses and 17 dogs were discharged from the hospital. 3 cases among bullocks, 4 among horses and 6 among dogs proved fatal during the last month." The above figures speak for themselves.

Bombay.

W. A. D. S.

ZOOLOGICAL NOTES FOR AGRICULTURAL STUDENTS.

SUB-KINGDOM II. *Celenterata* (Gr. Koilos, hollow; enteron, intestine).

General Characters.—Animals, whose alimentary canal communicates freely with the general cavity of the body, or somatic cavity; substance of body made up of two fundamental layers or membranes,—an outer layer called ectoderm,

and an inner layer or endoderm; no central organ of circulation or distinct blood system, and in most cases no nervous system; peculiar stinging organs or thread-cells on skin, reproductive organs in all, but multiplication often by non-sexual methods.

Class I.—Hydrozoa (so called after the Hydra or freshwater polyp which belongs to this class.) In these the walls of the digestive sac are not separated from those of the general body cavity, the two coinciding; reproductive organs external. This class also includes the familiar sea-firs (*Sertulaica*), sea-blubbers (*Aurelia*), jelly-fishes (*Medusæ*), and Hydrocorallineæ. The last sub-class contains two groups of marine animals which produce a regular skeleton of carbonate of lime often of large size, and which have generally been referred to the corals (*Actinozoa*). One of these groups comprises the well-known *Millepora* which are found contributing largely to the formation of coral-reefs in the West Indies and Pacific; the other the *Stylasteridæ*. The Hydrocorallineæ with the exception of some cretaceous forms allied to *Millepora*, are not known to be represented in deposits older than the Tertiary.

Class.—II.—Actinozoa: stomach distinct but opening below into the body cavity which is divided into a number of compartments by vertical partitions or "mesenteries"; reproductive organs internal. Under this class fall the sea-anemonies (*Actinia*), star-corals (*Zoantharia*), red-corals (*Alexonaria*).

The simple corals are generally of small size, and are found in most seas, for the most part inhabiting deep waters. The compound corals, on the other hand, may attain to enormous proportions, since they are formed by the combined exertions of a vast number of zoophytes working together, and forming a common skeleton. In the seas in which they flourish (Pacific and Indian Oceans and the Caribbean sea), the reef-building polypes are accumulating vast masses of calcareous matter which will ultimately form islands and continents. Even at the present day coral reefs are often converted into dry land and become the home of animal and vegetable life. It is true that the rate of growth of a coral reef is very slow, and the individual workers at the reef very small, but the aggregate results produced are on a scale of the most striking magnitude.

Coral reefs flank many parts of the coast of Ceylon, and the barrier reef on the S. W. coast is familiar to those who have travelled south from the metropolis by the coast railway service. The material, namely calcium carbonate, of which coralline structures are composed, are appropriated by the polypes from the sea-water. These reef-builders require a temperature somewhat above 68° to flourish, and they do not thrive below 100 ft. under sea-level. The great barrier reef of East Australia varies in breadth from 10 to 90 miles, and extends for a distance of 1,250 miles. A barrier reef is one that rises in front of a shore between which and the reef is a body of water; a fringing reef is one that extends from land seawards; an atoll is a coral island with a lagoon in its centre. The Lacadives and Maldives consist of a large number of

these coral islands or atolls. Darwin's theory of the origin of coral islands was that an atoll began by being a fringing reef; that it next became a barrier reef, and lastly a coral island. As the sea bottom gradually subsided, the coral reefs kept gradually rising as the result of the reef-builders' work. The fringing reef would thus tend to become a barrier reef, and after the submergence of the entire island, a lagoon would take its place, encircled by a coral ring. The further researches of Mr. Murray of the "Challenger" Expedition and certain facts relative to coral structures which he claimed to have discovered resulted in a counterfeeling against Darwin's theory; but within the last year or two the theory of Darwin has again come into favour owing to the "facts" of Mr. Murray having been proved to be very doubtful.

Coral-stone occurs in the north of the Island and is used for building purposes. Coral is burnt for lime in parts by the island—the lime being used for lime-washing houses, as well as for agricultural purposes. In the latter case quicklime or slaked lime is used for improving the condition especially of peaty land and heavy clay soils. For the many advantages attending the use of lime in agriculture, the student is referred to text-books on agriculture.

Coral lime may also be used with advantage in the forming of composts, as the lime hastens the decomposition of organic matter (such as sea weed), and also, owing to its organic origin, supplies small quantities of nitrogen and phosphoric acid, derived from the remains of the coral polypes.

Small quantities of red coral, apparently identical with the Mediterranean and Cape Verde species have been found on reefs a short distance from the S. E. coast of Ceylon, but in such small quantities as to be of trifling value.

FIXATION OF FREE NITROGEN.

Prof. Frankland, the well-known chemist, delivered the last of the Cantor lectures before the Society of Arts on "Recent Bacteriological and Chemical Researches." In dealing with the subject of nitrification in the soil, Prof. Frankland also referred to the fixation of free nitrogen by means of leguminous crops, and clearly defines the latest results of investigation into this subject. That the fertility of the soil was able to be improved by leguminous crops was known as long ago as 2,000 years, but by what means this was effected was not clear.

For nearly a century past agricultural chemists and vegetable physiologists have been debating as to whether the free nitrogen of our atmosphere can be assimilated by plants. This question was answered in the negative by Bousingault about fifty years since. The problem was again attacked by Lawes, Gilbert, and Pugh about thirty years ago, and their answer was in the negative also. In the course, however, of their continuous experiments on crops Lawes and Gilbert have frequently pointed out that whilst that nitrogen in most crops can be accounted for by the combined nitrogen supplied to the land in the form of manures and in rain water, yet in particular leguminous crops, such as pea, beans,

vetches, and the like, there is an excess of nitrogen found in the crop which cannot be referred to these obvious sources.

The question remained in this unsatisfactory state until again revived by M. Bertelot in 1876, whilst, subsequently the most conclusive experiments were made by two German investigators—Hellriegel and Wilfarth, who not only showed that this excess of nitrogen in the leguminous crops is obtained from the atmosphere, but, what is more interesting to us, that the assimilation is effected by means of certain micro-organisms flourishing in and around the roots of these plants, and where these same plants are grown in sterile soil the fixation of free atmospheric nitrogen does not take place.

The manner in which these micro-organisms assist these leguminous plants in the accumulation of nitrogen is exceedingly remarkable. When these organisms are present in the soil they occasion the formation of peculiar swellings or tuberosities on the roots of the leguminous plants, these tuberosities never being formed in sterile soil. On microscopic examination these tubercles are found to contain amongst their cells a ramifying growth which subsequently gives rise to a number of small cells having much the appearance of bacteria, although the precise group of organisms to which they belong is one of those numerous points on which morphologists cannot agree. As long as the point is still *sub judice* it is perhaps most convenient to call them bacteroids. These can be cultivated on artificial media like ordinary bacteria.

The careful investigation of these tubercle-producing organisms has shown that each species of leguminous plant has its particular bacteroid, which is more potent in the formation of these tubercles on the given species than the tubercle bacteroids of other leguminous species. In this connection some very striking and highly instructive experiments have been made by Professor Nobbe, of Maraud, who has found that if pure cultivation of the bacteroids from a pea tubercle are inoculated into the roots of a pea plant, a more abundant growth and fixation of nitrogen by this pea-plant takes place than if it is inoculated with pure cultivation of the bacteroid from the tubercle of a lupus or a robinia, whilst conversely the robinia is more beneficially affected by the application of pure culture from robinia tubercles than by those from either pea-tubercles or lupus-tubercles.

The exact manner in which the atmospheric nitrogen is rendered available for these leguminous plants possessing root tubercles is not perfectly understood, but the general impression is that the micro-organisms present in the tubercles take up the nitrogen and elaborate it into a form which can be assimilated by the plants. Whatever the secret of the process may be, it is perfectly certain that the presence and vital action of the micro-organisms, which give rise to the formation of the root tubercles, is the indispensable factor.

The great importance of this discovery in vegetable physiology it is unnecessary to dwell upon; we have to recognise in the micro-organisms the invaluable agents whereby the atmospheric nitrogen, which is in itself worthless both to animals and ordinary plants, is actually rendered available directly for the nutrition of plants

and therefore indirectly for the sustenance of animal life on our planet.

The R. A. Society's Journal just to hand contains news of still more interesting discoveries. Dr. Fream therein describes the experiments carried on by Schloesing and Laurent, which it is needless here to repeat the description of; suffice it to say that they have established the following conclusions:—

1. That the leguminose (papilionaceæ), as represented by peas, are able to draw largely upon the free nitrogen of the air for purposes of growth.

2. *Some of the inferior green plants (e.g., mosses, algae) possess the same property.*

3. In the conditions under which the experiments were conducted, bare soils—that is soils devoid of any apparent vegetation—failed to fix nitrogen in any measurable quantity. Oats, mustard, cress, spurrey, likewise failed to fix the free nitrogen under conditions identical with those in which peas fixed it abundantly. Dr. Fream concludes that the growth and decay of mosses and other cryptogams must enrich our soils with the nitrogen they acquire, and considers that the stores of nitrogen which our cultivated lands contain are probably due to the accumulated remains of mosses and other rootless plants.

Whether mosses and algae possess the power of direct assimilation of free nitrogen, or whether they effect a symbiosis similar to that which exists between papilionaceous plants and the nodule forming microbes, is a problem which still awaits investigation, and this will doubtless be forthcoming in due course. Meanwhile, the results of the experiments briefly noted here are of the greatest interest, and serve to add another link to the chain of facts which are so greatly modifying our views concerning the nutrition of plants.

A SUBSTITUTE FOR CATTLE MANURE.

DEAR SIR,—Cattle manure in sufficient quantities for agricultural purposes, especially for coconut cultivation, is very difficult to obtain. It has struck me that we should therefore strive to manufacture a compost resembling cattle manure as nearly as possible. Though the "bulk" of cattle manure is a drawback and stands in the way of its easy transport, yet I think I am right in stating that its chief manurial value is its bulk. A large quantity of vegetable matter decaying in the soil favourably affects the mechanical condition of both stiff and light soils, gives out gases to disintegrate them and absorbs as humus the ammonia of the atmosphere. If the very large quantity of water it contains could be driven off, it will be an advantage: but that is out of the question.

I think we have the basis for a compost to take the place of cattle manure in fibre dust. As it leaves the mills it is as full of water as a sponge. I think a press can be devised to expel it at a moderate cost. I know there are many who believe that fibre dust has no manurial value. I am not of those. But even if it has no manurial value, it is useful as an absorbent for the purpose I indicate. Husks are composed of over 75 per cent of Potash, and it

is hard to believe that in the fibre alone is to be found this valuable constituent.

The principal constituents of cattle manure are Nitrogen, Potash, Phosphoric Acid and Lime. Will not the addition of these to fibre dust, with the moisture expelled from it, give us a manure as valuable as cattle manure and less bulky because containing less water? If it will, the next question that arises is, what manures we must use in the compost to supply the leading constituents of cattle manure. For Nitrogen gas liquor suggests itself, for Phosphoric Acid and Lime Bones, and for Potash ashes, the chief objection to Gas Liquor is the large quantity of water it contains, and this is a serious objection where transport is considered. We want something more concentrated, and guano has suggested itself to me. Owing to its highly stimulating qualities it is a manure that is very little used: but with a large quantity of fibre dust to counteract that, I think the most cautious will not hesitate to use it. Guano is considered the richest and most concentrated of manures, and will therefore be the best manure for a compost to be composed largely of undecayed vegetable matter. A good guano, bought on a guaranteed analysis, will be able to supply all the Phosphoric Acid, Nitrogen and Lime the compost will want to assimilate it in composition to cattle manure, with the exception of Potash, which ashes will be able to supply. I suppose the compost will be far more concentrated than cattle manure, and will have a higher proportion of its leading constituents.

I shall thank you, Sir, for your editorial opinion on the suggestion I have made, for if it accords with mine, and the Fibre Mills can see their way to press the water out of fibre dust when occasion demands, a valuable manure will be within the reach of advanced agriculturists living in and around Colombo.

28th July, 1892.

[Received too late for notice in this issue.—Ed.]

GENERAL ITEMS.

Says the *Timber Trades Journal*:—Where trees naturally send their fibrous roots to a good depth below the surface, it is highly probable that the practice of digging about the trees is beneficial, but it is certainly opposed to common sense to suppose that the annual destruction or mutilation of the effective feeding roots of a tree should promote its health and luxuriance. On the contrary it is calculated to effect serious injury.

The advantages claimed for the practice of allowing the surface of land planted with trees, to be covered over with grass, are that the soil is permeated by them and through the operation of earthworms, and is thus kept aerated and sweet, the fibrous roots of the trees getting every opportunity of ramifying the earth. The grass also keeps the roots of the trees shaded and cool.

