

COMMENCED IN 1881.

"Step after step the ladder is ascended."—George Herbert, *Jacula Prudentum.*

THE TROPICAL AGRICULTURIST

A Monthly Record of Information for Planters

OF

TEA, CACAO, COFFEE, CINCHONA, SUGAR, COTTON, TOBACCO,
PALMS, SPICES, RUBBER, RICE,

AND OTHER PRODUCTS SUITED FOR CULTIVATION IN THE TROPICS.

J. FERGUSON,

of the "Ceylon Observer," &c.

"It is both the duty and interest of every owner and cultivator of the soil to study the best means of rendering that soil subservient to his own and the general wants of the community; and he who introduces, beneficially, a new and useful *Seed, Plant, or Shrub* into his district, is a blessing and an honour to his country."—SIR J. SINCLAIR.

THE JOURNAL OF THE

AGRICULTURAL CHEMICAL SOCIETY

◁ TO OUR READERS ▷

In closing the Thirteenth Volume of the "**Tropical Agriculturist**," we would once more direct attention to the large amount of useful information afforded and to the great variety of topics treated in the several numbers. From month to month, we have endeavoured to embody in these pages the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make our periodical not only indispensable to the planter, but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, beside being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have always taken care to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of common sense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

Special attention has, during the past year, been given to the extension of the planting enterprise in coffee, cacao and rubber in Mexico, Central and some parts of South America; to the wide field for coffee and other products in British Central, and by and by in British East, Africa; to new developments in coffee in the Malayan Peninsula, North Borneo, Sumatra and Java, in which last Dutch Dependency several Ceylon planters have been investing largely.

The Tea-planting Industry has sprung into so much importance in India and Ceylon that a considerable amount of space is naturally given to this great staple, and we think it will be admitted by impartial judges that the *Tropical Agriculturist* should be filed, for ready reference, in every Tea Factory in this Island and India,

"The Manual of Chemical Analyses" prepared by Mr. M. Cochran specially for the benefit of planters, and which was begun in January 1893, cannot fail to instruct all who give it a careful perusal.

The present volume is enlivened by the Collotype Portraits and interesting Biographical Notices of a number of the Pioneers connected with the development of the Planting Enterprise in this island, the whole forming an instructive chapter in the history of the Colony.

A full and accurate Index affords the means of ready reference to every subject treated in this, the thirteenth volume, which we now place in our subscribers' hands, in full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

We are convinced that no more suitable or useful gift can be made to the tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the thirteen volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industry.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval; for then, indeed, must the "**Tropical Agriculturist**" continue to do well.

J. FERGUSON,

COLOMBO, CEYLON: 1ST JULY 1894.

☞ All Planters of New Products or Pioneers in new lands should not fail to order this periodical as their best instructor.—Every Tea Factory ought to have a file of the TROPICAL AGRICULTURIST, which contains a vast amount of information about Tea, and a Record of the Tea and other Produce Sales.

ORDER FOR THE "TROPICAL AGRICULTURIST."

.....1894.

Sirs,

Please forward the above publication from the beginning of Vol. XIV. 1st July 1894.

Please send also (lettered as for..... Estate)

Vols. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII.,
AND
OR XIII, for 1881-2, 1882-3, 1883-4, 1884-5, 1885-6,
1886-7, 1887-8, 1888-9, 1889-90, 1890-91, 1891-2,
1892-3, and 1893-4.

I am, Sirs,

Yours faithfully,

Messrs. A. M. & J. FERGUSON,

"Ceylon Observer" Office,

COLOMBO, CEYLON.

SUBSCRIBERS

TO THE

"TROPICAL AGRICULTURIST"

are reminded that with the June Number, already received by them, and the Index and Title-page now issued, the THIRTEENTH VOLUME (1893-94) is closed.

SUBSCRIPTIONS are due payable in advance for 1893-94, at the following rates:—

In Ceylon	{	Yearly	... R12		In Europe, &c.	{	Yearly	£1 6s.
or India	{	Half-yearly	... R8			{	Half-yearly	15s.

N.B.—Subscribers to the *Ceylon Observer* or *Overland Ceylon Observer* R4 (6s.) LESS per annum.

Single Copies, R1 ; back copies, R1½.

Price of each Volume, elegantly bound, to Non-Subscribers, R15.

Those who have not settled for past subscriptions are requested to do so by return of Post, and to send Cheque, Post Office Order, or Bank Draft, in favour of A. M. & J. FERGUSON, Colombo.

Covers for binding the Thirteenth Volume, July 1893 to June 1894 (860 pages) can be obtained for R1.50. Cost of binding and cover R2.50.

WHAT IS THOUGHT OF

THE "TROPICAL AGRICULTURIST."

A gentleman resident in the Central Province, who has as good opportunities of knowing what is of benefit to planters as anyone we know, sent us the following explicit testimony to the value of the "T.A." :—

"Since its commencement, I have regularly seen and perused the *Tropical Agriculturist*. There can be but one opinion that its scope and object are highly important, and that it supplies a distinct desideratum, which it is to the interest of every estate proprietor to have available in the bungalow for the use of his *locum tenens*, or superintendent. As a magazine it provides interesting and instructive fresh literature at intervals deprived, as most in Ceylon are, of easy access to libraries; and as years go by it will growingly become 'The Ceylon Encyclopædia' with reference to agricultural operations. Viewing estate property as practically a permanent investment to any proprietor, the trifling charge of R12 per annum—a rupee a month—is certainly of no account, provided the separate numbers are kept, and bound together yearly as a book of reference, for the benefit of the manager and his successors. In that light, as the property of an estate to be handed over just as much as its office furniture, few proprietors would probably refuse to authorize its being taken and filed regularly (if the periodical was brought under their notice), more especially as on looking over the most recent volume one cannot fail to see how much valuable information on 'Tea' has been collated. In the belief that 'Tea' will restore prosperity to Ceylon, and that plantation property is a good investment for capitalists, such should not omit the office and connected equipment so advisable on all 'pucka' estates, a part of which should be the *Tropical Agriculturist*. I find I have gone on writing, but as I am getting the numbers for the past year ready to be bound, the volume is before me."

THE VALUE OF THE "T. A." TO CEYLON ESTATE OWNERS.—A planting correspondent, wrote some time ago:—"I think proprietors should supply every tea estate with the *T. A.* The information in it with regard to everything in connection with tea, &c., is invaluable: it would pay its value over and over again. Owners of estates should not leave it to hard-np superintendents to take it in."

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XIII.]

COLOMBO, JULY 1ST, 1893.

[No. 1.

CEYLON MANUAL OF CHEMICAL ANALYSES.

A HANDBOOK OF ANALYSES CONNECTED WITH THE INDUSTRIES AND PUBLIC HEALTH OF CEYLON FOR PLANTERS, COMMERCIAL MEN, AGRICULTURAL STUDENTS, AND MEMBERS OF LOCAL BOARDS.

By M. COCHRAN, M.A., F.C.S.

(Continued from page 734.)
Indian Teas.

HE following, from the work of Dr. Battershall "Food Adulteration and its Detection" are the results of the analyses by American chemists of samples representing 2,414 packages of Indian

Tea:—

Analyses of Indian Teas by American Chemists.

	Per cent.	Average per cent.
Moisture	5.830 to 6.325	5.938
Extract	37.800 to 40.350	38.841
Total Ash	5.050 to 6.024	5.613
Ash soluble in Water...	3.122 to 4.280	3.516
Ash insoluble in Water	1.890 to 2.255	2.092
Ash insoluble in Acid...	.120 to .296	.177
Insoluble Leaf	47.120 to 55.870	51.910
Tannin	13.040 to 18.868	15.323
Theine	1.88 to 3.24	2.736

Theine in Tea.

Dr. B. H. Paul of London is of opinion that the older processes for estimating the theine in tea are all more or less defective, giving in most cases results that are too low. He has accordingly adopted a different process by which he has determined the amount of theine in a great many different samples of tea. He finds that the theine in Indian and Ceylon teas varies in amount from 3.22 to 4.66 per cent, or in the perfectly dry tea from 3.43 to 4.96 per cent. The following is a table of 28 determinations of teas from various elevations in Ceylon and India. The value of the teas varied from 7d. to 3s. per pound, while No. 10 was valued at from 6s. to 7s. per pound. A. J. Cownley was associated with Dr. Paul in these determinations, and the results were first published in the *Pharmaceutical Journal*.

Theine in Ceylon and Indian Teas.
(PAUL & COWNLEY.)

CEYLON TEA.	Approximate elevation of place of growth in feet.	Moisture per cent.	Theine per cent.

Tannin in Tea.

The amount of tannin in Indian and Ceylon teas has been made a special subject of investigation by Mr. David Hooper, F.C.S., F.I.C. The process he employed is that known as the acetate of lead process. His results were communicated in a paper to the *Chemical News*, 1890. Of prior determinations of tannin he says: "Mulder's determinations of tannin in teas are often quoted in text books; his figures for black tea are 12.88 and 17.80 per cent. Dragendorff found in teas of Russian commerce 9.42 to 12.70 per cent; Janke obtained a maximum of 9.14 and a minimum of 6.92 per cent in eighteen samples. Wigner analysing some astringent teas reported as much as 27.7 to 42.3 per cent. Hassall gives as the average 15.24 in black and 18.69 per cent in green teas; Clark found from 5 to 19 per cent; and Geisler, an American chemist obtained 14.87 as the average percentage of tannin in a large number of packages of Indian teas imported into New York."

Mr. Hooper enumerates 29 determinations of tannin in Nilgiri teas grown at elevations varying from 3,100 to 7,800 feet. The amount of tannin found varied from 10.14 per cent in Aratapara congou (3,400 feet elevation) to 24.37 in Green Mandarin broken pekoe (4,000 feet elevation).

In six samples of Travancore tea grown at elevations from 2,500 to 2,600 feet, the tannin varied from 17.37 per cent in Poonmudlie pekoe (2,600 feet elevation) to 21.22 per cent in Seafield broken pekoe (2,500 feet elevation).

Three samples of Coorg tea at an elevation of 4,000 feet yielded 15.15 to 16.93 per cent.

In Darjeeling tea, at an elevation of 3,000 feet, the range was from 13.61 in orange pekoe to 17.74 in broken pekoe.

In Assam tea, grown at an elevation of 600 feet, he found from 16.18 per cent in pekoe souchong, to 20.80 per cent in broken pekoe.

The following are the results Mr. Hooper obtained from 13 samples of Ceylon tea:—

Determinations of Tannin in Ceylon Teas.

(HOOPER.)

No.	Name of Estate.	Description of Tea.	Elevation Feet.	Tannin in 100 parts.
1	Glenorchy ...	Broken pekoe	5,700	19.00
2	Do ...	Pekoe	"	17.90

From his analyses Mr. Hooper draws the conclusions "that the finest teas are those that contain most tannin, that there is a gradual decrease of this principle as we approach the souchongs and congous, and that elevation does not appear to affect the amount of tannin as is commonly supposed."

Tea Prunings.

Tea bushes are pruned about once in eighteen months. The prunings may be buried, left lying on the ground or removed either to be added directly or after burning to the compost heap. In any case it is interesting to know the amount of fertilising matter contained in the prunings.

Estimation of Fertilising matter and Oxide of Manganese in Tea-prunings.

The following is an estimation of the amount of fertilising matter and of oxide of manganese in tea prunings based upon an analysis of the prunings of ten trees from Madulkelle Estate, Ceylon. The prunings were received made up into two parcels for separate analysis, one of which contained leaves, twigs and a few seeds, the other the stronger portions of the branches together with some twigs.

Analysis of Leaves, Twigs and Seeds.

When dried the parcel was found to contain 56.67 ounces of dry matter. The dry matter yielded 2.794 per cent of nitrogen and 6.02 per cent of ash. The ash had the following composition:—

Analysis of Ash of Tea prunings (Leaves, Twigs and Seeds).

Lime ...	15.61
Potash ...	22.13
Phosphoric acid ...	5.91
Red oxide of Manganese ...	2.91
Other constituents ...	53.44
	100.00

The total weight of each of the above ingredients in the 56.67 ounces of dry matter was therefore as follows:—

Nitrogen ..	1.583 ounces.
Lime533 "
Potash755 "
Phosphoric acid ..	.202 "
Red oxide of Manganese099 "
Other constituents of Ash ..	1.823 "
Total Ash ...	3.412 "

Analysis of Branches and Twigs.

When dried this parcel was found to contain 46.257 ounces of dry matter. The dry matter yielded 1.26 per cent of nitrogen and 2.05 per cent of ash. The ash had the following composition:—

Analysis of Ash of Tea prunings (Branches and Twigs).

Lime ...	20.300
Potash ...	25.600
Phosphoric acid ..	9.350
Red oxide of Manganese ...	2.420
Other constituents ...	42.330
	100.000

The total weight of each of the above ingredients in the 46.257 ounces of dry matter was therefore as follows:—

Nitrogen ..	.583 ounces.
Lime192 "
Potash243 "
Phosphoric acid089 "
Red oxide of Manganese023 "
Other constituents of ash401 "
Total ash... ..	.948 "

The following then gives in tabular form the amounts of the important ingredients of plant food contained in the prunings of ten tea trees and also in the prunings of tea per acre of 3,110 trees:—

Important constituents of plant food in the prunings of 10 and 3,110 tea trees respectively.

	10 Tea trees.			Per acre of 3,110 trees.
	Leaves, Seeds and Twigs.	Branches with some Twigs.	Total of 10 trees.	
	Ounces.	Ounces.	Ounces.	
Nitrogen ...	1·583	·583	2·166	42·10
Potash ...	·755	·243	·998	19·40
Phosphoric acid ...	·202	·089	·291	5·66
Lime ...	·533	·192	·725	14·09
	3·073	1·107	4·180	81·25

Calculation of the amount of fertilising material removed per annum from one acre of land by the tea crop.

A sample of Ceylon unassorted tea (August 1892) consisting of one-third high-grown from the Great Western Estate, 4,400 to 5,200 feet elevation, one-third grown at medium elevation 2,400 feet from Roseneath Estate, and one-third grown on a lowcountry Estate, Degalessa, was analysed by Mr. R. R. Tatlock F.R.S.E., F.I.C., F.C.S., City Analyst for Glasgow with the following result:—

Agricultural Analysis of a sample of Ceylon unassorted Tea from High, Medium and Low Elevations. (TATLOCK.)

	Ash Analysis	
	Per cent.	per cent.
Moisture ...	4·82	—
Nitrogen ...	4·38	—
Potash ...	2·27	42·04
Lime ...	·57	10·56
Phosphoric Acid ...	·76	14·08
Total Ash ...	5·40	—

If we take the crop of made tea at 400 lb. per acre per annum, we can with the above data readily calculate the amounts of the important constituents of plant food removed from the soil per acre per annum by the tea crop, thus:—

Nitrogen ...	4·38 per cent of 400 lb. = 19·52 lb.
Potash ...	2·27 ,, 400 lb. = 10·08 lb.
Phosphoric Acid	·76 ,, 400 lb. = 3·04 lb.
Lime ...	·57 ,, 400 lb. = 2·28 lb.

34·92 lb.

The total amount of the important constituents of plant food removed annually from the soil by the tea plant, supposing the prunings are all returned, amounts to rather less than 35 pounds. If the prunings are lost, the total amount of important constituents of plant food withdrawn from the soil per acre annually is calculated by adding to the loss by crop two-thirds of the fertilizing material in the prunings, as pruning only takes place about once in eighteen months. The loss thus calculated amounts to 47·59 lb. of nitrogen, 6·82 lb. of phosphoric acid and 23·02 lb. potash—total 77·43 lb. When the prunings are burned and the ashes only returned to the soil, the loss to the soil is all the nitrogen in both crop and prunings, i.e., 47·59 lb; but the phosphoric acid and potash in the crop only are lost, viz., 3·04 and 10·08 lb. respectively—total 47·59 lb.

Manuring of Tea.

The planter naturally looks to the Agricultural Chemist for useful suggestions on the subject of

manuring, and it is certainly greatly to be desired that a simple rule could be laid down for compounding a manure for any particular crop that would yield economically the best results. There are, however, a good deal of data wanting before it is possible to calculate with anything approaching scientific accuracy the composition of a manure that will, even on a given estate, be agriculturally sufficient, without some ingredient being in excess. We require to know the proportion of plant food supplied in the annual rainfall and the proportion lost by drainage as well as the composition of the soil. The amount of plant food lost in the soil removed by surface wash would also require to be known and allowed for. Supposing the weight of soil lost per acre were approximately determined, an ordinary analysis of such soil would give an idea of the loss of available plant food by this cause, e.g., if the analysis were to shew 2 per cent of nitrogen, 1 of phosphoric acid and 1 of potash, then the loss of important ingredients of plant food would be 4½ lbs. of nitrogen, 2½ lbs. of phosphoric acid and 2½ lbs. of potash, in all 9 lbs. of available plant food per ton of soil lost.

The amount of plant food removed from the soil by the tea crop, and also by tea prunings, when these are not returned to the soil, has been determined with all the requisite accuracy, and the results have been recorded in the foregoing pages. The analyses of manures will be given in very full detail in the Chapter dealing with Manures as a special subject. The necessary data for arriving at the approximate commercial value of manures will also be there given; meanwhile, I give in three tables what cannot fail to be useful data for manuring experiments with tea. With reference to these I shall first offer a few words of explanation. The amount of manure required to return to the soil exactly what has been removed by crop only, or by crop and prunings may be termed a theoretical dose, and in this connection we confine our calculations to the three most important ingredients of plant food—nitrogen, phosphoric acid and potash. From the agricultural analysis of Ceylon tea and of tea prunings already given, we therefore calculate the theoretical dose of nitrogen, phosphoric acid, and potash (in the case of crop only) as the weight of these three constituents contained in two years' plucking, or 800 lbs. of made tea; and, in the case of both crop and prunings, as the weight in 800 lbs. made tea plus that in 1½ times the amount of a single pruning, as this operation is conducted at intervals of about eighteen months, thus:—

Theoretical doses of Manure.

Plant food.	For tea crop	
	For tea crop only.	For tea crop & prunings.
	lb. per acre.	lb. per acre.
Nitrogen ...	39·04	95·17
Potash ...	20·16	46·03
Phosphoric Acid	6·08	13·63

The nitrogen table, therefore, gives the weights of manures in pounds per acre which contain 39·04 lbs. and 95·17 lbs. respectively of nitrogen.

The potash table gives the weights of manures in pounds per acre which contain 20·16 lbs. and 46·03 lbs. respectively of potash.

The phosphoric acid table gives the weights of manures in pounds per acre which contain 6·08 lbs. and 13·63 lbs. respectively of phosphoric acid.

NITROGEN TABLE.

This table gives the weights of various manures per acre which will return to the soil nitrogen equal to that removed by two years' plucking, viz., 39.04 lbs.; also to that removed by two years' plucking and pruning, viz., 95.17 lbs., together with the respective weights of phosphoric acid and potash which accompany the nitrogen in the manures.

Experience in manuring experiments generally, has not proved that the best results are obtained by returning plant food to the soil in exactly the proportions in which it is carried off in the crop, especially when manuring operations are delayed till the falling off in crops demonstrates the necessity for manure. It might possibly be otherwise if manuring were begun while estates were still in good heart before one or more of the constituents of plant food had been abnormally reduced. Not only do differences in the resources of the soil affect the question of manuring, but also different degrees of solubility, and therefore of availability of different kinds of plant food and even of different combinations of the same kind of plant food.

The tables given will, therefore, not supersede the necessity for field experiments; but they will nevertheless afford useful data to the planter, as they will enable him to see more precisely what he is doing in the way of manuring, and how he may compound equivalent mixtures of various manures so as (with the help of the valuation table *vide* Chapter on Manures) to take advantage of the cheapest and most suitable manures available in the market.

Although all the manures mentioned will be more fully treated of in a subsequent Chapter, it may be well to explain here with reference to Ceylon Cattle Manures No. 1 and No. 2 mentioned in the tables, that No. 1 was cattle manure from cattle fed upon coconut poonac and guinea grass, the bedding being mana grass,

while No. 2 was cattle manure from cattle fed upon guinea grass only, the bedding being mana grass. The former proved to be much the richer in phosphoric acid, while the latter had the advantage in respect of nitrogen and (being drier) had also rather more potash. The phosphoric acid in this manure, however, was so deficient compared with No. 1 as to suggest the advisability of supplementing cattle manure made from cattle fed upon grass only with phosphatic manure. In both samples of cattle manure the proportion of potash was about double as great as is represented by certain well-known analyses of farmyard manure.

I have said that experience of agricultural experiments has not proved that a manure consisting of one theoretical dose of nitrogen, phosphoric acid and potash respectively gives the best results, so that instead of starting a series of experiments in manuring tea with the strictly theoretical dose, it would be preferable relying upon the known efficacy of good cattle manure, to begin by expressing the composition of good cattle manure in terms of theoretical doses of nitrogen, phosphoric acid and potash, and to start with such as a standard of comparison for a series of experiments. Doubtless careful planters are already acquainted with the amount per acre of good cattle manure which yields satisfactory results, so in conducting experiments with commercial fertilisers it might be advisable to start with a mixture which contains the important elements of plant food in the same relative pro-

portions as good cattle manure. The three tables of theoretical doses will be found very helpful in compounding mixtures.

Thus, suppose we take Ceylon cattle manure No. 1 as representing, which it does, a good sample of cattle manure, we see that 8,754 lbs. contains 39.04 lbs. of nitrogen, 23 lbs. of phosphoric acid and 83.14 lbs. of potash, whereas the strictly theoretical doses would be 39.04, 6.08 and 20.16 respectively. It will be thus seen that 8,754 lbs. cattle manure No. 1 contains in round numbers one theoretical dose of nitrogen, 4 of phosphoric acid and 4 of potash calculated for the tea crop only, and that in like manner for the tea crop and prunings 21,339 lbs. contain approximately one theoretical dose of nitrogen, 4 of phosphoric acid and 4½ of potash. Although artificial mixtures compounded so as to preserve the same relative proportions of the three most important ingredients of plant-food as they are found in good cattle manure might form a good starting point for a series of field experiments, experience would in all probability demonstrate that those proportions will be modified with advantage in the direction of an increase of the phosphoric acid and a reduction of the potash.* The commercial salts of potash are all so soluble that when these are added in considerable quantity to the soil much is apt to be lost in the drainage water. Hence it is more economical if the plant can be stimulated to supply itself, for the most part, with potash from the soil supplemented by manures, which, like castor cake contain potash in a less readily soluble form.

* In the case of coffee, as will be noticed in the next Chapter, the ordinary experience of the planter in manuring, has led him to adopt proportions of manurial ingredients widely diverging from the theoretical quantities, thus ½ lb. of castor cake and ½ lb. of bone-dust per tree contain plant food for coffee in the proportions of one theoretical dose of nitrogen, 20 theoretical doses of phosphoric acid, and 2 of the theoretical dose of potash.

Examples of commercial fertilisers specially prepared for the tea crop will be given in the chapter devoted to Manures.

Leaves of the Grevillea Robusta.

As the tea plant is found to flourish best under a certain degree of shade, the tree called grevillea robusta, a native of Australia, has been largely planted on Ceylon tea estates. This tree serves the double purpose of breaking the force of the wind and of affording a suitable amount of shade for the tea plant. It is therefore interesting to ascertain how far this tree competes with the tea shrub for the plant food in the soil. With this object in view, two ten pound parcels of leaves were sent to the author for analysis; one parcel containing 10 lbs. green leaves, the other 10 lbs. of sun-dried old leaves.

It will be observed from the accompanying tables of agricultural analyses of grevillea leaves and the comparison of their composition with that of tea leaves, that, while the tea leaves are very rich in the more important constituents of plant food, viz., the nitrogen, potash and phosphoric acid, the grevillea leaves are correspondingly poor in these constituents and are very rich in the less valuable lime. The tea and grevillea trees are therefore examples of different trees well suited to grow together on the same soil. It will further be observed that there is a very considerable difference between the grevillea green and old leaves. The latter shew a smaller proportion of ash when calculated upon the dry matter of the leaf, and the ash is of inferior quality showing more especially a remarkable decrease in the lime and potash and a correspondingly large increase in the siliceous matter. Supposing these old leaves to have lain on the ground for some time, part of this difference might not be in the constitution of the leaf; but might be accounted for by mineral matter being dissolved out and a small addition of persistently adhering soil, as an amount of adhering soil which would add a very trifling percentage to the weight of the leaf would add a considerable percentage to the weight of the ash of the leaf.

In the chapter which treats of Cocoa will be found tables shewing the respective amounts of plant food removed from the soil by equal weights and also by average crops of tea, coffee and cocoa.

THE CLIMATE OF SELANGOR.—The following particulars regarding the climate of Selangor are of interest. They are taken from meteorological observations for 1892 by Dr. Travers, the Residency Surgeon. It is stated that the mean average temperature for the year was 80.6° F., being slightly lower than during 1891, when the average was 81° F. The highest reading of the barometer was 29.997 on 6th April and 6th December. The lowest reading was 29.628 on 5th October. The highest temperature in the shade recorded at Kuala Lumpur was 94° F. on 10th, 15th and 22nd March and 4th and 7th April. The lowest was 61° F. on 9th February, 5th and 6th March and 13th October. The greatest range of temperature was at Kuala Lumpur, with an average of 24.8°. The total rainfall at Kuala Lumpur was 72.43 inches only, against 98.02 inches in 1891. At Ulu Selangor the rainfall was exceptionally heavy, no less than 180.26 inches being registered during the year. No particular season can be called a regular wet season in Selangor; thus at Kuala Lumpur the months of October, November and December were very wet in 1891, no less than 41.56 inches falling, while in 1892 only 14.77 inches were registered during the same period.

* Not determined.

THE AVERAGES OF UVA ESTATES.

A correspondent interested in Badulla sends us the following with reference to the averages of Uva estates:—

"I see you have corrected a mistake made in Messrs. Wilson, Smithett & Co.'s circular affecting a Badulla estate. This error is more important however, than you seemed to be aware of, since it very considerably affects the average for the Badulla district. In the circular before me Uva is fifth in order of the list of districts—so far as averages are concerned, Bogawantalawa being first with 11d, Nuwara Eliya next with 10½, Dimbula third with 10½d, Dikoya and Uva being bracketed next with 9½d. The mistake about the Narangalas, however, makes all the difference. When this is put right, the Uva average—that is the average for all the Uva districts, Madulsima, Badulla, and Haputale—is found to be not 9½d but 10d.

This makes Uva the district with the third best average, coming immediately after Dimbula, and only ½d, less than Nuwara Eliya. The proper order of the districts is thus:—

	lbs.	d
Bogawantalawa ...	3,000,000	11
Nuwara Eliya ...	2,500,000	10½
Dimbula ...	10,500,000	10½
Uva ...	2,449,000	10

But if Bogawantalawa is thus to be separated from Dikoya, I don't see why Badulla should not be separately shown. I have taken out the figures from the above list, and they work out for Badulla, Madulsima, and Haputale as follows:—

BADULLA AND PASSARA.—Average for the district 43.42 farthings or 10½d.

MADULSIMA.—Average for the district 38.60 farthings or 9½d.

HAPUTALE.—Average for the district 37.32 farthings or 9½d.

Badulla and Passara ...	10½d
Madulsima ...	9½d
Haputale ...	9½d
Average for the whole of Uva	10d.

From the above it will be seen that the average for Badulla alone was 10½d which gives the district the second best average in the Island and equal to that obtained by the Nuwara Eliya and Maturata district, much higher in general altitude. I think you will agree with me that justice to Badulla demands that you should publish these figures, as Messrs. Wilson, Smithett's statistics would lead the casual observer to think poorly of the result obtained by Badulla and Passara factories, whereas, taking their altitude into consideration, they obtain the highest average in the Island, and without any allowance at all, are only beaten by one district in the whole Island.—Local "Times."

THE CEYLON AND ORIENTAL ESTATES
COMPANY, LIMITED.
REPORT OF THE DIRECTORS.

The Directors beg to submit their Report and Audited Accounts for the nine months ending 31st December last.

The purchase of all the estates set out in the Prospectus was duly carried out, and, in addition, the second half-share of Oodewelle Estate was subsequently bought upon favourable terms. The Directors are glad to say that this last acquisition has proved even more profitable than they anticipated.

The weather during the year was unfavourable for Tea flushing, consequently the crop was not so large as expected, either from the Company's Estates, or the Island generally.

The entire crops (with the exception of 7,970 lb. Tea and 116 cwt. Coffee, the value of which is setimated) have been sold: the average selling price for the Tea, in London, being 9.22 pence per lb.

During the nine months the sum of £1,230 8s 11d has been spent upon new buildings and machinery, and £1,684 5s 0d upon extensions of Tea, Coffee and Cocoa, and those amounts have been charged to capital. Upon renewals and repairs of buildings and machinery the sum of £726 11s 10d has been expended and defrayed out of revenue. The extensions comprise about 230 acres of Tea, and 215 acres of Cocoa, interplanted with Coffee. The first clearing of 100 acres, planted with Cocoa and Coffee, on Pathraallga, promises so well that orders have been given to increase the cultivated area of these products by another 80 acres. Mr. Thring, who has recently visited and reported upon all the Company's estates, is of opinion that both the soil and climate of Pathragalla are eminently suited to the cultivation of Cocoa—the growth of the plants to date has been most vigorous and satisfactory. It is hoped that this estate will eventually prove a most profitable source of income. Mr. Thring has also assured the Directors that all the estates are in good order, and in charge of thoroughly experienced superintendents, and he is satisfied that the shareholders can look forward to an increased output of Tea at a reduced cost of production. Recent advices from Ceylon state that the weather was favourable, and the Tea bushes flushing freely. At foot will be found a schedule of the properties, and their respective acreages.

In pursuance of the conditions under which the Debentures were issued, viz., that at least 35 Bonds of £100 each be redeemed yearly, the first instalment of £3,500 was paid off on the 30th ultimo.

The balance at credit of Profit and Loss Account for the nine months' working, after paying all charges and interest, and setting aside £1,039 18s 10d. for the estimated loss on the deposit with the New Oriental Bank (but subject to Income Tax), is £5,122 7s. 9d., which the Directors recommend be appropriated as follows:—

	£	s.	d.
To writing off the Preliminary Expenses Account	1,339	16	11
„ reduction of the Debenture Issue Expenses Account	1,500	0	0
„ payment of the Preference Dividend at the rate of 6 per cent per annum	504	0	9
„ payment of an Ordinary Dividend at the rate of 4 per cent. per annum, free of Income Tax	1,485	8	11
„ carry forward to next account (subject to Income Tax)	293	1	2

The net earnings of the Company, it will be observed, show a return at the rate of about 12 per cent. per annum on the Ordinary Share Capital, after providing for the dividend upon the Preference Shares.

HUGH C. SMITH, Chairman, J. HUNTLEY THRING,
Managing Director.

HUGH CHAPMAN, Secretary.

A GALVANIC CATERPILLAR TRAP.—Where is invention to stop? We find the following in the *Horticultural Times* of April 15th:—

An electrician has invented a curious device to prevent caterpillars from crawling up trees. The scheme is simply to run alternate wires of copper and zinc around the trunk of the tree at a distance of about half an inch apart. When the wires have been placed in position, Mr. Caterpillar starts his ascent. He strikes the copper wire, pokes his little nose over it, and continues. Half an inch further up his feet strike the zinc wire. Immediately the current is carried through his body. With a squirm of pain, Mr. caterpillar drops to the ground or if the current be strong enough, remains a prisoner until the resper comes.

GOLD GALORE!
SOUTH AFRICAN MINES.

The prospects of an increased yield of the precious metal, whose "appreciation" according to some authorities is responsible for so much disturbance of business and currency, are, we are glad to think, greatly improving. From the Far West in Central and especially South America we have reports of new finds of gold; and British Guiana and other British settlements, such as Honduras, seem to promise really important additions to the annual yield of this indispensable metal. The Australian and New Zealand mines are showing increased signs of activity at present, and the latest report of a discovery of reef gold in North Borneo is certain not to be neglected. Here is a brief summary of the information, which we find in a Straits paper received by the French mail today:—

Sandakan, April 20th, 1893.—Captain Beeston, who has been for the last month or so prospecting for gold on behalf of the Governing Company in the district of the Segama and its tributaries, three days ago wrote to the Governor that he had discovered heavy reef gold, and accompanied his letter with samples which, if he is not mistaken in his assertion that there is plenty like it, will very quickly bring British North Borneo again to the front.

But the great hope of those who wish to see gold more plentiful in the world's money markets, undoubtedly rests on South Africa which is in a fair way to develop into a greater gold-yielding region than either America or Australasia. The Transvaal seems to be the centre of the principal auriferous region and already there are fourteen distinct gold fields marked out in this territory usually spoken of as the "Rand." The returns so far as reported of the yield of gold, are marvellous for the progress displayed, and at the end of 1892, "Transvaal" was officially proclaimed the third in the list of gold-producing countries: America and Australasia taking the first and second places. Russia and other gold-yielding countries are left behind; and very soon South Africa, if not Transvaal alone will reach the first place; for here is one table dated from Johannesburg of the progressive output:—

	<i>Gold in oz.</i>				
	1888	1889	1890	1891	1892

Total 230,640 382,364 494,292 729,213 1,223,031
1893—so far showing a large increase.

One list of dividends before us for some 27 Companies shows £838,212 distributed in 1892—the lowest being at the rate of 5, the the highest 125, per cent. The report of actual gold production gives a list of 74 Companies whose work, in 1892, is thus summarized:—

	oz.	dwt.	£
From Mill ..	973,291	9	3,506,787
From Concentrates ..	40,357	14	157,656
From Tailings ..	160,168	18	502,408
Alluvial ..	1,989	1	6,877
Other sources ..	35,111	14	123,882
Total ..	1,210,868	16	4,297,610

The tons of ore actually milled for the year were 1,973,354—produced by 2,530 stamps worked on 312 days, and representing 3.21 tons per stamp daily. The average yield of gold per ton was 9.777 dwt., or a value of £1 15s 3d per ton, irrespective of concentrates and tailings.

There can be no question that we are here face to face with an established gold-producing industry of world-wide importance. But according to some experts we are only at the beginning of the development of South African mineral wealth. One of the most important and impartial Reports made on the subject was that published a short time ago, by Mr. Hamilton Smith, a well-known mining engineer connected with the house of Rothschild. This received a good deal of attention from leading journals at home, and in London the conclusions arrived at by the expert seem to have been accepted as decisive, marking out the Transvaal as about the richest field of mineral wealth in the world. Mr. Smith dealt only with the Rand and with not more than 11 miles of reef, and he estimated that the product from this comparatively small district will exceed that from the whole of the United States. It is stated that the Rand gold mines will in three or four years more, produce gold to over 10 million ounces (against the 6½ million now given by America) at which rate it will continue for 30 years to come! Mr. Smith calculates that the one expanse of reef-body he examined has an average width of 5 ft. carrying 12½ dwts of gold to the ton, thus making a total of 100 million tons of ore of which three million tons had already been mined and crushed, leaving a balance of 97 million tons, in turn equal to a gross yield of 60 million ounces or a cash value of £215,000,000 stg. which will probably be increased by 50 per cent. from mines outside of the 11 miles dealt with, bringing up the total yield to £325,000,000 stg! The final results may perhaps exceed even this enormous sum. The trough of the Rand basin is conjectured to be 15,000 ft. in vertical depth below the surface, and it is thought it may be worked down to a vertical depth of 3,000 ft. or with an inclination of 5,000 ft. The maximum depth yet reached is 3,300 ft. in the Great Comstock lode, but the heat was almost unbearable. Considering the great development that has taken place in refrigerating science during the last few years, it is quite conceivable that 30 years hence, means may be discovered whereby cold air may be supplied to miners in deeper levels of the earth than have yet been reached.

Is it any wonder, we ask, that South Africa is being described as the great British Dependency of the future? True, these rich Rand mines are in the Transvaal Republic; but they are worked in the great majority of cases by British subjects with English capital and all admit that the day is fast approaching when every separate State in South Africa will have to enter the great South African Dominion of Confederate States. Meantime, let it be remembered that gold is not confined to the Transvaal. Many experts consider that Swaziland has reefs equally rich, while Mr. Rhodes is still sanguine about the development of gold mines in Mashonaland, and British Companies, as we know, have been taking up mining concessions in Portuguese territory. Altogether, there is a future

of immense importance before the gold-producing industries of South Africa—and one that is likely to bring an immense addition to the wealth and currency of the world; and which may also do more to redress the inequality with silver than all the efforts of the Bimetallists. This is perhaps, not saying much; but we certainly cannot help placing much faith in the Report and figures of the expert employed by the Messrs. Rothschild to examine the Rand mines; and who can say what effect, the addition of even 10 million ounces to the present annual produce of gold may have, if continued for thirty years. There is besides, however, the probability of other fields being developed in South and East Africa, in Borneo, New Guinea, British Guiana and Central America. Let no one fear, therefore, that the hidden riches of the earth in gold are about to be exhausted!

TEA PLANTING IN CEYLON AND MATTERS FINANCIAL:

THE OTHER SIDE OF THE SHIELD.

(From another Planter.)

"Mr. Wm. Taylor has refused £10,000 cash from Bandarapolla Co. for Hapugahalande in North Matale. [Hapugabalande has 240 acres of fine tea and 53 acres grass and jungle, so that this is up to £40 sterling or over 650 rupees per acre.—Ed. T.A.]

"What would some former owners think of this? According to your morning contemporary gold is becoming over-appreciated as compared to some scores of other articles. Tea land cannot be one of them. Truth is, the value of Ceylon tea property is only now being ascertained. As a security it is far before any ordinary Eastern or Colonial Bank, and has been considered dear at 8 years purchase, while Bank shares fetch, or did fetch, 16 to 20 years.

"An old planter writes from home:—"I have been watching the numerous sales to Companies, and the progress the shares make, which is wonderful; yet I must admit I have noticed nothing extravagant so far."

"The Banker and the Business Man, who wrote warning letters to your paper lately, were playing Cassandra too soon. Where else can such good security be got giving 8 to 12 per cent? All bankers here do not agree with this one, nor do the business men who get up Companies, and secure this business. Sour grapes?"

THE CEYLON TEA PLANTATIONS COMPANY, LIMITED.

IMPORTANT SPEECH BY MR. RUTHERFORD.

The sixth annual report of this Company was held this afternoon, Mr. Rutherford in the chair.

The Secretary having read the notice convening the meeting,

Mr. RUTHERFORD said: Gentlemen,—You will, I presume, as usual, take the report and accounts as read. The Directors have the pleasure of meeting you again with a statement of your affairs which, I trust, you will agree with us in considering satisfactory, as we propose to distribute among the ordinary shareholders for the sixth consecutive year a total dividend of fifteen per cent. on the year's working, after making due provision for depreciation and a substantial increase to our Reserve Fund. Before entering into the general details of the year's working I will briefly refer to the accounts which have been placed before you. You will note the issued share

capital has been slightly increased from what it was the previous year by the addition of 55 ordinary and 334 preference shares, the former having been issued to our estate superintendents and assistants, and the latter to the public, the premiums on which have been added to the Premium Reserve Account. The sum of £59,814 against bills payable may appear to some shareholders as being considerably in excess of former years; but this increase happened to be merely temporary at the close of the year. The capital expenditure stands at £285,885 or an increase of £24,159 on the previous year. This arises from the part payment of the purchase of the Stair and Glenlyon estates—which you sanctioned in January of last year—the acquisition of 49 acres of forest-land from Government in proximity to these properties, and of some small lots of land adjoining Mariawatte estate. It also includes an expenditure on planting with tea and for buildings and machinery £6,563. We propose to set aside £6,275 7s 3d for depreciation, by withdrawing that sum from the "Reserve from Premiums" and applying it to the reduction of the Capital Account, so that the Reserve, as it will then stand, can all be utilized, if necessary, for the equalization of dividends. The Reserve Fund from "surplus profits" has been increased by the sum of £10,781 12s 0d bringing it up to £25,000, or 11 per cent of the issued share capital of the Company, and it will be of interest to shareholders to know that we have invested part of this money in first-class securities, and we will continue to withdraw further sums for investment and so separate as far as possible the reserve from the ordinary risks of our business when we can conveniently do so. There is a sum of £129 11s 2d reserved to cover a probable loss from advances to coolies. The item is doubtful; but we have thought it best to err on the safe side by providing for it this year. Unfortunately we had one or two estate accounts with the late New Oriental Bank Corporation in Ceylon, and we have set aside on this account ten stillings in the pound, or, in all, a sum of £266 16s 2d.

Now, as regards the profit earned for the past year, it will be noted this amount (including the balance brought forward) to £38,359-10-1, and this sum represents 22 per cent. on the ordinary share capital after paying the dividends on the preference shares. When we consider that last year was an unfavourable one as regards weather for producing leaf, it is clear that with a diminished yield per acre of nearly 10 per cent. on the previous year, and practically the same price for our teas, there must have been causes operating beneficially to have produced this increase of profits. The important factors so operating were low exchange and cheap freights. I may here mention that, while we as growers benefit considerably by a low exchange, the Board has not overlooked the fact that our European staff suffers by the depreciation of the rupee, and I am sure the shareholders will be pleased to learn that for the past year we have allowed these officers a bonus of 10 per cent addition to their salaries to compensate them for the heavy fall in exchange. Our bought-leaf business and manufacturing tea for other proprietors, although showing a slight falling-off in volume of leaf, was more profitable than for the previous year. Coffee and cinchona are now almost products of the past on our estates, as they have been supplanted with tea, and although, as usual, they have assisted our profits, we look for little or nothing from these sources in the future.

I would now refer to the issue of ordinary and preference shares which was made early in this year, but which does not, of course appear in the accounts under review. These shares were offered *pro rata* to the shareholders, the former at a premium of £2 10s. per share, and the latter at a premium of £1 10s. per share, and I am pleased to be able to tell you they were readily absorbed by our shareholders. The premiums on this issue, amounting to over £5,000, will appear in next year's accounts to the credit of "Reserve from premiums or may be utilized for depreciation as may be deemed advisable. When the final calls have been paid, and

abares allotted to the vendor of Glenlyon and Stair estates, the total share capital will amount to £247,310.

As to future prospects, Your Directors have never in the past given you the full estimated crop expected in the current year from our properties, as all such estimates are for their due fulfilment so greatly dependent on the weather that they are often apt to mislead. It will, therefore, I think, be more satisfactory for shareholders to be informed in a general way that our Ceylon Manager, Mr. Talbot (who was elected a Director last year, but, having returned to his post in Ceylon, has retired from office) reports that our properties are in first rate order and the bushes, both on our young estates and on the oldest properties, in his opinion show every indication of yielding well for many years to come, and he estimates when the land we have under tea comes into full bearing we will obtain an increase of over 50 per cent. above last year's crop.

This probable increase in the crops from the Company's estates naturally leads one to consider the question I have been asked so frequently by those shareholders who are not conversant with the Island of Ceylon and the history of its tea industry, as to the fear of over-production from further large areas of land being opened out in tea, that I may be pardoned making a general statement on the subject.

The maximum area that was ever under coffee cultivation in Ceylon was 275,000 acres, and practically all the old coffee land capable of growing tea has been planted up with that product. As there is little or no upcountry forest land suitable for tea in private hands or belonging to the Crown, it follows that there is no reserve area available for growing the finer quality of teas which the island produces, and Ceylon is therefore within a measurable distance of yielding all it will ever be able to export of fine teas grown at high elevations.

There are, however, many thousands of acres of low-country forest and chena lands suitable for growing the common grades of tea; but not only are Ceylon planters chary of opening out fresh lands in the low-country (unless where there are exceptionally favoured blocks), but the Government are very wisely, I think, not inclined to dispose of large areas of these forests as both they and the planters are alive to the fact that over-production would be a fatal policy to pursue.

No doubt when increased consumption of tea demands it, the Ceylon Government will be prepared to part with it, and planters will be found ready to cultivate sufficient it areas to keep pace with the world's requirements.

Should the various markets in 3 or 4 years' time be able to absorb 100 millions of lb. of Ceylon teas, I do not fear any further natural increase from the Island materially affecting prices provided India does not abnormally add to the world's production. So completely has the public taste in this country been won over to British-grown teas that it will in a great measure rest with Indian and Ceylon planters to regulate the price of tea in the future by restricting, as far as possible, the opening out of new land, so that the supply will keep pace with, but not exceed, demand.

If Ceylon continues the energetic measures in pushing its teas into new markets in the way it has so successfully hitherto done through the co-operation of the growers and the sympathetic assistance of the Ceylon Government there does not seem to be any reason why our teas should not be maintained at a price that will continue to yield reasonable profits to producers. I do not think there is anything further that I can say regarding the Company's affairs; but should any of the shareholders present desire any further information I should be very pleased to answer any questions they may put as far as I am able. I have now to move, gentlemen "that the Report of the Directors and statement of accounts as submitted be received and adopted, and that a final dividend of 8 per cent. on the ordinary shares (making 15 per cent in all, free of income tax) payable forthwith be and is hereby, declared."

M. H. Todd seconded the resolution, which was carried unanimously.

Mr. D. Reid, Sevenosks, proposed, and Mr. Herbert Anderson seconded, a resolution for the re-appointment of Mr. Rutherford to the Chairmanship of the Company, which was carried by acclamation.

Mr. J. L. Shand begged to move a vote of thanks to the London and Ceylon staff of the Company, to whose energies the shareholders were indebted for their measure of success. He knew how assiduously the London staff guarded their interests and last year, when he was in Ceylon, he had opportunities of judging of the valuable services rendered by the local staff. Having been seconded by Mr. Seton it was carried.

Mr. Rutherford acknowledging the compliment, and begged to say that the largest share of merit was due to those who in the island had toiled through the heat and burden of the day.

AN EFFECT OF HIGH RUBBER PRICES.

A press dispatch states "it would appear" that preparations were being made by a number of men prominent in the rubber business for a trip to Rio Janeiro, Brazil, the purpose of the expedition being the "exploration of several thousand square miles of land near the Beni in southern Bolivia, which is said to have advantages for the production of cheap rubber." If the result of the expedition are as fruitful as "a French capitalist predicts, the Rubber Trust will have a most powerful competitor." The exploring party "has already organized the Beni Gum Company," and "will travel under the guidance of Melchor O'Baro, Bolivian Minister to the United States, who will also entertain them during the company's stay in Bolivia." The "trip will last six months," as the Amazon will be explored and trips to the Andes made. The *Boston Advertiser* says:—"It remains to be seen whether the developments will be of such a nature as to affect the Para grades, the trade in which has been more active of late. The new price list of the rubber-shoe companies is based on the estimate of 80c. rubber, which, it is believed by manufacturers, will be the average price during the coming season. New fine Para is now quoted at 75 to 77c., with coarse at 51 to 56c.—*Bradstreet's*, April 15th.

FROM THE HILLS.

(By Old Colonist.)

AMBAGAMUWA, 22nd May 1893.

Climatically, I am quite out of my element here. As well send your hens to swim in the lake as send me "to the hills" with a quill at this season!

The rain has not ceased for ten minutes—on end—I believe, since I left Colombo. Everything is drenched and dreary. I cannot even find a bit of dry humour! Old Hugh's joke about "our water being sure" is stale and musty. Evidently Ambagamuwa has "drowned the (Joe) Miller."

Better—infinity better—for me, is the interior of New South Wales where one inch of rain per month—is enough to make men, grass and trees rejoice. Or better still send me to the "Chicama haciendas" of Peru, where I found the oldest inhabitant had never seen a shower of rain; where visitors were desecrated 10 miles off by the dust they raised; and yet where the rich sugar-cane produced such sweetness, as Ceylon never dreamt of; and the jolly coffee planter sends off his beans for noodles to drink, while he and his "spiritual adviser" console themselves with the liquor distilled from the luscious pulp. No "drowning the miller" there I can tell you!

But to turn to our virtuous tea plant. It has certainly found a suitable home here, and where the jāt is good, the bush is quite as beautiful in appearance as the best coffee of old—while its large, tender, glossy leaves fill the basket with marvellous rapidity.

Well may old Rozelle rejoice in the change of product, and I could wish for no greater pleasure today than to meet the owner of those good green fields. Albeit, there is still room for improvement in that quarter.

Then the leaf-fungus no greater blessing was ever sent upon a country. Under any circumstance, the over-boomed coffee was bound to collapse and the agony could only have been prolonged by the absence of the sharp decisive visitation, which has proved the tenderest of mercies.

FINE TEA PLUCKING ON INDIAN GARDENS.

The cause of the latter averages obtained by Indian gardens last season, compared with those previously secured, is,—says the local "Times,"—generally admitted to have been a much finer system of plucking. It would appear from the following cutting from the *Indian Agriculturist* that the same is to be continued this year:—

"If the sanguine expectations of those interested in the tea industry are realised, the coming season is likely to prove a record one, in Calcutta at any rate, whatever the fluctuations may be in the English market. Fine plucking is, we understand, to be generally adhered to, and as the recent large extensions will not come into bearing, to any appreciable extent, for the next two seasons, there is less probability of a glut taking place. We say the sales in the local market are likely to prove a record, advisedly, for not only is competition among remitters for medium to be pretty keen, but as Mr. Lipton will enter directly into the field, and the quantity sent to auction here will be comparatively restricted, prices will probably rule high. Possibly, satisfactory news as to the introduction of the Indian article into the States may reach us about July from Chicago. We trust the warnings of the press will not, however, be disregarded, and that, until the visible demand for our teas is well assured, extensions will be kept within moderate bounds, and due precautions taken against flooding the market with coarser out-turn than the samples sent to the World's Fair."

TEA AND TEA DUTIES.

TO THE EDITOR "ECHO."

SIR,—In your issue of the 17th inst. you publish a report of a meeting in Poplar in favour of the total abolition of the existing duty on tea. If you will permit me — one who has worked in the wholesale tea trade for over ten years — to state a few facts on this most important question you will benefit thousands who, like myself, are interested.

In the first place, by abolishing the duty the public would not benefit by it—anyhow, to the extent it would be intended they should, and I am not far wrong in stating that out of the last reduction made of 2d (twopence) per pound the tea-consuming public have not gained one-third of that amount. If tea is any cheaper now than it was three years ago it is simply owing to competition in the trade. The wholesale dealer or middleman has either pocketed the extra profit or expended it in smart and expensive labels and wrappers, which all help to sell his tea and which are no earthly use to the tea-drinker.

Then again, bonded tea warehouses would have to close, which roughly speaking, would mean about 10,000 men thrown out of employment with no other trade at their hands, to walk the streets and starve with the already un-employed.

There is another point to observe, if it is not taking up too much of your valuable time and space. That is the country would be overflooded with cheap and poisonous teas, and as we are all too well aware there is enough rubbish in the shape of tea imported into this country already, and Customs inspectors, or those whose duty it would be, would have to be very stringent as to the quality of the tea landed, or we should have some fearful diseases to dread and deal with in addition to those we have already.

Yours, &c.,

E. K. C.

JOHORE TEA.

A report by the late United States Consul Wildman, at Singapore, gives some account of the above industry in Johore. He tells us:—

Under the wise and humane rule of its enlightened prince Johore has kept along abreast of the more stirring English civilisation of Singapore, and its 15,000 square miles is under as good cultivation as any part of the English colony and its 200,000 inhabitants as loyal and patriotic as their neighbouring Europeans. The Sultan, in his work of building up his country, has gone outside the natural products of the soil, and has experimented with staple productions that are native to other sections. In coffee, pepper, and tea his experiments have proven so far successful that today they comprise the chief output of his little kingdom, outstripping in value the native products of the soil—sago, tapioca, cocoa, pineapple, gambier, spices, and gums. Especially in regard to tea has the soil proved efficacious, giving it a delicious odour and flavour that to the taste of many connoisseurs places it ahead of the original Assam or the now famous Ceylon.

As the Sultan will send an exhibit of Johore tea to the Chicago Exposition, I have thought some description might be of interest. I am indebted to Dato (Lord) Walter F. Garland, M.I.C.E., Commissioner of Public Works in the Government of the Sultan, for aid in the compilation of this report. To Dato Garland's untiring energy and practical knowledge of the tea plant Johore is under great obligations for its successful culture. I would refer interested parties to him for any further information that they may desire.

The Michaelstowe tea gardens in the Sultan of Johore's territory have an area of 800 acres, of which 165 acres are under cultivation. In Johore no crop was picked until five years old, but this was due to difficulties in starting a new industry in a foreign country. Planting was commenced in 1852, when labour was difficult to find and expensive to keep; now, in 1892, thanks to the wise government of the State by its enlightened ruler, labour is cheap and plentiful. Coolies in these gardens receive 18 cents in Mexican silver per diem for every day they work. The whole garden has to be dug over three times a year, and with manure once in three years, is capable of producing an all-round average of 500 tons per acre. A description of the method of preparation, into which we need not enter, is then given.—*L. & C. Express.*

NEW TEA ROLLING MACHINES.

In the *Patent Journal* of the 26th ult. there are the following notices:—

20,964. December 1st, 1891. Tea. J. Y. Johnson, 47, Lincoln's Inn Fields, Middlesex.—(*W. Jackson; Colombo, Ceylon.*)

Rolling Machines.—Consists in means for preventing a rise of temperature during the rolling. Air is introduced into, or drawn from, the space in which the rolling takes place by means of a fan, air pump, etc. In the arrangement shown, a fan driven from the shaft which actuates the rolling surfaces is connected with perforated tubes extending along the sides of the casing and communicating with the rolling chamber.

20,965. Dec. 1, 1891. Tea. J. Y. Johnson, 47, Lincoln's Inn Fields, Middlesex.—(*W. Jackson; Colombo, Ceylon.*)

Rolling Machines.—Order to facilitate the circulation of the charge of tea leaf, the under surface of the upper plate, etc. is formed with a dome-shaped or convex projection.

COFFEE IN CHICAGO.—Many of our readers will feel interested in learning that the contract for furnishing roasted coffee to the World's Fair, requiring 700,000 pounds, has been awarded to Chase & Sanborn, of Montreal.—*Rio News*, April 4,

SCOTTISH CEYLON TEA COMPANY.

(LIMITED.)

Report of the Board of Directors to be presented to the Shareholders at their Fourth Annual Ordinary Meeting on 25th May, 1893.

The Directors beg to submit to the Shareholders the Accounts and Balance-sheet for the twelve months ending 31st December, 1892. The nett profits for the year are £7,016 11s 1d., which, with the balance of £807 0s 6d. carried forward from previous year, make a total of £7,823 11s 7d., available for distribution. A dividend of 5 per cent. (free of Income Tax) has already been paid, and the Directors now propose a further final dividend of 10 per cent. (also free of Income Tax), in all 15 per cent for the year.

Of the balance of profits remaining it is proposed to place a further sum of £1,000 to the Reserve Fund, which would then stand at £3,000, and to carry the remaining £673 11s 7d. forward to next account.

The season of 1892 in Ceylon proved abnormal, and resulted in a considerable general shrinkage in the estimated production of Tea, from which the Company's Estates also suffered, the estimate for the year being 587,000 lb. while the quantity secured was 520,969 lb. In view of this diminution the Directors consider the result quite satisfactory. The Company's Estates are all reported on as in excellent condition, and give every promise of favourable results for coming year. The factory on Lonach has been completed and is now in full working order.

It will be borne in mind that the total cost (£4,315 10s 2d.) of the original factories and machinery was paid for out of Revenue in the first year of the Company's existence, and no item for depreciation accordingly appears in the attached accounts.

The gross average price obtained for the Company's Teas in London was 10d-19s per lb.

The following is a list of the Company's properties, with their respective acreages :-

	Under Tea.	Coffee & other products.	Jungle Paths &c.	Total.
Invery ..	477	9	27	513
Mincing Lane ..	183	—	11	194
Strathdon ..	292	4	8	304
Abergeldie ..	170	5	18	193
Benachie ..	270	—	68	338
Lonach ..	241	—	165	406
	1633	18	297	1948

The Directors have again to express their high appreciation of the services of the Company's Staff in Ceylon and in London. The date for the General Meeting has been made rather later than in past years. The Board hope by this to enable the Ceylon Manager to be present. He is now on his way home and the Directors feel sure it will be a satisfaction to the Shareholders to meet him, and to have from him personally the most recent reports of the Company's estates.

CROP ACCOUNT, 31st Dec. 1892.

	£	s	d
To Cost of Cultivation and manufacture of Tea, &c. ...	11,930	15	9

	£8,507	2	7
By Balance from Crop Account	£8,507	2	7

THE TEA PLANTER'S FOES.

Next to mosquito hlight, red spider is probably the most injurious pest with which the tea planter has to contend. Hardly any locality is free from it in dry seasons, and the damage it occasions on some gardens has been estimated at many thousands of rupees in the year; for though it does not kill the bushes it saps their vitality to such an extent as to interfere very seriously with the yield of leaf. About six years ago attention was called, in a paper emanating from the entomological section of the Indian Museum, to the efficiency of the sulphur treatment, which had been successfully adopted in Florida for destroying a closely allied pest upon orange trees. The treatment seems to have been tried at the time by a few planters in Sikkim, but it attracted so little attention that even within the last two years costly and laborious methods of dealing with the pest by spraying the bushes many times over with decoctions of tomato leaves have been seriously discussed in planting circles. It is interesting, therefore, to find, in a publication recently issued by the trustees of the Indian Museum, a detailed account of an extensive trial by the treatment which has been carried out by Mr. G F Playfair on one of Messrs. Barry & Co.'s gardens in Coohar. Five tons of refined flowers of sulphur were sent up to the garden and applied over an area of 138 acres, and the results appear to have been so successful that the treatment is likely to be very widely adopted.

The sulphur was put into bags made of common marking cloth, which were shaken over the bushes so as to distribute the powder. In some cases the bushes first splashed with water, but in localities where water was not easily obtainable, the sulphur was applied without any previous watering. The sulphur was found to adhere fairly well, even dry bushes in spite of the high wind which was prevalent at the time. The average cost of the treatment has been estimated at Rs 4 an acre including the price and freight of the sulphur and the cost of application. The sulphur was applied in the first instance, at the rate of one hundredweight to the acre; but a large area was afterwards successfully treated at the rate of two hundredweight to three acres. An experiment was also made over some eleven acres, of sprinkling a mixture of one part of sulphur mixed with two parts of sifted lime; but this application does not appear to have been so effective as the undiluted sulphur. Besides destroying the red spider almost completely, Mr. Playfair is inclined to think that the sulphuring is useful against mosquito hlight. Upon this point, however, we are warned that it will be desirable to make further investigations, as mites like a red spider, are the only pest against which sulphur has hitherto been used successfully in other parts of the world.

It is interesting to notice that while the results of the dry sulphur treatment seem to have been so successful as to leave little to be desired—for eight or nine rupees per acre is a very small price to pay for securing healthy flushes over areas which would otherwise lie idle—an improvement upon the method has already been adopted in the United States and England. This consists in mixing the sulphur with soap, which is then dissolved in water and applied in the form of a fine spray, by means of a force pump. The cheapness of the little hand force pumps which have been invented for this kind of work, and the

speed with which large areas can be gone over with them are so great, that, we are told, this method of treatment is generally preferred to dry sprinkling. It is likely to prove both cheaper and more effective in the long run, though there is some prejudice against it on account of the initial cost of the force pumps. The value of this treatment is so well recognised in England that compounds of soap and sulphur are already being sold by some of the chief soap manufacturers ready made up for use. The possibility of applying insecticides by means of spraying apparatus over wide areas at a paying rate, has been recognised for a long time in America, and the demand which has sprung up for this class of apparatus is now said to be enormous. In England prejudice was so strong that it is only within the last few years that the system has been at all widely adopted, and only in the case of such valuable crops as hops and fruit. In India the system is still in its infancy, and there is an enormous amount to be done in the way of experiment before it can be placed upon a practical footing, though in view of the experience of the United States there can be little doubt that it will ultimately be taken up. Such valuable crops as tea and coffee seem to be peculiarly suited to this method of treatment. Mr. Playfair's experiments with red spider are a valuable contribution to the subject, and the importance of eliminating the uncertainty of yield so often induced by red spider will be appreciated by all who are interested in the tea industry. Mosquito blight, which is an even greater evil, still defies treatment, but the fact that it has been found possible to overcome the one raises hopes that the other may likewise be successfully dealt with.—*Englishman*.

THE GOLD IN THE COFFEE.

In the good old times (so long ago as eight or ten years) men planted coffee in Malaya and said that at \$15 per picul they could easily pay back the money lent them on the security of favourable forecasts. For in those ancient days the hearts of men were young, and their hopes were high; and bankers besought their customers to horror. Now coffee is at \$36 per picul, and those of the planters who are not dead or bankrupt are beginning to think that they may yet be able to "look the whole world in the face." And to this journal there comes a wondrous tale. Upon one estate in the Peninsula, the Javanese labourers have, at their own desire, entered into piece work contracts which appear to ensure to the estate a large profit. The estate is in full bearing and its average production is probably 4 piculs per acre—which is by no means a large production. The Javanese have offered to maintain the estate in order; to tend and pluck the coffee; and to deliver it ready for the market for a payment of \$11½ per picul, or \$10½ if certain machinery be provided. Beyond that the planter has only to supply the manure; to maintain the buildings; to run the coffee machinery; and to provide the cost of superintendence, which means his own cost of living or the equivalent in salary. The value of the manure to be supplied may be taken as \$10 per acre; and if \$8 per acre be regarded as sufficient allowance for the other expenses named, and if the yield be taken at 4 piculs per acre it follows that planter can put his coffee on the Singapore market at a cost price of \$15 per picul. He sells it at \$36 per picul. The difference between \$15 and \$36 constitutes the profit earned by the capital sunk in the estate. It may be said roughly speaking that to plant coffee and to tend it until it is in full bearing should cost \$200 per acre. Many estates have cost more than that; but it appears that the Javanese are willing to break ground and tend coffee for extension purposes at a charge which brings the cost of coffee in bearing to under \$200 per acre. The calculations submitted then assume the following shape. A thousand acres of land may be put into full coffee bearing for \$200,000. At the rate of four piculs per acre the estate will then yield four thousand piculs of coffee yearly. The cost of producing that coffee yearly and

bringing it to market will be \$15 per picul; and it will sell at \$36. The margin is \$21 per picul which, on four thousand piculs produced by one thousand acres, shows a net profit of \$84,000, per annum. The estate represents capital of \$200,000, so that the profit is at the rate of 42% per annum. It is further pointed out that, according to Messrs. Hill and Rathborne's return, an estate should yield much more than four piculs per acre; and that, on the contract system, the Javanese will have an especial interest in producing a larger yield than four piculs per acre. Therefore, still further possibilities of profit are suggested. Further it is noted that by the piece work system it is the interest of the Javanese headmen to see that their kongsees work hard and regularly; so that the planter is supposed to be relieved of all the most tedious and disagreeable part of his work. By the change in the labour scheme the planter, who was a broken-hearted coolie driver, becomes a jolly squire; while at the same time the fields round which he is to wander become "vast potentialities of wealth beyond the dreams of avarice." In marble halls, cooled by plashing fountains, the happy planter will pass the sunlit hours in amorous dalliance or in smoke-wreathed ease; and in the cool of the evening he will ride forth to look at the work of that self-guided labour which is laying the foundations of his Mayfair palace or his villa by the Lake of Como. So Alauscliar dreamed. We adopt the Eastern habit. The land of vain regret is lighted by the rays of facile hope.—*Straits Times*, May 9.

WEEDING OF ESTATES.

With reference to the remarks of our Rattota planting correspondent in yesterday's *Observer*, it may be well to republish the following from our "Planter's *Vade Mecum*" for the benefit of young planters:—

It will also be your duty to see that the weeding contractors do their work properly, and let me tell you there is no work on an estate more liable to be scamped than weeding, and generally it is the most expensive. The estate you are going to, we will suppose is weeded once a month, still it is not clean and the contractors are making very little if any profit off their contracts, so that much of the assistant's time is spent having frequently to visit the different weeding contract gangs. I am quite aware this is often the case, but think the contractors should pay for their own overseer. Thus if your estate is 300 acres, and weeded by contract at so much per acre per mensem, it is an easy matter getting the contractors to agree to a reduction of three or four cents per acre, and you appoint one of themselves on the sum obtained by the reduction, to be overseer of all the contracts. His duty will be to visit every contract, daily examine the previous day's work, and make them do it over again if badly done. See that the coolies have the regulation weeding tool, whatever that may be, that each of them have a cooly sack to put the weeds into, and that one or more large sacks are being used for receiving and carrying the weeds from the cooly sacks to the weed depot, that none are missed, or allowed to lie amongst the tea or in heaps on the roads. The weeds ought to be transferred from the cooly sacks to the large sack and not thrown on the road in a heap, to be gathered afterwards. At 4 p.m. the weeding overseer reports to you in the presence of the hanganies, and on the work generally the number employed on the various contracts, which statement you enter in your check-roll. If you find that with monthly weeding with the close supervision of an overseer, and your own periodical visits that the estate is still far from clean, then insist on the contractors weeding the same ground three times in two months for the same money as allowed for weeding twice in two months. It is only a matter of a few extra coolies the first month or two; afterwards the work becomes lighter and contractors will reap a profit where formerly they had a loss.

WHAT IS DONE IN THE MADRAS PRESIDENCY FOR THE IMPROVEMENT OF AGRICULTURE.

The Report on the operations of the Department of Land Records and Agriculture in the Madras Presidency in 1891-92 has reached our hands. We learn by it that the amount advanced to agriculturists by the Government during the year aggregated R1,688,481 against R271,504 disbursed in the previous year. This large increase is said to be due to the great impetus to well-sinking given by the drought which prevailed in several of the districts, as well as to the favourable terms under which loans were granted. Irrigation works seem to have received a good deal of attention during the past year. On two projects, which when completed are expected to protect an area of 292,400 acres, a sum of about 61 lakhs of rupees was expended; while another extension, to irrigate 6,000 acres, has been made. In addition to this, the improvement of two river deltas, increasing the protected land by 277,400 acres, cost about 30 lakhs. Sanction for further improvements and extensions have been accorded by the Government. Under the heading *minor irrigation* we read that an allotment of 472 lakhs of rupees was sanctioned for the repair of minor irrigation works, and that the sum was subsequently raised to R540,092, this amount having been fully expended.

Under *Agricultural Education*, it is announced that the minor department of Saidapet College has been abolished; and by way of compensation it is proposed to establish five "FARM SCHOOLS" in different districts, in which Agriculture and Veterinary Science will be taught. A new scheme is also about to be introduced in the curriculum of the College. An excellent idea in connection with the establishment of the Farm Schools is that the Inspectors who are to take charge of them have been deputed to make themselves acquainted with local agricultural practice prior to entering upon their duties.

In connection with "Dairy Experiments" the Director refers to the successful introduction of modern dairy machinery into the Bombay Presidency and to the fact that by its use the cost of supplying wholesome milk for the use of troops and in hospitals has been greatly economised.

An attempt is being made to establish a Trade in Kitul and Palmyrah Fibres in the presidency. Kitul is, by the way, spoken of as the fibre of the sago palm (*Caryota urens*). This is misleading; the real sago palm is *Metroxylon sagu*, the kitul being sometimes known as the "bastard sago." It will be read with interest that the experiments made by the Madras and South Indian Railway Companies in the use of Eucalyptus leaves as disencrustators for locomotive boilers have been reported to be very satisfactory. A proposal to revive the investigation of *hemeleia vastatrix* has been wisely abandoned, as it is not expected that anything of practical utility is likely to result. The Agri-Horticultural Society of Madras is said to receive a Government grant of R4,000 per annum, and collects about R3,000 in subscriptions. Large losses of cattle from starvation are reported, owing to the scarcity of fodder and water. Let our correspondent "Agricola" know that a Superintendent, Civil Veterinary Department, has a subordinate staff consisting of 14 Stock Inspectors to aid him in the suppression of Cattle Disease. Full statistics are supplied in the body of the Report of the number of animals (cattle, sheep, goats and horses) that died during the year, the causes of death being also noted. Cattle are said to have enjoyed comparative immunity from serious

disease (rinderpest, diarrhoea and dysentery, anthrax, foot and mouth disease, variola), the total reported loss being 87,000 or 58 per cent of the average losses and 15 per cent less than in the previous year. Rinderpest (even including under this head deaths due to dysentery and diarrhoea) did not cause one-third the average number of deaths that it had done in the previous four years. Only 10,359 deaths were registered under rinderpest. Snakes and wild animals are said to have caused some 12,000 deaths! The season for cultivation is described as having been "most unfavourable;" the results being shown in a considerably reduced area of crop and in poor average yields.

AN IMPROVED METHOD OF TEA MAKING.

We have received from Mr. A. Rajasingham an account of a modification of the Japanese teapot, which he has devised with the object of preventing as much as possible the extraction of tannin from tea leaves when making tea. For that purpose, he suggests that tea should not be infused and left "to draw" for a certain time, so as to "take the strength out of it," but that the leaves should only be subjected to a rapid percolation with hot water. In carrying out this plan of making tea, the leaves are placed in a cylindrical cup with a perforated bottom, and, while this is held or supported in the mouth of the teapot, hot water is poured upon the leaves. The difference between this arrangement and the ordinary Japanese teapot consists chiefly in keeping the leaves from contact with the infusion after this has passed through the perforated bottom of the strainer. The advantages of this method of making tea are (1) the freedom of the infusion from excess of tannin while extracting all the aroma; (2) simplicity and expedition as well as the inexpensive nature of the apparatus used. Mr. Rajasingham has sent a statement of the results obtained in a number of experiments in which the tea made by this process and by the old-fashioned method of infusion was tested as to the amount of tannin present in it; and the difference in this respect was found to be very marked in favour of that made by the percolation. Of course, the tea made by percolation is very much paler in colour than that made by infusion; but with moderately good tea it has a delicate aroma and a pleasant taste, without bitterness or the astringency caused by tannin, so that it can be drunk without either milk or sugar.—*British Medical Journal*, April 22

UPPER MASKELIYA ESTATES CO. LD.

At the general meeting held today (Mr. W. D. Gibbon in the chair) the report of the Directors and accounts for the past year were unanimously adopted.

The retiring Directors were re-elected.

The following was the report of the directors:—

The Directors have pleasure in submitting to the shareholders the accounts of the Company for the nine months ending 31st December 1892.

The yield of tea during this period was 135,686 lb. which realized an average net price of 54 cents per lb. The bulk of the crop was sold in London and but for the disappointing prices obtained for the later shipments of the season which arrived when the market for fine teas was greatly depressed, this average would have been better.

The profit shewn on tea manufacture account and from rents, &c. is satisfactory and as will be seen below, the Directors anticipate good returns from these sources during the current year.

After making ample provision for depreciation of buildings and machinery, the net balance of profit is R29,818-51 out of which a dividend of 10 per cent on the paid-up capital has been paid, absorbing R27,000. A balance of R2,818-51 therefore remains, which would permit of a further dividend of 1 per cent, but the Directors recommend that this

amount be carried forward to the current year's account.

The expenses incidental to the formation of the Company charged in the present accounts will not be incurred again and, allowing for these special payments, the net profit for the nine months is at a rate equal to 16½ per cent per annum on the capital of the Company.

The estimated crop in season 1893 is 190,000 lb. Tea against an Expenditure on the estate of R60,734, and the profits from other sources are estimated to amount to R12,612.

The above estimated expenditure does not include a proposed outlay on Capital account of R5,950 in additions to Buildings and Machinery.

In the Balance Sheet the Assets are thus stated:—By Property (Immovable) R262,610-13; Property (Moveable) held by the Company, R40,957-37; Debt due to the Company—Outstanding account (since recovered) R1,883-80; Cash in Bank on Current Account R6,630-55. Total R312,081-85. The Liabilities show; Capital:—R270,000; Debts and Liabilities of the Company—R9,263-34; Depreciation Account R3,000; Profit and Loss Account—R29,818-51. Total R312,081-85.

On the Working Account, for the nine months the following appears on the creditor side:—By net proceeds of 135,606 lb tea R72,986-16; By net proceeds of 14,828 lb cinchona R1,329-07; By Profit on tea Manufacturing account R7,685-87; By Rents and Sundry receipts on estate R3,151-11. Total R85,152-21.

The expenditure was R47,353-10; and the amount transferred to depreciation account R3,000; the balance transferred to credit of profit and loss account being R34,799-11. Total R85,152-21.

In the profit and loss account the following appears on the debtor side:—To expenses incidental to the formation and registration of the Company R984-10; to interest on purchase money R2,175; to interest on current account R32-35; to Directors' and Secretary's fees and office rent R1,725; to Auditor's fee R50; to stationery, postages and sundries R154-15; to balance R29,818-51.—R34,939-11. On the creditor side the items are: by balance transferred from working account R34,799-11; by transfer fees R140.—R34,939-11.

THE AMSTERDAM CINCHONA AUCTION.

AMSTERDAM, April 27.—At today's bark sales here 2,984 packages Java bark sold at 5¼ per unit on the average (or 15-16th d. to 1d per lb.). The prices range from 8c to 57c (equal to 1½d to 10½d) per lb for manufacturing bark in quills, broken quills and chips; and from 11c to 36c (equal to 2d to 6½d) for ditto root; from 9c to 76c (equal to 1½d to 1s 2d) for druggists' bark in whole and broken quills, and 13c to 14c (equal to 1½d to 1¾d) for ditto root. The principal buyers, in order of their quinine purchases, were the Auerbach Quinine Works, the Mannheim and Amsterdam Works, the Brunswick Factory, Matthes and Bormeester, and Briegleb.—*Chemist and Druggist*, April 29.

INDIAN PATENTS.

Applications in respect of the undermentioned inventions have been filed, during the week ending the 18th March 1893, under the provisions of Act V of 1883, in the Office of the Secretary appointed under the Inventions and Designs Act, 1888:—

No. 81 of 1893.—Thomas Cattell Jones, M.R.C.S., Eng., L.R.C.P. and L.M.; Edin., and George Winter, Tea Planter, both of Shumshernuggger Tea Estate, Shumshernuggger, Sylhet in Assam, British India, for a new or improved mixture for preserving tea bushes, trees and the like from the attacks of insects, to be called 'Red Spider and Blight Destroyer.'

No. 86 of 1893.—T. Drewet, Jr., and Palonji D. Chowna, both Engineers and Contractors of 17, Elphinstone Circle, Bombay, for improvements in fibre baling machinery.

Specifications of the undermentioned inventions have been filed.

No. 89 of 1882.—David Rowell, Engineer, of 5, Victoria Street, in the City of Westminster, for improvements in apparatus for withering or drying tea. (Filed 9th March 1893.)

No. 152 of 1892.—Henry Thompson of Gainsborough in the County of Lincoln, Engineer, but now residing at Ipswich in the County of Suffolk, for improvements in the method of and apparatus for drying tea leaf and the like. (Filed 10th March 1893.)

No. 302 of 1892.—Lionel Maynard Torin, Tea Grower, of Aldouric Estates, Agra, Ceylon, but now residing at London, England, for an improved method of and means for the drying of the leaves of tea and other plants. (Filed 19th April 1893.)

COCONUT CULTIVATION IN CEYLON.

One of the best little gardens we know in the island is that from which we are enabled on the best authority to give the return of crops gathered as follows:—

G.—B., 14 acres in extent, with 1,151 bearing coconut trees standing thereon, or about 82 trees per acre:—

Produce in 1883	...	57,000	lbs
" 1884	...	56,200	"
" 1885	...	57,600	"
" 1886	...	58,300	"
" 1887	...	59,000	"
" 1888	...	59,600	"
" 1889	...	60,300	"
" 1890	...	60,500	"
" 1891	...	61,000	"
" 1892	...	60,700	"

Total...R590,200 "

Average for ten years 59,020 nuts; per acre 4.215 nuts; per tree per annum about 51½ nuts. We do not think there are many places in the country that can show a better return than the above for ten years continuously.

A WARNING: TO BE COPIED INTO ENGLISH PAPER.—We are assured that the time has come for sounding forth a word of warning to young men in the old country—their parents and guardians—who may be looking to the Tea industry in Ceylon as affording a field for their energies. We are told that at this moment there are in the island, more "pupils" learning (after payment of premium,) "all about tea"—"creepers" is now the colloquial, local term—and passed Assistants looking out for billets, than there are, or likely to be, places for them to fill. The planting districts have now in fact, a full supply of Superintendents and Assistants, and it will not be wise for any more young men to come out to learn tea in Ceylon with the hope of getting employment here, unless they have beforehand, a distinct promise or guarantee to that effect. We trust all advertisements for pupils in English papers will therefore now cease, unless the Manager so advertising, is able to offer employment afterwards; and, it would be well if planters and others writing home should cut out and enclose this paragraph to their friends to prevent a further influx of young men who can only come out here to be disappointed. Already, we hear of a good deal of disappointment and of idleness—"got no work to do"—among would-be young planters in certain districts, which can lead to no good for themselves or others.—If we are wrong or premature in this announcement, we shall indeed be very glad to stand corrected on satisfactory evidence being forthcoming.

ESSENTIAL OILS.

The Semi-Annual Report of Messrs. Schimmel & Co. (Fritzsche Brothers) of Leipzig & New York, dated April 1893, affords us some interesting particulars respecting different products and industries in which we are more or less interested. Germany evidently exports a large quantity of Essential Oils, the value increasing from \$222,470 in 1891 to \$232,243 in 1892, in spite of the McKinley Tariff. In the introductory statement much satisfaction is expressed at the election of President Cleveland and we have the following paragraph about the Chicago Exhibition:—

It is to be expected that the colossal confluence of people which will take place on the occasion of the "World's Columbian Exposition," and the gigantic consumption of all articles of necessity and luxury that will result from this gathering, will react favourably upon German exports to the States, always presupposing that no cholera-epidemic comes to blast all reasonable hopes with a single stroke! But on account of this possibility the immediate future is regarded not without anxiety. The "Exposition" itself will doubtless throw into the shade all previous performances of this character. Its financial aspect, however, is calculated to raise serious misgivings, which already throw a shadow before. It is not astonishing that all imaginable sources should be tapped to assist in defraying the enormous expenses. But that even the available space for exhibits should be hawked out on the competitive plan among exhibitors, and that, in addition to this, the admission of exhibits should be hampered by all sorts of intrigues, are practices unworthy of so serious an undertaking, and which were unknown at previous exhibitions, that of Philadelphia included. The following is of interest as showing the scope of the work of the firm:—

The building of our factory at Miltitz near Leipzig, (to be used for the distillation of roses and other plants cultivated in the fields of that neighbourhood), which was begun last autumn, is now so far advanced that we can commence operations at the time of the flowering of the roses. In the following pages we refer to the specialities of this establishment. The experimental laboratory for the manufacture of perfumery and soaps, established by us last year, has fulfilled its objects thoroughly. It has been shown that by inaugurating it we have supplied a real want. Our scientific laboratory has been able to take a still more active share than previously in the results chronicled in the following pages. The strain upon all its available strength caused by the demands of current business was so great, that special arrangements became necessary to render the more expeditious publication of the available material possible for the future. We continue to look upon the careful study of the composition of the most important essential oils of commerce as our chief duty, for it is only by this means that it is possible to obtain definite results in the estimation of quality, in other words, the detection of adulteration. The pages of our Report show that considerable results have been obtained, and that there is a justifiable expectation of further success in the near future. Self-evident practical considerations have caused us to direct our attention in the first place to those important essential oils which offer sophisticators the widest and most remunerative field for their operations. It is to be hoped that after the lapse of a few years a similar reform will have taken place in the qualities of all leading essential oils as has been effected in Chinese Cassia Oil, which, by prompt and thoroughly convincing action, we have again restored to an

honourable position, and which now, all the world over, is judged and dealt in upon the basis of our quality-test.

From the references to the long list of Oils prepared, we quote a few paragraphs:—

ALMOND OIL AS AN ADDITION TO COCONUT OIL.—Three parts of Coconut Oil and one part of sweet Almond Oil, saponified with a soda-lye of 38° B., produced an excellent Almond-coconut soap lathering smoothly, and acting very pleasantly upon the skin. In washing, the soap shows the characteristics of a good fat soap, viz., smoothness and slight frothiness.

BETEL OIL.—This distilled oil, on the composition of which we reported in detail, from the results of our own investigations, in previous Reports, has unfortunately not yet excited any practical interest and continues to preserve the character of a curiosity. We have a few pounds of it in stock.

CASSIA OIL.—The statements made by us in our last Report (October 1892) concerning the origin of Cassia Oil have been repeatedly confirmed in the meantime. In the very interesting pamphlet:—"Report on a journey to Kwang-Si" by H. Schroeter, Hong-Kong 1887, the writer from personal experience reports as follows upon manufacture of Cassia Oil:—

"The shrubs destined for the production of the Cassia lignea proper are partly stripped during the summer months of their minor branches and exceptionally juicy leaves. They are then conveyed in huge bundles into the valley, where they are boiled in large vessels. From the aromatic juice thus obtained the esteemed Cassia Oil is recovered by means of a most primitive distilling-apparatus. (See illustration at the end of Report.) As the Li-kin stations on the road to Canton levy an excessive duty upon the oil, in addition to that exacted by the Imperial Customs, the oil is carried in tins across the hills to Pakhoi and thence transported, via Macao, to Hong-Kong, instead of reaching Canton by the water-way intended, by Nature, for its conveyance.*"

The centre of the Cassia-production is described as consisting of the Tai-Wo and Yung-Shun districts in the province of Kwang-Si and the prefecture of Lo Ting in the province of Kwang-Tung.

In the illustration joined to this Report, (a reduction of the original kindly presented to us by Messrs. Melchers & Co. of Hong-Kong,) which gives a faithful representation of the apparatus and utensils employed in the distillation of Cassia Oil, only the leaves of the Cassia-shrub are figured. The accompanying note in Chinese evidently refers to these. Unfortunately we have not been successful in obtaining a translation of the text before the publication of this Report, as the Imperial Chinese Embassy in Berlin has only condescended to answer our application for assistance in this matter after a delay of several weeks.

After these explanations the solution of the question as to the origin and preparation of Cassia Oil may be regarded as accomplished. The questions concerning the quality of the article are unfortunately not yet quite so clear. As we stated in our last Report, we had already at that time received information from China that oils of such a very low aldehydepercentage as 45 to 55 had again appeared upon the market. These oils are stated to be of thin consistency, pale in colour, and are declared to be perfectly pure by the Chinese. The latter maintain that fresh, imperfectly ripe raw material always yields such an oil, and as a matter of fact several months went by before normal Cassia Oil again appeared upon the market. Of course it was a matter of the highest importance to us to become acquainted with these oils of low value. We examined four parcels of them with the following result:—

			p. c.	sp. gr.
YEO TAOK,	Cinnamic aldehyde	61		1.066.
HING LOI TING	" "	44	"	1.066.
HING TAI	" "	46	"	1.066.
HING TAI	" "	43	"	1.065.

* These statements quite agree with those published as far back as 1892 in the "Journal of the Linnean Society."

All these oils were of thin consistency and pale yellow colour and, therefore, do not in any way differ in appearance from the best commercial qualities. Gross sophistications by means of resin, fixed oil or petroleum could not be proved. Unfortunately no thorough examination could be made in time for this Report. It goes without saying that similar oil was firmly rejected by the Hong-Kong houses, and probably only a little of it has found its way to Europe. It has chiefly, we hear, been shipped to the East Indies, where, as we know from experience, the chief stress in the purchase of essential oils is laid upon lowness of price, and where a proper discrimination of qualities is an exception.

The contention of the Chinese, referred to above, that young, immature raw material produces such an oil as here described, cannot be absolutely denied, as possibly a considerable proportion of aceto-cinnamic ether is present in the young leaves, from which, in the course of the maturing process, cinnamic aldehyde may be formed by oxidation. But we think it a more probable hypothesis that these oils of low value are prepared from other portions of the Cassia shrub, or from another variety of the species *Cinnamomum*. After the earlier history of the Cassia Oil question it will be admitted that we have no cause whatever to show great confidence in the Chinese, and we therefore propose to credit their assertions only after having convinced ourselves of their truth by distilling the raw material in question ourselves.

Under these circumstances careful control in Hong-Kong has become more urgent than ever. We take this opportunity of acknowledging that the Hong-Kong houses which learned from us the practical application of the cinnamic aldehyde test have acquitted themselves of this task with laudable zeal and dexterity, and have given us all the assistance in their power to carry out the reform of the Cassia Oil trade. The parcels of Cassia Oil imported by us since October last showed a minimum percentage of cinnamic aldehyde of 85, and a maximum percentage of 94.

Since the beginning of December arrivals of good, high-tasting Cassia Oil have again been received in Hong-Kong. It is asserted that, last season, the Cassia crop has yielded a considerably smaller result, and that this fact cannot fail to influence the production of Cassia Oil. At this moment prices are still normal. But besides this, the important stocks which have accumulated in Europe stand in the way of an advance in price, always presupposing that the reports of enormous damage caused to the Cassia plantations by the abnormal frosts (which reach us just before the close of this Report), are not confirmed.

CINNAMON OIL, CEYLON.—It is true that the quotations of the finer grades of Ceylon cinnamon have considerably advanced lately, but on the other hand cinnamon chips, which form the raw material for distilling purposes, have not, up to the present, been drawn into the movement, nor is there any danger that it will be possible to carry through an advance in the price of these. The exportation of cinnamon chips has experienced a fresh increase during the last few seasons.

The export-lists for the first months of the new year also show large figures.

The quotations for our finest heavy, sweet Cinnamon Oil are extraordinarily favorable. We consider it superfluous to call attention to the unsurpassed quality of our distillate.

OTTONELLA OIL.—Since our last Report no important alterations in price have taken place. The production, therefore, has trebled in the last decade. The low price has, of course, contributed chiefly to the colossal increase of consumption. As regards value for money this perfume is altogether without a rival.

LEMONGRASS OIL.—This East-Indian oil has kept its previous low price. Its use appears to be diminishing, although it is the only essential oil which resembles the popular verbena somewhat in odour without at the same time being so prohibitive in price.

MUSTARD OIL.—East Indian mustard seed, which has been obtainable at comparatively low prices, has provided a welcome substitute for the Dutch and Italian (Puglian) varieties, of which the quotations have been exceedingly high. We have also consumed several truck-loads of Russian mustard seed, pressed in cakes. The demand for genuine Mustardseed Oil has been particularly brisk, especially for Russia. It would not have been possible to satisfy it, if we had not refused to accept a number of orders on account of the limits being too low. The difference in price between natural and artificial oil is only small now.

NEROLI OIL.—During the last few weeks this important article has assumed an upward tendency, on account of the damage done to the orange trees by the severe frosts. Of course it remains to be seen whether the reports bruted about are confirmed in every respect. Still, it is a fact that fine grades have risen in price about 20 per cent. It is also rumoured that the proprietors of orange-gardens, discontented with the low prices which they have obtained for their flowers during the last few years, have formed a combination for the purpose of taking up the distillation of Neroli Oil and orange-flower water themselves. Every member of the ring is to deliver his entire output to the syndicate. The quantities which, under this arrangement, will be withdrawn from the control of the Grasse manufacturers are estimated at about 1,300 lb. of Neroli Oil and 135,000 gallons of orange-flower water. The price at which the syndicate propose to sell is Frs. 300.—per kilo (= about 7/1 per oz.) for Neroli Oil and 50 centimes per litre (= about 1/11 per gallon) for orange-flower water. Upon this basis the syndicate will be in a position to pay its members 65 centimes for every kilo of flowers, against an average price of from 35 to 50 centimes obtained during the last few years upon the open market, and, in addition to pay a dividend of 7 to 8 per cent.

This report also requires confirmation, but there is no doubt whatever that the success of such a project would place these manufacturers in Southern France who are not covered by contracts in a most embarrassing position. Our first thought upon the receipt of this information was that the carrying out of some such scheme as that suggested might assist in shedding some light upon the question of determining the quality of Neroli Oil, which is still involved in much obscurity. We are working continually at the solution of this problem, but we are obliged to possess ourselves in patience, as several years of research into our own and other distillates are necessary for the elucidation of the problem.

Of the great rose distilling industry we read:—

ROSE OIL (GERMAN).—The stock of our own distillate is quite exhausted and we are looking forward to the new crop with impatience. When this has been distilled we shall probably be in the gratifying position of being able to satisfy our numerous customers who wish to acquire large quantities. The researches that have been carried out in our experimental laboratory, show German oil to be preferable to Bulgarian, not only in general excellence, but also in strength and permanency of odour. Toilet soaps scented with equal quantities of oil of the two varieties afford proof of this. It is always important to place such facts on record, even though, in consequence of the still limited output, the trade at large cannot at present have the benefit of the German otto.

The rose bushes on our plantations have splendidly withstood the unusually hard and severe winter (during which the temperature fell as low as—13 deg. F. or 45 degrees of frost) and the general development of the plants leaves nothing to be desired. The many applications that have been addressed to us, as to the probable approximate quantity of German otto to be produced next season cannot, unfortunately, be answered definitely, as the rose-crop depends entirely, like all other agricultural products upon the state of the weather. According to our present know-

ledge the yield under normal conditions (*i.e.* if the weather is not too hot during the flowering) may be estimated at about 90 lb., and if the conditions should be unusually favourable it may even be much greater. Excessive heat during the harvest is here, as every-where else, the great enemy of the roses. A cool day, even a slightly moist temperature, is a *sine qua non* for a good crop of flowers and otto, and it is time to dismiss the antiquated superstition that the rose requires a tropical heat for its successful cultivation and the development of a fine aroma. In the Balkan-districts the temperature, in the course of the winter, falls almost year by year to 50 degrees of frost (Fabr.) and during the flowering period "cool weather" remains the ideal of the rose-farmer.

The factory for the preparation of our rose-specialities (Otto of Roses, Rose-water and Rose-pomade) in the centre of our rose-fields, approaches completion. This factory may, without exaggeration, be called unique. It has been our chief aim to avoid completely all accumulation of gathered roses. Immediately after collection the roses are consigned to the still, *i.e.* into the maceration-vat, and they therefore yield their perfume in its completest freshness and delicacy. In no other part of the world is sufficient attention paid to this important factor. In Bulgaria, for instance, part of the roses collected at dawn are not put in the still until evening, and it is notorious that in Southern France the flowers often remain piled up in heaps for hours before they are distilled. As our factory, as already stated, is situated in the centre of the rose-fields, we gather only the quantity of flowers immediately required for the manufacture of Rose-pomade, and within the space of a few minutes the flowers go from the bush into the prepared vat.

We have so many stills in readiness for the manufacture of otto that the roses will always go straight from the collecting basket into the still. The present capacity of our stills is calculated at a maximum daily consumption of fifty tons of roses, but we have already made the necessary arrangements to double the output at the smallest notice. Three containers with an aggregate heating-surface of about 356 square yards will generate steam. It will be patent to all who have inspected our works that the equipment of this new factory is in accordance with the severest technical requirements. Special attention is given to arrangements ensuring the minutest cleanliness in all departments, particularly in that of the manufacture of Rose-pomade.

Another paragraph of interest is the following:—

Through the kindness of the well-known co-editor of the "Pharmacographia indica," Mr. D. Hooper, (Quinologist to the Government of Madras), we received recently a small sample of the essential oil of the leaves of *toddalia aculeata* Pers. (N. O. Rutaceae) a shrub which grows wild on the Nilgiri Hills, and is locally known as "wild orange tree."

All parts of this plant have a pungent, aromatic taste. The root is used by the natives as a popular stomachic remedy under the name of "Malakarunnay." The ripe berries are employed as a spice, in the place of black pepper. The bark and leaves also are said to possess therapeutic value.

The oil is of thin consistency and pleasant odour resembling at once that of lemongrass and basilicum. Examination showed it to contain considerable proportions of Citronella-aldehyde (Citronellone) and along with this it contains an alcoholic principle which boils at over 200°. A closer examination was rendered impossible through want of material. The oil appears suitable for perfumery purposes and might become of practical importance if it could be procured at a moderate price.

We are glad to be able to seize this opportunity to express our sincere thanks to Mr. Hooper, who has always evinced the greatest interest in our work.

At the end of the Report there is a coloured picture given of a "a Chinese Still for Cassia Oil" in all its parts,

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, May 4th,

CINCHONA.—At the fortnightly bark-sales, held on Tuesday, a fair average quantity was offered. There were twelve catalogues, comprising:—

	Pkgs.	Pkgs.
Ceylon bark ...	984	of which 685 were sold
East Indian bark ...	1,820	do 1,198 do
Java bark ...	69	do 69 do
West African bark ...	191	do 77 do
South American bark ...	233	do 44 do
	3,077	2,073

The assortment was rather poor, the bulk of the Eastern barks consisting of ordinary *succirubra*, including one or two consignments of old import. At first the demand appeared fairly steady, but competition soon slackened and gradually the tone became more and more sluggish. Even the very moderate limits at which several parcels were held could not be reached, and the unusually large proportion of one-third of the supply was consequently bought in. The net result of the sale (which was generally anticipated) was a decided decline in value, the unit not averaging above 15-16ths d. per lb.—about as low as it has ever been—and nearly 10 per cent less than that of the last preceding auctions.

The following were the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Brunswick works ...	134,118
Agents for the Auerbach works ...	98,723
Agents for the Frankfurt O/M and Stuttgart works ...	72,000
Agents for the Mannheim and Amsterdam works ...	65,086
Messrs. Howards & Sons ...	35,092
Agents for the American and Italian works ...	24,557
Agents for the Paris works ...	10,430
Sundry druggists... ..	65,452

Total amount of bark sold ...	505,458
Bought in or withdrawn... ..	236,041

Total quantity offered ... 740,499

It should be borne in mind that the quantity of bark purchased gives no clue to the quantity of sulphate of quinine acquired by the buyer.

The following were the prices paid for sound bark:—

CEYLON CINCHONA.—Original—Red varieties: Woody and dull to fair bright quilly stem and branch chips 1½d to 2½d; a fine lot 3½d; dust 1d; fair to good bright shavings 2d to 3½d; common dusty root 1½d per lb. Grey varieties: Ordinary woody and dull chips 1½d to 2½d; fair shavings 1½d to 2½d per lb. Yellow: Fair chips 4½d to 4½d; good root 5½d per lb. Hybrid: Chips low and dusty 1½d to 2½d; shavings 3d to 3½d per lb. Renewed—Red varieties ordinary to fair chips 1½d to 2½d; fair shavings 2d to 3d per lb. Grey ordinary to good bright quilly chips 3½d to 5½d; good bright shavings 5½d per lb. Hybrid chips 3½d per lb.

JAVA CINCHONA.—Sixty-nine bags, trans-shipped via Amsterdam, of recent import, sold at 3½d to 5d per lb for fair Yellow chips.

WEST AFRICAN CINCHONA.—Of 191 bales, just imported via Lisbon, the greater part was bought in, only two parcels, sound bark of *Succiruba* character, in broken, rather irregular quill, selling at 3d per lb. and damaged ditto at 2½d to 2½d per lb.

SOUTH AMERICAN CINCHONA.—The only variety of South American bark offered was cultivated Bolivian *Callisaya* of which 234 bales were shown. For fair medium broken quill an offer of 5d per lb was refused; a somewhat duller lot sold at 4½d per lb.

COCOA-BUTTER.—Three hundred 2-cwt. cases of Cadbury's cocoa-butter sold by auction on Tuesday at from 13½d to 13½d per lb.

INDIARUBBER is dull of sale, with business in fine Para at 3s 1½d, and afterwards at 3s 1d per lb on the spot.

TEA IN JAPAN.

Researches on the manufacture of various kinds of tea. Bulletin of the Imperial College of Agriculture and Dendrology. By Y. Kozai, Assistant in the Agricultural Chemical Laboratory. (Tokio, 1890.)

Y. Kozai is a Japanese chemist who performed his researches under the control of Dr. Kellner, the Director of the Chemical Laboratory at Tokio. His paper includes the chemical constitution of tea, the effect of tea on mankind, the principal methods of manufacture employed in Japan, and the methods of preparing tea for consumption. These subjects are

all treated mainly from the point of view of the analytic chemist. The author appears fairly well acquainted with what the German chemists have done in the matter of tea.

We need not abstract much of his account of the constitution and properties of tea, as it is largely taken from European sources. "The chief action of tea, after it has got into the blood, is to excite the nervous system, it thus harmonizes the mind, drives out drowsiness, and awakens thought, stops hunger, and oures reptition, refreshes the body, and prevents headache"—and (it might be added) if taken too strong keeps you awake half the night. As to its constitution, tea contains (besides the common plant-constituents) theine, a volatile oil, and tannin. Theine is a rank poison, in toxic doses causing convulsions and paralysis, in lethal doses death, but in small quantities is (like strychnine) a delicate tonic. Of the volatile oil, Y. Kozai can affirm little beyond its well-known exciting action upon the organs of taste and smell, nor is it easy to follow it analytically through the processes of manufacture, the hot steaming employed (at near boiling temperature) in the green-tea manufacture does not appear to diminish the volatile oil sensibly, though Y. Kozai intimates that preparing green tea by boiling does dissipate the aroma. As to the properties of tannin, it is an astringent remarkable for its strong affinity for the albuminoid, hence if taken in excess, it may, by precipitating the ferments of the digestive fluids, cause indigestion.

The account of the chief Japanese methods of manufacture is of more interest and instruction to the European planter.

We may premise that there are two (main) kinds of tea, viz. black and green. In the manufacture of black tea there are four essential processes viz. (1) withering, (2) rulling, (3) fermenting, (4) drying. In the manufacture of green tea, the fermenting is omitted, and in Japan (for some kinds of green) the rolling also.

For the manufacture of black tea there is no real difference between the Japanese method and that practised by English planters in Bengal. The fresh picked leaf (*i. e.* tips of the young shoots) must be first withered, or the petioles and leaves break under the rolling, the exposure of an hour or two in strong sun withers the leaf sufficiently, if there is no sun the leaf must be withered by the aid of fire-heat. The rolling is done, even in Japan, by the aid usually of a box, and in Bengal often by a steam-power (and very roughly). The juices are thus expressed, and the leaf given a "nice" twist, *i. e.* a twist pleasing to the fancy of the tea-purchaser. What perhaps renders rolling so essential in the manufacture of black tea for it is not essential in the manufacture of green), is that it masses the leaf in a state conducting *without delay* to fermentation. Neither Y. Kozai nor the best Bengal authorities like to lose the juices more than can be helped. He also hazards the view that, by rolling, the juice is expressed from the cellular tissues of the leaves and impregnated upon their surface thus is produced fine aroma, and the leaves are more easily infused. Fermentation is the most important point in the manufacture of black tea, and by it (*vide* Y. Kozai) the leaves lose their raw smell, and the tea acquires its fine flavour. The fermentation is really only carried a very little way. Y. Kozai says it should be allowed, in a temperature of 104° F., to proceed only for about an hour. He thinks the process is a true fermentation, because if permitted to run too far the tea acquires an acid taste. He thinks it probable that the ferment is caused by a living organism, but he adduces very slight ground for this opinion and it has, in fact, been questioned whether there is any true fermentation in the process at all. But the English tea-makers are agreed with the Japanese in the importance of stopping the fermentation exactly at the proper point by drying the tea which is usually done by placing it first in the sun and turning it over till it is fairly dry, and then thoroughly drying it by fire-heat.

The result of all the Bengal experience is that the black tea is at least as good when these four processes are done simply and rapidly, as when much labour and time are expended in complicating them. In the early days of tea manufacture by Anglo-Indians great pains were taken to imitate with tedious minuteness the careful hand-processes (and repetitions of portions of the processes) as practised in China, but all planters now follow rapid short cuts to the finished tea.

The manufacture of green tea is nothing more than drying the leaf. It is so little practised in British India as to be of no commercial interest there, but Y. Kozai describes in detail three kinds of green tea manufactured in Japan.

1. *Japanese (not China) green tea.*—In this, the leaf is steamed in order to remove the raw flavour. It is then rolled and fire-dried, the two last processes being usually done together.

2. *Chinese green tea.*—In this, the leaf is roasted (while stirred with a stick) in an iron pan over a fire, then rolled a little, then roasted again, these processes being repeated even six or eight times, and the tea is then finally dried off.

3. *Flat tea*, the highest class tea of all. For this tea, the shrubs are usually kept shaded for three weeks before picking, so that the leaf is partly etiolated (bleached). The choicest leaves are selected before the manufacture is commenced. They are steamed, but never rolled nor, indeed, touched by hand at all, but carefully turned by aid of a bamboo stick. After sufficient steaming they are simply dried.

The author finds by analysis that there is 30 per cent more theine in etiolated leaves than in the leaves of the same plants grown in the light. He tried many experiments to test the chemical effect of the manufacturing processes. Among other tables given by him is the following:—A quantity of leaf was divided into three portions, whereof one portion is A, another portion is manufactured into green tea B, the third portion is manufactured into black tea C. Y. Kozai analyses A B C and finds:—

	A	B	C
Crude protein	37.33	37.43	38.90
Crude fibre	10.44	10.06	10.07
Etherial extract	6.49	5.52	5.82
Other nitrogen-free extract	27.86	31.43	35.39
Ash	4.97	4.92	4.93
Theine	3.30	3.20	3.30
Tannin	12.91	10.64	4.89

He remarks that the general result of the green tea manufacture is merely to dry the leaf, the black tea manufacture alters materially its chemical constitution. The principal change is the remarkable diminution of the tannin. He does not explain how this is brought about, nor is it easy to see how the incipient fermentation should affect the tannin.

The only teas exported to Europe from Japan are of low class, they are frequently "faced," and sometimes mixed with the leaves of various Japanese plants. Any plentiful leaf, not too unlike the leaf of tea will do for this adulteration, the leaves actually employed are (Y. Kozai assures us) all harmless and several contain tannin, but none of them any theine. As to the "facing," he says it can hardly be called adulteration; the quantity of Prussian blue employed to improve the appearance of green tea is (according to Y. Kozai) about 0.001 per cent the weight of the tea, perfectly innocent, and pleasing to the purchaser.

The author concludes with an account of the different ways of taking tea in Japan with some analyses of the prepared liquor.

1. In the case of flat tea, or of the very finest quality of Japanese green tea, the tea is ground to fine powder, and the whole infusion drunk.

(2) In the case of superior (*i. e.*, from the Japan point of view) tea, the leaves are infused for two minutes in water at 120° to 150° F.

(3) In the case of a medium tea, the leaves are infused for one minute in boiling water.

(4) In the case of inferior tea, the leaves are boiled in water.

The object to be aimed at in the preparation is to get the largest possible quantity of theine without dissipating the aroma, and accompanied by only a moderate amount of tannin. Y. Kozai gives analyses to show that this is effected (in the case of superior teas) by the infusion in water at 120° to 150° F., for two or five minutes. By superior tea, he understands worth five to seven shillings a pound in Japan. It is probable, therefore, that the highest class teas we ever have to deal with in England comes under the medium teas of Y. Kozai, which require infusion in boiling water for one minute at least. The majority of English people like a good deal of chicory with their coffee, and probably a majority also like a good deal of tannin with their tea and to them the analyses and recommendations of the Japanese writer are of small importance.

The paper will be of more use as food for reflection to the Anglo-Indian planter than as direct instruction. The palate of the Englishman is as yet only very roughly educated in tea. There can be very few Englishmen who would greatly prefer the superior teas of Japan and China to the ordinary Kumaon or Ceylon tea; most persons used to drinking the latter would probably prefer it to the most expensive tea made, say China tea worth 40s per pound in China. The English planter in Bengal has a tea garden of 200 acres (possibly still larger). His object is, by the aid of a steam-engine or other coarse help, to put his tea through, to keep his factory clear when he has a strong flush on. He has to carry the daily make through by the aid of uncivilized labourers and overseers. He must reduce every step of his manufacture to a routine, he must have no special tea separately and differently manufactured, and no current experiments. Few planters have made much profit by pekoe, and the green tea hardly exists commercially in India. There are no doubt many Englishmen who, having not a plantation, but (literally) a garden with some tea in it in India, have manufactured, not unsuccessfully so far as the flavour of the tea is concerned, green tea, pekoe, etc., but this has been a fancy article for their own drinking or for presents, and has never been put in any quantity on the market. To plant successfully in India, the Englishman has to proceed on a broad scale, his large cost and high expected profit cannot be got out of the close of superintendence of elaborate hand manufacture. Or, at least, it will be a long time before the public tea taste at home is sufficiently elevated to be willing to pay so large a price for such teas as would remunerate the English planter. For the present the object of the planter must be to produce the maximum quantity of tea that the English grocer can sell at 1s 6d to 2s 6d per pound. Hence to planters the utility of the paper of Y. Kozai must be mainly future.—*Nature* p. 12190. June 5, 18

HORTICULTURAL NOTES.

Bone dust and wood ashes will supply everything lacking for strawberries as a fertilizer.

Seed may be tested by putting them on a flannel cloth, covering them with another cloth and keeping them moist.

Pull herbs when dry and in their first blossom, hang in bundles, head downwards in a dry attic. If sun dried they lose some flavour. When you have spare time, strip the leaves from the stalk, powder finely, put in labelled tin boxes or glass jars with close-fitting covers.

Sodium prolongs the period of plant growth, not in the sense of lengthening the season of growth for the plant, but it makes the maturity of the plant less rapid.

Iron is essential to the healthy growth of plants. Without it the leaves lose their greenness even in the sun, and death ensues.

Sulphur is a necessary constituent in the formation of albuminoids, without which no plants can grow. Give the children each a fruit tree and get them

interested in horticulture. Let each one attend to his own tree and have the fruit it yields.

FRUIT TREES AND POULTRY.

There should always be fruit trees in the poultry run. They provide shade and shelter from rain for the fowl, and the fowl pay for it by enriching the soil, by keeping down the grass and weeds and by destroying insects. It is about the only place where plums can be grown, but it is also favourable to the pear or quince tree, if not shaded by buildings or larger trees.

SULPHATE OF IRON AND PLANTS.

Professor Sachs, of Wurzburg, asserted, and the Royal Institute for fruit and vine culture at Giesenheim has tried experiments and is apparently satisfied that sulphate of iron is a valuable stimulant to plants that are suffering from chlorosis, or absence of the proper green colour. They gave small trees 2-1.5th lb of copperas, and large trees 4 and 2-5th lb. The results, it is said, were most gratifying. Strange to say, in some cases where the trees were suffering from the attack of aphides as well as deficiency of colour in the leaves, the aphides disappeared, and frequently the leaves became healthy within a few days after the treatment. The sulphate of iron was dissolved in water and applied near the roots. Early spring is the best time to try the experiment. Some soils do not require the addition of sulphate of iron.

POTASH AND BONE.

The usefulness of nitrogen and phosphoric acid in slowly available forms, as they exist in bone, has been amply proved in practice, especially for slow-growing crops, in orchards, meadows, and in such other cases where a gradual increase in general fertility is regarded as important. A mixture of fine ground bone and muriate of potash, in the proportion of three parts of bone to one of potash, is used quite largely, and has proved a very effective and profitable manure for general use in grain farming. It furnishes all the essential ingredients, it costs less per ton than the average complete fertilizers, and it contains quite as much nitrogen and very much more phosphoric acid and potash. Under the present condition of the fertilizer trade and for purposes indicated, the substitution of ground bone, in part at least, for the more expensive though more available complete fertilizers, is in the line of wise economy.—*Horticultural Times*.

ON THE WEST AUSTRALIAN FAN PALM.—Baron von Mneller, in the *Victorian Naturalist*, November, 1892, says:—"It has been known since the discovery of the Hammersley Ranges, fully thirty years ago, that a Livistona Palm occurs on the Mill Stream there, isolated from any other species of that genus; but incomplete specimens led to the surmise that this Palm might be identical with Livistona Marise, a species restricted to the Palm Glen and several valleys of the Macdonnell Ranges in Central Australia. The last-mentioned Palm we know now through Mr. J. Edgar, of the Rockhampton Botanic Garden, to be while, in a young state of cultivation, much more robust and upright in foliage than L. Australis, besides the leaves at the early age of the plant being of a 'rich bronzy colour.' I have always found transmitted fruitlets considerably larger than those of the genuine L. Marise, and further some minor differences exist also in the flowers of the two species, as recently ascertained. The West Australian Fan Palm has, therefore, now been named L. Alfredi, in honour of H.R.H. the Duke of Edinburgh, at whose nuptial festival the Central Australian Palm was dedicated to the Princess Marie of Russia. What applies to many other Palms holds good also for L. Alfredi, namely, that the leaves are more strongly spinous in the young than in the aged plant. Mr. Beresford records this Palm now also from the Fortescue River and its tributaries, from the sources of the Robe River, and from Cave's Creek."—*Gardeners' Chronicle*.

COCONUT CULTIVATION IN CEYLON.