Musk-seeds now form a regular article of commerce, and are quoted among other products in the ordinary trade-lists; they are sometimes known as "graines d'Ambrette," and are the produce of *Hibiscus Abelmoschus*, a plant growing to a height of from two to four feet, be

longing to the mallow family, and widely distributed, both naturally and by cultivation, in nearly all tropical countries. The plant is generally known as the musk-mallow, in consequence of the seeds possessing the well-known strong musky odour which makes them valuable, or rather applicable, for perfumery purposes. These seeds are small, kidney-shaped or reniform, marked with parallel ridges, and when dry of a brown colour. In the West Indies the plant is known as the musk-ochra, and so long ago as the middle of the last century the seeds were not only known and valued for their perfume, but were also supposed to have medicinal properties, and had a high reputation as a cure for the bites of venomous reptiles. Tunan in his "Hortus Jamaicensis," says: "The seeds, when grown to full maturity, have a strong and perfect smell of musk, a few grains being sufficient to perfume a whole Loom. Barham says these seeds are a good cure for bad breath, and are cordial and expellers of wind. Browne observes that they may be used with great propriety in powders and pomatuns, nor does he doubt that they may be used in emulsions and many medicinal cases." The seeds yield about 62 per cent. of an odorous principle and resin. They were used many years ago in English perfumery as a substitute for animal musk, but they were never much in favour with perfumers, they fell into disuse. Piesse, in his "Art of Perfumery," published in 1879, says: "Musk-seed, when ground, certainly reminds our smelling sense of the odour of musk; but it is poor stuff at best however; for making cheap sachet-powder, it may be used for variety's sake. When hair-pow-

der was in fashion perfumers used to scent the starch of which the powder was made by mixing the ground Ambrette with the fecula. After lying together for a few hours the starch was then sifted away and packed for sale." In Northern India these seeds are used medicinally by the natives; they are considered stimulant, stomachic, and ant-spasmodic, and are used in hysteria and other nervous affections, atonic dyspepsia, &c.

The Poona Government Farm has now a dairy herd of fifty-five head. The dairy is being worked at a profit with improved European appliances, and has furnished a model for similar establishments in other parts of India. It is said to meet the whole of the commissariat demands at Poona for milk products, and has given a decided impetus to the adoption of scientific dairy methods.

The cause of "black rot" of sweet potatoes is a minute fungus (*Ceratocystis fibriata*) which lives in the starchy tissue of the root or grows through the soft stems of the shoot. When the dark areas characteristic of the disease are examined minutely they are found to consist of dead or dying tissue filled with the innumerable threads or vegetating portions of the parasite, and there, on account of their greenish colour, give an olive-green shade to freshly cut diseased portions. The characteristics of the disease are the presence upon the potatoes or the young sprouts of dark olive brown, or green patches, generally penetrating the tissue. These dark areas increase in size until they cover the whole potato, or cause death of the sprout by girdling.

THE MAGAZINE
OF
THE SCHOOL OF AGRICULTURE,
COLOMBO.

Vol. IV.]

SEPTEMBER, 1892.

[No. 3.

TECHNICAL EDUCATION.

[An Address delivered at the School of Agriculture on the 3rd of August 1892, by GEORGE WALL, Esq., F.L.S., in inaugurating "The Marsh Lectures": The Hon. Sir SAMUEL GRENIER, Attorney-General, in the Chair.]

In these days, every one needs a certain amount of education to enable him to pursue his ordinary avocations, and to maintain intercourse with his fellow-men. The measure of education each requires depends upon the position he occupies in the social scale. For a working man, the mere rudiments would be sufficient, if he were content with so little. That, however, is seldom the case, as men of that class generally see two ways of advancement before them; one by means of wealth, which is often hard to obtain, and the other by means of education, for which there are great facilities—and they choose the latter. For a man in the higher ranks of society a liberal education is indispensable. He must have a fair knowledge of classics, mathematics, and now-a-days, of the rudiments of science also, if only to enable him to read the literature of the day and to converse on equal terms with the people of his acquaintance.

The technical student needs the same equipment as others of his social status; but he makes a special study of science, not for mere literary purposes, or to talk about it, but for the purpose of applying its principles to practical use in the arts and manufactures.

The function of technical training may be defined as the application of the principles of science in general to practical use in arts and industry. That is the sense in which the term is to be understood in the present lecture.

I can imagine students present asking how it happens that technical institutions are of such recent origin, seeing that arts and manufactures have flourished for ages past. The question

is natural and reasonable, and may with advantage be answered at this stage, before proceeding further. Briefly then, science, properly so called, is itself modern. What passed for science in former times would not now be deemed worthy of the name. Chemistry, for example, was, in those times, the pursuit of mere figments of the imagination, such as the elixir of life, a thing that had no real existence, and the philosopher's stone, a substance which, if discovered would, it was supposed, transmute baser materials into gold. No one knows whence came the ideas of these chimeras, but nevertheless they were pursued with an ardour and perseverance worthy of a better object. In the course of these vain researches some facts were learned, but they were desultory, unconnected, and of little value. Astronomy had the advantage over chemistry in having something to look at, something real to observe and to speculate upon. The motions of the heavenly bodies were even then, in fact, made subservient to some use in navigation, but where observation ceased and speculation came into question, the ancient ideas were fanciful and wild. The stars were supposed to be fixed in a solid crystalline sphere, because they always maintained the same positions with regard to each other. We now know how very far that is from their actual condition, and the ancient theories of the universe were so unreal that it is impossible to conceive of any rational origin for them. It will be plain now to any questioner that such science as just described would have been of no use to arts and manufactures, and he will see why technical institutions would have had no place in those circumstances.

Perhaps another student might ask how the arts and manufactures of those former times got on without science.

The answer is that they proceeded very slowly, very uncertainly and blunderingly. Processes were handed down from generation to generation, and were pursued with a slavish persistence, everyone following in the footsteps of his grandfather. Trades and manufactures were conducted with all practicable secrecy. Some were confined to families and guarded most jealously. Others were carried on by guilds and societies, the members of which were bound under penalties to keep the secrets of the craft inviolate. Under that system there was no variety of style or method in the products. The articles produced were all of one

type and character, and there was little scope for the exercise of invention, which is an offspring of science. There was, nevertheless, one redeeming feature of that contracted system. There being so little scope for variety or novelty, the only means of attaining distinction in the crafts was by excellence of workmanship. It followed therefore that when a better system came into use there were highly skilled workmen to give it effect. Having answered the second inquirer, and shown how slowly arts and manufactures progressed under the ancient régime, let us contrast the modern practices with those just sketched.

Science is now pursued by reversing the former principle. Instead of starting with an imaginary idea, and trying to find a solid basis for it, the modern scientist begins upon a solid foundation of demonstrable truth. On this he builds upwards, and is careful to admit no stone into his structure until it has been fully proved and tested. Every step of his progress therefore is assured, and the principles he establishes may be safely relied upon and applied to practical use. The science of modern times is therefore available for the arts and manufactures, or, in other words, it affords scope for useful application, which is the function of technical teaching.

There is scarcely any remnant in the present day of the secrecy that characterised the trades and manufactures of times past. At Whitworth's famous works, there is a member of the staff whose special duty it is to escort the numerous and distinguished parties who visit the works, and to explain to them the refined processes there carried on. When last in London, in 1887, I noticed several shops where, instead of an array of attractive wares in the great plate glass fronts, there were rows of workmen at their work showing how boots and shoes are made, or how sewing and embroidery was done by machines worked by women.

The difference between ancient and modern practice will best be understood, however, by some illustrations. For instance, the manufacture of sugar has been known and carried on for ages. The process is very simple, consisting merely in evaporating the surplus water out of the juices of sugarcanes and other saccharine plants. It was boiled until the surplus water was evaporated, and only the sugar was left. In this process, however, considerable loss occurred from the formation of part of the juice into molasses of little value. Experience had shown that this result was caused by excess of heat, and therefore extreme care and skill had to be used not to subject the liquor to more heat than was necessary. Still, despite all precautions, loss was unavoidable. The science of evaporation suggested the boiling of the juice in a vacuum, which would require a much lower temperature. The inventor of this method constructed a pan from which the air could be extracted, and succeeded so well, that the vacuum pan, as it was called, was brought into general requisition, and the patentee is said to have realised £300,000 sterling by his invention; that is, for applying the scientific principle of evaporation to sugar boiling.

The smelting of iron is another process of such antiquity that no one knows how or when it

was discovered. For this purpose, no fuel would supply sufficient heat by ordinary combustion; but every housewife knows that fire may be quickened by blowing, though not every one knows the reason why. Iron has for ages been smelted in furnaces in which the temperature is raised by hard blowing. A foreman in the works of the famous ironmasters, Bairds of Glasgow, perceived that as the object of the blast employed was to increase the heat, and knowing that hot air would be equally effective for that purpose as cold air, and that the cold blast must tend to defeat its object, he tried a hot blast, and the result was most successful in economising fuel and saving time. The hot blast was speedily adopted, not only by Messrs. Baird, but also by other neighbouring ironmasters. As this invention was made by their foreman, Messrs. Baird declined to pay royalty to the patentee, and their neighbours followed their example. Mr. Neilson, however, sued the outsiders first, and obtained £80,000 compensation from them. He then proceeded against his employers, and they were cast in damages of £100,000, a million of rupees! A cheque was handed in Court by Mr. Baird to a friend of mine, who was Mr. Neilson's counsel in the case, for £106,000 on Masterman's Bank. The £6,000 was for costs in the case. £180,000 is a large reward for knowing how to blow the fire!

The history of the manufacture of steel affords another good illustration of the application of scientific principles to an ancient process. Steel was known long ages ago, but, until quite recently, it could only be produced in small quantities, and at considerable cost. Its use was confined therefore to the manufacture of small articles, such as knives, instruments for surgical and other scientific purposes, and such like objects. Probably the largest articles for which it was employed were cutlasses and swords. The actual nature and constituents of steel were not understood until they were ascertained by recent scientific research. When these were known, Mr. Bessemer conceived a new method of making steel upon a large scale, and after many experiments, he at length succeeded, at first somewhat imperfectly, but the new process, when further developed by himself and Siemens, the manufacture of steel, was effected in large quantities. Steel, in consequence, came into use for rails for railways, caunons, and even for building steam vessels. It is said that Mr. Bessemer has received over a million sterling, or ten millions of rupees by royalties for his invention. Such are the results of applying scientific principles to the improvement of old processes.

An accurate knowledge of the nature and properties of steam has also led to great results. For example, when I came out to Ceylon in 1846, I made the voyage from Southampton to Galle by P. & O. steamers in 36 days, during 33 of which we were under steam, and we were 3 days in crossing through Egypt, as there was no Suez Canal then. On that voyage, which was made in the largest and finest steamers then in existence, they consumed over 60 tons of coal a day. In 1887, when I made the same voyage, also in a first-class steamer,—we made the distance in 25 days, including

the passage through the Suez Canal, and the steamer consumed little over 20 tons a day. The voyage was made in much less time and with little more than a third of the quantity of coal that would have been required under the old system. This great economy was effected entirely by means of a better knowledge of the nature and properties of steam and of improved methods of treating it.

When I was a boy, indiarubber was used only for erasing pencil marks, but when the chemists took it in hand, they soon discovered new properties that it possessed, new forms and combinations of which it was capable, and the result of their scientific treatment has been to make it one of the most valuable materials, and of most general use in the whole range of arts and manufactures.

One other illustration must suffice. About 1853 there was a great controversy about rifles for the army, and there was much difference of opinion on the subject. There did not appear to be any established principle, either of the best form or proper construction of the weapon. A Commission was therefore appointed to receive the evidence of the best gunmakers, but that did not settle the question. Lord Hardinge therefore urged Mr. Whitworth to investigate the subject, with the aid of his celebrated appliances for accurate measurements and mechanical construction. The result was that an exhaustive series of experiments was conducted with great care to ascertain the necessary data, and to test the various methods then in use. When the requisite data were settled practically, and Mr. Whitworth's methods of construction were employed, a correct system was established. Twenty rifles on the new principle were supplied for the first Wimbledon meeting, and were there submitted to the crucial test of a great public exhibition. Lord Elcho, a principal promoter of the meeting, desiring to give it all the éclat possible, solicited Her Majesty to inaugurate the proceedings by firing the first shot, upon which the Queen asked Lord Elcho: Shall I be sure to hit the bull's eye? His Lordship had not been prepared for that electric shock, and had to retire to consult Mr. Whitworth before venturing to reply. His answer was prompt: "Tell Her Majesty she shall hit the bull's eye." Cautioned as to the serious consequence of failure, he repeated his assurance, and only asked if Her Majesty might be relied upon to fire within five minutes of being asked to do so. Lord Elcho, on his part, answered for that. The Queen was satisfied, and the gun was laid by Mr. Whitworth at 400 yards, Her Majesty promptly fired the shot when asked, and up went the signal of a bull's eye on the instant! Her Majesty gave a trill of joyous laughter and requested that the target might be brought for her to see. The one plate was speedily unscrewed and was borne to the tent by 6 or 8 men. And there was the shot mark, within half an inch of the centre of the bull's eye!

Such are a few of the triumphs science has achieved in improving old processes in correcting errors that had been persisted in for ages, and in showing the glorious possibilities that yet remain to be explored.

Hitherto, the illustrations adduced in proof of what science could do for the arts and manufactures were all in reference to improvements of old processes, but it would be an unpardonable omission on my part not to mention the far greater triumphs science has achieved in the introduction of entirely new inventions and means of material progress. During the short space of my life, there have been brought into use Railways, Telegraphs, Photography, Chloroform, the Atomic Theory, the Spectroscope, Phonography, the Electric Light, and many other things which I cannot now remember.

It will not be disputed, in view of these facts, that technical teaching is entitled to the rank of a special science, comprising the art of applying the principles of the sciences to practical use in the arts and manufactures.

It will be observed, however, that technical science is not equally applicable to all countries, and therefore needs special adaptation to each. A distinction, for instance, is to be drawn between old countries and new; that is between countries in which there is a dense population, and where all the available land is in cultivation, and those newer countries that are sparsely populated, and where there are large tracts of land unoccupied and available for cultivation. In such countries as these, the people would avail themselves of natural resources, and would take all they could from the soil. The United States of America, though not a very young country, has still vast tracts of available land and comparatively few inhabitants. They therefore produce and export raw materials, such as food grains, cotton, tobacco, and such like products. They do not yet engage largely in manufactures. They have not yet reached that stage. Four-fifths of their exports to Great Britain therefore consist of those natural products, and only one-fifth of manufactured goods. Great Britain, on the other hand, exports scarcely any raw material, except coal and iron, because they are wanted at home to feed her factories. But it was not always so with England. There was a time when the population of the Island was sparse, and a great deal of the land was unoccupied. It was then celebrated for the fine wool of its sheep, which was for a long period exported to Flanders, where it was made up into costly fabrics. A time came, however, when one of the Sovereigns, I think it was Edward the Third, sent over to Flanders and imported a number of skilled workmen, weavers, dyers and fullers. From that time England became a manufacturing country, and is so more than ever in the present day. By and bye, our American cousins will follow our example, and will get tired of exporting the raw materials and food, which they will be able to utilise themselves.

It follows that technical institutions will have different functions in different countries, and that brings me to consider the position and requirements of Ceylon; which is old in population and in the utilisation of its lauds, but quite in its infancy as regards manufactures. Here the rage is for higher education, and there are crowds of candidates for employment in the professions, in the Government departments, and for clerkships. Other spheres of occupation are urgently wanted, and that soon, for the case is pressing.

Technical education is wanted to pave the way for the utilisation of numerous products which are now running to waste, not because they have no value, but because they would not pay the heavy cost of transport to countries where they could be utilised. There are excellent tanning materials in the shape of barks, woods and roots, of which as yet but little local use has been made. Dyeing materials of many kinds also exist, some of which were till lately exported, and even yet orchella and sappan continue to be shipped. Paper-making materials abound on all hands, and there are numerous fibres that need only the necessary technical knowledge to turn them to practical and profitable account. The Bull's eye of science needs to be turned upon the natural resources of the Island, and many of the commodities that now figure among our imports could be supplied locally, affording profitable employment for the rising generation and a great economy to the consumers.

For this purpose it is that a local technical institution has been proposed, and for some time past discussed publicly and in the press. Indeed, it may be said to have been agreed upon by the Government, and the present lecture is intended as inaugurating the new establishment. In approaching this part of my subject, however, I feel some difficulty, as I should not wish to hold out any prospects on this occasion which would hereafter be found to run counter to the intentions of the Government. Although it is known that technical teaching in some form will be commenced shortly, nothing definite has yet transpired as to the course of instruction that shall be given. What is desired, however, is that the rising generation of educated youths should be so furnished with technical knowledge as to enable them to utilize the materials at their disposal, and to find profitable occupation in turning them to useful account. On one point, at least, there is perfect agreement on all sides, and that is a recognition of drawing as the basis from which the whole must commence. Drawing may be said to be the language of science, and especially of mechanics. Let any one endeavour to describe a machine verbally, and he will at once recognise the impossibility of giving any intelligible account of it. Drawing is indispensable. But mechanical drawing is a special art. Perspective is the soul of pictorial art, but is entirely inapplicable to mechanical drawings, seeing that every part of them must be subject to measurement. The practice of mechanics is to design their machines on paper, on some convenient scale, by means of drawings of front and side elevations and ground plans. The design is thus studied, and all the parts and dimensions approximately settled. When this has been done, the same drawings must be repeated on full size, and if their dimensions exceed the size of the usual blackboards, resort must be had to the floor. Many a time have I had to lie at full length to carry out work of this description on the floor.

It will also be necessary that the student who has acquired a competent knowledge of drawing should acquire the use of drawings in the workshop. He will also need to learn the principles of the tools that are used in mechanical work, and of their construction. For this purpose workshops are absolutely necessary, what-

ever course of instruction the Government may determine upon. It has been suggested that students might learn the use and construction of tools by being taken to factories where they may be seen at work; but that is not sufficient. It would be as unreasonable to expect to learn human physiology and anatomy by merely seeing a man at work. Tools must be taken to pieces and dissected, and the principles of their construction cannot be otherwise fully disclosed or practically understood. For this purpose a gallery of illustration has always seemed to me to be a primary necessity, where steam engines and working machines, such as lathes and other tools could be shown in operation, and also be taken to pieces and thoroughly examined. There the best models of mechanical contrivance should be exhibited to show students what has been achieved by mechanical means. The steam engine would be there dissected and all the parts and principles might be explained. The gallery would be furnished with necessary appliances for illustrating lectures to be delivered by the head of the Technical School, and possibly also by local experts.

INDIAN JOTTINGS.

The cultivation of Indian Corn in Ceylon in a more extended scale has been frequently advocated, but no great increase in its cultivation has resulted. When one sees the area of corn-fields in some parts of India and the quantities exported, the neglect in our Island to take advantage of this easily-grown product is appreciated.

I have watched with interest a plot of Indian corn about four acres in extent grown here. The first seed was thrown in about the 15th of May and cropping commences early in August; that means a period of only two and a half months.

The method of planting differs a little from our Ceylon style as well as that which is said to obtain in the greatest corn-growing districts of the world, the United States of America.

In the first place it should be mentioned that the land where the cultivation was carried on is very low, about three feet below the surface of the surrounding ground, and its level condition and situation reminds one of a Ceylon low-country paddy-field, minus the ridges.

March and April and a greater part of May are dry months here, and the soil had been loosened and levelled in the early part of May. Before planting, the soil is divided into beds by means of shallow drains made parallel to each other, having still smaller ones crossing them.

In these beds the seeds are planted in regular lines, a person with a mamoty digging holes, each about a foot apart, another throwing in a handful of manure (powdered castor cake), and the last man placing four to six seeds in each of these holes, not in the same place but a few inches apart.

When the plants grow up the actual space between them is something less than a foot between each line, and a few inches between

each plant in the line. A line generally contains from two to three plants abreast close together.

By the latter part of May or a few days after planting slight showers are experienced and the young plants begin to come up with great vigour. These showers are succeeded by heavy rains by the middle of June, as heavy or heavier than we experience in Ceylon, and continue till after the crop is gathered. Sometimes when the rain is heavy the whole field is seen under water for hours together or for a whole day, and at no time from this stage is the soil free from a large quantity of moisture. In gathering the crop the cultivators do not wait until the cobs are drying, but pluck them in a slightly greenish state and dry them before taking off the seed.

But what should be of great importance to those in Ceylon is the value of the stalks and the leaves of the plant as fodder. Just after the pods are taken, the plants are reaped down and bundled and removed for the purposes of feeding cattle. The cultivator, if he himself does not use it, gets a fair price for the leaves. Besides these great advantages from the extended cultivation of this plant in Ceylon, two other points of practical value strike one. First, the possibility of growing Indian corn in many of our Ceylon paddy-fields either alternately with paddy or, much better, during the season the fields are generally without a crop, which extends from five to eight months. It may be said, and it is partly true, that both paddy and Indian corn being crops of the same family, would soon exhaust the soil, but this exhaustion would be remedied by manuring, and it is by no means the most enlightened system to leave a land uncultivated, when there is a possibility of growing a crop, for fear of exhausting the soil. When the crop cultivated is not a permanent one, the object of the landowner should be to get as much out of the land as it is possible without keeping it idle and return to it in the form of manure the ingredients removed from the soil. How pleasant to the eye would be the sight of thousands of acres of waving corn-fields in places where meadow-like spaces are seen now for a greater part of the year. If the goiyias could be made to go in for Indian corn cultivation as a subsidiary product in their fields, they would perhaps be less liable to the blame which is often cast upon them of being lazy and idle during a great part of the year. The fodder which this plant would yield will go not only to improve our cattle and make them less liable to disease, but to increase their numbers materially.

The goiyias would not take to anything from the mere preaching of it. I am fully aware of that, and if pressure is made to be brought upon them, they will do it in such a way as to make it a failure, but if they are to be made to take it up they will require practical proof, and if a few persons undertake experiments in growing Indian corn in rotation with paddy and find the system a success, I have no doubt the goiyias will take to it in earnest.

Bombay.

W. A. D. S.

ZOOLOGICAL NOTES FOR AGRICULTURAL STUDENTS.

SUB-KINGDOM III. *Echinodermata* (Gr. Echin, a hedgehog, derma, skiu.) so called from the prickly nature of the skin in most members.

General Characters.—Simple marine organisms; the body of the adult more or less radiate, that of the young bilateral; an alimentary canal, which never communicates with the body cavity. A water-vascular system—a peculiar system of canals distributed through the body and usually communicating with the exterior, often employed in locomotion. Nervous systems radiate, composed of an esophageal ring and radiating branches. Sexes generally distinct, rarely united.

In this sub-kingdom are included the well-known sea-urchins (*echinoidea*), star-fish (*asteroidea*), brittle-stars and sand-stars (*ophiuroida*), feather-stars (*crinoidea*), and the *Holothuroidea*, commonly known as "sea-cucumbers," "trepangs," or "bêches-de-mer." These last-mentioned are found in all parts of the Western coast of the Northern Province of Ceylon, in from 2 feet to 7 or 8 fathoms of water, and the trade in the slugs is chiefly in the hands of the Chinese, who after fishing and "curing" the bêches-de-mer, ship them to China, where they are greatly esteemed as an article of diet.

SUB-KINGDOM. IV. *Annulosa* (Lat. annulus, a ring.)

General Characters.—Body more or less elongated, bilaterally symmetrical, commonly divided into similar segments which may be definite or indefinite; limbs when present in pairs; a nervous system is present, and consists of one or two ganglia in the fore part of the body, or of a ventrally placed double gangliated chain. (Ganglion, Gr. a knot; a mass of nervous matter containing nerve cells, and giving origin to nerve fibres.)

Division I. *Scolecida*. This division includes the tape-worms (*Tæniada*), in which the body of the adult is elongated and composed of flattened joints, the anterior extremity (head) covered with hooklets, or suckers, or both combined. There is no mouth or alimentary canal, and the young pass through a metamorphosis. The mature animal is hermaphrodite. In their mature condition the *Tæniada* are always found inhabiting the alimentary canal of some warm-blooded vertebrate animal; and they are distinguished by their great length, being composed of a number of flattened joints or articulations. The true animal is found in the so-called "head," while the joints are simply hermaphrodite generative segments which the head throws off by a process of gemmation or budding. The head is a minute rounded body which is furnished with the hooklets and suckers before mentioned, whereby the animal maintains its hold on the mucous membrane of the intestines of its host. No digestive organs and mouth are present, and nutrition of the animal is effected by imbibition. The head, however, contains no reproductive organs, and these are developed in the joints or segments. Each segment when mature contains both male and female organs, and is therefore

sexually perfect. To such a single segment the term "proglottis" is applied from its resemblance in shape to the tip of the tongue. Proglottides are only produced within the alimentary canal of some warm-blooded vertebrate, but the development of the ova contained in the proglottides cannot be carried on in this situation. For the production of an embryo it is necessary that the ovum should be swallowed by some animal other than the one inhabited by the mature tapeworm. To this end the ripe proglottides are expelled from the bowels after all the ova have been fertilised. After their discharge from the body the proglottides which for some time retain their vitality and power of movement, decompose, and the ova are liberated, when they are found to be covered by a protecting capsule. For development the ovum must be swallowed by some warm-blooded vertebrate and thus gain access to its alimentary canal. When this takes place, and after the capsule is ruptured, the embryo (now called proscölex) is liberated, and consists of a minute vesicle with 3 pairs of siliceous spines for boring through the tissues of the host till it reaches some suitable resting place. Here it proceeds to surround itself with a cyst and develops a vesicle containing fluid from its posterior extremity, when it is called a "scolex." When thus encysted the scolex consists simply of a head with a circlet of hooklets and four suckers, united by a contracted neck to a vesicular body. It contains no organs of any kind and cannot develop any further unless it be swallowed for a second time by a warm-blooded vertebrate. It may however produce fresh scolices by budding. Provided the scolex again reaches the elementary canal of a warm-blooded vertebrate, it attaches itself to the mucous membrane of the intestinal tube by means of its hooklets or suckers, and having dropped its vesicle becomes the head of the tapeworm and proceeds to put forth segments. To the entire organism with its head and mature and immature joints (proglottides) the term "strobila" is applied.