We direct attention to the very valuable notes for young coconut planters given below, compiled and placed at our disposal by "W. H. W."—initials which will be readily recognised as those of one of the most successful planters in the island. How he has made his Mirigama property so great a success will be at once understood after perusing his instructions to all who wish to follow his steps and have a thoroughly satisfactory coconut clearing and plantation of their own. How very differently many planters have acted is only too evident in what we see in many directions even in regular plantations; while native gardens are in the majority of cases planted after the most haphazard fashion. One exception to the rule in the case of small gardens was that for which we quoted statistics the other day and to which our esteemed correspondent "Polgaha" makes reference elsewhere. The garden in question is situated opposite the Mount Lavinia Hotel and was originally planted with very great care some time in the "forties" under the supervision of the Rev. J. G. Macvicar, the learned and accomplished Scottish chaplain of that day. Mr. Macvicar bought Mount Lavinia from Government (as a great bargain) and going to reside in it, he, in his leisure time, gave attention to planting the 14 acres of waste land opposite with coconuts. Very vividly did the chaplain's daughter, Mrs. Green—who has just gone to England—lately recall the scene to us when as a very little girl, she watched her father's careful selection of the nuts (after the fashion prescribed by "W. H. W.") for his servants to put in the nursery. The garden is on fairly good soil, much of it cabook, and it has been favoured with washings from the high road and higher land for many years. The trees which have yielded the average of $5\frac{1}{2}$ nuts each per annum for the past ten years must now be about 45 years old. "Polgaha"'s own experience is of special interest: he gives returns for the two best fields on a valuable plantation and the result is an average yield of 47 to 48 nuts, while the profit in a good year like 1892-93 reached so satisfactory a figure as £130 an acre. What more could be wished? Tea, no doubt, in special cases does better; but considering the comparative permanency of the two industries, such coconut land, we suppose, ought to be worth double the value of tea land yielding the same profit per acre? In this connection, we call attention to the information respecting the use of coconuts in Uva afforded by our correspondent "Viator."

COCONUT CULTIVATION.

HINTS TO THOSE ABOUT TO OPEN LAND UNDER COCONUTS.

Suitable land for coconuts having been purchased, it would, in my opinion, be very unwise to commit the common error of clearing it at once. One's first care should be the selection of nuts from well-grown, healthy trees whose branches do not droop or show a tendency to fall off prematurely; the nuts should be large and heavy with a full kernel. So strongly am I of opinion that a careful choice of nuts is most essential, that I would recommend paying £10 or 15 more per 1,000 than the rates ruling, in the districts where you buy, for the privilege of being allowed a free hand in their selection. On deciding what nuts will suit you, send your men once a month to pick one bunch from each of the selected trees; and when picking, each bunch must be lowered to the ground by means of a rope, or the nuts picked separately and dropped down one by one carefully.

When you have the requisite number of nuts for the acreage you intend opening, prepare your nurseries; the soil should be turned over well and burnt before levelling. Set the nuts close to each other, and in a slanting position; shade them from the sun, and water during dry weather. The nuts will germinate within four months from date of putting down, and if at the end of five months there are any which show no signs of growth, reject them, for they will never make healthy trees. When the seedlings are from 2 to $2\frac{1}{2}$ inches high transplant them at intervals of 18 to 20 inches in another nursery, where they would have more sun; ashes applied lightly after transplanting will help the growth of the plants greatly. The plants when twelve months old will be big enough to put out into your clearing, and sufficiently strong to withstand the attacks of white ants, one of the most formidable of enemies of the young coconut plant. On removing the plants from the nursery, carrying them by their branches must be strictly forbidden, as want of care in this respect is very likely to result in injury to the "cabbage." May being a wet month is the best time of the year for planting.

In getting your land ready do not stint money on holing, the holes should be cut 3 feet square and 3 ft. deep and lined 28' x 26'; burn as much wood and rubbish, as you can get in the holes, and fill in with surface soil till they are 18" deep when you should put down your plants, after trimming the roots carefully, and press the earth down firmly round the nut. In undulating land terracing is very desirable, while all ant-hills should be levelled to the ground and the earth from them applied to the adjacent coconut trees. There are 66 plants to the acre, but in your nursery it will be as well to allow an average of 80, so as to provide for supplying vacancies caused by drought, white ants, beetles, lightning, &c.

After planting give out your land on contract to native cultivators (goyiyas) for three years for the purpose of raising potatoes, cassava, &c.; in return for your granting them this privilege they must keep the coconut holes free from weeds and grass, and if they fail to do this they must submit to the forfeiture of one-half of the crops they raise. The goyiya must also undertake to report the destruction of any plant so that the vacancy may be filled immediately after the first rains. No vacancies should be allowed to remain unsupplied, as a property is greatly lowered in value by the presence of gaps.

As I have said the ill a coconut property is heir to are:—drought, white ants, beetles and lightning.

Of beetles the worst is the red kind (Sin. Kandapanwa). Any tree attacked by this fearful pest must at once be rooted out, chopped into pieces and burnt without allowing any of the insects to escape; the remedy here is very drastic but there is no other, and if the one I advise is not adopted the result will be the scattering broadcast of a perfect army of destroyers to ravage not only your own, but your neighbours' estates. I have myself made it a point to find out and burn trees attacked by *Kandapanwa* anywhere within two miles of my property; when a case is brought to my notice I send my own coolies to the spot to cut down and burn the tree, and as compensation for saving my neighbour farther loss I make him a present of 50 cts.

When a tree has been partially struck by lightning, steps should at once be taken to bleed it and the surrounding trees by boring holes at their bases with an anger, by which means a large percentage can be saved. Any tree, however, that has been irretrievably struck by lightning should at once be cut down and burnt to prevent the breeding of *kandapanwa* within it.

Drought.—I do not water any plants when they are once put out in the field; they should be planted during the May rains. I only water them when they are in the nursery and the plants are generally one year old where they are put out.

Again, I lose very few plants by white ants; there are sometimes places where they destroy them often, and in such places I put in 2 years' old

plants. Be careful in such holes not to allow any grass or weeds to be put in when filling them up.

I may mention that there are about 30 different kinds of coconuts and I do not as a rule prefer to get nuts for the nursery from any one district. I have seen very good nuts got from Veyangoda, from Negombo, Mirigama and Colombo. I get them from selected trees, not younger than 20 years' old, let the nuts be large and heavy, as I said before, with a full kernel.

In reply to the question as to the average yield of a coconut tree I may mention that during my experience I have seen trees which have borne 100 to 150 nuts each per annum; the yield of course depends on the nature of the soil, the locality and the manner of cultivation. I have recently visited an estate of about 150 acres in the Chilaw district which I valued at R1,000 per acre, and I was told by the owner, who has refused an offer of R1,200 per acre, that he gets over 100 nuts per annum on an average from each tree.

Land cleared and planted by me in May 1887 is now in partial bearing, 200 trees have borne a crop, from which copra was made and sold.

Kandangomwa Mirigama.

W. H. W.

A PLANTING REPORT FROM AN EARLY "PIONEER":—

ALL ABOUT "TEA" IN THE KELANI VALLEY, BY ONE WHO GREW COFFEE IN THE "FORTIES."

RUANWELLA, 22nd May 1893.

Regular monsoon weather alternating short sharp shower, slow drizzle, short blinks of sunshine, with an average daily rainfall of $\frac{3}{4}$ of an inch. Everything outside dark and dripping, everything inside damp and mondy. Flush falling off, but leaf accumulating in the withering houses. There was only a light flush in January and February; but in March, April, and the first half of May it was too rapid for the labour force to keep well in hand on most of the estates in this section of the valley. The teas made during this weather will mostly be defective in quality, and some compassion is due to the managers on the score of the "stinkers," due when they reach the market.

This section of the valley is perhaps not the most fertile portion as a whole, but it has within it some very productive fields, and even the oldest show no signs of falling-off. As the roots run to a great depth, they take in a wide foraging ground, and will continue to thrive for long years after the surface soil has been carried off, and the higher lateral roots are exposed above ground. Whatever the cause however, it seems certain that some of the oldest fields are still the best; but it is equally certain, different estates yield very different rates, and even different fields on the same estate, only separated by a ravine, give crops of from 50 to 100 per cent more on one ridge than on the other adjoining, and keep the same proportion year after year. Thus in low-country estates there appears to be no uniform suitability of soil, and to be situate in a generally fertile district, is no guarantee of value.

There can be no question about the general stability of the Ceylon Tea Industry; at least during the life of the present generation. It is true that the margin of profit, draws very near the vanishing point to many struggling properties, and any further fall in price will put the closure on the weakest; but the aggregate annual produce will not diminish, so long, as one penny per pound of profit can be realized. There is not the least chance of a general rise in the price of Ceylon tea; the conquest of new markets, is a slower process, than the measure of production, and even, if victory should be achieved all along the line there is never likely to be a time of deficient supply. Both India and Ceylon, could in a few years double their yield even at present rates, and would do it if encouraged by an increasing demand. There are few plants that would flourish over a wider range of the earth's

surface than tea; but only the lands, that can command cheap and abundant labour can command the markets of the world. It is impossible to decide, what places China and Japan would take, in a free and fair competition; but for the present, all the advantages are on the side of India and Ceylon. If the United States should succeed in producing tea at a cost of half a dollar per lb. they would no doubt shut us out by a $\frac{2}{3}$ dollar duty, but that time is not yet.

W. B. L.

[Well done "W. B. L." who is now, like Her Most Gracious Majesty, in his 75th year; may his shadow never grow less.—Ed. T.A.]

NOTES ON PRODUCE AND FINANCE.

THE FLAVOUR OF CEYLON TEA.—Messrs. Hawes and Co., in one of their market reports, recently called attention to the absence of choice flavoured Pekoe teas of Ceylon growth, whereupon Mr. Arthur C. Isham, writing from Clipstone, Northamptonshire, to the *Morning Post*, makes the following comments:—"In today's *Morning Post*, under the heading 'Produce Markets'—Tea—your correspondents, Messrs. Hawes and Co., report:—'It seems that Ceylon can no longer produce the choice Pekoe-flavoured teas that the island became famous for a few years ago.' As a tea estate proprietor, I want to know what this means. Ceylon has only produced tea in large quantities for a very few years, and yet the public are induced to believe that soil, climate, and the skill and energy of the planters are waning. I think Messrs. Hawes and Co. should at once qualify this remark, otherwise they will injure the Ceylon tea trade, which, to say the least, is worthy, from its extraordinary and rapid development, of every assistance on the side of truth that any trade reporters can give." Messrs. Hawes and Co. reply in the following letter:—"In reply to Mr. Isham's letter in your issue of today, we regard with regret the fact that, as a Ceylon tea proprietor, he has not followed the course and general reports of a market he is apparently so interested in as closely as he might have done, or he would not want to have the meaning of our views explained to him. It is the very truth of our report that probably he takes exception to; but, nevertheless, all dealers in Ceylon teas here will endorse the opinion expressed by us, 'that the general quality of Ceylon teas has steadily declined the last few years.' If Mr. Isham will call at our office we will fully convince him on this point, but cannot occupy your space by giving him a public education. The truth written on any article may influence its position in the market, and rightly so. We should be the last to write without good reason anything against Ceylon tea, we being personally largely interested in its success, and this falling off in the quality is a matter of serious concern to us as brokers and to all dealers in the article. Many Ceylon planters say that as much fine tea as formerly can be produced now, but it appears to pay the planter better to make a greater quantity at a lesser price rather than a smaller quantity at a higher price, as common teas are relatively very dear. We maintain, however, that this policy, although temporarily being more profitable to the growers, is entirely mortgaging the future of Ceylon teas."

TEA BULKING IN BOND.—A Cork tea merchant, Mr. J. N. Knott, has sent to the newspapers some correspondence which he has had with the Customs authorities with reference to blending or bulking tea in bond. Mr. Knott, having discovered a discrepancy between several chests of tea received from London and the samples from which he bought, discovered that the difference between the chest tea and the samples was due to the "bulking" of various qualities after the samples had been abstracted and sent out to the merchants. A personal investigation in the London warehouse where his tea was stored and communications from the Customs authorities confirmed this view. Two documents were received from the Board of Customs by Mr. Knott, "General Order 64, 1892," allows impor-

ters and brokers to "bulk" tea in bond in the case of lots not exceeding twelve chests or thirty boxes, even though the teas had arrived by different ships and from different gardens. In such cases the garden marks on the boxes should be obliterated, and the words "bulked" or "blended" put on instead. In the case of the bulking of teas from the same gardens, no indication need be placed on the chests to show that they have been touched. The dealers deny that any bulking takes place. One dealer writes:—"We cannot touch package that has not been duty paid, nor can any person, except the Customs officers, handle the same package." But the Customs regulations specially refer to the "bulking of teas in bond," and, as a matter of fact, the Secretary of the Customs Board writes under date of the 25th ult. informing Mr. Knott that "an order was signed for the bulking of packages" sent by the very firm whose statement has just been quoted. In the same letter from Mr. Prowse, the Customs secretary, it is stated that, "beyond seeing that the regulations of the department were fulfilled in the actual operation, the officers were not concerned in the matter." From his experience Mr. Knott concludes that the only way to protect merchants from being victimised is to insert on the "permit" given when the duty is paid the fact whether the tea has been "bulked" while lying in bond, with the date of the operation. The dealer could then see whether the "bulking" took place before he got his samples or afterwards.

COFFEE MIXTURES.—Grocers are not enamoured of Dr. Cameron's Sale of Food Act Amendment Bill, whereby he proposes, with regard to the sale of coffee and chicory, that the percentage of admixture shall be stated on the label. The coffee trade section of the London Chamber of Commerce have considered this matter, and have passed the following resolution:—"That this section of the London Chamber of Commerce hesitates to support the proposal to make a declaration of proportions of coffee and chicory compulsory, on account of the difficulty of proving what proportion of each substance a given mixture contains, and also that the proportions themselves are no guarantee of the value of the mixture.

HOLLY TEA.—Paraguayan tea or Yerba Maté is pretty well known. A writer in *Chambers' Journal* describes the four species of holly used in the New World as a herbage. These are "Ilex Paraguayensis" in South America, "Ilex gongonha" and "Ilex theezans" in Brazil. "Ilex Paraguayensis," Yerba maté, or, as it is sometimes called, Paraguay tea, is yielded by a tree twelve to twenty-five feet in height, very leafy, and which at a distance bears some resemblance to an orange-tree. It grows wild in large natural plantations in Paraguay, and also in various localities between the rivers Uruguay and Parana. It is supposed, also, at one time to have been indigenous to Brazil. Yerba maté has been in use among the South American Indians from time immemorial. Maté is sometimes drunk in the same way as we take tea; but the more usual method is to suck it through a tube, after the fashion of American drinks. Gourds are often employed as cups, and these may be tastefully mounted; and the tube or hombilla, which is furnished at the lower end with a perforated bulb or strainer to prevent the leaves entering the mouth, is often made of electro silver. The taste for the infusion is very soon acquired and once the habit of taking it is formed, it is very difficult to break it. It is extremely refreshing and restorative, especially after great fatigue has been endured, and many travellers have testified to its value under these conditions. It is also said to exert a beneficial action upon the internal organism, which tea and coffee are incapable of doing. The North Carolina species ("Ilex vomitoria" or "Ilex cæsiue") was a most important plant at one time, as is evidenced by the fact that every traveller of repute that has visited the country has made mention of it. In addition to being used as an ordinary beverage with milk and sugar it was at times partaken of by men only, with great ceremonial and awful invocations. Why it has fallen into disuse as a beverage it is difficult to surmise

Possibly its odour and taste, which are not so pleasant as in the fragrant tea of China, Ceylon, and India, has something to do with it. It is said to be cheaper than these teas; but we are afraid that this advantage will scarcely be discovered. In the Argentine and the adjacent countries mate-drinking is quite an institution. Although there are said to be about forty thousand square miles from Virginia to Texas upon which the plant grows, we fear it will never recover its ascendancy in popular estimation.—*H. and C. Mall*, May 12.

COFFEE PROSPECTS IN THE STRAITS.

The price of coffee continues to be high; and from Borneo, from the Malay Peninsula, and from French Indo-China comes news of coffee estate extension. It was only the other day that we referred to an innovation in the working of a coffee estate in Malaya, an innovation which, if it answered expectations, would show that there is more gold in coffee than in the average gold mine. The picture was fanciful, and only the bright side was presented. People have yet in their minds the incalculable suffering which fell upon Ceylon through the failure of coffee, while there are yet other circumstances outside the realms of fungi that make the life of the planter not altogether happy. Putting aside all the dreams of wealth, and the comments upon the probabilities, it is remarkable how well the coffee planting industry is now progressing in Malaya. On all sides we hear of good crops or how well the crop is coming on. The Straits Liberian coffee is of such good quality that applications for seed come in from the foreign countries in the neighbourhood. Tonquin, French Indo-China, has already received a consignment for planting purposes. We understand that the seed supplied to Tonquin came from Johore where the coffee is particularly free from leaf disease, an essential element in rearing coffee trees. The country in Johore is being more taken up for coffee; and, in Muar, there is springing up a demand for good seed coffee. In Selangor and Sungei Ujong, the former a most important country for this article of the table, coffee is reported to be doing exceedingly well as it is in other parts of the Native States where the soil has been found suitable for its life. The prospects for coffee planting in the Straits and Native States are good. Planters cannot be said to be laying themselves open to the danger which threatened and crushed Ceylon. Malayan coffee estates are not closely locked together, but are indeed wide apart and neither is the whole country thrown open to coffee only; so that should the monster fungi, or other similar disease, put in an appearance, it can only affect one or two estates at the most. Planters have good reason to be grateful for the rising market which is mainly due to short crops elsewhere. The outlook for Straits coffee is bright.—*Straits Times*.

MAROCQUEE (COFFEA ST.)—This superior Brazilian Coffee, a plant of which was introduced by the Acclimatisation Society of Queensland four years ago, continues to thrive admirably, and is at present showing signs of an excellent crop. The plant is now 9 feet high, with a spread of 6 feet 6 inches of the lower branches; in habit it much resembles the Liberian Coffee, the foliage being much larger than the Arabian sort. Last year's crop of berries was all sown, and about a dozen and a half of plants will be available for distribution in the spring. About 300 berries are already set on the plant, and about a similar number are in younger stages of development. Six grafted plants were sent out last year, but up to the present no returns have come to hand as to the success attending their growth. In good soil this Coffee should produce good results. The ground at Bowen Park, although rich, is not of sufficient depth to fairly test the plant's capabilities; but it is hoped that with some of the young plants being at present raised, experiments in more favoured soils and situations will prove this new Coffee to be a most profitable cropper.—*Gardeners' Chronicle*,

CALIFORNIA.

Mr. W. Laing Malcolmson of Aberdeen, whose experiences as a fruit-grower in California we gave in our issue of March 11, sends us the following supplementary details:—I mentioned that I had known "many instances of men landing in California without any other capital than their own labour, and working themselves (with the aid of a wife) up to such a position as to be able, through their savings and economy, to own an orchard or a vineyard within a few years of their arrival." These instances (which I could enumerate in detail) are cases of men who had been brought up to field work, and who within a few hours of their arrival in California could command immediate work at from £5 to £6 per month and their board; whilst, if they had a wife, she could command from £4 to £5 per month as a domestic servant. For the ordinary clerk, artisan, or mechanic, there is practically no work in California, as there are more labourers of this class in that State than there is work for.

From the correspondence I have received from those with a little money, and who, I think, would form splendid colonists, let me select a letter received a day or two ago; and in answering it, I will cover much of the ground of other inquiries which have and may be made of me. The writer says:—

1. "In what condition is the unbroken land?"
2. "What can the waste land be bought for?"
3. "What could land stocked with fruit trees, and bearing a fair return, be bought at?"
4. "Could you advise a person (who has money) to buy a going orchard that has had no experience in fruit-growing?"
5. "Would persons who have a young family and a few hundred pounds be successful settlers in California?"

I shall now answer for the benefit of your readers these questions as follows:—

1. "In what condition is the unbroken land?" The answer to this is, that generally the land in California suitable for fruit growing is level and of the richest description; no stones, shrubs, or trees; soil usually alluvial deposits, easily worked, and splendidly adapted for irrigation purposes.

2. "What can waste land be bought for?" Land suitable for fruit growing cannot be got for much less than £20 per acre, and may be as high as £50 per acre, according to situation and other facilities, although there might not be probably much difference in the quality of the land itself.

3. "What could land stocked with fruit trees, and bearing a fair return, be bought at?" This depends on the position of the property, its improvements, and its age; also the class of orchard. Orange groves bearing a net annual return of £200 per acre would, in proportion, be more than a young orchard or vineyard only a few years old; this question is difficult to answer.

4. "Could you advise a person to buy a going orchard that has had no experience of fruit growing?" Hundreds come out to California who have money, and rather than wait until an orchard comes into bearing, purchase an orchard or vineyard right out, and derive a handsome return from their investment. It is not necessary to have any experience in fruit-growing, as experienced help or assistance can be easily procured.

5. "Would persons who have a young family and a few hundred pounds be successful settlers in California?" There is only one answer to this. Most decidedly, yes.

I should like to mention also that I know of a property in California, situated in, perhaps, the best position of the State, known as Chino. The owner of this property, Mr. Richard Gird, has had lately erected on his property—which extends to some 55,000 acres—one of the largest sugar beet factories in the world. The settler on this property can, after he has planted his orchard, utilise the space between his trees for Beet growing, so that he can commence earning a return from his orchard, say, £6 to £8 per acre, within six months from his taking

up the land, and this advantage cannot be attained in any other portion of California.

Mr. Malcolmson's address is 102, Union Grove, Aberdeen, and he will be happy to answer all enquires addressed to him regarding California.—*Gardeners' Chronicle.*

PLANTING IN EAST AFRICA.

Milanji, British C. Africa, March 28.

OUR WAR SCARE

is over and those aggressive chiefs who made a row with the white man, as he is generally called here, have had to pay the piper by way of a fine for peace. Soldiers and blue jackets have all returned down country to their respective stations and gunboats.

OUR RAINY SEASON

is all but over and crop is showing signs of ripening. We have had an A 1 planting season during the past five months: over 60 inches of rain in 135 days recorded.

I see some of your correspondents wanting information about

UGANDA.

All I know is that coffee grows there indigenously, I presume, otherwise it has been introduced by Arabs from the North. Mr. Pigott shewed me at Mombasa a sample of

UGANDA COFFEE,

it was a very small bean of a grey or drab colour evidently produced in a dry climate. I am sure Uganda from what I have heard has not more than from 30 to 40 inches of rain per annum. Most of the

RAIN IN E. C. AFRICA

falls when the clouds come in contact with the range of mountains running parallel to the Indian Ocean about from 150 to 300 miles from the coast; beyond this range three or four months' severe drought is experienced and coffee (what is known to be in existence) about the lakes is regularly watered to keep it alive—this I know for a fact.

Awfully sorry to see

THE DEATH OF YOUR SENIOR EDITOR:}

Never will Ceylon get another to advocate the interests of the people and island as he did. All must mourn long and sincere for this sad loss.

I must offer my sincere sympathy to all related to the deceased.

H. B.

THE CHICAGO EXHIBITION AND INDIAN TEA.

The official catalogue of the British section at the World's Fair makes a portly volume of something like 600 pages, filled with matter bearing on the industries and manufactures of Great Britain, her colonies and dependencies. India is accorded a special heading to herself, though the enumeration of the varied exhibits which she has sent across the sea only covers a few pages. As compared with some of the colonies, indeed, this country makes rather a poor show. Thus Canadian exhibits cover an area of over 100,000 square feet, while New South Wales is allotted 50,000 and Ceylon fills, 22,000. Of the grand total of 500,000 square feet which represents the full extent of British participation in the gigantic American show, only 5,000 square feet have been appropriated by our Eastern Empire, which merely ranks for the occasion with Jamaica. On the other hand, a glance at the catalogue is quite sufficient to show that, considering the mild enthusiasm to which Government restricted itself in reference to the undertaking, the results achieved are far in excess of what might have been anticipated. The Indian Tea Planters' Association have clearly turned to the best account the contribution of £4,000 handed over to them as a Government grant, but this

sum cannot have gone very far towards providing the splendid display of the products of Indian plantations by which it is hoped to captivate American tea drinkers. The main credit clearly belongs to private enterprise, which will strike the world as less of a myth in India than is usually supposed. All the leading districts and estates are represented, Assam, Cachar, Chittagong, Darjeeling, Dooars, Kumaon, Sylhet, and the Terai vie with each other in spreading out their choicest products before the vast constituency of possible future customers who will frequent the Fair. Already, without the meretricious aid of a first-class "boom," Indian teas have commenced to find a considerable sale in America, but it is difficult to estimate what the present gigantic advertisement may do in opening up a still nearly virgin market.—*Pioneer*, May 26th.

ODDS AND ENDS.

(By an ex-Rangalla Planter.)

TEA MADE FROM AN ORCHID.

It is learned from a bulletin issued at Kew that the French have been making tea from an orchid, *Angrocum fragrans*, for 50 years. It grows in the forest of Bourbon and Mauritius, and is akin to the vanilla, which is likewise an orchid. Of the 10,000 species of orchids known, about twenty only have been turned to any use.

"TEA, COFFEE, COCOA AND MATE ANALYSIS" BY
J. ALFRED WANKLYN, M.R.C.S.

"Old Colonist's" quotation from this work, which I here repeat, is something awful:

"Tea, Coffee, Cocoa, and Mate Analysis" is the title of a book handed to me on leaving England. "A practical treatise by J. Alfred Wanklyn, M.R.C.S.," from which I make the following curious quotation for the information of planters (page 31):—"Coffee is a seed which grows in a pod like the pea or bean. The plant which produces coffee is a tree, *Coffea Arabica*.—It grows in Arabia, Ceylon, the W. Indies, Brazil and other hot countries. Before it is imported to Europe the coffee is deprived of the pod and also of another covering."

I wonder if Mr. Wanklyn has been spoken to on the subject, and how he feels when he remembers that a whole edition of his book, containing the above monstrous sentence, is being scattered about the world, holding him up to ridicule. It reminds me of a question I once read in an agricultural paper, put by a correspondent to the Editor, as follows:—"I am about to start sheep farming, and, as I am only an amateur in agricultural matters, I write to ask you to be kind enough to let me have your opinion as to which it would be best for me to use in my flock, a Leicester or a hydraulic ram!"

SPRAYING TEA BUSHES.

The following cutting from a scientific paper speaks for itself:—

"It has been demonstrated pretty clearly that neither copper solution nor arsenical washes, used for spraying fruit, are at all likely to cause any danger if used with any degree of common precaution; but it has lately been proposed to experiment with insecticides upon the tea plant, and the idea of drinking tea made from the leaves of tea plants that have been sprayed in China is at least rather disagreeable. Rightly or wrongly many people have less confidence in Chinese in the matter of poisons than in men of their own nation, and if it becomes a practice to spray the tea bushes in China with any such mixtures as Paris green our elderly ladies will be apt to have disagreeable fancies over their cups of tea. A late number of Bell's Weekly Messenger contains a proposition to spray the tea bushes with a mixture of benzine and naphthaline, which is said to act as an insecticide, and to evaporate so rapidly that it leaves the tenderest foliage uninjured and without the slightest trace of taste or smell. It may be so, but the idea is about as unpleasant as that of eating tinned rabbits said to have been poisoned with a substance uninjurious to human life."

COSMOPOLITE.

FROM THE HILLS.

(By Old Colonist.)

I suppose I dare not say

"WEATHER"

or I shall be put down as a grumbler. Yet although, it may be

"CHERRY CEYLON,"

the tea looking splendidly, and the prospect generally pleasing, one need not go through the country like an advertising merry-andrew!

THE TEA ENTERPRISE

may be more prosperous and remunerative than coffee ever was, the profits to the lucky proprietor—as I am assured,—being £7 or £8 per acre, while his well-paid Superintendent saps porridge and porter instead of the erstwhile humble curry-and-rice. Nevertheless, as a Briton I claim my right to take my pleasures sadly, and as I passed by the huge pile of old

COFFEE STUMPS

at Drayton. I am not sure I did not shed a few tears. It may have been only rain-drops, but in any case I brushed them away as I approached once more the classic grounds of

"TANGAPOO"

where in days of yore grand old *Guillemus primus* attained the climax of his "potestature"—entertained Royalty—hearkened to the voice of Hercules and silenced any local dog who dared bark in his presence.

How changed the scene! The same old undulating lands—the same grand water-fall;—but ye giants of old and poor king coffee, 'Faur are ye' Like the 'Flowers o' the Forest

'A wede away.'

And yet not all;—for the true

PATRIARCH OF THE DISTRICT

still flourishes, and I hope it may be my fate to meet him soon. It is 35 years ago next week, since this worthy planter first took up the reins at "tongal tottum" (Union)—the then *ultima thule* as the Tamil name implies, and I well recollect enjoying his hospitality soon after, when he enthusiastically described a magnificent water-fall he had just discovered in the jungle—the now familiar falls of Devon. What changes this interesting veteran has seen since then! And what an amount of splendid work he has accomplished. Surely, it is high time he were treating himself once more to a sniff of his native air on the East coast of Scotland, where so many of his friends are anxious to welcome him home again. It is only four months ago since I met half-a-dozen old friends of Gamrie and Rangalla days, who expressed the earnest hope of seeing Mr. M. at home this summer. Unfortunately he was not in Dimbula as I passed through, else I would have delivered the message in person. Hence this round-about way of getting at him.

NOW ABOUT KING COFFEE.

I was surprised to find about 100 acres still thriving on Craigielea, to which estate Dimbula owes much. It was the first to show the way into *Dimbula felix*, and evidently made up its mind to reserve this 100 acres of the old product as a warning to others, proving the hopeless futility of leaving a single coffee plant alive in this never very fruitful valley.

This coffee looks as green and healthy as coffee did 30 years ago with little appearance of bug and less of crop. I do not think the most sanguine or desperate V.A. could estimate one-tenth of a cwt. per acre. To cherish coffee under such circumstances shows at once a respect for the old product and a desire to experiment for the public good which cannot be too highly commended.

Passing along near to the bridge leading to

FOREST CREEK,

I was suddenly startled by an apparition. I am no believer in ghosts, but there was something so realistic in this illusion, if illusion it was, that had the

sun been shining I would have tried to fix it with my Kodak—if but to show how the stalwart descendant of “the fiddling clan” embraced my poor friend “Fat-un.” But as it was raining, I passed on—next wondering what on earth was the matter with the man who traced the lines for tea on yonder hill-side. Does the “creeper” whose duty it is to put the coolies in lines ever bless this man? And have the coolies invented any special slang for this unique field? Probably the *lining* was done by ‘the Boards’ in London who instructed the Superintendent to “place the pegs 3 feet apart and dig the pits 18 inches on either side of the peg.” “And where am I to put the soil?” said the puzzled dora. But lines or no lines, pits or no pits, plants or seed at stake, tea is altogether a phenomenal success where the *jat* is good; but there are a lot of bastard bushes about, and the marvel is, that it took so long to discover the paramount importance of “good *jat*.”

A very large proportion of the tea I passed through is not yet in full bearing.

Seeing this, few things surprise me more than the recent declaration of Mr. Rutherford indicating that Ceylon is near

THE LIMIT OF ITS OUTPUT,

and nearing the end of its tether as to extent of suitable land!

He would indeed be a bold man who would limit the capabilities of Ceylon to

DOUBLE ITS PRESENT EXPORT OF TEA,

and no one who has for ten years travelled over the length and breadth of the island will say that there are less than 500,000 acres—1/32nd of the island—eminently suitable for the growth of tea. Difficult as it may be to dispose of the produce, and pleasing as it might be to our Assam friends to hear of our limited powers of production, it is better to face facts; and these facts are, that after the 500,000 acres have been planted, the further extension will only be limited by the demand.

NOTES ON PRODUCE AND FINANCE.

MORE TEA THAN BEER.—The writer of an article “On the Consumption of Tea and other Staple Drinks,” in the March number of the *Economic Journal*, published by Messrs. Macmillan and Co., makes the statement, and gives statistics tending to prove it, that tea has become as much a national drink in the British Isles as beer, and that more of the former is consumed than the latter. Not that tea has taken the place of beer and spirits, but it has been a net addition to the comforts of the people.

THE FLAVOUR OF CEYLON TEA.—No further correspondence on this subject having appeared in the *Morning Post*, a member of our staff called on Mr. Hawes with reference to the controversy. That gentleman mentioned that some further correspondence had passed between himself and Mr. Isham, but the letters had not been sent to the papers. Mr. Hawes handed our representative a copy of a letter received from Mr. Isham: In it he says: “Your opinion in your letter of 5th inst., in reply to mine, cannot be gainsaid, but what I quoted from your newspaper report had a prospective as well as retrospective feature, and I still decline to believe that ‘Ceylon can no longer produce the choice pekoe-flavoured teas that the island became famous for a few years ago.’ Those who wish to sell Ceylon tea as proprietary articles are ever assuring us of the memory of the delicious flavours of thirty years ago, and the public verdict, borne out by Board of Trade statistics, shows that the tea grows in favour daily. Depend upon it, Ceylon is not played out yet, and will produce the choicest teas, the tea-taster to the contrary notwithstanding.” Mr. Hawes, in his reply, claims to have fully explained and substantiated the position he took up in his market report.

THE NEW SEASON'S CHINA TEA.—Comparatively there is little interest now taken in the news from China about the new season's tea. The season is

reported to promise fair, and the arrivals of tea at Hankow for shipment are very heavy. There is believed to be a heavy supply of low-priced tea. The Russian buyers have the market all to themselves, while London importers are for the most part just looking on.

OCEAN FREIGHTS.—A largely attended meeting of the Indian Tea Districts Association was held on Tuesday, when the question of ocean freights was fully discussed. The following resolution was unanimously adopted:—“That the draft agreement received from Calcutta does not meet with the approval of this meeting.”

AN ACTION ABOUT COFFEE SHARES.—In the Lord Mayor's Court, recently, before the Assistant Judge and a jury, the case of Lock v. Ross came on for trial. This was an action brought by the plaintiff, who is secretary to the Ceylon Land and Produce Company, Limited, to recover from the defendant damages for breach of contract in not delivering shares at certain prices to the plaintiff. The defendant had pleaded that there had been a mistake made in the price given by the defendant to the plaintiff for the shares, and that he was therefore not bound to fulfil the contract. It appeared that in November last the plaintiff was anxious to obtain some shares in the Company, to which he was the secretary. The Company was one that had been formed for the purpose of working a coffee plantation in Ceylon, and the plaintiff applied to the defendant, who held a number of shares in the Company, and who was one of the original vendors to the Company, to supply him with the shares. On Nov. 23rd the defendant gave the plaintiff the price of £5 preference shares at £4 6s 3d and the price of ordinary £5 shares at £4 11s 3d. This offer was to stand over until the defendant found out how many shares he could sell. On the 25th the defendant said he could let the plaintiff have forty of each kind of shares, and was about to give an acknowledgment of the bargain, in which he was putting down the price of preference shares at £5 6s 3d, being £1 difference per share to that which the defendant had previously given him as the price he could sell at. Plaintiff remonstrated and told him he was putting down the wrong price, when the defendant said that the price he had given to the plaintiff on the 23rd was a mistake, and he could not let the plaintiff have the shares at that price. Plaintiff had been unable to obtain the shares, and in consequence he had lost a profit of 2s 6d a share which he would have made if he had been able to supply the shares to his customer. At the end of the plaintiff's case, on the suggestion of the learned judge, the parties were able to come to terms by the defendant agreeing to pay the plaintiff the sum of £10 and costs. A verdict was entered for that amount for the plaintiff, and the jury were discharged.—*H. and C. Mail*, May 19.

TEA SHARES AS INVESTMENTS.

Indian Tea shares are in many cases really good investments; but owing to the fact that so few of them are quoted on the London Stock Market, and that those few are not easily and freely dealt in, they do not seem to attract so much attention as they deserve. We are informed on good authority that owing to the recent good crops, and to an inside demand, prices at which the shares can be obtained must be regarded as being rather high, and that there is therefore some risk of reaction. This may be true, and so far as speculators are concerned, is a deterring factor; but the investor who finds that these securities return him from 5 to 6 per cent. on their present prices will not be debarred from buying by any fear of a speculative reaction.

A few words about the more promising shares may be useful to investors who find it difficult to obtain a sufficient rate of interest on their money for their desires. The following selection of Tea stocks that are all quoted cum dividend, and which, in the opinion of a market expert, are not considered to be too dear at their present prices, may prove instructive:—

Darjeeling, cum total 6 per cent., 20 $\frac{1}{2}$., at about 20 $\frac{1}{2}$.

Dooars New Ordinary, cum final 7 $\frac{1}{2}$ per cent. (really about 4 per cent. only), 10 $\frac{1}{2}$., at about 14 $\frac{1}{2}$.

Jokai (1892 issue, not yet quoted), cum final 5 per cent., at 15 $\frac{1}{2}$ to 15 $\frac{1}{4}$.

Jorehaut, cum total 10 per cent. or more, 20 $\frac{1}{2}$ share, at 34 $\frac{1}{2}$ to 34 $\frac{1}{4}$.

Lebong, cum final 3 per cent. (and 2 $\frac{1}{2}$ return capital), 10 $\frac{1}{2}$ share at 11 $\frac{1}{2}$.

Attaree Khât, 5 $\frac{1}{2}$ share, cum final (?) 4 per cent. or 5 per cent., at 5 $\frac{1}{2}$.

Brahmapootra, 5 $\frac{1}{2}$ share, cum final (?) 9 per cent. or 10 per cent., at 10 $\frac{1}{2}$.

Doom-Dooma "B" shares, cum final 10 per cent., at 14 np.

N. and S. Sylhet Company, 100 $\frac{1}{2}$ shares, 70 $\frac{1}{2}$ paid, cum total 10 per cent., at 80 up.

Chargola Ordinary, 1 $\frac{1}{2}$ shares, cum final 5 per cent., at 21s 3d.

Chargola Seven per Cent. Preference, 1 $\frac{1}{2}$ shares (interest 31st March and 30th September), at 24s to 25s.

Ceylon Plantation Seven per Cent. Preference, 10 $\frac{1}{2}$ (dividends 30th June and 31st December), at 12 $\frac{1}{2}$.

It must not be supposed, however, that these exhaust the list, although the investor should be put on his guard against a few shares which he may be tempted, in one shape or other, to buy. Of the above, the first five are quoted officially, while the others are not. Jokai and Jorehaut shares are perhaps the most satisfactory from the point of view of prestige. Luckimpo descriptions, which are also quoted, should be avoided, as there is some fear of the Company amalgamating with the Majula, whose stocks are unquoted, and this might mean the loss of the market quotation. Further reasons for avoiding them are that they are speculative, and the gardens are not first class.

Among the others, Attaree Kabât shares are expected to pay an increased dividend; North and South Sylhet Companies do not issue any reports or accounts so that the holders have to remain in the dark and be thankful to receive their dividends; which, however, are very good. Doom Doomas and Brshmapootras are looked upon as being the very pick of the Assam Tea Companies, the Chargola shares are convenient, and the expenses of the Company are understood to be very light. Not included in the foregoing selection but deserving of mention, are Moabund issues, for the reason that the Company gets a very good price for its tea; Borokai, which are very good, but difficult to deal in; Nonoi and Chubwa, which are about to amalgamate; Jhanzies, which are easy to deal in, Scottish Assam and Mazdehee. Some of these shares would be difficult to get, but their possession would well repay the investor any little trouble that he might be put to.—*Bullionist*, London, May 6.

BARK AND DRUG REPORT

(From the *Chemist and Druggist*.)

London, May 11.

CINCHONA.—There were several parcels of South American barks of some interest at today's drug-sales. Thirty-two bales flat Calisaya bark, mostly damaged, good bright but partly small mixed, sold at 1s 2d for sound, and 1s 1d to 1s for damaged bark, which was about 2d per lb. below the valuation. Twenty-two serons Guayaquil-Loxa, ordinary rusty to fair brown quill, realised from 6 $\frac{1}{2}$ d to 12d per lb. Thirty-nine packages genuine Loxa bark realised exceedingly high rates, fair to good bright quill 1s 1d to 2s 1d, ordinary and broken ditto 5d to 10d per lb. A parcel of fair to good bright Huanoco bark sold at 10d to 1s 3d per lb., while a few lots of Guayaquil were bought in at a nominal price. Four packages rather ordinary South American red bark were all bought in, a bid of 2s per lb being refused for one lot. The April shipments from Java, which were stated in our last issue to have been 648,000 kilos were only about half that amount—viz. 649,000 Amsterdam lb. In the stock of bark in London the figures given for "East Indian" bark includes all barks of Eastern growth.

COCAINE.—The German makers are now offering Hydrochlorate at from 16s 6d to 17s 6d per oz. according to quality.

COCA-LEAVES.—Nine bales good green bright but broken Truxillo were bought in at 1s 6d per lb today. Another lot of one bale sold at 1s 5d per lb., showing some little decline in value.

CUBEBES.—The market is quite neglected, and to effect sales lower prices would have to be accepted. Owners tried hard to place some lots at today's drug-sales, but were not successful in the attempt. About 65 bags were offered and bought in at 8s 6d to 5s 8 per cwt. for fair, blue and brown mixed berries from Singapore, and at 70s per cwt. for dust. A bid of 14s per cwt for cubeb-stalks was rejected.

KOLA.—In small supply. Only 4 bags were sold today at 5 $\frac{1}{2}$ d per lb for medium brown bright seed.

QUININE.—On Tuesday a transaction of 10,000 oz second-hand German bulk was made at 9 $\frac{1}{2}$ d per oz on the spot. Further sales have been made today at 9 $\frac{1}{2}$ d per oz for German bulk in second hands.

VANILLA.—Under date of May 6th it is reported from Mahé (Seychelles Islands) that the vanilla-crop was estimated to yield from 35,000 to 40,000 lb. Although the quantity declared for sale at the drug-auctions was very small, there have, nevertheless, been rather considerable imports lately, and indications favour a further decline in the article at an early date. At today's auctions only a small quantity was offered, and sold at somewhat easier prices. Mauritius: Fine 6 to 8 inch chocolate, slightly crystallised 10s 6d to 14s 6d; 8 to 9 inch 15s 6d to 16s 6d; medium brownish 6 to 8 $\frac{1}{2}$ inch 7s 6d to 10s. Ordinary dark Madagascar 5 to 7 $\frac{1}{2}$ inch 7s to 8s 6d per lb.

INDIAN PATENTS.

No. 131 of 1893.—Dean Guntlett, Civil Engineer, Hyderabad, Deccan, India, for a new and improved terraced or sloped roof and ceiling for rooms, verandahs, and other covered courts or spaces of public or private buildings, such as offices, railway stations, churches, dwelling-houses, markets, etc.

No. 132 of 1893.—Messrs. Jessop & Co., Limited, Engineers, Calcutta, for an improved cart wheel specially suitable for Government transport work, planters, carrying contractors, etc.

No. 134 of 1893.—Melvin Linwood Severy, Manufacturer, of 567 Tremont Street, Boston, in the County of Suffolk, and Commonwealth of Massachusetts, United States of America, for apparatus for converting solar heat into continuous power.

No. 140 of 1893.—Tom Selmin Macaulay Brewer, of No. 3, Wellesley Street, in Calcutta, British India, Civil Engineer and Architect, for "a new or improved cement for building and repairing purposes."

No. 141 of 1893.—Scott McKenzie, Engineer, resident of Karachi, Sind, for a road-watering cart known as the "McKenzie Water-Cart."—*Indian Engineer*.

A TEA GARDEN IN LONDON.—A few days back I went to the Indian and Ceylon Tea Garden at the Crystal Palace, thinking I might find there something to interest my London readers. The garden is managed by a Mr. MacGregor, an Indian Tea planter, who has had previously some success at one of the London Exhibitions. He professes to shew you the tea plant in all its stages of growth, and also to shew the manner of preparation of the leaf with the necessary machinery. There were a large quantity of tea plants growing in pots, but they did not look as if the Palace air quite agreed with them. They mostly ranged between four and eight inches in height; one plant about two feet high which was said to have blossomed profusely last September, was the feature of the show. But even it looked decidedly uncomfortable. In a photograph book lying there I found a letter thanking the tea producers in England, in the name of the Queen, for the first box of Ceylon tea ever grown and prepared in England, and also for the plant of which the tea came. The whole place was very nicely got up, and the managers were most polite, but the condition of the tea plants left much to be desired and will hardly convey to those who have not visited the tea gardens of India or Ceylon an adequate idea of the tea bushes as they grow there.—*London Cor. Local "Independent."*

VARIOUS AGRICULTURAL NOTES.

THE ZANZIBAR EXPORT DUTIES ON SPICES.—In 1892 the export duty on cloves in Zanzibar yielded a revenue of 450,237 rupees. For the present year it is expected to bring into the treasury 525,000 rupees or over 75 per cent of the total revenues of the country. The receipts from export duty upon chillies for the current year are estimated at 12,000 rupees, those derived from the clove-stem duty at 5,000 rupees.—*Chemist and Druggist.*

TEA PATENTS seem to be increasing apace, most of them purporting to be improvements in drying and rolling. One, however, is a patent plucker and is registered in the name of John Jonas, Engineer, of London. We should be glad to know whether the apparatus for planting tea recently invented by a gallant Colonel has proved successful.—*S. I. Observer.*

TEA IN WYNAAD.—If it be true as the following paragraph in the *Madras Times* indicates, that Assam planters are beginning to look to the Wynaad for the development of tea, a considerable extension of cultivation may possibly take place. We quote as follows:—

There has been "a obiel among ns taking notes," with, I rejoice to say, delightful result as far as can be judged from an expression of opinion. I allude to a gentleman from Assam, who came to South Wynaad to judge of the possibilities of our district for tea. He made a most thorough scrutiny of such tea as has already been planted, and expressed it as his opinion that Wynaad was certainly suited for its cultivation. He seemed to be especially struck by the rapid growth of the young plants lately put out, and the enormous yield (as compared with Assam) of the old plantings. Altogether, he was evidently most agreeably impressed with the capabilities of our district, and gave us to understand that if we planted good jats of tea, and started with *proper* machinery, Wynaad had exceedingly good prospects before it. But unfortunately tea should be grown on a considerable scale to be remunerative, and that means that we must have enterprise and money introduced. But I am glad to say that from what I can gather, Wynaad is likely to be brought into more prominent notice, and therefore we may hope that better days are really in store for us.

THE "INDIAN FORESTER"; a monthly Magazine of Forestry, Agriculture, Shikar and Travel, edited by J. S. Gamble, M.A., F.L.S., Conservator of Forests, and Director of the Forest School, Dehra Dun for April 1893. The contents are:—

1.—Original Articles and Translations.—A plea for protected Forests, by "G. E. M."—Injury by insects and value of Forests of the enemies of those Insects:—Translated from the Forst und Jagd Zeitung by S. E. W. Part II.—Influence on the vegetation of a forest of the removal of dead leaves from the soil.—Dispersion of seed by birds (translation).—Imperial Forest School, Dehra Dun. The Annual Prize day.—II.—Correspondence.—Manchuria Tiger-Skins, letter from "Huntingdon".—A Departmental Blazer, letter from "Velleda".—Potato cultivation, letter from "F. W. Seers".—III.—Official Papers and Intelligence.—The Palmyra Palm.—Report on the effects of the late frosts on vegetation in Hongkong.—IV.—Reviews.—Annual Progress Report of State Forest Administration in New South Wales for 1891.—Report on Canal Plantations, N.-W. P. for the year ending 31st March, 1891.—Report of the Agricultural Department in Burma for 1891-92.—V.—Shikar.—The People's Tiger.—Sport in Austro-Hungary.—VI.—Extracts, Notes and Queries.—Roadside Arboriculture in Bengal.—Forest in Russian Turkestan.—Old Dehra-Dunite news.—Fellows of Coopers Hill.—Technical Education for Geologists and Foresters.—Sapless Cedar Block paving.—VII.—Timber and Produce Trade.—Churchill and Sim's Circular, March 2nd, 1893.—Market Rates of Products.—The Wood Trade in India.—VIII.—Extracts from Official Gazettes, Appendix Series.—Fibres used in Brush making.

ADVANCES UPON CINCHONA IN HOLLAND.—The manager of the Netherlands Bank in Amsterdam has agreed, says *Chemist and Druggist*, to include cinchona-bark among the articles upon which the bank is prepared to advance money. The value of the bark upon which a loan is asked is to be estimated by the bank's broker upon the basis of a double analysis of two specified chemists. Only barks equaling a minimum of 3 per cent of sulphate of quinine are admissible for advance, and the sum lent upon them shall not exceed 60 per cent of the value.

THE NYASSA COMPANY, recently incorporated by Portuguese Royal Decree, is undertaking the important work of administering and developing the district of Cabo Delgado and part of the district of Mozambique, comprising about 100,000 square miles, or 64,000,000 acres. The Company has the right to receive the customs and harbour duties, and all other taxes, in its territory. The management of this great enterprise is partly in English hands under the presidency of Baron Carl de Merok.

"**COFFEE CULTURE**" is the subject of an advertisement in the *Rio News* of rather a peculiar character. It says that coffee in Brazil pays better than any other agricultural work:—

Small farms of twenty to one hundred acres each are offered in exchange for manual labor. Ninety thousand acres of the first quality *terra roxa* coffee lands in the county of Araraquara, on the Jacare river, are to be had for the cultivation of them in coffee, a half interest in each farm given to the farmers who will work them. Address: The Farmers' Coffee Land Agency, Rua Direita No. 2, Sao Paulo. Care of Brazil. J. W. Cochman, Supt.

TANNIN IN CHINA AND CEYLON TEAS.—Says the *L. and C. Express*:—

One of our Colombo contemporaries has an article on the appendix concerning China tea to the report of the China Association, being that part of the memorandum drawn up by a sub-committee of the association rather more than a year ago, which has now been published. Our contemporary naturally defends Ceylon tea at the expense of China. On this we have nothing to remark for everyone is entitled to advertise his own wares to the best advantage. But when we are told that by the "thoughtless admission of the writer (of the memorandum) that, after all there is really very little difference in the quantity of tannin in China and Ceylon teas!" we must protest. The remark is contrary to fact, and also to the statement in the said memorandum, which reported:—"It is believed that the amount of tannin in a given quantity of *green* leaf, whether Indian, Ceylon, or China does not vary so much as might be supposed, and the quantity found in samples of tea in a prepared form is more a question of process of preparation than anything else." Precisely so; in the preparation of China most of the tannin is extracted, and at a very infinitesimal loss of its tannin properties. In Indian and Ceylon teas the tannin is allowed to remain to a great extent, and hence the pungent coarse flavour, which seems to find so much demand by all the poorer classes. It brews strooger. What the memorandum went on to suggest was whether the Chinese should not be approached to prepare differently by leaving more tannin, as found in the green leaf, in, and thus vend an article likely to meet the demand here, and compete with Indian and Ceylon.

But the *L. and C. Express* and other organs of China tea ignore the fact, that the quantity of tannin in any infusion of Ceylon tea can be regulated by the quantity of tea put in the pot and the time occupied in infusing. Thus it is possible to get more tannin in an infusion of China than in that of Ceylon tea if the former is kept long infusing; while a four or five minutes infusion of Ceylon tea gives scarcely any of the tannin.

SCIENTIFIC CULTURE.—The Editor of the *Horticultural Times* puts true science in a nutshell and we commend the following to the attention of our planters:—

Nitrogen is an indispensable fertilizer in some crops and soils, yet nitrogen must be backed up in most cases by a corresponding proportion of potash and phosphoric acid. Whether this is so or not, theorising upon the subject will not settle the question one way or another: the only way to settle the matter is "to put the question to the soil and get the answer in the crop."

FRUIT CULTURE IN NORTHERN INDIA.—The Rev. M. M. Carleton has furnished the *Horticultural Times* with very interesting notes of his experience at 4,500 feet altitude, 65 miles from Simla: which we shall reproduce in full in the *Tropical Agriculturist*. He gives results of apple cultivation (a failure comparatively); Kashmere apricots (a great success); hardy American grapes (a great success); common Himalayan walnut (also a success); European orange trees 8 years old gave over 200 oranges each year, yielding a profit of 16 rupees from 10 feet square of ground.

"AN AMERICAN TEA GARDEN"—(WHAT NEXT?)

—Such is the rather ominous heading of a long paper with interesting and well-executed engravings which we find in the *American Grocer*, reproduced it seems from another Far Western publication *American Gardening*. The experiment thus attracting such widespread interest is that of Professor Shephard in South Carolina to which reference has already been made in our columns. Mr. Henry Cottam has been his factotum and 12 acres have been planted with plants from Assam—Hybrid seed got from Ceylon: other seed being tried in separate gardens. The engravings show very flourishing bushes and neatly arranged rows packed by the sombre pines for which the Carolinas are famous. That it will not do to smile at such experiments, especially in these days of "patent pluckers" may be judged from the *Grocer's* editorial remarks:—

An experimental tea garden in South Carolina brings up the old question: Can tea growing be made a profitable industry in the United States? When the raisin industry of California was started, and the orange plantations of Florida, nearly every one was an unbeliever in the ultimate success or the respective enterprises. The absence of cheap labor was the cause assigned; the want of it is now regarded the chief hindrance to tea cultivation in the United States. Both raisin making and orange growing have passed the experimental stage and are in a fair way to displace the foreign grown article. Mr. Shephard himself reports:—

The Pinehurst tea gardens are none of them much more than three years old; the most have been very recently planted. They comprise altogether about twelve acres, and consist of plants grown from the Assam hybrid seed, which has been raised in the Southern States, and from the best Ceylon estates. Other gardens have Chinese, Formosa and Japanese plants, all raised from seed procured from those countries. It is probable that some gardens of Indian seed will be established ere long, as it is intended to experiment with all the leading varieties. This year's manufacture did not extend beyond Assam-hybrid plants, but another year Chinese plants should be available to a limited extent as well. In addition to the gardens, there are in hedges tea plants equivalent to a couple of acres of garden, which are later to be used in manufacture. The gardens have been located on several varieties of soil (sandy, clay loam and bottoms of reclaimed swamp), for the purpose of testing their relative fitness.

Americans do not give up their "ventures" in a hurry, and if machines be utilized, we may hear a good deal more of tea-growing even in South Carolina.

COCONUTS IN ZANZIBAR.—Mr. Fitzgerald in a report which we shall quote in detail by-and-by, speaks of palms favorably situated yielding up to 300 nuts per annum, though he admits that the usual yield is from 100 to 200—or 30 to 50 at a plucking four times a year. Very good indeed—indeed magnificent, most such returns be considered, if verified by experience for any time and over any considerable area.

A CHEMICAL-FACTORY IN THE TRANSVAAL.—The Johannesburg *Star* gives particulars of a new factory for sulphuric-acid manufacture, known as the "Transvaal Chemical-works," which has just been erected at Knight's Dam, in the Transvaal Republic, close to the Hungarian Ore-reduction Company's factory. The factory is under the management of a Mr. Bagshawe, who has had experience of similar work in Scotland and elsewhere. The works will be of great advantage, it is thought, to the gold-fields; they will use the pyrites obtained in treating the ore, and supply the gold companies with the sulphuric acid, of which they require large quantities. There are four lead-chambers, measuring 130 by 90 feet, and from 12 to 14 feet high, erected by English workmen.—*Chemist and Druggist*, April 22.

THE BRITISH GUIANA GOVERNMENT LABORATORY.—The Government analytical chemist of British Guiana has hitherto been allowed to carry on a private analytical practice in addition to his official work, but at the last meeting of the "Court of Policy" of the colony a motion was brought forward suggesting that the fees received by the analyst in his private practice (which were stated to amount to \$1,320 a year) should go into the Treasury. Ultimately it was agreed to allow the analyst \$1,200 a year in lieu of his private fees—the latter to go into the Treasury—to raise his salary from \$3,000 to \$3,600, with quarters, and to allow him two assistants (one at \$960 and one at \$480), instead of one as theretofore. The analyst clearly appears to have had the best of the bargain.—*Ibid.*

NEW PETROLEUM FIELDS IN SUMATRA.—A correspondent writes to a Singapore paper to announce new petroleum discoveries in Sumatra:—

It seem that Sumatra shortly will not only be known as producing the finest tobacco and coffee, but also as the Pennsylvania of the East, as it is apparently coming into the first rank as a petroleum producing country. It is not so long ago, that the first Sumatra petroleum from Langkat appeared on the Singapore market. Since then it appears that an oil field of far larger extent has just been discovered in Palembang by Mr. Schmitz du Moulin. Most of the petroleum wells he controls are lying close to the shore where the largest seagoing vessel can lie along side. Hence the facilities for shipping cannot be surpassed, as no costly system of transport or pipe lines are wanted for bringing the petroleum to the ship's side. The geological formation is believed to be much the same as in the oil-bearing districts of the States, undulating country, the petroleum formation being overlaid by a soft sandstone. Many are trying now to find petroleum further inland or to get concessions in the neighborhood, among them such well known names as those of Mr. Herrings of Assahan, Messrs. Schlimmer & Co., and others. Since the first wells have been found, there has been a real rush for concessions, a great many of which have been already applied for. What makes the discovery of Mr. Schmitz du Moulin still more important is that he declares that he has found there also enormous deposits of ozokerit, which is really a form of solidified petroleum. If there is truth in this asserted discovery, it will prove a great boon to our Eastern gas manufactories, especially as no really good gas coal has been yet found in the East.

A NEW RAIN COMPELLER.—Mr. H. W. Allen, formerly of the Nizam's Public Works Department, is, says a contemporary, the inventor of an ether spray rocket rain-producer capable of rising to a height of one mile or more and then descending slowly, like a parachute. "It has been admitted by learned scientists that intense cold must cause a cloud to discharge rain, but as to its continuing to rain for any prolonged period, there are still different opinions expressed on this point."—*Indian Engineer*.

STOCK AND WATER.—According to Sir James Garrick, the Agent-General for Queensland, water is the secret of the enormous increase in the number of Australian cattle and sheep; the former are now estimated at 6 million head, and the latter at 22 millions. It has been ascertained that there is a splendid artesian water underlying vast tracts of country of at least 55 million acres in extent, where hitherto it was a matter of extreme difficulty to maintain stock, but by reason of this discovery the stock is now carried with ease.—*Indian Engineer*.

MORE LAND FOR TEA.—If it be true as we hear that some time during the present year, the Government are to offer for sale about 1,800 acres of fine forest land near Nambapanne in the Western Province, there will be a further element to reckon with reference to the future of our tea crops. The land in question is said not to be far off a very fine tea garden and as it will be cut up into about half-a-dozen blocks there is certain to be good competition from gentlemen whose object will be to plant tea as quickly as possible. The sale is not likely to take place before September-October.

THE CURRANT CROPS IN GREECE.—Reporting on the trade of the Morea for the year 1892, the British Consul says of the currant crop, that the vineyards in the districts of Pyrgos, Olympia, Gastuni, and Zante, suffered from a severe attack of the "Peronosporos," by which the crop was reduced by about 40,000 to 50,000 tons. Almost all the Currant-growing districts of Greece were visited by this malady, but only in the above was the damage of any serious consequence. "This disease, which has at times caused such great damage to the vines in Italy, France and elsewhere, is in appearance somewhat like the Oidium, and shows itself first in the form of a white blight or fungus on the leaves, which it partially destroys. It then attacks the bunches at the period when the fruit is just forming, and causes it to wither and drop off. Experts have recommended the powdering of the plants in the spring with a mixture of powdered sulphur, lime and sulphate of iron, but the expense would be considerable, and it is, therefore, doubtful if the peasantry will have recourse to this preventive, although great fears are entertained of a recurrence of the malady in the spring." Some protection of British buyers against imposition in fraudulently stating one kind of Currant to be that of another, has been made by the Greek authorities. "By a law passed in July last by the Greek Chamber," it is stated that it is now a punishable offence to mark any package containing Currants for shipment to any foreign market with any name other than that of the district where they were produced. The British consumers can, therefore, now depend upon getting "Vostizza," "Gulf," "Patras" Currants should he buy a package which has been so marked in Greece. Formerly, all kinds of rubbishy Currants grown on the western coast of the Morea were branded as Vostizza, Gulf, &c. in order to deceive foreign customers.—*Gardeners' Chronicle*, May 6.

MADRAS'S MINERAL WEALTH.—During last month 6,052 ounces of gold were obtained from the Oore-gum gold mines. The topaz-bearing tract of country discovered in this presidency is reported to be sufficiently valuable to render exploitation a commercial success.—*Indian Engineer*.

WILD MEXICAN POTATO.—The Cornell University *Agricultural Bulletin*, n. 49, records some experiments made with this plant, which is the *Solanum tuberosum* var. boreale—*alias* S. Fendleri. The tubers are brown, with deep eyes, and tend to be flattened. They keep well; the flesh is very yellow. When cooked the flavour is rich, and possess a slight aroma which is not present in the common potatoes.—*Gardeners' Chronicle*, May 6.

MR. H. M. KNIGHT, who was requested by the Travancore Planters' Association to visit the congested districts with a view to importing labour therefrom, has been promised every facility by the Madras Government. We regret to hear that owing to a severe attack of malarial fever Mr. Knight has had to go to England; he hopes, however, to be out again before the end of the year, when he at once starts on his mission.—*M. Mail*, May 13.

MICA.—In collaboration with Mr. T. H. Holland of the Geological Survey of India, Mr. E. Thurston, Reporter on Economic Products to the Government of India, has produced a monograph on mica, dealing with the present knowledge concerning the character, occurrence and trade in Indian marketable micas, treated purely from an economic point of view. From trade statistics quoted, it is proved that India is the principal producer of this mineral in the world, and thus may be able to fix the price of an article for which there is a steady and increasing demand, which fact should be an encouragement to further exploration amongst our crystalline rocks.—*Madras Standard*.

CONSUMPTION OF COCONUTS.—We agree with the "Examiner" that the Blue Book statistics of area and crops of coconuts have, for many years, been a disgrace to the Civil Service and the Government; but our contemporary is wrong in supposing that every other estimate has been reared on a basis of guesswork. Some years ago, we went carefully into the matter as to the area covered with coconuts in the principal districts and in connection with our Directory got in returns, aided by planters, agents and headmen which though, to some extent, approximate, were decidedly worthy of a good deal higher rating than guesswork, and most fully justified us in raising the total extent cultivated to 500,000 acres. Before that date, no one had ever ventured to speak or write of more than 260,000 to 300,000 acres as covered with the coconut palm in Ceylon.—As regards the local consumption of nuts, we are glad to see that our contemporary most fully supports our correspondent's and our own estimates against the "Times" critic who has a great deal to learn evidently about what is a staple food with a large proportion of our population. The "Examiner" states:—

For our part—although there are some families which perhaps do not use a dozen coconuts in the year—we are inclined to think—looking to the very large consumption of nuts in well-to-do families—that the rate allowed per family (of one nut per household per day) is an under estimate; while 600,000 families are an over-estimate in view of the census investigation of 1891 having fixed the number at 560,000*** No account seems to have been taken of the immense number of nuts which the oil used for culinary and lighting purposes represents. Of course our correspondent and ourselves meant the figures given for local consumption to cover all household purposes: food, "culinary purposes," lighting, &c.

THE ORANGE CROP of Louisiana is placed at 500,000 boxes or 200,000 barrels. Less than one-fourth of the available land of the State is utilized for orange culture. New orchards are being planted rapidly and five years will double the present producing acreage.—*Planters' Monthly*.

CASHMIR WINE.—According to the Lahore paper 6,000 to 10,000 bottles of red and white wine are made a year by the Maharaja of Kashmir. He employs two Italians, one to look after the vineyard, and the other the factory. The red wine is rich and strong, and resembles Chianti. A good quality of cognac is made from this wine.—*Pioneer*.

JAPAN TEA.—Hand-musters of the new seasons tea have reached Yokohama and Kobe from the tea-growing districts, but no definite forecasts of the quality or quantity of the crop is yet made. If the weather of the past few days continues the crop will come on rapidly, but at present there is no trustworthy report as to the probable quantity or quality of the outturn.—*Japan Weekly Mail*, April 15.

AN AGRICULTURAL EXPERIMENTAL STATION has been determined on in Japan, and the Imperial Ordinance relating thereto was promulgated on the 7th inst. The *Choya Shimbum* announces that the site selected is Nishigahara, Oji, Tokyo; and that Mr. Sawano, jun., Chief of the First Section in the Agricultural Bureau of the Agricultural and Commercial Department, has been ordered to take charge of the experiments conducted there.—*Japan Weekly Mail*.

THE ACIDS OF FRUITS.—Mr. George W. Johnson, in his *Chemistry of the World*, says, in describing the "Vegetable Food of the World":—"The grateful acid of the rhubarb leaf arises from the malic acid and binoxalate of potash which it contains; the acidity of the lemon, orange, and other species of the genus *Citrus* is caused by the abundance of citric acid which their juice contains; that of the cherry, plum, apple, and pear from the malic acid in their pulp; that of gooseberries and currants, black, red, and white, from a mixture of malic and citric acids; that of the grape from a mixture of malic and tartaric acids; that of the mango from citric acid and a very fugitive essential oil; that of the tamarind from a mixture of citric malic, and tartaric acids, the flavour of asparagus from aspartic acid, found also in the root of the marshmallow; and that of the cucumber from a peculiar poisonous ingredient called fungin, which is found in all fungi, and is the cause of the cucumber being offensive to some stomachs. It will be observed that rhubarb is the only fruit which contains binoxalate of potash in conjunction with an acid. It is this ingredient which renders this fruit so wholesome at the early commencement of summer, and this is one of the wise provisions of nature for supplying a blood purifier at a time when it is likely to be most needed. Beetroot owes its nutritious quality to about nine per cent of sugar which it contains, and its flavour to a peculiar substance containing nitrogen mixed with pectic acid. The carrot owes its fattening powers also to sugar, and its flavour to a peculiar fatty oil; the horse radish derives its flavour and blistering power from a volatile acrid oil. The Jerusalem artichoke contains fourteen and a half per cent of sugar and three per cent of inulin (a variety of starch), besides gum and a peculiar substance to which its flavour is owing; and, lastly, garlic and the rest of the onion family derive their peculiar odour from a yellowish, volatile acrid oil, but they are nutritious from containing nearly half their weight of gummy and glutinous substances not yet clearly defined."—*Public Opinion*.

TEA IN JAPAN.—The writer of this paper which we take over from *Nature*, (see page 19) shows great ignorance of what Indian and Ceylon planters are doing, in speaking of the absence of fine teas (Pekoes) from their manufacture; but we forgive him, for the valuable confirmation he gives us, writing on a subject with which he is acquainted, in saying that no pure tea is exported from Japan,—all is "faced" and often mixed with other than tea leaves.

COFFEE.—In consequence of the imposition of a duty on Venezuelan coffee very little Maracaibo and Laguayra coffee comes to this country today, Europe taking the bulk of the supply. Never were stocks of those grades in first hands in this market so light as at present, and as they are very desirable sorts the market feels the shortage, prices for similar kinds being higher than they would otherwise be.—*Merchants' Review*, New York.

DARJEELING AND TERAI PLANTERS say with reference to a leading article which recently appeared in the *Englishman*, upon Red Spider, that the sulphur cure is no new idea. In 1878 Mr. Christison, of Tukvar, conducted exhaustive experiments with sulphur and published full reports of the result. A Calcutta writer expresses belief in treating spider by promotion of strong growth with liberal root treatment, constitutional rather than local. Thorough drainage, forking and the hoe, is, he says, the best secret of getting rid of spider.—*Madras Times*, May 16.

THE CULTIVATION OF RAILWAY SLOPES.—According to the *Indian Agriculturist*, the utilisation of railway embankments for agricultural purposes opens up rather a novel field for discussion in India, though in England and the Continent these artificial slopes are made to bring grist to the mill. It would, of course, be out of the question attempting to raise anything requiring actual cultivation, i.e., disturbance of the soil, as in most parts of the country the heavy rains would speedily destroy the earthwork; so that the choice of plants or cereals must be rather circumscribed. Timber likewise would have to be tabooed on account of the great risks of uprooted trees being thrown on to the rails, and the buttressing of the roots undermining the permanent way. The various grasses such as *sibi* and *son* or perhaps *rhea*, might do in such tracts where they would thrive their roots binding the earth securely, though in the dry season considerable inconvenience, if not danger, might arise from fire. Anything of an edible character would need rather elaborate fencing throughout the entire length of the area planted. The castor plant is, perhaps the best and most promising that suggests itself for such lines where the rainfall is sufficient, but will come to nothing in dry arid districts, and the fruit would form no despicable revenue; but from the disturbance caused by the rush of passing trains among the foliage, those who moot the possibility of raising such silk-worms as feed on it *in situ* would, we apprehend, be disappointed, though, concentrated, as one may say, the plant would be domesticated, worms could be fed on the fresh flushes, *ad lib.*, and though the railway people could hardly combine silk-raising with their legitimate avocation, the embankment could be leased at a very appreciable rental. True, castor-planting on railway slopes has failed in the Punjab; but the soil, especially on rapidly filtering slopes, is not of a character to retain sufficient moisture to afford the plant fair play. Other economic shrubs, suitable to the climate, will suggest themselves—*croton tigris*, for instance.—*Indian Engineer*.

THE INDIAN TEA ASSOCIATION.

At the annual meeting of this Association held in Calcutta at the end of last month a very comprehensive report of the work done during the past year by the Committee was submitted. It appears that a satisfactory agreement has been made for the conveyance of goods to and from Assam and Cachar, and it is hoped that the steamer companies may see their way to running feeder steamers up the smaller streams. The question of ocean freights seems to have occasioned a good deal of heart-burning, the main question upon which there were divergent views being that of rebate, but efforts are being made to bring about a satisfactory settlement. Investigations had been made into the cultivation and manufacture of tea from a scientific point of view and a report giving the results will shortly be published. Another very important matter was the drawing up of rules for the sanitary care of coolies under the Emigrants Health Act. The planting community represented by the Association are to be congratulated on the position it has now attained by the appointment of the Hon. J. Buckingham to the Legislative Council of the Viceroy. A proposal had been made by the Assam Government to considerably enhance the rents, but the opposition which it called forth has resulted in a substantial reduction being made in the proposed rates. After referring to what was being done in connection with the Chicago Exhibition, the President (Mr. J. N. Stuart) alluded to a subject upon which other speakers also expressed themselves very strongly, namely the urgent need for steps being taken for the protection of life and property in the districts of Cachar and Sylhet which during the past twelve-months have been the scene of a large number of dacoities and murders, and we sincerely hope that the joint representation to be made to Government by the Association and the Bengal Chamber of Commerce will result in the adoption of effective measures to put down the lawlessness complained of.

SUPERINTENDENTS OF CEYLON TEA ESTATES AND THEIR SALARIES.

We call attention as in duty bound, to the letter of "Superintendent" (on page 43) in which he points out that a principal cause—low exchange—which is proving so beneficial to estate proprietors, is very much the reverse of advantageous to their European employees. Immediately preceding this letter, there appears a short illustration from "Nemo" of what exchange means to the owner of a Ceylon plantation at the present time; and there can be no doubt that due consideration should be shown to the men whose care in oversight and good management conduce so largely to the profit on really paying properties. The Ceylon Tea Plantations Company Directors have acted prudently as well as generously in the arrangement made by them with their Superintendents, and we believe there are several other Plantations Companies as well as many individual proprietors who are equally considerate and liberal. They are indeed wise in their generation who, as proprietors and especially absent proprietors, endeavour to establish an identity of interest between themselves and their Superintendents in the case of all plantations worked with a margin on the right side. This can be done either by the grant

of privileges as to exchange, sick or holiday leave and reduced passage fare after a certain period of service, such as certain Plantation Companies allow—or by an allowance of a certain percentage—from 2½ to 5 per cent is we believe the general ratio—on the clear profits of the property under their care. It will be allowed, we suppose by "Superintendent" that all these privileges as well as half-salary in sterling would be too much to claim or expect, and therein will lie the difficulty of laying down any general rule such as it is proposed that the Branch Associations should be asked to recommend. In the first place, all Superintendents who are satisfied with their positions under Plantation Company terms, or otherwise, would scarcely join in the request; and in the second, all managers who share in profits would beg to be excused. This would make it very awkward in a general or even district meeting to bring on such a proposal, for the supporters would scarcely care to be noted as "discontented" either by Colombo Agents or home proprietors. It seems to us, therefore, that only by discussing the matter in the way we do today and so bringing it under the notice of all right-minded owners of profit-yielding plantations, can practical benefit ensue. We lay stress on "profit-yielding," because we have known cases of grumblers among Superintendents or Assistants on account of low salaries, although it was notorious that they and the coolies alone derived any benefit from the estate, while the poor proprietor either got nothing or found the balance increasing against him year after year. We fear there must be cases even now where the margin is narrow enough and therefore it will not do to condemn indiscriminately even in the case of "Sinne Durai's" or "Assistants" who draw less than the old-fashioned R83-34 a month. The law of supply and demand must be held answerable for a great deal: for, we know of cases where proprietors or big managers have said to an unfortunate applicant for a berth,—"I have really no place properly available; but since you are so pressing, I can make some work for you at so much a month, as a help, until you find a snitable vacancy elsewhere." Now in such a case, are we to condemn the employer who pays a very low salary very much as an act of charity? Indiscriminate criticism must, in such a discussion as the present, be carefully avoided. "Superintendent" and all who sympathise with him will find it by far the better way to discuss through the press in an amicable, practical way—as indeed our today's correspondent does—the state of the case and the remedy they would like to see applied without invoking either District or Parent Association. For our own part, we would, in the first instance, press on the attention of Directors of all local Plantation Companies earning a dividend of 10 per cent and upwards, the wisdom and advantage of placing their Superintendents on equally good terms with those of the premier Company specified by our correspondent; and in the second, we

would ask all individual owners of well-managed profitable Ceylon estates, to make quite sure they are dealing fairly and liberally by their Superintendents and Assistants and if they do not see their way to granting a share in profits, to consider carefully whether they cannot make the concession formulated on behalf of a good many of his brethren by the intelligent, hard-working planter in the letter signed "Superintendent" in another column.

LONDON MARKET FOR TEA SHARES.

THURSDAY EVENING, May 18.

The strained financial situation has reacted a little even upon the market of Tea Shares, and transactions have been on a more limited scale in consequence. Mining Lane keeps quite with prices on a somewhat lower level, though curtailed supplies seem likely before long to cause a reaction.

REPORTS AND DIVIDENDS.—The Doora Company issues its annual report, and announces the usual 10 per cent. dividend and 2½ per cent. bonus, besides which the reserve fund is raised from £5,000, at which it stood, up to £28,500! The year's working may be regarded as exceptionally satisfactory. Balijan shows a somewhat better account than last year, and pays 8 per cent. dividend. The Cherra and Endogram (Oacher Companies also issue their reports, but neither of them give anything to their shareholders. Hunwal shows an improved state of affairs—pays 7 per cent. inclusive of 2½ per cent. interim, and adds £1,000 to reserve, bringing it up to £3,000.

MEETINGS.—The Doom Dooma Company held its shareholders' meeting on Wednesday, and report of proceeding appears in another column. The Cherra and Endogram Companies also held meetings on Tuesday last for formal business. Special Meetings.—The Luckimpore Company calls its shareholders together on May 24th for the purpose of empowering its directors to negotiate terms of amalgamation with the Majuli (contiguous) Coy., and proposes what appears fair and equitable terms of amalgamation.

The following companies have already announced their dividends, and, for our readers' information, we give a comparison with last year's distributions:—

	1892.	
	Per cent.	Per cent.
Darjeeling Co.....	6	against 5
Doora Co. (including Coms.)	12½	" 10
Balijan	3	" 2
Borokai	10	" 10
Chandpore.....	10	" 5
Chuhwa.....	6	" 2½
Doom Dooma.....	13½	" 10½
Hunwal.....	7	" 2½
Indian Cachar	6	" 6
Leesh River.....	20	" 7
Lungla.....	7	" 5
Mazdehee.....	9	" 5
Nonoi.....	10	" 7½

CEYLON SHARES.—Ceylon Plantation Tea Company.—The ordinary are rather offered for sale, at the recent div., and £15 or thereabouts would possibly fetch a limited number of shares. The *prefs.* are in strong enquiry, but even at 12½ sellers cannot be found. Eastern Produce and Estate Company's ordinary shares have been taken at 32s 6d, an advance of half-a-crown on last price. The 7 per cent *pref. shares* of the Oriental Bank Estate Company (which have paid no interest for the last two half-years) have been taken speculatively, at from 2½ up to 3½, an advance on recent minimum value. Scottish Ceylon are asked for, but there are no sellers.—*H. and O. Mail*, May 19.

COMPLETE MANURING.

The judicious combination of green manuring, with the use of the concentrated fertilizers of commerce, is surely the nearest approach that can be made to the idle treatment of the soil for the production of paying crops. It may safely be said that it is the only treatment which will build up a soil to a condition of lasting fertility. The continual practice of either of these methods, uncombined with the other, is certain to prove inefficient in the long run. Two conditions which prevail with us in Florida, make this especially true for us—our sandy soil and the heavy expenses of producing and marketing the products of that soil. How would the grower prosper who attempted to produce a paying crop of oranges on pine land by the use of green manuring alone? It is universally admitted that one of the essential factors of success in modern farming is a quick return upon one's outlay, and this necessity is increased in proportion, as labor, freights and the other expenses of production and sales are larger.

On the other hand, all the weight of testimony both in theory and practice, is against the constant use of concentrated fertilizers when entirely unaided by a suitable amount of green manuring. We hear of one grove or another which has been brought up in this method and are told that it is the way par excellence to raise up a grove rapidly to sell. This may be so, but assuredly the eventual owner will discover that the future of his grove has been mortgaged to secure the appearance of prosperity in the present, and that the foundation of a lasting fertility has yet to be laid in his soil.

We touched above upon the point which, beyond all others, makes green manuring alone unfitted to produce paying crops. The inorganic matters and the nitrogen are very slowly given up for the use of the crop which follows, or which permanently occupies the soil. The living plant cannot assimilate the elements of the decaying matter until the latter has been completely disintegrated, and is in fit condition for absorption. Beside this particular in which the plan of green manuring is inadequate, we must remember the fact that the tendency of modern agricultural practice is towards intensive farming—the production of the largest possible crop on the smallest possible acreage—and with a view to this, the necessity of a liberal use of highly concentrated and quickly acting fertilizers is generally admitted. Even stable manure, Nature's complete fertilizers, has been left behind in the race as being too bulky and too slow. A further point which will naturally suggest itself in this connection is the readiness with which the commercial fertilizers can be adapted to the exact needs of the soil, or to any given state of the crop which occupies it.

On the other hand, to doubt the necessity of supplementing the concentrated fertilizer by some humus-forming manurial substance is to go in the face of the best authorities, whether theoretical or practical. The advantages of green manuring are many, and the majority of them are generally well known, even if often hardly understood. Not the least among them is the improvement of the texture of the soil. This bears particularly on the case of a sandy soil. A sandy soil is a close soil, and has a tendency to pack beyond almost any other kind. A soil which packs easily, loses its capacity for aeration, (and with this much of its absorptive properties), and capillary action. The introduction of humus by the practice of green manuring makes such a soil far lighter and more porous, and thus at the same time makes the results of cultivation more lasting. What practical farmer on the sandy soil of Florida has not had immediately after stirring the surface with the harrow, to deplore the action of a sudden heavy shower, which will, in ten minutes, almost entirely undo his work by forming a crust of the easily packed sand? The tendency of green manuring is to correct this undesirable characteristic of a sandy soil.

The actual supplying of nitrogen is another important function which is generally much underrated. An emi-

ment chemist found the crop of bean plants grown upon an acre of ground, for green manuring, contained 280 lb. of nitrogen. While this is probably a somewhat exceptional quantity, the fact remains that any of the bean family used as a crop for plowing under puts into the soil a very appreciable amount of this valuable element, and that not pre-existing in the soil, but entirely derived from the atmosphere and fixed in a fit condition for the use of subsequent or contemporary crops.

The moisture-holding properties of humus in the soil are too well known and too self evident to need comment.

From the chemical standpoint, besides the direct addition to the soil of nitrogen, the practice of green manuring is highly important, inasmuch as it produces such a large amount of carbonic acid in the soil. While but little likely to produce an excess of this valuable chemical agent, when the practice is followed on land bearing a permanent crop, the result on new land is far more direct. The large quantity of carbonic acid given off during the decay of a single crop of green stuff plowed under the surface, works wonders in dissolving the crude materials which exist in virgin soil, and, no less important, in causing beneficial reactions which fit the fertilizing elements for absorption as plant food.

By all means then let us combine these two important means of enriching our soil, the commercial fertilizer to give us quick results, and to intensify our forming and the green crop to hold the surplus of the commercial manure, to gather still more from the atmosphere, and to fit the soil mechanically for those all-important chemical reactions which invariably precede and accompany the assimilation of food by plant or tree.—*Florida Agriculturist.*

“PICKINGS” WITH A LOCAL APPLICATION.

The idea of CATTLE-BREEDING for a local beef supply is scouted by the Agricultural Record of Port of Spain, where we are told cattle will stand up to their knees in bright green and apparently nourishing grass without touching it! This curious conduct is traceable to the fact of the grass being rank and sour. In Trinidad it is said that only by hand feeding, at great cost, and with many minor difficulties can cattle be kept in any condition whatever. The cost and excessive care demanded has therefore restricted this enterprise solely to milch cows and draft oxen, which, when wellbred and tame, are valuable and pay for the extra expense and trouble, in spite of the fact that milch cows there give less milk by far than they do in other tropical countries.

There would seem to be some prejudice against the use of GUINEA GRASS as fodder for milch cows, among the natives of Ceylon. They have an idea that it (as they put it) “dries up the milk.” It is quite possible that the more succulent “water” or Mauritius grass, owing to the large percentage of water it contains, tends to the secretion of a larger quantity of milk, which however, cannot be expected to be of the same quality as that produced from a diet of guinea grass. The latter is admitted by all who have tried to be an excellent fodder for milking cows. In Venezuela it is said that the herds run wild on the boundless prairies consisting of nourishing guinea grass, which at most requires only occasional care and attention for its satisfactory growth. It is noticeable that along the higher parts of the railway line to Kandy guinea grass grows apparently wild and with striking luxuriance.

Observations have lately been made regarding the habits of the “PARASOL ANTS” (*Oecodoma*), which are the cause of so much damage and destruction in the farm and garden. The food of these ants is said to be the fruits of a fungus which is specially raised by these creatures on leaf cuttings which they

carry to their “nests.” The particular fungus has not yet been satisfactorily identified, but the description of the manner in which the ants manipulate the leaf for the growth of the fungus is rather amusing. The ants are said to “lick the leaf with their tongues” in order to sterilize it, by cleaning it in such a manner that no fungus spores should grow other than those of the species required for food. This material after being so treated is cut up, chewed into balls, and then formed into flocculent cellular masses on which the fungus grows in a few hours. The “parasol ant” is happily easily killed, the best method when nests are in the ground being by the application of coal tar or gas water.

It has been stated by a German chemist who has taken up the subject of the analysis of COCAO, that “in a natural fresh condition the cacao bean does not contain either Theobromine *caffeine* or *cacao* red, but a glucoside which is soluble in alcohol.” The glucosides of the bean were split up or decomposed by the process of curing, and Mr. J. H. Hart of Trinidad considers it possible that by an extended knowledge of the chemistry of the bean to obtain precise information as to how fermentation affects the order of change in the materials composing the bean during that process.

IN NEW GUINEA, where land is bought from the Government on condition that the purchaser shall introduce some new industry in cultivating the land, and shall carry out some specified extent of improvement within a given time; the price of the land alienated may be as low as two shillings and six pence per acre: if no conditions as to improvements are imposed, the price to be paid for land cannot be less an acre, than:—

- 1—For agricultural land.....10s
- 2—For pastoral land..... 2s
- 3—For land for trading or fishing purposes£5
- 4—For land for the planting of coconuts 5s

Land in parcels not exceeding 50 acres can be purchased at £1 an acre, the payment being made in instalments extending over 5 years. Land suitable for coconuts may be leased for 60 years. No rent may be payable for the first five years but for the next five it cannot be less than 6d per acre, and for the remainder of the lease not less than 1s an acre each year.

The MEXICAN MANGUEY tree it is said, furnishes not only a thread and needle, but many other conveniences. It is found generally near the door of Mexican houses loaded with clusters of beautiful flowers, and at the tip of each dark green leaf is a slender thorn needle that must be drawn carefully from its sheath, at the same time slowly unwinding the thread, a strong smooth fibre of great length, attached to the needle. Among its other uses the roots go to form a savoury dish, while the leaves make a pretty thatch and are so used by the Mexicans. The leaves also afford material for paper, and from the juices is distilled a favourite beverage. From the heavier fibres the natives make strong cords and heavy string cloth.

Look to your laurels, good old coconut-tree!

HORTICULTURE.

ANTS ON PLANTS.

Every now and then ants appear to combine forces and will take entire possession of a tree or shrub. There are three methods by which to circumvent the busy little pests. The first is the surest, but great care has to be taken in its application, for it is a fatal poison. Take lard and mix into it a small quantity of corrosive sublimate. Then dip a rag or a tow string into the mixture until it is thoroughly saturated therewith. Next lay the rag or string around the root of the tree at a little distance from the trunk, making sure to have both ends to meet, so that there will be no gate or entrance left. In a short time the ants will all disappear. They seem to recognise the poison and dread its effects. A colony of ants

was once driven from a obryanthemum plant, of which they had taken entire possession, by placing a bit of cloth 4 inches long and 2 inches wide near the roots, but not surrounding them. Of course this cloth was saturated with the mixture of lard and corrosive sublimate. Another method of application is; first to wrap a cloth around the trunk of a tree higher than children can reach; then wind two or three layers of the saturated string over the cloth wrapping. The ants will leave in disgust. If you will take the pains to run a circle around the infested trees with ordinary chalk, making a band about 2 inches wide and taking care to make this as smooth as possible, the ants cannot crawl over it. For some reason they slip and lose their hold. They will sometimes cross a chalk mark on the floor, but they cannot climb over a chalk band made on the legs of a table or on a tree.

HOW TO HAVE A NICE LAWN.

City people love to see a beautiful lawn in front of their houses, so do the folks in the country, hence we give the following, showing, how they ought to be treated. The charm of a lawn consists largely in its dark green colour, luxuriant growth and freedom from weeds. Many try to secure this result by covering their lawns with rotten manure in the autumn or early winter. A much pleasanter method is to sow a mixture of, say—equal parts nitrate of soda, superphosphate muriate of potash on the lawn this autumn, and then next spring give another dressing of nitrate of soda. Apply this autumn the above mixture at the rate of half a ton per acre, or say a small handful to each square yard. Sow it broad-cast, as evenly as possible. In the spring sow 300 lb. of nitrate of soda per acre, or say a small handful to each three or four square yards of lawn. The above treatment will not only greatly improve the lawn, but will also give increased luxuriance to the trees, shrubs, roses and flowers that may be on the lawn. For pasture lands many will think they cannot afford to be so liberal in the use of fertilizers. Perhaps not. But there is great pleasure in seeing a closely cropped pasture clothed with dark green, luxuriant grass that looks fresh every morning and smiles in the sunshine during our hot weather. We believe there is profit as well as pleasure in such a field of grass. Put on a good dose of nitrate and superphosphate and potash this autumn, and an additional dressing of nitrate of soda in the spring.

TRUNKS OF TREES

It is a general impression that the trunks of trees lengthen, but this is not the case. The trunk of a tree, being once formed, does not lengthen a fraction, no matter if it lives to one hundred years. A branch from a trunk that is now say, six feet from the ground will have the centre of that branch still six feet from the ground, no matter how many years elapse. If branches are, therefore, now too low they had better be cut off at once. Again, it is worth remembering in cutting off branches that they should always be cut close to the trunk or to any main branch, so that the wound may heal over. If the branch is very large, so that the wound is likely to take several years to heal over, it is better to paint in to keep the water from rotting the wood until it is properly healed. More good trees are spoiled through leaving an inch or two of stump to a cut-off branch than people have any idea of.

POTASH WOOD ASHES.

It is quite probable that much phosphate soon passes beyond the condition in which it can be used. While there is nothing in salt to take the place of phosphate it may be better to make phosphate in the soil available than an extra supply of that mineral. Potash, especially in the form of wood ashes, has also the same effect, with the advantage that the ashes, besides furnishing carbonic acid, are themselves a supplier of potash, one of the direct constituents of all plants. Wood ashes are a necessity to the vineyardist and orchardist. Possibly farmers raising crops that require less potash, can keep their soil fertility available, for a time at least, more cheaply by the use of salt.

But whenever the time comes that potash is exhausted, as it is apt quickly to be on sandy or gravelly soils, salt will no longer be of any benefit, and resort must be had to supplies of potash.—*Horticultural Times.*

LONDON PRODUCE REPORT.

TRAVANCORE TEA.

(From Patry and Pasteur, Limited,

May 17th, 1892.

TRAVANCORE.—Prices generally have ruled easier during this week for all classes, except those showing individuality, either in leaf or liquor. This depression is due to the too plentiful supply of low medium kinds from Ceylon, which has been going on for some weeks past.

Fine thick liquoring kinds, or teas possessing tip, are badly wanted, and command stiff rates.

The quality of the 899 packages under offer was good medium.

	Bro. Pek.	Pekoe.	Pek. Sou.	Souchong.	Bro. Tea Dust.	Quantity.	Av. about.
Bon Ami	10½	9d, 8½d	8d	..	8½d, 5½d	160 chs.	9½d
Seafield	1s 1d	8d, 7½d	6d	106 ½-ch.	8½d
Kuduwa Karnum	10½d	8½d, 8d	7½d, 6d	115 chs.	8½d
Corrimony	10½d	7½d	..	6½d	5½d	78 ½-ch.	8½d
Merchiston	9½d	8d	7½d	..	4½d	45 ..	8½d
Fairfield	11d	8½d	7½d	..	5½d	48 chs.	8½d
Venture	8½d	8d, 7½d	..	7½d	4½d	115 ..	8d
Invercauld	8½d	8d, 7½d	7½d	7½d	5½d	126 ½-ch.	8d
Glenmore	8½d	7½d, 7d	...	6½d	5d	80 ..	7½d

Balamore unassorted 50 half-chest 8½d. Linwood unassorted 46 half-chests 7½d, and Arnakel 18 chests broken pekoe 11½d per lb.

Total 899 packages, averaging 8½d per lb., against 8d last week, and 8½d for corresponding week last year.

MANURES AND THEIR USES.

If we consider the different substances used for fertilising purposes, their great variety must at once strike us very forcibly. There are, for instance, stable manure, compost, lime, bone-dust, superphosphates, gypsum, ashes, not to speak of the sundry artificial or commercial manures. The question then arises:—What is it that enables a substance to exercise manurial effect to promote and enhance the growth of plants? This consists of three things. Such a substance must afford direct nourishment to the plants or it must render the nourishing elements of the soil absorbable for plants; or it must improve the physical conditions of the soil by making it either more loose and porous or more compact and dense, or by warming it by its decay.

What, then, is it that affords nourishment to plants? The greater constituent part of all plants, aside from water, consists of combustible materials. Of these, again, the greater portion are woody fibre, starch, and other similar bodies, which are made up of oxygen, hydrogen, and carbon. The plant takes the material for those bodies from carbonic acid and water, which two substances are at its disposal, both in the air and ground, in sufficient quantities. Only a small portion of the constituents of a plant contains, besides carbon oxygen, hydrogen, also nitrogen. To prepare these the plant needs besides carbonic acid and water, also ammonia or nitric acid.

Now, in consequence of decaying plants and animals there is always ammonia in the air and the ground to be absorbed by plants through their leaves and

roots; but the farmer wishes to obtain the largest possible yield from a given piece of ground; he, therefore, must in most cases, provide the plants with ammonia through manure. How much of it may not be very easy to determine. But suppose when there is an approximately correct proportion in the raising of market products and feed plants, where the location of plants in crop rotation is a correct one and where the stable manure is treated in such a manner as little as possible of its substance is sufficient to provide for an ample supply of the needed ammonia. A correct proportion between feed plants and products for the market must be pre-supposed, for the reason that plants with small and quickly withering leaves, such as cereals, are able to absorb but little ammonia from the air, while plants with large leaves that remain green for a long time, such as pod-bearing plants like peas, clover, &c., absorb a great deal of ammonia from the air, and only when young are they in need of a soil richly supplied with ammonia.

The manurial efficacy of some substances is owing to the fact that they do not themselves directly supply the needed elements, but because they dissolve ingredients of the soil to be absorbed by plants. Many substances, such as lime and gypsum, are known to act mainly as stimulants, that is, as chemical solvents of other substances.

Here the objection may be raised that an application of such stimulants impoverishes the soil. This, however takes place only where a re-supply is not properly cared for. Besides, the quicker the ingredients of the soil are dissolved and made available for growing plants the greater are the profits, for the same rule applies here as in business transactions—the oftener the capital is exchanged the greater are the gains if the wheel is turned the right way.

The third manurial effect of a substance consists in an improvement of the physical properties of the soil. We all know that heavy clay soil is well loosened by fresh stable manure and warmed by its decay, and on the other hand, light soils become more compact and better capable of holding water by the application of manure, because this manure, being a humus-like substance, retains the water better than sand.

From this it is evident that such a substance to be used as manure, will be most valuable to the farmer which is effective in all three directions, and at the same time is the cheapest.—*Australasian*.

COOLIES AT THE STRAITS: WHITEWASHING IN EXCELSIS.

This is the title of an editorial in a recent number of the "Straits Independent" dealing with a lengthy letter from the Colonial Secretary to the Residency Councillor regarding coolie mortality. A copy of the letter had been submitted at a meeting of the Penang and Province Wellesley Planters' Association, and our Straits contemporary describes it as "one of the most remarkable documents of its kind we have ever perused, and, as a specimen of wholesale whitewashing, absolutely unequalled." It appears that a Commission had been appointed to inquire and report upon the high rate of mortality on Caledonia and Byram estates, and the letter referred to, embodies His Excellency the Governor's views with regard to the conclusions of the Commission. In it the Colonial Secretary states:—

"The gentlemen forming the Committee, to whom His Excellency is much obliged for the trouble which they took to investigate the causes of the mortality among the Byram coolies, comments at some length upon incidents in estate management which, in their opinion, required reform. They arrived at certain conclusions and made certain recommendations. But they failed to appreciate that their verdict was required on the simple issue of whether or not the estate was, owing to some inherent defect in the locality itself, unfit for the residence and employ-

ment of statute immigrants. They found that the unhealthiness which had been experienced was due to removable causes and their report, after it has been twice referred back for further information, was accepted as a decision that the estate was not unfit for Indian coolies."

The points upon which His Excellency's views are given are:—

(a) House accommodation; (b) Hospital accommodation; (c) Water supply; (d) Food supply; (e) Unreliable nature of death returns; (f) Discharge by mutual consent; (g) System on which death rate is to be calculated in Indian Immigration Agent's returns.

With regard to the first His Excellency does not consider it necessary to give any directions beyond expressing his confidence that the Indian Immigration Agent will, in regard to all estates, see that the obligation of the employer to provide "sufficient and proper house accommodation" is carried out. The P. C. M. O. and the manager of the estates had had a consultation with reference to hospital accommodation and it is added:—

"His Excellency has approved of the arrangements proposed by Dr. Simon and they must be carried out. Instructions for the management of estate hospitals have been drawn up and are now being printed, and will shortly be issued."

On the question of water-supply the following is the Governor's deliverance:—

"His Excellency has no hesitation in deciding that the "sufficient supply of wholesome water," which by law an employer is bound to find for his statute immigrants should be, in respect of Caledonia and Byram estates, a supply of the Nebong Tebal water conveyed to the estates in pipes (at the expense of the proprietors) in connection with the Government water-works. His Excellency trusts that the necessary works will be put in hand at once."

As to food supply no interference is recommended. With reference to the death returns it is stated:—

"Six men who died in Hospital were returned as 'discharged' because they were discharged from their employment during illness. There has, however, been no attempt at anything like concealment, and the alterations made in the books were initiated by the Colonial Surgeon. His Excellency regrets therefore the use of the word 'falsification' in the Committee's report."

The subject of discharge by mutual consent is thus referred to:—

It has sometimes happened that employers have given invalid coolies their discharge, thus ridding themselves of a burden and shifting it on to the Government. In the interests of the coolie, the practice is not to be altogether condemned, for it is conceivable that the mental condition of a labourer who despairs of recovery on the estate, may be so stimulated by the knowledge that he is a free agent, that he may regain strength and health.

On the other hand, the system of discharges "by mutual consent" is susceptible of great abuse if it is allowed to free an employer from obligation or to affect the death rate on an estate, and the attitude of the Colonial Surgeon in Province Wellesley should have been that of the Indian Immigration Agent, who wrote to the general manager, Penang Plantations Company, in April 1891, to the following effect commenting on the case of an immigrant who was admitted into Sungai Bakap Hospital on the 26th January, was discharged "by mutual consent" on the 29th January and died on the 16th February 1891.

This subject had been fully considered by Government with the result that the following section has been inserted in "The Indian Immigration Ordinance Amending Ordinance 1892" which was passed in December last:—

"50a. Any contract under this Ordinance with a statute immigrant may be determined with the consent of such immigrant and of his employer and with the approval of the Indian Immigration Agent, but such determination shall not operate to relieve the employer from any liability under this Ordinance for

the space of three calendar months from the date of the determination of the contract. Every such consent and approval shall be endorsed on the contract by the person giving such consent or approval." With regard to the system on which the death-rate is to be calculated, it is stated that the Indian Immigration Agent has been instructed to follow the forms in use in Assam. After a complimentary reference to Mr. Turner, the manager of the Company owning the estates, His Excellency alludes to the remarks of the Committee with regard to the management of the Byram estate hospital which involve a severe censure on the Colonial Surgeon and acquits the doctor of any intentional neglect. He also accepts an explanation with regard to the evidence of the manager of the Byram estate which the Committee had characterized as untrustworthy. The point which the "Straits Independent" makes is that the Report of the Commission had not been made public.

THE GOVERNMENT DAIRY.

Adjoining the Agricultural School is a very fine building capable of accommodating about 75 or 80 cattle. It is substantially built and tiled, the stalls being ranged round an open square, and from a sanitary point of view it is quite a model. Mr. C. Drieberg the principal of the Agricultural School and Mr. C. A. Lye the Colonial Veterinary Surgeon have taken a great deal of personal interest in the starting of the dairy and by the arrangements they have made one might say that there is absolutely no risk of the milk becoming contaminated as there is in the case of cattle stalled in ordinary byres. The stalls are strewed with coir dust and it will be readily understood how serviceable a material this is in a byre from its power of absorption. Everything offensive is removed as quickly as possible and there is an air of cleanliness about the building that at once strikes the visitor. With regard to the dairy appliances "up to date" is a phrase which exactly describes them. The most modern of separators and measures are used, and the milk is nicely cooled by being passed through a refrigerator in a room which it is intended to fit up with a patent window over which water will continually trickle so that the air in the apartment will be kept always cool. At present there are about 30 cattle in the stalls and the milk they yield is of first-rate quality, giving cream as thick as butter for which we should fancy there ought to be a good market in Colombo. The cattle recently imported from India are improving in condition wonderfully and the calves of which there are a dozen (and more expected) are thriving very well. Mr. Lye regularly inspects the cattle and see that they receive every care and attention.

INDIAN TEA SHARES.

Our contemporary *Truth* publishes the following letter:—

INDIAN TEA COMPANIES' SHARES.
Old Cavendish Street, W., May 5, 1893.

DEAR SIR,—I have read with much interest your article on this subject. While coinciding generally with your views, I venture to make one or two qualifying remarks.

1. You are correct, that the eyes of investors, large and small, have recently been opened to the sound nature of these companies. While, however, there has been a rise in values, there are still shares in good companies which can be bought on favourable terms, provided buyers are prepared to pick up those which are offered for sale.

2. You are no doubt right to recommend caution in buying, but you appear to unduly accentuate the risk (sic) attaching to the tea industry. In the case, particularly of the larger companies, this risk (although it does perhaps exist) is greatly minimised—(1) by the estates being spread over wide areas, subject to different climatic conditions; and (2) by the companies possessing larger reserves of undivided profit, applicable, in unfavourable seasons, to equalisation of dividends.

3. As regards the "wheat" and the "chaff" (to quote your own words), I would merely say (1), that the proportion of "chaff" is, relatively, small; and (2), that among the "wheat" there are, in addition to the companies you mention, many other sound concerns, among which might be mentioned Assam Frontier, Borelli, Jhanzi, Scottish Assam, Borokai, Chubwa, Indian of Cachar, Lungia, &c.

4. As regards the yield to investors afforded by recent dividends, you appear to have rather underestimated them, many even of the "market" stocks returning from 6 to 7 per cent.

5. It should be borne in mind that some of the companies do and others do not pay interim dividends in December. The following, exceptionally, do not distribute interims, and hence now carry the entire dividend—viz., Darjeeling, Jorehaut, Indian of Cachar, Scottish Assam, North Sylhet, and South Sylhet.

6. In regard to your special remarks, your opinion is correct that Jokai is the Consols of the Tea Market; Jorehaut and Lebong as solid and substantial companies, Brahmaputra and D. o. m. Dooma as the cream of Assam, but the younger Doars Company properties should not be overlooked (both its Ordinary and Preference Shares)—now great favourites with investors—nor the Ordinary and Preference Shares of the Ceylon Tea Plantation Company, which may be called the Consols of the Ceylon Companies.—Yours faithfully,

ANGLO-INDIAN.

. We are obliged to "Anglo-Indian" for his letter. Investors will decide for themselves whether they will look through his rose-coloured spectacles or through ours of plain glass.—*H. & C. Mail*, May 19.

NETHERLANDS INDIA: INTERESTING NEWS.

COFFEE.—THE BATAVIA EXHIBITION.

The Home Government have decided upon selling by auction at Batavia, this year, one hundred thousand piculs of Java coffee. The Netherlands Trading Company advised against it, on the ground that the Government coffee crop in Java, this year, is so short, the estimate being 150,000 piculs; and that the course adopted would lessen the quantity offered for sale in Holland. The BATAVIA EXHIBITION is short of funds. The expenses already reach one hundred thousand guilders, which have exhausted the proceeds of a lottery held to raise money to meet the expenditure. A second lottery is talked of, and the Governor-General is said to be not disinclined to sanction another lottery, so that there seems to be no fear of a deficit or a call upon the guarantors. The Queen and the Queen Regent of Holland have put at the disposal of the Batavia Exhibition Committee: 6 gold, 8 silver, and 8 bronze medal for competition. The Governor-General has given one thousand guilders as contribution towards the cost of medals and prizes.

The *Batavia Nieuwsblad* considers the sudden rise in tobacco prices in Holland as astounding and inexplicable to people in Java. For instance, 400 hales from the Deli estate of St. Cyr reached the enormous price of 370 cents per unit, and one brand attained the rate of 400 cents. When it is borne in mind that, in former days of big tobacco prices, 230 cents were the highest rate quoted, people do not know what to make of this violent reaction from the recent very low prices.

Advices from Menado in Celebes, to the 23rd April, mention activity on the part of a volcano there, called Loken, which had been looked upon as extinguished. On the 29th March, it suddenly began to show signs

of activity. A thick column of smoke issued from the mountain, the sight of which brought about a panic among the inhabitants of the neighbouring villages and they took to flight with all they could carry away. But, as the volcano remained smoking without anything worse happening, the panic ceased and the people returned to their homesteads.—*Straits Times*.

INDIAN TEA NOTES.

Our Lallamook correspondent writes on 20th May 1893.—The weather has been frightfully hot. Thermometer has been up to 92° for the last week, that was in an Eastern Verandah, 95° and 97° was registered in a Western Verandah. Two good showers of rain fell on the 17th and 18th—4½ and 30 inches. Further South on Thursday evening 1.50 of rain fell. Leaf coming on at last. The Burncherra Police Guard is costing R60 a month for 6 men.

The liberal amount of rain which has fallen during the past week will afford vast benefits to the tea districts. The Dooars and Assam planters, and Cachar and Sylhet teas under hybrid and indigenous alike, should now finish freely, and all the stronger for their having in places, of late, done indifferently. If as much rain as we have had here has fallen in the Surma Valley, we may expect to hear of floods. It will be interesting to hear what effect the downpour has had upon the freshly thrown up parts of the Dooars Railway embankment.

The new down-draft and T siroccos with fans, and slow careful firing, have caused complaints of soft teas to be much less frequently heard on factories, where these means of acquiring keeping qualities are used.—*Indian Planters' Gazette*, May 27.

CEYLON TEA PLANTATION COMPANIES.

(Communicated.)

The number of Companies in Ceylon has increased considerably during the past year, and the results generally have been very satisfactory and profitable to shareholders. An assuring fact in connection with the floating of these Companies being that proprietors when parting with their properties, in many instances retain large interests in the new concerns receiving a proportion of their payment in stock.

Doubtless but few investors at home have ever heard of local shares, and only a few Ceylon companies with sterling capital are quoted in London. Amongst which, Ceylon Tea Plantations, Scottish Ceylons, and Kelani Valley are probably the most prosperous; and holders of these shares have every reason to be satisfied with their stocks which are yielding them remunerative dividends. Investors who have been interested in the progress of these companies and are unable to obtain an interest in them except at a high premium would do well by turning their attention to the local market where investments could be made with good security to yield from 6 per cent to 10 per cent.

For the information of those interested in this subject we give a list, with notes, of some of the most important Ceylon Companies which have their capital in currency and are managed by local boards composed of Directors of experience in the island.

PRODUCE COMPANIES (TEA.)

"Mocha" is a well managed and prosperous Company of not very long standing—shares have been well taken up when offered by local buyers at R175 prem.

The dividend for this half will probably be 10 per cent, making with an interim of 5 per cent already paid 15 per cent for the year.

The investment on these figures would yield 11 per cent.

"Glasgows"—These shares are very firmly held locally at 50 per cent premium. Last half year's average for tea sold on the local market was 62½ cents per lb. The estate contains coffee and cinchona, but

it has been decided to replace these products with tea; as the crops for the former are uncertain, and for the latter the market is so low.

Investors at present would receive exactly 8 per cent for their money.

"Yataderias"—This stock is seldom in the market, and is always well inquired after by local buyers. At present quotation R240, the yield is a good 10 per cent. Last dividend 25 per cent.

"Yatiyantotas," like the above, are seldom offering. This Company has a record of high dividends. Shares R1,000 paid up at R3,300 would yield 9 per cent. Last dividend 30 per cent.

"Wannarajahs" were floated last year, a keen demand shortly after allotment ran them up to R200 premium. At the present moment they are available at a premium of R75. Investors would do well to consider them at this price; but must be prepared to wait for a year or so before receiving any dividend. When the property is fully developed it is expected to pay handsomely.

"Dunkelds"—For their first year had unfavourable weather resulting in a short crop, yet yielded a 10 per cent dividend for its shareholders. The present year so far has been more satisfactory. Last quotation 625.

"We Oyas" paid their shareholders 20 per cent for last year and are quoted at R225.

Among recent Companies which have not yet paid dividend "Agra Onvahs," "Great Westerns," "Eadellas" and "Maha Onvahs" are worth the attention of buyers.

Besides the above there are numerous other Ceylon tea stock which would prove good investments at a price, but the above list gives a fair criterion of well-known and carefully managed Tea Companies.

"Delgollas"—This is a promising investment and worth buying at R500. The first dividend declared was 8 per cent—which was subsequently increased to 9 per cent.

Being an estate wholly devoted to the cultivation of cocoa, coconuts, and Liberian coffee, it is popular with investors not caring for tea.

The coconut plantation has not yet reached maturity and contains many young plants which are yearly increasing in value.

Shipping and Landing Companies are represented by "Wharfs" and "Syndicates. The former being the safest investment in the island (excepting Government stock) for those requiring security and are satisfied with small dividends. At 100 per cent premium the yield is 4 per cent. This Company has a reserve of R157,500, against a capital of R200,000.

Hotels are represented for those desirous of taking up this class of investment. "G. O. H." take the first place and are considered good security—R230 gives buyers 6 per cent. Younger Companies which have not been long run are "Bristol," and "Nuwara Eliya"—the latter being situated in the hills and is much frequented during the hot season. A further addition is shortly expected in the way of a suburban hotel called the Brighton. This, however is being floated in London and only a few shares are reserved for Ceylon.

The local market is small, and business in any particular stock is not always possible at short notice. As holders are mainly planters scattered over various parts of the island, much time is lost in correspondence. The nominal value of shares in Ceylon vary as follows:—R50, R100, R400, R500, and R1,000; but R500 has been more generally adopted by the Tea Companies recently floated.

SILVER, GOLD AND TEA.