In the development, therefore, of the tapeworm we have to remember the following stages:—

1. The *Ovum* set free from the generative joints or proglottis.
2. The *proscölex* or minute embryo which is liberated from the ovum when the latter has been swallowed by a warm-blooded vertebrate.
3. The *scolex* into which the proscölex develops, when it has encysted itself within the tissues of its host.
4. The *strobila* or a dual tapeworm into which the scolex develops when received into the alimentary canal of a warm-blooded vertebrate, and consisting of head and mature and immature proglottides.

SUBSTITUTE FOR CATTLE MANURE.

The last issue of the Magazine contained an interesting communication in which the possibility of forming a compost that might be substituted for cattle manure was discussed. For the supply of nitrogen, gas liquor suggested itself to our correspondent who however states

that the chief objection against the use of this substance is the large amount of water it contains. A more valuable substance, however, that might be used with the same object in view is blood; but then neither of these two substances are available to any extent, and can be conveniently brought on to the land except where cultivation is carried on in the suburbs of the metropolis, or near a centre of population. Again, bones were mentioned for supplying the compost with phosphoric acid and lime, and here again a cheaper substitute that has come into much favour of late might be used instead, viz., Basic cinder or Thomas phosphate powder. The basis of the substitution, it is stated, should be coir fibre which our correspondent suggests ought first to be deprived of the large amount of water with which it is saturated as it leaves the coir mills. There is no doubt that fibre dust is an excellent medium for holding and distributing substances containing the more valuable ingredients of plant food. May not the water be even more conveniently and economically driven away by desiccation? Coconut fibre besides supplying, though tardily, a fair percentage of ash constituents is capable of yielding from 2 to 5 of nitrogen. But with a view to having a more concentrated substance for supplying the nitrogen, lime, phosphoric acid of the compost, our correspondent suggests that guano should be used. The higher qualities of this valuable manure still obtainable yield from 8 to 10 or 12 per cent of ammonia, and the poorer grades about 4 per cent and even less, with however from 30 to 50 per cent of phosphates; potash may be present in from 1 to 3 per cent. During heavy rains, such as we experience in Ceylon, especially on light soils, there is some danger of a part of the soluble constituents of guano being washed out; on fairly retentive soils, however, this danger would be reduced to a minimum. It would be most interesting if our correspondent would with a view to replacing cattle manure with a compost consisting of coir-dust, guano (of course of a fixed analysis, for there are guanos and guanos) calculate out the cost of manuring an acre of coconuts with the compost as compared with that of manuring with cattle manure. Given the percentage analysis, the ordinary units in determining the value of manures can be used for estimating the value of just so much guano as would be required to supply the same quantity of the ingredients supplied by cattle manure.

In connection with the discussion of the subject of a substitute for cattle manure, mention was made in the "Ceylon Independent" of a compost suggested by Mr. Perindorge many years ago in Ceylon. We have been kindly supplied with the following facts relative to this mixture:—"It consisted of jungle stuff indiscriminately, and the process of composting consisted in building up a stack thus: (1). A thick layer of green jungle stuff—leaves, twigs, grass, &c. (2) A sprinkling over this of liquid salts—Muriate of ammonia, sulphate of ammonia, chloride of sodium, sulphate sodium &c. in certain proportions. (3) No. 1 repeated. (4) No. 2 repeated, and so on to a convenient height, and then covering over the stack with a layer of earth. After thorough decomposition the compost was very like cattle

manure. "It was tried extensively," says our informant, "but it did not pay." And it is therefore we suggest to our correspondents to calculate beforehand as exactly as possible the cost of the compost he suggests as a substitute for cattle manure, so that the "will it pay" question might be at least well threshed out if not definitely settled.

GENERAL ITEMS.

The following are the guaranteed Analysis of Lawes' Guanos:—

<i>Lawes' Guano No. 1.</i>		
Moisture	10.26
*Water of combination, ammonia salts and organic matter	36.43
Monobasic phosphate of lime	13.66
Equal to tribasic phosphate of lime rendered soluble by acid	(21.39)	
Insoluble phosphate	6.32
Sulphate of lime	27.14
**Alkaline salts and magnesia	4.05
Silica	2.14
	-----	100.00
*Containing nitrogen	7.11
Equal to ammonia	8.71
**Contains sulphate of potash	1.96
<i>Lawes' Guano No. 2.</i>		
Moisture	9.43
*Organic matter and water of combination	30.56
Monobasic phosphate of lime	14.09
Equal to tribasic phosphate of lime rendered soluble by acid	(22.06)	
Insoluble phosphate	8.80
Sulphate of lime	29.54
**Alkaline salts and magnesia	3.95
Silica	3.63
	-----	100.00
*Containing nitrogen	5.42
Equal to ammonia	6.58
**Containing sulphate of potash	1.81

Mr. John Hughes reporting on these guanos says:—The ammonia has been rendered non-volatile by the addition of sulphuric acid, and there is consequently no danger of any of this important constituent being lost by exposure or otherwise. The phosphates have been rendered soluble to a great extent, and are therefore much more valuable than in raw guanos. The greatest care is paid in its preparation to ensure its being sent in good condition, and it may always be depended to be in a fine powdery state, thereby rendering it readily available as plant food, which is not the case with much of the guanos now offered. The analysis being guaranteed, the buyer can always rely upon obtaining the percentage of ammonia and phosphates stated, which he is unable to do when he buys without guarantee.

Giant caragua maize, seeds of which were sent to us by Sutton and Sons of Reading, is coming up well on the School of Agriculture grounds, and one or two Agricultural Instructors, to whom we sent a few seeds, report well of the growth. Sorghum Saccharatum also promises to be a success, but Sanfoiu and Lucerne though holding on, do not appear as vigorous growths. Mr. Gunasekere reports from Balangoda that kidney vetch, in addition to giant maize and sorghum, is doing well with him.

The plots allotted to the students at the School of Agriculture now show successful cultivation of radish, trunips, endive, tomatoes, yams, vegetable marrow, cucumbers (English and native), betel, manioc, sorghum, maize, snakegourd, onions, &c. Mr. J. A. G. Rodrigo, who is now acting as Practical Instructor is doing good work. Our thanks are due to Messrs. Miller & Co. of Kandy for a parcel of English vegetable seeds.

Lawes' chemical manure for cereals and grasses was tried on Mauritius and guinea grass as a top dressing in the proportion of 1 to 10 of fine earth. The results have been most striking, the grass showing rapid and vigorous growth within a week of the application.

TECHNICAL EDUCATION—ITS AIMS AND METHODS.

[Being the second "Marsh Lecture" delivered by DR. W. G. VAN DORT, at the School of Agriculture, Sept. 3rd, 1892.]

THE celebrated American humourist, Mark Twain, once offered, it is stated, to deliver a course of lectures on Chemistry, before the Royal Institution, urging as his chief recommendation his total ignorance of the subject, which he thought would give him free scope for quite a new and original treatment of this familiar branch of science. As far as ignorance of my subject is concerned, it may occur perhaps to some of you, before I have gone far into it, that I am not altogether unqualified, according to Mark Twain's criterion, to assume the rôle I have to fulfil today. Not having however the slightest pretensions to the quaint humour, the playful fancy, or the lively style of that witty lecturer, I fear there is little of novelty or originality I can offer you by way of compensation for any disappointment you may feel from my imperfect treatment of the subject chosen for my lecture this evening. My only excuse for touching on a theme so foreign to my proper province, so much discussed, so little understood, is that I have long taken a deep interest in it, and that in pursuance of certain inquiries bearing on the subject, I took the opportunity of a recent visit to Europe to inspect some of the Technical Schools in England, Scotland and France, and thus, to a great extent, dispel much of the mistiness which surrounds this question when one relies for information mainly on books. I regret however I could not see my way towards including in this lecture a description of any of the Schools I visited, within the limits of the hour assigned to me, considering the nature

and extent of the subject with which I have to deal.

In the Inaugural Address delivered last month by Mr. Wall, with all that eloquence and graphic power and charming felicity of illustration which characterise the utterances of such an accomplished public speaker, we were treated to a general view of the range and influence, the advantages and usefulness of Technical Education in its relation to Industrial, Scientific and Commercial Progress, from one who is known to be thoroughly conversant both with the theory and practice of his subject. My aim to day is a humbler and more limited one. Bearing on the same subject, but dealing with it more in detail, my object is to set forth, as well as I may, the *Aims* and *Methods* of Technical Education,—what it proposes to do, and how the ends it has in view are realized in the various teaching institutions which have been provided in the chief educational centres in Europe in response to the popular demand for such education. I shall endeavour to set before you in the first place the *objects* to be considered in any well-considered scheme of technical education. Next, I shall try to show you, both from the various treatises, reports, syllabuses, &c. I have consulted, and the results of personal inspection and inquiry in some of the schools I visited, how these objects are met in Europe and America. Lastly, I shall attempt (not unmindful of the warning as to the folly of those who "rush in where angels fear to tread") to shadow forth my views, however speculative visionary, and unpractical, of the system of Technical Education, which in my opinion is best suited to the requirements of the youths of this country, having due regard to their racial characteristics, our educational resources, and our industrial requirements.

First, then, we have to consider the *nature* and *aims* of Technical Education. You will remember what I said at the outset about my ignorance of the subject, and how I considered it, in one sense; outside my special sphere, as a member of one of the so-called liberal professions. Now I took a great deal of pains to dispel this ignorance, and nothing surprised me more, when I first became acquainted with the special literature bearing on this subject, than to find that *I had been a technical student*

all my life, and for a good many years during the latter half of it, a *technical workman* and *technical teacher* as well. Like Monsieur Jourdain in Molière's play, who was amazed to find that he had been speaking prose all his life without knowing it, I too, I discovered, was an unconscious possessor of an art which I had believed to be foreign to my vocation. You will suppose that I am referring to those pharmaceutical mysteries with which every student of medicine is supposed to be acquainted. Nothing of the kind. I am referring to my *ordinary infant school education*, when I was taught the mysteries of the three R's—Reading, Riting and Reckoning, to my *public school life* when I was trained up for a liberal profession, and to my *collegiate education* which was of a special character, and preparatory to a special profession. You will ask—what has all this to do with Technical Education?

Well, you have heard the definition of that term given in this place by Mr. Wall last month. You have heard him speak of it as "*the application of scientific principles to the arts.*" Now Reading, Writing and Arithmetic are *arts*. Are they not? And the enlightened methods of teaching these arts are *based on scientific principles* (or ought to be) on the principles of the Science of Education. And therefore *all elementary education* is, in a certain sense, *technical*. But, it may be objected, these are not the arts which were meant by Mr. Wall, only the *mechanical arts*—the arts connected with the *use of tools and machines*. But what is a tool but a labor-saving or time-saving device, and what is a *machine* but a complicated tool? How can you conceive of a mere ingenious tool than the *hand*, or a more perfect machine than the *human frame*, automatic in one sense, and to a great extent automatic, but needing no engineer to guide and control its movements, save the throbbing brain and self-regulative will? What again are letters and cyphers and "pot-hooks and hangers," but *tools* whereby the *labor of acquiring knowledge is diminished, and the operations of trade and commerce facilitated*? What are books but *instruments of thought, and ingenious means of saving time and mental labor*? What are Arithmetic and Mathematical tables but *machines* for facilitating calculation, and thus *saving time and labor*, like the ingenious but complicated machines in iron and steel, invented by Mr. Babbage and others, some of which are now actually employed in Government offices in England. What is the *pen* but a *tool*, and indeed the mightiest known, so far as its influence on civilization is concerned?

Still, it may be objected that the arts of Reading, Writing and Cyphering are not *Industrial Arts*, in the sense that Bootmaking or Carpentry may be said to be—the arts by which one earns a livelihood—but only subsidiary to the acquisition of knowledge. Is this so? Why, how many boys who leave school with no knowledge of the use of any other tools than these have to depend on them solely for their means of living, as clerks and accountants and salesmen &c. Are these offices not to be considered *industrial*, or the work not to be designated *mechanical*, because the only tool used is the *pen*, the only machine brought into

operation the *brain*? But I go a step further, and clam for all education that fits one for commercial or mercantile pursuits, not only a *sort of relationship* to technical education, but a *distinct affiliation* in a legitimate sense, inasmuch as Commercial Education is universally recognised as a branch of Technical Education, and is provided for in every technical school.

But even if the studies which count for a Commercial training may be considered technical, the higher studies of a Public School curriculum, it may be said, are not technical.

In so far as such education is not *directed with a view to prepare a boy for any special profession*, I admit it should be called *general* rather than *technical*, but whenever and where-soever the training is *preparatory and special, and adapted to the practical needs of after life*, even a liberal or classical education may be called *technical*. That I am not forcing the meaning of the term beyond its strict legitimate signification you can satisfy yourselves by referring to any good Dictionary. Here for instance is the definition in Annandale's Concise Dictionary:—

Technical—"Pertaining to the Mechanical Arts" (that is one sense of the word no doubt, and we are all agreed about that, but secondly) "appertaining in a special sense to any Art or Science, Profession, Handicraft, Business or the like"—and therefore to the *liberal arts* as well—the "Trivium" and the "Quadrivium" of the old schools, whence the retention of the term "*Arts*" in our Universities for the liberal or "humanizing" studies which are preparatory to the study of the liberal professions, divinity, medicine, law, &c.

Rev. Henry Solly defines Technical Education as that "specific training and teaching required to fit a person for any *trade, profession, or other calling* in life, over and above that general education which every person ought to possess according to age, sex, and other circumstances. "Hence it is needed as much," he says, "by lawyer or doctor, housemaid, ploughman, &c., as by carpenter, bricklayer, bookbinder or tailor. —*Nineteenth Century*, Aug. 1884.

Mr. Payne, the well-known educationalist, says with reference to early education in Europe during the historic period, the object of which was to train in the physical accomplishments chiefly, that it was "*technical or professional*, its purpose being to equip man for service as agents or instruments"—using the word "technical" in the sense of *special* directed to a particular end.

In this sense Sir Philip Magnus—one of the greatest authorities on the subject—would recognise even University teaching as *technical*. "In the history of education," he says, "a relationship has always been recognised between education and the practical needs of life, even the Universities having been founded as specialized or professional schools to minister to the needs of society"—instancing the University of Bologna founded for the study of Law, and that of Salerno for Medicine, and referring to the inclusion of Engineering as a new Faculty in the University of Cambridge, of Agriculture in that of Edinburgh, as subjects which are purely *Technical Industrial Education*.

Lord Salisbury, speaking at a meeting held at the Mansion House four years ago for establishing Polytechnic Institutes in London, identified Technical Education with Secondary Education, meaning the education which follows school education, including therefore the training for the liberal professions.

"In one sense," says Sir Lyon Playfair, lately raised to the Peerage,—by what title I do not know,—and who has been connected with the advancement of technical education for the last 50 years, "Technical Education should begin at the Kindergarten and end at the College, for its great object is to teach men to observe, to appreciate, and to think."

I could easily adduce other authorities, if necessary, in support of the view I have advanced, that in a certain sense the use of the term Technical as applying to all education that is preparatory to a special end, as distinguished from education which is of a general character only, whether it be disciplinary or developmental, is perfectly correct, legitimate, and well recognised. Now in this high and broad sense of the word "technical," you and I and nearly every one in this room, whose education has been of a preparatory or special character, including even the ladies who have been kind enough to honour me with their presence here today, and whose professional or special education may have been directed to such branches of practical work, as *needle-work and cookery and dressmaking and domestic economy*—all recognised branches of *technics*—or embracing it may be *Nursing and Hygiene* and the education of the young, are *technical students*; in this sense, I say, our elementary and public schools so far as they train for the liberal professions, the clerical service, for mercantile or agricultural pursuits, or other distinct callings, are *technical schools* in the proper sense of the word, and technical education, so far from being something new and foreign, which is about to be introduced for the first time, is a form of education with which we are already familiar, and the Government may easily cry off in answer to the popular agitation for technical education by pointing out that the boon demanded has been granted already. Now pray do not suppose that I want to hinder reform in our educational machinery by putting forward some fanciful crotchet to tempt your imagination astray. You know, or have heard, how in fox-hunting countries little boys out of mischief, or "in the interests of the fox," can spoil a hunt by dragging a herring across the scent. Now I have no such sinister motive to actuate me. My purpose is far otherwise, as you will see when we come to consider the question of technical education in reference to our local requirements.

For the present, however, I shall intermit the use of the term technical education in its broad and comprehensive sense, and employ it only in its strict, narrow, conventional signification, in the sense it was employed by Mr. Wall, in the sense in which it is generally understood by educationalists at least, for a more vague, elastic Protean term than that of technical education I do not know. Derived from the Greek root *tekne*—*art*, the strict

meaning of the word *technical* is "relating to art based on scientific principles systematically studied and developed." That is its strict meaning, but its actual signification or rather the various senses in which it is understood by different classes of people are far different. It is applied for instance with equal indifference to Industrial Schools, to Reformatories, to Trade Schools, to Manual Training Schools, to Schools of Design, to Mechanics' Institutes, to Evening Classes for workmen, to Engineering Colleges and Polytechnic Institutes of the Regent Street type, to Polytechnic High Schools of university character, and in no two of these various educational institutions which I have just enumerated are the objects of study or the methods of instruction exactly the same. Applied to education it means one thing to the *factory hand*, another to the *handcraftsman*, a third to the *trade designer*, a fourth to the *manufacturer*, a fifth to the *merchant*, &c. It means, for instance, the training in the *mechanical arts*, to the artisan or his children, who desire to find a substitute for the old apprenticeship now rendered almost obsolete. It means *Commercial Education* to the student desiring to prepare himself for clerical or mercantile pursuits. It means *Scientific Knowledge* applied to the arts, to the manufacturer who needs trained *heads* more than skilled *hands*. It means *instruction in the processes and operations of Art Industries* to the workman, who under the present system of "division of labor" is limited to a minute portion of work, and gains no intelligent knowledge of the machinery he serves, or the article he assists in turning out. Hence the great variety in the character of the different technical institutions in different countries, and even in the same country, to meet the varying requirements of different classes of people.

And yet fifty years ago there was no such thing as Technical Education known in Europe. When Jean Jacques Rousseau in 1762 "struck the keynote of technical education" in his *Emile*, in that memorable phrase "*comtez, pesez, mesurez, comparez*," and taught people that education consisted in the study of *nature and things* not in that of *books and words*, in *observation and experience* not in *book knowledge and theoretic speculation*, he was, as Sir Philip Magnus shews, fully half a century in advance of his age. People could not understand him, nor the system of education he advocated, because "it was out of relation with the occupations with which the majority of the people were then engaged." How much in advance, and how much in harmony with the wants and leading ideas of the present day may be seen from the fact that Rousseau makes *Emile*, his moral pupil, *learn a useful trade*. While being trained for a liberal profession, he is taught to be a good carpenter, so as to be able in case of necessity to live by it, and in the meantime to overcome and defy the prevailing prejudice against handiwork.

It was not Rousseau alone who was misunderstood, and whose teaching was ignored because it was out of relation to the wants of the time. Even Pestalozzi, with his objective teachings and Fröbel, the founder of the Kindergarten

system—the *pioneers of technical education*—were unable to influence the prevailing views as to education to any considerable extent during their lifetime, however much they may have revolutionized the entire course of education in Europe since then. It was not *infantile education*—not “learning combined with play”—“teaching without tears”—which many people conceive to be the essence of the Kindergarten system, but a complete undermining and uprooting of the fossilised mediæval system of teaching for one more in harmony with a true philosophical recognition of the true object of education, which, as Herbert Spencer has well defined it, is to *prepare one for complete living*, having reference to *the activities, the needs, the life-interests of the individual*. Fröbelsim is not child’s play but a system of education intended to *make men*, as Fröbel has it “whole complete men—men who can observe, learn by experience, and act up to their convictions.” It is a harmonious, all-sided, all-round education, which aims alike at intellectual growth, increase of will-power, and skill in the use of the hands and tools. It is the manual training movement, part and parcel of this all-sided education, which forms the *germ* of all the technical education of the present day. Next to Fröbel, the man to whom we owe the present “new departure” in education, is one whose name is hardly known beyond the country of his birth,—Uno Cygnæus, Rector of a Normal school in Finland, who was born in the early part of the century, and who died just 10 years ago; the first to found a Manual Training School, which has been so eminently successful as to furnish a model for an immense number of similar schools in Europe and America. The principle upon which his system was based was that education of the young must aim not at one-sided intellectual training, but at the harmonious strengthening and exercise of man’s in-born powers, with constant consideration of *practical aims in life*. It is the system of Fröbel carried on to a higher stage of a child’s education. It is much to be regretted that we have not a single infant school on the Kindergarten system in this country if only to serve as a model for primary instruction in other schools.

Herbert Spencer, whose definition of education I have already given you, arrived by a different process of reasoning from Fröbel at the same result as to the true object of education. He places the usefulness of a study, *i.e.*, its *practical science in life* in the foreground, in the choice of subjects for instruction, and finds also that the very subjects which are best worth knowing are also the *best aids to mental discipline*. Herbert Spencer goes even further than this, for in a private conversation with Mr. Oscar Browning, the latter relates how he (Mr. Spencer) had maintained that schools were an *excessiveness* and an *impertinence*, the only real education being that gained by life and experience.

But the causes which brought about the necessity for a special kind of training, a new system of education, were not the theories of philosophical doctrinaires like Rousseau, nor the far-seeing wisdom and practical views of

educational reformers like Comenius and Locke, like Pestalozzi and Fröbel, nor even the pressure of enlightened and educated public opinion. The true causes were the changed conditions of trade and commerce, due to the *invention of the steam engine* and the introduction of *labor-saving machinery* whereby not production only but distribution of articles of industry and locomotion and inter-communication between distant nations were stimulated and facilitated to an enormous degree. Time out of mind splendid houses were built, and beautiful clothes woven and dyed, and ships built, and roads made, and all manner of articles of comfort and luxury produced, but with the introduction of steam thousands of articles are manufactured now by machinery for one that a workman could turn out by hand in the same space of time. The old relations between master and pupil in the workshop have also changed into those of capitalist and labourer. The former has no time to teach the latter, and owing to the great principle of division of labor in all large manufacturing establishments the workman himself having only a minute piece of work to attend to, which he has constantly to repeat, learns nothing of the processes of the trade or the structure of the machinery in which he is engaged, nor can any other workman find time to teach him. Then again the demand for intelligent workmen trained in science with a knowledge of drawing, or possessing manual skill or artistic invention—for foremen and managers and masters to superintend and direct the work in large factories, is greater than the supply. New needs, new duties arise daily which the ordinary training in the elementary and even higher schools fails to meet. That training was found to be far too general, too aimless, too ill-adapted for the new demands of industrial life in the changed and ever-changing conditions of society, and a system of education more special, more practical, though not less disciplinary than purely intellectual culture had to be devised. Children had to be trained for the work in which they were likely to be engaged, workmen to be taught the processes of manufacture or the details of the craft in which they were employed, artisans to be perfected in the designer’s art, pupils training for commercial life to have their studies liberalized, and students seeking a higher education in practical science to be helped and encouraged to advance higher. Accordingly various kinds of teaching institutions were established to provide for these various classes, and in a very short space of time *Manual training school* for boys, schools of design for artisans, evening classes for workmen, and colleges and institutes for foremen, teachers, engineers &c. sprang up rapidly in the chief educational centres in Europe and America.