Mr. W. S. Wetmore sends a letter on the "Gold Question" to the *N. C. Herald*, which winds up as follows:—

In China, as is well-known, gold is in no way connected with the currency, and is simply a commodity, in every sense, as much as are teas or silk. Taking it, therefore, as a commodity, as it actually is, reference to the commercial circulars where it is regularly quoted, will show that it has advanced from

162 taels of silver per bar of standard weight and fineness, since 1866, to 261 taels (the highest point touched) in March last, or somewhat over sixty per cent. That the advance from 1873 to 1892, inclusive, may be properly appreciated, I have given the silver equivalents of gold in each successive year in the horizontal line under that of the aggregates of commodities, adopting the same standard 2,000 in 1873, as the starting point, and it will at once be seen how the commodity, gold has advanced above the silver plane 2,000 which silver, and all commodities including gold, occupied in 1873.

That this enormous divergence between the values of gold and silver is entirely owing to an advance of the former and not, at all, to any decline in the latter, is, I think, abundantly proved by the attached table, for if silver had really gone down, even five per cent., then the aggregate value, for 1892, of the commodities specified, would have been more, instead of less than 2,000 and, with a decline equal to the difference between the two metals, instead of 1,761, as it now is, it would have been at least as high as the other commodity, gold, which stands as shown in the table at 2,950.

TABLE OF INDEX NUMBERS FOR TWENTY CHINESE STAPLE COMMODITIES.

COMPILED BY W. S. WETMORE FROM THE RETURNS OF TRADE OF THE IMPERIAL MARITIME CUSTOMS OF CHINA.

[We quote only for tea.]

Silver value of Gold ...	2648	2730	2746	2539	2621	2950
--------------------------	------	------	------	------	------	------

The standard being taken at "100" in 1873 with gold at "2,000,"—in 1892, we find black tea at 66 or 34 per cent of a fall, while gold has risen nearly 50 per cent in silver value. Silver itself, Mr. Wetmore holds has not declined in value!

CEYLON TEA IN RUSSIA.

M. Rogivue has apparently given up advising the P. A. of his doings. The following is what he writes to one of our contemporaries:—

"In previous reports to the Committee of the Ceylon Tea Fund I very often wrote that, although the task of pushing Ceylon interests here is not an easy one, I am, however, very sanguine about success,

were I better supported from that direction. Mr. P. G. Spence, through your kind columns, has been many times my advocate for placing the matter before the eyes of Ceylon Planters, but, I am sorry to say, his efforts, as well as yours had, up to this time, very little effect as the Tea Fund Committee seems to be more interested in other, perhaps more important questions. They never replied to one of my letters, this being, it seems, their way of acknowledging and encouraging the services of their "pioneers" It is true that more than a month ago I received from Mr. Philip, the Secretary of the Planters' Association a copy of the resolution passed recently by the Committee, that a grant of 9,000 pounds of tea is to be made to me, but up to this time I have not yet seen the first pound of that intended shipment, nor even received any advice from Messrs. Whitall & Co., that the tea has been bought and shipped. "Your suggestion that half-a-dozen agents, on similar terms to mine, should be despatched to Russia to co-operate with me, may be a good one; but, besides being unfair to me, who did for the past two years the first or more difficult work, it would, I think, be useless unless very large sums of money were devoted for this purpose (in such a case I could see the funds myself, and I have no hesitation to say I can do alone the whole work wanted). Let, instead, all the available funds be sent to me in kind (tea) for money, and I will show Ceylon, in a short time, what I am still able to do for the extension of Ceylon tea in Russia. "Let, as you once suggested in your paper, as much as £1,000 a year be spared for my work for the next five years, and, like yourself, I feel certain that the money would be well laid out.

"Advertising by publications and by free distribution of tea, travelling and opening new agencies in the provinces, are the principal mediums for success; but having myself already spent a small fortune in doing this—my only reward up to the present time being to have worked for others!—I have no means to continue it, and therefore require the assistance of the Tea Fund.

"The fact that Popoff Brothers are about to establish an agency in Colombo for the purchase of Ceylon tea is certainly a very palpable evidence that my work had some effect, for it is to be noticed that that very firm was the most energetic enemy of Ceylon tea two years ago when I commenced operations and called at their office to offer them my produce. That they will sell Ceylon tea *pure in packets* I cannot say yet; it is well known that they mix it with their Chinese rubbish; but I fancy that the demand for *pure Ceylon* has so much increased by now that they must be in a position to deliver it to their regular customers. Another proof, amongst many others I could mention of the result of my work in Russia is to be found in Messrs. Gow, Wilson & Stanton's London circular of the 27th January, 1893, when they say: "One of the most noticeable features is the large quantity of Ceylon tea sent to Germany in 1892, amounting to very nearly one million pounds the bulk of which was most likely destined for the Russian market."

"You may be interested to hear that in the year 1892 I myself imported very nearly 100,000 pounds of Ceylon tea for the exclusive sale to the public *pure in packets*. I have now three retail magazines in Moscow and in Nijni-Novgorod, and fourteen agencies in the provinces. In your editorial note referred to above I notice you are under the impression that I have not sent for some time a report to the Tea Fund Committee I wrote them a long letter on the 13th-25th of November last, of which Mr. Spence has sent you a copy, but which for some reason or other has not been submitted to you as usual for publication in your valuable paper.

[Mr. Rogivue is wrong about the great Russian Tea House of Messrs. Popoff Brothers; for M. Popoff paid a visit to Ceylon in February 1891, went all over Abbotsford and expressed himself as greatly pleased with all he saw and as much interested in Ceylon tea which he was at once to study with a view to importations.—Ed. T.A.]

VARIOUS AGRICULTURAL NOTES.

RAMIE.—London *Industries* says:—"Ramie fibre is now being used in connection with the manufacture of paper intended for French bank notes. It is stated that the paper thus made is finer and stronger than the ordinary paper employed, and that much clearer impression can be made upon it."—*Planters' Monthly*.

TEA CULTIVATION IN INDIA.—In the latest Official Report from the Government of India just to hand, we see that at the end of 1891, there were 362,130 acres planted under tea (with reserves for planting of no less than 812,517 acres!) and of this 309,852 acres were under "mature plants" and 52,278 acres "immature." Taking half of the latter as bearing in 1893, we get 336,000 acres to give 125½ million lb. this year for export, besides a few million lb. for home consumption. [In 1891, the crop is returned at 123½ million, which the export was 119 million]. It will be observed then that the average yield for all India is not far short of 400 lb. per acre. If Ceylon gave an average of 350 lb. an acre this year, our total crop should not be less than 84½ million lb. But the total export may not exceed 80 million and the crop perhaps a million more.

"THE BITTER CRY OF MINCING LANE"—OVER CEYLON TEA—is the heading of a letter that reached us by last mail from a "City" gentleman whose name is unknown to us, but who is evidently an expert in tea. His letter is a renewal of the cry raised by Mr. Hawes which we endeavoured to answer when at home in the columns of the *Financial Times*. The line of argument we adopted was that if "the trade" encouraged fine teas by paying good prices for them, the Ceylon planters would certainly respond; and surely the experience of the past six months accentuates our argument. "Philpot" complains that Chairmen of Ceylon Tea Companies never refer to the quality of the product; but why in the world does "Philpot" himself not notice and explain the fact that from November till very recently, fine Ceylon teas were glutting the market so far as equivalent demand was concerned; that Broken Pekoes could not get nearly their value, expert Brokers being witness; until at last the ridiculous position was reached of our commonest teas realizing prices within very little (1½d to 2d) of the finest! What encouragement was there here, will "Philpot" tell us, for Ceylon to send home fine teas?—On the other hand, the fact is patent to the world that Ceylon teas have fallen off as compared with Indian, grievously of late. All Assam for last year realized an average of 11½d per lb. through "fine plucking" and this has succeeded so well, we are told, that similar plucking is to be the rule this year. Now in Ceylon, only one small district can show an average equal to Assam while for the island as a whole, last year's average was down to 9½d. Now, what in the face of these facts, are we to say to "Philpot"? We do not, and cannot, believe that a great part of our planting districts cannot still produce as fine teas as those of Assam, or as went home a few years back;—we can only conclude that *it pays the Ceylon Tea Planters better even in the upcountry districts to send home a coarser, commoner product on the whole than in earlier days.* "Medium" plucking (inclining to "coarse" perhaps when the market favours cheap teas) is we suppose, rather than "fine" plucking the rule in Ceylon; while Assam is reported to be going steadily for fine plucking and yet the total of Indian Tea Exports this year is to be 14 million lb. in excess of last year.

PLANTING IN SIAM.—In the opinion of the *Bangkok Times*, there appears to be misapprehension regarding concessions made to European planters in Siam. It makes out that few countries possess such facilities for acquiring land on favourable conditions. That journal states that no rent is required to be paid for three years, and at the end of that term only one *salung* per *rai*, (which about equals two-fifths of an acre) meaning practically about 2½ *salungs* per acre. It is understood that a concession of fifteen hundred acres is shortly to be granted in Bangkok.—*Straits Times*.

CINCHONIDINE IN INDIA.—We reported in October last that the Government of India do not propose to make cinchonidine sulphate there, as had been suggested, because they could import it cheaper from England if need be. Dr. King, superintendent of cinchona cultivation, now recommends that, instead of trying to make cinchonidine sulphate, it would be more economical to crystallise the alkaloids in the precipitates during the process of making quinine and cinchona febrifuge. He adds that an even cheaper plan would be to convert the quinine and cinchonidine into tartrates, without attempting to separate them, and to issue it as a tartrate of quinine and cinchonidine.—*Chemist and Druggist*, May 13.

THE MADRAS SEASON REPORTS.—Yesterday the Board of Revenue telegraphed to the Government of India for the week ending the 13th May as follows:—Rainfall is good except in parts of the Carnatic and Tinnevely, where a few scattered showers. Cultivation is generally commencing for early crops, and some sowings have already been made. Standing crops, which are few, except cotton, and those under wells, are generally fair; but more rain is required in Tinnevely. Pasture, fodder and drinking water are generally sufficient, and cattle is in good condition. Prices are almost stationary, but slightly easier in the Carnatic and Southern Districts. General prospects are favourable.—*M. Mail*, May 17.

ELECTRICITY IN AGRICULTURE.—Attention has recently been directed to the application of electricity to farming operations, and the designing and introduction of suitable dynamo-electric machinery for this purpose would no doubt be profitable both to the manufacturers and the farmers. Early in 1892 an electric power system was installed at the farm of the Agricultural Experiment Station, Auburn, Ala., the current being brought from the college laboratory by a line three-quarters of a mile in length, conducted by the students themselves. A 10 horse-power motor was used for ginning and pressing cotton, thrashing grain, cutting up feed stuff, &c., and gave entire satisfaction in every community where there is a water-power, electricity could be economically generated and used not only for the above-mentioned purposes, but also to run saws, planing machines, pumps, lathes, grindstones, cider presses, sorghum mills, churns, sewing machines—in short, for everything requiring power. What farmer would not welcome the exchange of smoky lamps for electric lights? The arc light may also prove useful in market gardening, some recent experiments made in France having shown that it has a marked effect in stimulating plant growth when sunlight is not to be had. Where sufficient water-power is not available, windmills might be used in connection with a system of storage batteries. Such a utilisation of the now wasted energies of nature would put off the coming of the coal famine that threatens future generations.—*Inventive Age*:

Correspondence.

To the Editor.

"THE BITTER CRY OF MINCING LANE"—OVER "CEYLON TEA."

London, May 5th.

SIR,—The conscience of the Tea Trade is labouring under an uneasy sense of discomfort just at present. The "trade" is being rudely awakened to the fact, that in sounding the praises of Ceylon teas, it has not only played a part—but played it rather too well. Importers, brokers and dealers have vied with each other in exhorting the ubiquitous tea drinker to fall into ecstasies of gratitude that he should be permitted to enjoy the privilege of using Ceylon tea. They have proclaimed to the universe with fervid eloquence, that at length the growth of fine tea was really understood, and Ceylon was the place to produce it. The use of Ceylon-grown tea was to solve the problem—how to replace the "fine China Congou" of thirty years ago." We have dismissed the unhappy China grower into well-merited oblivion, and have uttered words of timely warning to the Indian planter, lest a similar fate overtook him also. But there is a feeling abroad that these conclusions have been adopted somewhat too hastily.

Ceylon tea buyers have become painfully aware of the fact, that fine tea is conspicuous for its rarity. Our tasting boards illustrate with monotonous continuity, the vulcanised indiarubber flavor; the raw potato; the harsh metallic; the dull leathery; and other peculiarities of flavor equally mysterious and objectionable. Certain estates have made every Ceylon tea taster only too familiar with the remarkable characteristics of their produce, and revived a charitable recollection of former China experiences.

Chairmen of Companies display a marvellous reticence on this subject. Shareholders are congratulated on the lowness of freights; the depreciation of the rupee; the satisfactory condition of the foreign labour question; the fertility of the soil, but the quality of the product is a point that is modestly ignored. And yet in this trifling feature is involved the prosperity, or failure of the Ceylon tea industry. If dull mediocrity in quality is the goal of the Ceylon planters' ambition, then, there is abundant hope for the Chinaman, when the wave of popularity that floated Ceylon tea into consumption has subsided. If through preventable causes, planters permit the early promise of high quality, which excited our admiration and appreciation, to lapse into a faded memory, the unprejudiced British public will assuredly hark back to China teas. In this country we are familiar with the voice of the British farmer, bewailing the shortcomings of the "weather," but in this respect, the palm must shortly be awarded to the Ceylon planter. There is no eccentricity of flavor in Ceylon teas that is not amply accounted for by "the weather." Surprise and disappointment at the vagaries of tea manufacture, are assumed to be unjustifiable in presence of the "weather reports" from Ceylon, and so we reluctantly confess that our former jubulations on the triumph of Ceylon tea over its China rival were—to say the least—premature, and the depressing conviction is stealing over many English traders that *fine tea* had but a transient residence in the "spicy" Isle.

Apologising for trespassing upon your valuable space.—I am your obedient servant,

"PHILPOT."

PATENT TEA PLUCKERS.

DEAR SIR.—I see in your issue of 17th, a Manager of "extensive properties," writing against the use of Patent Tea Pluckers. Has he tried them? and has he tried them for long enough to be able to form an independent opinion. Say, a year at least? If not of what value is his opinion? I am trying them and will for a year ere I venture an opinion as to their merits one way or the other; but, I may say it is my opinion that every planter, especially the managers of large properties should try them on a small acreage—not only for the purpose of satisfying his mind as to their value as pluckers in lessening the cost of plucking by one-half—but to teach our labour force the use of them, in case of a scarcity of labour, when they would be invaluable, and which may occur any day.

ANOTHER MANAGER OF EXTENSIVE PROPERTIES.

COCONUTS IN UVA.

May 22nd.

DEAR SIR,—Your estimate of the local consumption of coconuts is by no means too high in the opinion of those who have gone about the island and observed local usages. As regards Uva especially, the sweeping assertion of the "Times" (which you quote to refute) is not warranted by the facts. Coconuts from Batticaloa can be any day seen in the Passara and Luungala bazaars. The villagers do use coconuts though sparingly. They cannot afford to use them so much as the maritime Sinhalese do, but when their means allow of it, the earliest and most pleasant addition to their diet is the coconut. I have often seen in several districts of Uva, Moormen and others carrying coconuts to the *village-bazaars*, and I have often had it in curries in the houses of villagers in many out-of-the-way places.

I by no means wish to lead you or your readers to suppose that coconuts are used largely or everywhere in Uva, but, I have to testify to the use being much more common than is generally supposed.

Another cause of the larger use of coconuts is the existence of a large body of Malabar coolies who do consume coconuts *as a rule*. This alone would account for many thousands of coconuts.

Coconuts are *very dear* in Uva, because the supply is not equal to the demand which has risen greatly of late years and continues to rise.

Yours faithfully,

'VIATOR.'

COCONUT CULTIVATION IN CEYLON.

DEAR SIR,—Not the least interesting of the valuable information which the columns of the *Observer* have recently afforded relative to the above industry, is the return of crops gathered on one of the best little gardens you know of as given in the issue of the 11th instant, on the best authority. Those readers of your paper who, like myself, are interested in the subject, would doubtless wish to know more about this excellent garden—the age of the trees, character of the soil and whether it has been manured regularly,—so that a comparison might be made with results obtained under similar conditions in other places.

For the benefit of such coconut estate owners as are sceptical of the profitable results which follow the judicious use of manure, you are at liberty to publish the annexed statement showing the yield, during the last 4 years, of two of the best fields on a coconut plantation of about 200

acres in extent, in the Western Province. The soil of which naturally a poor light sand, more suited to cinnamon than coconut, has been much ameliorated by cultivation and liberal manuring.

STATEMENT REFERRED TO.

Field A extent, 15 acres.

Trees in full bearing, about 45 years old..	1,123
" partial bearing, 12 to 15 years old	141
Total trees ..	1,265

Field B extent 10 acres.

Trees in full bearing, 45 years old ..	658
" partial bearing, 12 to 15 years old	66
Total trees ..	724

	A.	B.
Fields:		
In 1889-90... 52,322 nuts,		29,422 nuts.
" 1890-91... 65,055 "		36,329 "
" 1891-92... 60,650 "		32,331 "
" 1892-93... 65,324 "		38,025 "
Total ...	243,351	136,158
Average for 4 years ...	60,837	34,039
Per tree per annum...	48	47

The gross return from the larger of these fields in 1892-93 was R2,761.47, and the cost of production per 1,000 nuts R12.15, leaving a net profit of about R130 per acre.—Yours truly,
POLGAHA.

THOMSON'S PATENT TEA PLUCKERS IN CONNECTION WITH STALK IN TEA.

DEAR SIR,—In the conclusion of your leading article of 5th May last headed "Stalk in Manufactured Tea," you quote what you term a very sensible * extract from a letter from Mr. Cochran in which that gentleman says "when patent clippers are used I could easily understand an undesirable amount of stalk being taken along with the leaves." In reply to an enquiry from me Mr. Cochran informs me that he has seen a pair of patent clippers, but he does not reply to my enquiry as to whether he ever saw them being used. Mr. Cochran went home about the middle of last year and very few pluckers had been sold up to that date. He is good enough to say in his letter to me that given practised hands and trees in the proper trim, the pluckers are capable of doing excellent work. I enclose a letter from Mr. J. Ashington Thompson, the inventor and patentor of the patent pluckers, on the subject.—Yours faithfully,
E. B. CREASY,
Agent in Ceylon for Thompson's "Patent Tea Pluckers."

Calcutta, May 14.

DEAR SIR,—My attention has been called to a leading article in the *Ceylon Observer* of the 5th inst. under the heading "Stalk in Manufactured Tea"; in which it is suggested, that an undesirable amount of stalk being discovered in some samples of tea examined by Mr. Hughes in London, were possibly owing to their having been prepared from leaf cut by a "patent plucker." As I believe mine are the only "patent pluckers" in use in India and Ceylon, these remarks are calculated to prejudice my patent, and I trust you will take an early opportunity to correct the idea that my patent pluckers can only pluck coarse leaf.

A planter using my patent pluckers has as much control (perhaps more) over what sort of leaf he

* But our "very sensible" applied to the whole extract in which Mr. Cochran said a good deal besides, his reference to the "pluckers" —Ed. T.A.

will pluck than he who plucks in the old style—say he wants 2 leaves and the bud (which is the common plucking now in India),—well! he puts my patent pluckers on the bushes as soon as 2 leaves and the bud are grown; and it is surprising how regular and even the flushes rise, when the bushes have been some 2 and 3 months under the pluckers. As only 2 leaves and the bud are grown, he cannot get anything coarser than that; though he can, and does, get a good deal of leaf that is finer than 2 leaves and the bud.

If my patent pluckers are used according to my instructions, the planter will find after six months, that he gets as good leaf as by hand picking, with more tip in it, and at a much cheaper rate, while his bushes will have spread, completely covering the ground, and making it one even sheet of tea.

But why all this fuss about stalk in tea? It is nothing new in Indian tea—there is generally plenty of it in strong Assam Pekoes; and it is not disapproved of by the majority of planters, who consider that the stalk when young and succulent, improves the flavour of the tea. The "Observer's" correspondent writes that "both the Indian and Ceylon teas gave a larger proportion than did those of China, and that singularly enough, it was among the more expensive teas that the greater proportion of stalk was found."

But there is nothing singular in this. The Indian and Ceylon teas show more stalk than the China, because they are manufactured from a superior "jat," or variety of plant; take a vigorous high class Munnipuri or Assam indigenous bush, and it will be found that there is sometimes as much as 3 to 4 inches of stalk between the pekoe and sonchong leaf, whilst a low class China will only have some 1/2 inch of stalk. Then in the sorting, the stalk being thin and wiry, naturally goes all into the pekoe and broken pekoe classes: and so it happens, not "singularly" but naturally, "among the more expensive teas that the greater proportion of stalk was found."—Yours faithfully,
J. ASHINGTON THOMPSON.

SUPERINTENDENTS AND THEIR SALARIES:—AND LOW EXCHANGE.

May 29.

DEAR SIR,—We have recently and for some time past been treated to articles and letters on exchange, dearth of money, and the blessings (or otherwise) of cheap commodities (*vide* your morning contemporary on May 11th for this latter article), and there has been plenty of food for thinking men.

But no planter seems to have got upon one very warm scent in the hunt after causes and effects, though we have most of us been feeling the effects for some considerable time now.

The effect of low exchange on the Ceylon planter-superintendent is that salaries are one-third to one-fourth less than they used to be when exchange ruled at 1s 6d to 1s 8d. The cause is that we do not draw our salaries in sterling.

A simple remedy commends itself. Let all the Branch Associations of the P. A. take this matter up at once (the newly formed Northern districts one might take the lead and earn the gratitude of every Sinna Durai and many a Peria Durai too), and recommend that in future Superintendents be allowed to draw at least half their salaries in sterling, and while on leave the whole amount.

It is a reasonable request. For we only ask a half of our pay in sterling, recognising that exchange does not affect a few items of living, such as country-made shoes, drill and cloth, and rice and curry.

It is reasonable because proprietor Companies and individuals reap most of the advantages of low exchange, while we superintendents lose all of them severely. Our work as tea planters and factory managers is harder, more continuous and anxious

and more wearing and tearing than in the old coffee days, and salaries rule lower, especially to S. D.'s. Commencing at R100 per month used to be the orthodox start. More often R83.33 is now the rule and sometimes less; for I have heard of R60 per month being offered and accepted by Europeans!

That this is really a serious matter to Superintendents, especially to married ones, the following list of commodities &c., for which we have to pay in sterling, will clearly prove:—

Clothes, medicines, groceries, oilmanstores, hardware and ironmongery, stationery, literature and periodicals, steamer passenger fares, wines and liquors, Tennis and cricket material, sporting requisites generally, and finally health-trips home and children's education.

It has been objected that the proprietor element is too strong in the Associations for the agitation to prove successful. I cannot and will not yet believe it. Many proprietors have been superintendents themselves and know from experience a little of the worries and anxieties in making both ends meet; and filling a "stocking" for the health furlough, and trip to see the old folks at home.

When a public Company can shew that it is directed by men with hearts and consciences (like the Ceylon Tea Plantations Co. with its generous-hearted and just-minded managing director H. K. Rutherford)—vide your evening contemporary of May 16th,—we may surely hope and expect the private individual proprietor to have a share of that deepest source of all the keenest and most lasting joys of life, the human heart—and I confidently recommend my fellow planters to have a shot, a firm, steady, united and well-aimed shot at this fair game:—"HALF PAY IN STERLING."—Yours faithfully,
SUPERINTENDENT.

Civil Servants in the Colony are also interested in this question!

HOW ESTATE OWNERS LIVE BY EXCHANGE.

Colombo, May 30th.

SIR,—The crop of an estate in the year 1891, cost	..	R18,292	17
The proceeds (net) of the crop were		34,178	83
		R15,886	66

Taking the exchange at 1s 4d (a higher rate than at present); there would have to be deducted from the proceeds of crop to show what the result would be with exchange at the old par 2s, about 83½ cent or say R11,389 01.

So the account with exchange at 2s would stand			
Proceeds	..	R34,178	83
less difference in exchange between 2s and 1s 4d	..	R11,389	01
Expenditure	..	18,292	17
		R4,497	65

Profit with exchange at 2s

In sterling the profit would be			
Exchange at 1s 4d on	..	R15,886	66
Exchange at 2s on	..	R4,497	65
Yours obediently,		NEMO.	

"PUPILS" AND TEA PLANTERS.

SIR,—The subject of "pupils" on tea estates and "premiums," has several times been alluded to in your columns, and in those of your contemporaries, probably a "Madras paper" in your issue of the 2nd instant. I think that much that has been written shows an imperfect appreciation of all the facts of the case.

Advertising for pupils to learn tea planting is I think, a most undesirable procedure, to put it mildly. The advertiser presumably will know nothing of the character or antecedents of his pupil, and he will probably induce men to come to Ceylon, who would not otherwise do so, whilst many of them will come under a mistaken idea of the prospects and life awaiting them here. I am, therefore, quite at one with you in your strictures on the advertiser for pupils.

Apart from this point of the question, I, and I fancy almost every planter of experience in Ceylon, am constantly asked by friends and relations at home to start protégés of theirs as tea planters. For the last two years I have invariably opposed the idea in the case of young men without capital, though previously to that I was of opinion that the growing tea industry would afford openings for steady and energetic young men. At present I am of opinion that Ceylon offers as fair an opening as any country for young men with moderate capital, and I much question whether there is any colony where investments can be made with less risk. Now, as regards the term on which "pupils" are to be started on their career. I shall be glad, sir, if you will mention any profession in which inexperienced men are taken and a salary (their board and lodging is equivalent to a salary) given unless under an agreement for a term of years, by which the employer looks to getting the services of his employé at less than their value for the latter part of the term in consideration of his uselessness during the beginning of his apprenticeship. When a profession has to be learnt, and when no agreement of the kind is entered into, I question the possibility of finding any one to start a young man for nothing. Most men up-country are in charge of estates which already maintain the staff necessary for proper management. A manager so circumstanced is asked whether he will receive and train as a planter a young man fresh from home and newly entering upon the world. The charge is one of great responsibility, and often is in many ways extremely inconvenient.

The pupil is essentially a supernumerary, and it is preposterous to suppose that under such circumstances he will be taken, fed and lodged for a year, taught Tamil, estate accounts, and the working of a tea concern, without the payment of a fair and reasonable sum in return.

Personally, I have always considered that in taking pupils in response to the pressing wish of friends, the obligation is entirely on their side, and I should be sorry to accept the responsibility on any other understanding. I enclose my card and remain,—Yours &c.

AN UP-COUNTRY PROPRIETOR.

June 4th.

"THE BITTER CRY OF MINCING LANE:" OVER CEYLON TEAS.—No. I.

Colombo, May 27.

SIR,—The letter signed "Philpot" regarding the present quality of our Ceylon Teas has, I hope, drawn the attention of some to a most important feature in the Ceylon Tea Industry. It must be admitted the writer has some good ground for his statements and as one interested I am inclined to join issue with him as to the "preventible causes" by which the superiority of our teas over both Indian and China can be maintained. The fact remains that climatic causes play a most prominent part in the growth and manufacture of Ceylon tea and

they cannot be ignored, without going the length of making the "weather" responsible for every little "vazary." But does "Philpot" know that "want of cultivation," the absence of manure, added to the scant Labour Supply in some districts are the main reasons which must be made responsible for the falling-off in quality which of late has been so apparent. These can all be overcome unless further "Extension" is anticipated, which in my opinion would be fatal and much to be deprecated. A small full area highly cultivated must be the aim of all, if that superiority which Ceylon tea has attained is to be in the future maintained, and then only we shall hold our own against all comers!—Yours truly,

ROOD.

No. II.

DEAR SIR,—It is chiefly a matter of supply and demand, the demand has been almost solely for common kinds (teas for price) and the demand has been met.

There has been a limited demand for really finest kinds, but anything between that and common has sold with little reference to quality; consequently the coarser the plucking the better it paid.

Now, too much tea for price is going forward and we shall see these kinds fall, and then it will pay better to make finer teas.

No doubt India going in for fine plucking has increased the proportion of fine kinds as compared with common sorts; and so kept up the price of the latter.—Yours &c.,

QUIDNUNG.

No. III.

DEAR SIR,—All that I have got to say to "Philpot" is that the Ceylon planter is a very matter-of-fact creature, and he just works his estate on the lines that he considers *pays best*; the few that have from time to time tried to meet the longing cry of the buyers for fine teas have nearly all one after another had to give it up in disgust, poorer but wiser men. No, no, Mincing Lane buyers may send up as "bitter a cry" as they please, but they are not likely to get much fine tea from us at 9d to 10d per lb. Let them double their price and I have no doubt the article will once more appear on the scene. Buyers by their prices do more to discourage the making of fine teas than anything else.

TE-VE-A.

No. IV.

May 27.

DEAR SIR,—Seeing that the statements made by "Philpot" can only be met in a negative sort of way out here, and that replies to his letter therefore will probably fail to a great extent in carrying conviction to the minds of the outside public, I think the less notice taken of his communication the better. Leave him in fact severely alone, for it will be time enough to deal with the subjects he brings forward when they emanate from some responsible source.*

If you wish however to know my views on the merits of Ceylon teas, I believe we can produce and as a matter of fact, do produce as good teas as ever we did, but there may be a larger proportion of poorer qualities reaching the market now and if this is so, it presumably pays the producer best to make these teas. Of late there has been no encouragement to send good teas to the London market.—Yours faithfully,

NUWARA ELIYA.

* "Philpot" was duly and very specially authenticated to us.—ED. T.A.

No. V.

DEAR SIR,—With regard to the letter of "Philpot" my opinion is that it is a sensational one and written merely for the purpose of creating a prejudice against Ceylon tea to the advantage of China. Planters of undoubted integrity maintain that Ceylon teas are quite as good as ever they were, and I believe them in preference to "Philpot."—Yours faithfully,

G.

No. VI.

DEAR SIR—Your correspondent "Philpot" is a queer fellow. He tells us that "the conscience of the tea trade"—"my conscience" is uneasy because they are not getting fine teas from Ceylon, after they have got the public to believe in them! There were a good many more influences at work in pushing Ceylon teas to the front than the tea trade. It has never been suspected of having very much "conscience":—indeed the planters of Ceylon had to watch some of its members and proceed against them too, so rudimentary was it. But what is the use of crying out against common teas just now. When it is made worth our while to send fine teas, if it is not done, then it will be time to speak; but of late the better qualities have been sold at a sacrifice. The broker's circulars are full of this, and private advices echo the same, and these common teas which "Philpot" wails over, have had a boom.

Somebody must have bought them, and I should say they have met a want in the tea trade, paying it and us too. Of course you may have too much of a good thing and if better teas have their innings now, I should not be at all surprised.

MY CONSCIENCE.

No. VII.

Dear Sir,—My opinion is that not the slightest notice should be taken of these personal growls emanating from the "Lane," especially anonymous fulminations*; but that planters should be solely guided by the law of "supply and demand." Thanks to the modern packet-men cutting down prices in competition, robbing—not the consumer, but the growers, not lessening their own unrighteous gains, but those of the sweating planter, who, thanks to them, can scarcely make "both ends meet,"—in order to fill their vile packets at a profit to themselves, they must have some rubbish, and a lot of common sorts. With "all India plucking fine" (!) if all Ceylon plucks fine also, who is to supply the common sorts, which the packet men *must have*? This is the "demand." As it is, our fine teas do not sell for their legitimate value. What if we sent fine teas only? China and Java would find the supply of common sorts and for our fine tea, glutting the market, there would be no demand. But does India pluck fine? Does India ship no dust, souchongs and Pekoe souchongs? Every pound of dust and Congou supplies the demand for so many of the "cups of tea" that are drunk in the world. OLD HAND.

No. VIII.

Upcountry, 29th May.

DEAR SIR,—I think we ourselves with provincial—nay parochial—arrogance, have claimed a superiority for Ceylon tea which it never really possessed and we have advertised it into a position it cannot easily maintain. But chiefly, why? Because tea dealers borne down by the excessive competition of the packet-men and Lipton, will not give us the

* "Philpot" was duly and very specially authenticated to us.—ED. T.A.

same price they did—*nor half of it.* How do they expect us to make for 8½d the same average tea for which they once—say 7 years ago,—gave 1s 4d? With the “*finest tea in the world*” sold at 1s 7d in packets—it cannot cost more than 11d or 5d less than our average fetched before Lipton took up tea,—what encouragement then to make fine tea?

Your correspondent “Philpot” I take to be a man who was here some months ago, and a member of a firm who bought an estate in the Northern districts.* His brokers if I mistake not are Gow, Wilson & Stanton. Now I have twice lately had letters from one of the partners of that firm, assuring me that after testing preserved samples of the last few years, they have come to the conclusion that the teas now made are quite up to those of years ago—and that the falling-off is not in the tea, but in the market. I take the opinion of these brokers to be worth more than the not-even-witty taunts of a disappointed investor.

He says “If dull mediocrity in quality is the goal of the Ceylon planter’s ambition, then there is abundant hope for the China man.” But when did the importer get *fine* China tea for 8½d. Certainly not since the Russian became willing to pay many times that price for average *fine* China tea.

If “Philpot” objects to the “weather” as an excuse for the vagaries of tea manufacture, he should send out a glass roof for his estate. If London is to be covered with glass, why not—?

LOCAL EXPERIENCE.

No. IX.

May 29th.

DEAR SIR,—There are several causes that may account in some measure for the complaint of which “Philpot” makes himself the mouthpiece:—

1st.—The novelty of manufacturing tea has worn off and with it some of the care planters bestowed on it.

2nd.—Most men pluck more for quantity than quality: it may possibly pay them better at present, but it is doing the good name of Ceylon tea harm.

3rd.—A great many men are so hampered with instructions from Colombo or London, that it is almost impossible for them to make good tea.

They are asked to change something after each Break, whereas if they were simply told to make good tea, they could or ought to be able to do it.

The tasting powers of ninety-nine out of a hundred men, are not discriminating enough to deal with the teas as professional tasters would apparently wish. That they are not so discriminating is hardly to be wondered at, when we see how professional tasters differ.

I should be sorry indeed to think that the majority of our tea estates cannot send home good teas.

That there is some (a good deal) poor land from which neither flavour nor strength can be hoped for, cannot be denied; but I trust that what is complained of is not irremediable in the majority of cases.

I think it will do the name of Ceylon tea and consequently our interest very great harm should our teas compare as unfavorably with Indian teas, this, as they did last year. TEA PLANTER.

No. X.

May 28th.

SIR,—In reply to Philpot’s “Bitter Cry from Ming Lane” I would ask you to compare the London reports herewith on tea sold for this estate in 1891, with this year’s reports and note the prices.

* No — Our correspondent is mistaken; we do not think “Philpot” has any connection with Ceylon.—*Ed. T.A.*

I do not see there is any great falling-off in quality in the ‘93 tea exports. Do you? There is an uncommonly harsh coppery sound in the prices although every care is taken of the leaf in the manufacture. It is my opinion that the packet-men have ruined the demand for fine tea, or at least put buyers in the position that they are unable to give the old prices for really good teas. How can they give good prices when Lipton, an estate proprietor advertises the finest tea the world produces at 1s 7d. per lb.? Ceylon can produce fine teas, and will do so, when buyers are able to appreciate and pay a satisfactory (to the grower) price for them, but proprietors cannot be expected to rush the market with high class teas at the prices now paid for them. So soon as buyers can afford to give better prices and maintain them Ceylon planters will meet their wants with the high-class teas “Philpot” has so pleasantly reminded us of and for which he paid over 2s 6d. per lb.

I know nothing of the ‘India-rubber’ the ‘raw potato,’ ‘metallic’ or ‘leathery’ flavour teas, unless from what I have had to swallow in some of the Ceylon hotels and resthouses where they do not study the art of ‘tea making’ or if they do, they must buy the low-class cheap teas for reasons best known to themselves.—Yours truly
A TEA GROWER.

(Reports referred to.)

Jan. 1891.

1s 0½d. Rather dull, greyish. Broken Pekoe leaf, with a few not over-bright ends, even, infused leaf fair flavory liquor slightly pungent, rather wanting in strength

Feb. 1s 1d. Fairly even black leaf, some bright ends. Thin flavory liquor.

March. 1s. Rather even greyish leaf with a few tips. Infused leaf a little dark, fairly strong, slightly pungent liquor.

April. 11½d. Rather bold well-made blackish leaf with some bright tips, bright and even leaf after infusion, pure full liquor.

Jan. 1893.

11d. Rather pretty wiry leaf a trifle dull, very few fairly bright tips, rather dusty infused leaf rather dark but even. Fair flavory liquor a little light.

Feb. 10½d. Fair wiry leaf a little dull with a few brightish tips, infused leaf dark, rather full soft flavory liquor.

March. 9½d. Small wiry leaf, a little dull, few fairly bright tips. Infused leaf, rather dark, rather soft, slightly pungent liquor.

May. 9½d. Rather even blackish leaf with a few pale tips. Fair pure flavory liquor. Infused leaf fairly even.

No. XI.

30th May 1893.

DEAR SIR,—Philpot’s letter of May 5th is too narrow and onesided to seriously disturb the minds of Ceylon planters. Each sentence proclaims his identity as a dealer or broker (perhaps both combined) and we have been so accustomed in the past three years or more to hear this *bitter cry* simultaneously with a fall in the price of tea, that we can now foretell the nature of the coming reports by the weekly telegrams from the Lane. Will “Philpot” honestly affirm that the broken pekoes which have been lately selling at 9d to 10d. are not equal in quality to those sold at 1s 3d to 1s 5d six months ago? Does he imagine that planters are so credulous as to at once accept the various assertions advanced by the brokers and dealers at every change in the tone of the market?

Atmospheric influences have undoubtedly lowered the quality of the tea in some of the higher districts in the past twelve months, but this is only applicable to a comparatively small area and over this area exhaustion of soil or coarse plucking would not generally be ascribed as the cause of the deterioration in quality. Plucking has indeed

been finer and teas have been made with greater care than when prices for these high-grown teas were 3d to 8d better than now.

The question is purely one of supply and demand and immediately the demand arises for broken pekoes, the price will rise and likewise the opinion of the brokers and dealers. The outcry from the Lane by this week's mail is for stronger teas and as pekoe souchongs have not, judging from the sale lists, deteriorated in quality nor fallen in value we must conclude that the finer sorts are meant and that the object is to secure a still better tea for the miserable prices paid since November last.—A. F. S.

No. XII.

DEAR SIR,—What does "Bitter Crier" want? and how much will he pay for it?

Amongst many others one might name the following marks:—Kotiyagalla, Holmwood, Waverley, Ouvakkellie, Kandapolla, Goatfell, Labukellie, Norwood all of which have fine flavor and combined in some with body, others pungency, others softness, others good appearance of dry leaf; yet the Lane does not give an all-round price of 1s per pound for them. Throughout Ceylon, excepting on very few estates, plucking is being done for quantity by allowing leaf to grow beyond the point at which it produces tea with body and flavor. When the Lane can pay say 1s 4d per pound averages for shipments of fine flavored teas with good body, they will be supplied with them.

"MANAGER OF SEVERAL ESTATES.

No. XIII.

May 31st.

DEAR SIR,—I took the letter signed "Philpot" to be nothing more or less than "a draw" and that at no other time of the year could such a letter have been written or received. It is well known that prices are always lowest and reports less satisfactory at this time of the year than at any other; and it suits Ceylon that it has most "quantity" when the demand is most for this and not for "quality." This demand is proved by the better teas not realizing anything like their value of late, and home reports and valuations clearly show this. I have one just received, valuing some of my tea at 2d a lb. more than it sold for—&c. I do not see that "Philpot" deserves further explanation or that we are called upon to take notice of his attempt to draw us out or explain for his benefit the "why and wherefore" of fluctuations of markets or quality of tea. He knows the reason for the first and we know the reason for the last, and that what Ceylon has done before, it is most certainly capable of doing again. There is no doubt difference of experience on different estates; but Ceylon covers a lot of young tea still coming on, and full of flavour and life.

Indian teas generally show better averages than Ceylon at one season of the year and again Ceylon is highest at another. There is nothing new in all this and only by finer plucking can Indian keep up their higher prices and all this is just a question of profit or loss. The estate pays best which gives a large yield and fair average prices and any "fancy price" means simply finer pluckings from good estates. In giving credit for "higher prices" the yield of the estate should always be considered acre for acre, and the nature of the leaf manufactured for other estates—and the profit given for the whole year will prove what is the most profit for the planter, and Mincing Lane must look out for itself, and make it pay for planters to give better quality if they want it. 4,200 to 4,500 ft.

No. XIV.

DEAR SIR,—I think the best plan is to say as

little as possible on the subject of "Philpot's" letter. It could only be answered by a Mincing Lane man and then probably there is a grain of truth in it. It is not that the soil refuses to grow the same leaf as formerly and there is a great deal of young tea coming in, grown on rich young land; but the manufacture has altered in good deal to suit the wants of the packet-men at home who do not pack on the estates. They want a strong pungent, sharp tea which suits their purpose. Hence the *unfermentation* which is the fashion. It produces a sharp what they call a *stand-out tea*; but it is not nice tea to drink by itself, but no doubt it bends and mixes well. T.P.

No. XV.

DEAR SIR,—In reply to your letter asking for my opinion on the letter signed "Philpot," I think the question raised therein a somewhat difficult one to answer fairly and impartially.

It is possible, as some contend, that as the tea bush grows older and draws its food in an increasing degree from the lower soil, instead of mainly from the surface soil, the made tea becomes poorer in flavour and quality. So far however as my observation goes this is purely conjectural: I cannot find that there is more flavour and quality in tea made from young bushes—say four to seven years old—than in tea made from older bushes. On the contrary teas are very similar in both cases, whereas, were the theory alluded to a true one, there ought to be a marked difference between them.

While it is undoubtedly true that "the weather" can be made a convenient scapegoat at any time, it does not follow that it is always put forward to cover other faults: and my own conviction is that during the past twelve or eighteen months the weather has not been favourable to making good teas. If it be urged that this a *post hoc ergo propter hoc* argument I can only reply that applies equally to "Philpot's" contention.

The one certain fact is that to get first-rate teas requires careful (if not fine) and expensive plucking, and a smaller yield than would be otherwise obtained; and so long as ordinary teas obtain almost equally good prices with first-rate teas, so long it will pay the producer better to go in for quantity rather than quality.

If consumers really want first-rate teas, they must be willing to give a fair price for them; they cannot expect the owner to make them at a loss.—Yours faithfully GILES F. WALKER.

No. XVI.

DEAR SIR,—In reply to your inquiry I think the quality of Ceylon tea has fallen off, although to nothing like the extent "Philpot" would have us believe:—

1st. In response to a demand in the trade for common sorts at comparatively higher prices.

2nd. Owing to the exhaustion of some constituent in the soil, as the teas from nearly every estate seem to fall off in a few years; and to remedy this we require the agricultural analyst badly.

3rd. Owing to insufficient factory supervision, as a man cannot give the same attention to the large quantities being turned out, as he could when a small quantity was being made.

But the worst feature in the case is the way Assam is licking us out of time. Some people say they plucked fine; hence their good prices last year. Please append a foot-note showing the crop per acre and the rate per lb. for Assam and Ceylon for last few years, which will show our position clearly.

I make out that Assam not only got 400 lb. against our 340 lb. per acre over all the tea in bearing in 1892; but got in addition to this crop of 60 lb. an acre more than Ceylon, a penny per pound more for its teas!

Of course we cannot tell the cost of production in Assam which regulates the profit, but if one estate in Ceylon gave 400 lb at 11d and another 340 lb at 10d per lb, the *extra* profit made by the former would be at least R50 an acre.

Is Ceylon going to permanently "take a back seat"? L. D.

[From an official statement before us, we see that the average yield of 168,329 acres in bearing in Assam during 1888 was 356 lb an acre; in 1889, the bearing; area was 196,689 acres giving 391 lb per acre; in 1890 the average was 409 lb from 200,658 acres; in 1891 it was 434 lb from 208,407 acres; but in 1892 it must have been less, for though we have not the crop figures at hand just now, we see that the estimate for 1893 is only 88,930,560 against 90,399,362 lb plucked from a smaller area in 1891. This is the result of fine plucking. Assam beat Ceylon in average price last year not by a penny as L. D. puts it; but by the difference between 11½d and 9½d or 2½d per lb.—ED. T.A.]

NO. XVII.

NEWS ABOUT CHINA TEAS.

June 3.

DEAR SIR,—I think the object of "Philpot's" letter too obvious to require comment. I naturally assume he is one who wishes to revive the trade in China tea and who does not scruple to endeavour for this end to discredit the produce of Ceylon.

My London reports as well as my own experiments convince me that speaking broadly our teas now are as good as ever they were; but that at certain seasons the quality *does* vary on every estate in the island, independently of the style of plucking or manufacture, ordinary care and attention in regard to each process being of course presumed.

The late boom in teas for price was caused by scarcity of low Chinas: and our low-priced teas being what are called "self-drinking," whereas low Chinas require to be blended with fine Indian or Ceylons to be drinkable, accounts for the absence of demand for high-priced teas for blending purposes.

What then is the situation? Why, just this. Blenders have been able to lay in large stocks of fine teas at low prices, and London has for months past been signalling to China for stuff to blend with these finer teas at a price which will cut out the "self-drinking" teas of Ceylon. As a result we see Ceylon teas for price receding and a slightly firmer tendency in the finer grades.

Mail advices from London report that financial troubles in the City have adversely effected Produce Markets, but that the sharp fall in common tea has been more immediately brought about by the size of the first crops in China which are wired as much larger than those of last year. It is also thought that buyers at Foochow will have much difficulty in financing against teas to the Australian markets: consequently that the stream will be diverted to London.

FORT.

NO. XVIII.

June 4th.

DEAR SIR,—So far as my own experience goes, and judging by my brokers' reports, I find no evidence in support of "Philpot's" contention that the quality of Ceylon tea is not what it was.

With the exception of two periods, when I

plucked fine, (with a decidedly worse result financially) I have adhered to ordinary coarse plucking, but in no instance have my teas been described as possessed of any one of the wonderful and mysterious peculiarities of our candid friend. In fact my teas are reported on in almost identical terms now, with an average of 8½d to 8¾d only, as when I was getting 10d to 11d average for my whole crop.

The trade by the price they pay for fine teas, hold out no inducement whatever to pluck fine especially at medium elevations. If we have pekoe souchong down again to 5d, we may be compelled as in the early part of 1892 to pluck finer all round, and so reduce our output and thereby bring supply and demand into a more healthy condition. We have no doubt this very much in our own hands. On the other hand while the main demand is for teas for price the present fall will I anticipate drive our teas again into consumption. The low prices ruling in 1891-92 for the lower grades was I expect the chief cause of the increased consumption of our teas during that period and which more than kept pace with our increasing output. It was candidly admitted to me in the Lane, when I was last in England, that ordinary Ceylon pekoe souchong was 50 per cent. better for drinking purposes than ordinary China congou, and that the only advantage the latter had was in its appearance. No doubt the teas from the yearly rush of leaf in March, April and May are inferior to teas made at other seasons of the year, but the worst that can be said of them, is that they are thin and more or less common; though I have good authority for stating if they are fermented during the period of rolling only, that they ripen up to be sweet teas, mixing well with milk or cream.

The "bitter cry" it seems to me is the usual one at this season and I do not think need cause us any alarm. D.

"TEA AND CHEMICAL MANURE" is the heading of a letter on another page which gives an interesting account of some "rough and ready" experiments which are being made by a Tea-planter if we mistake not on the Nilgiris. He is greatly interested in Mr. Hughes' letters and it will certainly be instructive to learn how "Creighton" succeeds in his experiments. Mariawatte has, we believe, chiefly depended on cattle manure and the scavenging of Gampola with, we suppose, a proportion of castor-cake or poonac? At any rate on bulky, rather than chemical manures.

CINCHONA.—The prospects of the Cinchona market are by no means brilliant; but the Java planters undoubtedly can pretty well control the situation if they choose to do so, or rather if they are able to form a syndicate to regulate harvesting and shipments. It is no wonder though prices should be low at present, for, Java alone shipped no less than a million lb. of bark in April—a quantity equal in percentage of alkaloid to about 2½ million lb. of Ceylon bark. In the case of Ceylon, the exports to date are 1,963,835 lb. compared with 2,410,784 lb. to same date last year; but unless prices improve there ought to be a big comparative falling-off henceforward. There are authorities in our midst who believe that Ceylon has many more million of cinchona trees growing than are reported to us for Directory purposes, because many planters do not count on their cinchona now, though the trees are allowed to grow all the same. For India, the area under cinchona is put down at 10,862 acres, nearly all in the Nilgiri division of the Madras Presidency.

CEYLON TEAS:—THEIR QUALITY
AND REPUTATION:

“THE BITTER CRY OF MINCING LANE.”
IS INDIA TO BE LEFT TO SUPPLY “FINE”
TEAS AND CEYLON ONLY “MEDIUM” AND
“COMMON”?

We think it will be admitted that the discussion which we invited on the letter of “Philpot” has been productive of a number of interesting letters embodying a considerable variety of opinion and much useful information. Of course, the large majority of the more than score of replies have come from practical tea planters, and although some few have treated the inquiry of the home buyer and dealer as almost unworthy of attention; yet most of our correspondents have written to the point and in a way that must attract considerable attention in “the City” and generally among home tea-dealers. There is also abundant food for reflection afforded in these letters, for all of us who take an interest in the great planting industry of the island.

In the first place, we may place the substance of “Philpot”’s complaint in a couple of clauses:—first, he would have us understand that the representatives of the home Tea Trade are awakening to the fact that they were in far too great a hurry in sounding the praises of Ceylon tea; secondly, because they are now finding out that “fine” tea had but a transient residence in Ceylon and that “dull mediocrity” can alone now describe the “quality” of our product. Before entering on the consideration of these questions, it is well to notice that fault has been found with “Philpot” as if his only object was to exalt “China” tea at the expense of “Ceylon”; but a London dealer would scarcely address himself to a Ceylon journal seen chiefly by planters, if that were his object; nor would he insist so strongly on the thesis that the future prosperity or failure of the Ceylon tea industry depends on the attention given to quality. We have reason to regard “Philpot”’s letter as perfectly *bona fide* and from one whose interest is mainly in “fine teas.” But now, to deal with his letter, “Philpot” will find his statement denied about the home trade doing so much to create a demand for Ceylon teas by sounding their praises. It is maintained by very many that Ceylon planters and their friends all over the United Kingdom did the advertising in the first instance and to a great extent, by creating the demand, forced the hands of the tea trade. Consequently, the planters recognise no special obligation to the trade in this direction.

As to quality, taking the whole of the Ceylon tea crop of the past two years as compared with the earlier years, we believe there can be no dispute as to a comparative falling-off. A few years ago Ceylon tea was ranked as equal, if not superior, to Assam tea as the average prices for both showed; but it is plain that we have fallen far behind in the comparison now; for the Assam average last year was only attained by two or three of our best districts; while the average for all India was also considerably ahead of that for Ceylon. There are not a few planters who, in replying to “Philpot,” maintain that there has been no falling-off in quality, that their teas are as good as ever they were. But obviously this testimony can only refer to particular plantations and not to districts, much less to the whole island.

But when we talk of the island, we must point out the great disadvantage under which Ceylon labours when brought into comparison with Assam or other leading Indian districts. We have here a

“low-country” tea division in a special sense which may be said to be unknown in India, and our average must always be considerably affected by the large proportion of our tea produced on land very little above sea-level and within seven degrees of the equator. If it were possible both here and in Mincing Lane to treat the Ceylon tea crops, exports and sales in two great divisions—high-country and low-country teas—and to give the total averages and grade quotations separately for each, we should be in a much better position to challenge comparisons; for, of course, it would only be in the higher division that *fine* teas would be looked for, and a fair contrast with “Assam’s” presented.

But now to come to closer quarters with our correspondents, we may say that only in about six letters out of twenty, is “Philpot’s” contention allowed that our teas according to districts, have decidedly fallen-off in quality. To account for this, there is scarcely a writer who admits deterioration due to exhaustion of soil in any constituent, or to treatment or age of bush. The almost universal testimony is that as fine teas as ever were produced, can even now be supplied if it is made worth the while of the Ceylon planter. The great law of Supply and Demand is appealed to and the actual facts of the home market in respect of the prices paid for fine, medium and common teas since November last. More than one planter explicitly states that he has given up making “fine” teas, because it did not pay him so well as making medium and common kinds. Others show by Brokers’ valuations that though their teas have been as good as two years ago; yet the prices realized have been less, so driving them in the direction of quantity rather than quality. Still another authority shows how our finest marks have only been getting 1s average against 1s 4d last year—in other cases broken pekoes said to be uniform in quality have fallen from 1s 3d to 9d—while for common kinds the advance in price has been phenomenal. In fact “fine” Ceylon teas for some reason have been selling several pence below valuation even; and so it is no wonder that one gentleman largely interested in our enterprise, declares that recent experience would seem to show it pays best for India to supply “finest” and “fine” teas and for Ceylon to follow up with “medium” and “common.” The fact that Assam is going in again this year for “fine” plucking is adduced as a further argument for this course. Indeed, this side of the planters’ case in reply to “Philpot” is summed up in the most practical fashion and in the fewest possible words by the Chairman of the Planters’ Association when he writes:—“If consumers want really first-class teas (that is from Ceylon) they must be willing to ‘give a fair price for them; they cannot expect the owners to make them at a loss.’ Now, be it remembered that Mr. Giles Walker writes from a high district and if his sentiment is re-echoed as we believe it is at present by the majority of his brother-planters, there can be no question as to the policy inferentially to be adopted, namely, that Ceylon is to go in for supplying “medium” and “common” teas, leaving to India—that is to Assam and Darjeeling—the supply of “fine” and “finest” teas. We suppose there need be no question as to this being the right course for the lowcountry division of Ceylon. Nor perhaps can it be said to be advisable that the older districts of medium altitude—say 1,500 to 3,500 feet above sea-level—should aim at much more than “medium” teas. But it is as to the truly wise policy, even from a financial point of view in the long run, for all plantations

above 3,500 or 4,000 feet in the island that we would more immediately direct and concentrate attention. Here is the *crux* of the situation or discussion. Are planters in that higher region to follow the course of the market—to vary in “plucking” and manufacture according to prices, and supply and demand—and put the establishment of a permanent reputation for fine teas on one side?

These are questions which have arisen out of this discussion and which we think demand the careful consideration of all proprietors and managers in our higher regions. One of our earliest correspondents in the list, expressed the hope that there would be no more extensions of cultivation in Ceylon, but that our true policy was to go in for “a limited area and high cultivation” in every sense of the word. But if the decision be that Ceylon as a whole, is only to aim at supplying “medium” and “common,” rather than “fine” teas, there will be far less objection to farther planting operations on a big scale. Indeed, one good result of the low averages for Ceylon tea in 1892-93 is, according to another letter, that it must put our teas more freely into consumption than ever before. Still, if we return from this digression, to consider the case of our higher districts—all over 4,000 feet at least—we confess that we shall be very loath to receive any decision which should lead our higher plantations or districts, not to aim at competing with Assam and even Darjiling for the supply of fine teas.

Now it is in this connection that we would specially direct attention to the letter signed “Fine Tea” given on page 53, as one of the most suggestive and important drawn forth by the discussion on “Philpot’s” letter. This communication must surely afford cause for reflection to all planters between Adam’s Peak and Pedrotallagalla and onwards to Maturata, Udapussellawa and the rest of Uva. The writer maintains that scarcely any teas leave the island now as fine as those of seven and eight years ago; but that there is no reason why even the finest could not still be made. He proceeds to indicate the process in plucking and manufacture. He then shows how a comparatively steady market for Ceylon “fine” (1s 1½d to 1s 5d)—not finest (1s 8d)—teas can be created, and he gives, what seem to us, good reasons why at present such “fine” teas as are sent to the Mincing Lane, do not fetch their true value. He instances a case of a consignment worth at least 1s 6d in the Lane, selling for 1s 2d (resold soon after for 1s 10d) simply because no steady supply of “fine” Ceylon can be depended on. The only point on which we differ with “Fine Tea” is when he seems to advise “the whole island” of tea planters to “make principally fine—finest and stick to it.” This cannot be good advice from a planting as well as financial point of view for our low districts. Surely it would be wiser to insist on such a policy being best for all plantations above 4,000 feet? That would give us an output of from 20 to 25 million lb. of fine teas to deal with against 45 to 50 million lb. common and medium teas for the lower divisions. The former figure should ensure a steady supply of (and steady demand for?) “fine” Ceylon teas all the year round.

Let us, in this connection, recall once more the advice given to high district planters by Mr. Arthur Thompson, of the well-known leading Mincing Lane Tea-broking house, when on a visit to Ceylon some years ago. After visiting the districts around Nuwara Eliya and testing the teas, Mr. Thompson said that there was no reason, in his

opinion, why the teas of Upper Dimbula, Nuwara Eliya, Udapussellawa, Maturata, New Galway, &c. should not come near to those of Darjeeling in appearance and flavour; but he said it was no use expecting prices according to actual value until the trade could be assured of a steady and sufficient supply. When there was an appreciable quantity—several million of lb.—sent forward, then Mr. Thompson advised the planters concerned, to add to the marks on their boxes “Darjeeling-Ceylon” so as to attract the attention of the usual buyers of fine Darjeeling teas. This advice has never been acted on: at least not by all planters above 4,500 or 5,000 feet, the limit we believe Mr. Thompson had in view. Why should the Nuwara Eliya Planters’ Association not take the matter up and secure a careful discussion on the subject with a view to united action? Let the point of the argument not be lost sight of. It is no answer to say that “so-and-so” has given a full trial to “fine” tea-making and he is convinced it does not pay. That is just the argument answered by “Fine Tea.” Individuals cannot create or secure a remunerative demand for a limited quantity of “fine” Ceylon tea. It requires that all the proprietors in a district, or better still in two or three districts,—should band themselves together and declare unitedly for “fine” tea plucking and making, in order to secure the steady and appreciable supply which would ensure an equally steady demand and amply remunerative prices.

PADDY AND TEA IN MAHARA.

Mahara, June 4.—We expected a bumper crop this year, but the continuous rain have caused much damage to the growing corn. Unless we get a spell of bright weather our expectations may not be realized.

Fever is still prevailing and even the prisoners at the Mahara jail have not escaped. The dispensary at Mahara is doing immense good, thanks to our good doctor. It is strange that cattle have enjoyed immunity from disease this year.

Our good Mr. Brown has planted nearly 50 acres of tea this year, and I think his is the nearest tea estate to Colombo.

NITROGEN AGAIN—AND THE SOJA BEAN.

The following is an extract from a letter by Mr. Edward Atkinson of Boston, Massachusetts, to the Southern Planter of Carolina:—

“The deficiency in the dietaries of Europe is found to consist in nitrogen. The element of which we are depriving our soil without sufficient return is also nitrogen. The people of China and India comprehend this matter a great deal better than we do. I imported soja beans for distribution from the Cotton Exhibition in Atlanta in 1881, whence they went out in small parcels. Since then they seem to have attracted a good deal of attention in the South. I believe they were known before, but nothing had apparently come of the knowledge. In Church’s book upon ‘The Foods of India,’ testimony is given to the very great value of the soja bean in yielding the nitrogenous element of food which is so necessary in what are called ‘the rice-fed nations.’ There is no such thing as a rice-fed nation. The people would starve if fed only on the starch in the rice.

“It is absolutely certain that your soils must be renovated either with cow-peas, clover, or beans. I have reason to believe that the ‘soja,’ the ‘mung’ and some other East Indian varieties of beans are very much more nitrogenous than the cow-pea is as a rule.

"In 1861, in my pamphlet on 'Cheap Cotton by Free Labor,' I made a forecast of the whole cotton seed industry.

What is now being done with palmira-stalks in Ceylon, might be quoted in favour of the idea that cotton stalks may yield valuable fibre. Has the soja bean ever been grown in Ceylon? It seems to be the richest in nitrogen of all the legums.

NEWS FROM THE CENTRAL PROVINCE: PLANTING AND OTHERWISE.

(Notes by Wanderer.)

June 6th.

TEA PRICES.—Gow, Wilson & Stanton's circular of the 19th May was anything but pleasant reading; the average for the week being 8½d, what sort of read or reading will this circular be when we get the mail of the 2nd June, the average for that week being only 8d. Of the illustrious four estates mentioned in that circular only Ravenswood sent its tea in chests. Charley Valley tea was packed in boxes, and Henfold and Walaha in packages. The Bogawantalwa estates are certainly not to the front, but Glenalpine at 10d shows what Uva can do with good management and good machinery.

TEA CHESTS are getting very scarce. If the West Coast of India or the new Galle Company can supply us with good chests, we shall be more independent of Japan than at present. A cold-shiver passed through me the other day when told that Japan might soon stop the present export of shooks for tea chests.

TRADE AND FINANCE—indeed anything in which gold comes in—are bad at home. "London is panicky" were the words used by a London Correspondent by last mail. Australian Banks that have gone to the wall, will not be so easily reconstructed as some people imagine, and our Yankee Cousins are likely soon to have a bad time of it.

June will likely be a good month for the harvesting of tea, for the weather is still mild, and the leaf comes in gaily. Planters who end their financial year on the 30th instant, will thus be able to wind up with their estimates better realised than they some time ago anticipated.

COCOA.—The weather in Matale and Dumbara has been rather dry the last fortnight and the Cocoa is a little light in consequence Kurunegala has been favoured.

COCAINE-MAKING IN PERU.

May 18.

In an official report on the trade of Callao (Peru), which has just been issued, the name of one German firm (Bernard Pruess) is given as the manufacturer of crude cocaine at that port. The leaves used in the preparation of the article are those from the province of Huanoco, and the exports of cocaine during 1892 amounted to 2,672 lb. (value 16,362*l.*) to London, 932 lb. (value 5,711*l.*) to Hamburg, and 221 lb. (1,350*l.*) to New York—a total of 3,825 lb. worth 23,423*l.* We believe that there are at least three or four manufacturers of cocaine in Peru in addition to the firm named, and that the export figures represent their aggregate output.—*Chemist and Druggist*, May 20.

THE AMSTERDAM MARKET.

AMSTERDAM, May 13.

The cinchona auctions to be held here on June 1 1893, will consist of 39 cases and 5,695 bales, or about 500 tons, of bark, divided as follows:—From the Government plantations, 11 cases and 346 bales (at about 32 tons); private plantations, 28 cases and 5,349 bales (about 46 tons.) This quantity contains of druggists' bark: *Succirubra* quills, 17 cases; broken quills and chips, 282 bales 14 cases; root 8 bales. *Officialis* quills, 4 cases. *Hassharbiana*, 4 cases. Of manufac-

turing-bark: *Ledgeriana* broken quills and chips, 4,187 bales; root, 554 bales. *Hybrid* broken quills and chips 551 bales; root 70 bales. *Officialis* broken quills and chips 33 bales; root 10 bales.—*Chemist and Druggist*, May 20.

LIBERIAN COFFEE.

In Priaman, on the West Coast of Sumatra, the cultivation of Liberian coffee has been taken in hand with labourers from Java, though there is a source of labour supply among the people of the land. As the law now stands, planters there cannot enter into labour contracts with them for work locally, though the natives can engage themselves for labour in other lands. The Governor-General's instructions direct him to lay no needless impediments in the way of useful enterprises in Netherlands India, yet the law countenances the absurdity of allowing planters on that coast to recruit labourers there to work in other countries, while refusing these planters the right to recruit them for labour on the spot. Planters in business there hence have to engage labourers from other parts of Netherlands India, and find it highly expensive.—*Straits Times*.

THE GRASSE PERFUME INDUSTRY.

Our information from Grasse is to the effect that the orange and rose flower harvests are at present in full swing. The farmers are able to obtain fairly satisfactory prices for their flowers, 60c per kilo, being freely paid for orange flowers—a fact which is the more noteworthy as the demand for essential oil of neroli is generally poor, many consumers having taken advantage of the extraordinarily low prices of last season to lay in a stock sufficiently large to cover part of their wants for the present year. The violet industry, which had expanded greatly in the Grasse district since the olive-trees, a few years ago began to show signs of exhaustion, is unfortunately menaced by a danger so grave as to threaten its destruction. About two years ago the violet plants at the moment of flowering were attacked, for the first time, by a blight which caused them to fade and die. The blight, it now appears, is caused by a minute, bright-red insect, which attacks the under-surface of the leaf and destroys the parenchyma. The insect spreads with great rapidity, and the plague has taken enormous proportions this season. Watering with dilute infusion of tobacco (1 part by weight of 15 per cent juice to 20 parts of water) is recommended as a cure, but meanwhile the violet-growers are much perturbed by the visitation.—*Chemist and Druggist*.

FROM THE HILLS.

(By Old Colonist.)

THE GRAND STAND—KANDY RACE COURSE—GETTING
ABREAST OF THE TIMES!

June 6th, 1893.

I write from this spot for reasons that may appear further on. It's the first time—as far as I can remember that I ever entered a racecourse. It was only the other day I for the first time entered an opium den (I'm getting on!) and as I escaped from Little Bourke St., a wiser and happier man, so here I feel that if all racecourses are like the Kandy racecourse—the more the merrier for me!

In short, I'm a shareholder in this concern. Never you mind how infinitesimal my share may be. It is enough to give me a right to be here, and I may as well explain at once, that "the Ceylon Land and Produce Company" have taken a long lease of the interior of the course (about 30 acres) and are planting it up with tea—planting it very well too.

My chief object however, in climbing this mound was to obtain a view of the surroundings. But before I proceed to speak of this—just allow me a moment to moralize on planting matters generally, and if my language smacks clumsily of the stables—recollect where I am, and that I am a novice.

There is nothing, perhaps, I would more desire at the present moment than to see the august Editors of the Ceylon Press start fair here: I know which horse I would back!

And then in their turn, let them act as judges while we the planters trot out our favourites:—There goes "TEA"—she has of course got the bit in her mouth and is hopelessly distancing all other competitors we can bring forward today. But will it be always so? There is at present a remarkable rebound in favour of the CHOCOLATE HORSE who is proving much hardier and less squeamish as to food than at one time he was supposed to be.

This grand horse was introduced by my friend the late R. B. T. and acclimatization has unquestionably done a great deal for him; he looks better and thrives now where 25 years ago he would have died of "insidious defunction." At best however, I doubt if ever this horse will do more than come in a respectable third.

"CINCHONA."—Of course there is now no use talking of this old screw, yet he did Ceylon a good turn in his day, and disappointing as he was I cannot help taking a kindly interest in him. I was present when he was first trotted out of the stables near by—after careful training by Dr. Thwaites and Mr. Cameron—and Mr. MacNicholl. And have since seen his sires in their own native home, and though now not worth betting upon commercially, his interesting and useful life is well worth preserving.

The coming dark horse however—if I may reveal secrets, and offer "straight tips" all round—is a true descendant of the once prime favourite. The sire, an Arab; the mother a sturdy LIBERIAN;—herself a grand horse, never in my humble opinion sufficiently appreciated—never indeed, got fair play—for it is not a matter of opinion at all, but a *matter of fact* that she was on more than one occasion ruthlessly pulled up. May it fare better for her hybrid son—Ab-Lib.—for whom I would fain bespeak a kindly welcome.

And now let us once more take a look around at the grand amphitheatre of beautiful and familiar grounds.

Close by,

THE UNIQUE GARDENS

perhaps the prettiest tropical paddock on the globe. Whether it was the spot where Adam first delved we cannot tell, but this we know, he could not possibly have had a lovelier spot in which to spend his honeymoon.

Beyond the gardens lie the lands of the ever retiring BARNES. A splendid property (GANGARUWA) intrinsically worth more now than ever it was in the palmiest days, but surely the Sinhalese are being allowed to encroach upon it?

On the opposite side of the river stands PRIMROSE HILL—still 2,114 feet above sea level, and about to flourish again with a base of cocoa and a crown of tea.

Due north lies KANDY herself—the sweetest of all the long line of Lanka's Capitals. OLD HANTANE to the right is once more stretching out its bare arms—soon however to be clothed in the richest verdure, but as yet not one-half the property is under cultivation.

To the N. E. is MOUNT PLEASANT and HOPWELL, the real "Anthony Malle" where the elder Boustead accompanied me in the '60's—declaring as he gasped for breath, that the place was "only fit for Scotchmen and coolies!" Here also there is a little good cultivation, but the larger and better portion is still to re-open.

Below this are the quartz ridges where "Sandy Brown" was wont to reign supreme, and plant coffee with more energy than success; but those bare ridges are now clothed with quite a respectable garment and I wonder much what Sandy would think of these surroundings today?

He never really was a planter, in the same sense that R. B. T. — Peter Moir or even old Dickson and Jamie Martin were planters, because he never had the horticultural training to save him from gross blunders. Sandy was just the man to go in for bad jät, heedless of how it would affect posterity. At the same time he had energy, pluck and diction enough to demolish any dozen planters of his day.

I have not left space to write of the promising lands of MAHAOYA where a sheet of tea already covers the ground; nor to comment on the great valley of undulating land stretching from Nawalapitiya to Matale, which, with the exception of an occasional thin ridge might all if need be grow cocoa or tea. It is ridiculous to suppose that old WEANAWATTE or New PERADENIYA have any monopoly of suitable soil! There is one redeeming feature in these medium and lowcountry lands. The planter here has various strings to his bow, while on the cold damp highlands there is nothing to hope for, as far as we at present know, beyond tea.

I would like to say a word about my immediate surroundings. If NEW PERADENIYA was the property of a private owner, I would not dare to comment but with a "soulless Coy" I have not the same compunction, and briefly I would say to my fellow-shareholders we have here got a magnificent property though with an abominably bad jät of tea. Were I the V. A., I would insist even now on throwing out $\frac{1}{2}$ of the trees and replanting. I would also like to see the waters of the Mahaoya more conserved rather than deude the whole country-side to supply these engines with fuel.

I will return to this subject; meanwhile I leave these items to be digested by "THE BOARD."

UVA PLANTING REPORT.

BADULLA DISTRICT, June 6th 1893.

THE MONSOON was thought to have burst here on the 18th May, since which date we have had dry weather with a certain amount of wind, though not nearly as much as we sometimes get. The past few days however have been quiet and we have had good showers in the afternoons which have done good. The early part of May was wet and genial, and May, all through the district, has been a capital month for tea; it has been in this neighbourhood by far the best we have had for the year. June has started well too, but there is a great deal of tea to be pruned during the next few months; some estates have commenced already, and the output of the district will fall off very much between this and December. This has been a very favourable season for tea in Ouvah, and though parts of the district were dry in December, and January, most estates got rain then and tea has continued flushing pretty well without a check the whole year. Yields are everywhere fair and I hear of fields giving extraordinary returns. Our prices too have been good and our position in the district averages—second—is very satisfactory. Prices just now are discouraging, but Exchange being favourable we are not yet going to stop opening. I fancy there will be a very considerable acreage opened in tea in the coming monsoon.

COFFEE is at present looking fairly well, where it has been attended to, but no reliance can be placed on crop prospects now-a-days. I am very sorry to say bug has put in a very vigorous appearance, and on the lower estates is already doing harm. As we usually do not expect to see bug until nearly the end of the dry weather, and as we do not expect it to do much harm to crop until November-December, I fear this early appearance can only mean a bad season for this pest. Spring crops are still coming in, but they are of course nearly over. They will generally prove disappointing.

CINCHONA is fast disappearing from the district and there are now only a very few estates with any quantity left. Canaverella still has a good show, but it is only in such places where analysis and quality of bark are good that proprietors can allow it to cumber the ground; for at present prices it can pay few.

ROADS are progressing apace, and they will be opened for traffic, it is hoped, before the end of the present year.

LABOR in the district is fairly plentiful, but I have not heard of any fresh arrivals lately. Sinhalese are working regularly in the intervals of their paddy fields and chena works, and are a reliable force for clearings and other similar works on most estates in the neighbourhood of villages.

Correspondence.

To the Editor.

"THE BITTER CRY OF MINCING LANE"
OVER CEYLON TEAS:—No. XIX.

Central Province, May 28th.

DEAR SIR,—The subject of the letter headed "Bitter Cry of Mincing Lane over Ceylon tea" is a matter that has interested me very much for a long time. That Ceylon have deteriorated since 1885 in flavor and point, is a fact which admits of no dispute, although those incapable of judging on such matters, residing in the island, say it is simply the taste that has changed and not the tea. Well, they don't know what they are talking about. There are scarcely any teas shipped from Ceylon now as fine as we had in 1885,—in fact I question whether even the gardens turning out the finest teas now and averaging over 1s 2d a lb. are as fine as some we used to get. Personally I don't believe our teas have really got appreciably worse—that is to say if we pluck to make really fine teas we can still make them—though few try to make fine teas; but now every one wants to show the 300lb. or 400 lb. an acre or over—as a rule as much over as possible. Now in manufacturing tea, you have only to very carefully separate the top leaf and bud from the 2nd leaf, and the 2nd leaf from the 3rd, to see what a wonderful difference there is in the quality of the different leaves. Of course when you pluck 3 leaves and a bud, some of the juice from the coarse gets mixed with the fine and *vice versa*. But no matter, even so, taste the 1 leaf and bud—the 2nd leaf and stalk attached, and the 3rd leaf with its stalk and you will see in an instant that whereas in spite of coarse juice being mixed with fine leaf juice, you still get liquor with fine quality from one leaf and bud; fair liquor from 2nd leaf; and really coarse common flavour from 3rd. Now in ordinary manufacture as opposed to experimental, you must roll at some period with very heavy pressure, if you pluck say 3 leaves and bud, in order to get any strength in cup and the consequence is that a great deal of the coarse common-flavoured tea gets either broken in the roller into the fine tea or the juice from the coarse gets absorbed into the fine leaf. The result is you get only very medium tea; 15 per cent. of coarse tea will give 85 per cent. of fairish tea, a common touch of flavour which spoils its sale entirely in London and makes it into medium, rather undesirable tea, instead of being inclined to fine useful tea which would be most saleable, and it also adds a certain amount of flat untwisted tea to the samples.

It is not correct when people say—"Oh when we make fine tea the market always drops for fine tea." The error lies here. When they change they usually change from common tea not to fine, but to finest—a vast difference. Now the market can't absorb too much finest *i.e.*, tea over 1s 8d a lb. because there is not the demand for it and we send very little fine tea home—not enough in fact to create a steady demand for it. Were the island all over to go in for fine-ish plucking, *not extra fine*, but fine, so as to turn out plenty of teas averaging say 1s 1 $\frac{1}{2}$ d—1s 5 $\frac{1}{2}$ d, a steady demand would soon commence for such teas—say after 6 months of such teas,—and it would continue without doubt so long as plenty was

forthcoming* Now if a man buys a fine Ceylon, he may have to wait 2 months to get equally good again, and so lose his customers and name. Not so India. They always send plenty of fine tea, so that buyers can rely on getting it always and witness their prices. We send such a mere daub of fine to finest that people scarcely dare bid for it. Why I heard recently of a fine Ceylon being sold in open market at 1s 2d and resold in county at 1s 10d. Why so'd at 1s 2d? Because the trade dare not give high prices for what they may not be able to follow again. Make fine teas all round and the market will respond to it by giving higher prices, when it sees it can really rely on a constant supply of such teas. As soon as the market drops a bit, everybody here says, 'Oh no one will buy our good teas so we may as well go in for quantity.' Then when trade brightens up and buyers are ready for fine teas again, they are not to be got.

I don't think the *trade proper* have sounded the praises of Ceylon teas any more than of Indians or Chinas. All they care about is buying a tea which they can resell at a profit on cost price. Fine-finest can nearly always be resold to show a profit; common teas to medium not so always as the market is always jumping about up and down with such teas. A good Indian at 1s 3d—1s 8d is much safer stock than an 11d Ceylon. Sooner or later a dealer can nearly always sell the Indian because good teas are so often scarce and wanted and are not to be got in the open market, except during the months September—April, the period of the Indian tea season in the London market. But medium teas, why you can always get them in any quantity. The result is the dealer with medium teas only on his stock, has only got what everybody else has got or can easily get. And this medium tea is what nearly 90 per cent of Ceylon tea is. Now-a-days it is the exception, not the rule, for a big dealer to have any quantity of fine Ceylon on his stock list. How many parcels of Ceylon are sold at over 1s 8d say during the year? Of fine Indian he always has heaps, in the season. When once we recognise this fact throughout the whole island and make principally fine—finest and stick to it, then our prices will rise permanently to a high level, perhaps equal to Darjeeling, and dealers will not be so afraid to operate freely in "fine Ceylons" as they are now; for they will know a purchase can be repeated pretty nearly every sale and they will always be able to supply fine tea when asked for it and not, only once in a way as at present.—Yours truly, FINE TEA.

No. XX.

DEAR SIR,—It is perhaps, worthy of remark that so many planters in speaking of their teas, call their bro. or pek. or bro. pek. at 9-10d "fine tea"? They don't understand that 9-10d teas—or what 6 months or more to go were fetching 1/1 1/3—are not fine teas. They are good enough teas, pure, flavory, &c., &c., but they are only "medium teas."

Your correspondent "T. P." is wrong in calling under-fermented teas, "teas such as buyers would call stand-out." They might be called "pointy teas or sharp teas" but "a stand-out tea" is not simply a sharp or a pungent, or a thick tea, but one that stands out by itself for quality, leaf and

* Witness the splendid prices invariably paid for Darjeeling teas. Why? Because if a man buys fine Darjeeling tea he knows he can always get equally good again during the season as nearly all Darjeeling is fine tea, fine in liquor and not on account of tip or leaf.

richness above all those round and about it, a tea that would cause every one tasting it to stop for a second sip, to be sure that they gave such a tea the attention it would deserve.—Yours

THE LANE.

No. XXI.

June 5th.

DEAR SIR,—“Philpot’s” letter taken as a whole is simply blatant sensationalism and seeing he has been tasting fine China Congous for the last 30 years I should say the sooner he follows his Congous to the realms of well merited oblivion the better it will be for all concerned, as a tea taster with such an antiquated worn-out palate must be about as big a nuisance in the trade as our present Premier and his Home Rule Bill in the House of Commons.

In my opinion the Ceylon teas shipped during the past 12 months have been every bit as good, all round as those shipped years ago; but Lipton, Mazawatte & Co., must have teas at a certain price and the consequence is our lower grades have been fetching enhanced prices and our finer teas have sold comparatively for pence per pound under their value as all private advices will I believe bear out. L. M. & Co., handle no mean proportion of the whole tea trade, and it therefore stands to reason if they will have none of our finer teas, the market for these is considerably circumscribed and they suffer accordingly. That estates generally have gone in for coarser plucking I do not for a moment believe, though undoubtedly a very few stand-out estates have done so as a fair quantity is found to pay better than extra fine quality all the year round.

If coarse plucking generally had been adopted increased shipments would have shown up long ere this.

I do not think we ever produce really fine teas in the second half of the N. East monsoon, and it is these teas which start the well known yearly outcry at this season. Moreover when these teas reach the market, trade as a rule is dull, and our worthy Brokers having little else to do, sit down and amuse themselves abusing us till first arrivals from India and China give them something more to do and put them in a good humour again.

Brokerage and Commission on an eight penny tea compared to what it is on a shilling average is sufficient in itself to justify our most respectable London friends in sometimes saying swear. The main point is our tea continues to pay very well as judged by the dividends paid by our Tea Companies.—Yours faithfully,

SCEPTIC.

No. XXII.

June 3.

DEAR SIR,—Referring to the letter signed “Philpot” on the deterioration of Ceylon teas I am afraid there is much truth in what he writes, and I do not see, according to the laws of nature, how any other result could be reasonably expected. Here in Ceylon we have tea growing chiefly on old coffee land; and with few exceptions the soil is exhausted; but the wonderful climate has stimulated a vigorous growth and tea has flourished. Still climate cannot do everything; we must have soil and elevation to sustain the quality of the tea.

You remember a letter to the editor of the *Financial News* which I sent to you in London signed “Tropical Rustic”; just a year ago, he wrote:—“I am impressed with the fact that the areas in Ceylon at present in bearing which can produce the finest teas is limited in proportion to the area yielding good medium, medium and common teas, and that it is a fallacy to try and force the latter to compete

with the estates at high altitude.” In fact all through that letter he called attention to the more or less exhausted soil; and I frequently remark as I travel about Ceylon, “How tea grows on such soil. I cannot understand, in Darjeeling such poor stuff would not even grow weeds.”

The estates in Ceylon which produce high class teas are all favoured with natural advantages, viz., elevation, climate, soil, and good fat. Some of the fortunate managers who are lucky enough to manage estates thus situated, flatter themselves that their especial ability in the direction of the factory, their careful pruning, &c. influence the good prices; but experienced men know such is not altogether the case.

In my opinion there is a great future for men who have the capital to open out suitable land at a high elevation; but can such land be got in Ceylon? Yours sincerely,

“INVESTOR.”

No. XXIII.

Agra Patana, June 6th.

DEAR SIR,—Ceylon can make as good if not far better tea now than ever it could; we have more and better machinery and our bushes are more matured. But when the trade will hardly give more for the finest high-grown tea than for a common grade from the low country, it surely cannot expect a proprietor to be so financially mad as to interfere with his own interests to gratify the notions of “Philpot” or any one else—taking my last broker’s reports I see each break with reference to the former is said to be quite equal in quality, but my broken pekoe goes down in valuation (not value) from 1s 7d to 1s 3d. Vulcanised india-rubber, raw potato, leathery and so forth is mere bosh. Possibly tea tasters are a good deal overworked and their tongues have got leathery their digestions vulcanised. I don’t know the taste of a raw potato as “Philpot” seems to do. In dread of overproduction I notice everywhere I have been upcountry finer plucking and many of my neighbours speak of reduced yields. I know some tasters like a high fired somewhat burned flavor which would be condemned in Colombo, but I am confident the lower fired flavoury high grown tea is as good now as ever it was. I rather incline to the belief that familiarity breeding contempt has a good deal to do with the complaint. Moreover the China men whose occupation there is gone, cannot but be jealous and some of that jealousy must have its expression and consequences. That is my opinion whatever it may be worth.—R.W.W.

P.S.—While we condemn the sale of China tea under the name of Ceylon the suggestion of calling our teas Darjiling even with Ceylon added is simply audacious. I consider it would subject us to prosecution under the “Merchandise Marks Act.” Let us stand or fall on our own merits and not march under borrowed plumes from Darjiling or anywhere else. There is tea made in the Darjiling terai worse than anything sent from Ceylon—and the elevation of many of the so-called Darjiling gardens is under 400 feet.—R.W.W.

No. XXIV.

DEAR SIR,—I don’t fancy you will ever get all the planters to band themselves together to make fine teas. They all have so many theories and fads. But I maintain it would pay. I don’t think marking chests as Darjeeling Ceylon would pay one way or other apart from the fact that we scarcely have a right to make use of Darjeeling’s good name to enhance our own prices. Couldn’t Darjeeling object? Put Ceylon and say Ceylon-Java’s or Ceylon-China’s in the same form and what should we say?

I see you disagree with me about making fine

teas in the low-country. Why shouldn't we? In Cachar low down? I believe so. It can make fine tippy thick teas, as for instance Borokai Garden India Tea Company of Cachar. They make or used to make very fine teas. And so could low-country Ceylon. Not fine-flavoured perhaps, but thick dark liquoring teas with tippy leaf and any amount of body. If low country places would send some fine tippy flavory pointy teas, Ceylons would soon pull up. When we get a good proportion of fine Ceylons—say 30 per cent to 35 per cent of our exports—and send it, from high, medium and low elevations and stick to it, then we may see Ceylon take a place equal to Assam and even perhaps above it—and not before—and then and only then will the trade look out for fine Ceylons and establish a regular trade in it as they do now in fine Assam.—Yours,

FINE TEA.

P.S.—Later.—In answer to your suggestion *re* separating Ceylon's into two classes—high and low grown, I myself fail to see where the advantage would come in. Even lowcountry teas can be made to produce high averages as I have tried it at a place not 300 feet above sea level but it was real good plucking that did it, *i.e.* two small leaves and a bud and no bangies. Teas from such leaf even in bad districts will give very tippy pretty B.O.P.'s with dark liquors which are always saleable when tippy as well as strong liquoring pretty leafed pekoes. But these places all go for big lowcountry yields and poor prices and I am sure almost that eventually prices paid would actually leave more profit than present system of nothing but medium and common teas and scarcely any fine. Why the very fact of making our exports fall to say 50 or 60 million, and having it all either good medium, fine or finest would of itself raise prices as the demand would be greater than the supply. Then this wretched coarse plucking I suppose would seize on everyone again and prices would again fall. Advocate and advocate strongly all round fine plucking and advocate sticking to it even when prices are high, and try and induce planters not to swamp London with common tea just because common teas are fetching high prices at some particular time, and by hammering away at it you may gradually produce fruit of some value. Pluck fairly fine at every elevation and coarse nowhere is the "word" and the result will bring its own reward and with interest I should be inclined to say. I notice very few answers to "Philpot" touch on the real point at issue. They mostly say when the market will pay for fine tea we make it—but however can the market pay for what they hardly ever get. Ormidale sends it. Why not others. Most seem to imagine their best grade of B.O.P. at 10d is fine tea instead of medium or poor medium. Witness the Assam and Darjeeling sales.

If you advocate strongly going in more in Ceylon for a better class of tea altogether than we send at present, it may have some effect in helping to improve our teas. Coarse and medium coarse plucking ruins the delicate flavour of our teas and entirely swamps all semblance of delicacy which Ceylon once possessed.—F. T.

No. XXV.

DEAR SIR,—In your summary of the "Bitter Cry" discussion, you dwell principally, indeed, almost exclusively on the question of "supply"; but what about "demand"? You do glance at the fact that "Ceylon teas for some reason have been selling several pence below valuation." And to account for this, so far as "fine tea" is concerned, you instance the advice given by Mr. Thompson, the meaning of which is that the supply of "fine" Ceylon tea is not steady enough, nor large enough to create an active demand, or to insure the realization of fair prices for the little that is offered. We are asked to infer from this that there exists a demand for fine Ceylon tea, which the planters themselves keep down, or in a latent

state, by not awakening into active and permanent life by the stream of a full supply.

Well, sir, after all, the opinion of an average planter on the London tea trade cannot be of much practical value. We laugh at the brokers' opinions on practical tea planting, and doubtless they are justified in laughing at our ideas of conducting the world's tea trade. But as between London brokers and planters there is a test which should be applied. How many estates in Ceylon are now practically under the immediate and absolute control of London brokers? Are these estates not well known? And do they stand out in any way distinguished from the general working of Ceylon estates? Do the estates controlled by Messrs. Gow & Wilson, and by Messrs. Anderson Bros., &c. &c., show different in the price lists from all the others? Also, I know sundry Colombo brokers interested also as planters: is *their* method different from ours? It is for you, sir, to pick out these properties, to make the comparisons, and to draw the inferences. But this point wants clearing up.

Now as regards "Demand." Is not this all that a planter, as such has to guide him? What can he know about the under-currents of special demand? Surely there are trade secrets! But what you do not even touch upon in your summary, sir, is the bare-faced glaring "demand" of the middle-men who supply the consumer: the packet-men! Lipton who in himself combines planter, broker, merchant, middle-man and retailer assures the world that the "finest tea produced" can be retailed at 1s 7d a lb.! Take 4d duty from this, 2d expenses and 4d profit, (for your middle-man and his retailer are determined, in the end to get most out of it, whatever becomes of the planter), and all they can afford to pay for *such* tea is 9d a lb.! In elucidating this mystery, "What becomes of even the small quantity of high priced tea that is produced?" We must ascertain who are the consumers? What is the "demand" we are called upon to supply? Is there any other tea-drinking world or large country or class, not known to the planter? If this "demand" can be made clear to our intelligence we can then better judge how to meet it. Does any other "demand" exist that the middleman does not strive to supply? Who are the consumers of whose existence we apparently do not know, but who are anxious, and willing, to encourage the production of high-priced tea by paying for it, in face of the blends universally offered to them at 1s and 1s 3d a lb? Is not this actual demand of the middleman overwhelming in its bulk and extent, and yet, sir, you have not a word to say about it.

Many of my own friends, at home, are in the enjoyment of large incomes, and yet when I sent them broken pekoe at 2s 6d, free to their own door, they were dissatisfied because they could get it in packets from the shops at half that price, and they thought it "very fortunate" the servants liked the "dust" I send *gratis*, as that made the B. P. less expensive!

Does not this show the demand created by the packetmen? Can the "Lane" control the packetmen, or prevent them going from bad to worse?
OLD HAND.

COCONUT CULTIVATION IN CEYLON:
AN ANSWER TO CRITICISM.

DEAR SIR,—The leading article in last Wednesday's "Examiner" comments on the statistics quoted in your issue of the 26th ultimo, under the heading Coconut Cultivation in Ceylon, and

unjustifiably suspects that "a rough and misleading guess" was made with regard to an extent of one of the fields referred to, which it is arbitrarily suggested is "nearer 20 acres than 15."

In drawing this conclusion two things are assumed:—(1) that the trees in the field in question are planted farther apart than one would naturally infer from the figures given in the statement appended to the letter, and (2) that "Polgaha's" knowledge of the act of reckoning is too limited to enable him to calculate with any approximation to accuracy the extent of land covered by a given number of trees placed at certain distances apart from each other.

The reason adduced for the first assumption is that more than "84 trees to the acre would not be good planting" (I would fix the limit for "good planting" at 75); but the purpose of my letter and statement was not to show the results of good planting but to prove the profitableness of liberal manuring.

There was no guess-work whatever in the statement in question, and in describing field A as of 15 acres, I did so advisedly; the trees in this field as well as in the other referred to, are planted from 22 to 23 feet apart and there are a number of young plants besides the bearing trees.

What manures to use and how to apply them have already been recommended in your columns by the best authority on the subject in the Island, and if his advice be followed in the treatment of bearing trees and W. H. W's instructions be attended to in the opening of plantations, even larger profits than R180 per acre may be calculated upon with the rates now ruling for nuts.—Yours truly,

POLGAHA.

CEYLON BEETLES IN ENGLAND.

SIR.—In a recent number of the *Spectator* in an article on the Butterfly Farm at the Zoo appears the following:—

"Among the butterfly cages is a glass case which since its inmates first found their way to the Zoo has never failed to excite the utmost interest and curiosity. On the floor of the box, partly sheltered by a few green plants, are ten or a dozen gold buttons, with a red gold centre, on a lighter gold setting, edged by a round semi-transparent rim. If watched attentively the buttons presently move about on invisible legs, and perhaps, one suddenly splits, puts out a pair of wings and flies. These astonishing beetles, which are at present unnamed, are from Ceylon. Above they exactly resemble an embossed gold sleeve button with a rim of yellow talc. Laid on their backs the under side of golden beetle appears to be surrounded by the same transparent rim."

Can any of your readers identify these beetles. Is this a description of the gold beetle that is to be found on the Madras thorn when in bean?—Yours truly,

J. B. D.

PLANTING POTATOS.—The question of the right number of eyes to the piece of seed tuber has long engaged the attention of cultivators and experimenters, without receiving a generally acceptable answer. The experimental data brought forward at the Purdue University Agricultural Station, *Bulletin*, n. 42, 1892, prove that the number of eyes per piece is immaterial, but that the weight of the piece is a very important factor. The proper manner of cutting Potatos for planting, therefore, is to divide them into pieces of suitable weight (size), without regard to the distribution of the eye. Instead of attempting to have one, two, or three eyes pieces, as the case may be, the approximation should be to one, two or three ounce pieces, or some other definite weight.—*Gardeners' Chronicle*.

TEA:—QUANTITY VS. QUALITY.

A very interesting and suggestive discussion has just been concluded in the pages of our senior contemporary on the alleged deterioration of Ceylon Tea. It originated from the publication of a letter signed "Philpot," which professed to be a bitter cry from Mincing Lane over the falling-off in the original characteristics of the Teas of the Island which had earned for them so high a name. "The *Observer* asks, are planters prepared that the good name of the Island should suffer though this rush for medium qualities? The answer, we fear, to this question is that there are matters which more nearly concern the producer than the good name of the Island; and that, provided he honestly turns out a pure article which bears a proper relation to the price at which he can sell it, he must consult his own personal interests, rather than those of the Island. A consideration, however, which generally seems to be forgotten, is that, if quality be more persistently and generally aimed at than quantity, one result would be the reduction of the quantity of Tea thrown on the market—at any rate, the prevention of its undue growth. One main cause of the falling-off in prices has unquestionably been over production. While the extended manufacture of medium qualities has aided or maintained over production, adherence to quality might have to some extent maintained prices while checking the flooding of the market. Only a few writers have had the courage to say that the neglect of due cultivation is, if not wholly yet mainly, responsible for the lack of flavour in the Teas now produced as compared with those which were first turned out. Our best teas were not produced two or three years ago. They came into notice in almost the first years of the enterprise, as soon as the secrets of manufacture had been mastered. The bushes planted on virgin soil, or on soil from which the constituents required by Tea had not been drawn by the products which preceded it, yielded leaves of a decided flavour. Continuous pluckings and frequent prunings have naturally taken away much from the soil; and even rich land may have been impoverished of constituents helpful to flavour. How much more land which had long grown other products, or whose poverty should have deterred the prudent Planter from placing it under Tea. It will never do for men jealous for the reputation of the Island, or confident in their treatment of their own valuable properties, to lose sight of the fact that a large acreage under Tea represents poor or washed out land, and that the produce of such land cannot be high flavoured. We remember hearing of the Superintendent of one Estate whose produce had long topped the market, on his return to it some years after confessing himself unable to detect the old flavour in the Tea. He had no personal or unworthy object in making the statement, which was supported not alone by the falling off in the price of the Teas it produced but also by the loss of the position it had once occupied with reference to other marks. The secret was that the Estate had not been manured at all, and his acknowledged skill in manufacture failed to make any difference in the price. With Estates in poor heart it becomes almost an absolute necessity, if they are not to involve loss, to adopt medium or even coarse plucking; for even so there is not much to boast of in quantity; but if their productiveness be increased by liberal cultivation, quantity will not be greatly sacrificed by studying quality. Without denying that London Tea Tasters and Tea Brokers are at times erratic in their condemnation of Teas, and without questioning the force of other circumstances such as strikes and the uncertainty of the political outlook in influencing the Market, we lean to the view that more might be done by cultivation and in the Factory to improve the quality of our Teas. The question is one affecting European and Native alike not only because the whole Island benefits from the Tea enterprise, but because all classes are engaged in it, employes as well as those in the position of Proprietors; and we devoutly hope that the disturbing controversy will yet bear good fruit.—Local "Examiner"—June 12th.

FRUIT CULTURE IN NORTHERN INDIA.

The following interesting notes on this most important subject have been furnished by the Rev. M. M. Carleton.

Results of experiments made in horticulture at Ani, a village at 4,500 feet, in Kulu subdivision, 65 miles from Simla.

I. First experiment in apple cultivation. After ten years the whole experiment has proved well nigh a failure. American apple trees, as well as English, are not prolific in this climate at 4,500 feet. A few apples were obtained, and the growth of the trees has been all that could be desired, but apples brought from England or Scotland, or from the northern part of the United States and Canada, will not be profitable below, 6,000 feet. As an example of one variety, I introduced the Porter apple tree from New England, a standard apple for the last fifty years, both in Canada and New England. The trees grew finely, they are the finest in my orchard. They are now eight years old, but they have never produced even a blossom. This result is the same when trees from New England and Canada are transferred to the Southern States, especially Florida; they grow well, but never produce fruit.

II. Experiment No. 2 with Kashmir apricots has proved a remarkable success. The native apricot in this warm valley was not prolific, and, from analogy, we concluded that the place was too warm for the Kashmir, or English, variety. We, however, introduced ten trees from the Government Garden at Lahore. They grew very vigorously, and began to bear fruit the fourth year. They are even more prolific than the native variety in Kulu Valley. The fruit ripens about the 15th or 20th of June. I should advise the extensive cultivation of the Kashmir and English apricot in all the lower hills. The successful introduction of the famous Kashmir-American fruit-drying machines into Simla would enable enterprising persons to establish a very profitable industry in preparing dried apricots for the Indian markets.

III. Experiment No. 3 with American grapes has proved an unqualified success. My first experiment, made fifteen years ago, was with grapes from the Government Gardens of Lahore. The variety was called the Black Hamburg. After twelve years' experiment they proved an utter failure, scarcely a single cluster of grapes in the 12 years. About nine years ago I sent to America for a variety of hardy prolific grape, grown on the northern limit of grape cultivation, where the spring opens in May and frost comes in September. I held the opinion that such a variety would ripen in July before the heavy rain, because the spring opens the last of February or the 1st March. My experiment proved that the American grape in these lower hills is a great success. Only one vine lived of those I first received; that is about eight years old, and now, to-day (May 7) there are about 70lb. of green grapes on the vine. A few such vines around the houses of intelligent zemindars in the Simla district would give a handsome return, especially in the Simla market, in the month of July.

IV. Experiment No. 4 with the common Himalayan walnut is also a success. Very fine large trees in ten years, and very fruitful. In thirty-five years a grand change in the use of the walnut has taken place. In former times in Kashmir, Chumba and Kulu, the only use of the fruit was the production of oil to adulterate ghi. But now the demand for walnuts in the plains is greater than the supply. On account of the valuable timber the cultivation of the walnut should belong to the Department of Forestry. But in California the horticulturist has captured the species, on account of its valuable fruit. They have introduced the celebrated Persian walnut, and find it one of the most profitable fruit trees. We are surprised that the Department of Forestry have done little or nothing with the walnut in the Simla District.

V. Experiment No. 5 with the European orange has proved that the variety commonly called the Maltese orange can be grown in the lower hills, as

high up as 4,500 feet. In California orange cultivation is extending up the rich valleys of the Pacific slopes, and I see no reason why in these lower hills, orange cultivation should not be a success. This year, from one tree eight years old, we gather 220 oranges. They were of the crop of 1891, but they were taken from the tree February 25th. We follow the custom in California and Florida and keep the fruit on the trees till the new leaves appear, the last week in February. We have noticed one remarkable fact in this connection. In the winter of 1890-91 we had two snow-storms, the snow began to fall in the night, and it remained on the orange leaves till 8 a.m. next morning. I could not discover that the fruit was in the least injured, though after the snowstorm the leaves most exposed were somewhat injured. The crop of oranges should be gathered about the 1st of March, and kept in a dry, suitable place till the season opens in Simla. I learn that oranges sold from the Government Garden in Gujranwalla and other gardens usually fetch from five to eight rupees per hundred, and it is quite certain that Maltese oranges sent to the Simla market in April, where there is little fruit for sale, would fetch eight, and perhaps ten rupees per hundred. An orange tree eight years old that gives an annual crop of over 200 oranges could give the owner a profit of 16 rupees, and that on only 10 feet of square ground.—*Horticultural Times.*

SUGAR AND PADDY CULTIVATION IN THE PERAK.

From a Report by Mr. E. W. Birch of a trip through the Krian District, given in the *Perak Gazette*, we extract as follows:—

I was shown the Tamil Mission, which Father Fee assisted with \$4,000 by the Government, created. It numbers 130 families, or 650 souls. They have brought into cultivation 715 acres, and I have given instructions that their holdings are to be now demarcated and certificates of title to be issued at a quit-rent of 40 cents per acre, as was promised when the agreement with Father Fee was entered into. There is a chapel in the village, and the community is reported to be happy and contented. Their padi crops are very good and are sufficient for their own wants.

At 11-30 a.m. we left in the launch for Kuala Kurau. The Kurau is a fine river, and we passed several sugar estates on both sides of the river. On the left bank going down we landed and inspected Jin Wee's estate, where there are 1,300 acres under cane. It is kept in excellent order. It is about three miles from here to Gulaestate. The canes were exceedingly fine, and I went to the mill to see them crushed. The small mill only was working, as the other is undergoing repairs. It will soon be in order again, and then they will work both mills night and day, and expect to have enough canes to feed them. New and expensive brick and tile buildings to provide vats for the extra boiling are being erected. Mr. Baird, an engineer, lives on the estate and was so good as to take us over the works. From his house the whole estate can be seen, and beyond it for miles back the stretches of sugar-cane and the chimneys of other estates. The system of canals and water-gates is very good, and it is exceedingly satisfactory to see this permanent form of cultivation being carried on so briskly and extensively.

It appears to me that a great field for enterprise and capital is open to any one who would start a central factory and advance to, and buy from small cultivators. The Perak Government for a small quit-rent would, I imagine, give away land in square blocks of say 10 acres or so to planters, and if there was a market near at hand to take the canes, paying for the juice by measurement, I feel sure that the same confidence in the minds of the sugar growers would be created as is the case with the tin miners who deal with the Straits Trading Company.

Quite recently Messrs. Stewart and Kennedy have obtained a grant of 5,000 acres of land for

sugar planting in Krian, and they hope to form a company. I should have thought that a good central factory would have been a more attractive venture, because it would give quicker returns. Of course it must be certain that the supply of caes would be adequate, but it would be difficult to import Chinese and to make arrangements with the Perak Government. By this means an assured acreage would be planted up by the time the factory was ready. The new canal and road which has been ordered to be made from Bagan Serai for six miles to Ayer Itam, near the Gula Estate, will bring a good deal of land into a state fit for cultivation.

At the mouth of the Kurau river is a flourishing village where every kind of fish-curing is carried on and a good deal of money is being made. After steaming past it we returned up the river and landed at Bagan Siakap, a rising place. A sale of land in a back street had recently gone off very well. There should be a bund up and down the river for some way to keep out the tides, or it will never be a satisfactory site for a township.

An enterprising Chinaman has started a padi husking and pounding establishment and profited considerably thereby. He pays the cultivators, if delivery is taken on their land, \$5 for 100 gantangs of padi, and if they deliver it at his shop, \$5.50, and as he can sell often at \$8 his earnings may be easily gauged. I feel very strongly that the Perak Government would do well to get in a capitalist to start a good mill, and to pay the people a fair price for their padi. One, Leng Chiak, very business-like Chinaman in Penang, did enter into negotiations with the Perak Government last year, but nothing came of it. He has a rice mill in Kedah, and is not unlikely to come to Krian, if encouragement is given to him. At this moment he will not be able to do so, but he promised me in Penang, when I sent for him to see me, to think the matter over and see whether he could not approach Government early next year. He wants protection, and if he will give good prices for the grain, I think it would be well to give him the inducement he asks for.

From Bagan Siakap to Parit Buntar (9 miles) one passes through kampongs and padi fields stretching miles on both sides of the road the whole way. An enormous quantity of pumpkins are grown here by the Malays and heaps of them are stacked for sale and export all along the road, and in almost every shop and under almost every house. They are taken to Penang and largely used by the Chinese for cakes, and as a vegetable. The road between these points is metalled with the laterite brought from Pulau Kra, and is in good order. It only cost \$1,500 a mile to metal, and is very creditable to the Assistant Engineer, Mr. G. F. Bird.

A CEYLON PLANTER ON CALIFORNIA.

[Mr. W. Laing-Malcolmson referred to in the following long paper from the *Gardeners' Chronicle*, will be remembered as a Ceylon planter who went first to New Zealand and then to California and who has kept up his association with our *Tropical Agriculturist* and *Overland Observer*.—Ed. T.A.]

Mr. Malcolmson, a native of Aberdeen, but settled in California, and now on a visit to his old home, communicates his experience as follows:—“The great industry of California today, and one that in a few years will overshadow all others, is fruit-growing. While fruit has been grown in the States for over a century, having been introduced by the Mission Fathers over a hundred years ago in the southern part of the State, and by the Russian traders early in the present century, in the northern portion, it is only during the past twenty years that any rapid progress has been made in this direction. But in that time California has forced her way ahead of all other States in the Union, until she is today the garden and orchard

of the world. With a continually widening market for our orchard products, with stories of fabulous returns from investments in fruit-farms, it is natural that people of small means, desirous of making a home and an income, should seek for information in regard to it. To this class of my countrymen, I have much pleasure in giving the following particulars, and I think the information I give can be relied upon as authentic, I myself being one of the largest raisin-vine growers in the State, and owning a vineyard of over 160 acres. The intending settler will naturally ask—‘What assurance have I that my investment will be permanent as well as profitable? What are the causes that make California superior to other parts of the United States as a fruit producer? Will not other portions of America enter into competition with us, and overstock the market, and thus make our investment unprofitable, and our labour a failure? These doubts will quickly disappear with a knowledge of the advantages that California enjoys. These are climate, geographical position, and physical peculiarities. While descriptions of California's climate have become a household word, it is nevertheless, the one great cause of its superiority as a fruit section, and its climate depends upon its geographical position. California's position also gives it the world for a market; and while, with the continually-increasing home market, it is now beginning to ship large quantities of fruit to Australia, China, Japan, and India, and within the last few months shipments of fruit have been made to Great Britain. With, therefore, the United States and the rest of the world for a market, and the constantly-developing taste for California luscious fruits, there is no danger of over-production.

“To give some idea of the profits that can be made out of fruit-growing, I shall cite one or two instances which will go to show what one may expect for his labour and capital on only a moderate-sized orchard in California. Major Robert H. Nolton, formerly a railroad employe, nine years ago purchased the Mountain View Orchard, at Verdendale, consisting of 19 acres. It had been planted in fruit six or seven years before. He manages everything with railroad precision and neatness, and the following is his report from December 1890, to December 1891. (I give Major Nolton's report as an example of the various kinds of fruits that can be grown on such a small orchard as 19 acres, and the net results will, no doubt, startle many readers):—

“Major Nolton's family consisted of six. In this report no account is made of eggs, fowls, and two cows, the returns being consumed; but at a glance it will be seen that the handsome return of £629 was netted off such a small orchard as 19 acres.

“As another illustration, I quote the returns of a property near my own—that of the late Mr. F. R.

Storio, an Aberdonian:—My gross receipts from 4 acres of peaches amounted to £206. Among pears, I consider the Bartlett (Williams' Bon Chretien) the best variety. From 1½ acres of young trees I took off £25 worth of fruit. Nectarines are a very good crop, bearing and paying well. I have netted £20 an acre on this fruit. Apricots pay from £25 to £30. French prunes do very well, and from 4½ acres of this fruit I received £200. With a judicious selection of fruit trees there is much money in fruit.'

"Both of these accounts are very satisfactory, and it must not be forgotten that both Major Nolton's and Mr. Storie's orchards are still young, and that the older trees become, the heavier will be the returns. In giving such instances as these, although these are only two out of thousands, I do not wish readers to think that such results can be attained immediately on a settler's arrival in California, unless he is in a position to purchase outright an improved orchard or vineyard. Long weary months of anxiety and labour are necessary before either a vineyard or an orchard can yield such returns as the two cited. Still, in no part of the world can a man so soon see the result of his labour as in California, and in a very few months from the time of his going on to what may be considered a waste and useless piece of land, it can be transformed into a veritable paradise. As an instance of this, I may, *en passant*, cite my own vineyard, of which I took possession some few years ago in a desert state. Within some 60 days I had the whole 160 acres ploughed over twice, to a depth of 18 inches, and carefully harrowed, the whole planted with some 70,000 vines, 10 feet by 3 feet apart; some 5 miles of roads and avenues laid out, whilst on the borders of the avenues I planted alternately, fig and olive trees. In that time I also constructed some 7 or 8 miles of irrigating ditches and canals; enclosed the whole property under close wire fence; erected suitable buildings, stables, and coach-house; and planted an orchard consisting of no fewer than twenty-one different varieties of fruits, and a vine arbour of some twenty varieties of grape vines; whilst, as an adornment to the residence, I laid out a lawn and flower-garden. So that within the short space of three months [Is there not some mistake here?—Ed.] I had transformed into one of the most promising vineyards in California a piece of land which only sixty days previous might have been considered a barren piece of waste and useless land. This will give some idea of the forcing nature of the soil, and the magnificence of the climate of California.

"With such results as these, it is only but natural that the intending settler should wish to know what capital is required for the opening up and bringing into successful bearing a vineyard or an orchard. This, of course, is largely determined by the amount of capital he has available for investment; but my advice—with the experience I have had—is that it is better to own a well-kept 20-acre orchard or vineyard, than a 40-acre tract poorly attended to owing to lack of sufficient capital. But assuming the settler to have sufficient capital to open up and properly cultivate a 20-acre orchard or vineyard, until it begins to yield him a return—which cannot be calculated sooner than three or four years—I estimate that he should possess at least £500. With this sum, and provided he is willing to work, he ought, in the course of four or five years, to be in an independent position. With such a sum to commence with, he will be in a position to pay a portion of the price of his land, build himself a modest house, erect a barn, stable, and fowl-house, and purchase all requisites necessary for making himself a comfortable home;

and should he be further blessed with a thrifty wife, it will be no time before he is enjoying himself, with her help, under his own vine and fig tree. Although I mentioned this sum as necessary for the intending settler to possess before proceeding to California, I could enumerate hundreds of instances where I have known men landing in California without any other capital than their own labour, and working themselves with the help of a wife up to such a position as to be able, through savings and economy, to own an orchard or a vineyard within a few years of their arrival. In no country in the world can a man who is willing and anxious to get on, be so successful as in the golden State of California. . . . In this account I have given of California and its possibilities as a field for emigration, I refer especially to those who are willing and anxious to work, and who are at the same time not afraid to put their shoulder to the wheel. I do not wish readers to imagine that my description has been overdrawn, or that I have been carried away in my statements, as is generally credited to the ordinary American."