On the Continent, in France and Germany and Italy these schools and teaching institutions are arranged on a perfect system of gradation beginning with the elementary schools, and rising through a series of evening continuation classes and intermediate schools (Trade or Commercial) to the highest stage—the Polytechnic, equivalent to a University in its functions. In Great Britain there is an absence of this systematic arrangement and subordination of schools, the

teaching institutions not being under State control, so that though there is no lack of technical schools of every variety, there are far fewer facilities for a complete technical course except in centres like London, Manchester &c. The fact that technical education requires as an indispensable basis a preparatory training in the primary schools—long recognised and acted on in continental countries,—has only recently received recognition in England. In nearly every country in Europe, Drawing and Rudimentary science are taught as *obligatory* subjects in addition to Reading, Writing and Arithmetic. In most Continental schools Handicraft Instruction and Modelling are included in the curriculum for boys, and Needlework and Cookery and Domestic Economy for girls. While in England the only technical subjects taught till last year were certain branches of science called specific subjects, viz. Algebra, Euclid, Mensuration, Elementary Mechanics, Chemistry, Physics, Agriculture (principles) and Domestic Economy for children of both sexes and Needlework and Domestic Economy for girls. Drawing was an *optional* subject, and was taught to only about 25 per cent of the children. Science teaching, being also *optional* was almost completely ignored. One principal reason for the neglect of science in the elementary schools was said to be the want of competent teachers. In Birmingham and Liverpool, however, this difficulty was successfully met by appointing a teacher highly competent to go round visiting all the schools in turn within a certain area and carrying his apparatus with him, at a cost of about £10 per each school. There can be no question as to the economy of this arrangement, but I am very much inclined to doubt the value of science lessons given once a fortnight or so by means of apparatus which the children themselves are not allowed to handle and use. There is no greater mistake than to suppose that any science can be taught by imparting certain lessons by means of apparatus and diagrams by a teacher. That method of teaching is now exploded in all good schools, though I hear it still obtains in some schools here. Every child must perform the experiments by which he has to learn for himself, and from his very failures and blunders train his hands and eyes, train himself to observe rightly to handle skilfully, to reason truly. Where the "Laboratory method" of teaching is impracticable it would be far better to devote the time so wasted to some other study. But this peripatetic system of teaching should not be lost sight of in regard to other special subjects, at least in a country like ours where competent teachers are scarce. Take Drawing for instance and Manual training in the use of tools—the introduction of which as well as of Elementary Science into the curriculum of elementary schools forms the most noteworthy feature of the Revised Code of 1890. Whenever the Local Code introduces these branches of instruction into our primary schools, (and almost the first step in introducing technical education would be a reform in this direction in the teaching of the elementary and higher schools,) the difficulty of securing a sufficiency of teachers to furnish such instruction should not be made to stand in the way of such reform, in the principal towns at least, as the same teacher could

go round to half-a-dozen schools daily. When workshop teaching was tried as an experiment in the Manchester Board schools, a single joiner was found sufficient to teach several schools. Of the higher elementary schools in which technical teaching is further specialized, and of which there are admirable examples in France and Germany, there are but two of any note in Great Britain, the Central School at Sheffield and the Allan Glen institution in Glasgow. These two schools afford such a fair idea of the type of an ideal school giving "the best preliminary training for those who are about to enter industrial life at an early age" or to carry on their technical education by attendance at evening classes, or in a technical school of higher grade, that I regret very much the limits of my time will prevent me from entering into a detailed description of either of them, especially of the latter which I visited and inspected recently with great interest. The principal distinctive features of this school are the combination of technical instruction with ordinary elementary teaching from the very earliest age, and the progressive and extensive training in science and art and workshop exercises, due attention being paid at the same time to all the requirements of a sound general education which may be especially noticed in the lower classes of the secondary department; while in the two advanced of the technical classes special attention is devoted to the relation of science and art to manufactures and commerce. It was with reference to boys who had gone through this curriculum in Allan Glen's school that Mr. Mundella said in 1884 "these pupils were becoming not only the non-commissioned officers but the future captains of industry of the country. It was for such purposes that technical education was required."

As I mentioned before there are but few Schools of this type in Great Britain, but now that the Revised Education Code of 1890 has come into operation, and grants provided for encouraging technical instruction and manual training especially, a great change will shortly be effected in Elementary Schools which rightly directed will produce, it is confidently believed, most important economic changes in the country. It is worth while noting here that in the Charity Commissioners' Report for 1890 prominence is given to a scheme put forward by Mr. Assistant Commissioner Bond with respect to the advancement of the technical education of the poorer inhabitants of London in day schools, wherein he suggests three ways of accomplishing that purpose:

1. By teaching drawing and perhaps modelling and the use of tools as a part of the regular course of instruction in Elementary Schools.
2. By establishing higher Elementary or Continuation schools, in which in addition to these subjects in a more advanced stage, Elementary Science could be taught.
3. By establishing institutes in which evening classes should be held for instruction in *Art, Science and Technology*.

How far these views will suit our local requirements is a question which may have to be considered, but I have little doubt that it is

on lines of this kind that the foundation of any new scheme of technical education for the people of this country will be laid.

(To be Continued.)

SUBSTITUTE FOR CATTLE MANURE.

DEAR SIR,—It has afforded me much gratification to read your favourable opinion on the compost I suggested to take the place of cattle manure. Please allow me to offer a few remarks on your article on the above subject.

As you observe, the supply of blood is too limited to permit of its use in any extensive scale, and gas liquor has too much water in it to render its use economical. But what about sulphate of ammonia, the crystallised product of gas liquor? Is it manufactured at our gas works, and what becomes of the gas liquor? Sulphate of ammonia is described as the most highly nitrogenous manure the farmer can use, and is said to contain 20 per cent. of ammonia. Has the comparatively new manure, powdered slag, been imported into Ceylon as a substitute for the old phosphatic fertilisers?

You suggest the dessication of fibre dust as more economical than depriving it of moisture by pressing. How do you propose doing this? If drying in the sun, large barbacue space will be necessary and the period of settled dry weather chosen for the purpose, otherwise our passing shower will undo the work of days. I did not intend that the fibre dust should be perfectly dry, indeed I think a certain amount of moisture an advantage, only that the super-abundant water should be expelled from it. A stout door frame with a screw or lever through the lintel, having a stout plank or sheet of iron fixed at its lower end, something like a copying press, will give us a cheap and economically worked press. A box of stout boards or sheet iron, perforated and with collapsible sides, placed under the board or sheet of iron attached to the lower end of the screw or lever, can be used as the receptacle for the coir dust. Slight pressure will drive out the water from it through the perforations, when after the sides of the box are made to collapse, the coir dust can be taken away. This is but a curd idea and something better will occur to an engineering mind.

Will not the slow decay of the coir dust be an advantage if worked into the generally stiff soil of our hill region? It will extend the period of the soil being aerated by preventing the particles of the soil coming together.

It will no doubt be interesting to have a comparison of the cost of manuring with cattle dung and a compost composed of coir dust and guano. Cattle manure is an article of varying quality and price. For a comparison to be complete it will I submit be necessary to calculate the cost of applying stall-prepared cattle manure and of the coir dust-guano compost and to compare results both immediate and subsequent. The comparison of the cost of application alone will not do. You will pardon me, sir, if I respectfully submit that it will be very much more advantageous and authoritative if the experiment be conducted at the School of Agriculture and under your skilled direction. I would also suggest that it be tried on some other product rather than coconut, for with this

product the material results of manuring will show them themselves in the second or third year. By that time all interest that may be awakened in the compost I suggest will be allayed. You might arrange for the comparison of cost and results to be made on a small scale on Cacao and Tea outside your grounds.

I am afraid your informant of the composition of Perindorge's compost relied too much on his memory. I shall compress the instructions for its manufacture from the Prize Essay on manuring of Mr. E. S. Grigson, presently of Colombo, and you will see what an elaborate and costly mode of preparation it involves:—

First place a layer 18 inches thick of fresh weeds, grasses, leaves and succulent branches and any kind of green vegetable matter, on that a layer of cattle manure not less than 6 inches thick. Pour over the heap a "Pickle" composed of two (pounds?) of bone dust, one of ashes and a quart of lime previously prepared and thrown into a "Ferment" composed of molasses and water in certain proportions and well mixed with a large quantity of water and lime. Repeat the process till the required quantity of manure wanted be made. After a week make funnel-shaped holes one foot apart through the heap and to within 18 inches of the bottom, and pour into them "Pickle No. 2" composed of sal ammoniac, common salt, some "Ferment" and water mixed with some saltpetre or fresh cattle manure (of course all these are in fixed proportions). The next day make similar holes between those previously made and to within 3 feet of the bottom and pour in "Pickle No. 2." The next day make holes (where is not stated) to within 5 ft. of the bottom and pour in some more "Pickle." Cover with manure or soil, and in 10 days the compost will be fit for use. There! Can the one expensively and elaborately made compost with its "Pickles," and "Ferments" be compared with the other whose composition and manufacture is simplicity itself? No wonder your informant said it did not pay; but Mr. Grigson bears different testimony. He says he manured 30 acres of coffee with this compost at the rate of half a basket of it and 1 lb. of castor cake to a tree. The coffee was 25 years old and growing on very poor soil and much shaken by repeated attacks of leaf disease. The result was 9 cwt. per acre! I will not comment on this, except to say the cost of the application would have been very interesting. B.

"SALT" AS AN ARTICLE OF MANURE FOR FERTILISATION.

It seems to me that the value of "Salt" for agricultural purposes is much underrated, and those who have opportunities of employing it for manure in fields and gardens care not to undergo the trouble (certainly not expense) of putting it into the ground or applying it in a proper and sensible manner.

Of course "opinions vary" and cultivators who are clever in "generalities" and neglectful in "particulars" pay little heed to the improvement or manuring of their fields and gardens: so time flies on, and a deaf ear is turned to the teachings of Science.

I will now tell you what I have observed in my goings to and fro. Let those who read

judge for themselves whether my writing is of any use.

Not long ago walking round the edge of a paddy-field, I came to a channel cut from the river into it about 20 yards or so long, to allow of a boat being dragged to the head of it for safety. The field was then in the tender ear, and I noticed that wherever the wash of salt lake water entered the field, the stalks were higher and more vigorous, and the heads heavier and fuller.

Before this, too, I remarked that in fields which had been partially submerged, or damped with the salt water, the results were equally striking! This I noticed and took heed of.

On a large coconut estate, where the proprietor, a friend of mine, was putting in "supplies" to fill up vacancies in the holes on hard ground on one part of the estate, he put in handfuls of salt to keep away the white ants. I here noticed that not only did the salt effectually keep the white ants away, but that every plant to which salt had been applied was abnormally and remarkably vigorous, shewing the strong curl and dark green tint of a superior plant.

On many of our lake shores, those coconut palms whose roots are laved by the salt water, shew splendidly green, are remarkably vigorous, are thicker in stem, and bear *heavier by far* than those high out of reach of the water! and very seldom are they subject to attacks of the blighting and devastating *white worm and fly*, though they never "smell smoke" from one year's end to another.

And therefore I assert, that salt in certain quantities is highly beneficial in agriculture.

R. AHERTON.

GRAFTING MANGO PLANTS IN JAFFNA.

With reference to the interesting Indian Notes contributed by "W. A. D. S." to the last (August) number of your very useful Magazine, I must state that grafting mango plants is very common in my native place, Jaffna. I believe it was introduced by Mr. Dyke a late (the first?) Government Agent, who was well known as an expert horticulturist. The present energetic Government Agent, Mr. Twynam, now continues this practice of grafting; and many mango plants grafted with scions of the "Colombán,"* "Chempáddán," "Mánipayán," "Bombayán" variety are sold annually to the Jaffna gardeners at a nominal rate. It is well known that generally the half-educated natives esteem anything higher when they pay a price for it than when it is given them gratis, whatever the intrinsic value of the article may be; hence the policy of selling the grafted plant for a nominal price which is only too gladly paid by the Jaffnese for the valuable *Ottumankandu*. The fact that it was bought at the Kachecheri is always mentioned as a guarantee of the good quality of a mango tree; and it must be acknowledged that the excellent varieties of mangoes common all over the Jaffna Peninsula can mostly be traced to the grafting done at the Jaffna Kachecheri.

* Is it not curious that for some mysterious reason the very kind that is called *Japana Amba* or "Jaffna mango" in Colombo is termed *Colombán* or "Colombo mango" in Jaffna?—E. T. H.

The method adopted in Jaffna for grafting is by 'approach'; and is carried on pretty much the same way as described by "W. A. D. S."; but with the difference that instead of pots for growing the 'stock,' it is found more convenient to use the strong big Jaffna baskets which are manufactured out of the palmyra leaf or 'ola' and strips of the fibrous bast (nár) of the 'ola' stalks. There is also this difference, that instead of the primitive Bombay method of wrapping or covering the outside of the stock and graft about the point of union, with strips of plantain sheath, before they are tied together, we employ a kind of waterproof yellow wax-cloth, specimens of which may be commonly found in post offices where they use it for enclosing tappal bags, &c.

'Inarching' or 'Grafting by Approach' is generally the surest kind of grafting, though indeed it is a little more troublesome than other methods. Some of the principal points to be attended to in inarching are mentioned by Loudon, as follows:—

"1. To have the stock and the scion of the same thickness."

"2. To make the cuts exactly correspond, so that they might fit closely together without leaving the slightest vacuity between them.

"3. To unite the stock and scion as closely as possible, and particularly to take care that the liber of the one is exactly joined to the liber of the other.

"4. To preserve the wounds from any access of air, moisture or other extraneous matter by applying grafting-clay or grafting-wax about the point of union."

The practice of nipping off the flower buds for the first few seasons is also adopted by the Jaffna cultivators. This is done with the object of preventing a too rapid or undue demand upon the stock before the plant is fully developed, and the union between graft and stock perfectly established.

GRAFTING MANGOES.

(To the Editor, "The Magazine of the Colombo School of Agriculture.")

SIR,—The contribution of "W. A. D. S." from Bombay, on the subject of mangoes reminds me of another contribution on the same subject from the same place which appeared in the pages of the *Morning Star* some months ago. Both the correspondents speak highly of Bombay mangoes and the high price they fetch in the local market. It is said that grafting is being practised there on a large scale, and that the fruits are so many and fine that one soon forgets the existence of mangoes in Ceylon.