Mr. Malcolmson intends, through the influence of some of the most prominent citizens of Aberdeen, to arrange for the purchase of a most desirable tract of land, of some 16,500 acres, known as the San Fernando Rancho, near the city of Los Angeles, in Southern California, and to colonise the same with a thrifty lot of Scotchmen.

SCOTTISH CEYLON TEA COMPANY.

A FIFTEEN PER CENT DIVIDEND, AND AN ADDITION TO THE RESERVE FUND.

The fourth annual ordinary meeting of the Scottish Ceylon Tea Company, Limited, was held yesterday, at the offices, 16, Philpot-lane, E.O., Mr. H. L. Forbes presiding.

The Secretary (Mr. John Anderson) having read the notice of meeting, and the report and accounts having been taken as read.

The Chairman said:—Gentlemen your Directors are very glad to see you here again. There are certainly some faces missing, but we will take that as a vote of confidence in the company. We have very great pleasure in presenting you with this fourth annual report, and though, perhaps, it is not so encouraging as that which was laid before you last year, still, we look upon it as a very satisfactory report indeed. We must remember that Ceylon during last year passed through an abnormal season—peculiarly abnormal I may call it; for we had drought when we ought to have had rain, and rain when we ought to have had drought, and, considering the circumstances, we ought to be very well satisfied. Taking it all round, I think that the shortness of crops of something like 66,000 lb. may be looked upon as a sort of little blessing in disguise; for the market here for tea was already over-stocked, and I think sometimes that our tea bushes are too hardily worked, and would therefore be all the better for a little rest. If we can pay our 15 per cent with a shortness of crop, we ought to be well pleased. The amount available for distribution is £7,823 11s 7d, out of which a dividend of 5 per cent. has already been paid, and your Directors now propose a further final dividend of 10 per cent., free of income-tax, making 15 per cent. for the year, and the transference of £1,000 to the reserve fund, bringing it up to £3,000. I may here take the opportunity of telling you that the reserve fund has been invested in approved stocks, and the additional £1,000 will be similarly dealt with. The gross average price of Ceylon tea for the year 1892 was 9½d. per lb., and the company's teas show 10½d., or 10¼d. which is, I think, very satisfactory. The largest undertaking during the year, in the way of increase of capital, has been the completion of the Lonach factory, and, from all I can hear, it seems

to be not only a credit to the designer, Mr. David Kerr, but it is now one of the landmarks of Ceylon. You will recollect that, about this time last year, when we had the pleasure of meeting you here. I stated it might be possible, before the next annual meeting was due, we should have to call you together again to attend an extraordinary general meeting with reference to an issue of preference shares. Such meeting has been held, and, as you know, those shares have been issued, and were very much over-applied for, and the board regret that they were unable to grant the applications made by the various shareholders. The prospects for this present year 1893 are exceedingly good. The prices of tea are certainly not very high, but against that we have a very low exchange and abnormally low freights, and, given a good season, I see no reason why this present year should not be one of the best that we have ever experienced. You will join with me, I am sure, in expressing our high appreciation of the services rendered to the company by both our Ceylon and London staffs, and this gives me the opportunity and the pleasure of introducing to you Mr. David Kerr (our Ceylon manager) who will be very glad to give you any further information as regards the estates, which he only left about a month or six weeks ago. Both he and I, before the resolution for the adoption of the report is put, will be pleased to answer any questions.

Mr. Cooper: How is the reserve fund invested?

The Chairman: In Rupee paper and Midland four per cent preference stock.

Mr. Cooper observed that it was necessary that the reserve fund should be invested in something that was as good as ready money, and inquired how Rupee Paper was affected by the markets.

The Chairman, in reply, said that Rupee Paper was affected rather badly; but the directors had invested in it as a sort of hedge, as, when the company's profits went down up would go Rupee Paper. The first £1,000 of the reserve fund was invested in Rupee Paper and the second £1,000 in Midland four per cent. preference stock, and the £1,000 that was now to be invested would be put into something similar. The Chairman then proposed: "That the report and accounts be adopted, and that a dividend of 10 per cent., free of income-tax, be paid on and after this date."

Mr. D. Kerr seconded the resolution, which was unanimously adopted.

The Chairman: I now propose: "That Mr. John Anderson be re-elected a director of the company."

Mr. R. W. Forbes seconded the proposition, which was carried.

Mr. James Anderson moved and Mr. D. Andrew seconded the reappointment of Mr. J. B. Lannie as auditor, which was agreed to.

The Chairman next proposed a vote of thanks to the Ceylon and London staffs. The company's main success, he said, was not here, but in Ceylon; what was done in Ceylon was done well, and what was done in Ceylon came here and was done equally well.

This was seconded by Mr. R. W. Forbes, and carried.

Mr. Kerr, in returning thanks for the staff in Ceylon said that the men under him there were all that could be desired; but he would also like to say that a great deal of their success had depended upon the great encouragement they had received from the London directorate. All matters in connection with the Ceylon staff had been so thoroughly understood at home that he had had no difficulty in getting along and working smoothly.

The Chairman said he had omitted to mention that at a board meeting previously held Mr. D. Kerr had been elected to act on the board during his residence in England, a step of which he was sure everyone would highly approve, as Mr. Kerr had kindly undertaken to render every assistance while he was in this country.

Mr. Cooper, in proposing a vote of thanks to Mr. Forbes (the managing director), said it must be gratifying to him that, notwithstanding the bad year that had been encountered, he had been able to present so satisfactory a report. At first sight he, as

an outsider, thought the estimated production of tea was very far out; but he now understood that the calculations were made so long beforehand that no one was to blame. Another point on which he wished to congratulate Mr. H. L. Forbes was the great success that attended the issue of the preference shares some time ago.

Mr. Todd seconded the motion, which was passed unanimously.

THE CEYLON TEA COMPANY, LTD.

GENERAL MEETING.

Minutes of proceedings at the second ordinary general meeting of the shareholders in the Ceylon Tea Company, Limited under the patronage of the Planters' Association of Ceylon held within the registered office of the Company, No. 42, King Street, Kandy, on Thursday, the 8th June, 1893, at 3-30 o'clock in the afternoon.

Present:—Hon. L. H. Kelly, M.L.C., Chairman, Ceylon Tea Company Ltd., Messrs. Giles F. Walker, (Chairman, Planters' Association of Ceylon), W. D. Gibbon, J. Munton, A. Philip (Secretary, Planters' Association of Ceylon) and A. E. Wright by his Attorney W. D. Gibbon.

The notice calling the meeting was read.

Letters regretting unavoidable absence were submitted from Mr. J. H. Renton of Messrs. Bosanquet & Co., Colombo, Mr. A. Thompson of Messrs. Whittall & Co., Colombo, Mr. T. C. Owen of Hatale Estate, Wategama, Lieut. E. de Frisch, Vice-Consul for Russia at Colombo; also from Mr. E. Hamlin, Oriental Bank Estates Company, Limited, who had hoped to attend.

The minutes of proceedings at the first Ordinary General Meeting of the shareholders of the Ceylon Tea Company Limited (under the patronage of the Planters' Association of Ceylon) held within the registered Office No. 42 King Street, Kandy, were read and were confirmed.

The statement of the income and expenditure and a balance sheet made up to March 31st, 1893, together with the Director's Report were submitted as follows:—

Report of the Directors of the Ceylon Tea Company, Limited (under the patronage of the Planters' Association of Ceylon), presented to the Shareholders at the Second Ordinary Annual General Meeting of the Company held within the Registered Office of the Company.—

St. George's House, 42 King Street, Kandy, on Thursday, the 8th day of June, 1893, at 3-30 p.m.

The Directors beg to submit the Second Annual Report of the Ceylon Tea Company, Limited.

In view of representations made by shareholders and as likely to be convenient the Directors have decided to close the accounts of the Company annually at 31st March instead of at 30th June.

The statement of income and expenditure and the balance sheet made up to 31st March, 1893, laid before the shareholders are accordingly on this occasion for a period of nine months only, while the profits shown have accrued between 15th August 1892 and 31st March 1893.

The sum of Rs11-91 shown to debit of profit and loss account results by including, it will be observed, the following items aggregating Rs1413-74 partially liquidated out of profits from 15th August, 1892, to 31st March, 1893, viz., Manager, Tea Kiosk (H. B. Millar) additional loss on working Tea Kiosk up to 15th August, 1892, Rs675-93; advertising account Rs275-06, a portion only of which should be charged against the working of the Company during the brief period under review; Registration of Trade Mark (in Ceylon) Rs102-64, an item which will not again occur, and Sign Boards at Railway Stations (on account) Rs860-11; property chargeable to property moveable, and which when the contract for this work is completed will be so treated, a reasonable sum only for depreciation being debited to Profit and Loss satisfactory therefore on the whole as these statements of accounts are the Directors have now

deemed it advisable in the interests of the shareholders to enter into new arrangements by which the Tea Kiosk will have the benefit of European supervision, and management in Colombo.

It has further been decided to largely reduce the price of the Tea for sale at the Kiosk, and generally to endeavour to increase the value of business.

A reference to the accounts from 15th August, 1892, shows that during the seven months that have elapsed since the services of the late Manager were dispensed with, expenses have been greatly curtailed, the total expenditure on establishment including inspection and all employees amounting to only R1,521.49 against R3,040.59 for similar services in the previous statement for a like period.

The losses on the earlier working and the lock-up of capital in the New Oriental Bank Corporation, Limited, prevent any dividend being declared, but the Directors trust that future operations will warrant them in recommending one.

It may be added that the commissions earned on general business for the period under notice amounted to R1,325.44 against R107.44 as per last statement. Some progress has been made in opening up negotiations with foreign countries with a view to future operations and when it becomes more generally known that the Company is prepared to give attention to export orders through the Colombo Agents (Messrs. Whittall & Co.) it is probable that this branch of business will assume large proportions ere long.

Two Directors retire from office and as Mr. C. J. Donald and Mr. Harry Whitham have left the island, their names are chosen under clauses 79 and 80 of the articles of Association of the Company.

The Directors recommended the re-appointment of Mr. J. Guthrie as Auditor on the same terms as heretofore.

By order of the Board A. PHILIP, Auditor, Agent and Secretary.

I certify that the balance sheet, to the best of my belief, contains a true and correct statement of the capital and liabilities and of the property and assets of the Company. (Signed) JOHN GUTHRIE.

Kandy, 3rd June 1893.

We certify that to the best of our belief this balance sheet contains a true and correct statement of the capital and liabilities, and of the property and assets of the Company.

(Signed) L. H. KELLY, W. D. GIBBON, GILES F. WALKER and J. MUNTON, Directors.

E. & O. E. A. PHILIP, Agent and Secy.

Kandy, 31st March 1893.

The CHAIRMAN in moving the adoption of the report, dwelt on the very much more satisfactory statement laid before the shareholders as compared with that presented at the first annual ordinary general meeting last year. At that meeting it was decided to dispense with the services of Mr. H. B. Millar, the then Manager, and to generally reduce the cost of the Tea Kiosk establishment, which was done, with the result, that the cost for Manager's salary, servant's wages, &c., which had cost R3040-57 was reduced by about 50 per cent; the amount for a similar period that from 15th August to 31st March being brought down to R1521-49, while the cost of stationery, office forms, account, &c., has been reduced from R560-47 to R81-90. Advertising &c., has been reduced from R362-64 to R225 notwithstanding that this includes a full page advertisement in Cook & Son's Handbook of Information to Travellers, the Orient Guide and the Guide to Kandy. The item R675-93 against Manager, Tea Kiosk (Mr. H. B. Millar) is the further ascertained loss in working the Kiosk up to 15th August 1892. Registration of trade mark in Ceylon is of course an item which will not occur again. Sign Boards at railway stations have cost R360-11. The gross profit on tea sold from August 15th to 1st March amounts to R1123-15 and shows that sales were well maintained during the new regime. The profit on sales of refreshments at the Kiosk amounted for 7½ months to R1651-79, the loss in the former statement of R141-50 on aerated waters being converted into a credit balance. Rent of stalls and space remains about the same. The most satisfactory feature of the Company's working being that commission earned on general business amounts R1325-44 as against R107-14 as per last statement.

This returns show that on passenger days the Kiosk is well patronized and there never has been any question as to the excellence of the tea served in the cup. The considerable stock of tea left at the Kiosk by the late manager has been disposed of and only fresh monthly supplies as required will be kept on sale. The time has now arrived when your directors consider it to the advantage of the Company to make fresh arrangements as to the working of the Kiosk while appreciating the care and zeal with which the Secretary and Agent and his staff have carried, but the arrangements and working when the late European Managers services were dispensed with the Board feels that for really efficient working the kiosk requires European supervision on the spot, and Mr. A. J. Sawyer has been appointed to take charge of the management under the Colombo Agents of the Company; the prices of the tea have all been revised and reduced. As regards the Export business of the Company, Germany, Constantinople, France, Russia, Ireland, Syria, and India have all had attention, in

the last-named country the Chairman hopes to obtain a fair share of the business of supplying the messes.

The CHAIRMAN concluded by expressing the Board's appreciation of the services of the officers of the Company and expressed a strong conviction that the ends for which the Company was promoted would be attained and that matters were now placed on such a footing that at the next annual general meeting, he was sure that a most satisfactory report would be presented, and he saw every reason to expect that a dividend may then be recommended.

The statement of the income and expenditure, and the balance sheet made up to 31st March 1893 together with the director's report were then formally passed and adopted.

The meeting thereafter dispersed. A. PHILIP,
Agent and Secretary.

COFFEE.

Sir George Bonham, Secretary to the British Legation at the Hague, notices in an official report the approaching close of an interesting economic experiment in Netherlands India—that of the compulsory cultivation of coffee on Government account. About sixty years ago, the finances of Netherlands India were in an embarrassed condition and difficulty attended the raising of revenue from the impoverishment of the people, especially in Java. The Dutch authorities in the island had inherited from their native predecessors a system of compulsory labour and levying taxation in kind, so that a labour tax was in accordance with long established institutions and familiar to the people. Hence, a labour tax in the direction of a compulsory cultivation for Government of staple export articles was resorted to. The Government sold the produce and, from the profits realized swelling the revenue, the chronic deficits soon gave place to surpluses which continued until the outbreak of the Acheen War. Several articles were experimented with until experience directed the retention of only sugar and coffee for compulsory planting. Gradually, as Liberal ideas made way in Holland, the forced labour principle met with objection and the Government decided upon leaving sugar to free cultivation. Coffee remained untouched owing to its enormous revenue yield which rendered rash tampering with it injudicious. In Java, every head of a family in coffee-growing districts had to plant a fixed number of trees in plantations at a rate of fifty a year—and to keep a nursery of seedlings available under official inspection. The produce is sold by the growers to Government at a fixed price much below the market value, the difference being reckoned as revenue. The coffee thus grown was sold in Java and Holland. Lately, the exhaustion of the soil in Java and the growing wealth of the natives have suggested the substitution of free cultivation, and the levying of direct taxation. The current of political opinion in Holland sets steadily that way, and the gradual substitution of free coffee cultivation is within measurable distance, but the important fiscal interests involved point to caution in furthering change. On the West Coast of Sumatra, the compulsory cultivation of coffee for revenue purposes also prevails among the Malays under Dutch rule. The article is delivered to Government at a fixed price far below ruling quotations, and sold by the latter at periodical auctions in Padang. There, too, the forced cultivation has fallen into disfavour, and its modification accompanied by a poll tax on the Malays is said to be under consideration by the Government. Whatever may be the economic objection to a labour tax of this kind, it has in the past done good service in Java. In 1889, the quantity of coffee turned out by Government and the planters came respectively to 578,000 and 376,000 piculs, and that island's population has risen during the sixty years from six to about twenty four millions and the yearly revenue from thirty to one hundred and thirty two millions of guilders.

—Straits Times.

ARTIFICIAL MANURES FOR FRUIT CULTURE.

The subject of fruit-growing for profit is one that has during the last few years been attracting increasing attention, partly owing to the hope that it may prove a means of bettering the condition of the cultivator of land, and partly to the growing demand for fruit as an article of food. Evidence of the growing importance of fruit farming is supplied by the activity which may be observed in the manufacture of chemical manures. It appears that today the balance of opinion is against the total replacement, of natural by artificial manure, but many high authorities agree that a large proportion may be so substituted with advantage to the crop, and with economy to the cultivator. We are interested in observing that chemists of good standing are recognising the fact that, with profit to themselves and advantage to horticultural industry, they may devote serious attention to the chemical aspect of cultivation. It is significant that Mr. H. Brunner, the president of the Liverpool section of the Society of Chemical Industry, chose for his chairman's address the other evening the subject of artificial manures for fruit culture. And we congratulate the society on an occasion like this, that they can turn aside from the discussion of matters which, perhaps, are only interesting to the scientist strictly so called, to the consideration of a subject which is really of national importance.

Mr. Brunner, in the course of his long address, referred to his own experiments made on the cultivation of strawberries. He stated that, by employing chemical manures, far less potash, phosphoric acid, and nitrogen is required per acre than is the case with ordinary farmyard or stable manures, as, owing to their soluble form, they penetrate the soil, more rapidly and deeply.

With regard to the requirements of 1 acre of land planted with apple trees, it was stated that 20 tons of farmyard manure would be necessary once in three years, whilst the necessary ingredients contained therein would be supplied by the yearly use of 500 lb. of kainit (containing 13½ per cent. of potash), 120 lb. of superphosphate (containing 16 per cent. of soluble phosphoric oxide), and 360 lb. of nitrate of soda, or a total for the three years of 26 cwt. of material. From these data it is evident that in certainty of effect, in convenience of handling, and in distribution over the soil, chemical manures possess distinct advantages.

It must not be supposed, however, that Mr. Brunner is entirely biased towards manuring by strictly chemical means and methods; he does not recommend the complete discarding of farmyard manure, but rather the adoption of some system of rotation of manures, such as that advocated by Wagner of Darmstadt for the cultivation of vines, in which farmyard manure is supplied in the first year, and supplemented by chemical manure only in the second, third, and fourth years.

It has been urged against chemical manures that they render the soil poorer in organic matter, whilst farmyard manure has the reverse effect, but it has been shown by Joulie (*Mercure Scientifique, Supplement du Moniteur Scientifique*, June, 1892), that the more abundant harvests produced by the use of chemical manures have a larger proportion of residues in roots and otherwise in the soil, and consequently that there is no impoverishment, but an increase in the quantity of organic matter.

By the use of chemical manures each ingredient can be adjusted to the requirements of the crops, which is obviously not the case with natural manures; whilst Ville has shown (*Ville on Artificial Manures*, translated by W. Crookes, p. 105) that more than one-third of the nitrogen contained in the latter is lost to the soil on account of the decomposition which the manure must first undergo before it can exercise any beneficial action. The cost of carriage and of distribution on the land is also favourable to the employment of chemical manures.

Superphosphate is the most suitable form of phosphoric acid for the fruit-grower, and it further has the important advantage of supplying a considerable

quantity of a soluble lime-salt necessary for the building-up of healthy trees. Finely-ground basic-slag is also likely to prove of great value, since it contains 18 per cent. of phosphoric acid combined with lime in a fairly soluble form. The latter should be applied in larger proportionate quantity than the former, and will be found especially useful in preparing the ground before planting young fruit trees. Kainit affords the cheapest form of easily-soluble potash, but it only contains about 13 per cent. of potash, and as much as 40 per cent. of sodium chloride (common salt). Nitrate of soda is the best and most economical nitrogen manure for fruit cultivation; sulphate of ammonia is less suitable. *G. — Gardeners' Chronicle.*

THE RESPIRATION OF PLANTS WHEN INJURED.—Some curious experiments have recently been conducted by Herr Stich upon a large number of plants, in order to ascertain the effect of injury (from mere scratches to complete cutting up) on their respiration. He noticed in every case that there was an increased separation of carbonic acid gas when the plants thus had their tissues damaged. As might have been expected, various plants and their various parts behaved differently with regard to the extent and duration of this increased secretion of carbonic acid.—*Ibid.*

JULY, 1893.

[No. 1.]

TREE LEAVES AND TWIGS AS CATTLE FODDER.

OUR attention has been called by the editor of the *Ceylon Independent*, to a paper by M. Girard on the subject of tree

leaves as fodder for cattle.

Some months ago Professor Ramann of Eberswald drew attention to the feeding value of a special preparation of the twigs of trees. "The subject," says a correspondent of the *Rural Canadian*, "at least claims examination, especially as it has been tested by several practical farmers.

Bear in mind that all plants, whether annual or perennial, are built up from the same immediate principles—woody fibre or cellulose, azote compounds, sugar and fatty matters. The proportion of these substances varies largely in plants and in the organs of plants, yet even in the divers parts of these organs, according to their age. As a rule the younger the plant the richer it will be in digestible alimentary matters. For purposes of reproduction, nature forms at certain epochs of the year, alimentary deposits in certain parts of the plant; the grain has its depôt of food in the infant shoot till it has leaves and roots to draw nutrition from the air and soil. In the case of trees at the fall of the leaves, there takes place in the branchettes or twigs an accumulation or store of nutriment, to assist the development of the early stage of the budding, and that becomes twigs in the course of the year. Professor Ramann prefers the twigs of the beech and birch, having a diameter between one quarter and one-

half of an inch. These as shown by analysis, have a richness equal to average hay, and very superior to the best straw: they yielded 10 per cent of starch. The professor subjects the twigs to two operations; first, crushing, but not pulverization, and next fermenting the mass by adding one per cent of malt and wetting with warm water: in the course of three days, following the weather, the temperature of the mass will have risen to between 140 and 158 degrees Fahr; the fermenting principle of the malt, diastase, transforms the starch into sugar. Finally, this twig paste is eaten with avidity by cattle, horses, and sheep; it is digested with facility and in the excrements no undigested particles can be detected. Agriculturist Jena, of Coethen, mixes the preparation with beets, potatoes, chopped hay, etc., commencing by small feeds; in the course of five days the animals take to it. He gave it to 110 cattle, 17 horses, and many sheep, from 10th February to 10th May at the rate per day, respectively, $16\frac{1}{2}$, $6\frac{3}{4}$, $1\frac{1}{4}$ lbs.; stock gained 41 lb., superior weight than when the best straw was the basis of the ration mixture; the cost of the twigs, their preparation etc., is about 18 cents per hundredweight. M. Jena has further tested the fermented twig-food on 20 horses, 80 oxen, and 1,000 sheep, and finds it saved him in six months, \$500 for hay and straw. Several other German farmers are testing the novelty.

It is well-known that in India the twigs of trees are used as fodder for cattle in times of drought. The green leaf of the palmyrah palm, for instance, is extensively used as such in times of scarcity. There is little doubt that if the leaves of many trees are subjected to some process which will result in their being rendered soft, and to some extent also palatable, cattle will readily eat them. The process of ensilage is known to render thistles and brackens fit for consumption by cattle. But there are no doubt many leguminous trees whose leaves will be eaten in the raw state, and the richness of the

individuals of this order of plants in nitrogenous matter is admitted. *Dhall* (which cattle greedily consume), *Erythrina Indica* and *Sesbania grandiflora* may be mentioned as examples.

Since writing the above we have been favoured with a copy of an agricultural letter from Paris, in which the subject of leaf and twig fodder is referred to and reviewed in an interesting manner. The following are the references:—

Excepting the loss of forage plants—and the loss is great,—there are no other crops seriously affected by the abnormal drought of March and April. The injured cereals are recovering, root crops are making up for backwardness, and resowings will repair blanks. It is the fodder difficulty that has to be grappled with, hence the exceptional attention and importance given to all substances capable of supplying the deficit. Leaves and twigs are closely related: the former have in several regions of France been, since late years more or less utilized to stretch fodder, or as a permanent source of alimentation. It is only recently that twigs; have been introduced as ration for cattle, horses, and stock. It is a novelty, but has the appearance of having "come to stay."

Precise information is still wanting on the food value of twigs; more chemical analyses are needed; further tests in the practical feeding of animals with the new ration are essential. Imperfect as are existing data, their trend is decidedly favorable to the food; the resistance has been shown to come from, not the animals, but the agriculturists. Two authoritative German cultivators, Major Jena and M. Biebrach, attest, that during two years they have throughout the winter, fed and maintained in good condition, 30 horses and 60 oxen and cows, on crushed twigs properly fermented with a little yeast.

Deer and chamois have no other aliment in the forests during winter almost, but the tender tips of branches. Only those twigs with a repulsive flavor are not ranked as comestible. Twigs and leaves, like other alimentary plants, contain the same elements for the formation of flesh and bone. Analysis shows that the twigs of the oak in the month of May are twice as nutritive as meadow hay, and those of the acacia rank next; the twigs of the poplar, elm, birch, pine and beech, are superior to oaten straw, that of wheat being very poor in nutritive substances. Fuller information is required respecting the facility of assimilation of the different twigs as food. Professor Ramann, who is the sponsor of the twig novelty, has analysed beech twigs, and finds that they were one-and-a-half times richer in food principles at the fall of the leaves in October, than in May when the flow of sap was in all its vigor. M. Poessier has analysed both leaves and twigs of one-quarter to three-quarters of an inch in diameter, and finds very notable differences in the percentage of protein contained in both the leaves and twigs; in spring it is much superior, and the more the shoots the higher will be that percentage. This only corroborates what is already known, that the younger the organs of plants or vegetables, the richer they will be in nitrogenous or flesh-forming principles.

Professor Girard in his work on leaves as fodder, estimates that an acre of forest produces

nearly five tons of leaves, and the mulberry half as much more. In the South-Western districts of France, leaves have been always employed in cattle feeding both in the green and dried state: in the Gironde, they are mulched up with the rations for fat stock; in Algeria the forest leaves when green, support flocks of sheep, and in winter the leaves, chiefly those of the ash are stacked as provender for horses, cattle and sheep. The experiments made by feeding milch cows and goats on lucerne *versus* fresh leaves are not conclusive; no difference was found in the quantity and richness of the milk; perhaps something could be said on the point of taste. In any case the twig food merits the serious attention and intelligent trial of all progressive agriculturists. Doubling the forage supply would be within measurable distance of making "the two blades of grass grow where only one grew before."

OCCASIONAL NOTES.

With this number the Magazine of the School of Agriculture begins its fifth volume, having been started in July 1889. We bespeak for our little publication the support of our subscribers in the future, and the help of our contributors in maintaining the character of the Magazine and issuing it with the same regularity with which it has hitherto appeared.

The S.S. "Madura" brought 21 cows and one bull from Bombay for the Government Dairy Farm on the 31st May. Considering the long voyage, and the bad weather that prevailed, the animals were landed in very fair condition. They are now comfortably housed in the dairy buildings, and are improving in condition, while the milk yield of the cows that have calved is steadily increasing.

Among the apparatus indented for from the Dairy Supply Co. for the new dairy, are a milk refrigerator, a dairy herd recorder, and a dairyman complete milk tester with Barham's patent percentage lactometer. We have already referred to the refrigerator which will be used for cooling the milk in warm weather and when it has to be carried long distances. By means of the dairy herd recorder the milk given by each cow at each milking can be conveniently reckoned in pounds or pints, so that a regular record of the milk-yield of the animals may be kept. The dairyman's complete milk tester consists of a milk thermometer, 4 cream tubes in a registering stand with China index, and Barham's lactometer. The patent lactometer is intended to show the purity of milk, and the percentage of water, if any present.

Foot and mouth disease was prevailing in the neighbourhood during the month of June, and with the present unsatisfactory arrangements for inspection and control of cattle sheds in the city, the greatest vigilance had to be observed against its introduction into healthy areas, as the risks of cattle free from disease being infected are very great. Reports have also been made of the disease causing much havoc in other parts of the Province.

RED SPIDER.

The Red-Spider *Tetranychus telarius* familiar to agriculturists, is not a true spider but a spinning mite. It is distinguishable from the true spider in having its body and abdomen united into one piece, and not merely joined by an almost thread-like connection. When mature the red-spider is oval, furnished with four pairs of legs, two pointing backwards and two forwards: the head, body and abdomen form a solid mass, by which, as before mentioned, it is distinguishable from the true spiders which have the abdomen joined to the rest of the body by a fine stalk; and also from insects which have the head, body (thorax) and abdomen commonly distinct from each other, and which in their perfect state have never more than 3 pairs of legs. The head is furnished with a beak or sucker by means of which it draws the juices from leaves, and beneath the abdomen is a conical protuberance from which the threads are produced with which it forms its webs. The colour is various; of transparent yellowish white, orange red, or brick red, and other tints depending, as far as present observation shows, on the colour and nature of the food within, and partly also upon the age of the individual, as these mites have been noted as of a green colour in early life, changing with maturity to the rust colour we are best acquainted with.

Entomologists are not yet agreed whether there are different species of the red spider or whether the pests that attacks different forms of vegetation are all varieties of the one species. Mr. Murray, in his Handbook of Economic Entomology, thus describes the work of the mite: On leaves (especially the under side of them) it finds a fit hold, and spins its web, affixing the threads to the prominences and hairs of the leaf; and under this shelter a colony, consisting of both sexes in maturity, and young of all ages, feed and multiply with rapidity. The plant soon shows the influence of their presence in its sickly yellow hue; the sap is sucked by myriad insect-mouths from the vessels of the leaf, and its pores are closed by excremental fluids. The red spider causes enormous damage to hops in England (where it also attack the lime-tree, plum, rose, clover, &c.) in dry seasons, and its effect upon the leaves was until recently attributed to heat and drought and was called "fire-blast." These mites which are scarcely discernible by the naked eyes (except when collected together) spin their webs over the stems and branches and beneath the leaves of infested trees, giving a sort of glaze or silking lustre to the surface, and on this web they can travel easily.

Many preventatives against, and remedies for, red spider attack have been suggested, most of which are to be found in Miss Ormerod's "Manual of Injurious Insects." It is to be noted that the red spider does not thrive in the presence of moisture. Washing (by means of syringes or garden engines) with soft soap and water or even with pure water is one remedy. Miss Ormerod advises banking round the tree at a few feet distance and a few inches high, and filling the space enclosed with mud made as thin as would be retained by the raised edge. A liberal mixture of fish oil and soft soap so as to completely plaster round the foot of the tree and stick all the wandering

mites fast that touched it, could not fail to do good at a trifling cost. Sulphur is said to be one of the most active and efficient agents in preparations for destroying red spider, and sulphur and soft soap combined are among the most reliable remedies. One pound of flour of sulphur and 2 lbs. of fresh lime (an alkali is necessary for dissolving of sulphur in water) boiled in 4 gallons of water is a good mixture for washing. Miss Ormerod gives the following recipe: 3 gallons gas water, 1 lb. of flour of sulphur: these to be held over the fire while being mixed and soft soap added in such quantity as to make the mixture adhere. This may be applied to the branches with a brush, or after being diluted to a state in which it is a safe application, the liquid may be thrown over the leaves by means of a garden engine or spraying machine. Probably 15 parts of water to one of the mixture would be about the proportion, but this should be decided by trial.

 ZOOLOGICAL NOTES FOR AGRICULTURAL STUDENTS.

Arthropoda (or articulata, from the fact of its members possessing jointed appendages articulated to the body,) comprises the crustacea (lobsters, crabs, &c.) Arachnida (spiders, scorpions, &c.), Myriapoda (centipedes), and lastly the important class Insecta. The crustacea, the majority of which are aquatic, include also, besides crabs and lobsters, the shrimps, water fleas, woodlice, barnacles and sand-hoppers. The Arachnida comprise, in addition to the scorpions and spiders, mites and ticks. Spiders are all carnivorous, living upon other animals, and all of them possess the power of constructing webs, which they employ either in the capture of their prey or in the construction of their own habitations. The material of which the web is made is the secretion of a special gland, and it is moulded to its proper shape by being passed through certain conical little organs which are placed at the extremity of the abdomen, and are termed "spinnerets." The spinnerets are either four or six in numbers and each has its apex perforated by a great number of little holes. The silk is at first fluid, and hardens rapidly on being exposed to the air. A single filament of silk is thus produced by each of the perforations in the spinneret, so that what we call a single "thread" in a spider's web is really a cable, composed of a great number of the most delicate fibres agglutinated together. Many species do not form regular webs, but they all use the silk to form little cases or "cocoons" in which the eggs are protected, and which the parent sometimes carries about with her. Some claim the garden spider as a friend to the Agriculturist, explaining that it destroys many of the insects injurious to plants, and that its web often protects plants from the force of wind; but this is doubtful.

The mites and ticks are grouped under the order Acarina. The mites (acari) include many species injurious to plant life, and specially to fruit trees. As instances may be mentioned the "red-spider," which is really a mite, and the orange rust mite *Acarus domesticus* is the

common cheese-mite, another well-known species being *A. Destructor* which feeds on zoological specimens and thus causes much annoyance to the naturalist. *Sarcoptes scabiei*, another mite, is the cause of the skin-disease known as "itch." Mange in the domestic animals is due to three genera of Acari, viz., psoroptes or dermatodectes, symbiotes and sarcoptes. The true ticks (ixodidae) attach themselves parasitically by means of their suckorial mouths to the bodies of various mammals, such as horses, sheep, oxen and dogs. Another member of the Acarina is the curious little *Demodex folliculorum* which is found in the sebaceous follicles of man, especially in the neighbourhood of the nose. "It is probable," says Dr. Nicholson, "that few, if any individuals are exempt from this harmless parasite."

The Myriapoda are articulate animals in which the head is distinct and the remainder of the body is divided into nearly similar segments. They have one pair of antennae or feelers, and the number of legs is always more than eight pairs. The centipedes and millepedes are included among them.

THE LISTER-BABCOCK MILK TESTER.

This new apparatus was invented by Professor Babcock, Chief Chemist of the Agriculture Experimental Station of Wisconsin, U. S. A., whose English Agents are Messrs. R. A. Lister and Company. The following is an account of how the percentage of butter fat in milk is tested:—First, thoroughly mix the mass by pouring from one vessel into another, or by stirring, and then with the pipette secure the sample and put in a testing bottle. Add an equal volume of commercial sulphuric acid that has been kept stoppered, of 1.843 specific gravity. By a gentle rotary motion thoroughly mix the acid and milk. Then place the bottles in machine and turn for ten minutes, at a speed of eighty-six to ninety turns of the handle per minute, then stop, and fill the tank with water at a temperature of 190 degrees Fahr., and at the same time fill bottles to the 7 per cent. mark with water of the same temperature. This may be taken with the pipette from the hotwater tank (be careful not to have the water above 190 degrees as it may burst the bottles); when this is done, put the bottles back into machine, and turn it again for two minutes, the bottles can then be taken out, held in a vertical position, and the amount of butter fat read off in the graduated tube. It may be 3.2, 4.4, or 5.6, or more or less, and this determines the value of the milk, just as the assayer fixes the value of ores by testing samples.

At the recent Dairy Conference, Professor Primrose McConnell elicited the hearty plaudits of the company when he referred to the Babcock tester as a most reliable test of the percentage of butter fat in milk. By means of this new tester, together with a hydrometer and special set of tables arranged by Mr. Embrey, F.C.S., City Analyst, Gloucester, any one can easily determine for himself with the greatest accuracy not only the percentage of fat in his milk but also of solids not fat, so that he thus obtains an exact analysis of the milk. This tester was en-

tered for competition at the London Dairy Show, and Mr. Gilbert Murray, the well-known expert at Elvaston, Derbyshire, was appointed by the British Dairy Farmer's Association to test the appliance. For this purpose he provided Messrs. Lister with three different qualities of milk—one being very rich, having been drawn from the first prize Alderney cow in the show, one being taken from an ordinary cow in the show, and one being newly-separated milk. The three milks were duly tested by the Lister-Babcock tester and the results noted. Samples of the same milk were then sent to the Society's Chemist, Professor Llyod, to be analysed in the usual way, and the accuracy of the analysis of the milks obtained by the tester was so fully borne out by Mr. Llyod's analysis, that a special silver medal was awarded to Messrs. Lister for this valuable appliance. The apparatus has also been tried in New South Wales, where the following conclusions were drawn by the authorities by whom the trial was conducted:—

1. The Babcock machine may be relied on to give uniform and concordant results within a limit of one-fifth per cent.

2. Its results do not differ from those obtained by extraction with ether by more than one-fifth per cent.

3. The prolonged contact of the acid with the milk in the bottle before whirling has no effect upon the reading of the butter fat within the limits of time occupied by the test. Should the acid have remained for any great length of time in contact with the milk, the tank must be filled with hot water. In any case, we consider the readings are more reliable if hot water be added during whirling, but if the filling be done expeditiously, and the bottles rotated at once, the initial temperature is sufficient.

4. Scrupulous attention to the detailed instructions is absolutely essential, as are also strict cleanliness and accuracy.

5. The machine is sound in principle and easy to understand and to work.

6. The time required for the treatment of twenty-four samples is about one and-a-half hours from the filling of the first bottle to the reading of the last. Forty-eight samples may be done in two hours if two men are working. We would, however, always advise that each milk be tested in duplicate. Thus fifty samples could be treated in about three hours.

7. The cost of the acid used for charging twenty-four bottles is about 3d. Commercial sulphuric acid may be used, but it is important that it should be of the right strength. Its specific gravity should not be much more or less than 1.834.

8. It has the great advantage over gravimetric methods that it is more expeditious, and does not require any special skill in the manipulation; accuracy and cleanliness are absolutely essential. It should, in our opinion, prove of great use in butter factories. With a ready and effective means of testing the quality of the milk supplied, both buyers and sellers would be benefited, as a fair scale of payment, according to the richness of the milk, could be adopted.

According to Prof. Henry of the Agricultural Experiment Station attached to the University of Wisconsin, "the Babcock tester is used by several thousand creameries and cheese factories which pay for the milk by the fat delivered, and on thousands of farms for testing cows and weeding out poor ones. It is revolutionizing American Agriculture."

A FEW NOTES ON FODDER AND PASTURE LANDS IN CEYLON.

The village farmer has not yet attained to that degree of advancement in agriculture, necessary to appreciate the advisability of growing any special fodder crops for cattle. Of the enormous quantity of fodder required to keep cattle in condition he seems to be unaware. He does not take due care to raise fodder and only avails himself of what falls in his way by chance. In European and other countries where agriculture is in a prosperous condition, it is customary to grow special crops for cattle, such as the clover, lucerne, &c.

But, for the present, leaving alone the question of special crops for cattle, I wish to make a few remarks about the supply of fodder which is already at the disposal of the native cultivator, giving hints for improving it where possible.

1. The straw of Paddy forms the staple fodder used in this country; but care must be taken as far as possible, not to allow the straw to get exposed to the continual action of the elements and thus lose a good deal of its nourishing properties. Of course when it is stacked in the open field a certain amount of exposure cannot be helped, but it can be minimized by stacking the straw in a regular conical shape and placing a light portable umbrella-shaped ola cover called a *Kudil* at the top. The stubble left in the field after reaping the paddy is also available as fodder for the cattle for a few days. Just after the harvest the animals, if allowed a free run in the fields, will be found to become stouter and healthier.

2. After the harvest the fields are allowed to lie fallow for about half the year. But nature, a "mother kind alike to all," converts the paddy-field into a pasture-land in a short time, and until the next year's cultivation, the goiyas, black cattle and the buffaloes graze on it. Any one travelling upcountry by the train at this time of the year can form some idea of this transformation by looking at the paddy lands along the railway line.

3. The rolling patnas and the fertile valleys of the hilly districts abound in grass ranging from the tall 'mana' downwards, and supply food for the cattle. The European planters generally grow fodder specially for their cattle, but the native cattle-owners graze their animals solely on the grass of the patnas and valleys. In the dry months they set fire to the mana bushes, and after the very next shower fresh shoots come up from the old stumps, and the scorched patnas are soon again decked in green. It is thus that most of the upcountry pasture-lands are renewed for the use of the cattle. The moist climate of the hills is highly conducive to the luxuriant growth of grass, and the dark, glossy and stout buffaloes which freely graze on

the slopes and valleys there, contrast very favourably with the gray, haggard and lean ones of the low country.

4. Even in the driest districts the trees afford a welcome shade to the growth of grass. It is a pity that our cattle owners do not care to take advantage of this easy method of growing grass in districts where all the grass in the open is parched up by prolonged drought. They do not even care to keep the self-grown grass under trees clean of the weeds which choke it up. The late Mr. R. O. D. Asbury of Jaffna wrote thus in connection with growing grass under shade:—"What extensive and beautiful groves of palmyras and coconuts we have in Jaffna that can at once be set apart for this purpose—their shade being a protection to some kinds of grass."

5. In some parts of the North it is too common a custom to scrape out the grass in the compounds with an instrument called the *ulavaram* when it is required for feeding cattle. This is very injurious to the further growth of the grass on the spot, as it is thus scraped up with the roots. It would be much better to mow or cut the grass, if it has grown tall enough, or otherwise to leave the cattle to graze on it. E. T. HOOLE.

(To be continued.)

THE ORANGE RUST MITE.

The rust-like appearance on the fruit of the orange tree is often thought to be due to a fungoid growth, but investigations have lately shown that it is caused by a very small-legged mite, which punctures the oil cells of the fruit. When exposed to the influence of the atmosphere the exuding oil undergoes a change, assuming a dark rusty appearance, which depreciates the value of the fruit for the market. The mite which causes this discoloration is known as *Thytopus oleivorus*, and its life history and habits have been carefully investigated. It is said we do not know with what truth, that though badly-rusted fruit is small, the quality is improved rather than deteriorated. The cause of this improvement is said to be that the toughened rind preserves it from injury and decay and prevents evaporation from within. A solution of 1 lb. of whale oil soap in 50 galls. of water is highly recommended as a remedy; but several applications at short intervals are necessary. Flower of sulphur has also been put forward as one of the cheapest and most effective remedies, and it may be used in connection with the above mixture or other insecticides. Applications of insecticides should be made on the first appearance of the rust. Sulphur and washing soap has been reported to have done good when sprayed over the trees, while dusting with quicklime is also said to have produced favourable results.

A VISIT TO THE POONA DAIRY FARM.

The Poona Dairy herd when I visited the farm consisted of 42 head, being made up both of meat cattle and buffaloes. The following is Mr. Mollison's opinion on his dairy stock:—

"Aden cows are without exception the best milk breed of cows we have yet tested. They

are very docile, and their milk is not easily affected by irregularity.

If well cared for, the heifers mature earlier than with most Indian breeds, and come into profit sooner. The cows give an equal yield of milk to that of large breeds, on much less food. They come in "season" 6 weeks to 2 months after calving, and, if permitted, will milk up to the day they calve again. Our best Aden cow gives after calving 22 lb. milk per day, and never gives less than 10 lb. Our next best milker is a five-year daughter of this cow by a Gir bull. The Gir cows are not so satisfactory as the Adens, and my conviction is that they do not, under the best management, maintain in the Deccan the same milking qualities they possess when grazed on the Gir Hills.

The Adens are small in size and most of all the Indian breeds resemble our own native animals. The Girs are handsome creatures and are characterised by large pendent ears and broad prominent forehead, and they are of a mild disposition.

Buffaloes are in great favour on the Bombay side as milk and especially butter producers, and much surprise was expressed by those engaged in dairy at my statement that there is a insurmountable prejudice in Ceylon against buffalo milk and butter. In the Bombay Presidency nearly all the butter is made from buffalo milk, the produce being slightly dyed with anatto to give it the colour of real cow's butter. This is no sophistication, for the consumers are perfectly well aware that they are being supplied with buffalo butter. Colouring with a standard contract of anatto dye is of course quite common in English dairies. The Surat buffalo is according to Mr. Mollison, unsurpassed as a butter producer, and in the hot weather when I was there gave 1 lb. of butter from 10 lb. of milk, and the best milker produced 36 lb. of milk. With the price of buffalo butter at 12 annas or 75 cents per lb., a good Surat buffalo thus gave by sale of its produce nearly R3 per day. In Poona buffalo milk is sold at 16 lb. for the rupee, while 13 lb. of cows milk are got for the same money.

Of concentrated food about 4 lbs. of cotton seed is allowed per cow, and Mr. Mollison characterises this as one of the best and cheapest foods. Gingelly cake, however, he considers the best of all, but as it was found rather expensive to purchase, carthamus tinctorius, knsumbi (safflower) cake, bought at 10l lb. per rupee, was substituted. This latter has the advantage of keeping for months without moulding, though cattle have to get accustomed to it before they will eat it readily. Bran and chuni (or dhall husk) are the other foods depended on. When I was at Poona brewer's grain from the Deccan brewery was being utilized. Here is a sample of the diet of a dairy cow: 4 lb. bran, 4 lb. malt, 3 lb. oilcake and 3 lb. cotton seed, but the quantities of different foods vary according to the size milk yield of the animals. The cows were as a rule let out for a couple of hours in the cool part of the morning for a little exercise in the field.

It will be observed that the produce of the milk is reckoned in pounds. The term *seer* commonly heard in India is (like "maund") of

variable significance, and therefore milk is weighed by means of the dairy herd recorder which shows the milk in lbs. as well as imperial pints. The rule at Poona is to weigh each cow's milking and afterwards weigh the total produce again. A quart of milk weighs on an average 2½ lb. In the dairy I found a "baby" and "victoria" separator, a victoria churn as well as a refrigerator, and an alderney butter worker. I spent some time looking at the various processes in the manipulation of milk, and Mr. Mollison was most solicitous to place me in possession of all the information that I desired to have. He advised the use of four-wheeled spring carts for carrying the milk any distance, and to cover the vessels, into which the milk is put after being passed through the refrigerator, with canvas jackets that had been dipped in water, so that the process of evaporation that would go on while the milk was in transit might help to keep it cool.

GENERAL ITEMS.

Professor Wailey, in his work "A Practical Guide to Meat Inspection," thus refers to foot and mouth disease:—"That it is due to a micro-organism is proved by its nature and its course, and by its clinical and pathological characters: but this micro-organism has not yet been satisfactorily demonstrated, though Klein has described a micrococcus in the fluid taken from vesicular lesions. That the virus pervades the whole system is shown by the fact that the characteristic lesions develop more or less over the cutaneous surface, and in the mucous membrane of the alimentary canal, on that of the sheath, the vagina, the udder, and, occasionally the bronchial tubes. The virulence of the disease varies materially in different epizootics in different animals, and in different seasons; thus, in some out-breaks, a large percentage of animals die either from the effects of the fever or from the effects of the local lesions. In the vast proportion of cases the fever which accompanies its evolution is of so benign a character as to interfere but very slightly with the nutrition of the blood or of the flesh. But every now and again—especially when the sufferers are exposed to such adverse influences as cold or wet, to exhaustion, or to bad sanitary conditions—it assumes malignant characters, and its lesions partake of the nature of those produced by septic infection; there is induced, in fact, a veritable septicæmia."

Mr. R. Atherton writes of "Arrowroot" and Tapioca:—"Both these products have been largely grown in this district, particularly the latter, as the Manioc is grown in nearly every garden and chena in the Province, and the industry began last year to be extended to Jaffna and Trincomalee, in which places it was not formerly grown, regular cargoes of bundles of sticks (or slips) being purchased by the traders and carried away. Of late years though Arrowroot is found growing here and there in small clumps or *patche*, the growth of it in any great proportion has visibly declined. Enough Arrowroot has been made from the produce of one garden in town to last

one large family for over 3 years, but for many years to my certain knowledge none has been manufactured. The processes of making the impalpable powders called 'Arrowroot' and 'Tapioca' are exactly similar, viz., by macerating or pounding the root, steeping it, washing it in many waters and drying the powder in the sun or even in an oven. But while Tapioca is granulated, Arrowroot is left "en masse" and always retains its powdery form. Both Arrowroot and Cassava are extremely prolific and throw out new roots in great profusion, one single root of the former producing a large clump of 10 or 20 good tubers in about 12 months,—Cassava topping it in size and the ease from which it is grown from little slips. Some 30 to 40 years ago a large quantity of Arrowroot was manufactured in Colombo by the Industrial School, and any quantity could be had by importing it and that of an excellent and superior quality, but of late years I have not heard of any being made there. The ease with which the roots and slips can be obtained, the profusion with which it grows and its suitability for growth in our garden soils make it a matter for surprise that no special attempt has been made to extend the industry which must be a paying one. But very small quantities seem to be imported into the island, and that in a tinned form, each tin holding from $\frac{1}{4}$ to $\frac{1}{2}$ a lb. each; while as a "mainstay" if not exactly as a very nourishing food, Arrowroot might be much more largely grown and used. There is a variety of Arrowroot grown in some of our gardens which shews a beautiful cream and green mottled leaf, very showy and ornamental, but I know nothing of the quality of the tuber it produces.

The chemical analysis of milk, says an Australian paper, is neither complicated nor difficult. A small dish is accurately weighed, and the weight noted. Into it is now introduced a small portion of milk, and both are again weighed. By subtracting the weight of the dish from the weight of both, the weight of the milk is found and carefully recorded. The dish is placed over a steam jet, and the water of the milk evaporates, leaving a residue. It is this residue which passes under the name of "solids." A last weighing of the dish with the milk residue, less the weight of the dish, gives the weight of the

solids, and by a simple calculation the percentage is found. The solids of milk have been found by innumerable analyses to average about 13 per cent., and, while the fat varies in the milk from different cows, the solids left after extracting the fat are a very constant quality, hardly ever falling below 9 per cent. This gives the chemist a positive basis for his calculations, and enables him to state with great certainty whether or not the milk has been watered. The fat or oil in milk is determined by dissolving it by means of ether out of total solids, the residue remaining after the operation being termed "solids, not fat." The average fat or oil found in cows' milk is 3 per cent., and any amount less than this is commonly taken as showing that the milk has been skimmed. If analysis shows a decrease of fat, and solids, not fat, it is said to be certain that the milk has been watered, while, if the fat only is low, that the milk has been skimmed.

It is a matter of regret, as the *Indian Agriculturist* observes, that the permanent dyes of vegetable origin are being displaced by the cheap and fugitive productions of modern science. A collection of these permanent dyes is now being made in India for the Imperial Institute, and the latest Handbook, issued in connection with the Indian Court, gives an account of the *kamela* dye, which produces a gorgeous flame colour of varying shade, according to the process employed. The handbook is illustrated by pieces of dyed silk which are pasted into the book, and give an excellent idea of the rich colours to be obtained from the dye. The dye itself is merely the powder that coats the berries of *mallotus philippinensis*, which is found wild in India. In Ceylon the tree is known as *hamparila* among the Sinhalese, and *kapila-podi* among the Tamils.

The distress in some parts of India from failure of crops and destructive flood is said to have compelled the poor people to live on roots and fruits varied occasionally with pounded mangoe kernals, and a few mhowra flowers, and it was remarked that they seemed to thrive on such diet.

LIEUTENANT-GENERAL SIR EDWARD BARNES, K.C.B.

SIR EDWARD SELOUS, K.C.M.G.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XIII.]

COLOMBO, AUGUST 1ST, 1893.

[No. 2.

H. E. LIEUT.-GENERAL SIR EDWARD BARNES, G.C.B.,

Lieut.-Governor of Ceylon from 1st February 1820 to 2nd February 1822,
and Governor from 18th January 1824 to 12th October 1831.*

THE FOUNDER OF EUROPEAN PLANTING INDUSTRY IN CEYLON:—BY HIS ROAD FROM COLOMBO TO KANDY, AND THENCE THROUGH THE HEART OF THE HILL-COUNTRY, AND BY HIS EXAMPLE IN OPENING "GANGARUWA"—ONE OF THE EARLIEST COFFEE PLANTATIONS.

In some respects, Sir EDWARD BARNES was the greatest Governor who has ever administered the affairs of the Crown Colony of Ceylon. He had also the longest term of administration: first,

in 1820-22 for two years as Lieut.-Governor, and then from 1824 to 1831, for seven years and nine months continuously as Governor. These facts and the great amount of invaluable work performed during his term of office, make us all the more regret that, in the time at our disposal on the present occasion, we have been able to get so few particulars of his early career, distinguished as it was in many ways before Sir Edward Barnes ever saw Ceylon. Army Lists and other works of reference belonging to the early part of the century are wanting in our local Libraries, and although we have scanned a good many volumes of the "Annual Register," the results have been very scanty indeed. It may be truly said of Sir Edward Barnes that among the considerable list of Military Governors—some of them very able and distinguished men—who administered Ceylon during the first thirty years of the century,

he was the bravest warrior who ever buckled sword.

To substantiate this it is only needful to mention, as an evidence of his distinguished military career that Major-General Barnes was Adjutant-General to Field-Marshal the Duke of Wellington, K.G. at Waterloo. In the Duke's memorable Despatch to the Principal Secretary of State for War, dated "Waterloo, June 19th 1815," we find the following reference by the

Chief who was ever so sparing of words and praise,—“I had every reason to be satisfied with the conduct of the Adjutant-General, Major-General Barnes, who was wounded.” As a coincidence, it may be mentioned that six weeks after Waterloo, the news reached Downing Street of the capture of Kandy and the downfall of the Kandyan Kingdom in Ceylon.

From the statue erected to Sir Edward Barnes at the head of Prince Street, we learn that he was born in 1776 and so, at Waterloo, Adjutant-General Barnes was 39 years of age (seven years junior to the Duke), and consequently he was in his 44th year when, as Lt.-Governor, he assumed charge of Ceylon in 1820. He was still, therefore, not more than 55 when he left the island for India, in 1831; but no doubt exposure on many a hard-fought field in the Peninsula and elsewhere had told on him; because, after three years' service as Commander-in-Chief in India, returning home, he died in England in Oct. 1838, when only 62 years of age. The story we have heard is that after successfully contesting a seat for Parliament,—he was M.P. for Sudbury when he died,—he caught cold while attending a Levee at the Royal Palace, which developed a fatal illness. On his retirement from Ceylon—or rather in February 1831—he was made a Knight Grand Cross of the Bath, G.C.B.

Returning to his career in the East, and especially in Ceylon, with which we have more particularly to do, it is singular that so little reference is made to his term of office (1822-24) as Commander-in-Chief in India. But this is probably due to the fact that he did not get on well with the Civil authorities there, and was only too glad to exchange offices in the latter year with Sir E. Paget, and to return as full Governor to Ceylon. Here, by far the most interesting and vivid reminiscences of our great ruler are those afforded in his autobiography by the late Major Skinner, who was deservedly proud of having been, as a youngster, a special protege and favourite of Governor Barnes. But before

* To accompany an engraving. We regret that this first portrait is such a poor one, due to the fact that no photograph or proper portrait was available, and the engraving had to be prepared from an ordinary old wood engraving. The second and third Collytype-frontispieces—specimens of which have arrived—are very different in their style and execution.

quoting from Skinner, we may refer to some other and contemporary writers, and first here is the rather meagre summary from our Table of Events in Ceylon:—

- SIR E. BARNES, GOVERNOR, 1824-31.
1824. Lieut-General Sir Edward Barnes, K.C.B., Governor; Sir R. Ottley, Chief Justice; Hon'ble J. Rodney, Colonial Secretary.
- " Building of the Pavilion, Kandy; and of Mount Lavinia House, near Colombo.
- " Moon's "Catalogue of Ceylon Plants" published.
- " First regular Coffee Plantation opened. Although the first regular Coffee Plantation in Ceylon was opened in Ceylon in this year, the enterprize is usually dated from thirteen years later, in 1837.
1825. First English Steamer, the "Enterprise," in India.
- " Bishop Heber visits Ceylon; August 25, arrives at Galle; Sept. 15, Kandy; Sept. 29, leaves for India.
1826. The infliction of capital punishment upon women, by drowning, in the Kandyan Provinces abolished.
- " Uduvil Girls' Boarding School established by American Missionaries in Northern Province.
1827. The export of Coffee for the year equalled 16,000 cwts.
- " Foundation of the Kotte Christian Institution laid by the Governor, 8th November.
1828. Nuwara Eliya established as a Military Convalescent Station.
1829. The Commissioners of Enquiry (Mr. C. H. Cameron and Lieut.-Col. Colebrooke), who were appointed to report upon all matters relating to the administration of the Government of Ceylon, arrived at Colombo, 11th April.
- " The Colombo Pettah Library instituted by the Burghers, 11th April.
1830. Colombo United Service Library established.
1831. The Colombo Friend-in-Need Society formed, 16th March.
- " The Kandy Road via Kurunegala and Galagedara and that via Kadugannawa finished.
- " Series of successful Pearl Fisheries from 1828 to 1837.

Besides building the Pavilion, Kandy, and Mount Lavinia House,—of which works some curious information is extant,*—a third Governor's residence was built in 1829 in "Barnes' Hall," Nuwara Eliya, the Sanatorium having been first discovered to Europeans three years earlier, and selected as a Military Convalescent Station by Sir Edward Barnes.† But, undoubtedly, the far-seeing wisdom and enterprize of Governor Barnes were most fully

* On a rocky headland, which projects into the sea a few miles from Morottu, are the remains of what was once the marine palace of the governors of Ceylon; an edifice in every way worthy of the great man by whom it was erected—Sir Edward Barnes. But in one of those paroxysms of economy which are sometimes not less successful than the ambition of the Sultan in the fable, in providing haunts for those birds that philosophise amidst ruins, the edifice at Mount Lavinia had scarcely been completed at an expense which has been estimated at £30,000, when it was ordered to be dismantled, and the buildings were disposed of for less than the cost of the window frames.—*Tennent's Ceylon*.

† The first visit of Europeans to this lofty plateau was made by some English officers, who in 1826, penetrated so far in pursuit of elephants. Struck with its freshness and beauty, they reported their discovery to the Governor, and Sir Edward Barnes, alive to its importance as a sanitary retreat for the troops, took possession of it instantly, and commenced the building of barracks, and of a bungalow for his own accommodation. He directed the formation of a road; and within two years Neuera-ellia was opened (in 1829) as a convalescent station.—*Ibid*.

shown in his military and commercial roads between the sea-coast and the hill-country—his "Bridge of Boats" over the Kelani (which is only now after sixty years being superseded,) and his projection of main thoroughfares right through the Kandyan country to Badulla and Matale and thence North and East to Trincomalee. If the first and most potent means of extending civilization (according to Sir Arthur Gordon quoted by Charles Kingsley in "At Last") be found in roads—the second in roads—and this third again in roads,—to Sir Edward Barnes belongs pre-eminently the reputation of the far-seeing Statesman, the Educator and Benefactor of the people entrusted to his care. When the British landed in Ceylon in 1796 there was not in the whole island a single practicable road; before Sir Edward Barnes resigned his Government in 1831 every town of importance was approached by a carriage road. The permanent conquest and quiet settlement of the Kandyans who had baffled Portuguese and Dutch invaders for 300 years was undoubtedly due to Sir Edward Barnes' first-class macadamized road from Colombo to Kandy, including the alternative route via Kurunegala (which so completely answered the native tradition of their conquerors being those who should make a road through rocks) and the beautiful as well as substantial satinwood bridge (due to the genius of General Fraser) across the largest river in the island, the Mahawelliganga, at Peradeniya. The first attempt at a census—or an approach to an accurate numbering—of the population of Ceylon was made by Governor Barnes in 1824, the result being a total of 851,440 which shewed that including omissions due to the hiding of people, there could not be more than a million of both sexes and all ages in the island seventy years ago, against the three millions of our latest Census. But the same master-mind that conceived the system of carriage roads between the principal towns, was never satisfied until it demonstrated that there was an industry and trade in value capable of being developed in the hill-country far in excess of the fabled mines of precious metals and jewels which the Portuguese, Dutch, and even early British had credited the Kandyan monarch with controlling within his territory. The Dutch who began coffee cultivation in the lowcountry in 1740 were never able to export more than 1,000 cwt. in one year. Mr. Geo. Bird, under the direct encouragement of the Governor, began the first regular plantation at Sinnapitia, near Gampola, in 1824, and then Governor Barnes himself, to stimulate and encourage capitalists to settle, led the way next year, by opening Gangaruwa estate above what are now the Royal Botanic Gardens, Peradeniya—and a plantation which, under the care of Sir Edward Barnes' son—Mr. R. H. Barnes,* an accomplished meteorologist and careful planter—did well up to the sixties and seventies in coffee, while under cocoa and other products it is still a valuable property for its present owner and lessee. Had Sir Edward Barnes remained longer in the Island, coffee cultivation would have undoubtedly developed much more rapidly than it did, the export in the year he left being only a few thousand cwt., while in 1837—the year from which we usually date the active rise of the planting enterprise—it had risen to 30,000 cwt. The cause is clearly explained by Tennent when he writes:—

* He left Ceylon in June 1867 and sold Gangaruwa in January 1872.

So soon as Sir Edward Barnes had made such progress with the great central high road as to open a communication with the hill country, it was obvious to his clear and energetic mind that so grand a work would be limited to mere military exigencies, without conducing to the material prosperity of the island. Hence, even before its final completion, his measures were taken to emulate in Ceylon the industrial enterprise of India. The preparation of indigo was attempted, but unsuccessfully, near Veangodde; that of sugar was encouraged on the alluvial lands of the interior; and, taught by experience the inaptitude of the lowlands for the profitable cultivation of coffee, Sir Edward formed the first upland plantation about 1825, on his own estate at Gangaroooa, adjoining the gardens of Peradenia.

The example of the Governor was speedily followed; plantations were opened at Gampola and elsewhere, and the first attempt, though begun in a comparatively low altitude sufficed to demonstrate the superiority of the hill country over the low land, for cultivation, both in the quality and the abundance of the produce.

At this crisis the fate of the experiment was decided, by the adoption, in 1835, of a measure which Sir Edward Barnes had urged on the home government in 1826; the duty was equalised upon East and West India coffee, imported into the United Kingdom, at the moment when the failing supply of the latter turned attention eagerly and anxiously towards Ceylon. In the very next year nearly four thousand acres of mountain forest were felled and planted, and in an incredibly short time the sale of crown lands exceeded forty thousand acres per annum.

Sir Edward Barnes was also the means of encouraging the local preparation of coconut oil with a view to its shipment to Europe:—the first shipment being taken away in 1820 by Capt. Boyd (afterwards of Aceland, Boyd & Co).

In May 1821 Sir Edward Barnes arranged for the gradual emancipation of the children of certain native castes hitherto held as slaves; and here we may give a list of the Proclamations and Regulations still retained in the Ceylon Statute Book as passed during the rule of Sir Edward Barnes:—

Proclamation of 7th September, 1820.—Whereas good and permanent roads have been and are now making in the Kandyan provinces for public convenience, and it is highly necessary the same should be preserved from any damage or encroachment, &c.

Proclamation of 14th July, 1821.—Sales of land to be final unless otherwise stipulated.

Proclamation of 21st May, 1822.—Applications to register temple lands will be received, if given in before 1st September, 1822.

Regulation No. 26 of 1822.—For obliging the possessors of wells to raise the walls to a sufficient height to secure persons from danger of accidentally falling in.

Regulation No. 15 of 1823.—For making a general provision in respect to property found.

Regulation No. 18 of 1823.—Interest.

Regulation No. 14 of 1824.—For preventing the wetting of coffee, the growth of this island, with the intent of increasing its apparent weight or quantity.

Regulation No. 8 of 1825.—For declaring the legal and established currency of the Island of Ceylon to be the silver and copper current coin of Great Britain, and also the Ceylon silver and paper rix dollar, and the copper subdivisions thereof, already current therein.

Proclamation of 14th January, 1826.—Fictitious Transfers of Lands.

Regulation No. 5 of 1829.—To remove all doubts as to whether the Statute 10 Geo. 4 cap. 7. passed "for the Relief of His Majesty's Roman Catholic subjects," extends to and is in force in Ceylon.

A more important Regulation than any of these is that which we find in "Bennett" and

which we cannot help transcribing in full:—

REGULATION OF GOVERNMENT,

For promoting the Growth of certain Articles of Agricultural produce in the Island of Ceylon, and for the encouragement of Agricultural speculation.

Whereas it is proper and expedient to afford every practicable encouragement to Agricultural speculations and pursuits in this Island and more particularly to the growth of certain articles of produce hereafter specified. And whereas it has been represented to His Excellency the Governor that some persons have been deterred from engaging in such speculations and pursuits by an apprehension that they might be liable to pay a proportion, the produce thereby raised as a tax due and payable to Government.

1. For removing therefore all such apprehensions, it is hereby enacted by his Excellency in Council, that no part of any Coffee, Cotton, Sugar, Indigo, Opium, or Silk, of the growth or produce of the Island, or of any part of its Dependencies, has hitherto been, or will be demanded or claimed by Government for the period of twelve years from this date.

2. And whereas by Regulation of Government, No. 9, of 1825, therein referred to, Coffee and Cottons are permitted to be exported from any port of this Island, free of duty, but no mention is made of the other articles of produce herein enumerated, it is therefore hereby further declared that all Sugar, Opium, Indigo, or Silk, the growth or produce as before named, may be exported from any port of this Island or its Dependencies free of all duties whatever.

3. And it is further enacted, that all Implements, Tools, and Machinery used for the purposes of Agriculture, or of any kind of Manufacture, may from henceforth be imported into this Island free of all duty whatever.

4. And with a view to the further encouragement of Agricultural speculations, it is also enacted that all Labourers, of whatever nation or description, who shall be *bona fide* employed in any plantation of Coffee, Cotton, Sugar, Indigo, Opium, or Silk, or in the manufacture or produce thereof, shall be exempt from being called out in the public service during the period of such *bona fide* employ, except during actual war, and for the purpose of repelling invasion, or during internal commotion. Provided, that in order to exempt from such public service those otherwise liable, a certificate from the Proprietor of such plantation, or manufacturer, or from his Agent, be produced to the Collector of the District. And any Proprietor or Agent issuing to any Labourer a certificate which shall be wilfully false in any particular, shall, on conviction, be liable to a fine not exceeding Twenty Pounds; and in default of payment, to imprisonment for any term not less than Two calendar months, nor more than Six calendar months.

Given at Colombo, 21st September, 1829.

By order of the Council,

T. EDEN,

Secretary to Council.

The common idea is that Sir Edward Barnes confined his attention, chiefly, to what is now the Central Province. But there never was a greater mistake, as Forbes, Colonel Campbell, and Bennett—all of them contemporaries of Governor Barnes—clearly show. Unfortunately there was no Legislative Council in existence in those days, for the Governor to lay before it once-a-year a summary of his works and plans. There are no Administration or other Reports available, so that we can only here and there gather hints of the many and varied schemes for the improvement of the people and the development of industries, old or new, in every district of the island which constantly employed the fertile, active brain of Sir Edward Barnes. One of his first Regulations as Lieut.-Governor was to promote a local industry "For encouraging the preparation

of Salt Fish within the island." He freely patronised the "Literary and Agricultural Society of Colombo" frequently taking the chair at its meetings. He took a great interest in the development and proper management of the Pearl Fisheries, and was the first to introduce a Diving Bell to Ceylon. He encouraged the establishment in the South of the island of a "Tangalla Indigo Factory Company," becoming its patron himself, and granting 2,000 acres free of rent for a certain term of years, the Superintendent being Mr. John Tranchell (a Swedish gentleman of great ability, skill and enterprise) whose premature death and the departure of the Governor to India, put a stop to the experiment. The Company was one of 50 shares at £37 10s. each. The indigo was said to be growing wild. At the other end of the Island, in the Jaffna Peninsula, Governor Barnes took much interest in the "Potoor Well" with its daily influx and efflux of water, and (in 1824) as Tennent relates:—

In 1824, the Governor, Sir Edward Barnes, conceived the idea of using this apparently inexhaustible spring for maintaining a perpetual irrigation of the surrounding districts. With this view, he caused a steam-engine with three pumps to be erected at the well of Potoor. But for some reason, which I have been unable to ascertain*, the attempt was soon abandoned. In reporting the early progress of the experiment, the Government officer of the district represented that the pumps, though worked incessantly for forty-eight hours, and drawing off a prodigious quantity of water, had in no degree reduced the apparent contents of the well, which rose each day precisely an inch and a half between the hours of seven in the morning and one o'clock in the afternoon; and again between eight o'clock and twelve at night—falling to an equivalent extent in the intervals. The natives are perfectly familiar with all these phenomena, and believe that the well communicates with the sea at the Kieremalie, near Kangesen-torre, a distance of seven miles, from which they affirm that a subterranean stream flows inwards.

Colonel Campbell relates how it was a saying in the Service in his day that no one who was not prepared to work with all the energy at his command, would do for Edward Barnes. By the Governor's wish, he repaired Galle fortifications and planted trees on the ramparts. The Kirime Canal, North of Tangalla, was due to Sir Edward Barnes and was considered a great work in its day. At its completion the Governor personally distributed honours and gold medals to the Headmen engaged in the work. St. Sebastian lock on the Colombo Lake was also Sir Edward Barnes' work to permit of navigation between the roadstead and the inland canals via the lake.

One of the most appreciative notices of Sir Edward Barnes' administration is that afforded by the late Capt. James Stewart, Master-Attendant of Colombo, in his "Notes on Ceylon." He relates with reference to the progress of the Kandy road:—

When the portrait of the late Sir Edward Barnes was placed in the Kandy Library, the natives flocked from the provinces to see it. An old Chief, who had been a rebel in 1818, was so struck with the likeness that he was heard to exclaim—"All the same, come back again! Only not speak!" When the natives of the interior visit Colombo, they have been seen to bring flowers and place them at the feet of the statue of Sir Edward Barnes as symbols of their reverence;

*I have since been told that lands irrigated by the water procured from the well were found to yield no increase, the grain reaped being scarcely equal to the quantity of seed sown in the ground.

and not long since, when his son was travelling in Ceylon with a friend, the renter of a ferry, on discovering who one of his passengers was, ran and laid the money which had been paid him at Mr. Barnes' feet, declaring that he could not receive money from his late Rajah's son, and he was with difficulty prevailed on to receive payment of the tolls.

Stewart calls Sir Edward Barnes the "Prince of Governors," and shows how for three years before he left he had a revenue in excess of expenditure. In the early part of 1829, he sent his favourite Royal Engineer Officer, Capt. Dawson, with Capt. Stewart to inspect the several scours and channels in Adam's Bridge and to report on the improvement of the Panban Passage. A spirit of progress was generally infused into the community, and in 1830 (8th June) a meeting was actually held at Colombo to consider a plan for establishing steam communication between India and England, via the Red Sea, and between Colombo and the Presidency towns.

Col. Campbell who, like everybody who ever served under him, is full of admiration of the Governor, has an interesting reminiscence of Sir Edward Barnes' visit to Kurunegala on his first carriage drive by the new road en route to Kandy:—

(From Campbell's "Excursions in Ceylon.")

In going up to Kandy, Sir Edward Barnes stayed three days with us here, when he looked closely into every thing that we had done and were doing, but particularly at the roads; and was pleased to approve of our exertions to meet his views and wishes.

Forbes shews how greatly the new road was appreciated:—

(From Forbes's "Eleven Years in Ceylon.")

From Colombo I returned to Kandy by the mail-coach, and remarked the immense improvement that had taken place in the face of the country near the great road which was opened under the Government of Sir Edward Barnes. When I first visited Kandy in 1828, this line was unfinished; and the numerous obstacles which had been overcome or were in progress of removal, could not be overlooked: the rocks which had been blasted, the embankments that had been raised, were then bare; and the forests through which we passed showed how much of energy and perseverance were required to trace the road which was then forming. Now these obstacles would hardly be credited by any one who had not previously seen the country; for the shattered rocks and huge embankments were overgrown with vegetation, and the dense forest had almost disappeared from the vicinity of the road. In place of the rumbling ford and ferry of the Maha-oya, we crossed an elegant bridge at Mawenella, the design of Captain, now Lieutenant-Colonel Brown, R.E.; and, instead of the clumsy ferry boat at Peradenia, a light and elegant arch of satinwood, two hundred and five feet in length, spanned the Mahawelli-ganga. (This was constructed by Lieutenant-Colonel Fraser, Deputy Quarter-Master-General.) Immediately adjoining the bridge, in a bend of the river, and four miles from Kandy, is the Botanical Garden, a pretty spot, which owes as much to nature as to art for its beauties.

The last time I passed this way, in 1828, the able officer, Captain Dawson of the Royal Engineers, who had traced and directed the formation of this road, was in rude health and buoyant spirits: now his lofty monumental column gleamed on the summit of the Kaduganawa pass, the most elevated part of the road, and one thousand seven hundred and thirty feet above the level of the sea; his intrepid spirit and iron frame had sunk beneath the severe trials he underwent in the zealous discharge of his public duties.

Here is an incident of policy:—

(From Pridham's "Ceylon and its Dependencies.")

The tunnel on the Kurunaigalla road, one of the great public works undertaken by Sir Edward Barnes, has lately collapsed, and the road now winds round the hill, a further distance of two miles. The waste of treasure and human life on this undertaking, would scarcely appear defensible, but for the tradition current among the natives, that no foreign nation could conquer and retain the Kandian country, unless they obtained possession of Buddha's tooth, bridged the Mahavelli-ganga, and bored a road through a mountain. The two first feats accomplished, Sir Edward Barnes thought it politic to consolidate our empire by displaying before the eyes of the astonished Kandians the completion of the third. In less than thirty years, his successors have felt the British power so firmly based, as to see with unconcern one of the tests of dominion destroyed, and voluntarily to resign another. Nor can the recent emute be said to falsify the grounds on which they have acted, for it was but the efferescence of ignorant men acted upon by a wily and falling priesthood.

Bishop Heber's Chaplain makes several characteristic references:—

(From Robinson's "Last Days of Bishop Heber.")

Sir Edward Barnes's English horses (magnificent creatures) brought us into Colombo. In the evening we went to a small party of heads of departments at the Governor's, whose residence is called the King's House.

September 3rd.—The Bishop has been with the Governor this morning, and has laid before him his wishes with regard to schools. It is a subject of great difficulty, and has occupied many hours of consultation since we have been here. The Governor is ready to do whatever his lordship suggests.

To-morrow morning we start for Candy. The Governor drives the Bishop in his buggy, and I go with Mrs. Heber in a palanquin carriage. Six relays of horses are on the road, and we expect to reach Candy (78 miles) on Thursday morning. We shall all be glad of the comparative rest which this excursion will give us.

September 16th.—Sir Edward took us this evening to a beautiful ride, about a mile from the Pavilion, where a gorge in the hills displays a prospect which all agree to be the most lovely, even in Ceylon. It is more open and extended than any thing we have hitherto seen in this hilly tract, and is called Dombra Valley.

September 17th.—Our friend the Governor is an admirable guide through the beauties of his favourite Candy.

But of all admirers and writers about Sir Edward Barnes, none can equal Major Skinner in detail and interest, as the following specimen extracts from his autobiography must show. The extracts are made very much at haphazard where the Governor's name comes in, which will explain the abruptness:—

With such energy and judgment, however, did Sir Edward Barnes proceed, that within twelve months from the date of the order for surveying and tracing his new roads, one line of eighty-four miles, from Colombo, through the principal grain district, to Kandy, was so far opened, and his transport department so complete, that his supplies for troops and his post were conveyed by wheels to Kandy with ease and celerity.

The means employed in the construction of the first 200 miles of road by Sir Edward Barnes were a splendid body of pioneers which he raised, such of the native troops as could be spared for and were adapted to the work, and the gratuitous labour of the inhabitants, which, according to their own laws, they were compelled to render to this State.

Although those roads of Sir Edward Barnes were surveyed, traced, and opened, through a closely wooded, mountainous country, with a rapidity which allowed no time for the correction of errors, they fortunately exhibit no mistakes; they have mainly contributed

to raise the colony to the importance she has attained and on them she is still dependent. * * *

His personal intercourse with the official headmen and chiefs, and their families, was frequent; his conduct towards them was kind and encouraging, evincing an interest even in their private and domestic affairs, all tending to uphold their respectability and influence, while his knowledge of every district, and his frequent progresses through them, induced every member of his government, whether in the metropolitan or rural districts, to exercise the same line of conduct towards the natives, and compelled them to acquire the most intimate knowledge of the country, to prevent their appearing less informed than he was himself; he had no fears that the authority and influence of the native chiefs would be exercised prejudicially, and by protecting and upholding it, strengthened his own government and preserved order in all classes of society. His government was characterized by its decision and great energy; during the early part of it, he was compelled to exact much gratuitous service from the people, still he won the affections of all classes to his person, and their attachment to his government; his name is honoured throughout the land, as well by peasant as by chief.

Our reports were made weekly to Sir Edward Barnes and to the Deputy-Quartermaster-General. The former, whenever he had an opportunity, would correct our orthography and send back our reports for revision, to remind us of the interest he took in our doings, and this produced the good he intended it should, by keeping us all "up to our work." Sometimes there would be an encouraging remark made with his broad pencil, such as, "This lad with his Kandians is doing well." I also received a letter from an officer of the Quartermaster-General's Department, informing me that His Excellency had observed, and wished me to be told, that with my raw untaught Kandians I was accomplishing a larger quantity of work than an equal number of skilled labourers of a division of Pioneers. This encouragement was far more effective than any amount of fault-finding.

Sir Edward Barnes often came to inspect the work and to encourage his men. He kept the best table I have ever seen, and always insisted on living better when travelling than when at home in Colombo; in either case, he invariably dined off an entire service of plate. We were always his guests on these occasions, and naturally looked forward to the luxury of a good dinner served in a first-rate manner. * * *

Hearing that Sir Edward Barnes was in London, I called on him in Dover Street, and, as I was taking my leave of him, he said:

"How are you off for money, youngster?"

I replied:

"Very well, sir, and I expect to get my passage-money from the Colonial Office in a few days."

He told me to wait for a few minutes, went upstairs and brought me down an order on the Board of Green Cloth for £25, which he put into my hand, and told me to pay him when I returned to Ceylon. This generous thoughtfulness quite set me up in the world.

At length, however, difficulties were overcome, and I received my due; but unfortunately, on that occasion, a relative accompanied me to the Colonial Office, and saw me draw my money. He tried very hard to "borrow" a portion of it, but I had the courage to refuse him, and said that the first thing to be done with it was to pay what I owed. To his amazement, I ran off so fast that he could not keep pace with me, and I did not feel myself safe until I gained admission at 7 Dover Street. Sir Edward Barnes fortunately was at home. I was out of breath when I thanked him for his timely aid, and told him I had drawn my money only a few minutes ago. He wanted me to keep the £25 until I could repay him with greater convenience in Ceylon; but I persisted in his allowing me gratefully to repay him then when I could do so, and abruptly left his presence before I had well recovered

from the effect of my run up to his lodgings. I always had reason to believe him a noble fellow, but this little incident impressed it more deeply upon me than before. I cannot tell what would have befallen me but for his kindness.

Colonel Churchill, Sir Edward Barnes's Military Secretary, called on me, by order of the General, and said the latter officer advised me on no account to accept the adjutancy, but desired to know whether I should prefer to be one of Sir Edward Barnes's A.D.C.'s, or to be made Staff Officer of Colombo? My reply was thoughtlessly given, expressing my feelings on the subject: I said I never wished to be an A.D.C. to any man in time of peace, but that if His Excellency would make me Staff Officer of Colombo, which involved constant active military duty, I should be very proud of the appointment. The garrison then consisted of—a troop of Dragoons, a detachment of Royal Artillery, a detachment of Royal Engineers, a company of the Royal Staff Corps, 16th Regiment, a portion of this regiment detached, 78th Regiment, 83rd Regiment, 97th Regiment, Ceylon Rifles, Gun Lascars, Armed Lascorvyns. Several detachments were drafted from these regiments, but still the garrison was large, and its duties were conducted on the most strict and rigid principles. A field officer and two subalterns were on garrison duty every day; guard-mounting was done with the utmost formality; guards were "trooped" every morning, and not the slightest deviation from established forms was permitted without the field officer of the day being called upon to give his reasons in writing. The Commandant was present at guard-mounting about three days in each week. I do not believe that the garrison at Gibraltar could have been under stricter discipline than that of Colombo at this time.

When I went to thank His Excellency for my promotion, imagine my surprise at his asking me to take up my quarters at King's House, and to become a member of his family. I began to think I had not done so far wrong in being honest and straightforward in my dealings with men in authority. My error would have been in thinking that I should always meet with so great and noble-hearted a man, and such a true soldier as Sir Edward Barnes, whose equal, for largeness of views, generosity, and nobleness of mind, I have never known in any position of life: He was a Commander for whom any soldier would have considered it the highest privilege to have served even unto the death. It was impossible to ride in his *cortege* without being inspired with the most devoted enthusiasm. How well any man who ever served under that perfect soldier can realise the description the late Sir Robert Arbuthnot gave of a desperate attack which he once saw Sir Edward make on a French position. The scene of the attack was an orchard, walled all round, to which he took his brigade up in open columns of companies; when at the proper distance he wheeled them into line, and then, having fired his men with his own enthusiasm, he rode his charger at the wall, and, cocked hat in hand, cleared it in the most splendid style. Sir Robert Arbuthnot said it was the finest sight and most effective attack he had ever witnessed. Sir Edward was, at the time, an exceedingly fine, handsome man.

I was a very active little sprite, and was never late for one of those 6 A.M. guard-mounting parades, or for any duty, though I must not say how often, during those four years' tenure of office, I did not go to bed till after guard-mounting. One morning Sir Edward Barnes came down to the billiard-room, as he usually did, between 12 and 1 o'clock, where we all congregated after breakfast. Seeing me intent on a game, he said:

"What are you doing here, youngster? I thought you would have been at Negombo by this time."

"What to do there, Sir?" I asked.

"What! Have you not received your orders from the Quartermaster-General?"

"No, Sir; I have not seen him to-day."

"Go to him at once, and be quick in what you have to do."

It was nearly 2 o'clock before the Quartermaster General could be found. When I caught him he directed me to proceed to Negombo—an old fort twenty-three miles north of Colombo—to make a plan of the barracks there and to prepare an estimate for their repair, so as to fit them for immediate occupation.

This was rather a bore, for I was engaged to a very pleasant dinner party that evening, to which I knew the Governor and Lady Barnes were going. It was 2 o'clock when His Excellency saw me ride out of King's House grounds. I knew I could depend upon my grey Arab charger, so the moment I got clear of the fort I started at a moderate hand-gallop, drew bridle for a minute or two at every sixth mile, and found that I reached Negombo within the two hours. There was no time to lose; I hooked my reins to a tree in the barrack square, and took out my field book and tape; measurements for the plans were soon made, data for estimate all taken within the hour, my horse girthed up, and I in my saddle on my return to Colombo. I allowed my Arab to go his own pace, which was always good, and found he had done the twenty-three miles home faster than on going out. I had my bath, dressed, and jumped into the huggy of one of the A.D.C.'s, and arrived at the dinner party very nearly as soon as the Governor and Lady Barnes.

The moment Sir Edward saw me he came up to me; there was no mistaking when he was displeased, though he had never found fault with me before. However, I thought to myself, "I will have a bit of fun; for I see you think I have neglected your orders." I was not left long in doubt on that point; for the following dialogue took place between us:

"Well, youngster, what the— are you doing here? I thought I told you this morning to go to the Quartermaster-General for orders."

"So I did, Sir."

"And what did he tell you to do?"

"He ordered me to proceed to Negombo, Sir, to take plans of the barracks, to report the number of men they could accommodate, and to submit an estimate for their repairs."

"And what do you mean, Sir, by neglecting those orders; you ought to have gone off instantly. Colonel— should have given you your orders yesterday evening."

"I have not neglected them, Sir; I have been to Negombo, and your Excellency will have all the information you require laid before you to-morrow morning."

"You have been to Negombo?"

"Yes, Sir."

"And taken plans of the barracks?"

"Yes, Sir."

"And framed an estimate for their repair?"

"Yes, Sir."

"At what time did you leave King's House?"

"Two o'clock, Sir; reached Negombo at nine minutes to four; and left it at a quarter to five."

"And what did you ride?"

"My own charger, Sir."

I saw the satisfaction he felt by his expression; he turned round, and although I pretended not to be looking at him, I saw the glee with which he was repeating my little exploit to our host, the Honourable Mr. Granville, and other members of the party. It was a fair ride and amount of work against time, but much more credit was due to my dear little horse than to myself.

I was only a pound or two over eight stone and never tired of riding if allowed to go the pace. This little incident pleased my patron immensely; he was a perfect horseman himself, and there was nothing he liked better than to have things done quickly.

Sir Edward Barnes was himself the best mounted officer I have ever seen, he rode a magnificent bay Arab charger with black points, whose coat shone like satin. Lady Barnes presented this Nigitte Arab to her husband; he had cost her between £400 and £500, and was thought to be cheap at the price

For a staff officer to appear on parade badly mounted was considered almost a military offence. One morning after a field-day, Sir Edward called "Mounted officers to the front."

They accordingly trotted round and formed a semi-circle before him, when he thus addressed them: "Gentlemen, the next occasion on which I have the honour of meeting you here, I shall expect to see you all properly mounted. Outward face. To your respective corps. Trot; canter; gallop!"

Later in the year, or more probably it was in the beginning of 1827, I was surprised one morning by Sir Edward Barnes sending me a message that he wanted to see me directly. I began to take a retrospect of my late life, wondering what I could be required for, at that early hour. When I went to his dressing-room, which was immediately over my own bed-room, I at once saw I was about to "catch" it. The difficulty which presented itself to my mind was to determine for which of my many peccadilloes I was to be brought under His Excellency's displeasure, for, I must own that while I was acknowledged to be a good, smart officer in all matters of duty and punctuality, I was a very wild one. Always consulted, and the first to be referred to, when any piece of mischief was wanted, I had had so many little adventures lately of which I was the originator, that I was fairly puzzled when confronted by the Governor. With his face covered with lather and a razor in his hand, he exclaimed in a very angry tone:

"What have I done, Sir, to deserve this treatment from you?"

I had never seen him look so angry, or heard him speak with such austerity before; and I had some difficulty in restraining my feelings, for I felt extreme sorrow and contrition for having offended the best friend that any youngster ever had. Every naughtiness I had been guilty of seemed instantly to crowd upon my memory, as a personal offence against the kindest and most partial of patrons, and I was overcome.

I fancy I see him now, with his arm up, his razor just as he had taken the first sweep from his chin, as I stammered out:

"I am extremely sorry, Sir, that I have done anything to displease you; will you be so kind as to tell me what it is? Be assured I would not intentionally have incurred your reproof."

"I feel it very much, and thought better things of you——"

I could not help interrupting, and implored of him to tell me in what respect I had been so unfortunate as to displease him.

"I hear, Sir, that you are allowing a man to purchase over you."

I replied: "Yes, Sir; but I have no money, and you know I am too thoughtless and extravagant a fellow to borrow it; I might never be able to repay it."

"Why did you not consult me? You must have known I could have helped you, and might, I should think, have been sure that I have the inclination to do so. I cannot easily forgive you for your want of confidence in me."

On the 28th of March, 1829, I lost a very dear friend, and the service a most invaluable officer, in Captain W. Dawson, commanding Royal Engineers. The poor fellow died in my arms. The whole island mourned for him. Wherever he was known, he was dearly loved. Sir Edward Barnes had, notwithstanding Dawson's junior rank, selected him for the position of C.R.E., which was a colonel's command, for Sir Edward knew, from his Peninsular experience of him, the great merit Dawson possessed as an officer. A singular coincidence occurred in reference to the monument erected to his memory on the top of the Kaddoganawa Pass, which was one of the triumphs of his skill. The foundation of this column was laid at the same time as that to the memory of His Royal Highness the Duke of York, late Commander-in-Chief, at the entrance of the Park at the end of

Waterloo Place. The dimensions of these two memorials are identical, the only difference in them being that Dawson's monument is built of brick, whereas that erected by the nation to the memory of the Commander-in-Chief of the Army, in a conspicuous position in the metropolis, is of granite, surmounted by a statue of His Royal Highness. Dawson's remains were interred in a vault in Saint Peter's Church, Colombo.

This year, 1831, His Excellency Sir Edward Barnes was appointed Commander-in-Chief in India, and left Colombo for Calcutta on the 13th of October. He was kind enough to tell me that he would have taken me with him, but that he conceived I should, both to the colony and to myself, be much more beneficially employed in Ceylon than I could be in India.

"That may be, Sir," I replied, "but I hope, if ever I hear of your being on active service in the field, you will allow me to join you on leave."

Sir Edward Barnes left Ceylon on the 13th Oct-1831 for India to re-assume the office of Commander-in-Chief by express orders from home; but in less than three years he threw the post up from difference of opinions which sprung up with the civil authorities. He passed through Colombo again. This is Major Skinner's account of the event:—

In February, 1834, my dear friend and patron, Sir Edward Barnes, visited Ceylon on his way home having been recalled from the appointment of Commander-in-Chief in India in consequence of a difference of opinion with the Viceroy on the subject of the necessity for an army of exercise in the North-West Provinces during the cool season. He was dissatisfied with the want of organization and discipline that he found in the Indian army, which he considered perfectly unprepared to operate in any considerable force.

During Sir Edward Barnes's stay in India I corresponded with Churchill, his military secretary, and other members of his staff, and anything more truly prophetic than Churchill's letters eventually proved, could not be. The Sikh and China wars were fully anticipated by him, and he deplored the defects in the whole system of the Native army, which led subsequently to its mutiny. It was little matter of surprise that so true a soldier as was Sir Edward Barnes should have differed so widely and vitally from Lord William Bentinck and his councils. Could he but have got a large force of native troops together, he might have reformed the abuses which he was aware existed against discipline, and have averted that awful calamity.

The news of Sir Edward's arrival spread like lightning through the country, and caused great excitement. He was worshipped by the natives, and when a statue of him was subsequently erected in Colombo they would come in the night from the interior and lay offerings of flowers, rice, and money, such as they present in their temples, at the base of the pedestal, compelling us to surround the monument with a railing for protection.

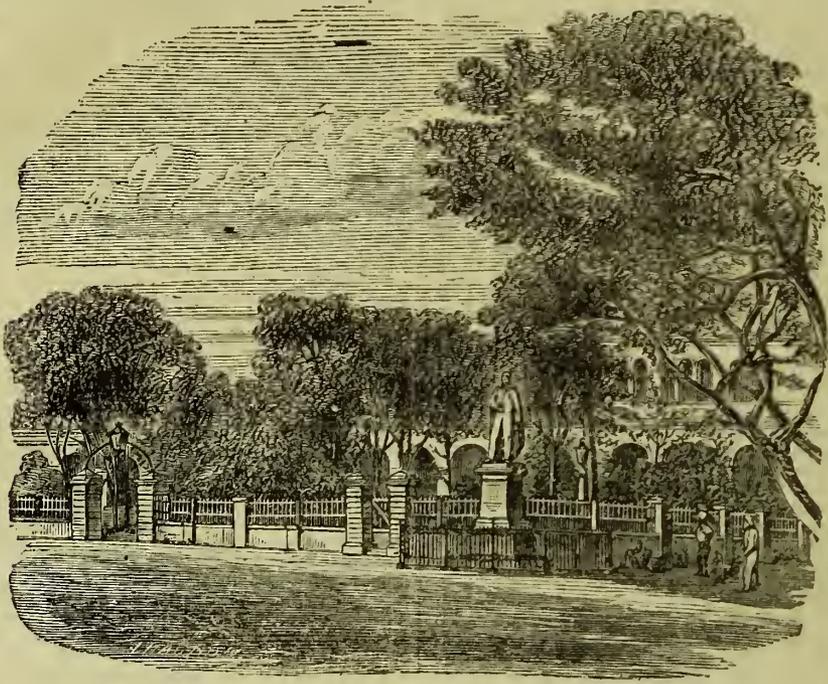

In England, Sir Edward Barnes, after a time, entered Parliament as M.P. for Sudbury, and though we do not read of his taking any part in the debates, it may be noticed that most likely this great Governor of Ceylon sat in the House with his great successor Sir Henry, then Mr. Ward.

Here is the closing entry for our record taken from the "Annual Register" for 1838:—

"In Piccadilly, aged 62, Lieutenant-General Sir Edward Barnes, G.C.B., of Beech-hill Park, near Barnet, Colonel of the 31st foot, and M.P. for Sudbury."

The officials and public of Ceylon erected a statue to the memory of their great Governor nearly opposite Queen's House and facing the beginning of the coach road to Kandy, which

road, with so many other beneficent works, afforded the best possible testimony to his genius and energy. The following engraving indicates the statue while we add the inscription below:—

LIEUTENANT-GENERAL
SIR EDWARD BARNES,
 G.C.B., K.M.T., K.S.A.
 ERECTED BY THE
 EUROPEAN AND NATIVE INHABITANTS
 OF CEYLON
 AND FRIENDS IN ENGLAND AND INDIA
 TO TESTIFY
 THEIR RESPECT AND AFFECTION FOR HIS PERSON
 AND TO PERPETUATE THE MEMORY OF
 HIS DISTINGUISHED MILITARY SERVICES
 AND
 THE IMPORTANT BENEFITS CONFERRED BY HIM
 UPON THIS COLONY
 DURING HIS ADMINISTRATION OF THE GOVERNMENT
 FROM 1820 TO 1822
 AND
 FROM 1824 TO 1831
 HE DIED MARCH 1838
 AGED 62 YEARS,

PROBABLE EXTENSION OF TEA CULTIVATION IN BALANGODA, CEYLON.

We have received intelligence which we fear will rather disturb the calculations of those who have been making out that there is no likelihood of any considerable additions to tea cultivation in Ceylon in the higher districts. Allusion has more than once been made to the great, unoccupied reserves of land in private hands in the Province of Sabaragamuwa. We have also referred more recently to the prospect of a good deal being taken up for tea in the Balangoda division. We now learn on good authority that negotiations have been opened by practical men with one or two Kandyan Chiefs who own a vast extent of forest-land in the Bambarabotuwa side, well adapted for tea, and that although they will not consent to sell an acre outright, for a rental of R1½ an acre, they are prepared to grant leases for any period up to 99 years. It is estimated that no less than 64,000 acres of good land adapted for tea are available for selection, and one well-known Dikoya planter (Mr. E. M. Leaf) has already got authority from England to take up a very large extent, prepare nurseries, build a central factory, and altogether to establish one of the biggest Tea concerns yet to be found in the Central Province. Others are likely to follow, and the prospect therefore is that within the next twelve months the BALANGODA-BAMBARBOTUWA district will have its cleared, if not planted, area with tea very largely increased.

THE COCO NUT PALM IN ZANZIBAR AND PEMBA ISLANDS.

(FROM MR. FITZGERALD'S REPORT.)

The second great cultivation of Zanzibar, coconut trees being found all over the fertile portions of the island, and very extensively cultivated. With the exception of solitary lanky trees scattered here and there, the coconut trees generally are robust and healthy, but great neglect exists; and I noticed, more particularly in the northern part of the island, many dead and dying trees, which could only be attributed to this cause. The cultivation is very scattered, and no regular order appears adopted in planting, solitary trees as well as thicker groves being observable everywhere intermixed with the large handsome mango trees, so striking a feature in Zanzibar. As a rule no regular plantations are made, many people only owning a comparatively small plot of land, on which are generally found collected all the chief products grown in the island, viz. cloves, coconuts, areca palms, mangoes, cassava, sweet potatoes, &c. As already remarked, no particular care appears to be taken once the trees are established, the only attempts at cultivation being the clearing of the ground beneath and this at irregular times, for the growth of ground produce, chiefly cassava though bananas are also frequently grown between the trees and in this case greater trouble is taken to keep the ground clean, but as a general rule it is thickly overgrown with grass and bush. Large plantations, however do exist notably that of "kokotoni," situated in the northern district of that name, covering over 1,000 acres and containing at one period 80,000 trees. Further reference will be made to this. Coconut trees are usually planted very thickly and closely together; in fact, some of the groves appeared overcrowded, giving the trees a lanky appearance. In other places the trees were planted 15 feet, 20 feet to 30 feet apart. A coconut tree is picked on an average four times a year, yielding each time, accord-

ing to the tree, 30 nuts, 40 nuts, 50 nuts, &c. In good situations, and where the tree is kept in good order and condition, it would yield 300 annually. But many trees neglected and uncared for will only give from 80 nuts to 100 nuts a year, and, with better conditioned trees, an annual average of 120 nuts rising to 200 nuts. Solitary lanky trees from 5 nuts to 50 nuts. Reason for poor appearance and yield being bad soil and often old age. Coconut trees growing amongst cloves are a rule lanky, and yield poorly. The bye-products of the coconut tree are comparatively neglected. Want of labour and of transport facilities—with the exception of a few carts in Zanzibar wheeled conveyances not existing and pack animals, viz., donkeys being very little used—are at present the two great obstacles to their development. Coconuts in a small degree, are exported to Bombay in dhows. Copra is also exported, and I understand that European firms are now paying especial attention to this. An English firm has now imported machinery for the manufacture of coir. Previously no use was made of the husks, heaps of these being met with thrown on one side, or else being burnt as fuel, the little coir that was made being manufactured in a crude manner by natives from the Comoro Islands, no Swahilis carrying it on, a basket of coconut husks selling in Zanzibar for 6 pice, 7 pice and 8 pice (the cost of carriage), and the beaten and cleaned fibre being shipped to Bombay.

The removal of the husks is effected by a sharp iron spike, called "tarimbo" (liberally, an iron bar), but the more general practice is to use a sharpened stick for the purpose, called "kifuo." Toddy is simply sold for drinking and for making vinegar ("su siki"). Toddy syrup, a species of sugar or syrup, is also made by boiling toddy in a pot for half an hour, and sold at 2 pice a cup. "Asali ya tembo," syrup made from toddy. "Asali ya mua," the boiled juice of the sugar cane.

Pemba coconuts are easily distinguished from the variety, being smaller in size and with very yellow mid-ribs, and the nuts are also very much smaller and a dark yellow in colour. They appear to be valued chiefly for drinking purposes, the water in the immature nut being very sweet.—*Zanzibar Gazette*.

HOW TO MAKE A CUP OF TEA.

(Eugene J. Hall in *Grocers' Criterion*.)

When Mrs. DeKalb, of West Fortieth street Gave her "five o'clock tea," 'twas a splendid affair; Mrs. Fitzburgh Whitehorse and Miss Coykendall Le,

The Frizzles, the Fowlers and Thompsons were there.

They talked of the arts of the gay Japanese, Of friezes, of dadoes, of ceilings and tiles, Of Greenaway costumes, of fashions in Greece:

When Pericles ruled o'er the isthmus and isles.

When suddenly Mrs. De Quackenbush Locke

Gave a practical turn to the drift of the talk:

"Ah, Mrs. DeKalb," she exclaimed in surprise,

With a smile of delight and a flash of her eyes,

"Your tea is delicious, its flavour is fine,

Its aroma perfect, its color divine,

I have tried for a month and I cannot obtain

Such a 'sleeper' as this, 'tis as good as cham-

pagne."

Then said Mrs. DeKalb, "You easily can,

'Tis a mixture of Oolong and new leaf Japan,

With a pinch of Pekoe to give it 'bouquet,'

That epicures always pronounce 'recherche,'

Take the purest of water, and, when boiling hot,

Pour it over the tea in a clean, china pot,

Let it stand just a minute, then serve it just so,

And your guests will pronounce it perfection, I

know."

—*American Grocer*.

[The above will show how much our American

cousins have yet to learn about the virtues of pure

Ceylon tea!—*Ed. T.A.*]

FINE TEA AND HIGH DISTRICTS.

Mr. Talbot sends us a very interesting and suggestive contribution to the discussion on fine teas; but it is surely an unduly discouraging one? If we only take a few leading plantations and the results for 1892 according to Messrs. Wilson, Smithett & Co.'s list, we think it will be seen that the trade do give good prices for fine Ceylon teas, and the only question is whether the average of the following, and a lessened quantity of tea, would pay the rest of the estates in the higher districts if they went in for equally fine teas? We quote as follows:—

QUANTITY AND AVERAGE IN 1892:		
lb.	d	
Ormidale.....	39,500	1 4 $\frac{1}{2}$
Norwood (E. P. & E.Co.)	123,000	1 2 $\frac{1}{2}$
Waverley (C. T. P. Co.)	294,000	1 1 $\frac{1}{2}$
Portswood.....	80,000	1 1 $\frac{1}{2}$
Tommagong.....	43,000	1 1 $\frac{1}{2}$
Silverkandy.....	21,000	1 1
Diyagama.....	457,000	1 0 $\frac{1}{2}$
Henfold.....	258,500	1 0 $\frac{1}{2}$
Edinburgh.....	78,000	1 0 $\frac{1}{2}$
Mocha.....	63,500	1 0 $\frac{1}{2}$
Kotiyagalla.....	199,500	1 0 $\frac{1}{2}$
Portmore.....	113,500	1 0 $\frac{1}{2}$
Mooloya.....	107,000	1 0 $\frac{1}{2}$
Kandapola.....	259,500	1 0 $\frac{1}{2}$
Hauteville.....	259,000	1 0 $\frac{1}{2}$
Invery (S C T Co.).....	168,500	1 0 $\frac{1}{2}$
Ouvahkellie.....	153,000	1 0 $\frac{1}{2}$
P. D. M.....	26,500	1 0 $\frac{1}{2}$
Kew.....	196,000	1 0
Glendevon (O B E C).....	184,500	1 0
Elbedde.....	147,500	1 0
Protoft.....	96,000	1 0
Bloomfield.....	50,500	1 0
Middlston.....	25,500	1 0

Total 3,454,000 lb. 1 0 $\frac{1}{2}$ (aver.)

We have selected all estates with an average last year, of 1s and upwards, and it is noteworthy that these (24 estates in all) represent the following, (among other) districts:—Maskeliya, Dikoya (including Bogawantalawa), Dimbula (with the Agra-patanas), Nuwara Eliya, Udapussellawa and Hewaheta. Perhaps the most notable case is that of Waverley belonging to the Company of which Mr. Talbot is Chief Manager and which sold in 1892 so large a quantity as 294,000 lb. at so good an average as 1s 1 $\frac{1}{2}$ d. Now of course, Mr. Talbot is by far the best judge as to whether it is feasible, or would be profitable, to bring all the plantations under his influence in the higher districts, up to the same average. Nearly as important is the case of the Diyagama plantation turning out so much as 457,000 lb. at an average of 1s 0 $\frac{1}{2}$ d—which is also, it will be observed, the average for the total quantity 3,454,000 lb. sold by the 24 estates we have quoted. Now, the practical point is, can Ceylon not send from her higher districts, 20 million lb. instead of 3 $\frac{1}{2}$ million, of a quality which would ensure a steady demand for such "fine teas" and an average of not less than 1s 1d per lb.? If this is possible—and profitable—there can be no doubt of the good it would do in raising the reputation of Ceylon teas in the estimation of the trade. This result, of course, would also come from a general improvement in plucking all over the country so as, if possible, to improve on last year's miserable average of 9 $\frac{1}{2}$ d for the island.

Mr. Talbot, however, supplies one very striking fact in the experience of tea from the young estate of Mudumana. How is it to be explained? Does it indicate general neglect of Ceylon teas on the part of the trade; or, otherwise, why should this carefully prepared tea,—virgin crops from virgin soil,—not be prized as much as were precisely similar teas a few years ago? This is a question, which we would call on "Philpot" or some other member of the home trade to answer.

CEYLON TEA AND THE "BITTER CRY."
No. XXVI.

FINE TEAS AT HIGH ALTITUDES.

Nuwara Eliya, 14th June, 1893.

DEAR SIR,—Referring to your suggestion that estates at high altitudes should make finer teas and mark them Darjeeling-Ceylon,—

I do not think it would lead to any good; the Superintendents of estates in the Nuwara Eliya district have gauged pretty well the London market as is seen by the prices realized by such estates as Portswood, Kandapolla, Court Lodge and Hethersett and no alteration in style would, in my opinion, get higher prices. The idea that there is not enough fine tea sent from Ceylon is, I think, a mistaken one as a great deal of well-made flavory tea goes from the Nuwara Eliya, Agra and Bogawantalawa districts: my experience of the London market is that the more fine tea you send them the less they pay for it.

With regard to the cry that Ceylon tea has deteriorated, this is I think without foundation; for there is not the least doubt that leaf is more carefully plucked and better manufactured than it was 4 and 5 years ago: it is true that the leaf from tea that has not been pruned down, makes tea of better quality than old pruned tea, but there is still a great deal of leaf from young bushes being put in the market and it does not fetch good prices; for instance our young estate of Mudamana which is just coming into bearing and which is partly plucked does not fetch perceptibly higher prices than the older estates in the neighbourhood, and not within pence of what Dunedin and Dewalakaunda fetched when they were the same age.

There is no resemblance between the Darjeeling flavour and that of our high districts; and it is probable that if we took the name it would set the trade against us.—Yours truly,—

G. A. TALBOT.

BAMBOOS AT KEW.—An interesting feature in the Royal Gardens is a plantation of Bamboos in the lower part of the grounds near the Rhododendron walk, and a few types have stood the recent severe weather. The well-known *Bambusa Metake* is full of health and vigour, and represented by several fine mosses. *B. Simoni* is also uninjured, the large examples of this graceful Bamboo having been little touched by winter frosts. The heavy mosses of rich green growth are remarkably effective, and in the variety *striata* we get a distinct variegation. This is a fine hardy Bamboo, and the same may be said of *B. viridis glaucescens*. A large group of this is delightful in the garden, and hardy. It is one of the most elegant and pleasing of Bamboos. *B. nigra* is very dense in growth, and seems little touched by the weather. Although less elegant than such a form as *B. viridis glaucescens*, it is a handsome kind, the leaves of a full green colour. One labelled *Phyllostachys bambusoides* has made splendid growth, the leafage pale green, spreading, and very handsome. It is apparently very hardy. A graceful Bamboo is *B. Quiloi*, compact, and forming a fine mass. Two of the most interesting kinds are *B. tessellata* (synonymous with *B. Raganowski*) and *B. Veitchii*. Both are dwarf in growth, spreading out in a dense mass. The former has superb leaves, fully 4 inches broad, and 14 inches in length, the colour full rich green. At Kew the plants form a bold group, and have a telling appearance. Those who wish for a good dwarf Bamboo should make a careful note of this kind. *B. Veitchii* is of similar habit, and a charming species. The leaves are broad, not so long as in *B. tessellata*, rich green, with deep creamy-white margin—a distinct and bold contrast. Its variegation is not weak, as we get a rich contrast—deep green against creamy-white.—*Gardeners' Chronicle*.

THE PROGRESS OF INDIAN AND
CEYLON TEA.

Messrs. Gow, Wilson & Stanton have published their annual Diagram-Circular under the above heading, and it is not one whit behind its predecessors in interest, or in the tasteful execution on fine paper of the many coloured diagrams. Writing to us on the 1st June, the Rood Lane Firm report that some days previous a large supply of the diagram circulars had been despatched to our address; but they have apparently failed to come forward by this mail. No doubt they will appear by the next steamer in good time for each of our subscribers to be furnished with a copy of this useful document as it will be published as a *Supplement* with the daily *Observer* and *Tropical Agriculturist*. The compilers report to us:—"This circular is issued partly with a view of showing to planters generally the various diagrams which have been exhibited in the Chicago Exhibition as well as in the Imperial Institute, and we think it will interest owners of tea estates to see what has been done in this matter."

The first diagram shows in a series of coloured blocks "Thirty Years' Record of the Tea Trade in the United Kingdom." Each square represents one million lb.; and the colours are red for Indian; yellow for Ceylon; and dark grey for China. In 1862 in a total consumption of 80 million, there was only $\frac{1}{2}$ a million lb. of Indian tea and none of Ceylon; indeed the first appearance of Ceylon (and for half-a million lb.) appears only in 1882—the comparative blocks being given at five years' intervals. In 1892, yellow (Ceylon) shows on the top for the large total of 63 million; Indian (red) for 110 million and China for only 34 million out of the total of 207 million lb. consumed in the United Kingdom last year. This Diagram, we are informed, is placed in an enlarged form in the Indian and the Ceylon Courts at the Chicago Exhibition and in the Ceylon Court at the Imperial Institute.

The second page repeats the same information in a more striking form by means of coloured circles with lines drawn to the several countries of supply on a section of the map of Asia. For some unexplained reason this diagram entitled "The rise of Indian and Ceylon tea and the eclipse of China tea."—in its enlarged form is only exhibited in the Indian Court. We read as follows in the letterpress appended:—

Had not last Season's Tea Crop from India and Ceylon proved to be considerably below the estimated quantity, the need of assistance from foreign markets would have been much more keenly felt. Simultaneous short crops from both countries proved a temporary relief to the industry in general, but increased production must be anticipated in the near future, and therefore no effort should be spared to develop every existing outlet, as well as to open up new markets, wherever such is possible.

On the third page we get "Thirteen Years' History of Ceylon Tea," the diagram showing the "Production in Ceylon" by means of green circles from a mere dot of 50 tons in 1880, to 31,083 tons in 1892; while the value is given next in oblongs rising in the same

way from £3,024 in 1880 to £2,766,050; then is shown the consumption (in blue circles) in Great Britain from 40 tons in 1880 to 28,170 tons. This diagram enlarged is shown in both Courts. The letterpress tells us:—

Increasing supply can only with safety be met by increased demand—a fact of vital importance to the welfare of the industry. Energy and determination can effect much, and if in two years the quantity of Indian and Ceylon Tea taken by markets outside Great Britain could be raised from *fourteen million pounds to twenty million pounds*, as actually occurred in 1890 and 1891, there is the strongest encouragement to foster this branch of the enterprise in every possible way.

With this object in view, the Commissioners for India and Ceylon at the World's Columbian Exposition have taken steps for the representation of Indian and Ceylon Tea at Chicago, where packets will be freely distributed, thus bringing these Teas prominently before the numerous visitors, who will assemble there not only from America and Canada, but also from Europe and, doubtless, many other parts of the world.

Finally we have a diagram showing the "Tea Consumption in the United Kingdom" from 1864 of the three kinds—Ceylon beginning as we said in 1880.

Altogether a more striking way of shewing the great progress made by India and Ceylon in ousting China teas in the United Kingdom could not be desired and if our American cousins only take to themselves the "object-lesson," we may hope to see China and Japan teas pretty soon beginning to give way before the purer British-grown article, across the Atlantic. There can be no doubt, at any rate, that Messrs. Gow, Wilson & Stanton deserve the thanks of all Indian and Ceylon tea-planters for the trouble they have taken in compiling and publishing this very elaborate and well-finished Circular-Diagram at this particular juncture.

MEDIUM OR COARSE AND FINE
PLUCKING OF TEA.

There would seem to be very little likelihood of this oft-disputed question receiving an early, final settlement. Indeed, we fear it is one of a class which cannot admit of a wholly satisfactory determination. So soon as one set of evidence appears to dispose of it, another, quite of a contrary character, is advanced which cannot fail to re-open the argument, leaving us no chance of finally making up our minds as to whether the advantage remains with the advocates for coarse or even medium plucking, or with those who hold that the reputation of our teas and the chance of maintaining prices are being sacrificed to such a course. Very recently Mr. John Hughes demonstrated by the result of his chemical analyses that it must pay our planters better to pluck for the commoner grades of tea than to endeavor, by sacrificing quantity, to secure quality. We had, scarcely had time to digest his advice, and to consider the full meaning of the scientific deductions made by him from his experiments, than we are assured by London tea authorities that the inferior quality of the teas received of late from Ceylon is forcing down prices most seriously;—so much so, indeed, that the trade, when the mail left, feared a falling-off in the general prices for our teas to a point lower than has yet been reached. This would seem to be confirmed by the bad news telegraphed from the Lank

today. Who then is to decide for our much-puzzled planters when experts differ so widely in the advice they tender to them? At this end, moreover, we have leading planters—and one of them wields the pen today—declaring that the quality of Ceylon teas has not greatly fallen off; but on this point we suspect there is no getting over the average price paid for Ceylons as compared with Assam teas. Not so long ago the advantage lay with Ceylon; what has sent it so largely the other way? In this very material direction, therefore, it seems as if our critics had the best of the discussion. It is most essential that the reputation of Ceylon tea, as a definite production in the gross, should stand high in the London market. We know to what a standard the past brought our staple, and to this attainment of a high position, we know that we owe the almost marvellous advance our present industry has made. The question naturally suggests itself whether it can be wise to risk the sacrifice of this enormous advantage in order to secure a larger present return for our output? Should we not by doing this be effectually killing the goose that lays the golden eggs. We know, unfortunately, how narrow is the present margin which separates profit from loss in not a few instances. It may have paid at the recent prices to send home tea by quantity; but if the results anticipated by the London brokers follow our continuance in doing so, it is not likely that that advantage will long remain. It is quite true, we do not for an instant doubt, that scientific research is conclusive upon the data afforded by the late condition of the market; but any argument based upon such data must be held to be falsified when the stern logic of fact shows us that the conditions can no longer be accepted. The consideration of the effect of large quantities of common teas in the market we think could hardly be expected to have entered into Mr John Hughes' calculations. His counsel is of the abstract quality only. He knows nothing of the outside questions that are under the daily observation of the professional tea-broker. When we are assured that one of the more experienced of these has been condemning the bulk of Ceylon teas passing through his hands of late, and when even a proprietor of some of these teas—who must naturally be anxious to see in his property the highest possible qualities—is forced to confess that what he has for sale is poor stuff, we cannot hold that these opinions are special exaggerations. There is no question that Ceylon sends a considerable proportion of fine teas from the higher districts and there must be many cases where, as our planting correspondent shows today, the broker's description of our teas, is not fair. But then regarded in the gross what is the logic of facts: our average which was 8½d on 29th May was last week down to 7½d and no one anticipates a better result this week.

We cannot help thinking, therefore, that in endeavoring to hold the balance fairly between the opinions of the professional scientist and those of the practical broker, we must incline, *volens volens*, towards the latter. He knows how the market is governed by conditions which science does not take account of. He knows that the quality and amount of supplies from other tea-producing countries sways the pendulum of prices, and therefore the prosperity or otherwise of Ceylon produce. Scientific fact must, no doubt, always be an important factor; but it is manifestly less of a sure guide than the daily vacillation in the volume of supply. It is difficult, perhaps, to decide upon the exact relative values of two

opposed counsels of perfection. But one fact is patent, and that is that under no conditions can it be a wise policy to lower the reputation of Ceylon tea. It is, on the contrary, all-important to the future life of the industry that this should be maintained. All other consideration must be held insignificant compared with the duty of maintaining a good name, and therefore it is that we consider that a sacrifice of some amount of present return must be made if the future of Ceylon tea is to be looked forward to with confidence.

TEA TRADERS' TALK.

Barry Pain is responsible for the following parody:—

Pour, vsrlet, pour the water.
The water steaming hot!
A spoonful for each man of us,
Another for the pot!
We shall not drink from amber,
No Capuan slave shall mix
For us the snows of Athos
With port at thirty-six
Whiter then snow the crystals
Grown sweet 'neath tropic fires,
More rich the herb of China's fields,
The pasture-lards more fragrance yield;
For ever let Britannia wield
The teapot of her sires.

THE TEA TRADE.

There is nothing like the tea trade
For merchants who would thrive,
And busy be like busy bees working in the hive.
With lives as sweet as sweetest honey
They are storing up the money
In a way that's most encouraging to see;
But in all the tea they handle
There's none can hold a candle
To the tea that's known abroad as honesty.
There's sobriety, society and best of notoriety,
Punctuality, frugality and shrewd sagacity,
There's modesty and jollity, the very finest
quality
Are blends and brands we all delight to see.
There's sociality, generosity,
And business reciprocity
And charity with flavour ever fit
Such tea will always draw,
And in them you find no flaw,
But integrity's the finest in the line,
But shun all sorts of animosity,
All flavours of moistosity,
And remember that composity
Was never known to please;
Though mixed with ingenuity
There will still be incongruity
That will make you a nonentity
In the handling of teas.
If you deal in best of Oolong,
Congou, Foochow or Souchoong,
Hyeon Skin or Old Bohia,
Do not practice infidelity,
Inebriety, profanity, or any sort of vanity
If you would serve humanity
In supplying them with tea
—*Detroit Herald of Commerce.*

SANDAKAN JOTTINGS.

May 29th.

TOBACCO ESTATES.

The quick development of this country depends so greatly on the success of the tobacco estates now operating, that you can imagine how the news of the high prices realized at the first tobacco sales at Amsterdam this year have been received by our community. It has been and still continues to be the chief topic of conversation, and has raised the hopes of many who

were becoming despondent. It is the same amongst the managers and assistants on the estates. At the same time, there is a general feeling of expectancy prevalent. The sales so far reported are only for Sumatra tobacco, and we want to see our home-grown leaf sold equally well, to confirm our hopes that a period of prosperity is before us. The fact that last year two crops at least were badly received on the market, through want of proper handling (so reported) during fermentation and baling, adds a touch of nervousness to the prevailing feeling. A recurrence of this would almost be certain to close the estates from which the tobacco is shipped. Reports from the different estates, continue favourable. Planting is being pushed on vigorously.

COFFEE.

The three coffee estates in this Bay are coming forward in a way that is very satisfactory to those concerned, and I hear the same reports as to the coffee estate in Marudu Bay, in which our Commissioner of Lands takes great interest. I see you have a paragraph, in one of your late issues, on Borneo gambier. The Chiuanan, who made the venture in planting this vine, is so satisfied with the results as to quality and value, that he is now extending his operations. He has another small parcel ready for shipment and there is no reason why this plant should not be cultivated on a large scale by the Chinese.—*Straits paper.*

COLONISING AND PLANTING IN EASTERN PERU—AT THE HEADWATERS OF THE AMAZON.

(By an Aberdonian Pioneer.)

Denville, 5th March 1893.

As I expect mules down with provisions for us soon I am taking the opportunity of sending you a line to let you know how we are getting along on the Perene. It is now over four months since we came down here and although we are passing through the rainy season in a great measure unprepared, we are getting along wonderfully well. Our few colonists have got themselves well established with good houses up and are I may say fairly comfortable, but owing to the difficulty of transport, our greatest drawback has been the want of proper food.

You will be rather astonished to hear that we have had a lot of fever down here, myself getting a dose among the rest. It is however very simple and easily got rid of and no doubt when the place is more opened up and better food obtainable this will pass away.

Mr. Mackenzie wisely refrained from sending down more people this season as it would have been impossible to have fed them. With regard to my own work I cannot say that I have much to tell you. I have only had two and three men working with me, and these I employed cultivating a few acres and building. I find great trouble with the ants and will have to abandon the flat piece and clear virgin lands. They don't touch maize rice much, but yucca they simply devour. In this way of clearing we have done very little having arrived too late in the season but trust that this time next year will have a better show.

A new road is being made from the camp at Paucartambo down the side of the Perene, and a number of colonists are settling round there. I am afraid it will take a long time to complete and until it is finished we can never expect to make much headway here. If plenty of labour was at command it would not be a great undertaking, but as things are it will take some time.

The question of labour is going to be a very serious one, for finding plenty of work around Chanchamayo, Obolas don't care to come so far down except at greatly increased pay. In two or three years time when our coffee comes into bearing it will be a serious thing if we cannot find sufficient

labour to take our crop off. The Indians around here cannot be depended upon as they only work when the fit takes them and that is very seldom.

In my last letter to you I mentioned that I had written to Mr. Mackenzie re the introduction of coolies. He now informs me that this matter is receiving due attention in London. It is my most sincere hope that they may be able to carry it through successfully as it means a great deal to us.

I do not know what is to be done re an outlet for our produce, but I trust it will be by the Amazon. I intend visiting the Cascades a little later on to see what they are like and see the lands on the way down.

A considerable number of people keep coming into the camp, but I would like to get more Scotchmen who had a trifle of capital to form in a way the backbone of the Colony. I have not the least doubt there are plenty at home who would gladly come if matters were properly represented to them.

We are now in the height of the rainy season and it is not disagreeable to live in. We have mosquitoes, but they don't bother us much. Gnats are the trouble and just now they are terrible. One of my hands is breaking out into sores through them.

No doubt they will disappear as the country is cleared. Everyone suffers more or less from boils on their arrival, but that is good for them.

Taking everything into consideration I feel very hopeful of this scheme being a success. With the labour question settled I would have no hesitancy in taking up a tract of land myself and feel confident of success. Difficulties we will have and in a country of this kind things are not done in a day, but with a little bit of perseverance and pluck we will get over them.

I have been written to regarding "China Grass" (*Bohmeria Nivea*) and although I have found what I suppose to be it from description yet I am in no way certain of it.

We have had lots of tigers (jaguars) coming round us and some good specimens have been seen, but nothing of any size killed. We have plenty of birds but other game is scarce.

I can't say that I have seen many orchids that I consider good, but I have not seen many in bloom yet.

TEA AND EXCHANGE.

The following is the letter addressed by the Hon. P. Playfair to the Indian Currency Association:—

I offer you a copy of a calculation we have made showing the profits earned by the Joint Stock Tea Companies of Calcutta during the past and previous years.

It seems that on a capital of Rs2,58,61,033 a profit of Rs26,42,031 has been made on Revenue Account, or 10.1.5 per cent. Of this surplus 6½ per cent appears to have been distributed to shareholders.

At first sight this appears to be an excellent return to investors, until the question of depreciation by Exchange is considered. As investors in tea are almost exclusively British, who have either brought out capital or hope to return to England with their capital, any variation in the sterling value of these investments must be of importance.

Between 1st January 1891 and 1st January 1893 Exchange fell 20 per cent (from 1s 6 13-12 to 1s 2 23-32d. Bank Bills on demand) which means Rs1,72,206 of the above capital, while the profits of these two years amount only to Rs38,94,636, leaving a difference of Rs12,77,570, say 5 per cent which, if it cannot at once be described as loss, does not, at all events, warrant the distribution of dividends.

But for very handsome profits made on Duars Gardens this depreciation would have been intensified. And here we decry the undue (temporary) advantage that new comers may have over older producers, £10,000 spent in the Duars having produced a garden four times greater than that formerly obtainable for the same money invested in Assam. The ultimate result to the country cannot produce good if it kills out the old settlers.

It may interest you to review the result of each district which are as follows:—

Aseam—Depreciation at 20 per cent, R17,45,585, profits 1891-92, R10,08,488, Dr. R7,37,097.

Cachar and Sylhet—Depreciation at 20 per cent R13,46,974, profit 1891-92, R10,01,975, Dr. R3,41,999.

Darjiling—Depreciation at 20 per cent R16 07,246, profits 1881-92, R8,08,846; Dr. R7,98,400.

Duars—Depreciation at 20 per cent R4,72,400, profits 1891-92, R10,72,327. Cr. R5,99,927.

Total—Depreciation at 20 per cent, R58,72,206, profits 1891-92, R38,94,636, Dr. R12,77,570.

Am I right in drawing the conclusion from these figures that Mr. Bell and the other Darjiling Planters with him were deceived in the notion that low Exchange was a benefit to capitalists having investments in tea?

The average value per lb. of tea you will observe was R2 higher than that of the previous year. But I find that the value of tea across in London between the months of August and January was 2d per lb. above the quotations of the previous year, which seems to go far to account for the better profits. Ocean freights, too, were abnormally low, as you know.—*Pioneer*.

[The position here maintained has been successfully overthrown by writers on the other side.—Ed. T.A.]

COFFEE PLANTING IN THE STRAITS SETTLEMENTS.

NEWS OF OLD CEYLON RESIDENTS.
(From an Ex-Ceylon Planter's Letter.)

Kuala Lumpur, Selangor, June 3rd, 1893.

I send you a list of the Liberian coffee estates which I have taken from our "Government Gazette." The planters seem to be having a good time of it with no difficulties to contend with. I wish however there were more of them.

The chief difficulty here is for young men to find a home to learn planting previous to investing their capital. In Ceylon of course it is different, and every new arrival has someone to go to. The British Resident (Mr. W. H. Tracher, c.m.c.) as you are aware visited the coffee districts of Ceylon some years ago and takes a great interest in all matters connected with agriculture.

My own opinion as an old planter is that there is not a safer investment in the Straits now that the pioneering difficulties are over, than coffee. In looking through the Singapore Share List there appear very few investments worth having. Of course people say that coffee is at a very high price now, but what would it be by the time a new estate came into bearing.

That is a question nobody can answer, but one can fairly say there will always be a heavy demand for tea and coffee.

The railway is being gradually extended into the interior and will shortly be finished to within easy distance of our future sanitarium, not quite a Nwara Eliya, but that we no doubt shall discover as the extension proceeds.

Ex-Ceylon residents here, you will be glad to learn are well and flourishing, our State Engineer (Mr. C. E. Spooner) is busy—Mrs. Spooner leave for England shortly on a visit to her family.

Mr. and Mrs. Vane and Miss Watson from Sungei Ujong have been welcome additions to our small community.

Mr. E. A. Watson has returned from the jungle very seedy but is now much better.

Mrs. Venning returns from Europe at the end of the year.

Messrs. French, West, Carey, Cuming, Gatehouse and Christoffelsz seemed to have settled down in their new home.

Our first Agri-Horticultural Show is arranged for next year and we all hope it will be a success and benefit the country.

I notice the Sarawak Government are erecting a permanent orchid house. It is an excellent idea as Borneo is the home of orchids and the hunting

ground of all European orchid collectors. I forget if Dr. Trimen has anything of the kind at Peradeniya or Hakgala.

A good deal of interest is being displayed in the expected arrival of the Australian griffins. The system in force here in connection with them is briefly this. A number of residents subscribe \$200 each and a batch of horses are sent for from Australia. On arrival each horse is numbered and drawn for by the subscribers. The Selangor Turf Club give a prize at their meeting which greatly adds to the interest of the thing.

COFFEE ESTATES.

The following return may be accepted in evidence of the bona fides of the planting community in the Kuala Lumpur District:—

Situation.	Name of Estate.	Proprietors.	Managers.	Total.	Average.	Remarks.
Batu 3rd mile...	Batu	H. Huttenbach	H. Huttenbach	500	120	
K. Lumpur	Selangor	H. Huttenbach The Salangor Coff Co. Ltd.	A. K. Hampshire E. V. Carey and R. Gatehouse	72	50	
Setapak	New Amherst	21, Mincing Lane, E.C.		1,000	200	
Setapak	Hawthornden	F. A. Toynbee T. Sword A. Currie W. Douglas (Executors)	F. A. Toynbee L. Dougal (Assr. Manager)	500	200	350 acres will be under cultivation end of 1893.
Setapak	Lincoln	Do.	Do	500	125	
Setapak	Aberscross	G. Murray Campbell	R. S. Meikle	400	110	
Setapak	The Mount	C. & J. Gordon	C. & J. Gordon	200	75	
Setapak	Wardieburn	C. & R. S. Meikle	Glasford	560	133	
Setapak	Batu Caves		C. Meikle		184	
Batu*	Weld's Hill				75	
Batu*	Kent					
Setapak	Kiang Gates		M. A. Stonor	300		

Further applications by Messrs. Toynbee & Co. for 500 acres, and by Messrs. Murray Campbell and M. A. Stonor for 200 acres each, have been granted during the past year. The land applied for is in each case adjoining the present estates of the respective applicants.

The road through Ulu Gombak now in course of construction will open up land worth inspection by intending planters.

* Returns not to hand. Kent estate is newly opened. Weld's Hill is fully cultivated.

EUROPEAN IMPORT DUTIES ON TEA.

Among the new features in the recently issued report of the Bengal Chamber of Commerce for 1892-93 is an appendix showing the various customs duties that govern the import of tea into European countries. Of these the highest appears to be that of Portugal where the import duty is equal to an English equivalent of 1s 11.5d per pound. Switzerland comes lowest with a duty of only 1.7d per pound. In Russia the duties are enormously high, being in the case of tea imported into any European port or over any European frontier, 1s 10.2d. On tea imported through the Irkutsk custom-house, by way of Siberia and the steppes, the duty is 1s 1.7d; but on what is known as brick tea so imported the duty is only 2.6d. Such tea as is brought into Russia, accompanied by accredited certificates showing it to be of Russian preparation, is allowed to enter on payment of 10.6d per pound. In England, Denmark, Germany, and Spain the scale ranges from 4d to 6.5d. In Greece, Italy, and Austria-Hungary, the duties are very heavy.—*Pioneer*.

SELANGOR.

The coffee planters have been complaining a good deal lately about the damage done by Chinese wood cutters on their estates. The planters say that where the sun finds its way in through the jungle the soil is materially injured for coffee planting. The wood-cutting men do not as a rule have much respect for the rights of private property, and recently four offenders were fined \$10 each for cutting timber on the Mount Estate.

Mr. Raymond left yesterday for Perak where he intends to reside. He has left many friends behind him who will be glad to hear of his success in that State.

Mr. Venning, Government Treasurer of Selangor, who has this year been appointed Visiting Commissioner to the Keeling and Cocos Islands, left Kang today for Singapore, from which port he leaves by H. M. S. "Pigmy" for the Islands. *Straits Times*.

CINCHONA, &c., REPORT.

(From the *Chemist and Druggist*.)

LONDON, June 1.

CINCHONA.—The fortnightly bark-auctions held on Tuesday were of fair extent, the ten catalogues comprising:—

	Packages	Packages
	811 of which	764 were sold
Ceylon cinchona	811	764
East Indian cinchona	1185	1038
Java cinchona	24	—
W. African cinchona	48	45
S. American (Calisaya) cinchona	185	185
do (Pitayo), &c.	618	463
	2,931	2,498

The barks offered showed no feature of any importance excepting that presented by the inclusion and the partial sale of 648 bales South American barks imported over ten years ago, most of which were now offered without reserve. There were also a few lots of common Ceylon barks seven years old, for which very low prices were accepted. The parcels generally were of medium quality with a fair sprinkling of Officials and a few good ledgers. The tone throughout the auctions was somewhat wavering, but upon the whole prices were lower, and sale may safely be said to have been one of the worst for sellers which have ever been held. The average unit probably did not exceed 7d per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works	146,572
Agents for the Auerbach works	85,995
Messrs. Howard & Sons	62,943
Agents for the Frankfurt-o/Main and Stuttgart works	40,913
Agents for the Brunswick works	35,636
Agents for the American and Italian works	35,149
Agents for the Paris works	29,412
Mr. Thomas Whiffen	18,824
Sundry druggists	61,800
Total quantity sold	537,741
Bought in, or withdrawn	97,572
Total quantity of bark offered	628,316

QUININE.—Business is practically at a stand still in this article. German second-hand bulk can be had at 9d per oz. from the second-hand; and the manufacturers' quotations are as follows:—Howard's vials 1s 2d to 1s 3d; tins 1s 1d to 1s 2d; Whiffen vials 1s 2d; tins 1s Pelletier vials 1s 5d; Milan vials 1s 1d; tins 11d; Zimmer, Jost, Auerbach and Mannheim tins 11d; Brunswick tins 10.4d per oz.

CEYLON PLANTERS IN NORTHERN INDIA.

(From an *ex-Ceylon Planter*.)

One of our largest Companies in Sylhet is now managed by an old Ceylon planter, Mr. E. Todd Naylor, formerly of Haputale. If you want a few facts about temperature it was 103° in the shade of my bungalow verandah a month ago, and it is now 93°—too hot to make writing pleasant!

NATAL TEA.

THE SEASON'S PRODUCTION.

Mr. G. W. Drummond, of Kearsney sends us the following special Natal tea report:—We have now arrived at the end of the tea season. On the whole it has been a good one. The outturn for this factory will be between 380,000lb. and 390,000lb., but the exact figures cannot be obtained for another week or 10 days. This means an increase of 30,000 lb. on our original estimate, and an increase of over 100,000lb. on the total outturn of last season. We are glad to know that the Clifton and Nonoti estates have also done well, and made a substantial increase on their last year's crop. The total outturn for Natal was estimated at the beginning of the season to reach 560,000lb. and we can now safely say that this has been more than accomplished. In fact, we should put the tea crop of the colony during the past season, 1892-93 at about 580,000 lb. in round figures.—*Natal Mercury*.

"PICKINGS" WITH A LOCAL APPLICATION.

The Department of Agriculture of New Zealand have offered a series of prizes for the best COLLECTION OF NOXIOUS WEEDS found growing in the colony, properly mounted, with scientific names attached together with the name of the place where gathered. Two prizes are also offered for collections of insects injurious to vegetation. There is an instance how a properly organized Agricultural Department could gather the information that is necessary for the study of the means whereby the interests of the agriculturist may be safe-guarded. It is a crying shame that the plea you have so often put forward for a properly organized Agricultural Department in this chief of the British Crown Colonies has found no commendation among those in authority.

Mr. R. Atherton, to judge from his contribution to the last number of the "Magazine of the School of Agriculture," has not lost faith in SUGAR CANE CULTIVATION in Ceylon. I wonder how many supporters he could count in his belief in the cane as a remunerative crop, when it is remembered how many thousands of pounds were lost and how many planters were ruined in the attempt to grow it. Your "Directory" account of "Sugar Cultivation in Ceylon" is just a tale of woe. Even in the exceptional case of Baddegama you note that the saccharometer shows a density only of 9° against 11° and 12° in other sugar producing countries. Mr. Atherton, however seems to hint that the right sites were not chosen for sugar planting, and urges that further experiments—Government, if not private—should be undertaken. Our present Governor himself is said to have expressed his surprise that the cane was not cultivated in Ceylon.

The "Planters' Monthly" of Honolulu mentions cases of 6, 7, 8, and even 10 tons of SUGAR being produced per acre, as showing what good cultivation can accomplish in exceptionally fine spots. The average yield, however, it puts down at 4 tons to the acre,

and says that this may be taken as the only safe basis when calculating the profit attending investments in the sugar business. And even to obtain this, we are told, requires not only good field work, but the highest skill in every department in the mill. The fact is that with the good prospects held out by tea, cocoa and coconuts, there are few capitalists that will venture to invest in sugar, especially with the bad record it has in Ceylon.

The German Experimental School has during the past year been inquiring into the action of KAINIT and other substances on manure. Kainit, it may be mentioned contains about 22 per cent of sulphate of potash, with sulphate of magnesia, chloride of sodium, and chloride of magnesium. Hitherto its chief value was held to consist in the potash it adds to the soil, but now well-known chemical authorities are agreed that it unites with the ammonia in manures, and that it also has another valuable quality of gathering additional ammonia,—most probably from the atmosphere. The following is the result of the German investigations: one per cent of lime caused a loss of 9.78 per cent of the nitrogen of dung; one per cent of plaster resulted in a loss of only .34 per cent of nitrogen; one per cent of sulphate of magnesia saved all the nitrogen, and attracted an addition of 5.06 per cent of ammonia; lastly one per cent of kainit saved all the nitrogen, and added 7.97 per cent to it. It is suggested that one pound of kainit should be either spread, or sprinkled after dissolving, in each stable or byre, to retain the nitrogen of manure. In addition to its preservative influence, kainit has also great purifying powers, and its free use is advised in horse and cow stables, muck and compost heaps, pig pens and chicken houses, as well as in closets, as it would not only keep down all offensive odours but would also promote the health and comfort, and lessen the mortality both in the dwelling and the stable. It is further advised, in order to make a complete and evenly balanced manure, that in addition to the kainit, dung and compost heaps should get half a bushel of bone dust to each cart load of manure.

THE ISLAND OF JAMAICA.

In his report to the Colonial Office on the Jamaica Blue-book for 1891-92, Sir H. A. Blake, the Governor, states that since the closing of the Jamaica Exhibition on the 2nd of May, 1891, many applications have been made for information about the island of Jamaica and its possibilities, and it may not be amiss to supply some general information that may be useful to inquiring capitalists. The island of Jamaica contains about 2,683,000 acres, of which about 413,000 are flat and the remainder hilly. There are 640,000 acres under cultivation, or about one-fourth of the whole; but if there is deducted from this the 372,000 acres in common pasture, the amount of actual cultivation is reduced to about 268,000 acres or one-tenth of the total. Along the centre of the island run ranges of hills attaining an elevation in the west of 1,800 ft. and in the east of 7,500 ft. There is a great variety of soil and climate, and every tropical product, save, possibly, those requiring the streamy swamps of tropical South America can be grown, while many of the products of the temperate zone can also be successfully cultivated. Lying as the island does with its longer axis from east to west, the north side, exposed as it is to the constant north-east trade wind, is several degrees cooler than in the south; but all round the island a strong sea breeze blows during the day, which is replaced at night by a cool land breeze blowing down from the hills. The climate is extremely healthy. The average death-rate of 22.4 per thousand hardly conveys a true impression, the mortality among negro children here, as elsewhere, being very high as compared with the children of the Caucasian races. The climate is particularly suitable for lung complaints and nervous affections. There are several mineral springs of great medicinal value. The temperature of the spring at Bath in St. Thomas-

in-the-East is 126° F., and that of Milk River Bath, in Oclarendon, 92° F. These springs are efficacious for gout, rheumatism, paralysis, &c. "The Jamaica Exhibition of 1891 was," says Sir Henry Blake, "conceived and carried out as an advertisement, a stimulus, and an object lesson. It was carried through without any interference on the part of the Government, the proposal being secured by private guarantees which were given to the amount of £27,000. It was opened on the 27th of January and closed on the 2nd May; during that time it was visited by 302,831 persons. The full result of the exhibition has not yet been shown, and it will afford a measure of the capacity of the people for improvement, but already there are gratifying evidences that the efforts of those who brought about the exhibition have not been in vain. There has been a considerable sale of improved sugar mills for small cultivators. Dairy farming has been started, and machinery imported similar to that exhibited, the beginning of what may be an important industry, as we import annually over 720,000 lb. of butter. Pottery works have been begun, as it was discovered that we have in Jamaica as good clays for the purpose as can be procured in England, and there had been generally excited an inquiring interest in possible additions to the products of the island that must bear fruit in the near future. While Great Britain, the United States, and Austria, Prussia, Germany, and Italy were represented the principal exhibitor was Canada, and the Dominion has laid the foundations of increased trade with Jamaica that already begins to show signs of expansion. The exhibition closed with a net deficit of £28,465 to meet which £19,000 has already been paid up by the guarantors."

FOUR WORDS IN COMMON USE.

Probably no four words in common use have become more tangled and confused in the minds of learned and unlearned than *cacao*, *coca*, *coco*, and *cocoa*, Dr. Eugene Murray Aaron points out that even critics themselves stumble in attempts to clear away the confusion, and he mentions that the four distinct products to which the names belong—the first and last of great importance—are commonly mixed under the one term *cocoa*. These products are: 1. *Cococa* (*Theobroma Cacao*), the chocolate berry tree. This is an evergreen growing from 15 to 45 feet, a native of tropical America but now become wild in Africa. It bears pointed pods, each of which contains a number of the nutritive seeds. From the seeds are derived "cacao nibs," "chocolate (the most important substance)," "cacao" (erroneously called *cocoa* in English countries), "broma," "cacao shells," and "cacao butter." 2. *Coca* (*Erythroxylon Coca*), the coca leaf bush. This shrub is found in the Andes, and is famed for the extraordinary stimulating properties of its leaves, which are known as "spadic" as well as "coca" and contain two alkaloids—cocaïn and hygrin. 3. *Co. o.* (*Calentum esculentum*, et al.) the coco roots. The name is properly applied, only to the tubers of several allied species of plants, which furnish a starch-laden food in tropical countries. 4. *Cococa* (*Cocos nucifera*), the coconut palm, which yields the well-known hard-shelled fruit, together with valuable fibre. —*Straits paper.*

[No distinction is made between the product of the chocolate plant, namely "cocoa" and the palm fruit in the above, so far as spelling goes. As it is impossible to get Mircing Lane to give up the use of "cocoa" for pods and nibs, to make some distinction, we on the suggestion of Dr. Trimen, have dropped the "a" in the palm's name making it "coconut" which is more in accordance with the botanical name *Cocos nucifera*. This has been followed, we are glad to see, by the Kew authorities, by *Nature* and other London papers. We seldom or never hear of "coco roots." —Ed. T.A.]

PLANTING AND MINING IN PERAK STRAITS SETTLEMENTS.

The Administration Report for 1892 of the British Resident, Mr. F. A. Swettenham, is a very able State Paper and affords a great deal of information under every head. It covers some 22 pages, besides 30 pages of statistical appendices. We are chiefly interested in the Planting and Mining portions, though it is satisfactory to note the flourishing state of the revenue as shown in the opening paragraphs:—

The Revenue of Perak for the year 1892 amounted to \$2,689,565, a sum \$331,593 above the Estimates and \$364,584 more than was received in 1891. There are eight districts in Perak, and all of them except Selama share in the increase. The sources of Revenue are classified under fifteen heads, and all except three have realised more than was expected. The principal increases are Customs \$232,171, Interest \$46,384 and Land Revenue \$40,224. Licenses, Fees of Office, and Railway Receipts have failed to realise the Estimates by a sum amounting in all to only \$35,517. This year's Revenue exceeded the Expenditure by \$640,075.

LAND AND AGRICULTURE.

Under this heading we said:—The Land Revenue collected in 1891 amounted to \$92,603, whilst last year it gave \$152,900, an increase of \$60,297 over the revenue of the previous year and \$40,224 more than the estimate.

Within the last three years this area of cultivated rice land has been largely increased, new land opened and old abandoned fields re-cultivated, but it must be remembered that imported rice is cheap, that our agricultural population is small and the people are naturally lazy, while the fact that mining runs alongside of and often into padi cultivation, and is itself a far more lucrative and attractive pursuit, tends rather to reduce than increase the area of rice fields.

Of the old fields there is a far larger extent now under cultivation than was the case when the Residential system was first instituted, and this ground is being cultivated, not by new arrivals but by Perak Malays who for years have neglected to work on it. The principal causes of this improvement are the increased activity of European and Native Officers, the construction of new roads and the issue of orders by Government in 1890 regulating the times for clearing the fields and commencing planting operations.

In Krian and Lower Perak it is different. There large tracts of virgin forest have been converted into rice fields, plantations of sugar, pepper, coconuts and other tropical products, and even in the heart of Kinta, the principal mining district in the State, a good deal of successful planting has been done, mainly by foreign Malays.

The Government may fairly take credit for the fact that in Krian there are now 37,000 acres of rice, 23,000 of sugar, and 20,000 acres of fruit trees, indigo, nipah and other products, while the settlement of S'tiawan, in Lower Perak, alongside the Colony's territory at the Dindings, promises in time to become an equally successful agricultural colony. Whenever the Government is prepared to road and irrigate suitable land there will not be wanting colonists to work it, and the cultivation of rice can by this means be greatly increased, but this does not concern the people already in the State, and it is hardly likely that colonists will be induced to come and settle in Perak unless the terms offered are attractive and unless there is a strong probability that they will be able to better themselves.

People will give neither their labour nor their capital for the pleasure of living in a Malay State, however superior its administration. The fact that the leading stations and the public buildings are well kept and pleasant to look at will not greatly influence the padi planters of the coast, who may not realise the difference between a Protected and an unprotected Malay State. Twenty years ago Perak was not a pleasant place to live in, but I never heard of any number of the Perak people leaving it for the neighbouring British settlements.

The settlers we get now, whether from neighbouring States, from Sumatra, Borneo, Siam or other places, are only got with trouble and on the assurances of their friends that it is worth their while to emigrate to a place where they will be welcomed and where they are likely to live in greater comfort and make more money than in their native places.

EUROPEAN PLANTING: PEPPER AND COFFEE.

The pepper garden at Chigargala, in Kuala Kangsar district, undertaken with Government assistance, is now an assured success and a valuable property. It will export 200 pikuls this year and probably double that quantity next year.* Many other pepper gardens have been started in different parts of the State and all those that are properly cared for will succeed. The Waterloo Estate (about 300 acres of Arabian coffee) and the Kamning Estate, about the same quantity of Liberian coffee both belonging to European owners and under European management appear to be successful ventures.

Other Europeans have applied for and obtained blocks of land on very easy terms but they have taken no steps to plant. Why it is difficult to say; the soil is good, rainfall and water supply satisfactory there are excellent roads in all directions, even into the hills—constructed purely as an inducement to planters—rice is cheap and the price of labour, if high, is not prohibitive. This last is the only objection I know of, and I think the supply might be increased and the wage rate reduced if there were any extensive demand for Indian agricultural labour. I understand that at Waterloo both Chinese and Malays are employed and give satisfaction.

It is interesting to know that the coffee planted about fifteen years ago at Slim by Messrs. Smith and Innes, and abandoned for ten years,—though surrounded by thick jungle andalang grass, is still strong and healthy and bearing heavily; cocoa trees planted at the same time and place appear to be also doing well.

In 1891 the Government alienated 229 town lots and 4,192 acres of agricultural land. In 1892 the figures were—town lots, 476; agricultural land, 8,030 acres.

POPULATION AND IMMIGRATION.

Returns of Arrivals and Departures are kept only at the two principal ports of the State, Port Weld and Teluk Anson, and they show that the arrivals have exceeded the departure by 21,563, and the population of the State at the present time is probably not less than 235,000. The numbers and nationalities were as follows:—

District.	ARRIVALS					Total
	Europeans and Eurasians	Chinese	Malays	Indians		
Larut.....	1,021	30,213	5,293	8,330	44,857	
Lower Perak ..		21,108	6,860	3,597	31,565	
Total	1,021	51,321	12,153	11,927	76,422	
DEPARTURES						
Larut.....	940	22,496	4,811	7,447	35,694	
Lower Perak		10,585	5,605	2,975	19,165	
Total	940	33,081	10,416	10,422	54,859	

RAILWAY CONSTRUCTION.

To the existing eight miles of railway in Larut have been added another nine miles, constructed at a cost of \$308,965, while railway surveys have been carried north to Selama (another 18 miles) and east to Kuala Kangsar and Ipoh, 55 miles. On the Kinta Valley Railway, from Ipoh to Teluk Anson (50 miles), a sum of \$782,989 has been already spent (to 31st December, 1892,) and 30 miles will be opened to traffic

* NOTE.—One pikul = 1 cwt. 0 qrs. 21.333 lb. Three pikuls = 3 cwt. 2 qrs. 8 lb = 1 bhara 164.5th pikuls = 1 ton.

by the middle of the current year. The whole line is due to be completed in August 1894.

This line will do for the Kinta district what the Selangor Railway did for Kuala Lumpur, and I shall be disappointed if it does not yield a revenue of a quarter million of dollars, or about 12 per cent on the capital invested.

Lord Ripon has been interesting himself—much to Mr. Swettenham's satisfaction—in the question of Land Taxation and the promotion of Agriculture including the settlement of Agricultural Colonies. Mr. Swettenham reports:—

That at the two places where, in Perak, colonisation schemes have gone beyond the preliminary stage, and that is in Krian and S'tiawan, remarkable success has been obtained. The experimental stage has been successfully passed in the case of a Tamil colony established some years ago in the Krian district by Roman Catholic Fathers, and yet again in a smaller and more recent settlement of Christian Chinese under the Roman Catholic missionary of Tamping, Father Gazeau. Father Gazeau has been able to return the entire sum lent by the Government to assist him in introducing the colonists, who are now permanently settled, and engaged principally in the cultivation of pepper. There are still two other colonies in the experimental stage, one a Siamese settlement at Pondok Tanjong, under Mr. Oboomsai, and the other a Tamil colony at Tuluk Anson which my predecessor began, but declined to carry out in view of the expense of introducing immigrants from India.

THE CONSUMPTION OF TEA AND OTHER STAPLE DRINKS.

Under the above title, Mr. C. H. Denyer contributes to the *Economic Journal* for March an article dealing at length with the consumption of tea, which, he says, "has long been outstripping every rival, and it is very probable that we now drink even more tea than beer." In 1891 we used 5.35 lb. of dry leaf tea per head, which, converted into a beverage at the rough average rate of seven gallons per lb., represent an annual consumption of no less than thirty-seven gallons per head, as against twenty-nine gallons of beer, so that we are almost justified in calling tea the English national drink, the more so as we take as much of it as all the rest of Europe put together; while the fact that our colonists in Victoria manage to consume per head two and a half times as much as we do points in the direction of greater possibilities yet in store for tea in this country.

THE LITERATURE OF TEA.

The literature of tea is interesting and extensive, and Pepys, Waller, Pope, Swift Defoe, and Cowper all furnish apt references to the historian of its introduction. To confine ourselves as much as may be to its economic aspect, we find that the tea which was a new drink to Pepys in 1661, and of which the East India Company made the munificent gift of 2 lb, 2 oz. to Charles II. in 1664, was used as much as a drug as a beverage. However, the company determined to push its sale, and either the tea, or the porcelain cups which were introduced to drink it from became very fashionable by the end of the century; and this, notwithstanding the bitter complaints of such old-fashioned persons as Mr. Henry Savile, who complains of those who call for tea, instead of pipes and bottles, after dinner, a base unworthy Indian practice, and which I must ever admire your most Christian family for not admitting; . . . the truth is, all nations are growing so wicked as to have some of these filthy customs."

On the other hand, in the very same year (1678) a Dutchman, Cornelio Bontekoe, wrote his very popular and often translated *Traactaet van het excellenste Kruid Thee*. Tea, he said, was the infallible cause of health, and if mankind could be induced to drink a sufficient quantity of it, the innumerable ills to which man is subject would not only be diminished, but entirely unknown. Indeed, 200 cups daily would not be too much.

In 1731 the import of tea already amounted to 1,793,000lb, weight the duty on which produced a revenue of £358,000. Tea had been liable to a duty since 1660 when 8d. a gallon was charged on the infusion as sold in the coffee-houses, which was as Dr. Short says, "no small prejudice to the liquor, and inconvenience to its drinkers, for the excise officer was to survey it before any could be sold, and was not to survey it above once or twice a day." This primitive method of levying the duty soon gave place to a tax on the dry leaf, but the excessive rate charged, while it hardly availed to check consumption, caused vast loss to the revenue. One of the chief values of tea was considered to lie "in the fact that the great revenue it pays the Crown lessens the general taxes to the poor," who did not then drink it; a doctrine which sounds strange beside the statement of the late Chancellor of the Exchequer that tea is now the one article by which many of the poor contribute to the revenue. So absurdly high, however, was the duty fixed in 1732 that the duty paid import fell from 1½ million lb. in 1731 to ½ million in 1735 while even the revenue was reduced one-third of its former level. Pelham took off half the duty in 1745, and the consumption of tea rapidly spread through the middle classes.

SMUGGLING AND ADULTERATION IN THE EARLY DAYS.

Smuggling and adulteration, however, render the official returns of consumption almost valueless till within quite a recent period. The proportion of tea smuggled into the country may be inferred from the fact that the reduction of duty in 1746 trebled in one year the number of pounds weight charged, and a similar rise took place between 1783 and 1785, when one of Pitt's greatest fiscal reforms increased the duty paid import from 5,800,000lb to 16,300,000lb a year.

Nor was the adulteration much less rampant, for Dr. Short, after seriously discussing the question whether a dealer who bought his tea from smugglers was an honest man, gives a long list of chemical tests for different kinds of adulteration, both English and Chinese. He complains that so great was the demand of the Chinese for terra japonica wherewithal to dye tea green, that the price of the said japan earth had risen from 4d to 18s a pound.

When in the last quarter of the Eighteenth Century, tea became a regular drink, even among farm labourers (*vide* Arthur Young's "Six Months' Tour," and Eden's "State of the Poor"), and at the same time the heavy duty kept the price high, a committee of the House of Commons discovered that 4,000,000 lb. of so-called tea were annually manufactured from sloe, liquorice, and ash leaves, and this at a time when the whole quantity imported, duty-paid, was only 6,000,000 lb.

The lessons taught by Pitt's early reductions of taxation were forgotten amid the pressure of the French wars. High duties again encouraged adulteration, and a Treasury prosecution in 1828 revealed an extensive manufacture of green "tea" from white and black thorn leaves dyed with white lead and verdigris. The Chinese, too, were not far behind in the arts of adulteration, for from an interesting paper read in 1839 by Dr. G. G. Sigmund before the Royal Botanical Society we learn that the remission of tea duties in the United States in 1832-33 caused a great and sudden demand for green tea at Canton, a demand which was met, in the absence of a supply of the genuine article, by refining a great quantity of damaged black leaves, and dyeing them green with turmeric and Prussian blue.

In spite, however, of adulteration and high prices, the consumption increased rapidly, so that in the first five years of this century it reached nearly 25 million lb. duty-paid, *i.e.*, 1½ lb. per head per annum. It appears that the further increase of taxation due to Napoleon's victories probably checked the consumption, and certainly increased smuggling; so that it was not till 1835-9 that the average annual consumption for a quinquennium rose from a constant 20 or 21 ounces to 23 ounces per head.

In 1834 the monopoly of the East India Company ceased, and an experiment was tried in the shape of differential duties of from 1s 6d to 3s per lb. for various kinds of tea. The experiment failed, for the Custom House officers were not skilled enough in tea-tasting, and a fixed duty was reimposed at the rate of 2s 1d per lb.

In 1820 came the war with China and 5 per cent extra duty. The price rose greatly, and the import fell from 40½ millions in 1838 to 28 millions in 1840. This war, however, opened the treaty ports, and prices rapidly fell to a far lower level. In the quinquennium from 1840 to 1844 the annual consumption was still only 11b. 6oz. per head; but lowered prices, and the improving condition of the country after Peel's reforms raised it between 1845 and 1850 to 11b. 11oz. The duty fell to 1s 10d in 1853, and to 1s 6d in 1854. Then the Crimean War raised it to 1s 9d, but it fell again to 1s 5d in 1857, and to 1s in 1863. This last reduction Mr. Gladstone declared to be a "final measure" yet two years later he again reduced it to 6d, while in 1890 it fell to 4d. Each reduction caused the consumption to leap up. From 21 lb. per head in 1852 it rose to 2 lb. 11 oz. in 1862, to 4 lb. in 1872, to 4 lb. 11 oz. in 1882, and to 5 lb. 5 oz. in 1891.

THE RISE OF THE INDIAN TEA INDUSTRY.

But we must now consider a new and most important factor in the tea supply. Just at the time when Dr. Sigmond wrote his paper on tea, a series of most interesting experiments in tea culture was being brought to a successful issue in the Upper Assam.

In 1763 Linnæus received the first living tea plant that had been brought to Europe, and recorded in his diary that he looked "upon nothing to be of more importance than to shut the gate through which all the silver went out of Europe." Tea-planting was accordingly enthusiastically tried in Southern France, but hopelessly failed. In India, however, botanical explorers had discovered that the tea plant, only found in a cultivated state in China, was indigenous to Upper Assam; the Indian Government did its best to encourage the production of British-grown tea, and in 1838 the first samples were sent home. Next year eight chests were sold in England; and, although the quality was not very good, the attraction of novelty made the tea sell at from 16s. to 34s. per lb. At about the same period the Dutch began tea-planting in Java, and the first crop fetched fancy prices in Amsterdam.

In 1839 the Assam Company was formed, and in spite of heavy initial losses owing to difficulties encountered on every hand, the company began to pay a dividend fourteen years later. In a few more years rival companies started in all suitable and many unsuitable parts of India. The fittest survived, production grew apace and in the last twenty-five years Indian tea has largely driven its Chinese rival out of the market and revolutionised the trade of the East.

CEYLON TEA.

Presently came the collapse of the coffee planting which had, since the emancipation of slaves in the West Indies, given prosperity to Ceylon. A parasite attacked the coffee-plant, and could not be extirpated. Many of the planters were absolutely ruined, but the rest grubbed up their coffee trees and tried tea instead. Their success has been phenomenal. In 1875 they only exported 282 lb., in 1884 they supplied 1 per cent. of the import into England; in 1885, 2 per cent.; in 1886, 3 per cent.; in 1887, 7 per cent.; in 1888, 10 per cent.; in 1889, 15 per cent.; while in 1891 no less than 25 per cent. of our home consumption came from Ceylon, and for it probably more than £2,000,000 was paid to the planters in that island. In this year, 1891, it appears that, for the first time, the consumption in England of Ceylon tea even exceeded that of Chinese. Of course the Indian trade, though of slower growth, is much larger than that of Ceylon, supplying, in 1891, 49 per cent. of the total English consumption.

THE DECLINE OF THE CHINA TRADE.

On the whole, we find that China and Japan tea has shrunk from 97 per cent of the total in 1865, to 49 per cent in 1887, and 27 per cent in 1891, showing a great actual as well as proportional decline. Now the principal reason for this substitution of Indian for China tea is the greater strength of the former, a fact which has much exercised the mind of the Chancellor of the Exchequer, for, previous to the last reduction of duty, the revenue from tea had lost all its elasticity. The Commissioners of Customs in their report for the year ending March, 1889, went fully into the matter, and assign several reasons for the decline of the Chinese tea in public favour. There are heavy export taxes in China-Chinese tea, forced down in price, has deteriorated in quality. Its sale has not been pushed with the extraordinary energy put forth on behalf of its rival, and much of it has been diverted to other countries where it is more appreciated. But by far the chief reason is that it is not nearly so strong as either Indian or Ceylon teas, for while 11b. of Chinese gives, say, 5 gallons of infusion, 11b. of Indian gives 7½ gallons. This proportion given by the Commissioners in the report referred to, is accepted in the trade as practically correct, and corresponds with the results of my own experiments.

When we add this consideration of increased strength per pound to the vastly increased weight consumed some idea may be gained of the quite wonderful way in which tea is gaining ground in this country.

Tea and sugar won their way to our homes even when duties were excessive and the price enormous, but of late years not only have duties all but disappeared, but the decline in first cost has been most marked. In 1887 the Chancellor of the Exchequer stated that whereas the average wholesale cost (apart from duties) of a pound of tea and a pound of sugar was 1s 10½d in 1866, it was only 1s 7½d in 1876 and 1s 1½d in 1886, and since then the price has still more rapidly fallen.

EAST END PURCHASES OF TEA.

A large tea dealer tells me that some forty years ago when he went to gain retail experience in a Tottenham Court Road shop, one of his regular weekly occupations was to make up 500 ½lb of brown sugar, and 500 ½oz of tea, these being the quantities sold for 1d. Now, a pennyworth of sugar is ½lb of lump sugar, and a pennyworth of tea is 1oz of strong Indian tea. My informant states that in Whitechapel and similar districts the demand for "pen'orths" of tea and sugar is enormous. The factory girls have the teapot by the fire all day, and it is very common for the same girl to come in five or six times a day for a "pen'orth" of tea and a "pen'orth" of sugar. They insist on having the strongest Indian tea, notwithstanding the serious nervous and digestive evils which medical experience shows to result from such excessive tea drinking.

Of Indian teas Darjeeling is the finest. It commands a high price, and, having a very marked and delicious flavour, is used for mixing with the less tasty China teas to retail as a high quality blend. Assam is very strong, has a marked and peculiar flavour, and is used for commoner blends. South Indian and Ceylon teas are strong, but less marked in flavour, and are largely sold unblended.

TEA AND THE CONSUMER.

It is to be feared that the average Englishman is a very bad judge of tea. His sole criterion of its quality is its colour and strength; its delicate flavour he draws in sugar and milk. These latter are not to be despised, for they constitute no inconsiderable portion of his food; but they certainly help to put him at the mercy of the tea dealer. Strong cheap teas (and cheap teas are now as a rule the strongest) have taken the place of the older and weaker Chinese blends. The consumer gets plenty of flavour for his money, but of real quality and price he is a bad judge. I hear, on good authority, that one of our largest firms of tea retailers, who, before the reduction of

the duty, were selling a certain brand of tea for 1s 6d., are now retailing the same article, though it costs less than before, at 1s 9d., and the public is delighted with it. Yet there are some connoisseurs, and the best Chinese teas would. I am assured, easily command 3s per lb. in the wholesale market, not to mention the sale in August, 1891 of a special consignment of Golden Tip Ceylon tea at thirty-five guineas per lb. This ridiculous price was merely the result of a vulgar advertising trick.

THE EFFECT OF SIR ANDREW CLARK'S ATTACK.

Without for the moment considering the merits of tea as a national drink, we may note that there is no doubt that the chief reason why tea has supplanted coffee in this country is our English impatience of the arts of cooking, coupled with the comparative ease with which tea can be prepared for use. Yet, easy as the process is, it is rarely properly carried out. Our favourite beverage is left far too long on the leaves, with the consequence that not only is there extracted its aromatic essential oil, "theine," but also that other and distinctly harmful ingredient, "tannin." This latter is present in very large quantities in Indian and Ceylon teas and many doctors have spoken strongly as to its effects on the nervous and digestive systems. Sir Andrew Clark, in a recent lecture to the students of the London Hospital, speaks thus:—"Indian tea has become so powerful in its effect upon the nervous system, that a cup of it taken early in the morning, as many people do, so disorders the nervous system that those who take it actually get into a state of tea intoxication, and it produces a form of nerve disturbance which is most painful to witnesses."—*H. and O. Mail.*

THE COCONUT INDUSTRY.

Ever since the cultivation of tea became an assured success in this island, the tea planters have been from time to time warned against the imprudence of putting all their eggs in one basket, and they do not deny the wisdom of the advice, although few of them seem to show much inclination to act upon it; but while every one from the Governor downwards (in his Message on the abolition of the paddy-tax) believes, in theory at least, in the imprudence of relying with too much confidence on the permanence of the prosperity of the tea industry, nobody, at the same time, seems to think it necessary to suggest the making of some provision against a possible collapse of the coconut industry. Yet the warning does not seem to be less needed in the latter case than in the former one. It has been lately discovered that there is in this island a larger extent of land cultivated with coconuts than with any other product, and the coconut planters—for some reason which they perhaps could not themselves very well explain—appear to be gratified at the discovery; but the circumstance of there being in this island more land cultivated with coconuts than with any other product is all the more reason why the coconut planters should take timely precautions for letting themselves down easy in case there should be a collapse of the industry on which they are dependent.

Should the cultivation of tea ever cease to be a generally profitable business in this island, it is probable that the decline of the industry will be brought about by overproduction, and not by any blight affecting the tea plant. As coffee had, previously to its failure here, failed in Guiana and in some of the islands of the West Indies, its being affected here by some fatal blight was a calamity to be expected and even if that had not happened, the coffee estates must in course of time have ceased to yield profitable crops in consequence of the exhaustion of the soil and of the vitality of the coffee bushes being impaired by old age; but there is no reason to anticipate a similar failure in the case of the tea plant because it has been cultivated for hundreds of years in China and Japan without being affected by any fatal blight or showing any symptoms of decrepitude, and experience in this

country has proved that when it is abandoned for many years it can hold its own against weeds and jungle vegetation in the struggle for existence. But the coconut palm has not everywhere shown a similar exemption from disease, nor is it, in this country at least, similarly capable of existing independently of the care of man. Coconut trees have been affected by fatal disease in the West Indies and Burma, and in this country when a coconut garden is abandoned for some years and allowed to be overrun with jungle growth, the trees present a sickly appearance, cease to bear and by degrees die out. We have no desire to diminish by evil forebodings the hopes which have been raised by the present prosperity of the coconut industry, but it would be foolish to ignore the possibility of the failure in this country from natural causes of a tree which has been proved by experience to be liable to fatal disease in other lands, and which has also been proved by experience to have too delicate a constitution to be capable of thriving long in this country when left entirely to nature. It is not likely that the coconut industry will ever become so unprofitable through overproduction as to cause many acres of coconuts to be abandoned, as may possibly happen in the case of tea; but it is unwise to be too confident that a tree having so many natural enemies as the coconut palm will continue in this country to be as exempt for all time to come from fatal blights as it has been in the past.

The recognition of the possibility of a failure of coconuts needs not have the effect of checking the extension of their cultivation, but it is a reason for endeavouring to grow other products in combination with them. In some cases tea has been planted among coconut trees, and the experiment seems to be more successful than similar attempts with cinnamon and coconuts have generally been; but there is quite enough of tea planted in Ceylon already, and it would therefore be advisable to try something else as an auxiliary to coconuts. The African palm oil tree thrives well in this country, and when planted among coconuts, it seems neither to injure them nor to be injured by them. Being a jungle tree, it is not so likely to be affected by disease as a tree which can thrive only in a cultivated state, and palm oil is more easily made than coconut oil. The value of palm oil is about the same as that of coconut oil, and as the United Kingdom imports about six times as much palm oil as coconut oil, there would not be much likelihood of the market for the former ever being swamped by overproduction.—Ceylon "Catholic Messenger."

TRAVANCORE TEA.

(From *Patry and Pasteur, Limited.*)

May 31st, 1893.

Prices have ruled easier for all classes, owing to the large supply of similar quality from Ceylon.

COFFEE LANDS IN MEXICO.

During the past twelve months, the Bureau of American Republics is informed, more than a million acres of coffee lands in the State of Vera Cruz, Mexico, have been sold to purchasers of various nationalities, including Americans, Germans, Frenchmen, Englishmen and Belgians.—*American Grocer.*

REJECTED TEAS FOR CANADA.

It seems that for some time Canada has been made the dumping ground for all teas rejected by the United States and English tea inspectors. During the past ten days the tea inspectors have rejected some 4,200 packages of Pingsucys. It was the vilest kind of stuff, and the arbitrators at New York refused to allow it to enter there. It is understood that it is the purpose to also throw these teas on the Canadian market. The Minister of Finance's attention was drawn to the matter a couple of weeks ago, and it is imperative in the interests of the trade that some stringent measure should be taken to prevent a continuance of the pernicious custom.—*Canadian Grocer.*

MEXICAN COFFEE.

"You have no idea of the fineness of Mexican coffee," said Senor Gonzales at the Continental. "Those who don't know may talk about Java and Rio and mixtures of these with any other coffees, but they all fall into disrepute when the genuine Mexican berry has been tasted. Very little coffee has been marketed at home, and sells at 39 cents per pound just from the tree.

"There are some varieties of coffee there that retail at \$1 per pound. This is all used by wealthy Mexican families, and the use of coffee is universal in that country. Thousands of acres of the finest coffee lands can now be purchased at prices ranging from \$2 to \$5 per acre. The title is secured from the Mexican federal government on easy terms. Trees bear a half crop at three and a full crop at four years of age. Three pounds to the tree is an average yield, although many trees bear from five to six pounds. An acre of land will support about eight hundred trees, and their average life is about sixteen years. Syndicates will own all these fine coffee lands inside of two years, and they cannot then be purchased at any price."—*St. Louis Republic.*

TEA AND EXCHANGE.

In our last issue we published a letter addressed by the Hon. Mr. P. Playfair to the Indian Currency Association on the subject of "Tea and Exchange." Mr. Playfair has made a calculation of the profits of the Joint Stock Tea Companies of Calcutta during the past and previous years. He draws from his figures the conclusion that "Mr. Bell and the other Darjiling planters with him were deceived in the notion that low exchange was a benefit to capitalists having investments in tea." His remarks are, however, pervaded by a fallacy which is common among officials and others who do not take a business view of such matters. His letter betrays a confusion of ideas which it is to be feared is not altogether absent from Viceregal circles. The commercial value of a property is not what it cost originally, as Mr. Playfair seems to think, but what it is now worth to its present owner or what it would be worth to a purchaser, as a going concern. This depends upon results as shown in the balance struck in the profit and loss account. In the case of a public company the public estimation of its merits is indicated by the price of the shares. If it earns good dividends its shares rise in value, and *vice versa*. The profit and loss accounts of the Tea Companies alluded to by Mr. Playfair would, we are of opinion, show much worse results had exchange remained at 1s 6½d. The fall in exchange has helped to reduce their expenditure and has increased their income. But for this some of them would doubtless have been working at a loss, if at all, and the value of the shares of those working would have declined in consequence. Planters, it must be remembered, do not study the low exchange from a theoretical standpoint. They know by experience that low exchange helps them to make both ends meet.

According to Mr. Playfair's reasoning it might be contended that the Presidency Banks are not paying their shareholders because investors who sent their money out to India when Exchange was at a high level, could not remit it back again except at a loss. Such shareholders have, of course, lost something in Exchange, but that has nothing to do with the question of the Banks' success. An investment may be earning dividends for its present holder, although the original value of the shares may have declined. Any original shareholder who has stuck to such a concern is decidedly better off if it is earning more than its expenses than he would be were it not covering expenses. Part of his original capital is gone, and must be regarded as having been written off; the remainder is bringing back something; in many cases a fair dividend on the original capital. The comparison lies, therefore, not between the profits made in bygone years, and those now being made; nor between the sterling value of the original amount invested in India at the time of investment and now; but between the profits made together with the present value of the property now, and the profits and the value that would have been recorded had the rupee remained at former level.—*Madras Times*

KEW GARDEN.

(From a Correspondent.)

Croydon, Surrey, June 9.

I had the pleasure of meeting Mr. D. Morris, F.R.S., the Assistant Director, and of congratulating him upon the honour of C.M.G. conferred upon him in connexion with the Queen's birthday. Mr. Morris kindly accompanied my companion and myself over several of the hot-houses, where we met many old friends in the shape of palms, ferns (including the late Mr. Wm. Ferguson's), &c. After a time Mr. Morris had to leave us, as he had an appointment with Sir Alfred Dent, the Chairman of the British North Borneo Co., who was coming down to Kew to confer with Mr. Morris on matters connected with the agricultural industry of "New Ceylon." Among the various plants we saw some from Bermuda; and "thereby hangs a tale," which Mr. Morris related

to us. The onion crop of Bermuda, which is sent to the New York market, and brings in some £30,000 a year, was a complete failure some years ago; and the assistance of Kew was invoked by the colony. It was then discovered that with the onion seed, which was obtained from Teneriffe, a fungoid disease had been imported, which was the cause of the disaster. A cure was effected; and in token of gratitude Bermuda is constantly sending rare and useful plants to Kew. This was my first visit to these beautiful and wonderful Gardens; and I was sorry that I was not able to spend a longer time there. One of the greatest attractions of Kew Gardens, to my mind, is the North Picture Gallery. One is lost in amazement at the skill and industry of the late Miss Marianne North here displayed in such a variety and wealth of colour.

INDIAN AND CEYLON TEA :
ANNUAL REVIEW.

38, Mincing Lane, June 1893.

By permission of the Proprietors we are enabled to publish some figures showing the result of another year's work on many of the estates whose produce is sold on the London market.

A comparison with the statistics compiled a year ago—which practically covered the same ground—shows that decrease in outturn in India has found compensation in higher average value of produce. Bearing in mind that growers have had the benefit of lower rates of exchange, and of cheaper freights than ruled in previous years, the returns—which are fairly representative of the entire crop—afford evidence that the past year has been a remunerative one, and has placed the industry in a position of strength and prosperity surpassing the expectations of those who have experienced the vicissitudes of its early history, and have taken note of the strenuous competition which always has to be encountered.

In one respect the season has afforded a contrast to all that have preceded it. For the first time the total production of India has shown an appreciable decrease in quantity: and for the first time since Ceylon became a producing country of high importance, the yield has ceased to show a large increase. In so far as this has been the result of bad weather prevailing in particular places it is a matter of general regret; but where it has resulted from the policy of trying to secure crops moderate in bulk but good in quantity, it affords grounds in satisfaction.

Increased supplies, both from India and Ceylon, may indeed eventually be called for by all the consuming countries of the world: but if producers would avoid the inconvenience of wide fluctuations in value, the increase should be gradual in its growth, attained by the natural development of the new acreage, and not by the sudden inrush of crops made at the expense of quality.

In another respect the past year has been very unlike the season which preceded it. The crop being of higher average quality has contained a larger percentage of good and fine tea—though not much more of the finest—and consequently less than before of the inferior grades. The effect of this has been gradually to alter the normal relative range of value as between "common" and "good," bringing their quotations very close together. While this has not adversely affected average value—which is, of course, the main consideration—it has certainly for the time being given some advantage to the producer of a heavy crop of low grade tea, and we fear it may prove a temptation to seek success in the quantity made rather than in its quality the more so as there seems to be an impression that the demand for the finer qualities is diminishing.

That the course of the market at one time gave some ground for this impression we cannot dispute; and it is necessary to add that those who ought to know allege that the widespread advertisement of "the finest Indian and Ceylon Teas" for retail sale at prices far below what such kinds realise at Public Auction is affecting the trade of those who used to sell them. But after due allowance has

been made for this, the fact remains that, taking the year as a whole, the best teas have rarely failed to meet with enquiry and to bring full prices.

While observant of the tendency for retailers to reduce their quotations under stress of the keen competition for the trade of the country, we note that more than ever are care and discrimination shown by the buyers in picking out the best liquoring tea; and we must, therefore, prepare for a speedy return to the low rates ruling for inferior sorts a year ago if the coming crops from India or Ceylon should give a large supply of them.

It is possible that those who produce at a low cost could face such a price with equanimity; and that those who make specially good tea might even benefit by it—but for the great mass of growers it would be a disadvantage.

The London Warehouse Returns, which we print at foot, do not afford the satisfactory feature of increased Deliveries, such as we were able to point to a year ago, except in the case of Ceylon which continue to make headway, mainly at the expense of China. But we do not think these returns necessarily prove that consumption in the United Kingdom is declining. We attribute the decrease in the quantity taken out of bond partly to the less prosperous condition of the trade and industries of the country in general, but more to the fact that for the last six months there has been comparatively little tea of any kind obtainable under 7d per lb., whereas during the corresponding period of the previous year, when the great increase in delivery took place, retailers were freely supplied with cheap tea selling from 4d to 6d per lb. The inference is that the invisible supplies held out of bond are now light. This we believe to be the case, and it is an element of strength for the near future, unless China should once more heavily supply us with Congou laid down at a low price early in the season.

The displacement of China by British-grown tea, has progressed so regularly for many years, that the fear of the process ever being reversed may seem a groundless one—but it should be borne in mind that consumers have no prejudice against China tea as such, and that its disuse has been largely due to the deterioration in its quality being so marked as to emphasize the superior economical value of our teas. It is at least conceivable that a change might take place, and we must not, therefore, allow China and its power of supply to be forgotten factors in our forecast of the future. In this connection the following figures, taken from Board of Trade Returns, showing the proportions in which the different kinds of tea have been used during the past two years, may be of interest:—

Duty payments for the year ending 31st May.

	1893.	1892.
	Per cent.	Per cent.
Indian	51.50	50.80
Ceylon	30.50	28.15
China and Java.....	18.00	21.05
	100	100

Exported from U. K. year ending 31st May :

	1893.	1892.
	Per cent.	Per cent.
Indian	9.20	11.30
Ceylon	10.00	8.20
China and Java.....	80.80	80.50
	100	100

In times past it has been customary to discuss in detail the measures which managers should take to secure the most profitable results. Practically, all that has been written before holds good today, but the evidence before us of the thorough efficiency of those who are responsible, and their general appreciation of the needs of our market, seems to render repetition superfluous. The

planters of India and Ceylon have passed the period of probation, and for the moment the burden seems to rest upon those who are called to watch over their interests here and in new countries. Consideration has been given, among other matters, to the question of regulating supply, both as regards the component parts of the crop and its even distribution to the market throughout the year; but discussion of the subject discloses such a variety of opinion amongst Importers and buyers as to the desirability, not to speak of the practicability of carrying it out, that at present the way does not seem very clear. The policy of such a course, however—whether taken from individual interest or by the general agreement of producers—may be considered from a somewhat different standpoint than has been usual in the past; for the Home Trade seems to be shifting from those who formerly were prepared to buy freely when Sales were heavy and to hold large stocks, to those who conduct their business on different lines and hold as little stock as they safely can, buying more or less regularly throughout the year. Experience only will show if the gain of a market comparatively free from fluctuations in value will compensate Importers for the expense of carrying stocks and the risk of deterioration in quality. : to ensure success, the whole body of Importers would need to agree and adhere to a common line of action.

During the Spring of this year the even course of business was interrupted to some extent by uncertainty as to the action of the Chancellor of the Exchequer with regard to the duty, and we must expect to be subject to this in the future. Remission of duty would probably raise the value of some kinds for the time being, and by increasing the number of those who retail tea would possibly cause a run on Stocks; but, unless the authorities are moved to take stringent precautions against the importations of rubbish under the name of tea, and the refuse of foreign markets, it is conceivable that considerable injury to the trade might eventually result from placing tea on the free list.

As regards the future—the latest information from India and Ceylon points to a larger supply during the coming year, but not to the extent that need cause anxiety as to the ability of the market to absorb it. When dealing with a total approaching 200 million lb., it is obvious that a margin of 5 or 10 millions one way or the other is not of such moment as it was a few years ago; and seeing that the total Stock is today at a lower point than has been reached since 1886, there is good reason to take a hopeful view of prospects for the season into which we have now entered.

London Warehouse Returns for 12 months ending 31st May :—

	1893. lb.	1892. lb.	1891. lb.

The progress of the Ceylon trade is shown by the following statistics:—

Year ending 31st May	Imported	Sold in Auction, (exclusive of reprints)	Avg. price.
	lb.	pkgs.	per lb.
1893	64 million	790,000	*94 d
1892	64 million	790,000	94 d
'91	47½ "	805,000	11 d
'90	31½ "	450,000	11 d
'89	26½ "	381,500	10½ d

The following figures (issued by Messrs. Alfred Harvey & Co. of Melbourne) relate to the trade in Colonies of Australia and New Zealand:—

	SEASON 1892-93	1891-92	1890-91
From Ceylon.....	5,700,000	3,500,000	2,812,000
From India	3,930,000	5,165,000	4,717,000
From China	14,913,000	16,038,000	15,376,000

Wm. Jas. Hy. Thompson, Brokers.

CINCHONA REPORT.

(From Chemist and Druggist.)

London, June, 15th.

CINCHONA.—Tuesday's bark-supplies were somewhat heavier than usual, the total of the ten catalogues being:—

	Packages.	Packages.
Ceylon cinchona	1,156 of which	1,133 were sold
East Indian cinchona	1,579 "	1,164 "
Javan cinchona	160 "	160 "
	2,925	2,457

For the first time for many months neither South American nor West African barks were offered. The quality of the assortment actually shown was exceedingly poor—worse probably than has ever been seen before. The bulk of the lots consisted of the commonest kinds of Succirubras, and the Officialis and Ledger barks scarcely reached the average quality in any single instance. The total quantity of sulphate of quinine represented by them was between 6,500 and 7,000 kilos or about 2 per cent on the average.

The tone throughout the sales was dragging, and the bulk of the bark sold at a decided decline in price, the average unit for common barks not exceeding 11-16ths d. to 3d per lb. being the lowest ever recorded in the history of the article. Good barks would probably bring a somewhat a higher unit. Our prices are now about on a par with those realised at the last Amsterdam auction.

The following were the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Brunswick factory	... 150,065
Agents for the Auerach factory	... 112,183
Agents for the Mannheim and Amsterdam works	... 59,184
Agents for the American and Italian works	... 58,001
Messrs. Howards & Sons	... 52,740
Agents for the Frankfort O/M and Stuttgart works	... 41,313
Agents for the Paris factory	... 23,170
Mr. Thomas Whiffen	... 16,160
Sundry druggists 46,802

Total quantity of bark sold	... 560,251
Bought in or withdrawn...	... 98,322

Total quantity offered ... 658,573

JAVA CINCHONA.—Succirubra and Hybrid chips 2½ d to 4½ d; Ledger branch and stem chips 2½ d to 3d per lb.

The exports from Java for the nine months ending March 31st have been as follows—

	1892-93	1891-92	1890-91	1889-90	1888-89
Amster- dam lb.					

Government plantation	473,714	515,352	470,212	445,940	558,712
Private plan- tations....	5,322,003	5,811,278	5,348,211	3,377,432	2,717,862

Totals.. 5,795,717 6,326,630 5,798,423 3,823,372 3,276,574

TEA PROSPECTS AT FOCHOW.—We call attention to an article on this subject from the Hongkong Press of special interest to Ceylon planters. It will be observed that shippers of China tea last year made money, but this was owing to the Indian and Ceylon crops falling short. This year caution is inculcated; but the teamen are not likely to think that the Indian and Ceylon estimates are to be exceeded, and so may ship more freely we suppose.

A HANDBOOK OF THE FLORA OF CEYLON.

We have just received a copy of the first part of Dr. Trimen's *magnum opus*—the work with which the name of the accomplished Director of our Royal Botanic Gardens will henceforward be always connected. The full title of the book is as follows:—

A Hand-book to the Flora of Ceylon containing descriptions of all the species of flowering plants indigenous to the island, and notes on their history, distribution, and uses. By Henry Trimen, M.B. (Lond.) F.R.S., Director of the Royal Botanic Gardens, Ceylon. With an Atlas of plates illustrating some of the more interesting species. Part I. Ranunculaceæ—Anacardiaceæ. With plates I—XXV. Published under the authority of the Government of Ceylon. London: Dulau & Co., 37 Soho Square, W. 1893. It is most clearly printed on toned paper; but what shall we say of its accompaniment—the Portfolio of 25 plates in illustration of our Flora? "Beautiful exceedingly" must be the verdict on what is done in the very best mode available to the publisher. We reserve anything like a due notice or review for the present; meantime mentioning that although the Volume and Plates have only now arrived here, the publication in London took place about the middle of May. We take the liberty of quoting as follows from a letter with which Dr. Trimen has favoured us, as the best and speediest means of making his wishes known:—

"I think its get-up is creditable, but publishers think too much of appearance and I wish the paper used had been half the thickness. [All the nicer for readers though.—Ed. T.A.] I must give up the idea of 2 volumes and have the book remain in its 4 parts as a permanency. This 1st one is the shortest of the four and I calculated about 800 pages for each volume which with the paper used will be much too bulky.

"Of course there are a good many misprints, one cannot avoid them in a book of this sort. Will you call attention to the local names. I have taken a great deal of trouble about them, but they are still rather chaotic, and I have numbers which I cannot allocate. The fact is many are merely descriptive and made up on the spur of the moment by people who do not like to say they don't know the name; others too are extremely local, and vary even in adjacent districts.

"I shall be glad of notes and corrections of these names, but no names are of any use unless given independently by several people over some tract of country, and they must be corroborated by actual specimens taken at the time from the plant."

COFFEE DISEASE IN JAMAICA.

The Ceylon Coffee disease caused by *Hemileia* has happily not been met with in Jamaica, though other less serious fungus pests have been discovered by J.D.A. Cockerell. These are the black rot, *Pellicularia keleroga*, which affects the leaves somewhat in the same way as the Potato fungus (*Phytophthora*) and the iron-stain "*mancha de ferro*," of Venezuela, which is attributed to *stilbum flavidum*, and which forms small pale brown spots on the leaves, which speedily fall off. Neither of these has any close relation to the *Hemileia*, and their effects are much less serious.

BULLETIN OF THE BOTANICAL DEPARTMENT OF JAMAICA.

The last number contains the Report of the Director of Public Gardens, for the year ending March, 1892. It contains an interesting account of the functions performed by colonial gardens, and a slight sketch of the history of each of the establishments in the island. "The value of the gardens existing in Jamaica, Trinidad, and Demerara, is so evident that lately Botanic Gardens have been

started in Antigua, Dominica, Montserrat, St. Kitts, and Nevis, amongst the Leeward Islands, under the direction of Mr. C. A. Barber, a Cambridge botanist; in Grenada, St. Lucia, and St. Vincent amongst the Windward Islands; and still more recently in British Honduras.

"The same movement is also going on in other parts of the world; for instance, botanic gardens have lately been established in Lagos, and the Gold Coast on the west coast of Africa.

"Botanic gardens in the Tropics do the work on the plant side, of agricultural departments in temperate climates. They are in themselves experimental stations; and are much more efficient in introducing new cultural products, and in distributing plants and imparting useful information than most agricultural departments.

"The whole of the botanic gardens in the British Empire are more or less in communication with one another, exchanging seeds, publications, &c., and all look up to the Royal Gardens at Kew as to their head for advice and assistance. Imperial federation is already in existence as regards the botanic gardens and their work. If any special variety of a plant, or any new culture comes into notice, information and plants are sought sometimes directly from the local gardens, sometimes through Kew as the botanic gardens' 'Clearing House.' The Director of Kew Gardens has at his disposal the services of experts in every branch of botanical inquiry, and is always most willing to aid colonial gardens in every way. Any intricate question that arises in chemistry, in diseases of plants, in insect pests, in the value of products, &c., can be determined by reference to Kew. Colonial gardens are therefore not isolated, but are branches of an agricultural department as wide as the British Empire itself." We are pleased to see that the resources of the Royal Horticultural Society have also been utilised. A closer interrelation between the Society and the colonial and foreign botanic gardens is greatly to be desired.—*Gardeners' Chronicle*.

TEA, COFFEE AND COCOA.—Every point scored for temperance is a gain to national health, and we have satisfaction in noticing says the *Lancet* such an advance as is indicated by a lecture delivered recently by Dr. W. Woodward on behalf of the Worcestershire Health Society. The subject was "Tea, Coffee, and Cocoa." As might have been expected, the first-named of these beverages received the largest share of consideration. Its varieties, its different qualities, its chemical properties, its mode of preparation true and erroneous, were discussed at some length, and with the happy result that it may be regarded as a wholesome stimulant and restorative of the nervous system which, if properly made and used in moderation, is guiltless of after ill-effects. A comparison between the different known methods of preparing tea is of some general interest, the Japanese plan—which allows infusion for about a minute and a half, and which does not require boiling water, cream, or sugar—having evidently an attraction for the lecturer. For general use, however, he recommends the ordinary British custom, the infusion being drunk whilst recent and not strong. In this country we stand in equal, if not greater, need of teaching in regard to the qualities and preparation of coffee and cocoa. The former of these wholesome luxuries was treated of in considerable detail. We should have welcomed a somewhat fuller exposition of the properties and uses of the latter. A recommendation of cocoa in the nourishment of infants is, however, noteworthy, and should prove of some practical service. The question of cost was not forgotten. The estimate for a cup of good tea (½d.) and of good coffee (¾d.) is instructive, when the prices charged in many restaurants for infinitely poorer stuff are held in mind.

Correspondence.

To the Editor.

PLANTERS AND EXCHANGE.

SIR,—The remarkable reasoning put forth by the Hon. P. Playfair in the letter, copied by the Ceylon Press, which he has recently addressed to the Indian Currency Association with the object of proving that low exchange has been the reverse of a benefit to the producers of tea, should not be allowed to pass without comment.

Mr. Playfair seems to have a pleasant simple idea that the value of a concern is what it has cost, and that a tea garden which cost, say, £40 sterling to create would today, whether profitable or unprofitable be worth that sum, but for the fall in the sterling value of the rupee. Of course it is not so; the governing factor in fixing the capital value of a concern being its profit-earning capacity. Generally, the tea gardens of India are profitable and therefore, they have a large capital value. Were the rupee raised to, say 1/9 they would cease to be profitable, and with the cessation of profit, I opine Mr. Playfair would see a shrinkage, if not a total loss of capital value even if the rupee stood at par.

Every European engaged in business or owning property in the East would, I have no doubt, like to see the rupee rise to its old value, if he could make sure that his present scale of rupee income would continue, but, of all others, it would indeed be fatuity for the producer of tea to believe that. For him (and I believe for many others) there could be no prospect of a permanent compensating rise in the value of his produce following a rise in the value of the rupee. With the increasing area of production in Ceylon and India, with the standing menace of a resumption of the China tea exports and with the certainty that consumption would diminish immediately, high tea prices would assuredly not follow high rupees.

It would not be difficult to refute Mr. Playfair's calculations on his own bases assuming for the moment that they were correct. The depreciation in capital value only happens once, while the benefit at present is annual (probably permanent) and not on the profits but on the gross value of each year's produce. As an estate would give quite one-third of its capital value in annual produce, the benefit in 3 years would wipe out the loss of capital and thereafter be gain.

I am, your obedient servant,
THOS. NORTH OHRISTIE.

St. Andrews, Maskeliya, 23rd June 1893.

THE FUTURE OF TEA.

Guildford, June 1893.

DEAR SIR,—In your *Overland* of 11th ultimo I have read a paragraph headed "The Future of Tea" the same being acknowledged as taken from London Cor. local "Times." It speaks of a "great gathering" of Ceylon men at a residence here. The gathering apparently consisted of three, so whose its greatness came in I don't know! There has been no other gathering here that I know of; had there been, I daresay I should have heard of it and should have had the pleasure of reporting proceedings to my old friend the *Observer*.

I write to contradict the statement that any such great gathering has taken place here, and more especially to contradict the assertion that I

joined in the theory that the days of high-priced teas are numbered. Such is *not* my belief; moreover were it so, I have too many friends and interests in Ceylon to admit such at a "great gathering!"

The London Cor. of your contemporary the "Times" speaks of my adverse opinion as "gaining ground on all sides." It is the first I have heard of it, and I am *occasionally* in the way of hearing good (sometimes bad) authorities on the future of tea.

Ceylon we all know has suffered much and suffered quietly during the last fifteen years, but much of its suffering has been caused by thoughtless writing, thoughtless estimates and thoughtless men. Were it not for the indomitable pluck of the Ceylon planter, I believe long ere this one of the finest specimens of the human race would have been crushed out of existence by sceptical, wet-blanketed men.

At this moment we are doubtless passing through a very bad time, but we must keep our spirits up, and not run our future down.—The tea market is about as depressing as depressing can be, but there are reasons for such, and what market is buoyant at present? Have you Mr. Editor ever seen good commercial times under a Radical Government? You will differ from me I know, but never mind! Look at Ireland and its stagnant trade; Ireland that but a short time ago bought largely of our fine teas, now it feeds but hand to mouth and finds such hard too. The present stagnant state of all trades can be put down, in nine cases out of ten, to the unsettled state of the country, and the unsettled state of the country is due to the present Government. "Home Rule," which however, thank God will never pass the Lords, is but the thin edge of the wedge applied to ruin not only Great Britain but her Colonies. We Ceylon men must do our best to fight the tea market throughout the world, send less stuff to it, and of better quality; do our best to convince the shippers of worthless rubbish, that they merely ruin their own prospects, and cut the throats of their neighbours. One hope, and a good one, with heavy shipments and low prices, China must succumb. Of our many millions shipped, how many are worthy of being sold in the greatest market in the world, and how many barely fit to hawk on barrows in the streets of our greatest city?

Fight as we have fought, and there are good times for us yet.—Yours
H. L. FORB&S.

TEA CULTURE.

SIR,—The following platitudes have been gleaned from two old planters upcountry.—Yours,

DEBATED TEA BUSH.

PLACID JOE.—Hallo Tom! glad to find you in. A drink, old man? That bill of yours has given me a healthy thirst. Ah! thanks, and how's the factory, totum and things in general treating you?

TOM.—Bad! very bad, P.J. Do what I will my tea instead of improving is deteriorating and that in spite of my almost *living* in the factory.

P. J.—Just so, you old fossil, while you are in your factory nursing your liver and making all hands unhappy there, your kanganies and coolies are playing "old gooseberry" with your bushes in the field. You surely don't expect to put strength and flavour into your leaves in the factory? No Tom, the *field* is the place for that and the sooner you pay more attention to the latter and less to the former the better for you.

T.—Why, bless my soul! My conductor and head kangani are men to be trusted and to do exactly

what they are told, what more would you have? there's no fault to be found with the appearance of my place.

P. J.—Of course, and they carry out your orders most minutely, why, if a branch of a bush, when pruning, is an eighth of an inch above the level they'll have it off even if to cut through an "eye," anything to get the bush level and please Master! If you will butcher the bushes so severely have at least a little mercy. They are long suffering and put up with a lot of bullying; at the same time, respond at once to a little kindness which they never get from you. The appearance of your totum is all right old man! but should yield more, and wants a little common sense introduced to it.

T.—Well, what about that? every one does his level best to get flat-topped bushes and I flatter myself I succeed as well as any. I admit the yield is poor but lots of other men are in the same boat. Bosh! one can't hurt a tea bush.

P. J.—Granted, but it's at the expense of your flushes if a branch be cut between two "eyes" it dies back to the lower "eye" and healthy, strong lasting shoots spring from it, but if an "eye" be cut through the half "eye" left, makes spasmodic efforts to live by throwing out weak sickly shoots that run up into stalky buds and soon turn bangy, succumb to constant plucking, or take at least two years to arrive at anything like decent wood, surely it's poor consolation to your hurt to know others suffer as well as you.

T.—Ah! some more of your nonsensical absurdities! Like your suggestion of burying green prunings. I tried that and it did no good, but killed a few of my bushes near where I buried them!

P. J. Yes it's a wonder you did not put the whole field out; when one walked through the place it seemed as if one was walking on a spring mattress, that sort of burying of prunings is simply a waste of money and suicidal; had you dug a trench across the row of bushes 1 foot or 18 inches deep in which to scrape the prunings and well mixed with the earth again trenched from above, thereby enabling rapid decay, you would have had a different tale to tell.

T.—There's something in that! as the old woman said when she dropped a sov: in her stocking, but I'm not going to disturb the roots of my bushes again in a hurry. Did you not read an article in the *Observer* some time ago from a coconut planter signed "B." in which he suggested that tea planters should never disturb the roots of their bushes in anyway as he had found that it did more harm to his trees than good?

P. J.—Yes, but he should have given his other initial "F." A coconut tree and a tea bush are totally different: from one fruit is required and the other leaf.

T.—You must admit all plants have three separate roots for three separate purposes, firstly mass of fibres that grow about the stem and cluster near the surface, these are for fruit-bearing purposes solely, secondly, a lot of roots varying in size and number, that strike laterally off from their close associate, the tap root, in all directions, these are the wood and leaf roots which travel deep and long distances in search of food for wood and leaf formation; now the more one tilths, thereby disturbing, cutting up, and killing the surface roots the better for tea and quite the reverse for coconuts.

T.—So I thought, at one time and to prove it I trenched a hill about 9" all over, but I'll never do it again!

P. J.—Considering the hill you trenched was almost as steep as the face of a horse the first shower of rain naturally carried the trenched soil down to the sea where it will no doubt make things easy for the railway that will some day connect the island with India. Tilth or trenching is admitted all over the world (barring our island perhaps) to be the next best thing to manuring; it answers several purposes, principally sweetens the soil and enables it to take in certain atmospherical chemicals, nitrogen of which is not the least and which your "totum" sadly requires,

T.—You seem to be a bit of a scientist; had you not better apply for Hughes' old billet?

P. J.—I'm neither a scientist nor do I believe in theory where I have proved it to be wrong by hard practical experience. Well good evening Tom, you've been too long in the island, old man, and are far too conservative to understand anything out of the ordinary old groove; better take a trip home or travel a bit!

ARE CEYLON TEAS DETERIORATING?

Hatton, June 27.

DEAR SIR,—A great many opinions have been expressed on this matter and hardly two alike although all admit the fact that tea is very low. The abnormal weather is blamed, heavy pruning and all manner of things, but I think the reason is to be sought elsewhere; our soils are no doubt gradually becoming worn out, but we cannot for a minute admit that in the short space of two years such a material exhaustion has taken place as to cause the prices to run down to their present low level in face of a strong statistical position. We are aware that just recently a "Shilling Canister" has been introduced by Lipton and followed suit by as many tea dealers as could afford to do so and further we are aware that trade generally has been in a very depressed state in the United Kingdom recently and this state of affairs has had a direct influence on the masses of the people and forced them to curtail their household and other expenses all round and to patronize the "Shilling Canister" and all cheap teas more so than at any previous time. Then a demand for the inferior varieties is bound to lower the rate of prices for the better sorts to a certain extent. The demand for the lower kinds has (as we have lately seen) increased the demand for these teas and brought the prices within measurable distance of the better kinds. As soon as this came about, a demand sprang up for the higher varieties and we shall now no doubt see broken pekoes and such like teas fetching a far higher range of prices than we have seen for some little time. It is needless to cast ourselves into a state of excitement over the manner in which we prune, pluck and make our teas to better our prices. We should carefully study the reason of the fall of prices, for it seems very plain that the above-named reasons are at work which cause the decline under the present seemingly strong statistical position. It might be asked, and has been if I mistake not why it is that Indian teas are now so much higher than Ceylon's? Can we wonder at the fact when we learn that the Indian position is so strong and the first arrivals have been so over delayed. Any one who has gone into a broker's room in Mining Lane and sampled some of the Indian and Ceylon teas knows that most of the former are very much stronger, darker in liquor and "creamier" than the Ceylon's. Up to May 3rd 1893 the Indian imports were 28 millions of pounds as compared with 32 millions last year and if I had these same particulars up to date it would be seen that the position is stronger still and when we take these facts all into account there is nothing to wonder at why Indians should now be higher than Ceylon's. The opinion was expressed some little time ago in London, "that Ceylon is working her own ruin." It may be as well for this party to know that we cannot afford to bolster up the prices of Ceylon teas by plucking fine so that China might push in her poor teas. If we can take this trade out of China's hands and make a better profit ourselves over coarse teas than for the pleasure of seeing a high average for Ceylon teas we shall do it. If anyone thinks that tea planting will end in ruin, let him take to heart the fact that we can at all times limit our supply according to the prices ruling at home. As soon as prices came down we shall curtail the supply by plucking finer and on the other hand if prices rise we shall go in for coarser leaf and finally, we shall pluck our flushes in the manner that will produce the best results.—Yours truly,

W. A. T.

No. II.

DEAR SIR,—Your printer's imp, in altering my signature from "OLD LAND" into "Old Hand," has spoilt its significance and taken much from the *raison d'être* of the letter itself. If "W. A. T." should cut up, and want to know in what he had given offence, let him explain what he meant by "the sellers not liking to come forward and say Ob, mine is a poor worn-out old article" &c. &c. With every coffee estate in the island turned into tea he should go about to the different District Associations and say this in person. Why, some of the largest and best paying tea estates were once abandoned coffee estates, too poor for the cultivation of that product!

Against this we have some tea estates formed out of the finest virgin forest land. With these teas before us for comparison why need we go back "eight years"? I know tea-land paying very well whose general level is from one to two feet below the level it was at in coffee days. Such hard land may disappoint its owners (the sellers) in "quantity," but as regards "quality," (the point under discussion), that is another matter. Probably the old land has often the best of it, notwithstanding W. A. T.'s new discovery of very old formula.

I need not trouble you again on this subject.

OLD LAND.

No. III.

DEAR SIR,—I have just read the letter so inscribed, and signed "W. A. T." One would think the science of "Agricultural Chemistry" had only just beamed upon the intelligence of this writer, or does he think that the world is as slow as himself? The principle he enunciates in half-a-dozen words in the closing lines of his letter is already as old as the hills. I learnt it in my earliest school-days, and Liebig had established it years and years before that, in volumes of encyclopedian capacity; and it has been doing duty all these years ever since like the alphabet in schools,—yet here we have it trotted out again as an object lesson for the planters of Ceylon! It is getting rather stale as a mere fact in science; but in connection with tea, "W. A. T." is no authority whatever. Other minds can see some connection between new soil, old soil and the quantity and quality of tea; but with more complications than "W. A. T.'s" very rudimentary discovery in 1893 discloses. Evidently the "Philpot's" of Mincing Lane are unable to see much connection, for to them the fine tea of virgin soil is worth no more than the make from old land, as you, Sir, recently pointed out. Let this point—to which attention has been drawn by so many—be settled, before we need pay much attention to amateur chemists like "W. A. T." We do not listen with much patience to Mr. John Hughes himself, because we think he needs practical as well as scientific—or mere laboratory—knowledge, which only a residence in Ceylon can give him. But to have such stale old lessons preached at us by mere Daniels suddenly come to judgment, mere newly-read-up amateurs, is slightly irritating. A good many points have to be settled and known before even a trained scientist can speak with unhesitating authority upon a mere chemical analysis of the made leaf. Chemical equivalents are so a most miraculously fine that a mere re-arrangement of the molecules consisting of the same elements will constitute a new product. If "W. A. T." has virgin soil let him be thankful if his prices satisfy him; but what he wants to know is something very much more than the mere A B C of

cultivation which everybody knows already, or think they know. But quality as well as quantity depend upon more considerations than enter into the philosophy of "W. A. T." No chemist, by a mere analysis, can lay his finger on any constituent and say: "The absence of this, or excess of that, is the cause of deterioration." Without its proper food in sufficient quantities, neither tea nor any other plant will grow at all. So long as the tea bush produces leaf that is essentially "tea," and the loss it produces in the proper climate, the stronger infusion it is supposed by practical men to make. "W. A. T.'s" whole letter is weak and jumpy. A chemical analysis is one thing, but to interpret that analysis, an immense amount of practical experience is required. OLD HAND.

No. IV.

SIR,—My attention has been drawn to a letter in your paper signed by "Old Hand." "Old Hand" is a clever man—in his own estimation—and it is certainly a great pity for his own sake that he cannot come forward openly and plainly—and if he is bereft of reason, a little of that commodity as well—and give us some information worth having instead of a volume of sneers which are generally a sign of weakness in the upper storey. He sneers at Mr. John Hughes and I am not surprised, as a man of "Old Hand's" scientific attainments can afford to sneer at "any one." "Old Hand" reasons like a man who turns over the foundation stone of an intended building and then turns round and says,—“hang it, I don't call that a house, it is only the 'rudimentary stages' of one and you are a mere Daniel at building.” "Old Hand" states that he learnt that soils deteriorated, when he was a school boy and that the fact was established years and years ago by Liebig, and as my statement was of a similar nature and nothing more, "Old Hand" has nothing to refute. I am quite aware and I presume every one else who has paid attention to the matter that no chemist by a mere analysis, can lay his finger on any constituents and say,—The absence of this, or the excess of that, is the cause of deterioration; but an analyst can easily furnish us with the constituents of a good sample of tea and those of a poor one, as well as the respective soils in which they were grown and having obtained these particulars in many and various ways, a thorough practical man versed well in Agricultural Chemistry would be able to tell us what we might add to our soils to procure a favourable result. "Old Hand" says that without its proper food in sufficient quantities tea will not grow; granted: what can we do better than find out the right food? And we must search further than this palm-fringed and tea-topped island to find the right man to do so. The testimony of experienced tea tasters is worthless to determine whether our teas have deteriorated in quality or not, for by changing the style of plucking we can turn out the finest of teas and the worst of teas from the same field of bushes and if the Mincing Lane people have had reason to complain about the quality of Ceylon teas it is because they have received coarser samples. What we require now in Ceylon is a man to make searching chemical tests of high and low grown teas, of good and of poor, and the respective soils that the analysed teas have grown in and then and not until, can we make a further move. This will take time and perhaps years, but nevertheless it is a matter well worthy of the attention of Tea Planters and if "Old Hand" who admits that our soils are getting exhausted will come forward, or anyone else, and give us some more information which will lead to some practical steps being taken to better our condition he will receive the thanks that he will merit from his brother planters.—Yours truly, W. A. T.

P. S.—I can assure "Old Hand" that my place is a worn-out old shop like his own.

LEAVES FROM A NILGIRI TEA GARDEN.

It was late on an April afternoon, after a seven teen miles' ride from Mettappolium up a steep and rugged path, that I first saw a Nilgiri tea estate, and as I stood with my host on the steps of his pretty bungalow, looking down into the plains spread out below in the glare of the burning afternoon sun, I felt it was good to be there, 5,500 feet above them. Behind us were the pine-clad, silent hills, rising range after range into the clear sky, all clothed as with a garment with the overflowing sunshine, while on either side was a fair pastoral country of mountain, ravine and fertile valleys, hills, and open common, where small brown cattle and buffaloes grazed, and flocks of sheep and goats roamed at will, herded by little Badega boys in quaint, dark-coloured draperies bordered with red. The country seemed smiling with plenty hamlets of red-tiled, roomy houses, surrounded by fruitful orchards and waving cornfields were dotted here and there on the hillsides, or nestled in the valleys near brooks which rushed down tumultuously over their rocky beds from their mountain homes.

Within the boundary of the estate long trim rows of tea-bushes rose on either side of the stream that draws its clear waters from the eagle-haunted hill behind the house. A jungle cock kept up his curious, haunting cry in the woods, long-tailed swallows flew twittering across the gleaming water, the liquid song of the Indian blackbird vied in sweetness with the half-brooding carol of the robin, flitting from bush to bush. Away in the woods rose the call of the wild grey pigeons, soft and musical as the notes of the ring-dove which was stolen by the lover of old for a love-gift when it brooded on the juniper-tree; and everywhere the hum of a thousand insects might be heard, as they flitted among the crimson-hearted roses or took long draughts of honey from the pale cream cups of the weeping gum-tree, whose long graceful tassels hung tremblingly over beds of—

"Carnations and streak'd gillyvors,

Daffodils that come before the swallow dares and take,

The winds of March with beauty; violets dim,

But sweeter than the lid of Juno's eyes,

Bold orchids and the Crown Imperial; lilies of all kinds,

The flower de luce being one."

Soon the hillsides were bathed in rosy light, and the western sky was aflame with the crimson glories of the sunset. As the sun sank slowly and the wonderful afterglow painted the sky with molten gold and red, the quiet spot suddenly became alive. Up the winding paths of the estate came lines of coolies, women and children these, the pickers, each with a white basket on his or her head, full of bright green leaves, the newly picked "flush" of the tea. Behind them came the pruners, men and older boys, who gave up their pruning knives to the maistry who accompanies each gang, and departed to their homes in the hamlets around, while the pickers formed a line round the tin-tea-house or factory door, and as their names were called from a list, by the writer, they entered one by one and had their "leaf" weighed and the amount of each basket entered in a book. A picker will pick from 5 lb. to 10 lb. of leaf a day, according to age and speed. 10 lb. is considered an exceptionally good day's work for an adult picker. On the floor of the tea-house a picturesque group were squatted round a heap of newly "fired" tea, just out of the "Sirocco;" children, mostly girls of 8 to 11 years, draped in yellowish-brown cloths, which they had drawn up tightly over their heads to keep out the tea-dust, which was flying in all directions, and a few boys in similar dresses, but with red worsted caps on. These were busily engaged in "sorting" and picking all the stalk and refuse out of the tea. This sorted tea was then sifted by three boys, who placed it in a large sieve, which they proceeded to rub briskly up and down on a wooden bench, the finer

tea falling into a sheet underneath, the coarser remaining in the sieve. The sifted tea was then taken possession of by another group, who fanned it with fans of coconut matting to remove all the tea-dust, which is sold separately. Many estates have sifting machines, but in some the old system of hand sifting is kept up, and some planters prefer it to the machines, as being more thorough. After the tea was sorted, sited and weighed, it was locked up in the big lead-lined chests that lined the walls of the tea-house. Work was then over for that day, but during my visit I had ample time to watch the routine of tea-manufacture, which is most interesting.

The tea-plant is a species of *Camellia*. It grows into a sturdy bush from 3 to 5 ft. high, and has beautiful waxy-white flowers. Its leaves are dark green, and it would make a beautiful shrub for hedges. The soil (a rich sandy loam is best) must be well drained, and it is essential that water should not lodge round the roots of the plants. Many of the tea estates of Southern India are on hillsides, and rise in terraces up the mountains, reminding one of the vineyards along the Rhine. Level ground is however as good, providing it is well-drained.

The low country coolies begin work at 7 a.m., and continue till sunset, with an interval in the middle of the day for eating their food, which they bring with them. The Badegas, or hill coolies, work from 9 a.m. till sunset, and have no interval in the middle of the day, as they only have two meals a day, in the morning and in the evening. Roll-call is held by the planter at 9 a.m., after which the pickers with their baskets, and the pruners armed with their carved knives, disperse, each gang with its maistry, to different parts of the estate.

A planter's life is a healthy open air active life, especially when his lot is cast in as perfect a climate as that of the Nilgiris. Here, as in most of the other paths of life, *l'air de maître* is everything, and the sooner people get rid of the idea that the planter's life is an easy-going, sporting, happy-go-lucky one, the better. My host, whose estate was one of about 75 acres, was busy all day long from 6 a.m. to 5 p.m., in tea-house or on the estate, directing the pruners, superintending the weighing, firing, drying and packing. He could seldom be absent from his estate for a day, and at the time of my visit, the busiest time of the year, tea-making was going on night and day. He would get up two or three times in the night to see that all was going on right in the tea-house. It is therefore, obvious that only active, energetic and thorough men can make planting pay. A few days' spent with a planter in his estate will supply information which no reading of books and papers can afford.

"Back care" and "smiling hope" in turns hover round the path of an Indian planter, and there is much excitement and no little fascination in a life which is as full of ups and downs as his, whether he be a grower of cinchona, a planter of tea or of coffee. The cinchona grower was a few years ago thought to have a great future before him, and visions of rapidly-to-be-made fortunes and success seemed to rise up before him, but the unit shrank, hope vanished, and ruin looked many a cinchona grower in the face, and he was counted lucky who only had to master "the great art of cheerful poverty." The coffee planter, too, had a bad time for years, when the price of his produce sank lower and lower though the quality increased. The crops too, became poorer each season, until the crisis was reached two years ago, and there were neither crops nor promise for the next year. Then suddenly the tide turned, prospects brightened, and new life seemed to be infused into the crops, and coffee, both with regard to crop and value, now stands higher than ever it did before. As to tea at this moment, no fortunes are to be made in it, for production increases, while prices diminish. But who can tell what the future may have in store for the tea planter. A turn may come to rickie Fortune's changing wheel, and this great industry of Southern India may yet thrive and flourish again, even more than it has done in the past.

—Times of India.

M.

VARIOUS AGRICULTURAL NOTES.

THE ORANGES, of which no less than 156 025 cwt. were exported last year, are of two kinds the "mandarin" or loose skinned, and the "coolie," or tight skinned. The former commands better price than the latter, but the average value of the two kinds is about 0.4d., or a little under ½d. per lb. These oranges like the fresh vegetables, and indeed the foodstuffs generally, are for the most part shipped to Hong Kong and the Straits Settlements.—*Swatow Circular Report for 1892.*

SAWDUST BUILDING BRICKS.—The sawdust is dried and screened, to remove the coarser particles, and is then mixed with cement, lime and sand in the following proportions: One part cement, two parts lime, five parts sharp sand and two parts sawdust. The sawdust is first mixed dry with the cement and sand. The final mixture is pressed into blocks, which are said to be cheap and useful. There is as much lime and more than twice as much sand as sawdust in them.—*Scientific American.*

TUSSER SILK.—Some stimulus is likely to be given to the cultivation of tussar silk in the Central Provinces by the recent orders of the Chief Commissioner, under which the feeding of the silk worms is to be accepted, with certain restrictions, as a legitimate undertaking in Government forests. The industry, it seems, has hitherto been somewhat discouraged by the Forest Department, owing to the damage done by the insects to the trees, but Mr. C. R. Cleveland has shown that the pollarded *saje* trees required for tussar cultivation can be worked for forest purposes upon a system of rotation, and that there is no reason why the silkworms should not be regularly cultivated upon areas marked out for the purpose.—*Pioneer*, June 18.

"CHINESE FOR BRAZIL"—Such is the heading of a rather startling announcement respecting the mission of Mr. Carlisle of Rio, who is on his way to China to engage 100,000 Chinamen to work on the coffee plantations in Brazil. There is nothing improbable in the whole story; for, we have no doubt the Brazil planters have had much trouble since Emancipation took effect and we can quite believe that a million sacks of coffee were lost last season for want of labour to gather the cherry and prepare the beans. The Chinese would revel in so hot a country as Brazil, and if 100,000 of them got settled through Mr. Carlisle, we suspect it would prove the beginning of a great change affecting the whole South American continent with its vast unoccupied areas. The yellow man would probably prove during the next century to be master of the situation.

WONDERS OF THE COTTON PLANT.—The cotton plant, which has for so many centuries furnished a large part of the population of the globe with clothing, seems to be almost without limit in its usefulness. From the seed a valuable oil is expressed, while the husks form an article of food for cattle in the shape of cakes. From the lint which clings to the seed after it has passed through the "gin" felt is made, while the oil extracted from the seed is applied to quite a large number of purposes. But, according to the British Consul, Mr. Portal, of Zanzibar, cotton seed is also capable of yielding sugar. A process has been discovered for extracting sugar from cotton-seed meal, and though the details of this process have not been disclosed, it is said that the product obtained is of very superior grade, being fifteen times sweeter than cane sugar, and twenty times more so than sugar made from beet. This indicates that sweetness is not due to cane sugar, but to some chemical.—*Public Opinion.*

Kew ROYAL GARDENS.—We have to acknowledge with thanks, the receipt from Government, of two numbers of Kew Bulletin:—(1) for February and March containing Palm weevil in British Honduras with two plates; New Orchids; Miscellaneous Notes; (2) Appendix II, 1893, New Garden Plants of the year 1892."

THE JAPAN TEA SEASON is in full swing, says the *Japan Weekly Mail* of May 6th, the first two shipments to America having been made by the last two outgoing mails. The Tea trade is increasing in volume, and purchases of new leaf are proceeding apace, but rates rule high. The *Boyeiki* gives the following statistics of the volume and prices ruling in the tea trade of Yokohama for the past five years:—

	Arrivals.	Sales.		Prices.	
		(Boxes.)	(Kin.)	(Before 1st shipment.)	(After.)
1892..	266,611	..	23,086,900	\$40 to 43	\$34 to 36
1891..	289,617	..	24,195,000	37 to 40	31 to 33
1890..	257,940	..	21,752,000	41 to 45	35 to 38
1889..	18,625,000 <i>kin</i>	..	14,481,500	45 to 47	—
1888..	18,175,000 <i>kin</i>	..	17,998,000	43 to 45	—

THE ORANGE : ITS MEDICINAL VALUE.—A writer, in the *Horticultural Times* treating of "The Orange from a Dietetic and Commercial Point of View" has the following:—

The orange is rightly considered a most healthy fruit; the juice is slightly acid, refreshing, stomachic, aperient, antiputrid, and antiscorbutic. It may be given moderately to persons with fever or subject to biliousness, when the patient does not cough and has the bowels free from irritation. The orange is particularly wholesome when eaten fasting, but after meals it checks digestion frequently, especially when not ripe nor sweet. Delicate persons, then, should abstain from this fruit after meals.

The custom in England and Ceylon (?) is usually to eat fruit, including oranges, at the end of morning tea, or other meal: in America and on the Continent of Europe, fruit and especially oranges form, more usually, a first course.

THE COCO PALM WEEVIL.—A Jaffna correspondent writes in a letter dated the 19th inst.:—"About here, coconut trees in full bearing, and generally the best bearing trees are attacked by the red weevil. The presence of the larvæ is detected by a black spot from which there flows a reddish liquid, sap or otherwise. I am told that the larvæ are killed and the trees saved by cutting a little into the tree at that spot, and applying fire. I have also read that driving nails into the trees will have the same effect. The alkali of the rust flows with the sap and kills the worms without hurting the trees." It is commonly asserted that a coconut tree attacked by the red weevil can be saved by cutting a hole in it, extracting all the weevil grubs that can be found, and fumigating the hole with the smoke of burned chillis to kill any grubs that may remain in the tree; but we do not think there is any experienced coconut planter who believes in this remedy. We have tried it without success; and we have also tried injecting turpentine into the tree with a syringe, but this also did no good. Of the alleged remedy of driving nails into the tree we have not previously heard, and it would not be safe to try it without being sure of its efficacy, because if it should fail the larvæ would mature into beetles and the beetles would in turn breed progeny to destroy more trees. As we have said before, we believe the best thing to be done with a tree attacked by the red weevil is to chop it in pieces, feed the fowls with all the grubs that can be found, and burn the remains of the tree so as to destroy any weevils or weevil grubs that may be concealed in the pieces. Our opinion is, that a tree attacked by the red weevil is doomed any way, and that all that can be done is to prevent more trees from being destroyed by the progeny of the weevil and weevil grubs which it contains.—*Catholic Messenger.*"

THE COCO PALM WEEVIL.—I notice in the current issue of the *Kew Bulletin* an article covering many pages of that periodical, on what is there termed the coco palm weevil, which is none other than our old friend the *Cooroominia*, the remedy for which has been told over and over again, but which seems not to have reached the West Indies, where the ravages of this beetle are becoming very serious. This was very destructive in the Negombo district in the "forties," but was eradicated by means of barbed instruments of iron which were thrust down the apertures made by the insects in the stems of the trees, and by being forced into their bodies, were the means of drawing them from their refuges before they had a chance of depositing their eggs therein. Young Sinhalese lads were employed, who were paid a certain sum per hundred of the beetles caught, and in this way the pest was arrested.—*London Cor., Local "Times."*

THE "AGRICULTURA GAZETTE" of New South Wales for May has the following Contents:—The Grasses of Australia, F. Turner—*Panicum divaricatissimum*, R. Br. ("Umbrella Grass"); Vegetable Novelties, Geo. Valder; Botanical Notes—Death of Dr. Woolls, Australian Flora, and Abnormal Inflorescence of Grasses; Report on the Tobacco-growing Industry in the Tumut District, S. Lamb and G. F. Sutherland; Tobacco-growing in New South Wales, S. Lamb; Tobacco as a Farmers' Crop for New South Wales, G. F. Sutherland; National Prizes for 1892—Irrigation, H. G. McKinney; Stock Breeding and Fattening in New Zealand, A. Bruce; Dropping after Calving, Exchange; Report on Insects affecting Sugarcane Crop on Clarence River, A. S. Olliff; The Hessian Fly ("*Cecidomyia destructor*," Say); Temperatures for Fruit Export; Cheese-making by Small Farmers, Exchange; Poultry, The Sub-Editor—The Australian Game, Note—Worms in Fowls; General Notes.