The process of grafting explained by "W. S." as carried on there is also practised in many parts of Jaffna. This is, no doubt, due to the great attention paid to fruit culture in the Jaffna Kachecheri premises by Government Agents from the time of Mr. Dyke to the present time. Though this useful method of improving the quality of mangoes originated in Jaffna, it slowly spread far and wide into the villages.

The appreciation of the process of grafting became stronger, when the Government Agent sent

men experienced in grafting to villages to find out trees known to bear fruits of superior quality, and to graft branches of such trees to plants grown for the purpose. At the time the plants are removed, the owner of the tree is generally allowed to have one or two of such grafted ones, which he plants in his garden and finds it a novel and a rare gift. This is how the quality of mangoes has been improved, and no doubt the name Jaffna mangoes so common in Colombo for good mangoes of which I made mention in one of my previous communications, owes its existence to the efforts of the Government Agents of the Province.

One peculiarity in the fruits of the grafted mangoes is that the fruits contain a certain kind of black insect within their seed, without any trace of them outside. How this big insect made its way, into the fruit, without materially injuring the same is a matter perplexing to the ordinary mind, though it is a never-failing proof of good mangoes.

It would seem impracticable to propagate grafted mango trees by means of seeds thus ravaged by the insect. It is therefore imperative on those who wish to have good mangoes in their fruit gardens to practise grafting on a large scale, as grafting serves (1) to maintain the excellence of mangoes, (2) to produce varieties of fruits that did not exist before; and by art help to perfect nature.—Yours truly,
R. C. MUTTAH.

GENERAL ITEMS.

The Government Agent, Sabaragamuwa Province, who employs three Agricultural Instructors and wishes for another, says in his Administration Report:—"The work done by each agricultural instructor is of benefit in and out of school. He teaches new methods of cultivation and introduces new products and vegetables to the notice of villagers, of which they would otherwise be ignorant, while he interests and instructs the elder boys in each school, to which he is attached in the theory as well as the practice of cultivation. It is too soon yet to see any results, but I think the system should be carefully cherished and encouraged. If a travelling inspector were attached to the Department for supervision of this branch, I think it would be advantageous." We have before urged the importance of inspection of the work of the Agricultural Instructors, and without such supervision the system of working through Agricultural Instructors must remain very faulty.

The same official urges "the establishment of an Agricultural Board, having for its object the extension and improvement of cultivation throughout the Island by (1) the education and payment of qualified agricultural instructors; (2) the purchase and loan of improved agricultural implements; (3) advances to cultivators in bad seasons; (4) improvement in the breeding of cattle, especially buffaloes; (5) extension of garden cultivation; (6) distribution of seeds and introduction of new products; (7) holding of local shows and bestowal of prizes. On this subject too we have often written before, and some of the daily papers have expressed them-

selves in favour of an Agricultural Board without which the control of agricultural affairs in the colony must remain very unsatisfactory. On such a Board should also sit, in addition to those whose names have been frequently mentioned in this connection, such philanthropic and liberal officials as Messrs. Wace, Ievers and H. P. Baumgartner.

The "Marsh lectures" have not been in need of helpers for the first series, which having begun under happy auspices is progressing very satisfactorily. The general public have not however been awakened into any very great interest in the instructive subjects of the course, nor, would it seem that the managers of most of the educational institutions in Colombo encourage the scholars to supplement their unproductive (of *practical* good) and surfeiting diet of Cambridge local mathematics and classics with healthy and useful knowledge.

Among the foreign manufactures that are carried on in Japan are cotton and woolen goods, silk, and glass. There are no less than 38 cotton mills. The glass articles manufactured are chiefly bottles for beer and wine and table glass of cheap quality: a small quantity is exported to China and Hongkong, but the greater part of the production is for home use.

Dacca cheese is familiar to all who have resided in North India. These cheeses as seen in Calcutta resemble a fat pancake, and are generally 5 or 6 inches in diameter. They are soft in consistency, and though rather milky to the taste, and of a smoky flavour, are much appreciated in North India. Dacca cheeses are imported to Burmah and even the Straits Settlements. From Juanshahi alone the annual produce is estimated at 501 maunds. If there be a sale for such cheeses in Ceylon, there should be no difficulty about making them.

Messrs. Ide and Christy, reporting on a small sample of fibre from *Sansiviera Zeylanica* (Sin. Niyanda) sent from Somali land, say:—"This is an excellent fibre of fair length and with plenty of "life." In character it strongly resembles the best sisal hemp with which we should have classed it, but from your (the Kew authorities) statement that it is derived from a *Sansiviera*. With the exception of its colour, its preparation is perfect, and even as it is, we value it today at £50 per ton. We are of opinion that if care were taken to improve the colour a considerably higher price would be readily obtainable, perhaps as much as £50 per ton, if a pure white fibre could be obtained without loss of strength and lustre.

Machinery has now been perfected in America for making bagging from cotton stalks. Expert cotton men say that the bagging is in every way equal to jute bagging, though a shade darker, and less inflammable. The machinery comprises heavy corrugated rollers, with vats of running water, carding machines, and bagging looms. It is estimated that by making bagging of cotton stalks two million dollars annually will go into the pockets of farmers for what is not cleared from the fields at our expenses.

[No. 5.

TECHNICAL EDUCATION—ITS AIMS AND METHODS.

(Continued from page 30.)

In most Continental countries there exist, in addition to the Elementary Schools, *Evening Continuation Classes*, to carry forward the education of the *children* of the working classes leaving school at or under 14, as well as to supplement workshop training. Nothing of the kind exist in Great Britain. On the other hand the evening classes for *workmen* in Science, Art and Technology, as organized by the Science and Art Department and the City and Guilds of London Institutes, are far superior to anything of the kind abroad, according to the Report of the Commissioners of Technical Instruction. These classes, first formed in connection with the various Mechanic's Institutes in every large manufacturing town, were placed under the Science and Art Department in 1856, soon after the First Industrial Exhibition, when the sum voted by Parliament for all expenses was £64,675. In 1890-91 the allowance was no less than £474,896, the amount expended on Schools of Science and Art alone being £186,864, chiefly devoted to grants to teachers on the results of the examinations of their pupils, to prizes, scholarships, building of laboratories, and maintenance of normal schools. Examinations are held in 25 subjects. The number of Science students in 1889 was 131,313, of Art students 88,969. The subjects are those bearing directly upon the industries of the country. The course of instruction for the 1st year comprises Mathematics, Frechand Drawing, Mechanics, Physics, and Physiography; 2nd year; Inorganic Chemistry, Physics,

Magnetism and Electricity or Physiography, Practical Geometry and Mathematics; 3rd year: Specialization of studies either Physics, Chemistry and Metallurgy; or Mechanics, Machine Construction and Drawing; or Mechanics, Building Construction and Drawing; or Physiography, Geology, Mineralogy and Mining. The examination consists of three stages: Elementary, Advanced and Honours, payment being made at the rate of £2 per pupil for a 1st class pass, and £1 for a 2nd class, in Elementary and Advanced subjects, with £4 for 1st class, and £2 for 2nd class in honours.

Another and perhaps even more important class of Technical Schools in connection with the Science and Art Department is that devoted to *Art Training*, and generally known as "*Schools of Design*." These schools teach Drawing, Modelling, Decorative Art and Design. The centre of Art Instruction is in South Kensington, and while every form of the Fine Arts is encouraged, the teaching is directed chiefly to train trade designers for the textile fabrics, for metal work, porcelain painting, wood engraving, &c. The grants made by the Science and Art Department are similar to those for Science teaching and vary from 10s. to £3 per pupil, while facilities of all kinds are offered to teachers in training, including free instruction in the National Art Schools and weekly stipends of £1 to £2 during the period of their study.

While the teaching of Science and Art is under the control of the Science and Art Department, that of Technology, or the branch of knowledge which deals with the various Industrial Arts, and explains the different processes and operations in the various trades, manufactories and workshops, has been taken in hand since 1879 by the City and Guilds of London Institute. The subjects taught in the Evening Classes are *connected with the trades*, but the *trades* themselves are *not taught*. Here for example are some of the subjects of instruction: the manufacture of Cotton, Paper, Silk, Steel, Pottery, Porcelain, Gas, Glass, Cloth, Alkali, Carriage-Building, Agriculture, Silk and Wool Dyeing, Calico-Bleaching, Telegraphy, Blow-pipe Analysis, &c. Each student is free to select the classes which will help him to make progress in his particular trade or business. The fees for the separate evening classes at the Technical College, Finsbury, vary from 15s. to 16s. for the session of about 8 months, apprentices under 20 being admitted at half fees. These evening classes at this Institution, which I visited in

the company of Sir Samuel Grenier, are attended by about 1,000 students from 14 to 40 years of age, the great majority of them being employed during the day in workshop or factory, while about 800 are apprentices. On account of the special character of the teaching offered in these Technological classes, necessitating the appointment of teachers well grounded in Science as well as practically acquainted with the details of the particular trade operations taught in each class, there was much difficulty experienced, I understood, in successfully conducting all the various classes, especially in some of the provincial schools. It is not every Science teacher, however well acquainted with the principles and practice of his Science who can be found to undergo a prolonged apprenticeship to any trade to teach the details of that trade to intelligent and skilled workmen who have already served their apprenticeship. On the other hand it is not every skilled workman who has also gone through the necessary Science training who has the gift of teaching, and yet it is such a triple qualification in Science and Art and special education in teaching that is needed for the conduct of a technological class. All the teachers of the Trade classes at Finsbury are men who have *worked* at their industry as *foremen*.

In addition to the Evening classes for workmen, there are *day classes* in connection with the Finsbury Technical College for pupils who are able to devote from one to three years to systematic technical instruction, either to fit them to fill important posts in industrial works, or to enter upon the advanced scientific and technical course of the Central Institution, London, or similar institutions elsewhere.

Of *superior* Technical Institutes combining the faculties of a University with those of a technical school corresponding to the Federal Polytechnic of Zurich, or the Polytechnic Schools of Germany, Austria and Italy, there are but few in the United Kingdom. Owen's College, Manchester, is said to be an institution of this character, and so also University College and King's College, London, but I confess I fail to detect the resemblance. The German Polytechnic is "coordinate with the University"—it is a University in itself. Here for instance is a diagram which will give you not only a fair idea of the scope and functions of a German Polytechnic, but also a general view of the subordination of the various schools in a German State. (It is taken from one of Sir Philip Magnus's works on Technical Education to which I am largely indebted for many of the facts I have put before you to day.)

In Munich, where early education is compulsory and gratuitous, as it is all over Germany, the population in 1885 and 1886 was 262,000, the average attendance of children 28,000, or 1 in 9 of the entire population. The Elementary School age is between 6 and 13, the cost of education is borne by the State and amounts to £640,000 a year. Children leaving the primary school at 13 pursue their studies in an Evening Continuation School from 3 to 5 years, where they learn in addition to elementary subjects Industrial Drawing, Bookkeeping, Elementary Science. Those intended for higher education leave school at 10 to pass into the Real Schule, where the

course of instruction comprises German, at least one other modern language, Science (Natural History, Physics, Chemistry), Mathematics, Geography, History, Drawing. They leave at the age of 14 or 16. They may now either enter the Technical College (*Industrie-Schule*), where the education of each student costs the State about £30 a year. Here the education is practical, and intended to fit them to enter directly upon commercial or industrial work. The school course lasts 2 years. There are four divisions according as the student is intended for engineering, chemical, building, or commercial work. The rooms are replete with models, and besides an art studio, a laboratory, a museum &c. which are indispensable features of such institutions, arrangements exist for workshop instruction on an advanced scale.

Children who intend to receive a higher secondary education leave at 9 and enter a first grade classical school, either the Humanistic Gymnasium with Greek or the Real Gymnasium without Greek. The study of Greek is commenced at 12.

From these schools the pupils pass on to the University or the Polytechnic High School. The latter, to which I shall confine my attention, is a University in every sense of the term, and consists of six special schools, the General School for the training of teachers, the civil engineering, the architectural, the mechanical engineering, the chemical and the agricultural. There are no less than 196 different courses of lecturers mentioned in the programme, and these are assigned to 36 professors and 34 teachers, besides assistants.

I regret that the limits of my time will not permit me to refer to the distinctive features of the methods of technical instruction pursued in France and in the United States, several of which are unique in many respects—*e.g.*, the *Model School* of Monge, in France, which though not a pure Technical School embraces technical instruction, but is peculiar in discarding *books, prizes, punishments, and home work*; the *Trade schools*, like that of the Rue Tourne Fort, in Paris, where in addition to the usual primary instruction, children of 6 to 10 have 3 hours' lessons in manual work, and boys of 10 and 11 are taught drawing, modelling, carving, joinerwork, smith's and fitter's work, whilst in their 12th year the instruction is specialised, each pupil taking to some special trade; the *Technical School for girls* started by Mme. Elisa Lemmonier in 1852, and afterwards taken under the protection of a Ladies' Society (*La Société pour l'enseignement professionnel des femmes*) with the object of giving a free general education and teaching some lucrative trade: dressmaking, wood engraving, porcelain painting &c., and last but not least the *Manual Training Schools* of the United States, the successful development of which has elicited the admiration of the best technical authorities in Europe.