TEA CULTIVATION IN CEYLON.—We are at issue with the Obairman (P.A.) when he says that deterioration is "purely conjectural." We believe it to be scientifically certain, whether observable in some localities or not. In the nature of things deterioration is inevitable, unless prevented by artificial means. As a fact of experience there are places where the quality of Tea formerly produced cannot by any skill or care, either in plucking or manufacture, be reproduced. Our taking up this position with respect to Mr. Walker is not argumentative, but practical. We have more than once lately pressed upon the attention of our planting readers that their lands cannot go on producing Tea crops from year to year from the same soil, without eventual exhaustion, sooner or later, of some one or more of those ingredients which are essential to the quality of the Tea that the land produced when it was first cultivated. It is because we fear the effect of the Chairman's letter might be to cause planters to go on exhausting the soil, without recognising the importance of scientific restoration of the ingredients that Tea requires, that we notice his letter otherwise than by the practical approval of the latter clauses. It may be, and we believe it is true that there are comparatively few tea estates where the restorative process has become imperative; but what we contend for is timely help to those which have not yet begun perceptibly to suffer for the want of it. Tea is a much more critical product for the cultivator than coffee ever was. Though the bush is hardy in growth, and in some senses easy to grow, the leaf, when grown, cannot in the course of nature remain permanent in quality while the soil that produces it is being drawn upon, year by year, for the same essential ingredients! One by one, as each in turn becomes rarer the leaf will feel more and more the deficiency. Tea planting in Ceylon is as yet a young enterprise. Estates that were old before they were planted with tea, become more quickly exhausted than younger ones; but, as yet, they do not form a large proportion of the whole and they would benefit by an early application of restorative ingredients and conditions such as are not of merely stimulating nature.—*Local "Independent."*

TEA AVERAGES IN COLOMBO AND CALCUTTA.—We see from a contemporary that the average for all teas sold in Calcutta during the past two years was as nearly as possible as follows:—
1891=40.62 cents; 1892=53.12 cents.

In Colombo, Mr. James Forbes is good enough to inform us that the average realised was as nearly as possible the same in both years:—
1891=41 cents; 1892=41 cents.

The London average for "Ceylons" went down a good deal last year, so that the above tells in favour of Colombo, against London Sales. The higher rates in Calcutta in 1892 corresponded with the improved average in London—due to fine plucking.

THE BOTANY OF TIBET.—Dr. Thorold, who, in 1890-91 accompanied Captain Bower's expedition through Tibet as a scientist, collected specimens of all the plants he saw during his journey across the country from west to east. The collection contains only 115 species, all told, showing the poverty of the Tibetan flora in the district traversed; a poverty which, however, is not astonishing considering that the greater part of the route lay over a country as high above sea-level as is the top of Mont Blanc. The 115 species belonged to no fewer than twenty-eight natural orders, and only about half-a-dozen species were quite unknown at Kew. One flowering-plant was collected at an altitude of 19,000 feet—probably the highest point on record in the history of botany.—*Chemist and Druggist.*

THE WILD ORANGES of the Society Islands, which are now an important article of export, owe their origin, according to Mr. Howe's report, partly to Captain Cook, who brought hither ships from Brazil, and partly to the early missionaries from the Australian Colonies, who introduced another variety. It is these two kinds, though left untended—for there are no plantations of oranges in the islands—which have by acclimatisation and self-propagation gradually merged into the one variety so favourably known in the market as "the Tahiti orange." The fruit, which varies from oblong to oval in shape, is large, thin-skinned, very heavy, sweet, and full-flavoured. The propagation of the Tahiti orange-tree is accomplished by "raiders," such as rats and other animals, who scatter the seed, which, owing to the moist, warm climate, germinates with taint and rapidity.

HUNASGERIYA, THE COX.—The eighth general meeting of the shareholders of the Hunasgeriya Tea Company was held on Wednesday last, when the usual yearly accounts and reports were put in and taken as read. There is a dividend declared of two per cent., which, considering the indifferent season of last year, is perhaps as good as could have been expected. The tea sold amounted to 232,948 lb., the cardamoms to 1,338 lb., and cocoa of the weight of two tons; altogether the total proceeds of crop sales amounted to £8,424; total outlay £7,561, which shows a profit of £862. A finer plucking was carried out; but owing to lower market prices only a fractional advance on the previous year's sale prices was obtained. There has been no addition to the total acreage of the estate, which stands as follows:—

Tea over six years old...596 acres.

Planted in 1887	...124
Do 1888	... 40
Do 1891	... 29

Total under Tea ... 789

Cocoa planted in 1891 ... 30

The condition of the estate is very favourably reported on, and the directors consider that the result of the past year's working shows that they would do well in succeeding seasons as the lately planted areas come into fuller bearing.—*Local "Times."*

CACAO CULTIVATION IN ASSAM.—We have an inquiry from a Calcutta firm about information respecting cacao, and they mention that an experimental plot is to be tried on an Assam tea estate. We shall watch the result of the experiment with the greatest possible interest.

TEA AND COCONUT PALM INDUSTRIES IN CEYLON.—The following extract is from the "Jaffna Catholic Guardian" and the comparison instituted is worthy of attention:—

The vast majority of the labourers on the Tea Estates are immigrants from India, while those in the Coconut plantations are almost exclusively natives of Ceylon. Accurate returns are given from year to year of the Indian immigrants who number about 250 thousand. Of the natives who are engaged in Coconut planting, it is difficult, in the absence of returns prepared officially or otherwise, to give anything like a correct estimate, but their number must be considerable. Besides those who are employed in planting, fencing, watering, manuring, picking nuts, converting them into copperah, and other operations, there are a great many persons who find a living by the pursuit of one or other of the various industries connected with the palm, such as the drawing of toddy, the making of jaggery, the distilling of arrack, the expressing of oil, the making of coadjans and the manufacture of coir and cordage. According to the Census of 1891, the number of Arrack Distillers was 1,009, of Arrack renters and Tavern keepers 2,407, of Toddy drawers 11,907, of Jaggery manufacturers and dealers 2,494, of Coadjan Maker, 1,368, of Oil Millers and Mongers 6,903, and of Coconut Driers and Copperah sellers 6,646. Of the industries to which the coconut has given rise, the one that supports or employs the largest number of persons is that of coir-making, of which Mr. Lee has given the following account:—

"In point of numbers, the Industrial Class comes next to the Agricultural, containing 485,766 persons or about one-sixth of the whole population. Of these, 64,845 persons, of whom 89 per cent are Sinhalese and 77 per cent females, belonging, three-fourths of them, to the Galle and Matara districts, are engaged in making and selling coir, the fibre of the husk covering the coconut. The beating out of the fibre from the husk, which is the first process after the steeping of the husk in water, is the work of the women, who, sitting half nude by the side of the water-holes, strike the husk with a short cudgel upon a stone until the fibre is separated. A woman working all day makes from 10 to 12 cents at this labour. The next process, which a so employs women and girls, is the winding of the fibre into twin rope. This is done in front of the houses and there is hardly a house on the sixty miles of road between the Bentota and Matara rivers which has not its little heap of golden coir-fibre and yellow rope. Middlemen collect the rope thus made for the merchants, by whom it is sorted, twisted and exported."

That the advantages indirectly conferred on the island by tea cultivation are incomparably great, we are prepared to admit; but from the few facts and figures given above, one feels justified in thinking that the coconut is of far more service to the poor inhabitants of the island generally than the tea enterprise, in keeping the wolf from the door. The writer of the above has scarcely recognised the great and increasing extent to which the Sinhalese are benefited by leaf-plucking and other operations on tea estates in the Kalutara, Kelani Valley and several other districts. Then he ought to refer to the chapter in our "Handbook" 's Agricultural Review showing the vast amount of work given to the permanent inhabitants of Ceylon by the great upcountry plantation industry, in factory work as artisans, in box making, building, in domestic service, in carting and trading; while all the villages in the Central Province along the road-sides may be said to depend mainly on tea. Finally of the 250,000 coolies on estates, a large proportion now regard Ceylon as *their* country, most of them being born and brought up here.

JAVA CINCHONA PROFITS.—At the annual meeting of the shareholders in the company for cinchona-cultivation, "Melattie" in Java, held in Amsterdam on June 7th a dividend of 7½ per cent was declared for the year 1892, after distribution of which the amount of 1,250/ was carried over to the reserve fund.—*Chemist and Druggist.*

CEYLON MEN AND COFFEE IN THE STRAITS.—Mr. E. V. Carey sends a chatty letter from Selangor:—"You've no idea what a strong Ceylon community we have in the little State—Spooner, the two Vennings, and French among the Government servants, Gatehouse, Cumming, and myself among the planters; F. G. We-t, who is piling up the collars for himself and his company over tin, and the Burgher contingent who are as plentiful as hens. A wonderfully strong cricket team we can play, too: Gatehouse has made one or two scores over fifty, and is looked upon as one of the best bats in the State on a fast wicket. Coffee grows very well. Come over some day and see 18 months old trees being *stripped* to get the wood on! But our friend Ramassamy is absolutely hopeless; compare him to his Ceylon brothers, and your soul is plunged in woe. He is the best workman to be got here, though, in spite of all his shortcomings, and when our Tamils have a few more of their woman-kind to keep them in the way they should go, things will improve a great deal. At present the average on most estates is about 10 per cent only of women, and if one loses her husband by any chance, the competition for her hand is something astonishing; the dora has to settle the question and adjudicate upon the merits and virtues which each competitor advances. I am told there is lots of sport if you like to go for it, and I have seen the tracks of tiger, leopard, pig, and deer of all sorts. The climate of Selangor is distinctly good, and Selangor men a real good sort. We shall do better still, I hope, when we get our church, which is shortly to be built, and is to cost \$10,000, half the amount being subscribed by the Government."

QUININE FOR THE MILLION!—The Government of India readily respond to the wishes of the Madras Government in the proposal we quoted the other day. "It is learnt with satisfaction," writes the Secretary, Sir E. Buck,— "that the Madras Government has resolved to reduce the price of the quinine packets." Suggestions for improvements in packets are however made, based on experience gained in Bengal. Then comes the following rather amusing paragraph in the official order:—

The Government of India are still advised that the simultaneous distribution of quinine and jalap powders is likely to afford a handle to ignorant village and country practitioners for discrediting the efficacy of the former drug. It is believed that poor natives seldom require purgatives, or that when they do they recognize the fact for themselves and resort to indigenous drugs which are effectual for the purpose. I am to suggest, therefore, that the separation of the jalap powders from the quinine may be tried as an experiment in selected districts. Dispensing establishments have to make up the packets; but it was objected in Madras that these were overworked already; an objection Sir E. Buck is instructed to overrule by submitting the following figures to show that Madras does far less for the money than other Indian divisions:—

Province.	Cost of establishments.	Number of patients.
R		
North-Western Provinces and Oudh.....	289,532	2,890,369
Punjab.....	250,433	2,580,496
Madras.....	420,054	2,580,746

In Ceylon over 400,000 patients were treated at 180 outdoor dispensaries in 1891, and perhaps about 830,000 paid by these patients on account of medicines, but we have no means of knowing what the total cost to Government was.

MOISTURE OF THE SOIL AND ITS EFFECT ON PLANT LIFE.

It is sometimes extremely instructive to compare general results derived from study of living plants in the field with special conclusions obtained by experience in the laboratory. As a general rule the last method of inquiry leads into a wilderness of conflicting and contradictory statements, especially when the experiments have been conducted by independent observers; of course, a single set of experiments conducted by one person is (if it give any conclusion at all), more or less harmonious. Still, when one does find any double confirmation of this kind, the result is probably more valuable than any reasoning from either method alone; and in the following few facts, I have found such a double confirmation.

A series of very excellent papers has recently been published in Germany on the different capacities for retaining and conducting water shown by different soils, and these explain certain peculiar phenomena in plant life.

Thus, if one arranges a series of soils such as, sand of a quartzose character, loam, leaf-mould with a certain amount of lime and sand, pure leaf-mould, clay and peat, these will be found to vary as follows:—

The thicker or denser soils will be able to retain a larger amount of water than the loose and sandy ones, and this result holds true (Prof. Wollny, *Forschungen*, vol. v., p. 1) in the same kind of soil if the particles are closer together in one case than in the other. For instance, beating the soil in a pot, and pressing it closely down, makes it able to hold more water than if the earth is lightly poured in. The reason, of course, is, that the particles are so close to one another, that they form narrow capillary passages which retain the water in the same way as ordinary capillary tubes.

For a similar reason these thicker clayey soils do not thaw so quickly as the loose sandy ones, and in long-continued drought, the cracks formed by the sun are fewer in number (though deeper and narrower) than those produced in the looser sandy ground; in fact, all changes in temperature are felt more rapidly and severely in loose sandy soil than they are in thick clay or loam, which becomes more slowly heated and cooled, though retaining the heat for a longer period.

This explains a point which always greatly puzzled me in Egypt. Between Cairo and the Pyramids there is a stretch of flat ground, mostly pure alluvial of the Delta, but turning into the ordinary desert sand, about half to a quarter of a mile before the low limestone hills on which the Pyramids are built. (Part of this forms the links of the Mena House Hotel.)

I noticed that when the soil was even very slightly clayey or alluvial, many small herbaceous plants and a few perennials grew upon it; but when there was no sign of alluvial, scarcely a single plant grew there, and the few which did exist, were all the regular desert forms which seem to subsist chiefly upon dew. The line was so well marked that one could almost have drawn it upon the soil, and in view of the preceding experiments, the reason is quite obvious. These little herbaceous Thistles and Plantains could not live unless the soil retained a certain amount of water for them, and it was only the fine-grained alluvial particles which were able to do this.

Another point brought out Professor Wollny and Herr Eser in the same *Journal*, vols. vi. and vii., is the effect of plants on the temperature of the soil. Thus it was found, that ground which was covered by plants did not become either so hot in summer or so cold in winter as that which was left exposed,

and the daily change in temperature was also much less than in bare ground. It was also found that ground covered with straw or manure was not so well protected against these changes as that covered with living grass, and that the closer and thicker the stems of grass or corn were planted, the better was the protection against changes of temperature. It seems probable, from other experiments, that these differences are due to the way in which evaporation from the soil is checked by living plants. The plant-covering acts as a sponge, and after a shower of rain retains a large amount of water, which is only given off gradually afterwards. This explains the familiar fact, that the disappearance of forests usually produces drought in hot climates, as instanced by the Cape de Verde Islands, which, when discovered by the Portuguese, were covered with forest and very fertile, and are now exceedingly barren and arid, and only possess a single tree. This probably, also in part explains why ponds which are sheltered by trees do not freeze so quickly as those which are exposed—for instance, St. James's Park, as compared with the Round Pond.

There is also a peculiar reaction of surroundings on plants, and plants on their surroundings in this connection. A tropical forest, where there is great humidity of the air, is always extraordinarily full of plants and exceedingly dense. The trees are very close together, and there is an enormous amount of undergrowth, while the creepers fill up every available space between the undergrowth and the upper branches. This extreme density of the foliage is not nearly so marked on the tops of mountains, and sometimes disappear altogether on the crest of a mountain or a plateau, where the wind can sweep the moisture away. One sees exactly the same thing in this country; any very narrow valley or glen among the hills is, when left alone, much more crowded with vegetation than an exposed wood, and grass grows much more closely on stiff or wet ground than it does on light and loose soils.

One might multiply conclusions and hints of this kind indefinitely, but perhaps enough has been said to show the value of such laboratory experiments, which seem unfortunately to be made only in Germany, and not to have found an abiding place in our own country, where agriculture certainly requires the best scientific assistance.—G. F. SCOTT ELLIOTT.—*Gardeners' Chronicle*.

HARDINESS OF EUCALYPTUS GLOBULUS AND E. COCCIFERA.

A note appeared in one of the New York gardening publications recently, setting forth the failure of a test for hardiness with seedlings of *Eucalyptus globulus* and *E. coccifera*. As these trees grow so rapidly, and are so very distinct in character, I think they are worth planting in the south of England; even though they get frozen every few years (say eight or ten), but they will attain a large size in that period of time. The experiments at Kew should be repeated with the supposed hardy types. I have not been in communication with the Gardens since the retirement of Sir Joseph Hooker, but perhaps some one there will see this note in your columns, and pardon me for any seeming want of courtesy. Kew is not Tasmania, and I do not see how it could be expected that young soft seedlings would survive an English winter. Unripened *Eucalyptus* wood will not endure 10° of frost. Young trees of 12 or 14 feet high are often killed back for 3 feet or more, with the thermometer barely touching 32° Fahr., when they are growing in swampy places. On hill sides they often escape, simply because there is less frost, and the wood is better ripened. It is well known that woody trees will stand considerable frost. I have had one out here which stood 22° Fahr. I then took it in, and wintered it out of pure pity, although I had to cut off 5 or 6 feet to horse it. Try again, and keep the young plants in pots until they are strong and woody.—JAMES MACPHERSON, Tasmania.—*Gardeners' Chronicle*.

AGRICULTURE AND NEW PRODUCTS IN THE DIFFERENT PROVINCES OF CEYLON.

(From the Administration Reports for 1892.)

EASTERN PROVINCE, TRINCOMALEE.

COTTON.—The experiment made from 1890 onwards at Andankulam continues. The cotton still proves itself likely to repay culture on a large scale on the edges of tanks, and the experiment, as far as it reaches, may now be considered finally successful. But to obtain healthy plants and a marketable product on a small scale is not necessarily conclusive proof that a culture on a very extended scale would give profit adequate to the risk of outlay. This I consider can only be proved by a large experiment, conducted on business lines by an experienced planter or syndicate. The growth of the cotton does not prejudicially affect the tank in its irrigation capacity. I repeat my remarks of 1891:—

The upper parts of tanks might be regularly cultivated with it, at great profit, as proved by the Andankulam experiment. Small dams would hold up the water of the early showers, and allow the land to be ploughed while damp. The people, however, have not sufficient intelligence to adopt a new cultivation, unless first stimulated by jealousy, and taught its value by European enterprise. The Andankulam experiment is proceeding.

NORTH-CENTRAL PROVINCE.

GRAZING CATTLE.

The splendid facilities this district afforded for breeding and grazing cattle so struck the late Mr. Elphinstone that he started a cattle farm at Minneriya. But troubles connected with coffee unfortunately prevented his doing more than making a beginning, which had soon to be discontinued. In this connection I would point out that almost all the coast cattle landed north of Puttalam are driven to the plains of Tammanakaduwa, whence they find their way to the upcountry and Colombo markets. The Principal cattle route is via Topawewa (Polonnaruwa) or Minneriya to Anguamedilla, and Elahera (on the Ambanganga) to Naula on the North road.

Besides the coconut, the palmyra palm is thriving in some of the lower Uva villages, and the cultivation of cacao is slowly but surely extending, the increase being from 730 acres in 1891 to 900 last year. For other products, here is Mr. Murray's Uva return:—

CULTIVATION IN UVA.		
	1891.	1892.
Tea	23,609	25,799
Coffee	19,650	18,150
Paddy	23,210	25,950
Garden fruit, vegetables, &c.	5,143	9,143
Other products	8,521	7,512
Fine grain	7,513	8,152

The tobacco crops of the Chilaw district are of well-known importance. Here are the statistics given by Mr. Noyes:—

TOBACCO CROPS.—The Mudaliyar of Pitigal Korale North reports that the tobacco cultivation in his division was not so good as in the previous year. Although a larger extent was sown, some damage was caused by untimely rains. The area cultivated was 190 acres, and the crop produced was 147,620 lb., the average price per pound being 75 cents.

The Mudaliyar of the Central Division reports that 114 acres were cultivated with tobacco during the year in his division, and that the weather was most favourable, and the crop better than in any other year during the past ten years. The value of the crop he estimates at Rs. 110.

In the Southern Division the Mudaliyar reports that about 375 acres were cultivated with tobacco, and yielded a crop of about 6,045,800 lb. which realised a sum of Rs. 1,209,060.

Mr. King has the following among other specially interesting paragraphs in his Report for Kurunegala:—

INDUSTRY IN SEVEN KORALEES.

The people of the Seven Korales are, of course, chiefly engaged in agriculture. A considerable industry has sprung up in the manufacture of casks for the transport of plumbago, and in making baskets for tea leaf. The plumbago mines at Dodangaslanda and Kagedara, the Batalagoda irrigation works, the railway and tea, cacao, and coconut estates are now giving employment to large numbers. In Puttalam the manufacture of salt maintains a considerable section of the community, and all along the coast there is an active business in fishing.

Under Mr. Parker's able and energetic supervision the channel and headworks at Deduruoya showed highly gratifying progress. Mr. Parker's management of Sinhalese labour is worthy of great praise. Men and women of every class and caste work side by side under his supervision, and he has often more applicants for work than he can give employment to. Had all other employers of labour in Ceylon the same happy tact, it would be a good thing for the prosperity of the country, and it would not be so much the fashion, as it is now, to denounce the Sinhalese as an indolent and improvident race.

Mr. Acland pushed on the survey of the extended Deduru-oya scheme, which ought to be finished about the middle of 1893.

Finally, we cannot refrain from picking out the following from Mr. Davidson's Report on Kegalla:—

NEW AREAS OF CULTIVATION IN KEGALLA.

PADDY.—The area under cultivation remains stationary at about 21,500 acres. The total extent as well-cultivated is about 28,600 acres, but a considerable proportion is only cultivated under exceptionally favourable weather. There has been an increase of only a few acres of newly cultivated land during 1892. It is probable that, given favourable weather in March and April, 1893, a considerable area abandoned as too poor to bear a tax may be re-cultivated.

TEA.—The area under cultivation has increased to about 22,718 acres, yielding nearly 8,000,000 lb. of tea. This includes most of the Kelani valley and a considerable part of Dolosbage and Yakdessa. The extent opened during the year has been about 1,800 acres. The prospects of this enterprise in this District were never more prosperous than they are now.

COCONUTS.—The area under this product is approximately 20,000 acres. On the whole, the yield cannot compare with that in more suitable localities. But the permanent nature of the product and the little trouble it gives make it the most attractive product to those whose lives are bound up with the soil.

ARECANUTS.—A very large extent of the native gardens, probably covering 20,000 acres, contain groves of arecanuts which flourish better in this District, their ancient home, than in any other part of the world. Wherever an arecanut palm will grow, it is planted, and a not inconsiderable area is now added yearly on tea estates both in the Kelani Valley and in Dolosbage.

CACAO.—This product still covers less than 1,000 acres, although land is being put under cultivation throughout the Four Korales. There are few parts of Three Korales where it is not too wet or too windy for cacao, but in Galboda and Paranakuru Korales the plant should grow to perfection. The cultivation is extending among the villagers, to whom 348 pounds from the Royal Botanic Gardens have this year been distributed at the Kachcheri in small quantities, and a record is being kept in detail of all the successes and failures. This product promises to develop into an important source of wealth for the District. Complaint of theft of cacao pods from estates are rare.

OTHER PRODUCTS.

One hundred and eight acres are under coffee, and 1,759 acres. Cinnamon, cotton, and cardamoms

are cultivated on 19, 20, and 35 acres respectively. But they have no future here. *Coca erythroxylon* is being grown as an experiment, and the District could glut the markets of the world already. *Sapanwood* is being grown to a profit. Quickly growing timber, such as *unumidella*, is being grown to meet estate demands.

I have omitted references to the hill crops grown on oheas, because it is very difficult to compute the area under cultivation annually. I do not think that in 1892 it has much exceeded 9,813 acres. *Kurakkan* (raggi) is the favourite product.

The acreage of the district is about 416,640, of which it is calculated that 102,847 is now under cultivation.

Apart from coconuts, under which it is estimated that there are now 19,993 acres in cultivation, the principal garden products are arecannts, which, however, yielded an exceptionally short crop, only 825 tons having been despatched by railway as compared with 1,158 tons the year before; plantains which are profitably cultivated for the Colombo market, 2,354 tons having been despatched by the railway alone, as against 2,462 tons the previous year; and jak, yams, breadfruit, cacao and cassava.

Of new products, cotton has been proved after an exhaustive trial, to be a failure in this district. Liberian coffee is very little cultivated, is not easily obtainable, and not much sought after. But cacao is rapidly coming into favour, and is a product the cultivation of which is gradually spreading. Up to date the Director of the Royal Botanic Gardens has furnished to the Kachechi for distribution 1855 pods; the history of all these has been carefully kept, and although there has been a large percentage of failures to rear so delicate a plant in its earlier stages, yet there are now, especially in the Galboda and Paranakru korales of Four Krales, flourishing cacao trees scattered throughout the dwelling gardens, and there is a ready demand for seed.

MR. H. L. FORBES ON TEA PROSPECTS.

We direct attention to the very sensible, not to say shrewd, letter sent to us by our old friend Mr. H. L. Forbes, (chairman of the Scottish Ceylon Tea Plantations Company. It will be found on page 97, and it will be seen that, while allowing for the adverse influence of home politics, in reference especially to Ireland, in unsettling the tea market. Mr. Forbes emphatically holds that the recent low averages for Ceylon teas are mainly due to poor quality; and he dwells on the special need for improvement in the teas to be shipped during the rest of the year. It is quite clear that Ceylon is in danger of losing its reputation for really superior tea, and of falling down in the estimation of the home tea trade to the position occupied by Java; and yet it is admitted on all sides that most of the Ceylon districts can send teas, if the proprietors and makers so choose, nearly if not quite equal to the standard of the plantations which even now show us what fine Ceylon tea really means. Mr. Forbes's advice and warning, therefore, have reached us very seasonably, and we trust that, although it may be at the expense of quantity, we may see a steady rise in the average price of our teas in Mincing Lane from this time to the end of the year.

THE CHEMISTRY OF THE COCONUT PALM: ON LIBERAL CULTIVATION—MANURES—THE USE OF SALT, &c., &c.

"The Manual of Ceylon Chemical Analysis by Mr. Cochran" which you are publishing in the pages of the *Tropical Agriculturist* must prove to be of much interest to the practical planter and at the same time must show him ways of procedure for gathering further knowledge.

One would have naturally expected to see in this work some light thrown on the much-vexed question of the value of salt in coconut cultivation. However Mr. Cochran cautiously leaves it where it was. It must anyhow be admitted that coconut trees growing along the sea-border flourish better and give heavier crops than those grown inland and the point that has to be determined is, whether this improved growth and yield of the plant is due to the large percentage of salt found in such places or whether it may be attributed to any other cause, such as the climate, rainfall or the chemical composition or the mechanical state of the soil.

It was desirable that at least one analysis each of the different coconut soils should have been presented to the readers; and until such data are obtained, no conclusions could be drawn on the point, though one may be quite convinced that salt plays an important and rather a peculiar part in the economy of the coconut tree.

The natural habitat of the coconut tree is the sea coast and the borders of the salt creeks, there it flourished without any cultivation whatever, and even when it was cultivated we find the growers selecting similar situations. The extended use of the free products of the palm demanded a larger area under it and gradually the cultivation spread inland, where we do not find it to flourish as well as it does in the coast. This fact strongly leads one to mark salt as the substance which causes the difference. However it has also been noted that these coast soils are generally free sandy soils whereas the character of the soil assumes a harder texture as we proceed inland. Even in inland districts the coconut thrives better in light soils than in heavy ones. The second observation leads one to the conclusion that the coconut thrives better in loose soils. Now it resolves itself to the one question whether the soils in the coast are superior to those which are inland, and if so where does that superiority lie? Only an analysis of these different soils could throw a light on this point.

The word coconut milk seems to be pretty generally used by foreign writers for the water in the nut. In Ceylon we use the word milk to denote the expressed juice of kernel, which in appearance as well as in composition closely resemble the genuine article after which it is named, and if six to seven parts of water be added to the thick expressed coconut milk, it would form a fair substitute for cows' milk, with rather a higher percentage of fat and less of sugar.

The tables Nos. 1 and 2 give the general yield of nuts per tree in different soils, and the manures, quantities, cost and yield respectively, given in the chapter on the products of the coconut palm (chapter iii) seem to require much explanation. The tables are quoted from a statement supplied to the *Observer* by Mr. Davidson. When the figures are analysed and tabulated some strange facts come to light which appear to be against the results obtained by practical planters. I give below an analysis of the above mentioned tables which I have made:—

I. Unmanured.		Yield.	
1	Poor soils (white sandy) ..	2	10 0
2	Dark mould ..	5	0 0
3	Reddish ..	7	0 0
4	Strong rich upland soil bordering the banks of a river ..	8	15 0

II. Manured with Hultsdorf Mills' Compost. Profit and Loss.			
	Cost of Manuring.	Yield.	Loss.
	£ s. d.		
1	Poor soil 14 0 0	10 10 0	= 3 10 0
2	Dark mould 10 10 0	13 2 6	plus 2 11 6
3	Reddish 7 5 10	14 0 0	„ 6 14 2
4	Strong rich soil 7 0 0	17 0 0	„ 10 0 0

* Ceylon Manual and Chemical Analysis by Mr. Cochran, vide "*Tropical Agriculturist*" for 1893.

III. Poonac mixed with bullock manure, &c.

	Cost of Manuring.		Yield.	Profit.	
	£	s. d.		£	s. d.
1 Poor soil	5	10 0	7 0 0	1	10 0
2 Dark mould	3	10 0	8 15 0	6	5 0
3 Reddish	2	6 8	9 12 6	7	5 10
4 Rich	2	0 10	10 10 0	8	9 0

IV. Tying a pair of bullocks for ten nights.

V. One Cart load of husks.

	£		Yield.	£	
	s.	d.		s.	d.
1 Poor soil	1	6 3	7 0 0	5	13 9
2 Dark mould	1	6 3	8 15 0	7	8 9
3 Reddish	1	6 3	9 12 6	8	6 3
4 Rich	1	6 3	10 10 10	9	3 9

Thus the poor soil yields £5 13s 9d manured with a cart load husks or by tying bullocks round the trees.

	£	s.	d.
The same soil unmanured yield ..	2	10	0
Manured with poonac ..	1	10	0

Whilst manured with Hultsdorf compost there is a clean loss of £3 10s per acre. The dark mould yield £7 8s 9d manured with husks or by tying cattle; £6 5s, manured with poonac and cattle dung; £5, unmanured and only £2 11s 6d manured with the compost. The reddish soil gives the highest return manured with husks or by tying cattle £8 6s 3d; poonac and cattle manure £7 5s 10d, unmanured £7, with the compost £6 14s 1d. The rich soil gives the highest return with the compost £10, followed closely by the husks or cattle with £9 3s 9d, unmanured £8 15s, and manured with poonac and cattle manure £8 9s 2d.

From the above it is seen that the manures which have proved most successful in all soils are coconut husks and fresh dung and urine from cattle tied under the trees. The costly compost is a failure in all soils except the richest, and strangely enough it has decreased the net profit in all other soils. The composition of this compost is not given anywhere and it would be interesting to know it if possible.

The mixture of poonac and cattle dung appears from the above table to be far inferior to coconut husks and in the case of a poor soil the profits are less than when unmanured. But the question comes now. Have the tables been correctly prepared? If so is it possible, that, coconut husk is a better manure than others?

That rich manures have no effect (comparatively) on poor soils? Or, does the coconut plant depend more on the texture of the soil and the moisture which it is able to absorb than on rich and concentrated nutritive matter? Does salt act in keeping the soil moist and porous and improve the condition of the coconut plant? These are questions which if even partly decided should prove of value to the coconut planter.

The values of the respective manures were computed above after deducting their costs. But if we look at them for a while without taking into consideration the cost of manuring, we find the compost standing first in the list, for it has been able to increase the crop nearly five times in the poor soil, and to a large extent in all the other soils. Poonac mixed with bullock dung and mud; coconut husks; fresh dung and urine from cattle tied under the trees, all take the same rank as regards the crops they produce. The cost of the compost prevents its profitable use in any but very rich soils.

Poonac and dung mixed together must according to the analysis of the manures contain more nutritive matter than husks. But in the yield of nuts they have proved to be of equal value with the disadvantage for poonac in its higher cost.

However well husks are represented in the tables referred to, many practical planters do not rely much on its value except perhaps in very heavy soils. Besides it takes a long time to decompose and be of use to the plant. Chemically the substances contained in the husks are not equal to those in other manures, however the former has a large percentage of potash; and has the great advantage of "quantity," and cheapness. It would be well to

ascertain from your numerous correspondents whether "husks" could be given so high a rank as a coconut manure and for my part I am sceptical on that point. Fresh dung and urine obtained by tying cattle round the trees have come up in the same rank as husks and poonac, as regards its yield and when the cost is compared it takes the first rank along with husks. As regards the chemical composition of this manure it is decidedly superior to "husks" and contain more nitrogen than the poonac, (in the absence of the composition of the composts there is no way of comparing with it). The only difficulty which presents itself in the way of adopting this form of manure is the want of a sufficient number of cattle to effect it systematically. W. A. D. S. Bombay.

(The above reviewed by W. J.)

The first part of W. A. D. S.'s paper deals almost exclusively with the question as to whether salt is the cause of the heavier crops yielded by coconut trees growing within the influence of the sea air, over those growing inland, or whether soil, rainfall and other conditions have a part in it. I am entirely of the latter opinion and deny that trees growing along the sea-borde are heavier producers than those growing inland in free soils such as are common along the coast. It should also be remembered that the coconut groves along the coast are thickly inhabited and are constantly receiving assistance from man, cattle, pigs, refuse, &c.; and a garden under the same conditions inland would bear equally well. I have in my Review of the chapter on the Coconut, in Dr. H. A. Nicholls' "Tropical Agriculture," already expressed my views upon this matter. Here is Liebig's opinion of salt as a manure:—"We have every reason to believe that where the crops are increased by manuring with common salt alone, or where the favourable influence of salts of ammonia or nitrate of soda is augmented by the addition of common salt, the operations of these three salts essentially depends upon their power of diffusing the nutritive substances present in the soil, or of preparing those substances for absorption. * * * As that part of the action of nitrate of soda, sea salt, and salts of ammonia, which consists in effecting the distribution in the soil of other elements of food, may consequently be replaced by careful tillage, the effects produced upon the crops by these salts affords a pretty safe indication of the condition of a field. If all other circumstances are the same, their effect will be much less marked upon a well-tilled field than upon one not in the same condition." Again after recording the results of certain experiments with salt he says:—"In both these series of experiments the crops of corn and straw were remarkably increased by the addition of common salt; and it is scarcely necessary to repeat that such augmentation could not possibly have taken place unless the soil had contained a certain quantity of phosphoric acid, silicic acid, potash, &c., capable of being brought into operation, but which without common salt was not assimilable." These extracts show that

SALT

can hardly be classed as a manure, as it scarcely, if at all, adds anything to the fertility of a soil; but that it is a most valuable agent for dissolving and bringing into an assimilable condition ingredients already in the soil, and thus increasing crops. But this very property would soon exhaust a soil unless the ingredients removed in the shape of crops were restored by suitable manures. W. A. D.'S.'s analyses of the tables given in "All About Coconuts," and quoted by Mr. Cochran are interesting; and, as he says, raise important questions which it would be well to have established or refuted. Especially is this the case with reference to the value given to coconut husks as a manure; they are placed on a par with pure cattle dung applied directly to the trees by tying cattle to them. This does not tally with experience, whatever deductions may be drawn from a chemical analysis of husks. If the analysis given in "All about Coconuts," of the "Total inorganic

and fixed matter drawn up annually by the deciduous parts of a coconut tree from an acre of land by 75 trees bearing 80 nuts per tree, &c.," is correct. These assuredly show the coconut husks are a most valuable manure; for they contain 611.04 out of 795.06 lb. Troy—the total quantity of mineral ingredients taken up by an acre of trees: that is to say that coconut husks appropriate to themselves $3\frac{1}{2}$ times as much nutriment from the soil as the fruit and other parts of the tree (stem excepted) put together! This is truly a revolution, and to me seems incredible. That planters should have had such a valuable manurial substance at their very doors, for almost next to nothing and still should not have known it sounds ridiculous; and if true, would brand us as, at least, a most unobservant lot of men. The husks, peduncle and spathe being restored to the soil, all that would be necessary, to keep an estate in perpetual good bearing would be to supply those ingredients removed in the shell, kernel and water of the nut, and these according to the analysis, would be as under for one acre of 75 trees giving 80 nuts per tree:

Chloride of Sodium	14 09
Salts of Potash	80 20
Phosphate of Lime	21 55
Salts of Lime	3 50

119.84

Not having any works of reference by me on this subject, I am not in a position to say how many lb. bone meal and how many lb. wood ashes it would require to furnish 80 lb. salts of potash, 21½ lb. phosphate of lime, and 3½ salts of lime. I should feel much obliged to any local chemist who would afford this information as it would be useful to compare with the quantities of those ingredients usually applied by coconut planters who cultivate. Most planters are aware that coconut husks contain a large amount of potash; but, believing that the increase in yield would not pay for the cost of burying, they burn them and apply the ashes; but few do even this systematically, or return to each tree its proper share. They should be burned as directed by me in my letter in the *Observer* of the 4th April last. What

WHOLESALE ROBBERY OF THE SOIL

must take place when coconuts are sold with the husks, and on estates where coir is manufactured! We are told that coir dust is of no value as a manure, therefore all the virtue must be in the fibre; let no one henceforth speak disrespectfully of old coir rope: what old rags are to tea, such are old coir ropes to coconuts! To burn husks does seem a waste of valuable vegetable matter which being incorporated with the soil would greatly improve its mechanical condition as well as afford food for the trees; but until it is proved that the increase in the yield of nuts will repay the cost of burying, and leave a profit besides, I think few will care to adopt the plan on any large scale. Husks are so unmanageable that they cannot be dug or ploughed into the soil like weeds. To anyone wishing to experiment on a few acres I would recommend digging a trench between every other row of trees, 2½ feet deep by 3 feet wide and fill in with a layer of husks and a layer of earth alternately; they decompose more readily when brought in contact with earth than when they are put in alone.

It would be easy enough to institute a comparison between the

THREE FIRST DESCRIPTIONS OF MANURE

applied, as their effects would be apparent about the same time and also be exhausted simultaneously; while the effects produced by the husks would only begin to be seen about the time the other manures were exhausted and would last for two or three years after. How then the comparison was arrived at it is hard to say; probably it was simply based upon the analysis of the constituents of the husks, and not by actual experiment; and this I think is very likely, and would account for such a high place being accorded to it. It remains however, to be proved by careful experiment, whether we may not have hitherto too much neglected what may turn out to be a

cheap and valuable addition to more costly manures. If I remember rightly the Hultsdorf Mills' compost consisted of night-soil, cattle manure, ashes, refuse poonac and the parchment covering of the coffee bean. This manure gave the best results on all soils, but owing to its cost the profits from it were not as high as from some of the others. I am a little puzzled however to know how No. 4 soil with one half the quantity of manure applied to No. 1 gave the same increase. The circumstance too that the increase from manures 2, 3 and 4 on all the soils is the same, is a very suspicious coincidence and tends to throw doubt upon the reliability of these labels; and to W. A. De S. belongs the credit of having drawn attention to them. The following table shows the yearly value of crop from the poor soils in an unmanured condition, and after being manured; also the enhanced value owing to the manuring:

Soils	Value of yield after manuring	Value of yield before manuring	Increase
No. 1.			
1	10 10 0	2 10 0	+ 8 0 0
2	13 2 6	5 0 0	+ 8 2 6
3	14 0 0	7 0 0	+ 7 0 0
4	17 0 0	8 15 0	+ 8 5 0
No. 2.			
1	7 0 0	2 10 0	+ 4 10 0
2	8 15 0	5 0 0	+ 3 15 0
3	9 12 6	7 0 0	+ 2 12 6
4	10 10 0	8 15 0	+ 1 15 0
Nos. 3 & 4.			
1	7 0 0	2 10 0	+ 4 10 0
2	8 15 0	5 0 0	+ 3 15 0

4	10 10 0	8 15 0	+ 1 15 0

GARDENING NOTES.

RHUBARB CULTURE.

I have found it best to open a trench 18 in. deep, and about the same in width, fill to within 6 in. of the top with well-rotted manure and fine soil mixed and trampled down. On this I place large pieces of roots having one strong bud, 8 ft. apart, and cover with good mellow soil, rounding it up in a ridge. This ridge will settle 4 in. to 6 in., and cultivation levels the service. Planting is done as early in the spring as the ground can be worked. The soil is kept mellow and free of weeds with cultivator and hoe, and the plants make a rapid growth. Late in the autumn they are covered with 6 in. of strong manure, which is raked aside early in the following spring.

THE MERGUI PEARLING COMPANY, LIMITED.

This young Company, floated in Singapore, has the distinction of having already obtained financially the strongest position of any joint stock enterprise in the Straits. It has been started to work pearl and pearl shell fisheries on the Mergui coast at the southern extremity of the province of Tenasserim in British Burmah. The fishery district, comprising the islands and narrow waters of the Mergui archipelago, has been divided into four blocks of similar area. Three of these are in the hands of native concessionaries, who hold them directly from the Burma Government. Block No. 3 is that held by the Company, and they have just acquired a lease for three years, ratified by the Government of Budat. The area is roughly 1,200 square miles, and approximately the concession is a parallelogram of 40 miles by 30. The directors reside in Singapore and are themselves the chief shareholders, there being no shares on the market.

In three and a half months' work the Company have raised 25 tons of pearl-shell, of the average value of £120 per ton, some realising as much as £126. The quality of the pearl-shell is much the same as that from Western Australia and Torres Straits, which may be put at from £90 to £150 per ton. £80 a ton is advanced on the shell by two firms in Singapore on delivery here, so that it can be seen that the Company are turning out a product of good market value. In addition about \$3,000 worth of pearls have been obtained, and besides these two of good quality, valued by a professional dealer respectively at R800 and R6,000, the latter, an exceptionally fine pearl, having been got just the other day. It will be sent down to Singapore, and will probably be exhibited on arrival. If disposed of in Hutton Garden it might fetch even £150 more than its local valuation.—*Free Press.*

THE CONSUMPTION OF TEA AND OTHER STAPLE DRINKS.

The following is the conclusion of the article contributed to the *Economic Journal*, under the above heading, by Mr. C. H. Denyer:—

Sir Andrew's attack on Indian tea created quite a stir in the "West End," and a friend tells me there were for a time so many applications for pure China tea that he had to keep a special canister at hand for it. In a few weeks, however, came the reaction; the Chinese product had not flavour enough, and all his customers returned to their old love.

Professional tea-tasting is now partly carried on by smell instead of taste, yet a tea-taster tells me that he and his craft suffer acutely from weakness and nervous affections, and are for the most part strongly tempted to keep out the winter's cold by liberal alcoholic potations. Would it not seem, then, that there is some possibility of danger if English people take too much tea, and take it too strong? Yet it is in these directions that the tide seems to be running: we may, therefore, well question the wisdom of any further reduction in the tea duty. It was not long since asserted in the House of Commons that the fact that the consumption increased 6½ per cent. when the duty was reduced to 4d. tended to show that there were still many persons kept from tea by its high price. It is urged, too, that every increase of tea drinking means a decrease of alcoholic intoxication. These statements require further proof. My own experience tends to show that tea, and sometimes strong tea, has largely been substituted for the gruel or milk and water which an old labourer assures me used thirty years ago to form the staple drink of workmen's children. Of course, the added sugar and milk make this tea, to some extent, nourishing, but, nevertheless, the medical profession is strongly and rightly opposed to the growing practice of rearing infants on a drink so utterly unsuitable as tea.

THE INCREASED POPULARITY OF TEA.

One hundred and twenty years ago Arthur Young complained bitterly of "the custom coming in of men making tea an article of their food almost as much as women; labourers losing their time to go and come to the tea table; nay, farmers' servants demanding tea for their breakfast with the maids! which has actually been the case in East Kent." ("The Farmers' Tour," vol. iv, pp. 350—2) One may contrast with the above the story my father tells of the consternation caused nearly fifty years ago in the then little village of Leyton, Essex, by the advent of a new groom from Suffolk, who actually asked to be allowed to drink beer instead of tea for breakfast, this being the custom of his home. The squire's wife would not hear of a man wanting beer for breakfast, so completely had the customs of the country changed, and that, though you could not then buy tea much under 6s a lb.!

So far as I have been able to ascertain, it is the usual opinion both of doctors and laymen that tea is by no means the thing to aid in the digestion of a heavy meal; yet the so-called "meat teas" have become in many parts quite a social institution. Our stomachs are hardly like those of the "Cannibal Tartars" of whom Dr. Short says:—"Their delicate dish is raw horseflesh, and when their dinner sits uneasy upon their stomachs, they drink of this (coarse green tea), and it rarely fails to restore their appetite and digestion."

William Cobbett, writing in 1821 (*Cottage Economy*, p. 13 *et seq.*), and vehemently urging a reduction in the tax on malt, so that the labourer might be encouraged to brew and drink his own beer, draws a highly-coloured picture of the ruin brought into the homes of the poor by tea. He says:—"The drink which has come to supply the place of beer has in general been tea. It is notorious that tea has no useful strength in it. . . . that besides being good for nothing, it has badness in it because, it is well known to shake and weaken the nerves." He maintains that an average labourer's family would save £4 a year by brewing their own beer and giving up "the troublesome and pernicious habit of drinking tea," and he goes even further:—"I view the tea drinking as a destroyer of health, an enfeeblener of the frame, an engenderer of effeminacy and laziness, a debaucher of youth, and a maker of misery for old age. If you fed a lean hog on tea messes instead of malt, he would starve," and the effect is as bad on men as it would be on hogs. Again, "Is it in the power of any man who has attained the age of fifty to look back upon the last thirty years of his life without cursing the day in which tea was introduced into England?" Cobbett's argument as to expense has long since fallen through, for the relative prices of tea and beer have now, largely owing to legislative interference, completely changed in favour of tea; and so coarse or no coarse, we drink four times as much tea per head as in 1821, while today tea is hailed by the advocates of temperance as having already done much to save the country from the curse of drunkenness.

We can perhaps adopt a *via media*. We may agree with the writer of a paper in vol. xv. of the Statistical Society's Journal, that "the consumption of tea and coffee has contributed materially to the sobriety, decency, and even morality of the inhabitants of this country;" but we must also remember that, as is maintained by the writer of the article "Tea" in the *Encyclopædia Britannica*, "the large quantity of strong tea taken by the poor, though it blunts the edge of hunger, works sad havoc with the digestive and nervous systems," and we can fairly claim careful consideration of the whole question before further legislative steps are taken in favour of tea as against beer.

Having discussed our tea at such length, and indeed, the garrulity connected with this beverage is one of Cobbett's serious objections to it, I do not propose to do more than glance at the other items in my list of staple drinks.

COFFEE.

Among non-alcoholic beverages coffee takes the second place; but comes, in this country, a long way after its great rival, the annual consumption in 1890 being only ¾ lb per head.

In the Mohammedan world, and in most Oriental countries, especially France, coffee is beyond question more popular than tea; but Mr. S. Dowell (*History of Taxation*, vol. iv., p. 231) assigns the three following causes for its secondary importance here:—(1) The incompetence, want of attention, and laziness of our servants in preparing the drink; (2) a belief that coffee is heating and more suited to a dry than a moist climate; (3) the heavy taxation to which it was subjected in former years, to which must be added in late years the cheapness and excellence of tea and white sugar.

Too much weight must certainly not be assigned to the last two points; for tea was always, and is still, more heavily taxed than coffee, and it was not till 1847, when the taxes on coffee had already been much reduced, that the consumption first began

to decline, a decline that has continued ever since, in spite of further reductions in the duty, which is now only 14s. per cwt.

Coffee is largely adulterated with the root of a plant which grows freely in Europe, viz., the wild cinchona, or chicory. It is possible that on the Continent chicory was used as a drink before the introduction of coffee; certainly it has been freely imported into England since 1833 to be mixed with coffee. Soon after this date its cultivation became popular in England; but by 1860, when duty was first levied on it, the home production had all but died away again under the stress of foreign competition. It has often been stated that the decline of coffee in public favour is due to the all but invariable presence of this bitter-tasting adulterant, but it must be remembered that the latter is no less used in Belgium and Denmark without causing any apparent decline in the consumption of coffee.

In their report for 1888, the Customs Commissioners note that some coffee mixtures sold by retailers contain as much as 90 per cent of chicory, and discuss the opinion of the trade that the sale of such mixtures injuriously affects that of pure coffee. This they admit to some extent, but urge that the growing preference for tea and cocoa is chiefly due to the small amount of time and trouble required in the preparation of these latter.

The duty on chicory is slightly less than that on coffee, and the receipt therefrom vary from 32 to 38 per cent of these from the latter. In 1882 a tax of $\frac{3}{4}$ d was imposed, by means of a stamp on the label, on every $\frac{1}{4}$ lb. of coffee mixture containing any vegetable matter other than coffee or chicory. There were 2,242,739 such labels issued in 1882, but the number rapidly declined to 887,753 in '89, though it rose slightly in '90.

The Customs Commissioners would probably not be sorry to lose the modest £200,000 or less yielded by coffee and chicory, seeing that whereas we consume 72 per cent of the cocoa we import, and 87 per cent of the tea, we only keep 29 per cent of the coffee, the duty on which is thus necessarily collected at a high comparative cost.

COCOA.

Cocoa is generally classed by the Chancellor of the Exchequer in what is called the "coffee group," and thus undeservedly comes in for a share of the annual sigh heaved over the want of elasticity shown by the group.

Cocoa and chocolate are manufactured from the exceedingly nutritious fruit of the *cacao theobroma*. Since 1832, when the previously heavy duty was reduced, the drinks prepared from cocoa have been rapidly and deservedly rising in public favour. The consumption was only 018 lb per head in 1831; in 1852 it was 121; in 1872 244 and in 1891 571. In 1888 the Customs Commissioners noted that the consumption of cocoa had increased 75 per cent in eight years, owing to its nutritiousness, its ease of preparation, and its cheapness in public cocoa rooms, of which the number was rapidly growing. They held that it was "largely displacing coffee, and no doubt also alcoholic drinks."—*H. and C. Mail*, May 9.

THE USE OF KOLA.

With reference to the report of the recent sale of a large quantity of kola-nuts in Holland in our last issue, Mr. Thomas Christie writes:—"I hear that the kola-nuts that were sent from Holland to France were wanted for two purposes—the better quality for the food of man, and the common quality to improve the 'horse-bread' which is being made in France to replace hay. The French have never been clever in making, storing, or cutting hay for transport, but this year the hay crop in France has failed altogether, and so a demand for food to be pressed into brick-bread, or 'briquets,' after being ground and mixed, has sprung up in that country. The Americans have already had to face this question and have found that nothing answered better

than poplar-wood as a base for the 'briquets.' I was recommended by friends in Paris to adopt this wood for more than one reason, especially as it is known and they can command any quantity. We have supplied kola-powder for years to certain feeders of horses here, and a small quantity mixed with the food answers well."—*Chemist and Druggist*.

CLEARING OFF OLD CINCHONA BARK STOCKS.

We call attention to the following curious episode of bark sales related by the *Chemist and Druggist*:—

In our Trade Report we refer to an extraordinary incident at Tuesday's cinchona auctions, viz., the sale of 463 bales of hard Pitayo bark, imported ten years ago, when good bark of this kind was still quoted at 2s per lb. The greater part of this particular parcel was bark of very poor quality, however, and even at the time of its importation it went from London to the Continent, and *vice versa*, without finding a buyer. At an average value of, say, 6d a pound, the 463 packages which were old on Tuesday represented, at the time, a value of about £1,500. They have been since quietly resting in a warehouse, the owners of which, failing to find the warrant-holders who are responsible for the rent, advertised them for sale "without reserve" the other day, in accordance with an Act of Parliament which gives them the right to dispose of unclaimed goods in this manner after a certain period. The warrant-holders, of course, knew better than to reveal their identity, and at the bark sales about two-thirds of the bark was sold, much to the amusement of all present, at the record breaking prices of one-eighth to one-sixteenth of a penny a pound for the greater part, while the best lots brought from 1 $\frac{1}{2}$ d to 2d. per lb. The aggregate amount realised by the lot was about 180l. for which the happy buyers secured about 26 tons of cinchona. Everybody was amused excepting probably the original importers who are said to have refused from 4d to 6s per lb. for the parcel ten years ago. The lowest-priced lots were bought by German quinine-makers the remainder by various druggists. Even the best lots do not contain more than 1 per cent., while the commoner kinds are said to represent less than $\frac{1}{4}$ per cent. of sulphate of quinine. Still, the bark purchased by the druggists is partly packed in hide-serons which are worth when in good condition about 5s. a piece.

COFFEE NOTES.

A telegram from the city of Mexico says that energetic preparations are being made in Vera Cruz and Oaxaca to extend the cultivation of coffee. Large sales of land suitable for the purpose have taken place, and the culture is expected to assume great proportions in a few years. It is also stated that this year's coffee crop in Oaxaca will be very large. There is no doubt that the ruling prices of coffee are stimulating coffee production in all the countries that have suitable land to spare, but for some years the effects of the increased planting will probably be slight, as the coffee tree does not bear until the fourth year.—*Merchants' Review*, New York.

An editorial in the *American Grocer* ridicules the notion that the duty on Venezuelan, Columbian and Haytian coffee has materially enhanced the value of all kinds of coffee in this market, but an advertisement in the same paper, over the signature of a jobbing firm, stated that owing to the duty shortening the supply from those countries, the advertisers are importing Java coffee to fill up the gap. The supply of Java in this market is very much heavier than a year ago, which fact bears out the statement in the advertisement. Java coffee is more costly than the

grades that have been partly excluded by the duty, and it is easy to see how the duty has indirectly affected the pockets of the American consumer when a higher-priced substitute has been used in some cases. We say, in some cases, because Brazil grades have also taken the place of Maracaibo and Laguayra coffees, at a higher price than they would have realized if Maracaibos and Laguayras had never been discriminated against. It is strange that some papers will not admit that import duties enhance prices, when they are so unwilling to have the duties removed. If the duties do not increase prices, they must be useless; and if they are useless, why not remove them.—*Ibid.*

THE AMSTERDAM CINCHONA AUCTIONS.

(Telegram from our Correspondent.)

AMSTERDAM, Thursday evening.

At today's cinchona-auctions 5,734 bales Java bark were offered, of which only 3,235 found buyers, at a decline of 5 per cent upon the last auction rates, the unit averaging on this occasion $4\frac{1}{2}$ cents (=about $\frac{3}{4}$ d per lb.) For manufacturing bark in quills, chips and crushed from 5c. to 59c. (=1d to $10\frac{1}{2}$ d.); ditto root, 9c. to 32c. (= $1\frac{1}{2}$ d to 5 $\frac{1}{2}$ d.); druggists' barks in quill, broken quill and chips 10. to 51c. (=1 $\frac{1}{2}$ d to 9 $\frac{1}{2}$ d.); ditto root, 14c. to 27c. (=2 $\frac{1}{2}$ d to $4\frac{1}{2}$ d per lb.) was paid. The principal buyers, in the order of their quinine-purchases, were the Brunswick, the Amsterdam and Mannheim, and the Anerback factories, Messrs. Matthes & Bormerster, and the Frankfort-on-Main and Stuttgart work.—*Chemist and Druggist*, June 3.

PURE COCOA.

SIR,—Referring to my letter in your journal of May 20, Messrs. Van Houten direct my attention to the fact that their cocoa is not described as "pure," but as "pure soluble." There may be more in this distinction than *prima facie* appears. There is no cocoa in the market which is "absolutely pure," strictly speaking. Every manufacturer either removes a portion of the fat or adds something to the ground nib to make the preparation more palatable when infused. A cocoa may be correctly described as "pure soluble" from a dietetic point of view, although it has been treated in a perfect innocuous manner, so as increase the proportion of soluble constituents.—Your very truly, D. B. Dorr.

104 South Canongate, Edinburgh, May 31.
—*Chemist and Druggist*, June 3.

PLANTING "PICKINGS" WITH A PRACTICAL APPLICATION.

The "cures" for all the ills that flesh is heir to are legion, but probably many people have not heard of that common agreeable and cheap medicament to wit SUGAR. "The sugar cane" is the title of a long description in the *Produce Markets Review* of how sugar of which the patients are advised at first to take not more than $\frac{1}{4}$ lb and never over $\frac{1}{2}$ lb (though $1\frac{1}{4}$ lb. may be taken afterwards) can cure indigestion, pains, oppression, acidity, nausea, insomnia, loss of appetite, debility, nervousness, wounds, sores, spots of hard skin, ulcerated ears, laryngitis, &c., &c., &c. Let there be no fear of any dangerous results from this treatment, for we are told that "of 202 patients treated with sugar only 5 died." What a good time there is in store for our little ones among whom there would seem to be a prospect of much sickness (though not of a fatal nature) in the near future, and for the grocerymen too, who will be as so our druggists. Our doctors of medicine would do well to throw physic to the dogs and take to sugarcane culture.

The stock movement reports in the *Queenlander*, give one an idea of the scale on which stock farming is carried on in the southern continent. Here

are a few items: "Today there are passing through Jundah, 1 112 bullocks from Spring Creek, Georgetown. P. Collins owner, George Blackall in charge. The bullocks are in exceptionally fine condition." "On the 12th inst. Mr. Wigglesworth, with 13 000 good wethers from Beaconsfield, destination Yundilla." "1,000 bullocks and 600 cows, the property of T. B. Nimmo, passed on the 18th." This is something like farming!

The following quotation from the *Melbourne Leader* of June 3rd is of interest at the present moment:—

It may not be out of place, without any necessity for creating a scare, to call attention to the desirableness of improving our system of CATTLE INSPECTION, more particularly with reference to the dairy herds. The growing importance of the dairying industry in connection with the interests of the producers and consumers alike demands a complete revision of the present extremely slipshod system. The staff of stock inspectors attached to the Department of Agriculture has not, we believe, at any time been subjected to a very severe veterinary examination test as a condition of admission to office; but if it be granted that some of the older officers in the service may have some practical experience in lieu of professional qualifications, that should certainly be no excuse for laxity in later appointments. It may of course be regarded as sufficiently in order for a Public Service Board point of view to transfer—as per a recent instance—a telegraph line repairer to a postal stock inspector, but to those outside who have no access to the sources of wisdom which actuate the members of that peculiar institution, the action is not altogether destitute of apparent anomaly. Even supposing the status of the stock inspectors was improved in a professional sense instead of weakened, it might be argued that the field of inspection is now becoming wide enough to demand even a more numerous officered system than the Department of Agriculture in these retrenchment times is likely to be able to command. In such case it might be as well to remember that clause 24 of the Public Health Amendment Act authorises borough and shire councils to register all dairies within their districts and appoint inspectors. Surely this is a duty that these bodies should undertake. For an annual fee that need not be beyond the ability of these bodies to easily defray the services of a competent veterinarian might be obtained to act jointly for several districts. One of the metropolitan districts, we note, has recently seen its way to adopt this course, with the result that already upwards of a score of cows have been marked as unfit for dairy use. It is not at all improbable that these condemned animals may have been transferred to some other district where inspection is not so methodically carried out, and if so that only adds weight to the reason why each local body should appoint its own inspector.

The *Auckland Weekly News*, under "Science and Inventions" refers thus to VEGETABLE IVORY, alluded to in our columns some time back:—This is furnished from the Andean palm tree, one of the most beautiful of all the palm tribes, a native of South America, but found especially in Peru. The stem of the tree is straight and short, and the crown ends in a splendid tuft of light green foliage, somewhat resembling an enormous ostrich plume running up for about 30 ft. or 40 ft. in height. The fruit is of great size and contains a number of cells or drupes all close together. In these cells are a number of nuts, each about the size of a hen's egg, which, when ripe, are extremely hard and known to commerce as corozzo nuts. The kernels are quite white, and have a very close resemblance in their general appearance to ivory. Many millions of the nuts are now imported into this country. The resultant ivory-like substance is of very wide utility, and in various parts, Birmingham especially, the material is already being used for many purposes, useful as well as ornamental, for which previously true ivory was exclusively employed. In this curious natural product—or the resultant substance—there probably lies a great future, since there appears to be no practical limit to the production of the nuts.

CULTIVATION OF COCOA IN CUBA.

The French Consul at Santiago, in a report to his Government, says that the cultivation of cocoa is closely connected in Cuba with that of coffee, and is carried on at the same time and on the same properties. In fact, every coffee planter, if the nature of the soil permits him to do so, sows between the rows of young plants cocoa berries, which will produce trees that will continue to bear crops when the coffee plants have ceased to produce. It is impossible to discover the precise date at which the cultivation of cocoa was introduced into the island, but as this plant was cultivated in Mexico and New Grenada before the Conquest, it cannot long have remained unknown to the Spanish colonists in Cuba, who kept up constant communication with the possessions of Spain on the American Continent. It was not, however, until about 1830 that several planters made an effort to introduce cocoa into Cuba, and at this time plantations of a certain importance were formed at Figueroa and elsewhere. Unfortunately, for many years the cultivation of the cocoa remained unprofitable, in consequence of the small demand and the low selling price. The price slowly rose however, the number of cocoa plantations increased, and by 1860 every coffee plantation in Cuba combined the cultivation of the cocoa, if the nature of the soil permitted it. The cocoa tree lives longer than the coffee plant, but it is much slower in producing. It takes, in fact, five or six years before the newly planted cocoa begins to bear fruit; it is at its full bearing at the end of the seventh year, and begins to decline at the end of fifteen, but without ceasing to bear; on some old estates there exist cocoa trees of upwards of fifty years of age, which still produce. The cocoa is usually planted in spring, by preference directly after rain; an interval of 10 to 12 feet is usually left between the plants. The kinds which are most used are those of Caracas, Guayaquil, and the Creole variety, which latter is said to come from Trinidad. The Caracas and Guayaquil varieties bear the finest fruit, but they are not so hardy and do not bear so well in Cuba as the Creole variety. The Caracas, however, fetches the best prices. The crop is gathered from the month of October to the month of August. During this period the trees are covered with blossom, and little bunches of ripe and half-ripe pods. The crop may therefore be gathered day by day, but as it is difficult to obtain the laborers necessary for the work, the owners generally prefer to harvest monthly or fortnightly. To prevent fraud as much as possible, the laborers are paid by piece-work and receive wages calculated upon the number of measures of fruit which they pick. There is no harm done by leaving the pods on the bushes for one, two, or even four weeks, except in the spring, when if possible, they should be picked at shorter intervals. The cultivation of cocoa, like that of coffee, is undertaken with the aid of colonists, who are hired by the day. The day is calculated from 6 a.m. to 4 p.m., for which time a man is paid about 2s. 6d., if food is not included, and about 6d. less if it is. The colonists are farmers to whom the proprietor of a coffee plantation has let a piece of ground, with the right to cultivate fruit or vegetables, but with the obligation of yielding the planter half or two-thirds of the cocoa gathered on the same piece of ground. Cocoa is weeded in the same way as coffee, but as the cocoa tree sometimes grows to a height of 15 or 20 feet, it is not so much troubled by coarse weeds as the coffee is. The spread of weeds is moreover, checked in

cocoa plantations by the continual fall of leaves, which soon cover the ground. The cocoa is pruned the same way as the coffee tree, with a view to prevent each plant growing too high and mingling its branches with those of its neighbours. It is necessary always to take great care to remove the suckers which are continually being thrown up from the foot of the tree. As soon as the pods are ripe, they are picked and broken on the spot. The berries, which are full of a curious syrup are measured and piled up in heaps, covered with leaves. These heaps are allowed to ferment for two or three days, the fermentation being regulated every morning by a rearrangement of the heaps. This process softens the bitterness of the berry, destroys the gum which surrounds it, and enables the cocoa to dry more rapidly. Moreover, the color of the berry depends on the proper conduct of the fermentation. Cocoa, like coffee, is then spread for two or three days on a sort of platform made of cemented stones, called a *secadero*, there to be exposed to the sun and dried. As soon as the cocoa is thoroughly dry, it is rubbed, cleaned of all the detritus which has gathered upon it, placed into bags, each containing about 105 lb. of cocoa, and sent on the backs of mules to the market at Santiago. The conditions of transport are the same as in the case of coffee. Each mule carries two sacks, or 210 lb. of cocoa, and travels ten leagues every day. Each group of twenty mules is led by a *capataz* and two watchmen, and travels by night to avoid the heat. The conductor, or *arriero*, is responsible for the arrival of the convoy, which is paid at the rate of 5d. per mile and per mule, or from 5s. 6d. per day's journey of ten leagues. Part of the cocoa grown in Cuba is consumed in the island, but the berries of the finest quality are sent abroad, and generally to Barcelona. France imports no Cuban cocoa whatever. The Cuban cocoa is, says the French Consul, exceedingly fine in quality, and it appears strange that there is no market for it in France. The price of cocoa in Cuba varies from 12 to 16 piastres the quintil, and sometimes, but rarely, rises to 18 piastres. The Caracas berries are sold one piastre dearer than the other varieties. The Consul says it would be difficult to foretell the future of cocoa cultivation in Cuba. Many cocoa plantations were destroyed during the civil war, but cocoa has suffered on the whole much less than coffee from the effects. In many of the largest plantations in the island, the cultivation of coffee is now entirely abandoned, and the cocoa plants only are depended upon for a return. Many planters, moreover, prefer cocoa planting, because for small planting it is an industry which requires much less outlay than coffee.—*Journal of the Society of Arts.*

THE PREPARATION OF GRAPHITE.—The action of nitric acid on graphite, to which H. Luzi has drawn attention, is stated to be of considerable practical importance. The mechanical preparation of graphite is not perfectly satisfactory in its results, and the Prodir method has also its disadvantages, in that it leaves a graphite containing hydrogen and oxygen and resembling lamp-black rather than graphite. Luzi moistens the graphite with concentrated nitric acid, and then ignites immediately. A number of fibres then form on the graphite which largely increases in volume. These fibres are chemically unchanged graphite, and are so light that they float on water, whilst the inorganic constituents liberated by this change of volume sink to the bottom. The nitric acid can be re-collected.—*Indian Engineer.*

MR. J. H. ROBERTS ON THE PERMANENCE
OF TEA IN CEYLON.

At a time when the question of the permanence of our present staple industry is widely discussed, the opinion of a practical authority in the tea trade with respect to it, is of considerable interest. Such a critic is undoubtedly Mr. John Roberts of Messrs. S. Rucker & Co. He has shown himself not only one of the most reliable authorities as to our teas in the home market; but he seems to have seen the various methods of tea planting in many of the countries wherein it is pursued. There has been much conflicting testimony adduced from time to time relative to this question of permanency. The importance attached to it by the planters of this island was strongly evidenced by the expression of adverse feeling which followed remarks by Mr. J. L. Shand in his speech at the dinner given by the Ceylon Association in London to Sir Arthur Havelock. Mr. Shand assigned a possible failure to what is a comparatively remote epoch, but even this view did not find a willing acceptance by his audience! It is but natural that the planters of Ceylon should wish to remain under the assurance that as regards tea they have not to look forward to such a failure as attended the cultivation which preceded it. Therefore they will gladly read what Mr. Roberts said on the topic to our London Correspondent, as reported in his present letter. Not only does Mr. Roberts fully believe in the permanence of the tea-bush, but he further credits it with exceptional powers of resistance to visitations of the character which have almost entirely destroyed the coffee trees that once thickly covered our hill-sides. The argument advanced by him to support this opinion would seem to be cogent enough to warrant his holding it. The facts he adduced are well-known to all of us. In this respect he is no doubt in a much more safe position than that multiplicity of counsellors in whom we fear that as yet we have not found the safety traditionally assigned to them. In fact no matter that has as yet come under public discussion has evoked a greater contrariety of opinion than has this particular one of the permanence of tea. Foremost among those who have of late contributed to this subject has been Mr. John Hughes. That well-known expert has told us that tea is a most exhausting crop, far more so than is coffee, and that therefore it behoves us to take heed how we continue to draw upon the constituents of our soil without in some way ensuring to it the return of those constituents. Mr. Roberts does not dispute that from the chemical expert's point of view alone, this advice is to be justified, but he contends that in his judgment it has been based upon insufficient consideration of the structural peculiarities of the plant itself. These, he contends, make it to a great extent independent of the constituents of the surface soil, which he presumes to be that from which Mr. Hughes obtained the sample upon which he has experimented. Deductions based upon such experiments, Mr. Robert asserts, might be fully justified in the case of coffee, while they must be utterly misleading in the case of tea. He reminded our London correspondent that the roots of the first are essentially surface roots, having but little hold on the

soil. When these roots, as the result of leaf disease, became weakened, they could not take up the nourishment, however liberally provided in the shape of manure. The case of tea Mr. Roberts believe to be entirely different. The long deep root seeks a soil which coffee had never touched. It was, in the case of Ceylon therefore, a purely virgin soil, and to that fact Mr Roberts attributes the wonderful vigour which has been developed by the tea bush in Ceylon. Such a soil, he further argues, cannot become exhausted for centuries (?) yet to come!—and it promises to give the tea tree a permanence and hold of the soil that could never be anticipated for the coffee tree. In addition he points out that the tea bush is now known to take up a large proportion of its nourishment from the air and from the moisture falling upon its leaves, and he contends that this fact largely increases the relative probabilities of the permanence of tea when compared with coffee. He declares his conviction that with respect to tea, this island is possessed of a virgin soil abundantly supplied with all the constituents required for its healthy and long-continued life. Practically, he believes that we may regard our present cultivation as one having a very permanent character.

So far as the comparison between the coffee and tea bushes and the greater vigour and longer life of the latter in an average Ceylon soil and climate are concerned, we are with Mr. Roberts. But in speaking of a permanence covering "centuries," we fear he goes too far. The subject is, however, a very big one; but on the facts related by our correspondent, two qualifying questions arise in our mind. First, did Mr. Hughes analyse soil taken from the depths reached by the tap root of the tea bush, or only that obtained merely from the surface, or a foot or two below it? Secondly,—has Mr. Roberts sufficiently borne in mind the fact that in many localities wherein tea has been planted the depth of soil, though ample for coffee, can hardly be sufficient to satisfy the needs for any long number of years of the deeper-seeking tea bush? On the replies to these two queries must depend to a considerable extent, the amount of relative value to be given to the opinion of Mr. Roberts and Mr. Hughes respectively.

TEA AND "THE BITTER CRY."

LONDON, June 23.

The letter which expressed to you "the Bitter Cry of Mincing Lane" has called forth a large amount of remark and attention here. Observing how widely this was the case, it appeared to me to be desirable to seek the opinion of Mr. John Roberts of Messrs. S. Rucker & Co. with respect to that letter. That gentleman had not seen anything of it or of your editorial remarks upon it before the interview had by me with him. He was much interested in the perusal of the extracts shown to him, and observed:—"I confess myself unable to even suggest any present solution of the question as to fine and coarse plucking. It seems to me that in time it will find that solution for itself, but without any attempt by any expert to forecast it. To do that, in my belief, is a simple impossibility, for it depends on so many varying considerations and conditions. Still we are not without a precedent to guide us. Don't you recollect when the continental demand was all for Rio coffee, and when fine Ceylon fell as low as 70/ and remained at that figure for an appreciable time? Well Rio went up and up in the market until it reached 60/. Then the buyers for the Continent—mainly Germans—began to think that with

a difference of only 10s between the coarse Brazilian kinds and the best Ceylon plantation it was time they changed their operations and bought the latter. They were tempted by the narrow margin. The demand for Rio fell off and prices began to dwindle correspondingly. That for Ceylon improved, and prices went up as the result. Now that is precisely the same state of things, it seems to me, that we have to face now. The cry is everywhere for cheapness. It is probably the blending trade which is largely accountable for this, but certainly the reduced means of the general consumer is quite as largely responsible for it. What do we see as the consequence? Pekoes and Souchongs approaching each other so nearly in price that the margin is a very narrow one indeed. Directly the large buyers begin to see that there is no appreciable relative difference, they will seek the better sorts again. Then up will go Pekoes, and Souchongs will probably remain stationary, for I do not think it possible they can fall much lower than they are at present." It is evident Mr. Roberts does not think anyone can offer your planters reliable advice as to the quality of the tea they shall send home. At the same time he admits that it is a disgrace to Ceylon that its name should father a very large proportion of the stuff now sold at the auction as Ceylon tea. He fully endorsed the remark made to me by the broker who, as you were told by me recently, was seen by me fuming with rage over a dozen or so of liquored samples of your tea.

IS TEA EXHAUSTING AS COMPARED WITH COFFEE?

In the matter treated of above you will see that I failed in getting any directly useful suggestion from Mr. Roberts, but further conversation had with him on another point of recent controversy had a more useful result. On my asking Mr. Roberts if he was of opinion that tea was an exhausting crop as compared with coffee, he replied:—"I should say decidedly not. No doubt Mr. Hughes was perfectly correct in all that he stated to you, but it does not seem to me that chemical analysis alone should decide this question. There are other important points which must not be lost sight of in determining this matter, one which we know has been left open to much dispute. It is my belief that, as regards Ceylon, tea has every prospect of being permanent. It may be true that the tea bush requires great nutriment, but then it certainly derives much of this from the air and also from moisture falling on its leaves without calling again the soil to furnish it. I think sufficient distinction is not drawn between the structural characteristics of the tea and coffee plants, and those have a most material bearing on this question. Coffee has wide-spreading roots, but they go to no great depth. It is dependent therefore upon the first foot or two in depth of soil for its nourishment, and readily takes up manure applied on the surface around it. It has no great hold on the soil, and my belief is that the weakening of the plants by repeated attacks of leaf disease so relaxed the roots that they were powerless to supply from the surface soil, that there was no strength to support the tree. The roots did not nourish it. Now with tea the conditions are quite the reverse. It sends down a tap root deep into the soil, soil which had never been drawn upon in any way by the roots of the expired coffee. In Ceylon, therefore, when tea took the place of the latter cultivation, the planters had what was practically a virgin soil to draw upon. From this arose no doubt the vigour with which tea flourished in Ceylon from the first, and my

view is that it must be centuries yet before tea, which draws only a proportion of its nutriment from the soil, shows any signs of exhaustion or could suffer materially by any attack of wide-spread disease. Under these conditions it appears to me that it must be useless to apply manure unless it was dug down to a very considerable depth; and moreover, as I have said, the deeper subsoil is yet of too virgin a character to need this, of course I don't attempt to deny anything of what Mr. Hughes has written, but I should like to know whence the soil was taken of which he made analysis. If, as may be suspected perhaps, it was only surface soil, it seems to me that the constituents found do not affect the case of the tea tree as they did, undoubtedly, that of coffee. In the latter instance the surface soil had certainly become greatly exhausted had no nourishment to yield. How then can the facts be explained that, following the almost entire failure of coffee, tea, flourished from its first planting in Ceylon in an almost unprecedented degree? Simply because its roots drew nourishment from a soil which had never been, and could never have been, drawn upon by coffee. Now it seems to be evident that a few years of tea cultivation could not possibly have produced exhaustion in a great depth of feeding ground, and, as I have said, it is my belief that for centuries to come the tea bush is likely to flourish in Ceylon as greatly as it has hitherto done, and I really think that manuring is and would be for a long time yet, quite an unnecessary expenditure. Aeration of the soil by turning it over to a considerable depth must, however, always be a good thing, whether manure be applied or not. You denude the tea bush of the greater part of the leaf through which agency it takes up both nitrogen and moisture from the air, and therefore it might be well to aid the plant by thoroughly aerating the soil as deeply as possible. Beyond doing this, it does not seem to me to be necessary to adopt any measures. Rely upon it tea has practically an unlimited life before it in Ceylon, at least that is the opinion of my own experience, and what I have been able to learn from experts, has led me to form."

So much has been written of an alarmist character respecting the permanence of tea that no doubt the favourable view expressed by so practical an authority as in Mr. Roberts will be consoling to many. His opinion seems to me to be supported upon a common sense reasoning.

TEA IN AMERICA.

I found that Mr. Roberts is not at all sanguine as to the future chances of tea in America. He doubts if the climatic influences of that country will not prove too strong for you:—"Look," he observed, "at the character and variety of the drinks which the Americans prefer. They are all strong and highly flavoured. They evidently meet some want due to climatic causes. Hence strong coffee must always remain the favorite beverage of the Yankees. If they drink tea, it must be sharp and biting, and a large amount of green tea is in consequence drunk by them. The delicate flavored teas of Ceylon will never meet this requirement, and it is impossible to ignore the demands naturally due to the peculiar character of the American climate. Consequently I never expect to hear that Ceylon teas will ever obtain a hold upon the people there except among the more refined classes, who have probably acquired a taste for delicate teas during repeated visits to Europe. But that it will ever become popularized I more than greatly doubt."

Mr. Roberts' views on the several points above dealt with have been given by me at considerable length, but previous experience of the value of his opinions has inclined me so to give them.—London Cor.

PLANTING REPORT FROM THE UVA DISTRICTS CEYLON.

Badulla, July 5th.

For the past ten days the WEATHER has been very extraordinary. Dull, cloudy, heavy showers. On the 23rd there was a heavy storm and a very sharp fall of hail. I never remember such weather in June—in OUVUH, before. We are now once more having bright sun, with a little wind.

It has again been a favourable month for TEA, and Factories have been busy; but pruning has now commenced generally and there will be comparatively little tea sent away from the district for the next few months. Prices of our tea, in common with those of other districts have been disappointing.

Considerable acreages of COFFEE are now being cut out for tea and there will be a large acreage put under that product in the coming year. The wet weather has been against poor old COFFEE, and unless July-August are dry months very little coffee will leave the district next year. Autumn crops are everywhere short, but high coffee is looking fairly well and only requires a little dry weather to blossom. I think bug has received a check. It does not strike me as having spread at all during the last month.

The Indian Government action with regard to EXCHANGE is the subject—naturally—of conversation; while no doubt it will give investors confidence, it is without doubt a heavy blow to producers for the time, already crippled by the present wretched prices for tea. We can only hope they will rise with the value of the rupee. It would have been a satisfaction had the Indian Government given the public some assurance that they did not propose raising the rate to 1/6 at an early date.

PLANTING AND PRODUCE IN NETHERLANDS INDIA.

Consul S. R. Lankester writes to the Earl of Rosebery from Batavia, March 9th, enclosing his report on the trade, commerce and general matters relating to the Island of Java for the year 1892. Mr. Lankester states:—

Generally speaking the year 1892 has been a fairly prosperous one from an agricultural point of view, crops of most export products having been normal ones, and in the case of some articles, such as tea and tobacco, considerably above the average, whilst prices, except for tea, ranged on about the same level as during the preceding year.

Importers have also reason to be satisfied with the results of the year's business, demand having been good and money plentiful, while the general advance in prices of manufactures in Europe prevented excessive shipments during the closing months of the year, thereby imparting a healthy tone to the market.

EXPORTS

SUGAR.—As mentioned in my last report, the weather during the planting season, May to September 1891, was anything but favourable, and although the case in most parts of the island recovered in great measure from the effects of the drought, thanks to the rains during the early months of 1892, the quality of the juice especially in East Java, seems to have suffered, thereby increasing the cost of extracting the sugar. Very little was heard in West and Middle Java of the once formidable *seres* disease, and even in the eastern districts where it still continues more or less prevalent, it has not spread to any alarming extent nor is it expected to influence much the prospects of the coming crop.

The more enterprising among the planters have continued their efforts to keep abreast of the times by the introduction of the newest appliances for simplifying and perfecting the manufacture of sugar, and sundry minor improvements are being made year by year in the method of treating the cane.

Prices opened on about the same level as in the previous campaign, but were even better maintained so that the average rates obtained by planters were higher than in the preceding year. The total production exceeded that of 1891 by about 16,000 tons, about 6,000 tons of which increase is due to the output of several new estates in East and Middle Java.

Up to Dec. 31st the exports of the 1892 crop were:—

Country.	1892 Tons	1891 Tons
To Europe ..	117,548	149,900
Australia ..	40,800	42,594
China ..	52,213	64,227
America ..	89,792	51,039
Sundries ..	17,162	10,317
Total	317,515	318,077

The prospects for the coming sugar crop are satisfactory, and by the end of 1892 more than half the estimated production had already found buyers, at rates showing a considerable advance on those ruling for the crop just harvested. For a considerable proportion of the sugars sold, the buyers have stipulated the option of taking delivery in an assortment suitable for the United States, which fact points to the probability of a good demand from that quarter during 1893.

No final decision has yet been come to by Government as to the form the tax shall take, which is intended ultimately to supersede the export duty on sugar. As a provisional measure, however, a tax has been imposed, to be levied first, during 1893, on all sugar estates not producing sugar exclusively for consumption in the country.

Each estate will be taxed in proportion to the average income which has been derived therefrom during the three preceding years, and the total sum annually levied will be equivalent to the amount which the Treasury would have received on an average for export duty during the three preceding years had the latter form of taxation not been suspended.

COFFEE.—The crop of the past year on private estates did not quite come up to expectations, as many of the low-lying lands suffered from drought, but on the whole was a satisfactory one, and with the high prices ruling at some points have given good results to planters. Prospects for next year, owing to heavy rains in August-November, which prevented the blossom from setting, are unfavourable, the crop will be one of the smallest on record, but the plantations in general look very well, the rains having brought the trees forward, and after the present rest they should bear well in 1893-94.

The estimates published of the Government crop in the early part of the year were largely exceeded, the output having been about 42,000 tons, of which quantity it is understood that about 12,000 tons will be retained for shipment in 1893.

For the coming year the yield of Government coffee estimated at not more than 9,000 tons.

TEA.—Statistics show an increase of from about 6,000,000 lb. in 1891 to 9,000,000 lb. in 1892, but prices in Europe ruled on such a comparatively low level that planters will hardly have been compensated even by the extremely heavy crops obtained.

Tobacco.—The production was exceedingly large, especially of scrubs as usually produced by the natives, with the exception of the Bezoekie Residency, where the crop, being a late one, was almost ruined by heavy rain. The quality was fairly good, and prices ruled much the same as the preceding year.

RICE.—In consequence of the drought in 1891, the crop although it eventually turned out a large one in East Java, was much retarded, and imports took place on a large scale during the early months of the year, especially in Mid Java. The harvest was, however, abundant in the east of the Island, and the

natives in that part of the country had so little need to work that labour could only be procured with difficulty in June, July, and August for sugar and coffee estates. The exports, which concern principally West Java, showed a considerable decrease as compared with 1891, having only amounted to 18,895 tons.

COCOA.—A larger area is gradually coming under cultivation, but in consequence of less propitious weather last year's production was rather smaller than during the previous twelve months. Prices in the European markets, however, were somewhat higher; and planters were thus partly compensated for the smallness of the crop.

CINCHONA BARK.—The production of both Government and private estates (vide statistics) was considerably smaller than in 1891 and prices in Europe ruled low, so that this culture cannot be said to be in a flourishing condition. Planters are discussing the advisability of erecting a cinchona manufactory in Java in order to save the heavy charges now incurred by the export of the bark. Nothing definite has, however, yet been decided.

COPRA.—The exports last year were quite insignificant; the coconut trees, in consequence of the wholesale manner in which they had been despoiled of their fruit during the previous season, yielded this year little or none, beyond what was required for consumption in the country, and for the local extraction of oil. It is expected that a fair crop will be obtained in 1893, but it is likely to be rather a late one.

Annex I.—Sugar Crop from July to June of following year.

Country	1889-90 Tons	1890-91 Tons	1891-92 Tons

PLANTING PROGRESS AT THE STRAITS.

From the Report of Mr. C. H. A. Turner, Senior District Officer on the Sepang district in the *Selangore Government Gazette*, June 23rd; we quote as follows:—

The District is purely an agricultural one at present, and, with the exception of the large concession at Sepang, planted with gambier and pepper (10,111 acres), the other holdings are only small ones. The cultivation of arecanuts had been abandoned for the more remunerative product, coffee. About 350 acres are now grown with padi, the culture of which has been patronised by H. H. the Sultan, by a very substantial loan of over \$3,000 to the people in the District, who have promising fields in Tanjong, Duables and other places.

The Raja Muda's property at Bandar has no longer the melancholy aspect of neglect which it bore last year. The small Malay holdings are being slowly cleared under the influence of the Penghulus of the mukims. The small coffee plantations on Jagra Hill, worked by Tagils, is prospering, and I am glad to say that a neglected coffee garden, held under a loan from Government, has changed hands, and with the short attention it has received looks promising and remunerative. The Javanese gardens at Klang are all that can be desired, and a great many of these useful and industrious people, who last year deserted their holdings, are returning. Attempts have been made at Klang, by Chinese and Javanese, at indigo, tobacco and patchouli, which gave good results, but the minds of the agriculturists of the District are now set on coffee, the present price of which I hope will continue for some time in the interests of the people and District.

Planting in Loh Cheng Keng's large estate at Sepang continues to extend, but I think it is more in favour of pepper than gambier. The output of pepper from the estate was greater than last year, but that of gambier was less.

The soil laid bare by the opening of the Klang-Langkat Road is surprisingly rich, on which coffee, sugar, indigo, padi, fruit and vegetables could be grown successfully and remuneratively, and with a little pecuniary help from the Government and some spread of a knowledge of a District so little known in planting circles, I see no reason why the whole region between Bandar and Panghalan Batu should not be opened up and cultivated. On the whole, I consider that agriculture has progressed during the year, as indicated by the large export of garden produce, such as pepper, arecanuts, indigo, &c., over last year.

THE DUTCH MARKET.

AMSTERDAM, June 15.—The cinchona-auctions to be held in Amsterdam on July 6th will consist of 246 cases and 6,364 bales, about 557 tons, divided as follows:—From Government plantations, 343 bales (about 33 tons); from private plantations 6,021 bales and 246 cases (about 524 tons.) This quantity contains: Of druggists' bark—*Succirubra* quills, 186 cases; broken quills and chips, 68 bales and 48 cases; root, 23 bales. *Officialis* quills, 12 cases. Of manufacturing bark—*Ledgeriana* broken quills and chips, 4,615 bales; root 912 bales. Hybrid broken quills and chips, 492 bales; root, 68 bales. *Officialis* broken quills and chips, 154 bales; root, 32 bales.—*Chemist and Druggist.*

THE QUALITY OF CEYLON TEA.

[The most serious view yet expressed bearing on the "Bitter Cry" discussion is surely that sent out from London by the veteran London correspondent of the local "Times" with a full realization of his responsibility.—Ed. T.A.]

You will not have failed to notice a passage in the after-dinner speech of your Governor, on the 14th inst., in which he cautions Ceylon planters as to the policy of maintaining the good name they have won for their tea by not allowing the quality to fall off. This advice was well intended, and was well timed if the assertion so often made by your "annexation" contemporary is correct—that planters can make as good tea as they have ever made if it would pay; but that it does not pay. Now that point is one that deserves special attention at the present time, when Indian tea-growers are constantly asserting that Ceylon is going back in the quality of much, if not most, of its tea. I have discussed the matter with any number of Ceylon men and Ceylon brokers, and, however unwillingly, they have had to confess that, owing to some unknown cause a number of once well-known teas which took a

high position in averages are now low down in the list. I might name several of these, but refrain from doing so, not wishing to sit in judgment on the quality of any particular outturn of leaf, nor is it necessary I should do so, as the fact must be too well-known to need illustration. There are now Broken Pekoes and Broken Orange Pekoes coming to market and selling for 8s, which early in last year or the year before realized 1s 6d or more. The teas show no inferiority of make: there is no fault to lay at the factory door, for they are in appearance as good as ever they were; but the *old quality is not there*. It is useless to continue to live in a fool's paradise and delude ourselves with the belief that Ceylon planters can make as good tea as ever. They cannot, and the fault does not lie with them. It is not a question of fine or coarse plucking, of careful or indifferent make; the leaf is no longer the same; it has lost the old malty flavour—so soft and so fragrant—which was formerly the feature of your high-grown teas. Now all this has left them, and they come out in the cup a weak, watery liquor tasting of nothing in particular. My object in putting all this before your readers is to lead them to think the subject out and take action. There is no doubt that some element which formerly was in the soil, and which gave high-grown teas their fine delicate flavour, is now absent and the course to be adopted is to my mind, to obtain the services of a highly-qualified chemist for a term of years, whose duty it shall be to determine what steps are necessary to return to the soil the element of which it is deficient. Ceylon is spending £20,000 to open a market for its tea in America, 1s it not worth while to spend a few thousands in maintaining existing markets by improving the quality of your teas? It was thought at one time that Ceylon had a great advantage over other tea producing countries in that the bush could be plucked throughout the year. May not this be a disadvantage! May it not be possible to give the bush an artificial rest, and so help to improve quality? These are questions that may be worth considering. What is taking place with high-grown tea from crack estates happened to my knowledge thirty years ago with high-grown coffee; so long as there were certain elements in the soil on which the coffee bush could feed high-grown coffee from the Ramboda, Pussellawa, Maturata and Upper Hewsheta districts fetched in the London market 20s per cwt. more than coffee from Kurunegala, Dolosbage and such districts; but in time this advantage disappeared, for the reason that the element in question had become exhausted. It *must* have been so!

On the above the local editor remarks as follows:—

The position taken up by our London correspondent on this subject is not likely to commend itself to Ceylon planters, nor do we think it tenable. It may be perfectly true that certain estate teas which once fetched a higher price in the London market no longer do so. But why is this? It is because they are receiving less for the same class of tea made from the same class of leaf as before, or because they are making common teas in larger quantities. We believe that, if our London correspondent makes due inquiry, he will find the latter to be the case. The real test after all is this: Are the estates he refers to paying better now, when they are receiving poor prices for their teas, than before, when they obtained higher prices? If the answer is that they are doing better now than before all the talk about "deterioration" will not alter the mode of manufacture now pursued. For ourselves we believe that, given only the stimulus of high prices for really fine teas, and Ceylon would produce a larger number of really "stand out" full-flavored teas than ever before. But inducement must first be offered, and the remedy does not wholly lie in the hands of planters.

But we think most readers will agree with us that if only to satisfy criticism, there ought to be a P. A., if not a scientific, inquiry.

THE ZANZIBAR CLOVE-CROP.

The 25 per cent *ad valorem* export duty on cloves constitutes the chief part of the revenue of Zanzibar. This duty, says the British Consul, is always collected in kind, and the sums realised by sales in the course of the year, together with the balance remaining in hand on December 31st calculated at the current rate produce a total value of 500,340r., which falls short 14,896r. of the total realised in 1891.

The clove-crop as has been frequently pointed out, suffers from the insufficiency of available labour in Zanzibar. Domestic slave labour is, under present conditions, a steadily diminishing resource, and the Arab proprietors mortgaged as they are through both the islands to the Indian money-lenders have no available money, even had they the habit and inclination to hire additional labour. They barely contrive to make both ends meet by such crops as they can gather in with their domestic slaves, whom they pass on reciprocally from farm to farm when the short gathering season arrives. A considerable proportion of the crop always remains ungathered, and it is noticeable that large portions of various big estates are falling out of cultivation.

It is not surprising, therefore, to find that the total produce of the clove-crops in '92 has fallen short of that of '91 by some 50,000 frasilas, while that of '90 again was upwards of 100,000 frasilas better than that of '91. The steady decline in the produce of Pemba has in '92 been somewhat compensated by a considerable extension in the Zanzibar crop, but the cultivation generally seems to be decreasing; the crops for the current year do not promise to be very heavy, and prices may therefore still further advance. —*Chemist and Druggist.*

INDIAN PATENTS.

No. 161 of 1892.—Alfred Horatio Bell Sharpe, Engineer, 32, Foss Bank, Lincoln, in the county of Lincolnshire, England, for combined steam-boilers and hair-heaters for tea-driving and other drying purposes. (Filed 5th June 1893.)

No. 28 of 1893.—Sammel Cleland Davidson, of Sirocco Works, Belfast, Ireland, Merchant, for improvements in apparatus for drying tea or other vegetable substances or other material. (Filed 7th June 1893.)

COCONUT PALM WEEVIL IN BRITISH HONDURAS.*

I.—INTRODUCTION.

The industry of coconut palm growing, established within recent years in British Honduras, has been seriously discouraged during the past five or six years by the attacks of the insect commonly known as the Palm Weevil on the trees, a large proportion of which have been killed. In the year 1888, the Government of British Honduras recognised the fact that the annual loss thus incurred menaced the prosperity of the Colony, and therefore appointed a Commission to examine into and report on these attacks. The Commissioners issued their report early in 1889, and the Government, acting upon the recommendations contained in it, issued a draft ordinance. This ordinance, which was designed to enforce under penalties the destruction of attacked trees, and was of a very stringent character, was not persevered in and did not become law. In the autumn of 1892, specimens of the mature beetles were received at the Royal Gardens, Kew, both from the Government and from Mr. C. T. Hunter, of Belize, who is largely interested in the industry concerned. The specimens belonged to two species of weevils, of which the majority were, as was anticipated would be the case, examples of the well-known American Palm Weevil (*Rhyncophorus palmarum*, Linn.). It was then decided to publish an account of the known habits and economic treatment of this insect, so as to present

* With two plates, in Kew Bulletin.

them in a convenient form for the use of planters engaged in coconut palm growing, who, according to the Commissioners, appear to be generally "unacquainted with the various stages in the existence of the Weevil;" and to serve as a guide towards obtaining a more thorough knowledge of the insect's habits and of the class of measures most efficient in keeping it in check. The present paper has been written and is published as the result of that decision.

II.—SOURCES OF INFORMATION.

The Palm Weevil of Central and South America (*Rhynchophorus palmarum*, Linn.) is one of the tropical insects, with which zoologists have been longest familiar.

There is another and distinct species, the Asiatic Palm Weevil, or "red-beetle" of the planters, (*Rhynchophorus ferrugineus*, Fabr.), a native of India and the Malay region, which also attacks the coconut palm, and closely resembles its American congener in habits. There has always been a tendency on the part of writers to confuse these two species, a tendency which no doubt has caused the geographical vagaries referred to. Though closely allied they differ in appearance, if not in habits; and it is desirable to remember that writers who speak of the Palm Weevil in Asia as *Rhynchophorus* or *Calandra palmarum* are referring to *R. ferrugineus*, and not to the American weevil. Attention to this point is necessary, particularly in the study of periodicals devoted to tropical agriculture, in which the mistake is constantly made.

III.—HABITS AND LIFE HISTORY OF THE PALM WEEVIL.—The Palm Weevil is one of the largest insects contained in that very important and extensive group of beetles, the Weevils, of which the most characteristic feature is the prolongation of the head forwards so as to form a snout or *rostrum*, sometimes of great length, into the sides of which the horns of *antennae* are inserted. The snout, which is always distinguishable in the true weevils, bears at its extreme tip the mouth, very small but nevertheless efficient.

The mouth is used for feeding, and by the females in drilling holes, which operation is rendered possible by its position at the end of the snout, or in nibbling patches from the rind of plants in which the eggs are then laid. There has been a good deal of misunderstanding about the snout of the Indian Palm Weevil, and it has been several times said that that insect possesses no alimentary apparatus whatever. This is not the case. The beetle, like other weevils, which are, as a rule, long-lived insects in the adult state, can and does feed, and the observer, mindful of the elephant, has probably looked for the mouth under the head, at the base of the snout, which he has taken to be merely a horn with penetrating power limited by the force with which the beetle can drive it in. The insect can pierce far harder tissues by gnawing than it could ever do by mere pushing.

When the grub has become mature by continuous feeding, broken, however, by intervals when it changes its skin and emerges from its old garment clad in a new and larger one, it transforms by a further change of skin into a *pupa*. This takes place near the surface of the plant, so that the perfect insect, whose burrowing powers are in most of the true weevils limited, can break without difficulty through the structures which shield it from the air. The *pupa*, sometimes enclosed in a cocoon or covering constructed by the grub, resembles the perfect insect, but is soft and pale with the wings and limbs neatly folded down on its under side. The limbs are separately enclosed in a thin skin which is not continuous over the surface, as in the pupa of a moth. As a pupa the insect lies dormant for a shorter or longer time, taking no food and being absolutely harmless. At last the perfect beetle, which has slowly matured in the pupal covering, throws it off and issues forth. It is at first soft and pale, and remains in shelter till its outer integuments have hardened, when it sets forth on its work of feeding and reproduction. If an American Palm Weevil is carefully examined from above, it is seen to be a large oval beetle with its upper surface slightly flattened

and of a deep velvety-black, with little or no lustre. Specimens which are glossy appear to have lost their velvety pile by being rubbed, and have probably emerged some time; they frequently have a shiny streak along the middle of the back, while the sides are dull.

The statement that all the larger and more bulky specimens are females is wrong; both sexes are very variable in size.

The structure of the weevil is not adapted for burrowing into hard vegetable tissues, and it does not do so, though it may creep into crevices, or dig its way into loose, rotten material and soft structures like the split cabbage of a palm, in which they are sometimes found. In boring beetles the body is narrow and cylindrical, so as to fit the burrow, and the snout, if present, is short and strong, while the shanks, as a rule, are strengthened with teeth or spines set along their outer edge, sometimes for excavating, usually to resist the friction of burrowing, and to throw out of the burrow the debris that is bitten away. The Palm Weevil, with its unarmed shanks and its very small mouth, would have great difficulty in making a hole big enough to accommodate it in the trunk of a tree, and when specimens are found inside a tree, they have got there either through a wound, by entering the hole of another insect, or the soft parts of the split bud, or have been bred in the tree and not yet quit it. In the latter case the immature beetles will be found near the surface with a thin layer of rind between them and the outer air, through which they can easily break. One observer speaks of finding the "parent beetle and three large grubs wrapped in the fibre about three inches from the bark." The beetle certainly was not the parent of the grubs, and it must be distinctly borne in mind that, except perhaps when the tree has external wounds, the beetle does not bore but lays its eggs from the outside.

The perfect weevils are mainly nocturnal in habit, and fly at dusk or by night with a loud booming noise (the Indian weevil is said, however, to fly frequently by day as well). They hide from daylight in rubbish at the foot of the trees, and occasionally, it is stated, burrow in sand; they are also to be found concealed in the folds of the leaf-sheaths and the matted fibre of the head of the tree, or in the holes made by other insects. They feed freely on decaying sap or fruit, such as mangoes or bread-fruit, and on the rotten tissues of the palm and cabbage pith, to which they are attracted by the smell of the fermenting juices, a circumstance that affords the readiest and best means of capturing them.*

In the adult state they are not known to injure the palms for the purpose of feeding, and as they are the parents of further broods of destructive grubs, the chief point for study in their habits is the method of egg-laying, which is regulated by the instinct of the insect to place its eggs in a situation where the inactive grub can, upon hatching, get the food it requires.

Whether a tree is selected for egg-laying in preference to others is obviously determined by its condition at that time. As a rule, the act of egg-laying passes unnoticed, and the health of the tree only becomes a subject of inquiry sometime later, when the work of the grubs is apparent; and the inquiry is therefore complicated by the necessity for distinguishing between an unhealthy condition occurring as a result of the infestation, and one which may have originally brought it about.

The female is stated to lay her eggs singly, in accordance with the habit of other weevils, by perforating the rind of the tree and depositing an egg in the hole made. The appearance of the eggs and the number laid by each female have not yet been recorded.

It is desirable to know the exact spot selected for oviposition in order that it may be artificially protected. At present the evidence does not place it beyond doubt. It is generally admitted that eggs are not laid in

* They also frequent freshly planted sugar-cane sets, in which the female deposits her eggs; this habit is as yet unrecorded from Honduras.

the leaf-stalks nor upon the leaf-spike, when their hard silicious surface is unbroken; and the laying of eggs on the stem is limited below by its maturity, and the consequent presence under the rind of hard wood, for the grub is not a hard-wood feeder, but devours the pithy interior of the stem, and, as before stated, the beetle will not lay its eggs where the young larva cannot get its proper food.

The vulnerable point lies, therefore, about the upper part of the stem, below the attachments of the leaves, and above the woody portion. In young trees, where the wood has hardly begun to firm, and the stem is only from one or three feet long, any point above ground is open to attack, and even, according to Mr. Bellamy, below it. But fuller evidence is required in support of this statement, which may rest on the erroneous interpretation of observed facts.

In the Commissioners' report, the practice of trimming the leaves is condemned, but a reason is not given, and cannot be inferred from the statements there made about egg-laying. But in India this fact has been more generally recognised. Mr. Ridley writes about the weevil, "it finds its way to the base of the leaf-stalk of the palm, and pushes the egg as deeply into the body of the tree as it can. Some persons affirm that the beetle lays its eggs in the base of the tree, and that the grubs then burrow upwards. I have seen no case of this. . . . I have certainly seen burrows made by some insect in the old stems of the cocoa palm, but I do not believe that they were the work of this animal, but probably of some *Lo. gigon* beetle."

All observers agree in condemning the practice of stripping off the old fronds, which by their leaf-sheaths so thoroughly protect the tenderest part of the stem. The simplest plan of dealing with them is to bend them down without breaking them, or even to tie them up. It is doubtful whether it is sufficient to cut off the fronds at some distance from the stem. If the stalks are not dry the exudation of sap from the cut ends probably attracts the beetles.

The female is also ready to take advantage of any wounds on the surface or cracks in the bark of the tree in which to lay her eggs. Such wounds may be made by other insects, for example in India by the Rhinoceros or Elephant beetle (*Oryctes rhinoceros*, Liun.), in the burrows of which into the head of the palm the weevils take shelter; they may also be caused by unskillful trimming of the leaves and fibrous sheaths, and thus afford another reason for giving up this practice. The cracking of the rind is to a large extent due to the same act which prematurely exposes it.

From the egg of the grub, at first minute, hatches and begins to bore into the pith of the tree. An observer should be able to recognise the grub, and distinguish it, even when small, from other larvæ to be found in the palm, those of longicorn beetles and of other weevils especially. In several accounts of grubs being found in trees in various stages of decay, there is nothing to show that they did not belong to some other species of insect. The larva, or *gru gru worm* is, when fully grown, about two to three inches long, and of a yellowish-white or brownish-yellow colour. Its body is slightly bent and is very stout in proportion to its length, so that the skin when stripped off is nearly circular. The head is large and horny, and the mouth is at its lower and anterior part; the jaws, which work, as in all insects, sideways, are short, stout and rather blunt. Its colour is a deep pitchy brown and the jaws are the darkest parts. It is set with a small number of bristles, and there are also a few on the hind segment, while the rest of the surface is hairless. The skin of the body is loose and wrinkled, and, if the underside be looked at, is seen to be thrown into 11 folds, so as to divide the body into 12 rings of segments. These folds are continued round to the upper side, where there between most of them an additional transverse fold. The body is stoutest at the seventh or eighth segment and tapers sharply from the ninth to the tail.

The boring of the grubs is said to be upwards, a statement that Mr. Ridley contests. They feed on the soft pith that fills the inside of the stem up to the

growing point, and can be found in any part of it. The tree is killed by their feeding at the base of the cabbage and injuring the growing point, whereas damage done to the pith in the lower part of the stem does not necessarily prove fatal. There is some confusion as to their feeding in the head of the tree or not, due partly to the larvæ of other insects being mistaken for them, partly to a loose use of the term "cabbage," the limits of which are not taken to be the same by different observers. It is the pith immediately below the true cabbage that appears to form their favourite source of food. The grub in boring makes a tunnel corresponding to the diameter of its body and becoming larger as the latter increases in size. It does not make holes on the outside of the trunk which can serve as a conspicuous sign of its presence. When approaching maturity it returns to the outside of the tree, according to Dr. Gahb by enlarging the channel along which it has come, a process that must necessitate its turning round in its tunnel. Arriving near the outside, it eats away the inner rind so as to leave a thin shell, "of the thickness of foolscap paper," between it and the outer air, through which shell the beetle can easily break. It then retreats a little way and constructs a close oval cocoon of the fibres surrounding the pith, that is, of the fibro-vascular bundles running to the fronds. This cocoon is three or more inches long and about one and a half in diameter, and consist of a dense mass of interlacing fibres, mostly arranged circularly and suggesting a bird's nest. No gum or silk is employed in the cocoon, within which the grub casts its skin for the last time, and appears as a *pupa*.

The *pupa*, perfectly harmless—for it takes no food and cannot quit the cocoon—has a general likeness to the beetle to which it changes. It is light-coloured with a thin delicate skin; the snout, antennæ, legs and wings are neatly and symmetrically folded on the underside, the snout extending along the middle of the body, the two anterior pairs of legs doubled up and covering the wing-cases and wings. These are shorter than in the mature insect and lie over the hind legs, the wings projecting beyond the wing cases. The upper side of the abdomen is exposed and its spiracles are now conspicuous.

Under the investing skin of the *pupa* the beetle slowly develops its organs, and at last splits it and emerges. Soft and pale, it does not leave the tree at once, but waits until its integuments have hardened and have acquired their full colour. Then it breaks through the rind which shelters it and comes out as an adult weevil. A certain number are unable to escape from different causes and perish in the tree.

The holes made by the exit of beetles are conspicuous, and may afford the careless observer the first clear sign of the mischief that is going on. They occur anywhere in the soft part of the palm stem, and most frequently just below the head. Cocoons are not to be found in the cabbage, but only close to the outside in the neighbourhood of the fibre from which they are made.

The length of life of the perfect weevil and the time passed in the early stages have not been ascertained, nor have the periods at which egg-laying is performed. These points are less important in tropical than in temperate countries, where the life-periods of an insect are closely related to seasonal change. But in the tropics the dry and wet seasons, at least, influence the stages of insect life, and an effort should be made to obtain accurate knowledge of matters which are of so great importance. Prevention of egg-laying for example is likely to be more successful if carried out in reference to the seasons of oviposition should any such exist.

The Palmetto Weevil of the Gulf States of North America (a feeder on *Sabal Palmetto*) is said by Summers (13) to emerge as a perfect insect in September and October, to live through the winter and lay eggs in the early summer, the grubs being found in the latter part of June and July. Adult weevils are usually long-lived, and it is possible that the Palm Weevil lives nearly a year as a perfect insect.

Mr. Hunter believes that there is more than one brood a year, which is probable, and specimens in all stages are said to have been taken from the same tree. This would show that seasonal development is not well marked, but the observer may have been mistaken as to the identity of some of the younger specimens found.

The American Palm Weevil feeds on several kinds of palm, probably on almost any kind, particularly of the soft-stemmed palms; among the species it is known to attack are the coconut palm (*Cocos nucifera*), the Cohoon palm (*Attalea Cohune*) the cabbage palm (*Oreodoxa oleracea*), the Big Thatch palm (*Sabal umbraculifera*) and the Macaw tree or Gru-gru palm (*A croecomia sclerocarpa*).

It also attacks sugar-cane. Its range extends from South California over Central and South America as far as Brazil, and it is found in the West Indian Islands. The Indian species occurs throughout the Oriental region of naturalists (India, Borneo, Java, &c.), and is also a general feeder on palms, particularly on the coconut palm and the toddy tree (*Phoenix sylvestris*) (35.)

The range of the coconut palm is therefore wider than that of either insect, and being largely independent of human agency is so extensive—while its original home, which De Candolle finally considered as being in the Old World, is so doubtful—that it is now impossible to speculate on the length of time that the tree and either species of weevil have been in association. But whether it has always served as food for the American Palm Weevil or not, it is now perfectly clear that the insect is not dependent on that tree alone, and that "its extirpation could not be effected in Honduras by cutting down and destroying every single coconut palm in the colony."

Honduras possesses as large if not a larger variety and number of palms than perhaps any other region where the coconut is cultivated, and the greater proportion of the country is in a wild state and cannot be dealt with by any economic measures; there at all events, it would appear that the natural food of the insect consists of wild palms, from which its attention has been diverted to the coconut plantations.

Of these wild species the chief is the common Cohoon or Corezo palm, which does not grow in the same situations as the coconut tree, but in the rich alluvial soil of the Orozal, or cohoon ridges. These ridges are really depressions between the series of quartz elevations running more or less at right angles to the seaboard.

The coconut, a lover of sandy soil near the coast, is grown in plantations as a rule not nearer than five or six miles to the cohoon ridges, but which in some cases lie close to them. The land of the ridges is valued for banana growing, and for this purpose, and not for growing coconuts for which the soil is unsuitable, the cohoon and other palms have been extensively felled and allowed to lie upon the ground; this has resulted in a large increase in the numbers of the weevils, which have bred in the felled trunks. As long as they are feeding on wild plants they are not likely to multiply fast, because a balance will have established itself between the rate of increase of the trees and the causes tending to diminish the number of the beetles on the one hand, and the rate of propagation and destructiveness of the latter on the other hand—otherwise beetles or palms must gradually die out; and observers in Jamaica and India have noticed that the number of wild palms is not sensibly affected by the presence of the weevils.

But if this balance is disturbed by external causes such as the cutting of cohoon palms, which favour the weevils, a large increase in their numbers will result.

There is good reason for supposing that the extensive injury to coconut plantations is largely due to the swarms of weevils thus bred. In the Commissioners' report Mr. Baber in his evidence states that he considers the proximity of a cohoon ridge to be a source of danger; and Mr. Hunter has informed the writer that little was known of the beetle until about 1888, a period which coincided with

wholesale felling of cohoon palms in order to bring the ridges under cultivation.

As there is a particular age when the coconuts become liable to attack, namely, at the time of its first bearing, between four and six years old, it is possible that there is merely a coincidence in time and no further connexion between the clearing of the ridge and the damage done to the palms on their approach to maturity. Mr. Schofield, however, states that among some 2,000 trees planted about seven or eight years previously only a few isolated cases of disease had appeared until the end of 1888, "some five trees altogether having succumbed to the attacks of "the bug." This tends to negative the idea of a coincidence for the majority of his trees must have reached maturity without being immediately attacked.

As before mentioned the palm does not prove attractive to the beetle till it begins to come into bearing at an age from four to seven years, when the terminal bud becomes larger and more juicy. At this period the tree has some three feet of stem, and it remains liable to attack until it is about 12 years old and has some 12 or 14 feet of stem. If it is free up to that age it is rarely attacked afterwards. The greatest damage takes place from the middle to the end of the dry season, that is, about July to September, and perhaps corresponds to a period of egg-laying at the beginning of the season. It has been stated of the Indian weevil, "insects of the above class multiply rapidly in times of protracted drought, and it is during such periods of abnormal weather that they commit the greatest amount of mischief."

An infested tree shows at first little or no signs of injury, unless the points at which eggs are laid are discoverable by a skilful observer. The Commissioners' report says that "by careful observation small holes may be discovered with a little gum oozing from them, but by that time the larvae have attained considerable size and have eaten their way far into the heart of the tree." Mr. Ridley says of the Indian weevil:—"It works entirely inside the tree, and makes little or no external marks. By listening at the side of the tree the grub can be heard gnawing the wood. But usually the withering and fall of the central shoot is the first sign that anything is wrong. In some cases a tree exudes a shiny liquid, having an unpleasant sour smell, which is a sign of serious damage." To listen for the grub feeding may be more practical than it sounds; the ear should be placed against the tree, or against the end of a piece of seasoned deal, used like a stethoscope, with its other end on the trunk. Another account of the same insect, evidently from the pen of a careful observer, states that "if the heads of the trees are frequently inspected by skilful beetle searchers many trees may be saved by cutting out the grubs, their presence being known by the searcher either finding a cocoon in the tree or, more generally, by noticing slight wounds on the smooth skin (if I might call it so) of the leaf spike, which are unintentionally made by the grub in eating the soft pithy mass through which it pushes its way."

THE KANGRA VALLEY TEA planters are at last becoming alive to the immense value of the water power that at present runs to waste at their very doors. This has been recently utilized by the Manager of the Bunda Tea Company Limited who has erected a 'Hercules' type turbine for driving his tea machinery. He is the first to avail himself of water power in the Kangra Valley. If his example is followed it will, says the Lahore paper, almost revolutionise the tea industry and save lakhs of rupees to the large concerns which at present use steam, firewood for which has to be carried on coolies' heads at great expense. Moreover, the indiscriminate cutting of timber has a direct influence on the rainfall and nothing whatever is being done by *goshi* or private individuals to plant out.—*Madras Mail*, June 13th.

CHINA TEA AND PROSPECTS.

Consul B. W. Mansfield, in his latest report, on the trade of Foochow, to the Earl of Rosebery, states:—

The days of empty steamers coming to lie here to await high freight's on the opening of the tea market have gone never to return. The Foochow tea business in London is now so small that shippers absolutely decline to ship in empty bottoms, which means flooding the market with more tea than is wanted at one time and an unnatural depression of prices. When the market opens in June the ordinary liners call in on their way home from Shanghai and take whatever cargo may be offering.

After referring to last year's tea trade experiences, it is stated:—

A good deal has been said of late about a reaction of taste in the United Kingdom in favour of China tea, but it is slow in becoming apparent to those engaged in the trade of the Far East.

It is idle to talk of the remission of the *lekin* tax, or partial reduction of the export duty, as the Chinese Government will not listen to it; but assisted in this way, were it possible, China tea would be placed on fair competing terms with India and Ceylon, and a resuscitation of the trade come about. Each session for 12 years past the supplies of tea have grown smaller and smaller, and this season proves no exception. The falling off is about 20,000 chests of Congou, or 6 per cent the figures being 327,000 chests against 347,000.

Unless something be done towards lowering the heavy charges by the Chinese Government on teas before they leave the country, it is hopeless to expect the Foochow article to compete with the untaxed product of India and Ceylon, and the trade must inevitably dwindle away. The charges I allude to are, roughly speaking, per picul—*Lekin* tax and other charges from the producing districts to Foochow, Tls. 2.70; export duty, Tls 2.50; total Tls. 5.20. This is an enormous percentage, especially on the cheap Congous which form the bulk of the Foochow export. By their short sighted policy the Chinese authorities are thus gradually but surely killing a once prosperous industry which gave employment to thousands of their people. A removal or even a considerable reduction in these imposts would doubtless go far to revive the trade even now in almost its moribund state, for the cost of production must always be less than in India and Ceylon, and the question of price is, I take, after all the crucial point. If fair China tea is to be bought in England considerably cheaper than other kinds, the poorer classes will inevitably use it. I merely record the above opinion, but have little expectation that the Chinese authorities will ever be induced to take this practical view of the question.

NETHERLANDS INDIA:

COFFEE—TOBACCO GROWING.

The Surabaya *Courant* states that, in East Java, the coffee crop has turned out disappointingly short. Planters complain, too, of unseasonably wet weather which seriously interferes with clearing operations.

Papers laid before the Netherlands States General show that tobacco growing in Palembang does not answer expectations, as, out of 15 estates leased out in 1891, only two are now under cultivation. On one of these remaining estates, the yield is found too small to prove remunerative. On the other estate, the outturn was larger, but the quality fell short. In Indragiri, a European has started tobacco growing with encouraging results at the outset, but further trials show that the cultivation of the leaf does not turn out profitable there. In Sambas, three tobacco plantations, passing by the names of Serube, Sikampong, and Lorong have raised large crops.—*Straits Times*, July 4th.

A TEA GARDEN AND FACTORY AT THE CRYSTAL PALACE.

(From a Correspondent.)

London, June 28.

On page 739 of the *Tropical Agriculturist* you refer to the tea garden at the Crystal Palace. You may not know that it was Mr. Gaselee who was induced to embark in this speculation. The loss he sustained so preyed on his mind that he committed suicide by shooting himself. It was a wild speculation and was unknown to his friends until it was too late to extricate him from his liability. I enclose you the only card I have:—

MACGREGOR & GASELEE, Tea Planters, late of Assam. Royal Indian Tea Factory, Near North Tower, Crystal Palace, S.E.

Mr. Gaselee had been for years in Ceylon and India, an uncle of his was a judge in India for years.

"THE MAGAZINE OF THE SCHOOL OF AGRICULTURE."

In the July number, with which begins the fifth volume, the discussion on the subject of supplementing our fodder supply by pressing the leaves and twigs of trees into use, is taken up, and the latest researches and opinions on the subject noticed. The articles on red spider and the orange rust mite deal with the nature of the work, and methods of meeting the attack, of these common pests. A description of a new apparatus for conveniently and rapidly testing milk (known as the Lister Babcock tester,) zoological notes for agricultural students, and an account of a visit to the Poona Dairy Farm, together with the occasional and general notes make up the rest of the number. It is to be hoped, as the editor remarks, that those for whom the Magazine is intended, will give the publication all the encouragement it deserves, now that it has served their interests unintermittingly for four years.

NOTES ON PRODUCE AND FINANCE.

KOLA.—Planters in search of something new should turn their attention to kola. Some useful information with reference to this valuable plant is contained in a report on the botany of Sierra Leone presented to the Colonial Office and published as an official paper by Mr. O. F. Scott Elliot. The tree, *Kola acuminata*, Mr. Elliot says, grows freely everywhere, and is found from the sea level to fully 3,000 ft. at Sumbawa, in the Talla highlands. It appears to thrive wherever planted, and is well able to hold its own in the original native bush. Mr. Elliot could not find any special conditions of soil as necessary, but it certainly grows on disintegrated gneiss, red grit, or laterite, dolerite, and occasionally on dry alluvium. He does not think he ever saw it on marshy ground or soil liable to be overflowed, and in planting the tree such places ought to be avoided. It begins to bear in seven years, and is in full bearing after eight to ten years. Each tree is said to yield £3 to £4 per annum, and hence a plantation ought certainly to include a large number of these trees. The yield given by Mr. Fawcett is 125 lb. or 4,000 seeds per tree—that is, £8 to £10 per tree, or £800 an acre. At present the nuts are chiefly used by the natives; but so much has been done of late years to bring their valuable properties before the public that it may be safely said that the demand in Europe is sure to increase. The following are some of its properties. A nut, or even half a nut, will enable a man to go without food and support great fatigue for twenty-four hours or more. It is an excellent nerve tonic, and is specially good for keeping the brain clear and active at night. It, however, prevents sleep almost too thoroughly, and should not be taken less than four hours before bed. A property not understood is that of rapidly clearing foul water and improving beer. It is also said to remove immediately and thoroughly the unsteadiness and stupidity due to drunkenness.—*H. and C. Mail*, June 28.

BRITISH NORTH BORNEO NEWS: COFFEE.

(British North Borneo Herald)

We understand that a small sample of Liberian coffee grown on the Trading and Planting Co.'s Segaliud estate has been valued in London at 89/90 per cwt. Captain Beeston who is now prospecting the Kumpong (Pallas) river for gold reports getting colour all the way up and the samples improving as he got higher. He has procured a number of specimens which he will bring with him to Sandakan on his return from Tunku which is the last of the rivers he was sent to explore.

The cultivation of coffee is gradually extending amongst the squatters at Kudat. Several applications for land at \$1 per acre, adjoining the country roads have been received. One larger application for 2,000 acres to be selected at Banguay has been forwarded to the Land Office. The high prices realized in Singapore by consignments have opened the eyes of the squatters; who, hitherto, preferred to direct most of their attention and time to fruit planting. But now that tobacco estate managers find that their coolies spend too much of their earnings in buying plantains and pineapples, the export of these fruits to land concessions in the Bay is forbidden and orchards are at a discount, so the coffee trees receive more care now.

The total tobacco shipment for the season of 1892-3 from Province Alcock is as yet uncertain but 4,918 bales weighing 786,880 Dutch lb. may be taken as an approximate figure.

A Hongkong firm, is said to be negotiating for a lease of the Sikwati oil spring, the samples of oil having been favourably reported.

QUININE DEPRESSED.

The interest in quinine from a speculation point of view seems to have subsided. Nobody at the present time can be found who is willing to buy the salt as an investment, notwithstanding that the market, so far as future prospects go, seems to be in better shape than it has been on many occasions when the speculation fever was at its height. There is no good reason to doubt that the manufacturers have reached a final conclusion not to sell as freely for future delivery as they have been in the habit of doing in the not very remote past. The fact that they will not accept orders for deliveries extending over sixty days is proof of this. There is also very good reason to believe that there exists an understanding among the producers to keep prices up to the present level, and there is ground for the presumption that they have entered into an alliance to keep the price of bark down. The returns from recent bark sales seem to show that. There are strong features in the bark situation, which ought, in the ordinary course of events, to be reflected by the quinine market, but the facts are that selling prices have weakened steadily though gradually during the last few weeks, and the margin between manufacturers' and second hand prices has increased until at the present time the difference is fully one cent per ounce. That is to say, while none of the manufacturers' agents is at liberty to accept less than twenty cents per ounce, second hand holders have taken or are said to be willing to take nineteen cents and it is even intimated that a firm offer of eighteen and three-quarter cents would not be declined. In seeking a cause for this depression there are two or three things to be considered. These are the falling off of actual consumption, the absence of speculation interest and the anxiety of holders to dispose of their stocks. Perhaps the financial distress which is such a marked feature of the commercial situation today, induces some holders, at least, to turn their quinine into money. The Government statistics giving the imports for the past nine months show receipts during that time of nearly 550,000 ounces in excess of the quantity brought in during the corresponding period a year ago, a good deal of this represents manufacturers deliveries direct to consumers, but no small part of it was bought on speculation, and remains unsold.—*Drugi Reporter.*

CHINESE EMIGRATION TO AFRICA.

Consul Fraser at Kiungchow reports to Lord Rosebery:—

New fields for Chinese labour have lately been opened in Africa, both East and West. It was lately reported by a newspaper that there were 500 employed on the Congo Railway in the west. As regards the East Coast, on August 10th appeared in the *Berliner Tageblatt* and *Handels-Zeitung* an interesting letter, a translation of which made by me into English appeared in the *Hongkong Daily Press* of October 29th. It appears from this that on July 25th the British steamer "Flintshire," chartered to convey Chinese labourers for the German East African Company and the German Plantation Company, brought to Bagamoyo direct from Singapore 240 Chinamen, 243 Javanese men, and 25 Javanese women. It is intended to employ these men in the cultivation of tobacco, cotton, coffee, cocoa, vanilla, rice, indigo and perhaps opium. Chinese may also find employment, it is expected as house-servants, boatmen, smiths, market gardeners, washermen, and cooks, and also as policemen for harbour, toll, or custom-house, or plantation purposes.

The regulations promulgated by Governor Baron von Soden, to come in force on May 1st 1892 restrict the landing of Eastern Asiatic laborers to the ports of Dar-es-Salaam, Bagamoyo, Tanga, Pangani, Kilwa, and Lindi. Provision is made by regulations, which it is to be hoped will be stringently enforced, to ensure that they are voluntary emigrants; that they shall be properly treated, and that they shall be sent home at the expiry of their contracts. "These regulations," says the *Daily Press*, in an editorial article, "must in the main command general approval; and it is gratifying to find the German Government exhibiting such solicitude for the proper treatment of the Asiatic emigrants in the East African Territory."

In September a steamer also took coolies from Macao for Anjos; and a letter was received here from a person in Hongkong, inquiring about the prospects of reviving the Chinese emigration to Cuba and Peru. It is to be hoped that with greater knowledge of and interest in the condition of the Chinese abroad, which the Chinese Government has lately evinced, and the patriotic zeal or national pride which its representatives in foreign countries have of late shown so conspicuously, that the strictest possible measures will be taken to prevent the ill-treatment of the emigrants in these and other far-away corners of the world and on the way thither.

THE TRADE IN CASSIA AND ANISE OILS.

In 1892 there was a most remarkable development in the export trade of star-aniseed and the essential oils of aniseed and cassia from the Chinese port of Pakhoi, reports our Consul there. In the former article the advance has been from £15,185 in value to £35,579, or considerably over 100 per cent and in the latter the export has more than trebled, reaching a value of £41,408 as against £13,074 in 1891. Chinese traders who alone have any knowledge of the trade in star-aniseed and essential oils, assert that this extraordinary increase is due solely to increased production, and further state that every alternate year there is a large increase in the trade. This latter statement is, however only partially verified by the Customs returns for past years in the case of star-aniseed, and not at all in that of the essential oils. The consul is, therefore inclined to account for the great increase in part at any rate to a change of route, and believes that whereas in past year these goods have been sent in native boats to Macao by the West River last year, possibly owing to increased taxation by that route, the trade has been diverted to Pakhoi. The essential oils of aniseed and cassia are mainly destined for export to Europe, where the demand, stimulated no doubt by the heavy fall in silver has greatly increased. Inquiries have been made by European firms with a view to

purchasing the oils in Pakhoi, but the trade is entirely in the hands of the Macao merchants established there, who prefer to send them to Macao before sale to foreigners and shipment to Europe, and it seems improbable that they will ever be purchased at profitable rates, or indeed at all, in Pakhoi.

The exports were as follows:—Star-anise—1893: 1,722,000 lb., value £35,579; 1891: 775,710 lb., value £15,185. Cassia and anise oils—1892: 204,864 lb., value £41,408; 1891: 74,048 lb., value £13,074.—*Chemist and Druggist.*

INDIAN TEA AT CHICAGO.

The Indian Tea Association have, we see, received a letter from Mr. R. Blechynden, reporting the successful opening of the Indian Pavilion at the Chicago Exhibition on the 22nd May; and on that and the three succeeding days, that is, up to the date of Mr. Blechynden's letter, the place seems to have been constantly crowded with people thirsting for tea.

After paying a warm tribute of praise to Mr. Tellery's arrangements, Mr. Blechynden says:—

"The tea itself is, I am exceedingly glad to be able to say, appreciated by the majority of people in a manner which, I much admit, surprises me, although I had some hint as to how it would be from what I gathered at the bazaar I referred to and at the club and parties. I have but little doubt now that the action taken by the Association will have good and early results, and if our plans included the selling of tea by the pound we could sell quite a large quantity daily.

"The experience of the first afternoon satisfied me that it would be impossible to keep up the distribution of tea at the same ratio many hours per day. On Tuesday I commenced at 11 o'clock, and before 3 p.m. had exhausted our stock of cream $5\frac{1}{2}$ gallons. Yesterday we opened half an hour later, and had finished 6 gallons by the same hour in the afternoon, and today opening at 12 had the same experience.

"I have screened off portion of the hall and reserved it exclusively for ladies, and from tomorrow I propose to serve tea only here from 11 o'clock to 1 p.m., and after that to all. I foresee that to check the unmanageable crowd we will have to serve tea at certain hours, with intervals sufficiently long between to force people to move on,—say from 9 to 12 and then from 3 to 5-30. This will also keep the people who made this their midday lunching place in check to some extent.

When the sample boxes arrive and we begin to distribute samples, I am afraid we will have to make a charge though I would prefer not to, and sell the tea in the cup at certain hours, giving away samples at those hours only.

I think I may say we have got a good start of Ceylon whose buildings are not yet ready, and our Pavilion, now that one can see the direction in which the crowds move is in a better place than theirs.

The exhibition, as a whole, is still very backward, whole sections in some buildings being closed. A number of the State buildings are also incomplete, and as a whole I know of no building but our own which is ready. New South Wales, Canada, Hayti, Sweden, Ceylon, Great Britain, are all closed to the general public and many others. I only mention those near to us. Great Britain's building is only for offices for the Royal Commissioners, and the cost, £30,000, is quite out of proportion to the space the exhibits occupy in the Exhibition Buildings.

Mr. Blechynden seems to be having a warm time of it. It is to be hoped he has insured his life heavily. Probably any tea, served free, gratis and for nothing, would have attracted similar crowds. Still it is reasonable to anticipate that among those crowds there will be a fair proportion of discerning ones who will discover that what they had been previously accustomed to consume as tea was trash, and who will insist on getting the real thing ever after. Have the Association made adequate arrangements for meeting any demand for Indian tea that may immediately spring up, as a consequence of this experiment? In all such cases it is essential to strike while the iron is hot.—*Capital*, July 4.

MANGROVES AND THEIR EFFECTS.

LONDON, June 23.

Everyone in Ceylon is well-acquainted with the mangrove plant, and dwellers by the seashore in the less-frequented districts well know the depressing effect they have upon the view of the coast lines, sometimes for miles of its length. They no doubt, however, serve a useful purpose, and the following extracted paragraph indicates this to be the reclamation of swampy land and of that of localities liable to flooding by the sea at high tides. Doubtless some of your older residents have been able to watch the gradual advance of portions of your shore line due to the growth of this very uninteresting-looking, indeed rather repulsive-looking plant:—

MANGROVES AND THEIR EFFECTS ON THE COAST LINE.—In his interesting report to the Colonial Office on the scientific results of the Anglo-French Delimitation Commission which he accompanied to Sierra Leone, Mr. Scott Elliot states that the effect of the mangrove in creating alluvial soil could be very clearly seen at Mahela and in the Samu country generally. Mangrove trees seem in fact, he says, to have been designed by nature to change any bay or indentation of the coast line into fertile soil. Thus the whole of the country from Mahela to Rokou and round from Digipali to Kitebon seems to have been at one time a wide bay or arm of the sea, in which sand and mudbanks accumulated through the action of the tides and currents. Wherever such a mudbank is in process of formation, the mangroves grow upon it, gradually advancing seawards as the silt accumulates. They require brackish water, and their mode of growth is thoroughly adapted to this habit. The trunk divides at the base into six or seven curved buttress-like roots, each of which subdivides repeatedly, so that it covers a wide area, with curved, grasping supports. This is, however, but the first stage of growth; after a very short time long hanging roots are sent down vertically from every branch of the tree, and about the level of high tide each of these pendent roots divides into five or six grasping fingers, which grow down into the water and root themselves so firmly in the silt that they cannot be torn up by any ordinary force of current. As each branch of every mangrove acts in this way, the soil becomes pierced by roots in every direction, so much so that, where the natives have made a clearance for rice-growing, the numerous standing roots in the ground seem like a harrow with the points turned outwards. Hence the leaves of the mangrove and all the silt and soil in the water are held by this mesh-work of roots and rootlets, and the accumulation of soil advances rapidly. As the level of the ground (through this accumulation) rises above high tide, the mangroves, which require a constant supply of brackish water, die off, and the whole grove advances seaward, leaving behind it a mass of rich vegetable, alluvial mud, better suited for rice than probably any other soil in existence. In mapping out the windings of the Mahela creek the members of the Commission constantly saw how the mangroves were blocking up the channels, and no doubt, in course of time, the whole creek, Mr. Elliot says, will become solid land.—*London Cor.*

POTTING PLANTS.

In practice, "Pot that plant" really means, give it a larger pot—that is, more room for its roots. Repotting, however, sometimes in practice comes to just the opposite of this, and the experienced potter in shifting his plants determines his course by root-condition. If that is good, vigorous, and obviously cramped, he gives a larger pot; if otherwise, he not unfrequently puts it into a smaller one. There is no resuscitating process so prompt and effectual as this in the case of many plants. Worms, bad drainage, indifferent or unsuitable soil, unskilled watering, may have converted the root-roots into quegmires of sour, putrid earth, in which the roots are sickening toward

death. Remove the whole, wash the roots clean if needful, as it often is, and re-pot in very light, porous, sandy soil, or fine sand, placing the roots in the smallest possible pot, and give such extra nursing as advised after potting off, and the roots may be re-established in health and quadrupled in numbers in a few weeks, and the plant saved. So soon as this renovation is effected, the plant may be re-shifted into a larger pot, and treated as advised for others. The time for shifting plants must be determined by condition, and with but little reference to the calendar. At one time, however, the spring and early summer months were mainly devoted to the potting of plants. This was carried so far that plants were shifted in April or May, whether they wanted it or not. No doubt these general pottings at such seasons suited the majority of plants; hence the practice survives to this day. Accepting as an axiom, that no plant should be pruned and potted at the same time, whatever its condition, as such a double check hinders alike the formation of roots and the growth of top, there are three general conditions of plants favourable to their re-potting or shifting. The first is soon after starting; the second, in the middle of their growth; and the last, just before their growth is ripened. And these seasons, determined by condition, apply to all plants without exception, whether hard or soft-wooded, herbaceous or bulbous, exogens or endogens.—From "Cassell's Popular Gardening" for April.

THE FUTURE OF TEA.

Under this head we have received a communication from a correspondent signing himself "Hard Times," who is interested in Indian and Ceylon tea, and thinks it time that planters should be warned not to take too cock-sure a view of the tea market. Our correspondent thinks if planters are not more careful about quality there will be a reaction against Indian and Ceylon tea. The tone of our contemporary's letter is very pessimistic and we cannot endorse all that he says, but his remarks are entitled to consideration. He thinks that the reason medical men have made such a dead set against these teas is that the consumer as a rule brews them too long and too strong, and that stomachic trouble arises in consequence which medical men cannot fail to detect, hence the tone they adopt in regard to Indian and Ceylon teas, and hence also the necessity for imparting more knowledge on the subject of brewing tea to the ignorant consumer. As regards the edict in China against adulterated tea, he says:—

"It is well known that, for many years past, Sir Robert Hart, the head of the Chinese Customs, has not ceased to urge the Chinese Government not only to abolish the liken-tax and export duty amounting altogether to about 2d. per lb., but to issue edicts punishing severely the adulteration of tea. At the same time, in order to enable the Chinese tea growers to compete with their Indian and Ceylon opponents, he recommended that schools should be opened in the tea districts, where the Indian mode of preparing tea for the London markets could be taught to the students, who would likewise be accorded the advantages of Indian experts and English tea machinery. Perhaps this advice is at last going to bear fruit.

"The Chinese Government could not have a better time in which to set about the task of attempting to regain a once thriving trade with England. From some cause or another it is a notorious fact that both Indian and Ceylon teas have fallen off in quality very lamentably of late. This is notably the case with regard to Ceylon.

"The Indian and Ceylon tea planters will have to bear heavy export duty on their product, if it is true that an import duty on silver is to be

levied by the Indian Government, and also a mint tax. With the taxes on tea abolished in China and imposed in India, the Chinese tea growers would probably be enabled to compete successfully with their opponents. It is, therefore, quite on the cards that in a few years to come we may see in the grocers' windows invitations to 'Drink Pure China Tea.'

"How can the Indian and Ceylon tea planters now hope successfully to exploit such desirable markets as the United States offers, already enamoured as they are by the delicately-flavoured, pale straw coloured infusions obtained from the exquisitely prepared Japanese teas, which by the way, are just as little known in England as Indian and Ceylon tea is in America at the present day, after years of vain attempts to introduce them. In the United States Japanese tea has wrenched the bulk of the tea trade from the Chinese, so no wonder that the Government of the latter country are at last showing signs of waking up. Since the Whitentide holidays Indian and Ceylon teas have lost about 12½ per cent. in value, and unless the quantity sent to London in future is lessened and the quality correspondingly improved hard times would appear to be in store for the British tea planters."—*H. & C. Mail*, June 23rd.

THE DUTCH MARKET.

AMSTERDAM, June 26.

CINCHONA.—All the analyses for our sales on July 6th next have been published now. The manufacturing bark contains 25 tons sulphate of quinine, or 461 per cent on the average. About 6 tons contain 1.2 per cent, 49 tons 2.3 per cent, 141 tons 3.4 per cent, 152 tons 4.5 per cent, 93 tons 5.6 per cent, 54 tons 6.7 per cent, 39 tons 7.8 per cent, and 1 ton 9.10 per cent sulphate of quinine. The auctions contain 556 tons, instead of 557 tons as formerly stated.—*Chemist and Druggist*.

A CEYLON PLANTER IN BRAZIL.

(For the "Ceylon Observer" and "Tropical Agriculturist.")

COFFEE

is the only thing that holds its own: the Fazendeiros or Coffee Planters continue to increase their fortune with low exchange, for the gold value of coffee still keeps up. The coffee crop for Rio is estimated at 2,700,000 bags of 60 kilos. Santos nearly as much. In S. Paulo old coffee will give little owing to a long drought last year, but there is a large extent of young coffee coming into bearing, which dry weather did not much damage, which will make up the deficiency on the old. In that State labour forces are being kept up by European immigration.

A law was passed last year for allowing Chinese Immigration, and a Mission consisting of an Ambassador and staff went from here a month ago to China, to make a treaty with the Celestial Empire. They will have past by your port before you receive this. A war ship is to join them in eastern waters and it will call at Colombo. She arrived at Port Said fifteen days ago.

By the way the ex-Minister of Marine Custodio de Mello was in Command of the Brazilian man-of-war the "Almarant Barrosa" the same vessel now going to China and which was in your port when news of the Brazilian Revolution in Nov. 1889 was telegraphed. He, I noticed, wrote a letter to your paper in reply to some reports of Brazilian sailors having been flogged. He was the leader of the Revolution which made Theodore resign. He has since been rather satirically "badgered" about his ship when at the head of the fleet on that occasion sticking in the mud of the Rio harbour just as the inhabitants of peaceful Rio de Janeiro expected he was to blow their great city to "smithereens."

A. SCOTT BLACKLAW,

GRAPE-GROWING IN CALIFORNIA.

Now that public interest is excited by the recollection of the great anatomist, Sir Richard Owen, the following record of the adventures of one of his grandsons in California may be read with interest:—

Misled by the representations of interested persons, Mr. Owen leased a 30-acre vineyard lying 1 mile outside of Santa Barbara, expecting to realise several thousand dollars from the year's crop. He undertook to cultivate it himself, but, after smashing three ploughs in his endeavour to train a spirited horse to rustic accomplishments, he called in help. Before the summer was over, the pay-roll of his vineyard had mounted to a very pretty sum, but he still looked confidently at the handsome bunches hanging in the shelter of the green foliage, and counted his harvest. At about this time he bethought himself that it would be a good idea to negotiate his crop with some fruit dealer. To his surprise, he found that not a single fruit dealer or grocer of Santa Barbara would agree to take it at any price. A few Italians sometimes bought Grapes for wine, but their offers were so low that to accept them seemed a craven retreat from his high expectations. San Francisco was too far away and freights too high to send his Grapes there.

"The Grapes are there," said he, "and they are exceedingly nice Grapes—except where the mildew struck them. There is just one thing left to do. I shall not stand by and see them spoil on the Vines. I will peddle them from house to house," he said.

Some one mildly suggested to him that he might suffer disagreeable experiences, but he was not to be balked by fate or the storekeepers. He bought an old waggon from a peddler and as soon as his Grapes had taken on a deep colour he began his new career. Being very anxious to be the first in market, and to sell his fruit while prices were high, he started out before Dame Nature had served the Grapes with their full portion of saccharine matter: That evening he presented himself at a neighbour's house in a state of riotous indignation. He presented his hostess with a basket of Grapes.

"I have had the most extraordinary experience to-day," he announced. "Everybody is accusing me of selling sour Grapes. Now, these Grapes seem sweet and delicious to my English palate. Will you be kind enough to try them, and give me the benefit of your opinion?"

The lady did not make a wry face. "They are very nice," she said.

The keen sense of the young Englishman detected the reserve in her speech.

"I shall have to give up," he said, with a merry laugh. "And I'll own to you, that these are some of my choicest specimens. All that I took out did not come up to these. And you Americans have such an awfully sweet tooth. Still, I would have got along very well if I could only have persuaded my customers to try my samples."

"I picked out my nicest and ripest specimens and put them in a basket, along with a few other bunches that were not so ripe," he continued. "The first house that I visited was that picturesque Swiss Cottage on the hill. It is inhabited by an old maid. How do I know? A feather duster hangs beside the door, as a suggestion to people to brush the dust off their feet before entering. Wherever a feather duster is hung out in Santa Barbara there is an old maid within. It is an infallible sign. This lady was very nice, however, and when I asked her if she wanted to buy some Grapes, she responded with a cordiality that made me rejoice in my calling. 'But it is very early for Grapes. Are they sweet?' she asked. 'Try one,' I rejoined, with confidence. I pointed to a luscious bunch. She reached beyond it for another, and my heart quaked. She made a wry face. 'Try this one,' I insisted, pointing to one of my samples. 'I prefer to try this,' she replied, and to my horror she reached for another that was a little off colour. Then she beat a hasty retreat, saying politely, 'Thank but I believe

I do not care about any Grapes to-day.' I have repeated this experience all day, in different keys. Fortunately, I started out with but little fruit. Now I shall lay off for a week or two, till the Grapes are riper."

A couple of weeks later Mr. Owen took up his new profession in good earnest. He was snubbed and patronised, haggled with over prices, impatiently turned away, or kindly invited to rest, and his wares were praised as cordially by one customer as they were depreciated by the next. He enjoyed some experiences that he would not have been likely to encounter if he had canvassed the United Kingdom for a life-time in a similar capacity. Kind-hearted old ladies noticing his refined manners and his English accent, were perpetually inviting him to take a cup of tea, attentions which he appreciated, but, it is needless to say, courteously declined, for he was disinclined to mix social and business matters. Occasionally he had an amusing encounter. He aimed to avoid the houses of his few acquaintances, but now and then he stumbled upon one, and explanations ensued, or an embarrassing scene occurred, according to the real gentility of the people.

Alan Owen's career as a peddler was of short duration, but he did not forsake it because he was at all daunted by its results. He had been for some time conducting negotiations for an important stock range over the mountains. The bargain was consummated. He sold the remainder of his Grape crop to the Italians, a younger brother and two other young English gentlemen came out from England to join him, and he is now herding his cattle over 75,000 acres of land. He has taken out his first naturalisation papers, and expects in a few more years to become an American citizen.—*Gardener's Chronicle.*

THE CULTIVATION OF CINCHONA IN

JAVA.

At the general meeting of shareholders in the Western Java Cinchona Company, which was held in Amsterdam on May 26th, it was stated that the next receipts by the company from the sale of cinchona during the year were 151,610fl., the year's trading showing a net profit of 58,522fl. The company owns four plantations, and derives practically the whole of its revenue from cinchona. Two of the plantations are being uprooted, and at the meeting aforesaid it was decided to uproot the third plantation also, and to sell the cleared ground at the first opportunity. The fourth plantation, Panjairan which is considered an exceedingly valuable one, and promises well for the future, although thus far no bark has been harvested from it will be continued.—*Chemist and Druggist.*

THE TEA TRADE AT HOME.—I do not think there is any trade in London in which the competition is so fierce as in the tea trade. It is a simple fact to state that every grocer and provision man in London has visits each week from at least 40 travellers. But this is not all. The trade is simply choked up and sub-divided to an enormous extent by the men who, in the old drinking days, used to "go into the wine trade" and now in these temperance days "go into the tea trade." A private business is doubtless very nice, if there were enough of it procurable to make it pay expenses. But everybody has a relation or friend in the tea trade who can get their tea for them "wholesale"; every hotel-keeper, canteen, hydropathic establishment, and other kindred places, is already secured by some one interested in the supply to make a profit out of it. There is but one chance of doing a turnover which will pay and that is through travellers or heavy and continuous advertising. Neither of these channels for securing a tea trade can be gone into by inexperienced individuals. The result is certain loss.—*Cor., local "Times."*

VARIOUS AGRICULTURAL NOTES.

BRAZILIAN COFFEE.—In the *New York Herald's* account of the Agricultural Building at the Chicago Exhibition the following occurred:—Brazil, now a sister republic, sends the entire national display from last year's exhibition at Rio Janeiro. Coffee is naturally the staple of the exhibit, and it will be in evidence from the berry to the liquid in the breakfast cup. The entire process of its production from first to last will be elaborately illustrated, and a series of samples will show the different varieties. It will be the most complete showing Brazil has ever made.

THE ENGLISH COFFEE TRADE thinks that some of the vendors of the "finest French coffee" and other similar compounds of chicory are not too particular, but we (*Produce Markets Review*) think that even they will be amused at the unblinking impudence and absence of any moral misgiving shown in the following copy of an actual letter recently received in America:—"We have mailed you samples of steamed, cooked, and prepared peas, and Germanian coffee, which we trust you will not cast in the wastebasket without inspection. If you sell ground coffee we confidently state that you are not in it. Where are we now at? Test these goods, and you will find your trade and bank account increased by their use. Write us, and we will give you special prices according to quantity. Be sure to draw and test these goods; you will find you have struck a bonanza.

"**AUSTRALIAN AGRICULTURAL INDUSTRIES**" are most favourably reported on by Miss Shaw, the *London Times's* Special Correspondent, whose letters have recently been attracting a great deal of attention. Her latest letter published about a month ago and from which we extract on our last page, cannot fail to have an influence in restoring confidence in Victoria, where "small farming" especially is rapidly advancing. The great want here, as in every one of the Southern Colonies, is of course described as "population"; but then the population to benefit the community as well as themselves out there, must be of the right sort—willing to work in the country rather than lounge about the towns. In this connection, attention may be called to "the Agricultural Paradox" as discussed by the *Australasian* elsewhere.

THE ORANGE TRADE OF JAFFA.—Jaffa Oranges, which have appeared in the English markets of late in increasing quantities, seem to have become such an important item of export in the trade returns of Jerusalem, that a new system of steam communication has been established for their rapid transit to this country. This was established last autumn, with the object of shipping the Oranges direct to Liverpool. According to the report of Mr. Consul Dickson on the trade and commerce of Palestine for the year 1892, one firm sent on an average a steamer every ten days from the commencement of the Orange crop, each vessel loading from 15,000 to 20,000 boxes at a time, the freight varying from 1s 8d to 3s or 5s per box. This system of conveying Oranges direct to the United Kingdom has not only proved a profitable business to the steamship companies, but great service has been rendered to the shippers, as the fruit reaches its destination in a shorter time and in better condition than if sent *via* Egypt. In former years the Oranges were forwarded to Port Said in the coasting steamers, and then transhipped in vessels sailing for the United Kingdom, but by this method much damage was occasioned as well as delay. Nearly three-fifths of the whole Orange crop of Jaffa is now shipped to Liverpool, the rest being exported, for the most part to Austria and Egypt.—*Gardeners' Chronicle*.

CACAO CULTIVATION is extending in East Java we read in a *Straits paper*; but in certain districts the inhabitants will not lease land suitable for the purpose except at exorbitant rates. The Government are not inclined to lease out Crown land for this line of cultivation in that neighbourhood, because the still available area must be reserved for the use of the people.—*Straits Times*.

BRAZIL is waiting (says *The India-Rubber Journal*) with open arms to welcome at least a million immigrants. Unless more labor can be procured the rubber and all other crops will suffer. Nevertheless we do not advise anyone to rush of without full enquiries as to cost of living, &c. When Amazonia separates itself from Brazil, the case will be different.

TEA IN GERMANY.—A *Calcutta paper* calls attention to Germany as a new market for Indian tea, and remarks:—"If Indian tea is only pushed with skill and energy it may have a great future before it in the fatherland. Only let us beware that Ceylon does not get the start." The advice is well-meant, but comes a little late, says the *Madras Times*.—Why this jealousy of Ceylon we ask? What both India and Ceylon have to do is to fight China.

NORTH MATALE "COCOA"—selling up to 181s per cwt. No wonder though, as we learn from Mr. D. Edwards, the Ceylon Land and Produce Co., already the owners of a considerable extent under the chocolate plant, should have lately been freely extending its cultivation. We wish Mr. Edwards, who is now the sole representative of the Company in Ceylon, all success in his further development of this very desirable branch of cultivation. In tea, the Company has also some very valuable properties; but the Chairman, Mr. Wilson, returned home after his recent visit to the island, greatly strengthened in his belief, in the future of "Ceylon Cocoa."

THE "RATNAPURA" TEA DISTRICT—is coming to the front. Mr. Dunbar's fine property, part of which touches the gravets of the town, is doing so well that it is expected 100,000 lb. of made tea will be got from the 200 acres cultivated (some of it young) during the coming year. Fifty additional acres are to be planted. There is also to be a new clearing on the adjacent property, a share of which Mr. Hardie has just sold to the Meers Lamont. It is quite cheering to hear of the old veteran, Mr. W. B. Lamont acting the tea-wattle superintendent, and doing rough work and long walking trips too, as if he had not borne the heat and burden of planting life for over the half century. We trust he and his son and their partner will be very successful in this new venture.

"**SOME ECONOMIC PLANT OF "SIERRA LEONE"** is the heading of a concise paper in the *Pharmaceutical Journal* being an abstract from a Colonial Report by G. F. Scott Elliott and we are republishing it in the "TA." A wild native bush coffee (*coffee stenophylla*) is described which grows freely, yields as much as Liberian and in the opinion of some people, has a superior flavour. The cultivation of "Liberian" is said to be extremely profitable in the Sierra Leone district. So with "Kola" which grows freely (especially on disintegrated gneiss or laterite) from sea-level to fully over 3,000 feet, begins to bear in 7 years and each tree yields £3 to £4 per annum! Coconut palms (so spelt by Mr. Elliott) long established are said to bear 12 dozen nuts a year; there is one big plantation in full bearing 10 years old but troubled by beetles.

A TALL GUM TREE YARN.—The tallest tree on earth so far as is known is a gum tree (*Eucalyptus regnans*) in the Cape Otway Range, Victoria. It is 415 feet high. Gum trees grow very rapidly; one in Florida shot up 40 feet in four years with a stem one foot in diameter, and another in Guatemala grew 120 feet in twelve years, with a stem nine feet thick. This is at the rate of 10 feet a year, or nearly a foot per month.—*E. Mail.*

TEA PRODUCTION AND ADULTERATION.—The *Review* of New York of May 4th had a lengthy article on the subject of tea production and adulteration. It contained the statement that "the present consumption of tea *per capita* approximately 1.33 pounds per year. We derive about 51 per cent of our tea from China, 42 per cent from Japan, and all but a small fraction of the remainder from the British possessions."—London *Cor.*

THE ACTION OF LIGHT ON BACTERIA AND FUNGI SPORES.—Professor Marshall Ward, at a recent conversazione of the Royal Society, exhibited by the aid of the electric lantern some photomicrographs illustrating the action of solar and electric light on the spores of bacteria and fungi. He demonstrated that the action of strong light is to kill these when the exposure is long enough, amounting in some cases to two hours, and the blue rays are most powerful in producing the effect; the less refrangible waves of the spectrum have little influence in the matter. You will perhaps recollect that I noticed in these letters some time back a lecture on a kindred subject by Professor Ward demonstrating the effect of strong sunlight on bacteria.—London *Cor.*

MICA IN INDIA.—We have received No. 1 of the Indian Section Imperial Institute Series; being Guides to Commercial Collections. This is a guide to collections of 1892, and is published in Calcutta and the following are the subjects very briefly treated:—

Adhatoda Vasica; Coal; Cotton:—Bengal, Madras, North-Western Provinces, Central Provinces, Assam; Cutch; Fibres used for brush-making; Indigo; Ipeacuanha; Iron:—Southern districts of Madras, Barakar Iron Works, Bengal; Jute; Mica; Morinda (Al dye); Padank Timber; Podophyllum emodi; Resin and Turpentine from Indian Pines; Sida Fibre; Silk; Castor oil; Linseed; Gingelly (Sesamum).

We quote the page of most local interest:—

Rough and cut mica (Muscovite) from Bengal mines, obtained in the Calcutta bazaar. Raw and prepared mica (Muscovite), ruby-tinted. From the Gaya District, Bengal. From the Monghir District, Bengal. The following specimen from the Inikurti mines, Nellore District, Madras:—Length 3 ft., breadth 2 ft. 6 in. weight 63 lb., remarks excellent quality.

Collection of paintings on mica from Benares, Calcutta bazaar, and Trichinopoly is purchased from the Marakoyers (a class of Muhammadans) of Negapatam, who purchase large quantities of mica every year from ships arriving from Calcutta, for making their big taboots for the Kaosthiri festival. Curtains spangled with mica. From Lahore, Mica fans from Poona. Fans ornamented with mica from the Calcutta bazaar. Mica ornaments (flowers, flower-trees, etc.) and lamps used in processions in Calcutta. The United States are the principal consumers of Indian mica, and the quantity exported from India has increased coincidentally with a falling-off of production from the North Carolina deposits. It has been estimated that from Bengal alone there will be an output of 500 tons during this year, which is about one and a half times the production of North Carolina from 1868 to 1887, and more than fifteen times the amount raised in the United States in 1887.

HEAVY RAINFALL.—Mr. Clement Wragge, the well-known meteorologist, has, says the *Globe*, drawn attention to the fact that at Crohamurst, Queensland; no less than 77 in. of rain fell in the four days from February 1st to 4th last. On the 3rd nearly 38 in. fell during the 24 hours. Such heavy rainfalls have been observed in India, but probably the above makes the record.

CHINA TEA EXPORTS.—Our Special Telegram from the Far East conveys to us, the unexpectedly good news that the tea shipments from China and Japan to date to the United Kingdom are no less than eight million lb. less than at the same date last year. It is evident therefore that there was no room to operate during the days of very low exchange; for as was said here, the first China crop had probably been disposed of, and before the second comes into play we may expect to be on more equal terms even in respect of exchange. At any rate China buyers for London have a good deal of leeway to make up before they are on a level with last year's shipments.—The Indian shipments for June are only 6 million lb.; from Ceylon 7½ million—so that, altogether the home market should become firmer in view of limited shipments.

TEA IN WEST INDIES.—Lord Brassey in writing of the West Indies says that the future "of the islands will depend on the introduction of new tropical cultures, among which those of fruit, cocoa, coffee, tobacco, nutmeg, are specified." To that list the London *Spectator* adds:—"And, as we should think, tea, may safely be reckoned. It is to be noted, as a curiosity in commercial history, that the taste for spices once world-wide has seriously declined, and in some countries may be said to be extinct." The *Spectator* is not wise in adding "tea" considering the dearness of labour in the West Indies. Lord Brassey if we mistake not, was influenced by the objections we offered at the Royal Colonial Institute and elsewhere to the spread of tea cultivation under British auspices beyond India and Ceylon.

"A COMPANION FOR THE QUEENSLAND STUDENT OF PLANT LIFE," by F. M. Bailey, F.L.S., Colonial Botanist—is the title of a pamphlet of over 100 pages issued by the Department of Agriculture, Brisbane, Queensland; and which cannot fail to be very useful to colonists. It is stated that copies can be obtained free by such persons interested, on application to the Under Secretary for Agriculture, Brisbane, the object being to interest residents in Queensland in the plant life of the country. There is a helpful "Introduction or Prefatory Notice," (15 pages) giving information in a popular form to help the beginners. Mr. Bailey states:—

The compiler has been frequently urged to publish a full glossary of the terms used in botanic descriptions and in complying with this request he has aimed at combining with a glossary a view of plant life in general. Thus, not only are explanations of the terms used to designate the various organs or parts of plants given, but some account will be found of the functions of the organs themselves.

The main portion is thus headed:—

Glossary of Botanic Terms, their Explanation and Application, Functions of the Various Organs, &c., and Hints about Plant Life in General.

In Addenda, specimen descriptions are given having particular reference to Australian plants. Altogether this little companion ought to be very useful to the Australian colonist and Mr. Bailey has to be congratulated on its compilation.

CORRUGATED IRON BUILDINGS.—Messrs. Bruce & Still Ltd. of the Mersey Galvanizing Works Liverpool, who are advertising in the *Tropical Agriculturist* have issued a beautifully illustrated catalogue of which we would recommend our readers to obtain a copy. It shows substantial and artistically designed corrugated iron buildings suitable as residences, clubs, warehouses, halls, &c., and the prices stated seem very moderate.

TEA CULTIVATION: PROSPECTIVE EXTENSION.—We take the following from the *H. and C. Mail*:—

A notable feature of the past week is the issue of a "confidential" circular to its shareholders by the administration of the two large Glasgow companies engaged in tea planting, informing them of their intention to increase the joint capital by the issue of £800,000 of fresh capital for the purpose of extending operations to the Bramapootra Valley and Ceylon, in both of which districts land has been applied for. One-half of this same it is intended immediately to offer to existing shareholders in the two companies.

Can this have reference to the pioneering already reported in our Balangoda-Bamberabotuwa district?

CEYLON TEA EXPORTS.—The total for the half-year, according to the Customs accounts, is 43,913,878 lb. as compared with 39,639,796 lb. for the same half-year of 1892. This would point in the case of the current year to an aggregate total as per Customs, of about 82 million lb. But the Chamber of Commerce figures for the half-year indicate a total for the year under rather than above 80 million lb., for the shipments during the second half of the year have always been about ten per cent less than in the first six months; while if fine tea-making becomes more general we may even see a shorter outturn. Messrs. Forbes and Walker give the exports to date (6th July) as follows:—

To United Kingdom	...	41,461,000 lb.
„ Australasia	...	3,032,000 „
		44,493,000 lb.

One reason, undoubtedly, why the total of our exports has not reached larger figures in proportion to acreage during the past eighteen months, is that a good many corners put into tea on some of the older coffee estates, have latterly been left without plucking. The acreage so treated may be comparatively trifling in each individual case, but when the aggregate is made up for the whole country, it is undoubtedly appreciable. Tea is such a hardy plant that non-cultivation does not affect it in the same way as coffee, and in the event of a better market and higher prices by and by, a resumption of plucking, after getting the bushes into order, might take place in the cases referred to. It will be of interest to see how our total acreage under tea works out this time for our Directory. We are not prepared to say as yet; but hope before long to be able to lay the figures before our readers.

THE ACTION OF LIGHTNING ON THE VINE.—A memoir, having the above title, has just been presented by E. Rathay to the Academy of Science at Vienna, in which the following affirmations are made:—

1. Colladon's statement with regard to the reddening of the Vine-leaves during thunder-weather is confirmed. It had been impugned by Caspary, but Rathay finds that it is common amongst all Vines, the leaves of which redden in the autumn.

2. The reddening of the leaves occurs in *Vitis sylvestris*; it does not affect some of the American Vines.

3. The phenomena are comparable to those which result from various mechanical injuries,

4. The colouring is an immediate consequence of the lightning, and is followed by troubles in the cambium, and by decortication.

5. The fruit suffers, and appears to wither.

A number of statements of less importance are also made.—*Gardeners' Chronicle*.

SENEGAL RUBBER should be "looking up" a little, as the Belgian Vice-Consul at Gorée says, only five or six years ago the exports of caoutchouc only attained 50 to 60 tons, but in 1892 they reached 306 tons. He states that the quality has been sensibly improved "by processes that the natives have borrowed from Europeans." Cayamance is the district where rubber collection has most progressively developed.—*Electrical Trades Journal*, June 8.

PRUNING OF TEA.—No hard and fast rule can be laid down for this important work on a tea estate. A mistake many of us have made, was in cutting down our bushes too soon, and getting leaf out of them before they came to maturity. One of our most successful coffee planters, as he is as a tea planter—Mr Blackett or Dolosbage—is now reaping the fruits of being in no hurry to cut down or to prune. Jât, soil, and climate have all to be taken into account in this important work. It cannot be managed from Colombo at any rate.

PLANTS AS BAROMETERS.—A French observer, named M. Cade, has been for some time past closely observing the action of several common plants when the barometer indicated a change of weather. He found that if the heads of clover and other leguminous plants stand upright there will be rain. If the leaves of sorrel turn up, it is a sure sign of storm, which is also foretold by the leaves of willow grass slowly turning up. The closing of the flowers of convolvulus indicates rain, which, as is so generally believed, may be said of the flowers of the pimpernel, and also the hibiscus flowers. When the flowers of the sorrel open, it is said to be a sure sign of fine weather, but if they close it will rain. If the flowers of the carline thistle close, there will be a storm. The expanding flowers of cinquefoil suggest rain, but their closing means fine weather. The African marigold flowers close before rain; while the scales of the teasel, pressing close together, pretty surely mean rain.—*Boston Commonwealth*.

PLANTING AND TRANSPORT IN HAPUTALE.—We learn that planters in Eastern Haputale are on the whole well-pleased with the railway rate equivalent to 1½ cent. per lb. on their tea to Colombo. This has hitherto been the cart rate from the Koslands end of the district to the capital, and steps are now being taken to secure carts on estate account to work to and from the Haputale railway station. Of course this will add somewhat to the transport charges down; but there will be a saving on goods up, apart from the immense advantage in time and safety *en route*. There is a talk of a wire shoot through Kelburne to connect with the railway station as there used to be of one between Batgodde and Idulgashena when that station was projected. More likely will be road extensions to serve the Eastern valleys from Bandaravella, though it will not be easy to get a route that will be convenient for all.—We hear very good accounts of the prospects for an autumn coffee crop; green bug is not so prevalent, and still more satisfactory, some fields that were treated to a brushing of lime solution after a severe pruning of the bushes, have kept free of bug since. We sincerely trust that it may be possible by fighting bug with lime to keep in profitable cultivation, even a remnant of coffee in Haputale and other Uva districts.—Cacao in some parts is also doing well.

puffy sort of strain? Were this limited to the describing of the natural beauties of the island, truth would not be violated;—but when the same inflated style is applied to our agricultural industries—it may be at some sacrifice of veracity—and this invariably does harm, in the long run.

The fact is this is a very poor country: one enterprise has failed after another, and but for the perseverance and special aptitude of Ceylon men for surmounting difficulties, the island would have been abandoned (by planters) a while ago.

Our standard product tea shows signs of instability; any how, it has had to take a *back seat* against Indian tea, within last season or two, and for aught we know—may have to remain there.

“Is our tea deteriorating”? is the question of the day. I would reply that any falling-off is yet but inappreciable, as regards quality. In fact with improvements in factories—and better appliances—our tea is likely, all round, to be *much* better made than formerly. Indian tea is stronger and *harsher* and more suited to disguise inferior stuff for the “canister” trade—which has developed enormously of late; this with hard times at home—accounts for our low prices—and the difference to Indian tea.

But it would be unwise to neglect precautions against “deterioration.” You, sir, are instant in warning, on the subject of cultivation and the expediency of growing as many products as possible. There is wisdom in this. Neglect of such precautions can only end in disaster more or less emphatic.

At the higher elevations, we are confined to the one product—tea—and there does not appear, at present, any other product as an adjunct—to grow profitably, though something may be found. It was well remarked by that observant and highly-gifted writer “Old Colonist” that a lowcountry estate has the great advantage of being fit for a variety of products as compared with those situated at high and cool elevations. So it is; but those in each condition must just work to gain all possible good results. Cultivation on the hills is most difficult, and no doubt deterrent in a measure from the not very certain results. . . . The first great drawback is the generally poor soil to be dealt with. The excessive *wash* of the same from the heavy rains, which nothing can prevent, unless we could terrace the land on the stupendous scale—practised by the Etruscans of old. The soluble constituents of the manures applied are in part lost by this heavy rainfall. For months on end the sunshine is deficient and in the clear weather, cold nights do harm in retarding growth or “flush.” Shall we sit down with folded hands and await the upshot of circumstances? Certainly not. Much can be done, enough can be done; but is enough being done in cultivation? I fear not; if so, “deterioration” in quantity and quality of our tea, is a certain sequence, and not a very remote one. Some soils in patches here and there in favoured localities may stand the strain on them for a considerable time; but in general most require cultivation to keep them up to a profitable standard of fertility. To quote “Old Colonist” again. In writing on farming in Australia, he said that agriculture as a science is the same all the world over; no doubt about that, it only varies in practice to suit conditions of differences.

Now, Mr. Editor, I must differ from your dictum that Ceylon is a good place to learn Tropical Agriculture in—*vide* your remarks lately regarding young men of the “Creepers” persuasion. All young men can learn much better in England or in some of the continental states the science of

agriculture with practice combined. Tillage, manuring, rotation of crops, the effect of seasons and the thousand and one facts &c., belonging to the craft of the cultivator. The money sometimes given by “Creepers” in premium to men, without any special knowledge of “the reason why” in agriculture would have paid for a training at Cirencester College! Here the usual routine is but weeding, pruning, and plucking &c., with the contingency of seeing some manure put out at haphazard; this to a young man not to remain in the island is little worth his while.*

One *evil* more in “Cheery Ceylon” is our Labour Supply—always uncertain, dear and generally bad. It has undoubtedly “deteriorated.” From the fairly good gangs of people in their prime which used to come to us in the good old days of coffee, we have come down to a lot of *ruff-raff*, the aged and decrepit, “halt” “lame,” and “blind” &c., bringing to mind the company (in the parable) invited to the rich man’s supper.

This leads me to expatiate on the Advance System—a veritable curse to those concerned. It is allowed by all that our labour force is demoralized by the system, and there is no feasible remedy for it; at least experts say that the system can only be altered, abated or abolished by the united action of the employers of the labour. This union is, I think, just as likely to come in our time, as the Millennium!

Now, Mr. Editor, you who in a few leaders with your incontrovertible facts and invincible figures, have done much already to alter the destinies of this “the land we live in” (and I believe “annexation to India” would in most respects be advantageous to Ceylon) can you not suggest a practical remedy for this “Coast Advance” evil? There can be no mistake, local advances amount in effect often to a species of bribery: employers with a press of work on, out-bid each other for labour. Kanganies will naturally go where they can get more money at the time, regardless of future consequences. Now if this is an evil, in the long run to both parties, I think the only and correct plan is that a law be made making *local advances* for immigrant labour illegal. For advances *bona fide* given for road expenses, some simple precautions might be made, such as the payment of the money in India &c.

I trust you will be pleased to look into this matter; with your powerful position, in the matter of a thorough knowledge of both sides of the question it is not beyond you, but it is beyond the control of individual planters. A railway to join us to India, of which an annexation scheme is the precursor, would doubtless help us with labour amongst other benefits.—I am, yours faithfully,
“SENEX”

BIG TEA BUSHES: BALANGODA TO THE FRONT.

HALDUMULLA, July 14th.

DEAR OBSERVER,—As the big tea bush season appears to have set in again, I send herewith measurement of a tea bush that I measured last week on Keenagaha Ella. They were taken 4 in. above ground surface:—

Diameter 13 ft. and 10 ft.
Girth of Stem 3 ft. 3 in.

Several other bushes measured 11 ft. and 8 ft.

* Surely there is an advantage in learning how to work coolie labourers, and in seeing how tropical planting and preparation whether of tea, cocoa, coffee, etc., are carried out.—ED. T.A.

in diameter. This is not bad for trees growing in old coffee land.—Yours faithfully,

H. H. KIRBY.

[Well done the Balangoda-Haldmulla region! We had long ago heard of the magnificent growth of tea on Mr. Bastard's fine plantation. The above champion trees are not quite equal to the St. John's one.—Ed. T.A.]

HOW TO IMPROVE CEYLON TEAS.

Upcountry, July 18.

DEAR SIR,—Don't you think that a good plan for a start in improving the quality of our teas would be for Superintendents when in Colombo, for a holiday; to take lessons in tasting from the brokers, two or three of whom could hold an 'exam' and give a diploma, according to qualifications. I only throw this out as a hint. At present one brain manufactures for a Company—rule of thumb—but if a man had a diploma in degrees, he would no doubt be allowed to use his own brain a bit; then the best brain would get its reward. A little science in manufacture would cost less than in manuring and would have the advantage of not increasing the output.—Yours truly,

AN OLD COFFEE STUMP.

GUTTA-PEROBA AND NEW PRODUCTS IN THE PHILIPPINES.—CONSUL WEBB, OF MANILA:—As far as is known to the department of forests and mountains of the Philippines, the caoutchouc or India-rubber tree is not found in the Philippine Archipelago; it is certain that India-rubber has never been a product of this consular district. But it is quite probable that an exploration of the hitherto unexplored jungles of the southern islands would result in the discovery of this valuable tree, for the climate and apparently the soil are favourable to its growth. There is a widespread conviction that this archipelago will yet be made to yield many articles of commerce the existence of which is yet unknown here, for the whole vast country, with the exception of the environs of the three principal ports, Manila, Iloilo, and Zebu, is almost as completely wild and undeveloped as it was three hundred years ago. There are hundreds of square miles of jungle rich with botanical treasures that are never disturbed by human foot, black or white, and it will probably never be known what they really contain until the Spanish Government awakes to the advantage and necessity of removing some of the obstacles that stand in the way of immigration to the Philippines, and of encouraging American and English capital to come in and develop the country. But it may be of interest to those engaged in the rubber trade to know that about fourteen months ago Gutta-percha found its way to Manila and that it promises to take a prominent place among the exports. For several years the natives of Zamboanga, Jolo, and other southern islands have been sending the crude Gutta-percha under the name of "goma," by sailing vessels, to Singapore, from whence it was shipped to England, and it, apparently, never occurred to them that a market might be found for it in Manila until some enterprising Chinamen sent a consignment here, which was promptly sold at \$12 per picul of 140 pounds. Since then the price has steadily advanced and Gutta-percha is sold now at \$34 per picul. Within the past year about 1,000 piculs have been received, all of which has been sent to England, and agents have been sent to Zamboanga and the Sooloo Islands by two English houses in Manila to endeavour to secure larger quantities than have yet been sent here. For the past four months the receipts have averaged about 100 piculs per month, and four houses are now handling it instead of the one which received the first consignment.—*Electrical Trades Journal*.

THE COCONUT PALM AND ITS ENEMIES.

On page 117 will be found the first portion in an abridged form of the valuable paper on the "Coconut-palm Weevil" or beetle which is responsible for special ravages in Honduras. This paper appears with a series of admirably executed plates in the June number of the "Kew Gardens Bulletin." We give today an instalment of what we have marked, and the balance will follow in another issue. There is no need that we should enter on a review of the contents of this paper; for we have received one from a gentleman who is about the most competent to discuss the subject of any we know in the island. He writes as follows:—

Thanks for sending me the Kew "Bulletin of miscellaneous information" for February and March, containing the paper on the "Palm Weevil in British Honduras." The paper is a most valuable and interesting contribution to our knowledge of the history of the Coconut Weevil. It is thoroughly exhaustive; and as far as I know it leaves scarcely anything more to be said upon the subject. Every intelligent coconut planter should have a copy. Plate I. gives capital illustrations of the American palm weevil in all stages of its life, and is easily recognizable as identical with our Ceylon red beetle (*Rhynchophorus ferrugineus* SINHALESE, *Kandapanuwa*), only that the colour is a velvety black, while the Ceylon variety is red, with 5 or 6 black spots on the upper surface of the thorax. Judging from the drawings the American variety is a little larger, more powerful and evidently more destructive. Such alarming havoc as it commits in Honduras is fortunately quite unknown in Ceylon. The habits of the two insects seem to be identical, and their life history the same. Several remedies are suggested for the prevention of egg-laying in the trees, and for the cure of those injured; but I doubt if any of them would be of much use; though where from 30 to 40 per cent of trees are destroyed one cannot be surprised that a variety of remedies have been suggested. With such an insidious enemy to combat, constant and careful examination of the trees would be necessary to detect the first signs of attack and to apply a remedy early. When there are signs of the spike leaf beginning to wither it is too late to try remedies; for the tree must die. "The above list of remedies is intended to include all that have been tried and are likely to be of success under different conditions. THE PROTECTION OF TREES AGAINST EGG-LAYING, BY NOT TRIMMING THEM, AND THE CAPTURE OF THE WEEVILS ARE, TOGETHER WITH THE CAREFUL DESTRUCTION OF THE KILLED TREES, THE MOST PROMISING." I have underlined this para for small caps, as it contains in my opinion, the whole secret of preventing destruction by these insects. Of all the methods suggested for the capture of the beetles that by bait strikes me as the best. It is recommended that the stumps and soft tissues—the split cabbage—of the destroyed coconut palms should be left exposed, and when the surfaces dry, split again, to expose other fresh surfaces; the fermenting juice will attract the beetles, and they can be captured by examining the baits at stated intervals. "As the weevil, like many other kinds, seeks shelter, by day, the stumps and other baits should be visited at different times, particularly at day-break, to find out when the insects frequent them most; and the stumps will probably last longer and keep fresher if protected from the sun with a light covering of leaves and fibre, which can be removed to get at the insects." It is also suggested that fermenting mangoes should be used as attracting

baits. It is so seldom that the mischief going on in darkness, is discovered in time to admit of attempts at cure, that it is rare for any one to try a remedy. It is only on estates where systematic hunting for Rhinoceros beetles is carried on, that there is any hope of trees attacked by the weevils being discovered before their destructive work has been carried too far; and I doubt if there is any estate in Ceylon where spearing of the black beetle is now attempted, it being generally believed that more mischief is often caused by the use of the spear than there is harm done by the beetle. The late Mr. David Wilson however had a good 'try' at saving trees attacked by the weevil. He had made a receptacle of iron—a cylinder 6 inches long and 4 inches deep, with a hinged lid, and a nozzle 6 inches long at each end. Into the chamber was put coarse tobacco leaves and sulphur which were ignited. When as much as possible of the affected portion of the tree had been removed with chisel and mallet, and all the grubs within reach destroyed, the orifice was shut with a piece of board and clay, leaving only a small opening at one corner; into this, one nozzle of the instrument was inserted, and into the other the snout of a small hand-bellows, by the gentle use of which the smoke was forced into the tree. This was continued for about a quarter of an hour each day till there was no sound heard of the gnawing of the grubs. If the work of destruction had not proceeded too far this remedy proved effectual; but in most cases it was tried too late.

"The coconut palms of Honduras appear also to suffer from disease, and disease of an obscure kind not due to insects. It is known as *fever*, &c." This disease from its obscurity and proving rapidly destructive, would, if it spread to any extent, be far more to be dreaded than the weevils which can be combated. Fortunately nothing of this disease is known in Ceylon. W. J.

MEDICINAL PLANTS FROM SIERRA LEONE.

KOLA—VANILLA—CUBEBS.

A report on the botany and geology of Sierra Leone has just been published by the Foreign Office. It is the joint work of Mr. G. F. Scott Elliot and Miss Catherine A. Raisin, and contains some information of pharmaceutical interest. Mr. Elliot was attached to the Anglo-French boundary commission, which has lately traversed the interior of the country and he had therefore exceptional facilities for collecting specimens of native plants of medicinal and other economic value. He has brought with him about 2,000 specimens of these, most of them quite unknown to European *materia medica*. Some of them have already been identified, others are at present being examined by Mr. E. M. Holmes, who proposes to publish the result of his investigations shortly. Some of the native medicines may ultimately acquire a footing in Europe, but most of them are not likely ever to possess more than an academic interest. Of the kola, Mr. Elliot says that it "grows freely everywhere, and was found from the sea-level to fully 3,000 feet at Sumbaraya in the Tallia highlands. It begins to bear in seven years, and is in full bearing after eight to ten years. Each tree is said to yield 3*l*. to 4*l*. per annum, and hence a plantation ought certainly to include a large number of these trees. The yield given by Mr. Fawcett is 125 lb., or 4,000 seeds per tree—that is, 8*l*. to 10*l*. per tree, or 800*l*. an acre." Mr. Elliott's views of the market value of the drugs which he describes are likely to lead to disappointment if anyone should be induced to start drug-collecting or drug-growing in Sierra

Leone upon the strength of them. Thus he would have it that African vanilla would be worth from 20s to 25s per lb., whereas it is hardly likely, even when of fine quality, to catch more than half that figure; and he tells us that cubebs, *Piper Clusii*—(sic)—grows freely at Sierra Leone, and that "its seeds are worth some 20*l*. per cwt." Apart from the fact that even true cubebs are not worth now a third of the figure mentioned, a little investigation would have shown Mr. Elliott that the fruits of *Piper Clusii* are quite unlike those of the true cubeb in their medicinal action, that they are well known to pharmacologists, and would probably be unsaleable if consigned to our drug-market.—*Chemist and Druggist*.

A NEW FORAGE PLANT has appeared—says the London *Globe*—in the form of the *Polygonum Saghali* which grows in the island of Saghalien, near Japan. It shoots very fast, and in three or four weeks is over six feet high, and covered with large leaves, of which cattle are very fond. When cut it rapidly pushes a second growth. A single plant covers more than a square yard, and the weight of leaves is stated to exceed eighty pounds. The new plant has been tried experimentally at Alliers, in France, and is said to require little or no care.

COFFEE CULTIVATION IN THE STRAITS.

Bukit Nanas, Sungai Ujong, Malay Peninsula, 7th June.

TO THE EDITOR OF THE "STRAITS TIMES."

Sir,—Your late articles, and the letters subsequently published in your paper lead me to hope that the public are taking somewhat more interest in the agricultural future of the Native States than has hitherto been the case. Herewith, you will find sundry crop returns for the year 1892, which I trust may prove of general interest; in looking at them, it will be well in all cases to note the age of the field referred to. Whilst I was in England in 1892, certain estimates were published in connection with a proposed scheme for the opening of the Government Plantations in the State of Selangor, and in reference to them it was stated that it would be more satisfactory to the public and more reliable if such returns were available from Government sources. In reply, I would wish here to explain that the return per acre has always been open to Government verification both as to the areas from which the crops have been gathered and the amount of such crops; indeed it was part of the original understanding upon which the concessions were made, and the Residents have been notified to this effect from time to time by me; if therefore, the Government have not taken such steps, it is to be premised that they are satisfied of the correctness of such statements as have been laid before them. The system that has been followed in arriving at the area of any given field is the number of plants that have been put out originally making no subsequent deductions for deaths; and in all cases when surveys have followed, the area stated has been proved accurate or rather less than that stated thus increasing the yield per acre. One acre is 43,560 superficial feet, therefore, planted 9×10, would contain in a clearing of 50 acres 24,200 plants and so on. With these remarks in explanation, I send a few notes on the yields for 1892 and other matters in connection with planting in the Native States. The system of cultivation followed has not been altogether in accordance with the more modern Ceylon school of absolutely clean weeding at all times, which in my opinion has its cheapness as its chief recommendation; for, paradoxical as it may sound, it is much cheaper to keep an estate clean, than in weeds if under control; the more so in each series of years. Perhaps the results have justified the means. The formulas followed for manuring have been, if I may say so, in accordance with the most advanced system of enriching the soil at present followed in Europe. And, whilst differing with the system of Monsieur George Ville as to the manner of application, the actual manures used have been generally in accordance with the formulas recommended by him; although the system followed was arrived at by correspondence held by a large proprietor in Ceylon with the late Baron Liebig and which I had the advantage of having held at my disposal some years ago. I took the opportunity of my last visit to Europe to enquire with care into these matters, with the result that in a series of years for the future I should look with confidence, always premising that the climate remained the same, of attaining at least equally favourable results. Whilst there are many planters who disbelieve in what they are pleased to call "artificial manures," I would call their attention to the experiments at Rothamstead, by which it has been proved to be practicable, to grow the same crop on the same land for 30 to 40 years in succession with artificial manures alone, and in instances the results, not a few, have equalled that of land yearly manured with cake-fed, farm yard manure

at the rate of 14 tons per acre per annum for the same term of years. These papers are open to the consideration of all by the great liberality of Sir John Dawes and Dr. J. H. Gilbert. In comparing these examples with a perennial cultivation like coffee, the value is very great; owing to the same crop having been and continuing to be grown on the same land for a long term of years. On the other hand, we find further corroboration starting later on so far as I have been able to learn, only published in a more summarised form in the book published by M. George Ville entitled "Artificial Manure." After looking carefully over the formulas, for manuring employed on Rothamstead, it is most reassuring to find that the nearer the manures employed approach to that advocated by M. George Ville, notwithstanding the variety of the crops generally, the results are the most favourable; thus, by an independent source proving the enormous value of the work that has been done at Rothamstead to the whole agricultural community of the world. The kindness, consideration, and liberal way in which Dr. Gilbert assists and lays his stores of knowledge open to visitors is worthy of the highest public gratitude and greatest praise. You will observe from the foregoing that I am of opinion that high cultivation is necessary to produce large crops and that the soil in itself is not rich enough to bear a succession of large crops; this is so, and whilst nature has most richly endowed the Malay Peninsula with an extremely fertile climate, the soils, neither by analysis nor results without cultivation, are found sufficiently rich to produce a succession of heavy crops without skilled manuring and careful cultivation. When it is brought to notice that for each picul of clean coffee (in which the returns are given) it has taken 9 piculs of fruit to produce it, the desirability of high cultivation becomes at once apparent. On looking back over a series of years of the crop returns from different fields it becomes plain that, for many years, I have been removing a gross weight of from 4 to 5 tons per acre. The year 1892 was a late one and, owing to the concentration of the rainfall and the numerous unusual short spells of hot dry weather, a good deal of coffee that would under ordinary circumstances have ripened and been gathered during 1892, was not gathered until 1893; thus in all probability if the year 1893 continues as favourable as it has been hitherto the yield will be large.

LINSUM ESTATE.—With regard to the yield of field No. VII during its third and fourth year, it is a remarkable indication of what may be done in four generations of selected seed from selected trees. No. VIII, a clearing planted in 1891 October to December, will certainly give a crop of 10 piculs from the 50 acres within 26 months of planting and I shall be much surprised if in 1894 it does not beat the record of No. VII.

SILIAL ESTATE.—77 piculs of clean coffee were gathered off, in January; of course going into the 1893 crop account. Although it was ripe previous to the 31st December, the labour was not available to pick it.

BATU CAVES figures speak for themselves and, having little cultivation, shew some falling off on the older coffee; the durians are responsible in some measure.

WELD'S HILL.—This Estate is on an isolated hill near Kuala Lumpur and it shews some falling off also, there are also a very large number of durians on the estate which are now being removed; and when this is completed I expect the crop to go back to what I consider normal, under the system of cultivation followed. In connection with this estate, I attach the Weather Report taken at the General Hospital within a mile as the crow flies, shewing that, against an average number of days on which rain fell for the preceding 7 years of 180 days per annum, rain only fell on 110 in 1892.

This I submit is worth consideration on the part of the Selangor Government, as to whether it would not be to the advantage of the State to have the lalang fields and bare hills of mine-refuse lying exposed to the rays of the sun for a large area surrounding Kuala Lumpur economically re-afforested, either the *Tumbooso* (as seen in Singapore)

or *Albiggia Moluccana* grow in the lalang, if not burnt, and eventually smother it. Having removed the tin which is part of the capital of the country; in all equity to future generations, some steps should be taken to preserve another important capital item; the climate.

Kamuning Estate, Perak; there are many vacancies in the early plantings owing to the usual pioneering difficulties in a new district. The soil is beyond the average and as the later planting, i.e. supplies come into bearing I have no doubt that this estate will give a good account of itself.

NOTES ON CEYLON PRODUCTS.

PLUMBAGO.—The Reichstag has passed the "German Army Bill" and dealers are expecting a better time than before. They are in hopes of hearing that Europe will send large orders for the Mineral, and that the large stock—cured and uncured—lying in the stores will soon disappear. However, the market is still very weak, and there is no demand whatever for low qualities. Inquiries are made for *Chips* and *Dust* of the finest quality only, which some dealers call the "Ashk Bee" mark. Since my last notes appeared, only two transactions have been made in the Colombo market in these two grades. In *large lumps* and *ordinary* no business is being done at all. These remarks stand good for Galle too. Still the closing of pits is the chief topic among owners, and news has been received here that several pits have been closed and are being closed at Pannu Korale, too. Some exceptionally fine plumbago (uncured) turned out from a pit at Kurnnegala has found a purchaser in a rich European house here. The dealers are very chary about making purchases of the uncured stuff before finishing off the large quantity they have in hand; and the result is that the price of plumbago in its raw state at the mouth of the pits is very low.

CINNAMON.—Fairly good supplies are finding their way to the market, both from down South and the Negombo district. As a rule, the cinnamon brought from the South does not fetch a good price. The make is clumsy and the colour and flavour are poor; while Negombo supplies the best stuff and peelers pay special attention to the turning out of pretty quills. For the best plantation cinnamon from the Negombo District the price varies from 30 to 42 cents per pound while the price for usual assortment now prevailing in the market is 35 to 36 cents per pound. The supply of chips is also increasing slowly, but surely. During the last week about one hundred candies found their way to Colombo market and the prices paid were from R36 to R40 per candy.

COFFEEH AND COCONUT OIL.—The price has gone up since the last notes appeared by 50 cents and the price paid this morning for "Calpenty" was R51 per candy. Madampe and Maravilla fetch R43 to R48.

There has been no marked improvement in the arrivals of the boats. It is believed that this being the season for the Festival of St. Anna, the copperah Dealers and the Boatmen (the majority of whom are Roman Catholics) prefer to attend the services, and a lull in the market may possibly ensue.

During last week about two dozen pipes of chekkoo oil arrived. Up till yesterday morning, R14.87½ per cwt. was the closing price and today there was a decrease of 12½c. Oil dealers are also doing very little business now. In the Port, during the week ending yesterday only 500 cwt. of dealers' oil were purchased by a firm at R15 per cwt. There is a demand for oil at Calcutta, Bombay and Singapore, but Native shippers cannot buy oil at the rates demanded by the sellers. This is chiefly due to the sudden rise in the copperah market. Chekkoo oil cannot be shipped in the state in which it is purchased. It has to be cleaned and filtered, when it becomes merchantable.

COCONUT POONAC.—There is nothing doing in this stuff. A native "Miller" has in his hands three contracts to supply mill poonac to three European Houses. The contracts were made about a couple of months ago. R75 to £0 per ton F O B is about a fair value for the article now.

CARDAMOMS.—Native dealers have about a couple thousand pounds in their hands unsold. Some of them have commenced to "bleach" with a view of effecting sales sooner or later—(the latter more likely.) The native dealers, as a rule, find a market in Calcutta and Bombay; but there is not much of a demand now. "If we get very cheap, we'll buy" is the sentiment of the day. As cheap as dust, of course! and let the poor native dealer go to the—! One Calcutta merchant is offering for sale locally about two thousand pounds of good 'Mycore' for which he cannot find a market at Calcutta.

ARECA NUTS.—The season for these nuts will be in very soon and the Coast Moormen and Chetties who monopolise the trade are making preparations for receiving and curing the large supplies expected.

SAPAN WOOD.—No arrivals at Colombo during last week.

—Local "Examiner," July 19th.

Correspondence.

To the Editor.

THE INDIAN TEA CROPS.

Indian Tea Association, Calcutta, July 1.

DEAR SIR,—In reply to your favour of the 16th ult., I have posted to your address as requested statements giving the statistics you ask for. The comparison with past years will be given from 1st April to meet the new conditions.—Yours faithfully,

W. PARTOHL, Aest. Secretary.

[We wished to know whether any change had been made in the Estimate under the new arrangement by which the Season is counted from 1st April. It may be well to repeat the figures sent us for the benefit of our planting readers:—

Actual Outturn of Crop of 1892.

	lb.
Assam	46,307,348
Cachar	16,110,506
Sylhet	17,744,557
Darjeeling	6,796,315
Terai	2,807,530
Dooars	14,889,006
Chittagong	830,293
Chota-Nagpore	201,328
Dehra Dun, Kumaon and Kangra	4,000,000
Private and Native Gardens ..	4,000,000

113,686,883

Original Estimate of Crop of 1893.

	lb.
Assam	50,326,320
Cachar	18,216,560
Sylhet	20,387,680
Darjeeling	7,330,430
Terai	3,427,200
Dooars	16,085,056
Chittagong	1,008,000
Chota-Nagpore	267,000
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native Gardens ..	4,000,000

125,548,246

being 11,861,363 lb. over the actual outturn of the crop of 1892, but $3\frac{1}{2}$ million lb. less than original estimate of that crop. Estimating shipments to the Colonies and other Ports with local consumption at 9 millions, there will remain about 116 $\frac{1}{2}$ million lb. for export to Great Britain.

—ED. T.A.]

THE FINEST TEA BUSH IN CEYLON.

July 7th, 1893.

DEAR SIR,—A correspondent in your paper challenged anybody to beat his big tea bush, the other day. I do not know what his dimensions were, but on this estate there is a tree

13ft. 9in. in diameter

and over 41ft. in circumference measured last week. What were his dimensions? This bush was pruned about 3 months ago. So that its present diameter is *pruned wood*. I have no doubt this is the finest bush in Ceylon.

WALTER W SEVIER.

[The challenge came from a Travancore correspondent to the *Observer*, was copied into the *Madras papers*, and from there as something new into the local "Times" and other papers! The Travancore dimensions given were:—Diameter of plucking surface 9ft. 2 $\frac{1}{2}$ in., height 3ft. 8in., tree 7 years old," so that it is quite clear the bush Mr. Sevier has measured on St. John's, is by far the larger; and probably the champion tea tree in the island. It ought to be photographed:—

—ED. T.A.]

"BIG TEA BUSHES."

Abbotford, Nanuoya, July 10.

DEAR SIR,—I had the pleasure of seeing the St. John's giant tea tree some three years ago and I had then no doubt it was the largest tea bush in Ceylon as it probably is still.

We, on Abbotford, might have had a look-in for premier place had we not circumscribed the size of our larger bushes some five or six years ago as we found them inconveniently large for plucking purposes.

I have measured one of our larger bushes today and I find it is only 11' 3" x 9' in diameter with a circumference of 30 ft.

The tree has a stem girth of 30" and is not at all a bad specimen, but as it has not been pruned for some time, it is not in it with the giant of St. John's.

We have some enormous masses formed by root-suckers from the original plant but as these might be encouraged in the course of time to cover acres, I do not think they would be a fair comparison to a tree standing on its own footing as, if I remember rightly, the St. John's tree does.

These enormous bushes are all very well for bringing forward like the "big gooseberries" of the season—as your Travancore correspondent did with his bush (only to be beaten though);—but for ordinary paying purposes give me a few hundred acres of good fat ordinarily-sized bushes 4 ft. or so across and I don't want anything better or bigger.—Yours truly,

J. F.

THE CHAMPION TEA TREE?

Gallebadde, Galboda, July 10th, 1893.

In last evening's issue of the local "Times" the following letter appeared:—

SIR,—I noticed in the "Times" the other day that an ex-Ceylon planter had seen a tea bush in Travancore which measured over 9 feet in diameter and wished to know if Ceylon could beat that. There is a tea bush on this estate, grown from a single plant, which measures over 13 feet in diameter, and would be more than that had it not been pruned recently.—Yours &c.,

W. WILSON SMITH.

[In a note the "Times" editor asked:—"Now Travancore is 'knocked out,' can any other Ceylon estate beat this?" For answer we would refer to the letter of Mr. W. W. Sevier of St. John's, which appeared in our issue of the 8th inst. Mr. Sevier there stated that on his estate there was a tree 13 feet 9 inches diameter and over 41 feet in circumference.—ED. T.A.]

CEYLON, "A POOR COUNTRY":—ITS LA-
TEST STAPLE AND CLIMATE; AND NOT
THE SCHOOL FOR TROPICAL AGRI-
CULTURE; ON COAST ADVANCES
AND DEMORALIZED LABOUR
RAILWAY TO INDIA.

Dimbula, July 1893.

DEAR SIR,—“Cheery Ceylon”—is it? Perhaps so—to favoured individuals like the talented Mr. Clement Scott who came here in the best weather, went to see the best tea estate in the best climate and sees everything, figuratively speaking, on but one side of the shield—on which is not the haec metal.

Now I like to call a spade—a spade; and a spade is a *spade*—and nothing more. With this premonition—may I ask why most people in writing of Ceylon fall into a sort of gaseous, exaggerative or

AUGUST, 1893.

[No. 2.

OCCASIONAL NOTES.

COCA seed for planting should be obtained from pods growing on the stem of the tree. It does not germinate sooner than the seeds from branch pods; but I have observed it grows into a more robust plant than the latter. Since adhering strictly to this rule, and sowing the seed in small baskets made of areka bark, and planting them out just when they were two months old, during the middle of April last—in fact planting them out whenever a couple of days' rain gave me a chance, albeit the proper time for planting or not—but with sufficient artificial shade to protect it from the direct rays of the sun; I have found that even after that protracted drought of twenty-three days between April and May last, the mortality among them from want of moisture in the ground was not at all what one might have expected under these circumstances. I assure my readers that in a field of 3,000 of these plants where I expected 90 % damaged, there were only about 200 failures!

It is not advisable to get the cacao seed to grow too soon as many people do by placing it about half an inch below the surface of the soil; for the result then is a very thin and wiry-looking plant liable to be blown down by the wind or scorched by the heat of the sun. On the contrary, plant it flat $1\frac{1}{2}$ inch deep;

it takes from two to three weeks to rise, when only good seeds grow and give fine strong plants.

Although the genera and species of the two are wide apart, there is a strong affinity between the cacao and the jak fruit tree—both produce fruits from the stem as well as from the branches. It strikes me therefore as likely that the reason why jak trees cannot be evenly grown, even where the seed has been obtained from the best and largest fruit, is because the fruit has been one grown from the branch of the tree. In 1877 I planted several thousands of jak seed at stake along the roadsides of that well-known coffee estate "Gallekoluan," then only a new clearing, from fruits procured from the adjacent villages. These of course must have been fruits plucked from different trees and different parts of the trees. It was a severe disappointment to me to have seen that more than half of these seedlings had failed—some growing very poorly, and only a very small number rising up to beautiful plants. The estate has since changed hands and partly abandoned, but the jak plants that survived are now lofty trees in full bearing. Who can say whether these trees were not grown from *stem fruit seed*, and those that failed were all from *branch fruit seed*? A resident lately advertised in the local newspapers jak seed for sale at 50 cents a bushel. If these were of the proper kind I have indicated for planting, they ought to sell at several rupees a bushel.

Your readers have no doubt heard of Kola and the wonderful hunger-satisfying virtues of this valuable article of commerce from Africa. Mr. George Wall, I think it was that introduced it into Ceylon, and one of his plants growing on Ankanda estate is now in bearing. Plants raised in the island are known to have changed hands at R5 a piece, I would venture to draw attention to

another tree which is indigenous to Ceylon. A fruit, with edible seeds, that has a strong resemblance to the Kola pod is produced by *Sterculia Foetida*, the "Telamboo" of the Sinhalese. My readers who have tasted the kernel of the Cajunut need only be told that the Talamboo-nut tastes similar if not more delicious. I have not tasted a Kola-nut, but from what I have heard from those who have, I think the Telamboo-nut might reasonably occupy its place in Ceylon. A specimen of these seeds might be seen at the Museum of the School of Agriculture, sent there by the writer.

"ALL PRODUCTS."

SALT IN AGRICULTURE.

The Salt Union, Cheshire, has issued a circular drawing attention to the value of salt in agriculture. The pamphlet is no doubt intended as an advertisement, but it is valuable as indicating, under separate heads, the various way in which salt benefits the land and stock of the agriculturist. Exception may, however, possibly be taken to one or two points raised in favour of salt :

1. Salt consists of two-thirds chloride and one-third soda, and as the solvent powers of chloride are 20 times greater than those of rainwater, it is undoubtedly the most powerful substance known for breaking up the soil and setting its constituents free and available to nourish the roots of the plants. If the soil be stiff and dry, it is useless, and the roots cannot spread. An ordinary quantity of rain is not sufficient on stiff or sloping land. In all cases Salt hastens weathering.

2. Salt absorbs moisture from the atmosphere, and retains it in the soil, thus compensating for a deficiency of rain.

3. Salt purifies and decomposes all inert matter.

4. Salt makes stubborn soils easier to work.

5. Salt quickly destroys all kinds of noxious vermin, wire worms, slugs, and turnip fly.

6. Salt renovates old pasture lands, making sour grasses sweet and palatable for cattle and sheep. Where Ground Rocksalt is freely used for this purpose, the animals are healthy. It also neutralizes the injurious effect of rank grasses on new pastures. At the rate of 1 ton per acre in spring, it has a wonderful effect.

7. For strengthening the straw of cereals, the use of Salt is most important, owing to the fact that it seems to be the only substance which has the chemical power of setting free the requisite quantity of silica to nourish the stems.

8. For root crops Salt is valuable when previously incorporated in the soil, on account of its powerful moistening properties as before mentioned, and there is conclusive evidence that it prevents disease in potatoes.

9. If Salt be mixed with other manures, it will make them far more effective by dissolving the various constituents, and keeping them moist.

10. A plentiful application of Salt to the dung heap will not only fix the valuable ammonia, but will destroy millions of vermin, which would otherwise be carried on to the land and damage the crops.

As to the application of Salt, it is difficult to lay down hard-and-fast rules, as so much depends upon the condition of the soil and the seasons. From 8 to 10 cwts. per acre for cereals, and 10 to 15 cwts. for roots, is generally recommended, upon the breaking up of land or the month before seed time (but not with the seed). Light shallow soil requires more Salt. Repeated top-dressings in small quantities during the spring will be found very beneficial. It should be liberally applied to fallows, and on the stubble.

All animals are fond of Salt, and always prefer marshes and salted grass. Lumps of Rocksalt should be placed in all stables, shippens, pig-styes, and fields, as it improves the appetite, hastens fattening, prevents many diseases and epidemics, especially rot in sheep. A solution of salt and water is one of the best remedies for scab. Recent trials prove that for fattening pigs and keeping them healthy, it has a surprising effect. It also improves the coats of horses.

For sweetening and preserving fodder, and to prevent hay from fermenting and becoming mouldy when stacked, the antiseptic properties of Salt make it a most valuable remedy.

DROUGHTS.

A drought is generally taken to mean in agriculture a want of rain. This condition is a very common one in the Eastern tropics, and is attended with special disaster in rice-growing districts. The want of rain is frequently given as a cause for the failure of the paddy crop, while from the fact that grass and other short-rooted fodder crops are easily killed out during severe droughts, the prolonged absence of rain has a most important bearing on the management of stock. On a recent visit to India we found that the severe drought that prevailed in the Southern districts during the first part of the year was the means of greatly reducing the number of cattle in those parts. On enquiry we learnt that the owners of stock, driven to their wits' end in the fruitless attempt to keep their animals from starvation point, were compelled as a *dernier resort* to part with them for one-fifth and less than a fifth of their value either for the butcher or to be removed to less drought-stricken districts. We have since read of how even English stockowners have been compelled to part with their animals to the butcher during the late unusual drought that prevailed in England: while in France a similar condition of affairs drove farmers to look for fodder in the trees of the forest, whose nutritive qualities Necessity has brought to light. Indeed the apparently general drought that lately prevailed compelled the natives of some parts of India to find sustenance in mango kernels and mhowa flowers.

Professor Warrington, the well-known Agricultural chemist, has seized the opportunity when farmers in England were sorely troubled for lack of rain to deliver a homily on "drought," in its scientific aspects, and it would be worth our while to ponder over what he has said on the subject.

In agricultural text-books statements will be found as to the power of certain soils to maintain

a moderate degree of moisture, even in the absence of rain. We are told that clay and humus are hygroscopic, especially the latter; that is, that when they have been perfectly dried, and are placed in moist air, they absorb a certain amount of water. The true hygroscopic action is, however, very limited even under favourable circumstances, and the amount of moisture thus obtained would be quite insufficient for plant nutrition, save in the case of the small growths of some of the lower organisms. The condensation of moisture from the atmosphere may, however, become considerable when changes of temperature intervene, and water is deposited in the soil as dew, and this is undoubtedly a powerful agent in renewing the moisture of the surface soil. The soil being cooled by night radiation, the moisture of the atmosphere is condensed, not only upon it, but within it if the soil has undergone a proper tillage; and the plants, which in the evening appeared limp are in the morning again fresh and vigorous. The water thus condensed at the surface may not in all cases be derived from the air; the vapour of water rising from a moist subsoil may be condensed at the cold surface; but for this to take place after drought has long continued, a soil of very open texture would be required. In the case of gravels, this supply of water vapour from below is very important. For the condensation of water from the air to be of really practical effect, it is of course essential that the air should be sufficiently moist, and this condition generally fails when a drought has long continued. Land in the neighbourhood of the sea possesses considerable advantages in this respect, and crops in such localities suffer distinctly less in time of drought. As already mentioned, the amount of condensation in a soil depends greatly on its being in a porous state, the result of good tillage.

The amelioration brought about by atmospheric moisture can be looked on only as a mitigation of drought; for any considerable supply of water in the absence of rain we must look to the stores already in the soil. Much depends on the distance of the water level below the surface; if this distance is only a few feet, crops should suffer but little in time of drought. Where, as is generally the case, the water level in the soil is at a considerable depth, the supply of water at the surface must depend (1) on the power of raising water by capillary attraction possessed by the subsoil; (2) on the water-holding power of the soil and subsoil; (3) on the amount of evaporation taking place at the surface.

The height to which water can be raised by capillary attraction depends on the narrowness of the passages through which it rises; the narrower, however, become the passages the slower becomes the rate of ascent, so that a practical limit to the action of capillarity is soon reached. The action of capillarity in bringing water to the surface from a considerable distance beneath is much smaller than is commonly supposed. When the surface soil is far above the water level its water-holding power is determined by the amount retained on the surface of its particles, in its pores, and in the finer capillary tubes; the wider tubes are all empty. Humus has a far greater power of holding water than either clay or sand, being far more porous in its nature. According

to Schloesing, some extremely fine sands, containing no cementing material, exceed clay in their power of retaining water. Such fine sands, resembling silt, constitute some of the most fertile soils, especially when of a good depth. Much may be done to increase the water-holding power of heavy soils by deep tillage and subsequent pulverising of the soil; also by increasing the proportion of humus by the use of farmyard manure or other means.

The next important point to be borne in mind is the loss of water from the soil by evaporation. All soils when saturated with water lose by evaporation at an equal rate, but when partially dry, evaporation proceeds more rapidly in a coarse soil than in one consisting of fine particles. Here again the advantage of good tillage is apparent. The greatest amount of evaporation takes place when the soil is occupied by a crop in full vigor of growth.

The object of the farmer in a time of drought is that the crop shall have the full benefit of the water still in the soil, and that as little as possible shall be lost by surface evaporation. Much may be done to attain this result. By shallow surface cultivation, leaving in a loose state a couple of inches of the surface soil, the evaporation of water is greatly hindered. When the soil remains solid any loss of water at the surface is replaced from beneath, and so the loss becomes continuous; but after the surface soil has been stirred, it dries without again absorbing water from below, while it effectually protects the lower soil from the action of sun and wind. The mulching employed by gardeners, and the application of cocoa-nut fibre, are still more effective plans for preventing useless evaporation from the soil.

A Veterinary authority treats of the effects of drought on animal health in an article in a late number of the *North British Agriculturist*. He states that a scant and diminishing supply of water, which threatens many parts of the country, affects in many ways the well-being and life alike of man and beast. As essentials for animal life, next after continuous supplies of fresh air, come frequent supplies of pure water. The bodies of the domestic animals contain nearly 60 per cent. of water, which is not only a necessary constituent of every tissue, but is requisite for digestion, absorption, and nutrition; for the regulation of animal temperature; for the solution and washing out of waste products. From air passages, skin, kidneys, and bowels, fluid matters are almost continuously excreted, and the loss thus sustained must be made good by the ingestion of water or watery food. During such hot weather as has been recently experienced, the skin secretions are greatly augmented, necessitating increased recuperation of fluid matters. Horses at work during hot summer weather, and living on mixed diet, will take daily 15 to 25 gallons of water, while cattle will drink even more; and sheep, although popularly believed to be independent of water, when the air and food are dry, consume 2 or 3 gallons daily.

A restricted water supply seriously interferes with thriving. The thirsty animal will not eat, no matter how tempting the food may be. So long as strength remains, it moves restlessly about; the mouth and throat are dry, and the tongue usually swollen and protruded; febrile

symptoms supervene; and, where privation of water is absolute, exhaustion and death occur in a few days. Occasional, or even, continued, shortage of the fluid nutriment does not always produce notable immediate effects. The hair or wool may be observed to be dry and harsh, the animal does not grow or gain weight, the bowels are usually torpid, the urine may be high coloured and concentrated, and hence will irritate the excretory passages. Unless, however, the restriction is of short duration, more serious and permanent mischief results, especially in young cattle and sheep. The animals become gradually more thrifless, there is gastro-intestinal derangement, the skin is scurfy, the mucous membranes pallid, frequently jaundiced. Change of food, good nursing, and medicinal treatment in such cases are seldom of much avail. The patient pines, and perhaps six months after the mischief has been done dies, and the chief morbid condition discovered is a shrunk, hardened, fibroid liver.

Protracted drought not only affects the quantity, but also the quality, of the water supply. In a densely-populated country, the risks of sewage contamination are greatly increased. As rivers, streams, springs, and pools rapidly evaporate under the solar heat, and are freely absorbed by the dry-baked soil, the water is apt to contain a larger percentage of impurities, notably of injurious organic and organised materials. It is thus that springs, wells, and more especially pools, particularly if they have no fresh stream constantly passing through them, become dangerous sources of drinking water. Such contaminated water produces diarrhoea, often of a serious, sometimes of a fatal, choleraic type. Not infrequently such supplies become deadly from admixture with anthrax virus, and the increase of such cases recently reported from various localities may probably be thus accounted for. Many instances are on record of pools, which for years had with impunity been used for watering the stock of the farm, becoming during dry seasons so impregnated with putrefaction products that fatal anthrax occurred, not only in cattle drinking therefrom, but in the horses, hogs, sheep, and even in the poultry.

When any particular variety of food fails, others may usually be substituted for it; but there is no substitute for water. Practically, there is also but one source of it, namely, the clouds. Notwithstanding American projects, neither electrical nor other methods will coerce them to part with their contents. The best must, accordingly, be made of available supplies. In view of dry seasons like the present, live stock farms must be better furnished with such a prime necessary. An adequate permanent supply must be got, even if the cost be considerable. Streams and springs must be more carefully and economically utilised. Loss and waste must be guarded against.

ARROWROOT SUBSTITUTES.

The true arrowroot flour is, as is well known, got from the tuber of *Maranta Arundinacea*, but many other tubers are said to yield a very similar product.

Curcuma pseudo-montana, a yellow flowered variety belonging to Zingiberaceæ, is found spring-

ing up all over the Konkan in the rainy season. From its oblong bulb there grow, hanging by fibres, small potato-like tubers, which are perfectly white in the inside.

Arrowroot was manufactured from the tubers at one time, but now they are boiled and eaten in times of scarcity.

Curcuma angustifolia, "East Indian arrowroot," is also yellow-flowered, and common in India. What is known as "Travancore arrowroot" is prepared from the bulbs, and a good deal of it is imported. This flour is often mixed with that of *Maranta arundinacea* or the flour of Cassava.

Curcuma leucorrhiza.—Roxburgh mentions that a kind of arrowroot is prepared from the tubers of this plant.

Curcuma caulina.—From this arrowroot is manufactured in the Bombay Presidency.

Aresama tortuosum (var. *heliborefolium*) and other species of *Aresama* are used in the same way as arrowroot tubers in parts of India.

Arun maculatum produces Portland Island arrowroot.

Tacca Pinnatifida, according to Hooker, affords the South Sea arrowroot. Its tuberous roots, as large as a fair-sized mango, yield a great quantity of beautiful white starch, of which it is said the best flour for confectionary and puddings is prepared. Drury says the fecula much resembles arrowroot and is very nutritious.

Species of *Araceæ* are also mentioned as substitutes for arrowroot; among these come the pann-ala and kidaran of the natives of Ceylon.

GRAFTING ORANGES.

The process of inarching or grafting by approach, by its simplicity and perfect adaptability to the atmospheric and other cultural conditions obtaining in the tropics, is said to recommend itself, above all other modes of grafting to the non-professional operator. Inarching has been before referred to in the pages of the Magazine in connection with the propagation of mangoes, and on a recent visit to India we saw the process most successfully carried on in the neighbourhood of Bombay and Poona. Dr. Nicholls, in his work on "Tropical Agriculture" mentions inarching as the most certain of all kinds of grafting, and as being extensively employed in the West Indies for the multiplication of plants of the better kind of mangoes. In the Bulletin of the Botanical Department of Jamaica, issued last April, the following description of the method is given:—

Procure seedling orange plants, sweet or sour, one to two years old, from the thickness of a goose quill to half an inch in diameter. Place them singly in good soil, well compressed in bamboo pots and nurse them until properly established. They will then be ready as stocks on which to inarch the improved or favourite variety. Tie each pot separately to a branch of the favourite, strong enough to bear it up, and at the same time, at a point from which the middle portion of the stock can easily, and without much pressure, reach and lie parallel to a twig or small branch of the tree of or about the same diameter. The

operator should now cut away leaves and spines, if present, at and near to the point on the stock above indicated, and then with a sharp thin bladed knife, cut out of both stock and scion a longitudinal slice, from 2 inches to $2\frac{1}{2}$ inches or even 3 inches long, gradually deepening, about the middle of each cut, to near the pith or half-diameter, at the same time taking care that the cuts may be so straight and in width, at least, equal, so as to readily allow their surfaces to meet without resorting to too much force. So important is it that the cuts on both stock and scion should be, at least, of the same width that, theoretically the corresponding inner or lower edges of their barks should, when opposed, come into perfect contact; and with the beginner it will be as well for him to consider this as being absolutely essential to success. Having thus fitted stock and scion, they should now be bound together with threads of cotton or worsted, or with shreds of calico or bast fibre. The tying material must not be drawn so tightly as to either cut into or bruise the bark, the object being merely to keep the edges of the wounds in contact. In addition to such tying, it is nearly always necessary to wrap the wounds with shreds of calico, previously saturated with a solution of wax, oil, etc., purposely to keep out rain as well as to exclude desiccating air.

Procure equal weights of bees wax and common resin. To a quarter of a pound of each add a tea-spoonful of cocount oil, or even animal fat; put into a vessel and boil. This must be done close to the tree on which the operation is being performed. The shreds of calico should be one inch wide, and long enough to thoroughly wrap the wound. When ready take hold with the hands of both ends and let all but the ends sink into the boiling wax until saturated, then draw it across the edge of the vessel to dislodge all excess of wax and allow it to cool until it can be touched by a damp finger with impunity. This part of the operation is of the utmost importance, inasmuch, as the application of the waxed cloth too hot, will scald the tender bark and thereby neutralize all hope of success; on the other hand, if applied too cold it is rendered unsuitable for the purpose intended.

When the requisite temperature has been attained, the waxed shred must be wrapped tightly and carefully round the wound, and this completes the operation. Kind nature will accomplish the rest. It is now only necessary to keep the soil in the pot moist; and to prevent undue evaporation, the space between the surface of the soil and the top of the pot should be stuffed loosely with either moss or hay. If the tree sought to be propagated is of moderate size a hundred or perhaps two hundred pots might be fixed to it at one time. It would cost very little more to water and otherwise nurse two hundred inarched plants than it would one hundred. In about six or eight weeks after the operation, with a view to aid in weaning, if I may so express myself, the scion from the parent tree, a notch should be made in the scion, immediately below the point of union, reaching almost to the pith. In two weeks thereafter the notch ought to be deepened, but not widened through and slightly beyond the pith; and finally in a week or two weeks more, if the weather is moist, the scion

should be severed and the new plant taken from the tree, shaded from the sun, and for a time most carefully nursed. It may be well to state that the beginner should not attempt to sever the scion from the parent tree unless when its leaves are developed and matured. When it is evident that the plant is out of all danger, and when active growth has set in, the stock, above the graft, should be cut back, a piece at a time, until finally foreshortened to the upper end of the grafted part.

VEGETATION POISONOUS TO CATTLE.

In all countries there occur forms of vegetation, whether plants, shrubs or trees that possess poisonous properties, and which if consumed by stock may produce fatal results. It is a popular belief that cattle like birds are endowed with special instincts by nature, by which they avoid eating poisonous vegetation when met with under natural conditions, that is growing in the field; but that when such poisonous vegetation is cut and fed to stock together with other fodder, they either lose the power of discriminating between poisonous and non-poisonous vegetation, or trusting in the good intentions of man, do not refuse to partake of the objectionable food. Whatever value may be placed upon such belief, it is a fact that very seldom is it the case that cattle die from eating poisonous vegetation found growing in the field, and we have heard of cases where animals that would not browse on the foliage of a poisonous plant when it was in a living and growing condition, have consumed the same after it was cut and thrown upon the grazing ground or in the stall.

In western countries yew and laural are the most common causes of death by poison, but until quite lately we had not heard of stock in Ceylon having died from eating the leaves or other parts of poisonous plants. Two cases of sudden and unaccountable death occurred among the cattle kept for slaughter at the Dematagoda Slaughter House last month. On examination of the grass (Mauritius or water grass) provided by a contractor, large quantities of *Datura* (*Sin. Attana*) leaves were found in the bundles. The seeds of this plant contain the alkaloid daturine which is used as a narcotic anodyne, but which, when given in any quantity produces death by poison. The leaves of *datura* are also known to possess poisonous properties, though perhaps not so pronounced as in the case of the seeds. There is little doubt that the cattle in question died by the effects of such poison, though direct proof was wanting, for an examination of the stomachs failed to show any traces of the succulent leaves or stems of the poisonous plant mixed up with the half-digested pulpy grass that filled them. It is a common deception among grass suppliers to conceal the leaves of trees among the grass they supply, in order to make the bundles of standard size or weight. What is suspicious in the cases referred to is, that the leaves of a plant so well known among the natives as possessing poisonous properties should have been used. It would be interesting to inquire whether a mixed diet of *datura* leaves and water-grass, though not producing

the death of the animals, would impart any noxious properties to the meat after the cattle are slaughtered. The alkaloid daturine occurs in datura as well as in henbane (*Hyoscyamus Niger*). It is described as bitter, very poisonous, and as strongly producing dilatation of the pupil of the eye. We have not heard of any tests by which the presence of datura poison in the system can be ascertained. It is, as has been hinted, almost impossible to detect the presence of the leaves or leaf stalks in the stomach of an animal, owing to their being of such a succulent nature and occurring in so intimately mixed a condition with the pulp of grass. But the fact that cattle can be poisoned by datura leaves deserves serious consideration. It behoves stock owners to ensure careful examination of the grass that is supplied to their cattle, and to destroy all datura plants (for it is rather a common weed, and is, moreover, found springing up in Mauritius grass plantations) found in their gardens; while we must look to our chemical analysts and physiologists to discover some tests for the poison, and some definite post-mortem evidences which would go to prove that death was due to the poison.

Professor Wallace, in his book on India, in referring to intentional poisoning of cattle by the natives, makes the following statement:—"It (poisoning) is usually accomplished by throwing the leaves of some species of datura, or a plantain leaf spread with arsenic to a cow which is perhaps tethered out at pasture." Let us hope that our natives are not drawing upon the wisdom of the Hindus, and that the suspicious cases at the Slaughter House are after all traceable to purely accidental causes.

HORSE-BREEDING.

The Indian authorities hold out every encouragement to the ryots to carry on horse-breeding. The department entrusted with the work of encouraging breeding operations, has established depôts in various places where they keep selected stallions, so that the horse owners may avail themselves of them. This is not all that is done, for in addition to the depôts there are a few central stations or breeding farms entirely under the control of the officers of the department. These officers also periodically visit the villages and examine the mares in the possession of the owners, as to their fitness for breeding purposes, and brand them accordingly; for great care is taken not to allow undesirable animals to be bred from diseased or deformed dams. Each district has its Annual Horse Show, when prizes are awarded for such deserving animals as are exhibited by the villagers, and lectures and instructions are given on the best method of treating the animals.

The demand for horse-flesh is so great in India, especially for Military and Police use, that a large number of animals have to be annually brought down from Arabia, Persia, the Cape and Australia; and hence there is ample scope for profitably raising animals on Indian soil.

What are the conditions of soil and climate best adapted for horse-breeding? This is rather a general question, and one which cannot be satisfactorily answered offhand. It has, however,

been found out, that localities favoured with a hard sandy soil or a good loam with an undulating surface is the best adapted. When animals are bred on lowlying moist ground they lose their spirit, whilst animals bred on ragged hillsides generally are stunted in growth. Another important item necessary in a horse-breeding district is a plentiful supply of fresh water. The question naturally occurs to me whether horses could not be profitably bred in Ceylon, and if so, which system would commend itself to our circumstances, there being two systems in vogue, breeding farms where a large number of dams are kept, or the village system where the people keep a few mares. The last is no doubt the best and the most feasible, though it is not the most profitable. The absence of professional advice in such cases does not stand much in the way of the would-be breeder, for the attention and care which he could bestow on the few animals belonging to him, and constant personal contact with them, tend to produce better animals, than when a whole stud is maintained though under professional supervision.

The cost of breeding a foal may be summed up as follows:—

- (a) The cost of the services of a stallion.
- (b) The loss of the mare's services, say for three months.
- (c) Extra food for the mare.
- (d) Extra food for the foal.
- (e) The risks of losing the dam, or the foal or both.
- (f) And the interest on the initial cost of the mare.

It naturally follows that in order that horse-breeding may become profitable, the value of the foal produced should not only meet the above expenses, but also give a fair margin of profit for the trouble of the breeder: and under ordinary circumstances, this is effected.

No one in Ceylon has paid sufficient attention to horse-breeding, though it would be seen that the climate and soil in many parts of the Island are better adapted for the purpose than in India: and above all, in many districts we hardly ever suffer from a scarcity of water during any part of the year.

We cannot hope to make horse-breeding a general industry in which our goiyias could take a part, for though in India the ryots do not find it at all a difficult work, the goiyias will require ample demonstration as to the profits of an industry of which they know practically nothing, and will need to acquire a knowledge of the details of the treatment and care of an animal of which they hardly care anything about. Under these circumstances, it is left for those who know and understand to make a beginning.

Bombay.

W. A. D. S.

(To be continued.)

GENERAL ITEMS.

With reference to "All Products" note regarding *Sterculia Foetida*, we may mention that there are no less than six members of the genus *sterculia* indigenous to the Island, viz., *S. Foetida* (S. Telambu), *S. Urens* (T. Kavali), *S. Guttata*, *S. Balanghas*, (S. Nava), and *S. Colorata*. The Kola nut tree is *Sterculia acuminata* which is not a

native species; but a specimen can be seen at the Royal Botanical Gardens, Peradeniya. The seeds of *S. Foetida* if eaten raw are said to bring on nausea and vertigo, but if roasted are edible. Whether they possess any properties similar to those of kola has yet to be ascertained. The leaves and bark are valued as remedial agents by the natives. There is no reason, however, why *S. Accuminata* should not be grown systematically in Ceylon, especially after Mr. T. Christy wrote as follows:—Should any of your (*Daily News*) readers feel interested in this nut, and have at their command lowlying damp land in the Colonies, such as would exist on the shores of Ceylon, I would strongly advise them to cultivate the kola, as it is one of the most promising products of the future. Among the exhibits sent from Ceylon to the Imperial Institute was a case of kola-nuts.