I have thus endeavoured to give you (very briefly and very imperfectly I fear), a bird's-eye view of the chief methods for providing technical education in some of the chief industrial centres in Europe.

And now I come to the practical and local application of this problem of Technical Education

which we have hitherto considered in its general and foreign aspect. What is the form of Technical Education which will but suit our local requirements having due regard to the character of the people, our available teaching resources, and our industrial needs? Notwithstanding the careful attention I have given this subject for a long time, I confess I approach it with considerable hesitation and diffidence. I am aware that my views, whatever they may be, will fail to give satisfaction to some one or other section of the public who are interested in the solution of this question. I can anticipate the charges which local critics will fulminate against my opinions, however carefully matured, as those of an "amateur theorist," a "visionary doctrinaire," a "dilettante educationalist" emerging from his study with a confused solution of ideas picked up from musty books to blow soap bubbles with for his own gratification, &c., &c. That ancient hackneyed quotation *ne sutor ultra crepidam* will once again be furbished up on my account, and I shall be advised to stick to my proper sphere and not meddle with matters beyond my ken. Before a problem of such magnitude, in the solution of which even our local authorities thoroughly acquainted with our educational needs, and practical men like Messrs. Mitchell, Wall, &c. quite conversant with the subject in all its aspects, are slow to take the initiative, prudence and discretion at least should counsel either a judicious silence or at most a noncommittal policy. But it has been my misfortune all my life long not to listen to the dictates of prudence or discretion where a sense of duty, (however mistaken), has urged me to independent action. I have never forgotten a piece of advice I came across in my student life given by Sir Astley Cooper to a medical student: "Look for yourself. Never mind what other people may say. No opinion or theories can interfere with information acquired from actual observation," and I have always tried to act up to it.

That the problem of Technical Education in reference to our local needs is a complicated and difficult one admits of no question. Even in Europe where this system of education has been on its trial for fully half a century, where all possible conditions for successful experimentation exist—unlimited national resources, and liberal State support, and munificent private benefactions, and teaching agencies and instruments innumerable, and the right class of teachers to teach pupils who appreciate the dignity of labor, and are not ashamed to handle the spade or the plough whatever their social position—there is hardly a single system of technical instruction which has received unqualified approval from all authorities, while there are numerous educational questions of the highest importance in which they are constantly found to disagree. How much more difficult must this problem be in an infant colony where technical teaching is to be introduced as an experiment for the first time, not in response to an urgent demand from the people, but in the interests of a policy, wise and far seeing it may be, (I do not say it is not,) which endeavours to forecast the future needs of the community rather than to meet its immediate pressing requirements,

where the people themselves of feeble physique, conservative in their habits and ways of thinking, despising physical labour, swayed by caste prejudices, and influenced by false ideas of gentility which the tendency of the present system of education only tends to foster, where the resources available for experiment with any new system of education as regards funds, teachers, appliances &c. are necessarily limited, and where few of the conditions exist which urgently demand a technical training, or which could provide suitable employment for those willing to undergo such training! Everywhere else educational progress has followed in the wake of social and industrial changes, but reacting in its turn and leading to further social improvements ultimately, but here in Ceylon we are for ever borrowing western ideas and western instructions, admirable enough perhaps among a highly-civilized people trained to political freedom and habits of independence and self-reliance, and foisting them on to a country and a people existing under totally different conditions without even a thought or a question as to their fitness or unfitness to the people on whom the experiment is to be tried. True educational progress is *growth* and development from a living stock—not that artificial caricature which results from the transplantation and forcible introduction of a branch from an exotic plant. Any educational reform, it has been well remarked, which does not fit into and grow out of an existing system is not a practicable or even a desirable reform. I admit however that in a country like ours, where all the thinking for the people is done not by the people themselves but by the constituted authorities, it is not the *present requirements* only but the *future needs* of the country which the Government have to provide for. I would go further and even contend for the Socialistic view that it is the duty of the State to provide for a man's *needs* while he himself provides for his *wants*, the distinction being between *wants* as necessities which a man recognises for himself, as food and clothing, and *needs* necessities not recognised by the individual, but which in the interests of the community are necessary to his life, such as education. &c. And certainly as regards any special kind of education, if it be urgently needed, if there be a great and earnest cry for it, the people themselves in a colony like ours cannot in the present state of things be expected to provide that education for themselves, it would even be the duty of the Government to foresee and provide for such education against a demand for it which is likely to arise in the near future. But it would be of no use to devote time and money to provide schools and classes for pupils who when trained may find their education of no earthly use to them, no market for their special wares, no employment to provide them with means of livelihood. Nor would it be of any use to embark in any expensive school of education which is unsuited to the character or the habits of the people, which they have no willingness to receive, or which they may even obstinately reject.

So that the first question to be considered in studying such a problem as this is what is

the need for Technical Education just at this stage? How is it shown? And then only having proved that it is necessary or even desirable should the next question be considered, how, when, to whom and by whom should Technical Education be given?

We have already seen that in England and America the necessity for technical instruction arose from four causes chiefly: (1) the introduction of machinery to supplant hand labour; (2) the abolition of the old system of apprenticeship; (3) the demand for trained heads and skilled hands in factories and workshops to keep pace with the constantly changing conditions of production and distribution, and to protect national interests against foreign competition; (4) the recognition of the necessity for scientific instruction of a practical character for the highest classes of workmen. But here in Ceylon which is fully quarter of a century at least behind the rest of the world, where is the pressure from altered conditions of labor, where are the factories which need the trained intelligence and superior skill of scientific workmen *trained in a technical school*, where the apprentices, the artisans, the workmen, the foremen who are likely to join a technical class? Only the other day we read in a local paper how a Ceylonese lad who had gone through a thorough practical training as a fitter, and with good testimonials applied in succession to each of the four factories here (the only four which exist at present) which were likely to need the services of a fitter, only to be informed in each instance that his services were not required. I can quite understand it. Each of these factories trains up just as many hands as it needs for subordinate work and indents for foremen and managers from Europe. Can any Technical School or workshop give the same training as that which the apprentice lads now receive in the Government Factory or Railway Yard? Will the Government or the private firms who conduct the two principal manufacturing establishments here cease to engage men not for the highest posts only, but even for the subordinate offices in these factories once a Technical School is established here? Will the scientific departments of the Government—the Surveyor-General's Department, the Telegraph Department, the Public Works—employ the locally-trained pupils in preference to the men who are now got out from England? It is to be *hoped* so, for it is not at all likely there will be many vacancies for them in private engineering firms.

But perhaps it may be said that that is not the class of pupils for whom the Technical School is to be started—not Engineers and Foremen and Constructive Machinists whom the School will turn out, but a humbler class for the lower grades of industrial work. Be it so; but if so let that fact be fully understood, and it will give rise to no heart-burning and disappointment hereafter. But there arises the question why, if that be the only object of a Technical School, should the Government interfere with the existing arrangements in the Government Factory and the Railway Yard. No workshop training in a Technical School could give the pupils the same opportunities for acquiring the knowledge and skill and dexterity to be derived from the special training which obtains

in these establishments at present under the stimulus and pressure of work which has to be completed in limited periods of time.

Again, it has been suggested that the Technical School may do good and useful work in improving and developing the trades, like the Industrial Schools in Kandy and Haputale and at Wellawatte.

Perhaps so. On this point I would rather not venture an opinion. It should be remembered, however, that the only Schools of the kind which exist in Europe, known as Trade Schools, or Apprenticeship Schools, arose from the failure of the old apprenticeship system, while here it continues in full force to this day, nurtured by the caste systems which prevail, and the tendency to recognise craftsmanship as an hereditary talent. Besides, the same deep-rooted caste prejudices which exist among the Sinhalese and Tamils, and the foolish ideas which prevail among certain classes of the Burgher community about "genteel" and "low" employments, doomed as they are to disappear under more enlightened views from the extension of education among the masses, have yet to be taken into account in any experiment made in this direction. It should be remembered also that in England trade is never taught in any Technical School, because it has been found by experience that the instruction given in a school workshop under the best circumstances can never compete with the training given in an actual trade workshop. Three elements, it has been well said, enter into the formation of Manual Skill—Speed, Order and Accuracy. Now, in no school workshop, where the stimulus of pressure, for production to keep pace with the demand, is wanting, can excellence of workmanship combined with rapidity of execution be expected, nor those habits of order and accuracy in the practice of trade where economy of time and division of labor are essential conditions. Again, as far as practical knowledge and skill go, and even beauty of workmanship, I believe our carpenters and masons, our jewellers and cabinet-makers, our basket-weavers and lace-manufacturers can hold their own with any foreign workmen. Their chief defects arise from the imperfection of the tools and materials which they use, from too slavish an adherence to the traditions of their art, from ignorance of the scientific principles which underlie the operations of their craft, from inability to adapt themselves readily to the constantly changing demands of fashion, and generally a want of inventive genius and artistic taste. In all these respects a Technical School may be able to introduce great improvements, provided the right sort of teachers could be procured and the right class of pupils.

Again, the establishment of an Art School has been proposed as a possible solution of the difficulty. There is no doubt that in a short time more when Drawing is made an obligatory subject here, as it should be, and as it is according to the Revised Code in England, Drawing masters will be required to a very great extent, far beyond what local talent could supply at the present time. And the Technical School will be fulfilling a very useful function if it could only facilitate in this way the training of Art teachers for the Elementary Schools. Mr. Leland, the great American educational reformer, whose success in the management of Infant Manual Training Schools has been almost phenomenal, has

given it as his opinion derived from special experience that "every child not an idiot can learn to draw when properly taught."* And the importance of universal instruction in drawing which Mr. Wall so well characterised as the language of Science, and it may be added of Art as well, is a matter which admits of no argument. There is scarcely a trade in which a knowledge of drawing is not useful. And apart from the pleasure to be derived from the cultivation of an æsthetic taste and the habits of accurate observation and careful study of Nature learnt by the art student, Art knowledge has a distinct commercial value both to the individual and to the community to which he belongs. The cheapest material is rendered valuable, and even the precious metals, made more valuable in the hands of a genuine artist. To encourage Art and art productions by disseminating art teaching all over the country would therefore be a wise policy on the part of the Government, and fortunately in this respect at least no difficulty can arise from the want of superior teachers. It is only to be hoped that Art teaching under western influences may not wholly obliterate and sweep away the characteristic artistic taste of the nation as evidenced especially in Jaffna Jewellery work, in brass chasing and embossing, in the inlaying in ivory, in wood carving &c., which have a character and beauty all their own, and which remain to us as the only living evidence we possess, and that is worth preserving of the genius of an ancient and extinct civilisation. Mere Science teaching again, however important a place it should occupy in a general scheme of education, would be of no value in a Technical School whose essential character is that its instruction is of a practical character,—the application of scientific principles to the arts. But such application must be preceded by instruction in the principles of Science whether included in the curriculum of a Technical School, or provided for in a previous course. And it is in this direction I think that a Technical School will prove of most value, and I am glad to find that Mr. Wall entertains much the same opinion. The natural resources of our country are almost boundless, and except in the case of one or two of our mineral productions, and a few, very few of our vegetable products, may be said to be almost unexplored. Glance down the list of our exports, and with the exception of Plumbago and Precious stones, which represent our Mineral products and Cinnamon, Coconuts (and the articles derived from the latter, Oil, Yarn, Copperah, Arrack), Madder and Sapanwood, Pepper and Arecanuts, Cardamoms from our indigenous plants, there is hardly anything else which finds a place there, save the cultivated plants introduced from other countries:—Tea and Coffee and Cinchona and Tobacco and Sugar. Now, whatever the extent of our mineral resources may be, and only a competent mineralogist can tell us whether they are limited to our two chief articles of export, the vegetable products which have been hitherto discovered and utilised are trivial compared with the inexhaustible wealth which Nature has bountifully provided for our use. The plants which

are useful as sources of food and clothing and building material and furniture, which furnish medicine, and oils, and gums, and resins, and fibres, and dyes, and perfumes, are innumerable, and only await careful scientific research and proper technical manipulation to yield an immense harvest. It is in the study of the economic uses of plants, in the application of chemical science to our natural products to determine their uses and commercial value, and the elaboration and invention of means by which their most valuable ingredients can be extracted, (all processes comprised under the term technology), that I think the *widest and most important field lies for technical education, study and investigation*. In our Agricultural School, so successfully and admirably managed by its present Principal, there should be no difficulty found to create a Technological Department with Museum, Laboratory, Teaching Appliances and proper staff of Teachers to aid in developed the natural resources of the country. Agriculture properly speaking is a *Technological Science*, so that it would be quite in keeping with its present place in a scientific system of Education to add Technological Instruction to the other and manifold branches of Science which are being taught there.