The *Kew Bulletin* for February and March contains an exhaustive paper on Palm Weevils in British Honduras. In it reference is also made to a disease of an obscure kind not due to insects, and known as "fever." Mr. Fawcett, Director of the Botanical Department, Jamaica, is of opinion that the disease is due to an organised ferment which attacks the tender tissues. Firing the fibres at the base of the leaves, though the production of fruit is temporarily retarded, is said to be effectual in the early stages of the disease. The application of salt to the cabbage is believed by some to do good. The following is also recommended: 1 lb. bluestone, 1 lb. freshly burned lime, 5 galls. water. The bluestone should be of good quality and dissolved in the water; the lime is slaked and stirred into a solution which is made up to the proper quantity with water. It should be used fresh and kept stirred, as the copper hydrate formed soon settles. It can be applied into a syringe or spraying pump to the cabbage. It is advised that the soil round the trees should be scraped away from the roots, and ashes together with some manure applied.

The *Straits Times* of May 23rd gives an extract from the Education Report of the Inspector of Schools for 1892, in which reference is made to paddy growing. It appears that the natives plant seed from the same land for 15 or 20 years in succession; in fact, seed from the same land is sown year after year until the crop failed, when fresh seed was obtained elsewhere for planting. That for so many years, under this system of cultivation, there continued to be a crop at all, is, says the writer, probably due to the practice among Malay paddy growers of transplanting the seedlings and manuring the roots when doing so. The Inspector in question is at present awaiting reports of the result of cultivating with seed paddy obtained from new districts. He hopes that the superior results from such a method will induce the paddy cultivators to always supply themselves with new seed, for, he says, "I have no doubt that the Malays are sufficiently alive to their own interests to follow this course for the future."

The fibre of *Amphidonax* (order Gramineæ) has been suggested as a source of pulp for paper-

making, being tough, cohesive, and readily rid of the resin contained in the stems. *Capital* asserts that the fibre of *A. kurka* offers a field for exploitation equal if not superior to esparto. A report on some prepared fibre sent to a leading manufacturing firm in London places its suitability beyond doubt, and it now only remains to ascertain the probable margin. At present the fibre is used in India for making mats, string and rope. In Ceylon we have two species of *Amphidonax*, viz., *A. Heynei* (*Zenkeria elegans*, Trin.), and *A. obtusifolia* (*Zenkeria obtusifolia*, Benth). Thwaites mentions that the habitat of the former is Katnapura, and that of the latter the Southern and Central Provinces.

It is reported that the unsatisfactory arrangements by which the Agricultural Department of Madras has no independent status, as the result of which it appears "impossible for any honest desire to do good service in the direction of agricultural improvement to be fulfilled," is compelling Mr. Benson of Madras to retire. The present case recalls that of Mr. Robertson, who when he found his freedom of action restrained "after he had been for a short time relegated to educational work, was driven from the country in disgust." It is a matter for regret that the services of two such excellent officers should be lost to India, owing to the authorities refusing to relinquish a false and faulty policy.

Salt is said to exist in such incalculably large deposits, that there is not the slightest apprehension to be entertained of any succeeding generations finding themselves without the universal seasoning. Thus for example, with reference to the rock-salt of Kohat we read of a stretch about 8 miles long, more than $\frac{1}{4}$ mile in width, and with an exposed thickness of 1,000 feet,—one of a series of the largest known exposures of salt on the face of the globe; and further, hills 200 feet high are sometimes formed of pure salt.

There are several Schools for industrial training in the Madras Presidency, and in these engraving, carpentry, blacksmithy, tailoring, lacemaking, embroidery and other handicrafts are taught.

The *Indian Agriculturist* asserts that irrigation works in India are, both in size and completeness of arrangements, on a scale surpassing those of any other country. In 1890-1891 the area irrigated is computed at upwards of 10 millions of acres, the average value of the crop per acre varying from R25 an acre in Madras to R92 in Bombay.

In 1892, there were in India 126 cotton mills with a capital of eleven crores, or taking the rupee at nominal value, of eleven millions sterling. These factories run 24,670 looms and 3,272,988 spindles, employing 112,000 persons.

A resident of Nuriotpa, South Australia, has written to the local Press drawing attention to the drought-resisting and stock-feeding properties of tagasaste, or tree lucerne, which was

introduced to the colony about twelve years ago by the late Dr. Schomburgh. The tagasaste is a species of *Cytisus* or *Laburnum* indigenous to the Canary Islands, where it is utilised to a great extent for feeding horses and cattle. It forms a dense spreading tree, with foliage closely resembling that of lucerne, and much relished by all kinds of stock. It grows rapidly upon even the poorest land, and under the most favourable conditions, which comprise a warm climate and a loose, sandy soil; it frequently attains a height of from 18ft. to 20ft. with a diameter of from 12ft. to 15ft., within the short space of five years. However, by close planting and constant cutting or feeding off it can be kept quite dwarf and bushy, and the more often it is cut the more valuable it becomes. In the report of the Adelaide Botanic Gardens for 1882 it is stated that stock fatten more quickly on tagasaste than anything else, and it is recommended to mix it when fresh cut with half its weight of chaffed straw. Horses are particularly fond of tagasaste, and keep in first class condition, and work as well on this as when fed with the best wheaten hay. The seeds may be sown at

any time, and the young plants set out during the winter months 4ft. or 5ft. apart each way. It will be necessary to cultivate between the rows occasionally for the first two years, after which stock may be turned in and no further cultivation required.

It has been estimated by Reanur that a single aphid, which lives only for a few weeks, could, if destructive agencies were withdrawn, be the progenitor of no less than 5,904,900,000 individuals; the unrestrained increase for 300 days would reach to marvellous figures—indeed, according to Professor Huxley's calculations, the descendants of a single aphid would, in 300 days—if restraining influences were removed—amount to such an enormous weight as to leave no room for man or any other creature.

We acknowledge with thanks the receipt of the following periodicals:—St. Thomas's College Magazine, Our Boys, Native Opinion, Jaffna Patriot, Royal College Magazine, La Croix, and the Diocesan Gazette.

COLOMBO, SEPTEMBER 1ST, 1893.

[No. 3.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

A. M. FERGUSON, C.M.G.*

LASTAIR MACKENZIE FERGUSON—the subject of this notice—was born in Wester Ross in the North of Scotland on 23rd January, 1816, and he died in Colombo on the 26th December, 1892, within a few weeks of com-

pleting 77 years, 55 of which with but brief intervals, were passed in Ceylon. With no exceptional advantages in education, his natural endowments and literary ability early manifested themselves, a few of his youthful poetical writings receiving insertion in the *Inverness Courier* from so good a judge as Dr. Carruthers (the editor of Chambers' "English Literature") at a time when some of those of Hugh Miller were rejected. These writings attracted the attention of "Seaforth," the Rt. Hon. J. A. Stewart-Mackenzie (after a member of whose family A. M. Ferguson was named), a distinguished statesman, under whose auspices he came up to London and afterwards on his being appointed Governor, out to Ceylon. Mr. A. M. Ferguson landed at Colombo on November 7th, 1837, and he was fond of describing the woefully deserted and depressing appearance of the open Colombo roadstead with its few native dhonies and perhaps one "sailer" at that time, as compared with the wonderful development twenty and forty years later under the influence of the planting enterprise and still more with the picture presented by Sir John Coode's magnificent breakwater, the big mail and commercial steamers and the manifold signs of trade and prosperity in the present day. From 1837 to 1846, Mr. A. M. Ferguson had a varied experience of the island, in business, as a planting pioneer in Uva, and as a Customs

Officer and Acting Magistrate at Jaffna. In 1844, his marriage took place there with Miss Maekerras who had come out from Scotland and who died in August 1890, their married life extending over some 46 years. Mr. Ferguson from the day of his arrival in Ceylon had been a frequent and esteemed contributor to the *Colombo Observer*, then owned and conducted by Dr. Elliott, and the latter in 1846 invited him to become his Assistant Editor. With the career and development of the *Observer* from that year onwards, his name was inseparably associated. He continued as co-Editor up till 1859 when Dr. Elliott, becoming Principal Civil Medical Officer and head of the newly-created Government Department, sold the *Observer* to his colleague. The death soon after of his long-tryed friend the Doctor, the best-loved colonist in Ceylon, tried Mr. Ferguson very seriously, a severe attack of fever nearly carrying him off,—this being almost his only serious illness during 55 years in Ceylon, until the last. We came out and joined our relative as Assistant Editor in November 1861, and enabled him to take his first holiday outside of the island in March 1863. Mr. Ferguson had then been nearly 25½ years in Ceylon without a change—he had never seen a railway, the first of the London suburban lines being under construction towards Blackwall as he left in November 1837, while Mr. Faviell and his staff arrived in Colombo to begin the line to Kandy, a few days after his holiday commenced. He went home via Bombay, making his first railway trip over the Bore Ghaut. While in England, where he remained a year, he lost his eldest daughter suddenly, whom he had expected to bring out, his eldest son having died there two years before. Returning to Ceylon, after some years of work he was able

* We had intended our Senior to come later in the list, but the non-receipt of "Old Colonist's" account of Mr. Tytler obliges us to make a change.—ED. T.A.

to revisit the old country in 1867 and bring out his "Souvenirs of Ceylon," a handsome oblong volume with illustrations, as a gift-book, giving a popular account of much connected with the island. A further visit was made in 1871, and it was then that in consequence of a threatened break-down, Sir Wm. Gull advised him not to venture back to England, at any rate save in summer, as his constitution was evidently thoroughly acclimatized to the tropics. We may next refer to Mr. A. M. Ferguson's labours as Ceylon Commissioner to the Melbourne Exhibition of 1880-81, for which he was chosen by universal acclamation, while his services were acknowledged by his fellow-colonists with a purse of R10,000, a gold watch and service of plate, followed from Her Majesty, on the recommendation of the Governor, by the honour of C.M.G. It is not for us to say how well-deserved these tributes to good work were, or how his exertions on behalf of Ceylon tea in Melbourne bore good fruit in increasing exports to Anstralia, which have gone on to the present day. No more visits were paid to Europe, but Mr. Ferguson made several trips to India—to the Nilgriris and to Darjeeling as well as other parts—in connection with his promotion of the cinchona and tea planting enterprises which he did so much to develop by his example as well as by his writings. In this connection it may be mentioned how heartily he welcomed the appearance of *The Tropical Agriculturist* which we had started during his absence in Victoria, a stranger bringing a copy under his notice before our first issue and advice had reached him. In the same way each successive "Handbook and Directory" and each "Planting Manual" from our press excited in him the liveliest interest and satisfaction, while to many of them, of course, he made valuable contributions. His own first "Commonplace Book and Directory" appeared in 1859, and it was peculiarly interesting for its "Planting Gazetteer" which we have often wished to revise and republish. Directories were continued in 1860 and onwards; but they were small volumes until developed into the larger "Handbook and Directory" so well-known of recent times. From 1879 onwards, Mr. Ferguson had been spared the necessity of coming to his desk in the newspaper office; but he was always reading or writing in the public interest while in Colombo, and when at Abbotsford his letters "From the Hills" were very regular. The illness of his wife in 1889 necessitated another trip to Australia, and her removal in August 1890 made a great blank; but he made himself happy with sons, grandchildren and nieces in the intervals of his occupations.

He was, as is well-known, never happier and never more his natural self than when on Abbotsford plantation, Upper Dimbula. He loved every

hill and stream, knoll and dale, aye almost every tree on the property which he had seen changed from original forest into fields of coffee and cinchona and tea and of useful and ornamental trees. Until quite an old man up to and over his 70th year he was accustomed to take such walks on the plantation, a long and steep one, and into the jungle, as often tried the mettle of far younger men. Indeed, it became a proverb in the neighbourhood that "old Ferguson" could walk the most muscular young planter off his legs, while all the time keenly enjoying the vegetation and the scenery, the distant hills and cloud effects, or the note of birds and the flower of a striking or new plant close at hand and at the same time pouring out information intermixed with shrewd inquiry and keen observation. Nothing afforded him greater pleasure than taking visitors over Abbotsford,—his readiness and enjoyment in this way equalling that of his great prototype (if we may so say) Sir Walter Scott in the Abbotsford home he had created by the Tweed, in the early part of the century.

And now of Mr. Ferguson's character and work as colonist and journalist for fifty-five years in this island, what need of us to speak? He was the oldest British editor in Asia by a long way. He belonged to the old school of journalists who were far more literary and descriptive writers, than politicians, and busy social critics ready to watch and develop any turn of public opinion. The comfort of the good old days when there was only a fortnightly mail with ample time to digest all its news, was much more to our senior's liking than the hurry and worry of more recent years, and his power and taste lay more in descriptive writing than in editorial work. He has never been excelled in his description of the natural beauties of Ceylon, and his was a poet's prose, for he had the poetic Celt's imagination highly developed, and some of his writings of "the fifties" describing visits to the Dumbara Valley, to Kelebokka, to the Matale hill ranges &c. have only been equalled as word-paintings by the wealth of language which in later years he lavished on Upper Dimbula, Nuwara Eliya, Hakgalla and the surrounding panoramas. An accomplished Australian journalist—now editor of one of the leading papers—told us after a year's observation in Ceylon. of our senior, that his was one of the most interesting personalities he had ever met from Carlyle onwards—unique and picturesque in his journalistic and book writings, but scarcely intended for the constant and trying duties of "daily" editor. And yet never was there one more ready or determined to defend the right as he saw it, against all odds—never a public writer more ready to stand up to, and denounce, mistaken autocrat or wrongdoer,

whether Governor, civil servant, planter, merchant, or native. There could be no tampering with conscience in his case, and especially where his religious convictions were concerned, was he immovable, so that of him at his best in his fullest powers, it were surely apposite to quote the Laureate's lines on one of England's greatest and most honest sons:—

O good gray head which all men knew,
O voice from which their omens all men drew,
O iron nerve to true occasion true,
O fall'n at length that tower of strength

Which stood four square to all the winds that blew!
"Such was he whom we deplore." And yet great injustice would be done to a man of whom the public too often only saw the stern fighting side, if we did not dwell on the other and softer phase of his character. One of the kindest and most generous hearts that ever beat when one came to know it—full of fun and humour. A poor speaker, so that he could only stammer out halting sentences when we came to Ceylon, in the sixties, after his visits to Europe he developed into by far the readiest and happiest public speaker in the colony. Indeed, he appeared far too seldom in this capacity. Had he gone to planters' and other meetings after his retirement from active editorial work, he would have become better known to, and more appreciated by, the younger generation of colonists. He especially made his mark in Victoria as a speaker, and at the various Exhibition banquets it was declared again and again that the Commissioner for little Ceylon was the most notable man amongst them when on his legs. He was more than once asked to go into the Legislative Council, notably by Sir Arthur Gordon, but it was to take an "acting" appointment, and having contended on principle that there should be no acting appointments, he was far too consistent to accept an offer which, in reality, would have led on to the permanent seat a few months later. He prided himself in the early days on being the means of securing cheap newspaper postage for Ceylon, of freeing printing paper from Customs duty and of securing the simplification of our tariff at a time when it was more cumbersome even than at present. His good work in connection with the Carrier Pigeon Service of the *Observer* will not be forgotten: it extended over seven years; but no one welcomed telegraphs, railways or other modern improvements more heartily than he did. How he urged Harbour Works and Railway Extension for years is well-known. In respect of improved social and general legislation he did much by his writings, supporting the abolition of Polyandry, opposing the loose Muhammadan Marriages Registration Bill, criticizing in a long State Paper for Sir Arthur Gordon's benefit, the Buddhist Temporalities measure; while the consistent stand he took in opposing the Paddy

rents abolition while retaining the Customs rice tax, is fresh in everybody's memory. But all this and much more belong to the record of a life which if written in detail could not fail to offer much of instruction to his brother Colonists.

We had vainly hoped that Mr. Ferguson would have been enabled to take a voyage to England—as a farewell visit—and for the first time to see America (and Chicago) during 1893; but it was fated otherwise:—

God's finger touched him, and he slept.

And yet, of course, with all our regret and the weak human thoughts of "what might have been," no one can call this an untimely death, or speak of it as a life cut short in its usefulness. Rather it was prolonged and rounded off and filled with good useful work far beyond the common, especially in the experience of tropical colonists of British blood. The subject of this notice had surely fought the fight, finished the course and kept the faith, and in his case the promise we know has been made sure.

The name of A. M. Ferguson, C.M.G., cannot fail to occupy a prominent place in the annals of Ceylon for a longer period than that of any of his contemporaries. He watched over the rise of the planting enterprise, and he saw it reach its high-water mark in coffee, in cinchona, and shall we say in tea? He lived to see the population well-nigh double what it was when he first arrived—an undeniable testimony to good government and easy taxation whatever critics may say—he watched the multiplying of roads and bridges, the rapid extension of railways and the multiplied establishment of dispensaries and hospitals, and the great spread of education. He helped on in every good work, and was a main force in some causes; but the world moves on; and if much has been done, much remains to be done—and one lesson to all of us is not to regard the vanities, the honours or temporal rewards, but to keep on in the straight line of work and duty, remembering,—

The world will turn when we are earth—
As though we had not come or gone;
There was no lack before our birth,
When we are gone, there will be none.

But of Mr. A. M. Ferguson's career as a planting pioneer in Uva in the early "forties," and thirty years later in Upper Dimbula, we must offer some further remarks before closing. He did some rough work in cutting out extensive blocks of forest land above Badulla, afterwards fanned into the well-known Weywellhena, Gowrakella and Cannavarella plantations. He lived in a Kandyan Chief's house while engaged in this duty, and he frequently referred to his experience in after years. We quote what he himself wrote on the subject in the "Planting Gazetteer" of 1859:—

This is a District of which the compiler of this work, ought to know something, seeing that he was one of the

Pioneers of Planting in Ouvah. Our predecessors there in the planting line, (and they were only just commencing,) were Major Rogers, Dr. Galland, Sir W. Reid and Dr. Sortain. That was in December 1840. The three first have been long dead. One fell by the lightning stroke in the midst of his active, and useful career. Another, wasting under consumption, sought in vain to prolong life in the climate of Texas. "The sea, the blue lone sea" is the resting place of the third. The fourth is living (and long may he live,) although we believe he has ceased to have any interest in Ouvah or its Coffee. Our individual task was to report upon, cut the boundaries of and plant Nurseries in an immense tract of Forest, extending from Weywelhena and Gowrakella at the foot of Namanakoola Kande, on through Cannavarella and Nahavilla to the extreme end of the range where Hindugalla looks down on the hillock-dotted plains of Wellasse. There were 3,700 acres in this one block, and, including another piece of land near the Fort of Himbliatawella, up on the way towards Newera Ellia, we have the satisfaction of believing that we launched into planting existence some 4,000 acres of as fine coffee land as can be found in Ceylon. We left in June 1841, just as the nursery plants were peeping above ground, and we have not seen Badulla since then, excepting as a feature in the grand and varied view from the top of the Newera Ellia Pass. We trust some day to revisit scenes which we remember with pleasure.

In a humorous and descriptive piece of verse written a few years later, he made further references worth giving:—

THE SONG OF UVA.*

Ye hills and vales of Badulla,
 When we were first acquaint;
 Ye were but rarely visited,
 Your riches little kent;
 But now, from Nam'nacooly's base
 To Hapootelle's crown,—
 The Coffee shrub is springing up,
 The forest going down.

Auld Willie Reid and douce Sortain
 First "prospected" thegither;
 I followed,—and the pleasant cracks
 We had wi' ane another!
 Now Rogers, Galland, Reid have gone
 The path that all must go;
 While we life's battles still must fight,
 Sortain, my' worthy jo!

Past ane an' twenty busy years,
 An' lo! the wondrous change;
 Those Hills are now the white men's homes,
 Which were the wild beasts' range;
 And, mixing with the torrent's roar,
 The steam-pipe's puff is heard;
 While rattling round the pulper goes,
 As merry as a bird.

And good and true men live and work,
 If good and true are gone:—
 There's Wood and Brown and Norman Stewart
 And clever Henry Don.
 There's Byers with harmoniums twain,
 For light or sacred song;
 And Cruwell of the thunder tones,
 As pliant as they're strong.

There's Herjee Franjee of Bombay,
 John Oliver of Lews;
 Canadian Irvine, who can tell
 Of sleigh drives and snow shoes,
 And, to repress those crimes which with
 Prosperity increase,
 There's H. C. Bury, grave and stern—
 The Justice of the Peace!

There's Pineo with the foreign name,
 And Jenkins born in Wales;
 While Scottish Celts stride o'er those hills
 MacColls, and eke MacPhails;
 And Dr. Kelson roams around,
 With potion and with pill,
 To keep the sturdy Planters all
 From ever getting ill.

We've Dawson, Kirkton, Linton, Smith,
 Imlah, and Atwells (two);
 With Johnstone, Geddes, Bayley, Sikes,
 Roaming our forests through.
 There's Cummins (not the Crown Court Beer),
 And Handyside my friend;
 And more, whose names if I should write,
 My song would never end.

There's Russell with the treble voice,
 But masculine of mind;
 A better man to fill his post
 You might go far to find.
 There's A. Y. Adams, who as Judge,
 Has everybody's praise;
 And last (not least) there's "Billy Hall,"
 The man who mends our ways!

And Ouvah's crops are bumper crops—
 The quality is prime;
 The climate all that could be wish'd,
 Good roads will come in time;
 No doubt the Planters have their griefs,
 Their grievances and fears;
 But if they knew what we endured—
 Old Ouvah's PIONEERS!

For, few and scant our comforts were—
 The leaders of that band—
 Whose cosie cottages now rise,
 Bright homesteads o'er the land;
 So while for all that's still to do,
 Ye strive with high resolve—
 Let grateful thoughts too, have their play,
 As ye THE PAST revolve.

Ye Hills and Vales of Badulla,
 When we were first acquaint;
 Ye were but rarely visited,
 Your riches little kent.
 But soon from utmost Ouvah's height
 To Ratnapoora town.
 THE ROAD!—will help the Rice Carts up—
 The Coffee Bandies down!

[Of all named in these verses, only Messrs. Byers, MacPhail, Jenkins, Pineo, Sikes, Atwell, Geddes, A. Y. Adams and perhaps Dr. Kelson, remain in the land of the living.—En. T. A.]

In the "seventies" Mr. Ferguson threw himself with great ardour as proprietor of Abbotsford into all that concerned practical coffee cultivation—and especially into the combat and struggle against "coffee leaf disease" (*hemileia vastatrix*), writing a full account of the same in pamphlet form. No one again did more to pioneer cinchona cultivation and to introduce fresh and valuable seed or to arrive at a right understanding of the best mode of cultivating and harvesting, together with the mousing and other processes. And finally Mr. A. M. Ferguson was, equally, a pioneer with tea culture in our hill districts, as he was in the low-country with Liberian coffee and cacao. With each of these products he experimented, and at the same time wrote in the *Observer* and *Tropical Agriculturist* very fully on every department of their cultivation, preparation, &c. For no one was ever more ready to impart the results of his experience than the subject of this notice, while he took a special interest in the work and success of his planting neighbours.

* Written by A. M. Ferguson, Esq., C.M.E., in 1862.

Peace to the memory of a man of worth!

"COCOA CURING IN CEYLON."

(From Bulletin of the Botanical Department, Jamaica.)

The following information received from Dr. Trimen, Director of the Royal Botanic Gardens, Ceylon, will no doubt be of great interest to planters in Jamaica.

"You ask about Cocoa curing. We always carefully wash off with repeated ablutions every particle of mucilage from the seeds. No doubt this lessens weight, but much improves the sample and I think one of the principal reasons for the generally high price Ceylon cocoa fetches in London is the clean bright look of the bean. Another and perhaps more important thing is thorough drying. On estates this is always done by a current of hot air drawn by a fan through a small house, the seeds being spread out in layers on trays and turned over several times. No Planter here would allow a speck of mould to be seen on a Cocoa bean. I gave a description of the ordinary style of drying house for Cocoa to Sir W. Robinson of Trinidad a few years ago, and he printed it in the "Agricultural Record" of that Colony for 1890. I enclose a leaflet which is distributed with Cocoa seed to the native villagers."

DESCRIPTION OF CEYLON COCOA DRYING HOUSE.

"The house is about twice as long as broad, built of brick, and is provided with double doors, but with the exception of the opening for the ingress and egress of the hot air, is hermetically sealed. The interior is fitted with a number of upright frames into which slide, one above the other, the trays upon which the beans are spread; these should be made of narrow pieces of split bamboo, not of wire or coir-matting. The heating apparatus is outside in contact with one end of the building, and consists of a large stove standing in a short tunnel which opens into the house. At the other end of the building, also outside, is a powerful fan, fitted in another short tunnel; this is worked by hand (three or four coolies needed) and by its rapid revolutions draws the air through the house. By passing over and round the stove the air is dried and heated; that which passes out is hot and damp. The flue of the stove passes under the floor of the house and contributes to warm it. A drying house of this sort is very simple and its cost only about 120* rupees; it does its work perfectly, and nothing more elaborate or costly is required.

"It is found desirable here to dry Cocoa as slowly as possible, provided the risk of mould be avoided. This appears in the interior of the beans in twelve hours and on their outside in about twenty four in wet weather if they are left cold, but by passing them rapidly through the hot air house, so as to have them hot when taken out, it is found that they will remain for a night or so in the store without injury."

"[As the annual average number of rainy days in Ceylon is from 80 in dry districts, to 328 in the wet, and Cocoa is grown only in the moist regions of the Island we may assume that at least four-fifths of the Cocoa exported from that colony is dried artificially. The rainfall in the best Cocoa Districts of Trinidad appears to average between 80 and 100 inches. The total yield as before stated is 12,500 cwt. representing an enormous crop and an immense number of people dependent upon it.†]"

"INSTRUCTIONS TO NATIVE CULTIVATORS OF THE CACAO OR CHOCOLATE TREE, 1884.

"1. *Localities, soil, climate, &c.*—Cacao is a completely tropical plant, and its cultivation should not be attempted above 2,500 feet, and only in warm situations well sheltered from wind. Flat ground is better than sloping. The climate must be moist, but a well-marked dry season, if not too long, is no disadvantage. The soil should be deep and well drained; good forest soil is, of course, best, but that of native gardens is generally very suitable.

* Should be R1,200, as given by Dr. Trimen.—Ed. T.A.

† This no part of Dr. Trimen's writing. Probably Sir W. Robinson's addition.—Ed. T.A.

"2. *Planting.*—The seeds must be sown as soon as possible after they are gathered, as they quickly spoil for germination after becoming dry. Germination commences soon and proceeds very rapidly, and the young plants are very impatient of being transplanted, unless with the adoption of such precautions as will prevent any injury to the roots. Arrangements must, therefore, be made either for growing the seeds in a nursery in such a manner as to allow at least a foot between each seedling, so that they may subsequently be taken up with the earth about their roots, or for sowing them singly in bamboo or other pots or for putting two or three seeds in each place it is intended a tree shall occupy, afterwards allowing only the strongest seedling of these to remain. The last plan is the best for native cultivators. In plantations the trees should stand at from 10 to 15 feet apart, according to the richness of the soil, 12 feet being a good average distance.

"3. *Cultivation.*—It is necessary to shade the seedling plants when young; this is effected by branches fastened in the ground of any tree which retains its withered leaves—as cinnamon, mora, &c. There is no occasion to provide any permanent shade in most parts of Ceylon, but sheltered from wind is of great importance. Plenty of light and a free ventilation of air are essential for the production of good and abundant crops. The ground under the trees must be kept perfectly free from weeds, and may be littered with decaying leaves and other vegetable matter. Manure is very beneficial. The trees should be kept from growing higher than 10 or 12 feet, and the primary branches be encouraged to assume a horizontal direction; redundant shoots from these or from the trunk must be pinched off when young. The principal trunk and branches should be kept very clean, and great care should be taken that the small and delicate flowers are not rubbed off or injured.

"4. *Gathering.*—A first crop may be expected on good soil in the third year. The fruit must be quite ripe before it is gathered; this is known by the rind having a yellowish colour when cut into. The pods should be cut off cleanly with a knife, and not too closely to the stem. They can be easily split by a blow from a wooden mallet, and the seeds and pulp are then taken out and put into baskets to be carried to the curing place.

"5. *Curing.*—The seeds should be heaped together to "sweat." This may be done in pits or boxes, or better on a platform covered with coir matting; the seeds should be covered over with matting, gunny bags, or a tarpaulin. Every other day they must be thoroughly turned over until the process of fermentation has gone far enough, which will be in seven, eight or nine days; on the proper duration of this depends the goodness of the sample. The mucilage and pulp round the seeds is now ready to be washed off, and this washing requires several repetitions with plenty of water. As soon as clean they should be at once spread out on mats in the sun to dry, avoiding, however, the extreme heat of the day, and in about three days they will be fit for the market. In wet weather the drying must be done by artificial heat in the house.

"When well dried the "beans" should be perfectly clean, with a thin pale cinnamon-brown skin, of one colour all through, and entirely free from damp or mouldiness.

HENRY TRIMEN, Director, R.B.G.

UVA PLANTING PROSPECTS.—We are glad to see so encouraging a planting report from Uva as that furnished on the present occasion by our correspondent. In respect of the future of tea, he is especially strong and under these circumstances, it is all the more aggravating and inexplicable, to learn that there has been a suspension of the work on the roads which are required as feeders to the Railway. Can it be that the Government do not want to draw more traffic to their Haputale or other stations?!

HIGHEST RAINFALL IN TWENTY-FOUR HOURS.

With reference to the paragraph quoted in your notice of this week's *NATURE* from the *Indian Planter's Gazette* of Jan 28th, 1893, the most elementary knowledge of Indian meteorology would suffice to show that the remarkable figure, 48 inches, supposed to represent the fall of a single night in January at Dehra Dun, is simply a misprint for 4.8. The entire rainfall of the winter season in no part of India exceeds one-half this amount, and I have no hesitation in declaring such a figure as 48 inches in twenty-four hours to be absolutely without precedent, and, in my opinion, so extraordinary at such a season, that, if it really were 48, it would require us to regard all existing Indian meteorological data with suspicion. Thirty inches in twenty four hours has often been recorded at Chirapunji in June and July. Can any one show a single instance of even 20 inches in twenty-four hours at Dehra Dun?

Moreover, the whole annual supply at Dehra Dun is only 75 inches, while that of Chirapunji is 600 inches!

—*Nature*, July 29.

E. DOUGLAS ARCHIBALD.

COFFEE NOTES.

A commission of the commercial association at Santos made a revision of the stock of coffee in that port on the 1st inst. which was found to be 58,000 bags in first hands, 59,000 bags in second hands and 3,000 afloat, in all 120,000 bags.

During the past twelve months, the bureau of American republics at Washington is informed, more than a million acres of coffee lands in the state of Vera Cruz, Mexico, have been sold to purchasers of various nationalities, including Americans, Germans, Frenchmen, Englishmen and Belgians.—*Rio News*.

CROPS IN JAVA.

AMSTERDAM, Aug. 2.—The Chamber of Commerce in this city has issued its report for 1892, from which it appears that there has been a larger decrease of trade, which is generally ascribed to the protective measures introduced by foreign countries, especially France, which prevents business. The exports to the United States were, however, double the value of those in 1891, and the following articles have much contributed to this result:—Coffee, \$1,074,126 in 1892, against \$309,643; Tobacco, \$4,573,702 in 1892, against \$837,246. As regards Netherlands East India the report mentions that the sugar crop was larger than in 1891, and the total exports of Java sugar to all ports amounted in 1892 to 7,207,681 piculs. The coffee cultivation did not answer the expectations, and the exports were 416,700 piculs private, and 302,074 piculs Government coffee. The tea crop was more abundant, but the cinchona cultivation is nearly ruined by the constantly drooping prices. The tobacco cultivation in Java was profitable in some districts, while the prospects for the Sumatra crop improved.—*London and China Express*.

BARK AND DRUG REPORT

(From the *Chemist and Druggist*.)

London, Aug. 2.

COCOA-BUTTER.—At auction on Tuesday 200 2-cwt cases of Cadbury's cocoa-butter sold at 1s 2³/₄d to 1s 3³/₄d per lb. showing a steady market.

CARDAMOMS.—A moderate supply was offered today. It consisted of about 161 boxes, for which comparatively little interest was shown. Good qualities were a little easier, but common fruit sold at steady prices. Ceylon-Mysore medium good pale are held for 2s 6d; for a yellow lot a bid of 2s 7d was refused. Small to medium fair yellow brought 1s 11d to 2s; long medium brownish 1s 6d to 1s 7d; small long brown 1s 5d to 1s 3d per lb. Ceylon-Malabar small round brownish brought 1s 3d to 1s 4d; very small dull greenish 1s 1d to 1s 2d per lb. A parcel of 16 cases small grey (salvage) brought 10d per lb.

CINCHONA.—A parcel of 29 serons Guayaquil bark, in fair, long, brown quill, sold at 1s to 1s 2d per lb. for sound quality. Three serons fair, somewhat thin Lza (a kind which is exceedingly scarce), were strongly competed for and brought the high price of 2s 6d per lb.

CINCHONIDES.—Two cases of 1,000 oz. each, were offered today, and bought in at 2d per oz., there being no offer. The price is, of course, much above the value of the article.

COCA-LEAVES are gradually coming down in price. Eleven bales of brown dull Huanoco leaves were bought in at 1s 6d; and broken, but good and rather pale Truxillo at 1s 2d and 1s 3d, also retired.

THE ORANGE CULTURE IN FLORIDA.

A very interesting communication on Orange-tree blight and the cultivation of Oranges in Florida has recently been made from New Orleans to the Foreign Office. "Many persons," it is said, "who have hitherto taken pride in their Orange trees have been grieved to see them sicken and gradually die without apparent cause. Close examination will disclose the fact that the bodies of the tree, their branches, and even many of the leaves are covered with a brownish substance, which might be mistaken for dust; attempt to brush it off, and it will be found to adhere closely in the form of minute scales. When hatched, the young insects move about for a while, then attach themselves to the tree, and form the scale over the bodies, and literally suck the life from the tree, attacking the lower branches first. Twice a year (spring and fall) they send forth broods of young, when the old insect dies, and at such times the scale is found dry, loose, and easily washes off. Then the young insect can be seen by good eyes, but an ordinary microscope will show scores, if not hundreds, of the young to each square inch, actively running about. While the insect, when enclosed under the scale is hard to kill by any safe application, when young and exposed they may be easily destroyed by the following simple emulsion, which was first recommended by Professor Riley, the Government entomologist:

"The remedy is: one bar of soap, dissolved in 1 gallon of boiling water, to which add while yet hot, 2 gallons of coal-oil. Immediately churn by violent agitation in a demijohn; or better still, by a hand force-pump, in an open vessel, and in a few minutes it will become thoroughly mixed and assume a creamy consistency. Test it on a pane of glass, and if it adheres without being oily, it is ready for use as soon as cold, but before applying to the tree it should be diluted with nine parts of water to one part of the emulsion. After thoroughly shaking, it may be applied with a brush to every part of the tree which can be reached, but a better plan is to attach a spraying-nozzle to the force-pump (often used in gardens), and thoroughly spray body, branches, and leaves. The young insects are now moving about, and one application will kill most of them. However, as a matter of precaution, the trees should be sprayed with this emulsion two or three times, a few days apart."

Referring to Orange culture in Florida, it is stated that the crop has reached such large proportions, that for some time past the growers have been looking elsewhere for new markets. Last year the State produced 3,500,000 boxes; this year's crop amounted to 3,000,000 boxes. It is said that the Florida Orange has driven, or is driving, the Spanish and Italian product out of the American market, and that besides this a large trade has been commenced in Europe.

A short time ago, a shipment of Oranges, amounting to 9,566 boxes, was made to Liverpool. The shipment was by a British steamer. The vessel had a stormy passage, which caused the fruit to reach England in a more or less damaged condition. The said fruit, however, sold at such good prices as to leave the shippers a handsome profit. The shippers of this cargo propose to put on a regular line of fruit-carriers from Florida to England, and parts of the Continent. It is thought that from 100,000 to 300,000 boxes will be shipped to Europe next year.—*Gardeners' Chronicle*, Aug. 6.

VARIOUS AGRICULTURAL NOTES.

THE INDIAN FOREST DEPARTMENT is the subject of a striking introduction to one of Rudyard Kipling's best stories ("In the Rukh") in his latest book. The introduction runs as follows:—

"Of the wheels of public service that turn under the Indian Government there is none more important than the Department of Woods and Forests. The reboisement of all India is in its hands; or will be when Government has the money to spend. Its servants wrestle with wandering sand torrents and shifting dunes: wadding them at the sides, damming them in front, and pegging them down atop with coarse grass and spinning pine after the rules of Nancy. They are responsible for all the timber in the State forests of the Himalayas, as well as for the denuded hillsides that the monsoons wash into dry gullies and aching ravines; each cut a month crying aloud what carelessness can do. They experiment with battalions of foreign trees and coax the blue gum to take root, and, perhaps, dry up the Canal fever. In the plains the chief part of their duty is to see that the belt fire-lines in the forest reserves are kept clean, so that when drought comes and the cattle starve they may throw the reserve open to the villager's herds and allow the man himself to gather sticks. They poll and lop for the stacked railway fuel along the lines that burn no coal; they calculate the profit of their plantations to five points of decimals; they are the doctors and the midwives of the huge teak forests of Burma, the rubber of the Eastern jungles, and the gallnuts of the South; and they are always hampered by lack of funds. But since a Forest Officer's business takes him far from the beaten roads and the regular stations he learns to grow wise in more than wood-lore alone; to know the people and the polity of the jungle; meeting tiger, bear, leopard, wild-dog, and all the deer, not once or twice after days of beating, but again and again in the execution of his duty. He spends much time in saddle or under canvas—the friend of newly-planted trees, the associate of uncouth rangers and hair trackers—till the woods, that show his care, in turn set their mark upon him, and he ceases to sing the naughty French songs he learned at Nancy, and grows silent with the silent things of the under-bush.

COFFEE IN QUEENSLAND.—Mr. W. J. Thompson is writing a series of papers in the *Australian Agriculturist*, July 1, on the cultivation of coffee made practical for Queensland, and adapted for the age in which he writes:—

Expensive, slovenly, and pernicious as the Ceylon and Indian system was, I must freely admit that no other course was open. Had there been one the class of men who have made Ceylon what it is today would have found it and acted upon it. Let us look at the advantages offered by a new and virgin country like Queensland. From the very verge of the coast to above and beyond the Barrier Range, we have mile upon mile of virgin forest and scrub land, in fact the richest of the rich, that no previous generation has ever sown or reaped. The climate is warm and humid, suitable to the growth of the tenderest fern to the giant hardwood; the scorching heat of the Indian coast is but rare with us; in fact, our climate is identical with that of Ceylon at from 6,000 to 8,000 feet. It is hardly to be wondered at that one at least of the products of Ceylon has made its home with us, almost unknown to us. The question at once arises—If we are going to cultivate that product for our own and country's benefit, shall we blindly follow the system which we know to have propagated leaf disease in Ceylon and India, or try to think out a system of our own, based upon the highest agricultural principles, while making use of the natural advantages we possess. These advantages are briefly as follows:—1st.—The surety by ocular demonstration that the coffee tree has made its home with us, and will even stand neglect that would kill it in any other country. 2nd.—It has made its home on flat land on the coast where the bulk of our scrub land is situated. 3rd.—That on flat land the plough and the cultivator will take the

place of cheap labour at less than half the expense, while the upreep will cost less than one-fourth of the old system. 4th.—That by river or road a few miles will convey the crop to the market or ocean-going steamers, while in India 150 miles by bullock carts has to be paid for before it reaches the coast. With these advantages before us, that which has so long appeared a disadvantage entirely disappears and becomes a blessing and a saving that will enable us to compete with any country in any market, to say nothing of the natural increase we may expect by bringing true agricultural principles to bear on a product that has previously been planted in pot holes, among roots, fungus, and half-burnt logs.

With their advantages, it is curious that coffee in Queensland has made so little progress.

GERMAN EAST AFRICA.—We call attention to the long letter from Mr. W. H. Cowley, on page 179, formerly of Nella Oula estate, about his new planting home in East Africa, and in defence against unwarrantable criticism made by the only Ceylonese who seem to have turned out failures, as settlers in the African plantation. What we are told about climate, food, medical attendance, &c. is very interesting.

PLANTING &C., IN LOWER PERAK.—Mr. Noel Denison in his latest monthly report on this district, states:—

I am not giving out much new land at present, confining myself to improving what has already been planted up. Coconut trees are now being planted between the nilams; many thousand coconuts will be planted out this year. The pigs are the great difficulty and the curse of the place, destroying the coconuts in every direction if they can find an opportunity, and again,

The accounts from S'tiawan this month are very satisfactory. At Ayer Tawar the padi crop has been very good, the Ketuah here getting as much as 800 gantangs of padi, and as it is said, that 300 gantangs will suffice a whole family for a year, the people are more than satisfied. If the crop at this place, Surg or Tiram and Lumut is good this year, there will be a rush for padi land in this portion of the State for next year's planting. During the month some more Kelantan and Javanese settlers have come in, bringing in the same language, 30 head of cattle for the settlers here. These are the cattle the Sultan assisted the settlers with. The cattle are a fine strong lot; 11 head have been trained to ploughing, and we shall now soon have five cattle ploughs and two buffalo ploughs at work at S'tiawan, and one buffalo plough at Pasir Panjang.

The Straits officers are very wise in encouraging native agriculture. Their "land revenue" is becoming a considerable item.

COOLIES FOR TEA PLANTATIONS.—From a resolution of the Bengal Government upon Dr. Macleod's report, it appears that a very considerable increase took place last year in the number of coolies supplied to the tea districts under the free emigration system. The figures show nearly 26,000 free emigrants for 1892, against little over 18,000 in 1891. A noticeable feature of the year is the increase which has taken place in sardar system of recruitment as opposed to that by contractors. The number of sardars employed by garden managers in the work was double that of the preceding year, and the corresponding increase in the coolies amounted to nearly 4,000. On the other hand, contractor's coolies fell off by more than 3,000, though no particular reason is assigned for the change. Upon the whole the statistics of the year are normal. A few cases of cholera are reported, but there does not appear to have been any special outbreak, and the results may, therefore, be looked upon as satisfactory in this respect. —*Pioneer*.

A TEA-TASTING contest at Minneapolis has been conducted as follows. The committee were given several boxes of teas of different marks and prices the prices in sealed envelopes, corresponding to the marks on the tea. These envelopes remained unopened till the contest was over. From the several teas, the committee chose three changed the marks, and after infusion presented them to the competitors to taste. Five minutes were allowed for valuations, which were recorded by each taster and passed to the committee in sealed envelopes, opened and compared with the prices as registered and the competitor who made the nearest approach to the right figures got a handsome prize. American tea tasting is certainly in its infancy.—*Indian Planters' Gazette*.

"COFFEE-TEA."—Some time ago we learned how a Treasury official had sent in a great hurry for a Ceylon planter (Mr. Huntly-Thring) to ask what our product, "Coffee-tea" was, and whether its export from Ceylon was likely to increase, as no provision had been made in the Customs Tariff for it! "Tea we know and coffee we know," the official seemed to say, "but what is Coffee-tea"? Mr. Huntly-Thring was able to allay any anxiety as to quantity then; but we suspect the Treasury will think seriously of amending the Tariff regulations when they find from Messrs. Geo. White & Co.'s latest circular that some more of the duty-free product has been coming forward for sale. We quote as follows:—

Two small lots, printed as Coffee Tea "Duty Free" sold as follows:—2½ chests at 93d per lb, and 3½ chests at 10½d per lb.

STRONG TEA.—Mr. C. H. Donyer scribbles the preference for India and Ceylon teas to their having a greater strength, in the proportion of 7½ gallons of infusion per lb. against five from Chinese. He declares the Indian leaf is too strong for the nerves. He deplors the habit of factory girls drinking tea five or six times daily. (The late Mr. Nicholson, and surgeon of local repute 30 or 40 years ago, held the same opinion, and expressed it very strongly.) "Professional tea-tasters suffer from weakness and nervous affection." Yet the love of "the liquor of the fragrant leaf" grows and on the other side of the argument is the experience of Australian bushmen and shepherds and African explorers, including Mr. Selous, who are associated with nerves of iron and sinews of steel, not with debility.—*Sheffield Telegraph*, June 29.

A NEW EVIL IN TEA.—Dr. J. Murray-Gibbes has discovered—according to the *Daily Chronicle*—a new evil which attends too much tea-drinking:—"In the current number of *Hygiene* he declares that Mrs. John Bull and her daughters are the largest consumers of the contents of those cups that cheer but do not inebriate, except indeed their colonial cousins in Australia, whence the doctor has sent his contribution on the effects of stimulants generally. Dr. Murray-Gibbes sees a distinct connection between the movement to secure women's rights and too great a consumption of congo. To tea-drinking the doctor appears to trace the growing desire felt on the part of the fair sex to enter the professions, and, in fact, to take the place of man as bread-winners. He views with alarm what he regards as a struggle for supremacy between man and woman, and believes that woman's brain-power must develop at the expense of her physique. In short, if things go on as they are going, the worthy doctor fears that a century hence man will have become a toothless animal, and woman also. What a prospect is this for the dentists of coming generations! Perhaps people will give up their tea rather than their teeth," adds our London contemporary; but the good sense of the English people will see that both tea and teeth can defy such absurd statements as those of Dr. J. Murray-Gibbes.

THE OUTPUT OF TEA IN NATAL for the season just closing is set down at 580,000 lbs., being 20,000 lbs. more than was estimated. This is satisfactory, and shows that the tea industry is going along satisfactorily in the Colony. Natal has some fine tea country, and a good deal ought to be made of this product before long.—*Colonies*.

PEARL FISHERIES.—The Mexican Government has leased to a company the pearl fisheries of the Island of San José, in the Gulf of California, for a term of sixteen years. During the first three years the lessees are to pay in cash to the Government the sum of \$10 per ton of pearl oyster obtained, and \$12 per ton during the remaining thirteen years.—*Financial News*, Aug. 1.

FRUITS ARE THE LEADING PRODUCTS of Southern California, and hitherto have been almost entirely consumed in the United States, being despatched, as a rule, overland. According to British Consul Donohoe at San Francisco, there is apparently a surplus for export, which in the near future must be largely increased; but the question whether these fruits, or any of them, can be profitably disposed of in the English markets, cannot, on account of the great distance and the cost of transportation, be said to be definitely settled. Oranges are the leading fruit, and it is believed that in the course of a few years, instead of the crop amounting to 60,000 tons, it will come up to about 200,000 though there is no present visible domestic market for such a quantity.—*London Chamber of Commerce Journal*.

WHAT AMERICAN EXPERTS THINK OF TEAS AND CONSUMERS.—Says the *American Grocer* after reproducing Messrs. Gow, Wilson & Stanton's diagrams under the heading "the eclipse of China tea:—

We think that the advocates of these teas fail to take into consideration the effect of climate on taste, which is also influenced by social causes. The rank and coarser sorts of coffee and tea are in most favour in the newer portions of the country, while in the older established sections, especially those where wealth and culture are most marked, tea and coffee of the most delicate flavour are in highest favour. Boston, New York and Philadelphia are the best markets for the finest Formosa and Foochow Oolong; in the leading cities of the South, great attention is given to favour. In New Orleans the best grocers use the very finest grades to be had in the American market, taking the finest Congou, English Breakfast, Foochow, Formosa Oolong, Moyune, Gunpowder and a little India and Young Hyson and a very little Japan. In the country districts of the South, price rather than quality is the first consideration. Country jobbers will buy black teas ranging from 12½ to 30 cents, and are indifferent as to whether Amoy, Foochow or Formosa Oolong. In purchasing low grade greens attention is given to well made leaf so that Pingsueys are in favour. It is said that in and about New Orleans country dealers take about two packages of green to one of black, while in the city, dealers take two of black to one of green. A correspondent in Philadelphia states that Formosa Oolong has for many years been the favourite with old Philadelphia families; the custom prevailing with them tends to affect the demand of the entire community. The newer element in Philadelphia are quite partial to Formosa Oolong, which at first was mixed with Foochow Oolong until the demand gradually and steadily inclined towards straight Formosa. The popular tea with the masses of the people is one that retails for fifty cents. Japan and Green are used only to a limited extent. It is said also that the medium and common grades of English Breakfast have been more freely used during recent years owing to their cheapness. Blended teas have made little headway in Philadelphia, although some of the prominent retailers have been very successful in pushing a mixture of Ceylon tea.

CEYLON MANUAL OF CHEMICAL ANALYSES.

A HANDBOOK OF ANALYSES CONNECTED WITH THE INDUSTRIES AND PUBLIC HEALTH OF CEYLON FOR PLANTERS, COMMERCIAL MEN, AGRICULTURAL STUDENTS, AND MEMBERS OF LOCAL BOARDS.

BY M. COCHRAN, M.A., F.C.S.

(Continued from page 7.)

CHAPTER V.—COFFEE.

VARIETIES OF COFFEE—RELATIVE SIZE OF VARIOUS KINDS OF COFFEE SEEDS—RAW AND ROASTED COFFEE SEEDS—MOCHA AND EAST INDIA COFFEE—COMPOSITION OF COFFEE SEEDS FROM DIFFERENT COUNTRIES.—ASH OF VARIOUS COFFEES—COMPARISON OF THE ASH OF COFFEE AND CHICORY—COMPOSITION OF PARTS OF THE BRAZIL COFFEE TREE—ASH IN CEYLON COFFEE LEAVES' PARCHMENT COFFEE AND PULP—PARCHMENT COFFEE FROM BADULLA—ESTIMATE OF CONSTITUENTS REMOVED FROM THE SOIL PER ACRE, BY AVERAGE COFFEE CROP—MANURING OF COFFEE—TABLES OF USEFUL DATA FOR MANURING EXPERIMENTS.

The coffee plant belongs to the natural order rubiaceae, the best known species being *Coffea Arabica*, a plant indigenous to Abyssinia, where its useful properties have been known from the earliest times. It appears also to be native to Arabia where it was a common article of diet in the 15th century. The plant is now naturalised and cultivated in a great many countries, such as India, Ceylon, Java, Sumatra, Bourbon, Celebes, Fiji and islands of the Pacific. In Africa, besides its home Abyssinia, it is grown in Egypt, Mozambique, Natal and Western Africa. It is cultivated in Central America, and the country of Brazil is said to furnish one-half of the world's supply. Botanists have distinguished eight species. In commerce different varieties of coffee are named from the countries where they are grown.

The coffee fruit, technically termed "cherry," from its size and general appearance resembling that of a cherry, consists of an outer fleshy part of a saccharine glutinous character. Imbedded in this are usually two seeds each enclosed in two integuments; the inner one called the silver skin is of a membranous character, the outer one is called the parchment skin from its resemblance to ordinary parchment. The seeds vary in size to a considerable extent as indicated in the following table from Thorpe's Dictionary

of Applied Chemistry. Liberian coffee does not appear in the list. The figures given represent the number of seeds required to fill a measure capable of holding 50 grams of water. The sizes therefore are inversely as the numbers:—

Size of Coffee Seeds:

Fine brown Java	187
Fine Mysore	198
Fine Neilgherry	203
Costa Rica	203
Good ordinary Guatemala	207
Good La Guayra	210
Good average Santos	213
Fine long berry Mocha	217
Good ordinary Java	223
Fine Ceylon Plantation	225
Good average Rio	236
Medium Ceylon plantation	238
Manilla	248
Ordinary Mocha	270
West African	313

The following are some of the standard analyses of raw and roasted coffee "beans" beginning with the older analyses of Schrader and Payen:—

Analyses of Raw and Roasted Coffee. (SCHRADER.)

	Raw Coffee.	Roasted Coffee.
Peculiar Caffeic principle	17.58	12.50
Gummy and Mucilaginous extract	3.64	10.42
Extractive62	4.80
Fatty oil52	2.08
Resin41	
Solid residue	66.66	68.75
Water and loss	10.57	1.45
	<hr/>	<hr/>
	100.00	100.00

Analysis of Raw Coffee. (PAYEN.)

Cellulose	34.00
Hygroscopic water	12.00
Fatty substances	10 to 13.00
Glucose, dextrin and undetermined acid	15.50
Legumin, gluten	0.00
Caffeate of potash and caffeine... ..	3.5 to 5.00
Nitrogenous substance	3.00
Free caffeine... ..	.80
Concrete essential oil... ..	.001
Aromatic fluid essential oil002
Mineral substance	6.697
	<hr/>
	100.000

The following are Dr. Hassall's analyses of raw and roasted coffee:—

Analyses of Raw and Roasted Coffee. (HASSALL.)

	Raw.	Roasted.
Water	8.26	.36
Cane Sugar	8.18	1.84
Caffeine	1.10	1.6
Fa	11.42	8.56
Gluten	10.68	12.00
Extractive (Caramel Gum Tannin, &c.)	14.03	26.28
Cellulose	42.36	44.96
Ash	3.97	5.17
	<hr/>	<hr/>
	100.00	100.00

With the exception of water the substance which suffers the greatest decrease by roasting

is the cane sugar, which is for the most part changed into caramel.

The following are Dr. Bell's analyses of Mocha and East Indian Coffee:—

Analyses of Coffee. (BELL.)

	Mocha.		East Indian.	
	Raw.	Roasted.	Raw.	Roasted.
Caffeine ...	1.08	.82	1.11	1.05
Saccharine matter	9.55	.43	8.90	.41
Caffeic acids	8.46	4.74	9.58	4.52
Alcoholic extract containing nitrogen and coloring matter...	6.90	14.14	4.31	12.67
Fat and Oil	12.60	13.59	11.81	13.41
Legumin or albumin	9.87	11.23	11.23	13.13
Dextrine				
Cellulose and insoluble coloring matter...	.87	1.24	.84	1.38
Ash ...	37.95	48.62	38.60	47.42
Moisture ...	3.74	4.56	3.98	4.88
	8.98	.63	9.64	1.13
	100.00	100.00	100.00	100.00

The following by O. Levesie quoted in Thorpe's Dictionary from *Archiv. der Pharmacie* gives a tabular view of the percentage composition of coffee seeds from seven different countries:—

	Caffeine.	Fat.	Tannic and Coffee Tannic Acid.	Cellulose.	Ash.	Potash.	Phosphate Acid.
Finest Jamaica plantation	1.43	14.76	22.7	33.8	3.8	1.87	.33
Finest Green Mocha	.64	21.79	23.1	29.9	4.1	2.13	.42
Ceylon plantation	1.53	14.87	20.9	36.	4.	—	.27
Washed Rio	1.14	15.95	20.9	32.5	4.5	—	.51
Costa Rica	1.18	21.12	21.1	33.	4.9	—	.46
Madhar...	.88	18.80	20.7	31.9	4.3	—	.60
East Indian	1.01	17.00	19.5	36.4	—	—	—

Ash of Coffee.

The following analyses by Messrs. Graham,

Stenhouse and Campbell represent the composition of the ash of various coffees:—

	Plantation (Ceylon).	Native (Ceylon).	Java.	Costa Rica.	Jamaica.	Mocha.	Netlhertry.
Potash	55.10	52.72	54.10	53.20	53.72	51.52	55.80
Soda	—	—	—	—	—	—	5.68
Lime	4.10	4.58	4.11	4.61	6.16	5.87	8.49
Magnesia	8.42	8.46	8.20	8.66	8.37	8.87	8.61
Ferric oxide	4.5	.98	.73	.63	.44	.44	3.09
Sulphuric acid	3.62	4.48	3.49	3.82	3.10	5.26	6.00
Chlorine	1.11	.26	.26	1.00	.72	.59	.60
Carbonic acid	17.47	18.13	18.13	16.34	16.54	16.98	14.92
Phosphoric acid	10.36	10.60	11.05	10.89	11.13	10.15	10.85
Silica	—	—	—	—	—	—	—
Sand	—	—	—	—	—	—	—
	100.63	100.20	99.97	99.06	100.18	99.68	100.04

The remarkable features of these analyses are the high proportion of potash and the absence of soda and silica. These characteristics together with the small quantities of chlorine and ferric oxide are useful in enabling the analyst to decide whether or not a sample of coffee has been adulterated with chicory:—

Dr. Winter Blyth furnishes the annexed table shewing the characteristic differences between the ash of coffee and of chicory.

Comparison of the Ash of Coffee and of Chicory.

	Percentage.	
	Coffee Ash.	Chicory Ash.
Silica and sand	None	10.69 to 35.88
Carbonic acid	14.92	1.78 to 3.19
Ferric oxide...	.44 to .98	3.13 to 5.32
Chlorine	.26 to 1.11	3.28 to 4.93
Phosphoric acid	10. to 11.00	5. to 6.00
Total soluble ash	75. to 85.00	21. to 35.00

The following are analyses of the ash of coffee and of chicory by Dr. J. P. Battershall:—

Analyses of the Ash of Coffee and of Chicory.

	Java Coffee Ash.	Chicory Root Ash.
Potash	53.37	23.00
Soda	—	13.13
Lime	5.84	9.40
Magnesia	9.09	5.88
Alumina	.43	—
Ferric oxide	.53	5.00
Sulphuric acid	3.19	9.75
Chlorine	.78	4.93
Carbonic acid	15.26	4.01
Phosphoric acid...	11.26	8.44
Silica and sand	.25	16.46
	100.00	100.00
Total ash per cent	3.93	4.41

Ceylon Ground and Roasted Coffee.

Two samples of ground roasted coffee prepared in Ceylon were sent to me in order that I should certify to their being free from chicory. This

I was able to do from the result of a microscopical examination of the sample confirmed by the examination of the solubility of the ash. One sample yielded 5.44 per cent of ash, of which 83.45 per cent was soluble in water. The other yielded 5.38 per cent of ash, of which 78.8 per cent was soluble in water. Roasted coffee of course contains a higher percentage of ash than raw coffee. A sample of Liberian coffee (raw) grown in Ceylon yielded ash 4.23 per cent.

In Levesie's table of analyses of coffee seeds already quoted the total ash varied from 3.8 to 4.9 per cent, shewing an average of 4.28 per cent, while the figure for Ceylon plantation was 4 per cent. The following are additional determinations of the ash of coffee from Dr. Hassall's work on food and its adulterations:—

Mineral Matter in Coffee.

Percentage.

Total Ash. Soluble Ash.

Coffee	4.75	—
„	4.50	—
„	4.17	—
Mysore Coffee	4.29	3.53
East India „	4.07	3.24
Jamaica „	4.59	3.71
Average	4.56	3.49

An interesting table of ash analyses of the different parts of the Brazilian coffee tree by H. Ludwig appeared in the *Archiv. der Pharmacie* which has been extracted without criticism for the article 'Coffee' in Thorpe's Dictionary of Applied Chemistry. I therefore quote them here, although I think it would be desirable if some other analyst would take the trouble to verify experimentally, the results arrived at. Ludwig's figures shew a tendency of phosphoric acid to accumulate in the roots of old trees, the proportion in the ash of the root of an old coffee tree being about five times as great as in the ash of the root of a young coffee tree in bearing. The analyses undertaken to investigate the effect of different soils on the composition of the ash of the coffee bean yield very remarkable results. The limestone soil yielded a bean, the ash of which was poorer in lime and phosphoric acid than, but contained more than three times as much potash as, the ash of the bean grown on gneiss soil. The latter soil also yielded proportions of ferric oxide and sulphuric acid which seem to me to be phenomenally high. Soda, which was absent from the ash of coffee beans analysed by Messrs. Graham, Stenholme and Campbell was found in both cases by Ludwig to the extent of fully 5.8 per cent. Alumina, which is an ingredient very sparingly assimilated by plants was found in considerable proportion in the roots (young), leaves and parchment skin.

Ash Analysis of Parts of the Brazilian Coffee Tree.

(H. LUDWIG.)

No. 1	Root of a young tree in bearing.
2	Root of an old tree.
3	Leaves.
4	Pulp of the pericarp.
5	Parchment-like coating of Coffee beans.
6	Coffee beans grown in gneiss soil.
7	Coffee-beans grown in lime-stone soil.

The above analyses of the ash of Ceylon coffee leaves and coffee pulp differ widely in some respects from the corresponding analysis of Brazilian coffee. Ceylon ashes are richer in potashes but not so rich in phosphoric acid.

The following is Mr. John Hughes' estimate of the constituents removed per acre by an average crop of coffee, assuming 7 cwts. of parchment from 1,200 trees:—

Estimate.

	Seed.	Pulp.	Leaf	Total.
	7 cwts. Parchment = 784 lbs.	Fresh Pulp = 849 lbs.	Partially dried 240,000 leaves = 247 lbs.	Weight = 1,880 lbs.
Water	104.3	664.8	24.0	793.1
* Organic matter	653.8	168.7	24.2	1026.7
Mineral (Ash) matter	25.9	15.5	18.8	60.2
lbs...	784.0	849.0	247.0	1880.0
* Containing nitrogen	11.5	2.8	6.6	20.9
The Ash consists of:—

lbs ..	25.9	15.5	18.8	60.2

Manuring of Coffee.

The following tables show the quantities of manures required to return to the soil, the important elements of plant food removed by the coffee crop, basing the calculations on the preceding estimate by Mr. Hughes. Seven cwts. of parchment coffee is no doubt much above the average crop, but for manuring purposes it is a safe basis to go upon.

The theoretical doses of nitrogen, phosphoric and potash required to return to the soil, the amounts of these important ingredients removed by the coffee crop in two years, i.e., 14 cwts. of parchment coffee with accompanying pulp and loss of leaf; but not of prunings, are,

Nitrogen	...	41.8 lbs.
Phosphoric acid	...	7.4 "
Potash	...	46.6 "

The staple manures for coffee are cattle manure, castor cake and bone dust, to which are some times added salts of potash.

The following tables are drawn out on the same principle as those already given in connection with the manuring of tea. The nitrogen table gives the weight of manures which contain the theoretical dose of nitrogen, viz., 41.8 lbs. The phosphoric acid table gives the weight of the manures which contain the theoretical dose of phosphoric acid, viz., 7.4 lbs. The potash table gives the weights of manures which contain the theoretical dose of potash, viz., 46.6 lbs.

Nitrogen Table.

This table gives the weights of certain manures which will return to the soil nitrogen equal in amount to that removed from the soil by two years' crops, including pulp and leaves, viz., 41.8 lbs. nitrogen together with the weights of phosphoric acid and potash in the manures:—

Description of Manure.	Weights of manures in lbs. which contain 41.8 lbs. nitrogen.	Weights of phosphoric acid in lbs. in the manures.	Weights of potash in lbs. in the manures.
	Ceylon Cattle Manure No. 1	9,372	23.4
Do do No. 2	6,490	6.0	69.3
Castor-Cake (best)	597	17.3	7.5
Do (lower quality)	836	12.5	12.5
Bone dust	1,194	275.0	11.9

Phosphoric Acid Table.

This table gives the weights of certain manures which will return to the soil phosphoric acid equal in amount to that removed from the soil by two years' crops, including pulp and leaves, viz., 7.4 lbs. phosphoric acid together with the weights of nitrogen and of potash in the manures:—

Description of Manure.	Weights of manures in lbs. which contain 7.4 lbs. phosphoric acid.		
	Weights of manures in lbs. which contain 7.4 lbs. phosphoric acid.	Weights of nitrogen in lbs. in the manures.	Weights of potash in lbs. in the manures.
Ceylon Cattle Manure No. 1...	2,960	13.2	28.1
Do do No. 2...	8,042	51.8	85.9
Castor-Cake (best) ...	255	17.9	3.2
Do (lower quality)...	493	24.7	7.4
Bone dust ...	32	1.1	.3

Potash Table.

This table gives the weights of certain manures which will return to the soil potash equal in amount to that removed from the soil by two years' crops, including pulp and leaves, viz., 46.6 lbs. potash together with the weights of nitrogen and phosphoric acid in the manures:—

Description of Manure.	Weights of manures in lbs. which contain 46.6 lbs. potash.		
	Weights of manures in lbs. which contain 46.6 lbs. potash.	Weights of nitrogen in lbs. in manures.	Weights of phosphoric acid in lbs. in manures.
Ceylon Cattle Manure No. 1	4900	21.9	12.3
Do do No. 2...	4391	28.3	4.0
Castor-Cake (best) ...	3723	261.0	103.1
Do (lower quality)...	3106	155.3	46.6
Nitrate of Potash ...	11.6	1.8	—
Muriate of do (80 %) ...	5.8	—	—
Snlphate of do (50 %) ...	9.3	—	—
Kainit (13.5 %) ...	34.5	—	—

The results of ordinary experience hitherto in the manning of coffee, had not shown, except perhaps in the case of nitrogen, that the important elements of plant food should be added to the soil in the proportions in which they are removed by crop, etc., thus when using cattle manure No. 1 instead of adding the important ingredients of plant food in the proportions of 1 theoretical dose of nitrogen, 1 of phosphoric acid and 1 of potash, these are added in the proportion of 1 of nitrogen, 3 of phosphoric acid and 2 of potash. Mixtures of Castor-cake and Bone-dust, such as planters have been long accustomed to use, depart still further from the theoretical quantities; thus a mixture of $\frac{1}{4}$ lb. of Castor-cake and $\frac{1}{2}$ lb. of Bone-dust added to each tree represents per acre 1 theoretical dose of nitrogen, 20 of phosphoric acid and 0.2 of potash, and when a mixture of $\frac{1}{2}$ lb. of Castor-cake and $\frac{1}{2}$ lb. Bone-dust is added per tree, such a manure adds to the soil $1\frac{1}{2}$ times the theoretical dose of nitrogen, 21 times the theoretical dose of phosphoric acid and 0.3 of the theoretical dose of potash. The mixtures of artificial manures which planters have been accustomed to use, thus: fully keep up the supply of nitrogen, add many times the theoretical quantity of phosphoric acid, but fall far short of the theoretical quantity of potash. For some years past the addition of potash salts to manures

has been practised by some, but with what success compared with the method of manning with Castor-cake and Bone-dust only, there do not appear to be any published numerical data to show.

Some of the special commercial manures for Coffee cultivation will be found in the chapter on Manures.

THE FUTURE OF THE AMERICAN-CEYLON TEA PLANTERS' COMPANY.

The latest information to hand relative to the proceedings of the above Company would appear to warrant some hope that the good work accomplished by Mr. Elwood May and Mr. Pineo is not to be left to utter failure. Very large interests in the welfare of the undertaking have been created by Mr. May's arrangements for advertising entered into with several leading American newspaper proprietors. These last evidently see that, failing some effort on their part, there is no chance of their obtaining any return for the speculative work they have hitherto done under that arrangement. For the first time we had lately made known to us, and that in a very striking way, the results hitherto obtained by the Company. We propose to recapitulate the figures showing the progressive nature of the business done. From October 1890, when work first commenced, to January 1891, the gross profits made were only 697 dollars. From the latter date to May of the same year 1,290 dollars were obtained. From May 1891 to January 1892 the profit equalled 2,586 dollars. From January 1892 to April 1892 it was 1,856 dollars; while from the last-mentioned date to April 22nd of the present year the return had risen to 8,830 dollars. Now although the last-mentioned amount of profit is certainly not large, it shows a very striking bound upwards. Indeed the figures would seem to indicate quite a sudden appreciation of our teas in America, the evidence of which has only just been forthcoming as unavoidable misfortune has fallen upon the company. With such indications of rapid progress in the future, it will be a thousand pities if some mode of carrying on the work so well begun cannot be found. Such, no doubt, is the feeling which now actuates the proprietors of the American newspapers who have interested themselves in the operation of the Company, and who are its creditors to a very large amount. We see it stated that the value of the advertising done in one form or another represents the sum of 99,855 dollars. To that extent Ceylon tea has been prospectively benefitted, and this without any outlay whatever by this island beyond the value of the grant made by the Tea Fund of 9,000 lb. of tea. This grant we see is assessed in the Company's accounts at 1,892 dollars, or an average of about ten-pence the pound. Taking the general analysis of profit and loss, which includes the amount due for advertising the debit balance stands at 220,655 dollars. This is a serious amount; but it is, so far as the advertising account goes, in part only a nominal loss, and by no means represents any financial result to actual trading. All the figures would seem to show that the crisis had arrived just at the juncture when the large outlay on advertising was about to bear fruit. We observe that it had been determined that the claim of Messrs. Watson and Farr is to be "vigorously resisted" or opposed, according to the Committee's report, "to the terms of their agreement with the Company and to the common understanding had with all the parti-

interested." Into the merits of this threatened resistance we cannot, for want of sufficient information, enter. It is a matter which must be determined by the good faith of those against whom the claim is made. Apparently it is proposed to consult the present stockholders individually, as to the best course to be pursued for the future. We cannot observe that any distinct proposition for future working, or for the continuance of the Company, has as yet been formulated; but we think we see in the activity of the parties chiefly interested—and these we have pointed out are mainly the newspaper proprietors who have gratuitously advertised the Company—a promise that means will be found for continuing its operations. If so there seems little doubt that Mr. May will yet remain at the helm, for he has received a strong expression of the confidence felt by all concerned in his management.

GOVERNMENT AND PLANTING IN EAST AFRICA:

BY AN EX-CEYLON PLANTER.

THE MOMBASA MISSION, PLANTING & C.

In a letter accompanying the appeal which appears in our advertising columns, Mr. J. R. W. Pigott writes:—

As I know you are interested in good works I send you the enclosed and may be you would see your way to help us either directly or through your valuable paper the *Observer*, which I hope still flourishes as it did in the days when I had the pleasure of digesting its contents with my dinner on Alloo-wharie. I need say nothing of the wants of Mombasa as they are fully set forth in the notice.

"Things here are not very bright. No one knows what is to become of the country whether Government will take over or whether it will be annexed to the Zanzibar Protectorate.

"We are expecting Sir Gerald Portal back from Uganda early in August.

"There is nothing to be done here in the way of planting at present except perhaps in coconuts, cotton and tobacco as the rainfall on the coast is so very uncertain; but when the railway is an accomplished fact, things will, I think, change; there is some very fine country inland, but the difficulties of transport make anything beyond experimental cultivation impracticable.

"I see the *T.A.* every month, but have not yet the time to read it so carefully as I could wish; being Acting Administrator my time is fully taken up.

"I am always looking forward to seeing Ceylon again. I have had a somewhat varied and rough life since I saw you last in April 1885. Thanking you and our other friends in Ceylon for the generous way in which you are going to help us."

PATENT TEA PLUCKERS

There is no escape from the fact that we are on the eve of a revolution in the mode of harvesting tea leaf, and one that may have a considerable economical and especially 'labour' influence. "Thompson's Patent Plucker" has so far alone been before the planting public; but there are rumours of another "Richmond" coming into the field very shortly. In the meantime we have been favoured with copy of a Report made to the patentee, of the operations extending over twelve months of the one available Tea plucker and we have not the slightest doubt that the Ceylon planting community as a whole will receive Mr. Dobree's letter and figures with the careful attention they merit. "Thompson's Patent Pluckers" we ourselves can vouch for as very handy and attractive in appearance;

the instructions for their use are simplicity itself; and better still there can be no doubt of the meed of approval which they have secured from men of a thoroughly reliable practical character. For instance, apart from Mr. Dobree, we had testimony today from one of the best authorities we should say, in the island, that for use during the four months' plucking following on a tea bush coming round again after pruning, he considers "Thompson's Plucker" perfect. For continuous use onwards, our authority is not prepared to speak in the same terms, simply because he has not as yet had sufficient experience. In the meantime, he speaks of what he does know and for the rest here is the testimony of a planter so careful and experienced as Mr. Dobree:—

J. ASHINGTON THOMPSON, ESQ.,

Dikoya, July 12th, 1893.

DEAR SIR,—I have now used your Patent Pluckers on two fields on Dikoya estate of 15 acres each for 12 months, and I send you the returns of leaf plucked or rather tea made from each field, and the total cost of plucking of all the tea made from leaf plucked by your plucker since I began using them, i.e., 55,000 lb. made tea at 4.35 cents per lb.

If this tea had been hand-plucked it would have cost me at least 10 cts. per lb., so I consider I have saved 5.65 cents per lb. in the plucking.

The leaf on the whole has been rather better than if hand-plucked, as I have been able to go round regularly from 10 to 12 days, except for 2 rounds at the burst of the S.-W. when the coolies did not turn out well, and the leaf ran to 13 days on two or three days.

I never had a runaway of leaf during the forcing months of April and May, which I consider most important as during those months we get in most leaf. When tipping for the first two or three rounds after pruning, I get rather more stalks than with hand-plucking, but these are easily picked out and the slight disadvantage is much more than made up in other ways.

There can be no question of the great improvement of the bush under your clippers. My bushes have spread out and covered the ground in a way I never expected and as all the tea on which I have been using them (with the exception of one field of 15 acres) was cut down to 15 inches, the spread is the more remarkable, and next year when pruned higher the bushes will quite cover the ground, as they are not high yet and planted in land opened for 43 years. I think the result most satisfactory. I have used your clippers on all tea that I have pruned for the last year, i.e., 12 months, and intend going on using them for 12 months after tipping. After that as the shoots get smaller, it may be advisable to hand pluck, but it will depend very much when the 12 months are up. If the 12 months ended on 1st April, then I think you could easily go on using the clippers till the end of May or till the S. W. had checked the flush.

I think it advisable to hand pluck every field under the clippers 3 or 4 times during the 12 months, say once a quarter to take off baggy thoroughly and give the smaller shoots a chance.

This year there has been plenty of labour and the want of coolies in April and May has not been felt, but when coolies are short, as they probably will be next year, those who are using your clippers will have an immense advantage. During April and May I could keep my flush in hand with about 100 coolies, less than I used in 1891-92.

To the objection, that you can't use small children to clippers, I would point out that after you have them in full swing, there will always be a portion of the estate over 12 months from tipping on which the children can be put to hand-pluck.

The higher the jāt the more suitable it is for the clippers. I do think they can be used economically on very poor jāt. They want a lot of personal supervision at first to teach the coolies how to use them, but when once the coolies get to know them, they

like them and the saving in labour and cost of plucking speaks for itself.—I remain, yours truly,

(Signed) T. S. DOBREE.

TEA PLANTERS AND THE RUPEE.

No planter is likely to object to the Commission of Inquiry in reference to the "Sixteen-penny rupee" proposed by Mr. T. N. Christie. What importers would say if they were represented in the Association is another matter. It may, however, be felt that the Commission might well be delayed a few months until the effect of the new departure, and of other changes anticipated in America, was seen more clearly. But the Commission even if appointed at an early date, need not be in a hurry to report or to make recommendations; it can indeed furnish more than one Report, delaying its final conclusions until the future of silver, under the new conditions, is more clearly revealed especially in America.

In the meantime it is evident that Mr. Christie himself has no doubt about the answer to be given to the question raised in the first part of his Resolution. He first asks that the proposed Commission should "consider and report on the probable effect in Ceylon"; but in the second clause, the answer seems to be afforded when the Commission is requested to "consider the measures it may be expedient to take to protect the interests of the Colony under the altered nature of the currency" as, in the opinion of this Association, the prospect of the Colony has been seriously endangered. This scarcely gives the Commission the free hand which the first clause would imply; but practically, that is not of much consequence since no one can say what further developments we may see in the silver world. Meantime in connection with the Resolution and the status of the Tea-planting industry, we think it well to reprint in full an editorial which appeared in the London *Financial Times* of the 30th ult. on "Indian Tea Companies." Several references are made to Ceylon, and we may at once challenge the disparaging comparison made in regard to our Tea Companies with the exception of the premier one, the Ceylon Tea Plantations Company. We can assure our critic that the large majority of the Ceylon Companies known to us are as sound investments to judge by what he himself says, as the Indian Companies he recommends. The cases of Loolecondura—tea fields some 25 years old, and Mariawatte—thirteen years, not to speak of others of our older plantations—are sufficient evidence of the position of tea in Ceylon. It is reassuring to read once more that experts are against the idea that China tea, even with exchange greatly in its favour, can regain the position it has lost in the United Kingdom. But here is the article referred to in full:—

INDIAN TEA COMPANIES.

Among the many phases of the Indian currency question not the least important or interesting to the British investor is the manner in which the new departure is likely to affect industrial and agricultural enterprise in our great dependency. Doctrinaires and experts have as usual expressed exactly opposite opinions on the subject, and in the multitudes of councillors wisdom has not yet been found. We are only concerned here with one particular branch of this complex question, but that an important one—the prospects of the Indian Tea Companies. It is a matter of common knowledge that exports of Ceylon and Indian tea have increased enormously of late years, Chinese competition being in many directions almost annihilated. An idea of the pecuniary stake that we have in this industry may be obtained from the fact that the capital, including debentures, of some sixty companies having head offices in London comes to something like five millions sterling. Now, as three-fourths of the expenses of these companies are disbursed in silver in India, and their produce for the most part sold for gold in London, it is easy to conceive that a low

We learn that Mr. Thompson, the patentee, has prepared a new and much improved pattern of the "Tea Plucker," and that a supply has just arrived and is available, as advertised, for distribution.

rupee is no disadvantage to them, but the reverse, and some apprehension has been expressed by shareholders as to the effect of the value of the coin being definitely fixed at 1s 4d. Regarded abstractly there is, of course, no question that any advance in the exchange must diminish the Companies' profits by increasing their expenses in India; but, on the other hand, 1s 4d is not a ruinous quotation, and the Companies have done very well when the rate was as high as 1s 9d. But there is another side to the question, for there can be little doubt that if more stability were given to the rupee investors would have greater confidence in Indian undertakings, and, being contented with a smaller yield, would buy shares at higher prices. This prospect tends to counteract any depreciation of value following upon a possibly smaller margin of profit.

Another point which has been insisted upon with more zeal than judgment by writers in the Press is that the new measure will give undue prominence to Cingalese and Chinese competition with India. As far as Ceylon is concerned, this statement is absolutely untrue, because the conditions of currency and therefore of the rupee are practically identical in Ceylon and India, and will continue to under the new departure. If a legislative enactment be necessary in the Island, it will do no more than fix the official *cachet* upon a state of things that will be called into existence whether or no. Both countries being therefore—so to speak—in the same boat; there can be no question of favouring Ceylon in the matter. It is otherwise with China, whose tea, owing to the much lower rate of exchange, will have an increased advantage over that of India, as far as price goes, in the European markets. Experts, however, do not stand in much dread of Chinese competition, even under these conditions. In the first place, they assert that the taste for the stronger and rougher teas of India and Ceylon is so pronounced that ordinary China Congou, though much lower in price, is almost unsaleable in the London market, and the appetite for Indian tea is growing on the Continent, in the Colonies, and even in the United States. In the next place John Chinaman, being an eminently conservative person, sticks to his antiquated methods of production, dries his plant in the sun and is too poor and unenterprising to adopt modern machinery. It is partly owing to this backwardness and partly to his fondness for adulteration, that China has been so distanced in the race that exports of Chinese tea to this country for the year ended May, 1893, only amounted to about 17 per cent. of the whole, whereas 83 per cent. came from India and Ceylon. It must not be forgotten, moreover, that the taste for Indian tea has been created by the enterprise and intelligence of producers. Although, then, it is possible that the trade of China in this respect may receive a temporary stimulus from the lower exchange, there is little reason to fear that it will inflict permanent injury upon the Indian Companies. These considerations may help to allay any alarm as to the effect upon these enterprises of the practical adoption of a gold standard for India.

Let us now look a little at the present situation of the Indian Companies. Taken as a whole, they have progressed of late steadily and rapidly. One or two exceptions may be found, no doubt, but the great majority are in a very much better position now than they were three or four years back. Their increased strength is due in some measure to heavy betterments; that is to say, extensions of area and improvement of plant, which have been largely charged to revenue account. Most of them have also accumulated good reserves of untraded profit, while the great bulk are free from any debt worth mentioning. With the exception of the Ceylon Tea Plantations Company, which is in every respect a sound, strong undertaking, the Indian Companies are in a better position than those of Ceylon, many of the latter being offshoots of moribund Coffee and other Companies, and handicapped by liabilities taken over from former undertakings, which, however, they are gradually shaking off. Another circumstance in favour of Indian Tea Com-

panies is that there is a much freer market in the shares now than there used to be, owing to the greater publicity given to their quotations. The FINANCIAL TIMES has contributed something to this result by publishing weekly a table of quotations, one of which will be found in today's issue, and for which we are indebted to Mr. George Seton. Still these shares can be picked up even now at a comparatively low cost, yielding the purchaser a return, roughly speaking, of from 7 to 8 per cent. A question which will no doubt occur to a careful investor is whether the properties are not liable to be exhausted after some years' working. The answer to this is reassuring, as far as India and Burmah are concerned. With proper cultivation and attention there is little reason to fear exhaustion of the soil, and only the other day the chairman of a Company working in the District of Sylhet, Assam, assured a shareholder that over 400 acres of their oldest plant—say, 20 years old—were yielding still the handsome return of 600 lb. per acre. Opinions vary more about Ceylon. There are people who say that Ceylon cannot last not having a sufficient depth of soil, but the industry is not yet old enough in the Island to allow of an authoritative statement being made on the subject. In India, on the contrary, we have a quarter of a century's production upon which to base an opinion. Lastly, we may ask what fear there is of production outrunning the demand. To this inquiry also a satisfactory reply is forthcoming. Vast fields of consumption have yet to be opened up for Indian tea. Thanks chiefly to the enterprise of Ceylon growers, efforts have been made to introduce it into the United States, Holland and even Russia, with promising success. Already $\frac{1}{4}$ of the tea consumed in Australia hails from India, and Canada is rapidly taking to it. With these great areas of consumption barely scratched growers, if they have any energy, may rest easy about finding markets for their surplus stock. With regard to the present crops reports both from India and Ceylon are favourable to a moderate increase over last year's yield, though it is rather too early to say anything about quality. There is, therefore, every likelihood of the past year's dividend being maintained, despite the silver bogey, and, on the whole, the shares of Indian Tea Companies may be recommended to the speculative investor as a lucrative and comparatively safe field for the employment of capital.—*Financial Times*, June 3rd.

NEW COFFEE ENTERPRISE IN MEXICO.

An English company has bought between 60,000 and 70,000 acres, situated near Suchil on the Isthmus of Tehuantepec, Mexico. It is their intention to go into the coffee and tobacco culture, and they will probably introduce immigration from England. They expect to begin active operation next season.—*American Grocer*.

PLANTING ENTERPRISE IN KLANG.

Mr. W. W. Skeat, the Assistant District Officer at Klang, gives the following particulars of estate progress there in his report for May:—

Over all the acres of coffee in bearing, the proprietors of Tremelhyr Estate on the Langat Road expect three pikuls an acre. A small quantity has already been exported and has fetched \$35 a pikul. There are at present 35 acres of pepper on Tremelhyr Estate, of which 15 acres are in full bearing. Gathering has been going on for six weeks and the crop is a splendid one, but the price is under nine dollars. From Beverlac and Ebor, Mr. P. Stephenson reports the exportation of 106 pikuls of pepper during the past few months, while another 50 pikuls are in store.

Mr. Hurth on Enterprise Estate is doing fairly well, and says that the estate already covers its expenses. The pepper crop for this year is expected to be 250 pikuls, and it is intended to open up fresh ground with coffee in 1893.

I have not had time to obtain information as to Glenmarie.—*Strait's Times*.

PICKINGS WITH A LOCAL APPLICATION.

Says an Australian exchange, referring to the Rice-Crop in Cairns: "The average return is 2 tons of paddy per acre against 1½ tons last season, while the estimated total cultivation is expected to produce 1,000 tons of paddy. The quality of the rice is reported to be excellent, and it is possible the extent of cultivation will be greatly increased next season. As the paddy is a marketable commodity when shipped south, growers need not fear that an output, however large, would congest the local market, and we hope next season to see 1,000 to 1,500 acres under crop."

A very interesting series of tests have been made at the Wyoming experimental station to determine the quantity of water necessary to irrigate an acre of land. A continuous flow of one cubic foot per second during May, June, July, and August was found sufficient, with a rainfall of about 6 inches, for over ninety-five acres of land which had never been irrigated; but the next year, with a rainfall of nearly 7 inches, it would have sufficed for over 216 acres of such previously irrigated land. The need of water varied with the kind of crop. Thus one second foot through the four months would have supplied 167 acres of oats, 295 acres of sugar beets, 336 acres of sorghum, 588 acres of peas, 735 acres of corn, all growing on land close to the irrigation canal. The previously estimated duty of water for Wyoming is about 100 acres to the second foot through four months.

Experiments made at one of the Scottish experimental stations, if they have been properly carried out, go to upset some of the common notions of GRASS PASTURE. It is generally believed that short pasture is more nutritive than long. It will, however, be conceded that the value of any grass is in direct ratio to its power of extracting salts from the soil. The experiments alluded to go to show that pasture when eaten short does not supply half as much nutriment to stock, as if allowed to grow say 8 inches long. The leaves condense the sap by evaporation of water from their surfaces and finally assimilate the material that was carried up to them in solution; thereby causing the roots to extract more food from the soil. If the plant be eaten short it is deprived of this power of extraction or absorption, and its value as pasture is in consequence greatly discounted. This is the manner in which the results of the experiments are explained. Overstocking therefore, is bad policy in more senses than one.

A Russian paper thus refers to the AGRICULTURE of the country:—"In 1891 the Government lost three hundred million roubles, viz., one hundred and seventy millions spent in famine relief, and one hundred and thirty millions deficit in ordinary revenues. But the country lost more than three times that amount altogether, not less than one thousand million roubles, and all this because our population is ignorant of the elementary principles of agriculture; in other words, we have lost this milliard by our own darkness, by our want of knowledge in that very subject (agriculture) by which nine-tenths of the nation live, and on which depends the whole of our economical and financial prosperity."

A writer on Cocoa in the *Scientific American* believes that in a few years the supply will exceed the demand, though for years to come it will remain an important factor in the earnings of many tropical planters, passing current in some places (as it has long done in the Upper Amazons) in the place of money.

The same writer objects strongly to the term "SOLUBLE COCOA" as misleading. No cocoa in the market, he says, contains more than 10 to 30 per cent. of matter soluble in water, unless the material so dissolved is foreign soluble material that has been added during the process of preparation. Cocoa should be so finely divided that the insoluble part will not be quickly deposited, and will be in a condition in which it can be better acted upon by the digestive juices. It is a common practice and one much to be deprecated to add a foreign substance such as starch or sugar to render the liquid of so high a specific gravity or so pasty that the insoluble matter will not deposit.

Here is a most instructive bit of reading (from the *American Grocer*) which however much it may be marked and learned will we fear be found rather indigestible:—ANTIPYRINE, which people use a good deal nowadays, is made by the condensation of a halogen butyrate and phenylhydrazine; the methylphenylpyrazine resulting is converted by a weak dehydromethylphenylpyrazine, and this by methylation yields dehydromethylphenylpyrazine.

LETTERS FROM JAMAICA:—NO. 36.

COFFEE PLANTING, &C.

Blue Mountain District for Packet of June 13.

The Editor,

DEAR SIR,—I last addressed you not long after my return from my visit to Montserrat: and now take up my pen to record what has happened in Jamaica since that date, that may be of interest to your readers. As I write it is blowing and pouring in heavy squalls of wind and rain, we are surely experiencing what are here termed the May seasons, but in Ceylon would be called the LITTLE MONSOON. Since towards the end of March we have had showery weather, not good for curing coffee or weeding, but capital for vegetation, after the rather long spell of dry weather that had hitherto prevailed.

As regards

BLUE MOUNTAIN COFFEE CROPS

they are very backward this year, and will probably last on till the end of June, and will as a rule, from what I gather, be smaller than last year, with the exception of one or two more favoured properties. Our high mountain coffee does not seem to bear heavily two years running: this is much more marked than it was in Ceylon, as most fine estates used if I recollect right to give a very good average, quite equal to our one tierce, or say 7 cwt. an acre: here the average must be very much smaller. Our estates are so few that the Blue Mountain crop cannot much effect the home market except in there being a smaller quantity of good coloury coffee available: and now that Ceylon coffee exports are getting less and less every year, and such fancy prices are given for pea-berry coffee, surely our celebrated berry should also maintain its deservedly good prices in the market. A great deal of coffee appears to be finding its way to England in parchment: no doubt it answers well for Central American planters to have their

COFFEE CURED IN LONDON,

as it enables them the quicker to get their large crops off the estates, and they have undoubtedly obtained better prices for London cured coffee. But to us in Jamaica with our not heavy crops, and with all the necessary machinery at hand on the spot, it is best to continue the old time process. We have no trouble in gathering or preparing the crop for market: it is the getting the coffee dry enough for the mill that most bothers us, as we have no very long spells of settled weather up in the mountains; very pleasant but showery weather is more frequent, so that it is often very risky to put half, or three quarters dry parchment on the barbecues, and so a sufficient force has to be kept ready to put back the coffee in time in case of a sudden shower, and this is what causes the curing to be expensive. As to what is here termed "picking for market" there is no difficulty, as the more respectable and well-to-do women, who will not do any field work are very ready to come for this work, and as regards the milling, winnowing and sizing, that is soon done especially where there is water power.

BANANAS

from what I learn by the newspapers have not been paying as well as they did a few years ago; competition by other countries is beginning to tell unfavourably, so that except for three or four months in the year, before the home grown fruits begin to come in, the demand in the United States becomes slack, and much smaller prices have to be accepted by our local growers.

The most paying occupations in Jamaica appear to be

PEN KEEPING

as stock sell well and where the property also grows Pimento and Logwood trees: giving quite a park-like appearance to the pastures, all the more profit is made by the fortunate owners of these properties which do not require a large force of labour for the upkeep, as is the case with coffee and sugar.

SUGAR PLANTERS

have a "boom" this year, because of the partial failure of the Beet root crop; if present prices were to be maintained many of the old time properties would probably be re-opened, and more coolies indentured for and were the system of central factories (or Usines) adopted, running the most improved machinery, sugar might yet give the Jamaica planter a very good return for his investment.

As to COCOA OR CHOCOLATE, as the natives here will call it, a great deal more could be grown as there is plenty of land for it at 500 to 2,500 feet above the sea; but unless it is prepared Ceylon fashion, it is not likely to fetch higher prices than it does at present; lately more attention has been paid by one or two growers, and the result has been most satisfactory and now the Botanical Department have published the Ceylon mode of curing, it is hoped Jamaica cocoa will come to the fore for the quality is good enough, it was the curing that was defective.

The two batches of

COOLIES

last arrived appear to have satisfied sugar and banana planters for the present, as there were not sufficiently numerous applications to enable Government to order another shipment this year. I am told that the coolies which came last, are physically a stronger set of men and women, and came not from Bengal, but from Oudh, and the neighbourhood of Lucknow. Our local Legislative Council had rather a long sitting and passed a good many laws rather rapidly. A new feature was that the Governor no longer presides over the Assembly, but an outsider has been appointed by the Secretary of State to fill that honourable and responsible post. Dr. Phillip, is already a member of the Governor's Privy Council, and a well-known and respected member of the community very long resident in Kingston. There were some rather unruly proceedings; notably that the members positively refused to appoint a Vice-President and more scrupulous order might have been maintained had the Governor presided as before. Amongst the laws passed, is one authorizing whipping for the practice of "Oheah," which "sub rosa" is still very prevalent, and proves how little comparatively fifty years of freedom and Christianity have yet served to eradicate this heathenish belief, and what is still more sad to contemplate, is that many respectable and educated people apply for assistance to the Oheah man. Our member for St. Thomas and Portland named William Andrews, a lawyer spoke and voted against the flogging as degrading to human nature, and so forth; but

fortunately the other members held a different opinion. It is known that Oheehism has caused many deaths by poisoning, surely flogging is not too severe for the perpetrators of such a crime. At home it was only the "cat-o-nin-tail" that stopped "garrotting," and were it lawful to use fire-arms against burglars who have broken into your house, I am sure there would be fewer burglaries. Flogging is also to be administered for crimes against the person.

Education has been made free, and may become compulsory in certain towns, or places if it is so proclaimed by the Governor, the result has been a large increase in

SCHOLARS.

To meet the education expenditure an extra house tax has been imposed which of course is not popular. There were some unpleasant scenes also over the railway extension; now that it is too late, the mistake of having handed over the railway to an American Syndicate and Improvement Company is being found out, and when we shall hear the last of it "no fellow can tell." A Major York, R.E., railway expert has been sent for, and is now reporting on the two completed sections, and the Americans have had an expert on their own account. The colony is still responsible for the £700,000 due on the old Government Railway on which interest has to be paid out of general revenue, and can only be paid off gradually by a Sinking Fund; Jamaica sold the railway, which was paying well and doing better every year for £100,000 cash and £700,000 visionary secondary Debentures; the interest on which is not payable until 3 per cent has been paid on the first Debentures representing the capital expended on the new line. The Government has guaranteed this three per cent, so that until the line pays that return it will have to pay the interest on the new line, as well as on the old as above stated; and it seems a bad lock-out. Jamaica, has as it were given away a paying railway, which it could have retained, and have made the extensions, by employing Contractors like David Reid, on capital easily borrowed in England, at 3½ per cent on Government Guarantee.

The Governor, Sir Henry Blske has had a very sharp attack of quinsy, his throat had to be lanced several times: he is now convalescent, but the doctors have ordered him a sea voyage, so he is leaving very shortly via New York, and will only be at home a few days, waiting for the first Royal mail steamer. Lady and Miss Blake remain in Jamaica. Major-General Black C.B., will act as Lieut.-Governor; he is the officer who commanded the party of H.M. 24th Regt., which recovered the colours, after the death of Lieut. Coghill and Melville, who it will be remembered so nobly saved them after Isandhlwana. W. S.

RAMIE IN JAVA.

Mr. B. S. Rairden, U.S. Consul at Batavia writes as follows on this subject:—Ramie imported from China, is grown in Java and cultivated on the same principle as paddy. The temperature of the climate where it is cultivated is about 70 degrees in the summer months—from November to April—and 60 degrees in the winter months—from April to November. There is only one crop a year, grown during the rainy season—from November to April. Before sowing the seeds, which is done usually in December, the soil must be well dressed with manure. The seeds are sown on the top of the ground and covered with mats, which must be kept well watered, so as to be always damp. As soon as the seeds have taken root the mats are removed, and the plants are allowed to grow till

about ten inches high, when they are transplanted about six inches apart. After being transplanted the ground must be kept moist, and this is done by inundation, as with paddy. After nearly four months the plant is gathered (cut near the ground), dried and packed in bales of 60 to 100 pounds in weight and is used for making ropes and twine. As far as I can ascertain there is not enough grown for export, and the bales are only roughly packed for transportation through the island. This is done by hand as is also the rope-making.—*L. and C. Express.*

THE WEST AFRICAN OIL TRADE.

In a recent report on the botany of Sierra Leone Mr. Scott Elliot says that the export of palm oil and kernels forms by far the largest part of the West African export trade. In 1890 the value of the palm oil exported from Sierra Leone was £13,599, and of the palm kernels £107,827. The tree is more abundant further down the West African coast, and appears to prefer alluvial, often marshy ground near the sea. It particularly seems to thrive on the rich soil of the mangrove accumulations. There are large numbers of palm trees in the Mahela district, where a factory once existed, and there are also a considerable number up the Scarories River and in the lower part of the Limba district. It grows also on low sandstone or gneiss hills, but probably does not produce so much in such places as on the low-lying, rich alluvials. The palm is propagated from the offshoot that appear at its base, and these are said to begin in the second or fifth year, and in full bearing about the 10th to 15th year. They continue producing for 60 years. A single tree yields from one to three gallons of palm oil, or, according to Semler, 16 litres annually, and this amount of oil will give from one-sixth to half a hundredweight of kernels. This would be a profit of from 2s to 6s a tree per annum, as about 300 gallons of palm oil give a ton of oil and about 2½ tons of kernels. Hence plantations of these trees should be profitable in time. It is, however, exceedingly difficult to get any trustworthy information, and the above, Mr. Elliot says, must be regarded as very approximate. The palms require no care and are not, apparently, attacked by any injurious insects. The preparation is of a very rough and makeshift character; the fruits are thrown into a tank and left till decomposition begins. They are then boiled and afterwards pounded in a mortar. Probably 25 per cent of the oil is lost in preparation.

FUJI CIGARS.

The exportation of these in large quantities has commenced, Mr. Sketchley having shipped a consignment of 25,000 to Sydney by the s.s. "Rockton," on Wednesday last, to test the market there. In addition to this, a standing order for 10,000 a month has been received from London, to initiate which trade, a parcel of 20,000 will go forward by next opportunity.—*Polynesian Ga. ette.*

PLANTERS' AT LAW:

A TEA MANUFACTURING DISPUTE.

An action which has been raised in the District Court of Badulla and has been fixed for trial on the 24th inst. is at the instance of J. H. B. Cockburn, Badulla and G. E. M. Nuttall, Bogawantalawa, proprietors of Hopton estate, Madulsima, against J. M. Mason, Yspama in Lunugalla for R843-19 being the amount of loss they say they sustained in consequence of the defendant who had agreed to manufacture their Hopton leaf at Keenagoda factory, having in December 1891 forwarded to their agents in Colombo (the Commercial Co.) 5,940 lb. of tea inferior in quality and other than Hopton which when sold in London

in January, February and March 1892 realised only R2,791-80 whereas their shares of the tea manufactured would have realised R3,634-99. They therefore claim the R843-19 as the difference between these two sums. The defendant denies the agreement as stated and says that there was at the end of October 1891 due from the defendant to the plaintiffs 4,729 lb of tea. By letter dated 4th November the first plaintiffs on behalf of the plaintiff's requested the defendant to despatch a break of tea as soon as thereafter as possible to them. Accordingly on the 10th November he delivered into carts at Keenagoda 5,940 lb of tea for the plaintiffs of which they took delivery knowing that it was in excess of the amount due to them. He denies that that tea was shipped to London by plaintiffs' agents or that the plaintiffs share would have realised R3,634-99.

TEA PLUCKING AND PATENT PLUCKERS

(From a planter.)

I saw a statement from—of Dikoya to the effect that in the fields he used Thompson's Clippers his plucking for the year showed a saving of 5c per lb. of made tea. There is a rumour that another Clipper is coming out—that is to knock the other one clean out. What I have seen of it shows the idea to be good, but I fear it will be expensive. Thompson's Clipper is far too dear: R6 for one. A cooly has to pluck a lot of leaf extra to make up for the price, viz R6, and has yet to be proved if a flat bush gives more leaf than a conical one.

THE BRITISH NORTH BORNEO COMPANY,

PLANTING PROSPECTS.

The twenty-first half-yearly meeting of the shareholders in the British North Borneo Company was held on 4th inst. at the Cannon-street Hotel, Mr. R. B. Martin, M.P. presiding. The Secretary (Mr. Benjamin T. Kendersley) having read the notice convening the meeting.

The Chairman in moving the adoption of the report and accounts stated that by the deed of settlement a shareholder holding less than ten shares was not entitled to be present at the meeting or to vote at a poll. The directors had no desire to keep the shareholders from the meeting, but as long as the law stood as it was at present it was their duty to acquaint the shareholders with it, so that there might be no misunderstanding. During the past year events in North Borneo had been progressing in a manner not altogether to the disadvantage of the company. They were still passing through a serious crisis in the East, but they had managed to hold their own. The receipts fell in 1892 by \$51,000, compared with those of 1891, but the expenses had been reduced by no less than \$82,000. He feared, however that they could not reduce the expenses further. They were now within measurable distance of seeing the scheme for telegraphic communication between this country and Borneo practically completed. Owing to the depression in the East their land sales account had naturally fallen off considerably, and, in fact, so sharp had been the crisis that many tobacco estates had been abandoned. The proposed extra duty of 1 per cent per pound on tobacco would make a considerable difference in their revenue if the profits on the tobacco trade proved to be anything like what was expected. Another product to which considerable importance was attached was coffee, which grew well and strong there, and seemed to be able to throw off the disease which caused the destruction of the coffee estates in Ceylon. The timber trade looked promising, and their experts and surveyors were finding gold which experience wou

to show was of good quality, and therefore, they did not despair of becoming in time, and in a small way a gold-producing country. To those who had invested their money in Borneo it must be disappointing to find, year after year, that the prospects were more or less good, but that dividends were altogether absent. They were unable to declare a dividend, and they were also unable to promise that a dividend would be an event of the very near future. On the contrary they were financially, in very low water, and it was his duty to inform the shareholders that, although, owing to the arrival of an unexpected remittance, they were in a better position than the accounts showed, yet the time might very possibly come when they would require to make another call upon them to keep sufficient money in hand for emergencies. The call, however, would not extend to more than £1, and would be spread over some considerable time. They had from time to time, with fairly successful results—results that promised to be even more successful in the future—advanced money to different trading concerns in Borneo. He would like the shareholders to study as far as possible the comparative statements and accounts which were appended to the report. They were very instructive because they showed the progress of the Colony more than could be shown by any words. They would see that the reductions and expenditures were spread very fairly over all items, the largest reductions being in the Constabulary and some of the European employes. Nothing had been more painful to the directors than to be under the necessity that they had been during the past year of dispensing with the services of men who had gone out to Borneo and served them well and faithfully in a trying climate. With regard to the paragraph about the railway on page 4 of the report, there was no disparagement to the gentlemen who had the preliminary concession. He did not think it at all surprising that they had not been able to carry the scheme to a successful issue during the last year or so. He knew of no new enterprise during that period which had been successfully accomplished, and it was not to be wondered at that this should be among those that were absolutely abortive. At the same time there had been an expression of feeling conveyed to the directors from the shareholders that the scheme was on too large a scale, and that in giving away so much territory as they did, they were buying enterprise rather dearly. Be that as it might, the directors were prepared to complete their share of the transaction providing the railway came into being, but at the present time it seemed unlikely that it would be carried out. From fresh sources, however, there were proposals for smaller light railways as through communication to open up certain definite tracts of country. The directors were anxious to do all they could to open up the country. In conclusion he moved that the report and accounts be adopted.

COFFEE AND COCOA IN JAVA.

Ceylon has just been favoured with a few weeks' visit from Mr. Dorrepaal who has been twenty years' resident in Java without any change home to his native Holland. During that time his work has been on a plantation only about 600 feet above sea-level, and indigo, coffee and cocoa cultivation has been his chief pursuit. Our visitor has been much pleased with all he has seen in Colombo, Kandy and Galle and a visit to the Peradeniya Gardens and another to Pallakelle estate, Dumbara, have much interested him. Cocoa planting is rapidly spreading in Java, and he also speaks favourably of Liberian coffee which does exceedingly well in the plantations where leaf disease had practically killed out *Coffea Arabica*. The Liberian is usually topped at 6 feet high and it then crops well. Mr. Dorrepaal has nothing good to say about cinchona in view of the low prevalent prices for a

long time past and the poor prospect. In the East of Java nearly all the new plantations have Arabian coffee and are cropping very well. He speaks well of the land taken up by Mr. Fairweather and other Ceylon planters and thinks coffee should bear very good crops upon it and that cheap good labour can be commanded from Javanese and natives of the neighbouring islands.

Our visitor has favoured us with the following translation of an extract from the latest number of the *Indische Mercur* in confirmation of what he has told us about Liberian Coffee:—

"In many parts of Java, where the plantations of Coffee Arabica seem to become less profitable there will be a better future by planting Liberian Coffee, because this species does not want such a rich soil and climate and does not suffer so much from the blight. Till at present, the Government has not done much in planting Liberian for their own account, but seeing the good results, private planters were getting with Liberia Coffee, it proposes now to give a great extension to that culture. Up to present time only 2,800 acres are planted by the Government, and the Javanese are extending for their own account also greatly that species."

On this our visitor remarks:—"Number of coffee trees, *Coffea Arabica* and Liberian planted by order of the Government 88,850,400—1891-92. Free Javanese plantations the crops of which must be handed to the Government (being then free from all taxes) for 15 fls. per picul, 193,363,800—these figures speak volumes, the Javanese would not plant on this condition if they did not have a fair profit. And the free plantations are increasing every year."

In an American paper there is a long article on "Coffee in Java," which we have had the privilege of submitting to our visitor and now append with his remarks on each paragraph:—

THE JAVA COFFEE INDUSTRY.

The present system of coffee cultivation in the Netherlands, India, is unsatisfactory. There is a growing disposition to replace the monopoly in cultivation enjoyed by the Government by a system of free cultivation by planters.

[I agree there are some parts of Java, where it would be better to abandon Government coffee culture and I am sure that the present Minister of Colonies and Governor-General, both very clever men, assisted by a most clever staff of officials, headed by its Vice-President of the Council of N. India, Mr. Groenewaldt will manage these affairs better than formerly was done. It is not burdensome where the soil is good and yielding good crops. Many Javanese plant on their own risks and perils (monosocco) and are getting fair profits. In those districts where coffee arabica exhausted the soil, Liberian coffee will yield a fair and paying crop to the Javanese planters. As regards quality I only refer to what is said in the brochure of the *Indische Mercur* where very fine qualities are named. The great consignee of the Government, the *Nederlandsche Handelver*, writes—the coffee of the Government sold in public auction in 1892 (crop 1891) was of very satisfactory quality, only a few parcels were somewhat inferior.—*Cor.*]

The present plan is burdensome to the natives subject to compulsory coffee cultivation and fails to develop the highest state of the industry both as regards the quantity and quality of the bean. Various plans have been proposed, but none upon which all interests are inclined to unite. It is also believed that a radical and sudden change is impracticable and that reform must come gradually. At all events it is evident that the old system has served its time and purpose and that coffee cultivation in the Dutch East Indies must be put upon the same plan it is in Brazil, U. S. of Colombia, Central

America, Mexico, or other country where the industry is left almost wholly to the free action of planters.

[I don't agree that the old system has served its time. If properly managed the Government could still have beautiful crops and great revenues from it. And I am sure it is better for our colony that these profits come greatly to the Government, that is to say to the whole community then and remaining in the Colonies than to fill exclusively the money bags of foreign shareholders draining the capital from Java exhausting the soil and abandon the enterprise when it does not pay more. There is for the capital still a great working field in Java except coffee. I now only name cocoa, sugar, kerosine, &c., and all should be right if the writer in the American paper could offer to the Government a perfect good working scheme of new taxes, balancing the revenue of the coffee. But I think as long as the Javanese is not changing in character a habit he will prefer selling coffee for 1/5 per picul coffee to the Government, then paying a money tax.—*Cor.*]

The profits of the Dutch Government have dwindled, partly owing to the exhaustion of the soil. In some districts there is free cultivation and direct taxation, and this plan is likely to be extended.

The Financial Minister has pointed out the difficulties growing out of fixing an arbitrary uniform price for coffee whether grown on the Crown lands or on private property, viz., 15 florins (\$6 00) per picul, (133 lb.) Very difficult indeed to manage, because one man having an acre of good soil might get from that 5 piculs at R15 which would be a good return, whereas a man with the same extent of land but not so good soil might only get 2 piculs which would not pay his labour.—*Cor.*]

As both the suitability of the ground for coffee growing and the conditions of labor vary throughout Java, a fixed price below the market value must inevitably press unfairly on some growers, and render cultivation unprofitable in some parts of the island where a land tax in proportion to the net produce might have had an opposite effect. Furthermore, in cases where the harvest does make such a price remunerative, it is a question whether less labor might not have been employed with advantage, than has hitherto been the case, for it is a generally accepted maxim in agricultural matters that when a certain point is reached the application of additional labor and capital does not lead to a proportionate increase of production. In coffee cultivation, moreover, there is the special condition that the quantity and quality of the crop depend to no small extent upon the time and care bestowed upon the gathering of the fruit, and it furthermore depends upon the price obtained how far this time and trouble are remunerative. Another difficulty made very evident by the report of the commission appointed to investigate the matter is the fact that as the coffee plant only comes into bearing in its fourth year, the capital and labor expended are meanwhile unproductive, a state of things rendered particularly unsatisfactory in the case of the native, who is usually entirely destitute of capital or ready money, and consequently has to borrow, if possible. To assist this class it has for some years been the practice of Government to give special advantages for the growth of "intermediate" crops, *i. e.*, crops grown between the rows of coffee plants; but this system has again certain disadvantages. The fact that land suitable for coffee cultivation is no longer to be found in the neighborhood of the village causes the crop to be looked upon as an auxiliary one where the cultivator has other resources to depend upon. During the four years that a planter derives no income from his coffee he devotes his attention to the cultivation of indigenous crops, and ends by regarding these as his principal source of income, the coffee being entirely subsidiary. So that a man may plant as few as fifty trees annually, thus leaving himself ample time to grow other crops. The case of the free coffee farmer is entirely different; he plants not by tens, but by hundreds and thousands. Coffee planting is his principal business, occupying all his time and

resources. To work any coffee plantations of importance he must either have large means or good credit to tide him over the four years of waiting for the first full coffee harvest.

[This all would be true if the Javanese coffee planters had no other revenues. He is generally proprietor of gardens, dry and wet rice fields etc.; dry rice fields are named gogo, if irrigated, sawah.—*Cor.*]

A hardship in the case of the native planter under Government, mentioned in the Indian reports, is that he bears all risks, so that should any planting that he may have undertaken by superior orders fail, then all his labor is lost. According to a witness well able to judge of practical results, losses seldom become apparent, because, as yet, they only affect the native population. Such cases may, no doubt, be alleviated by the before-mentioned facilities for growing "intermediate" crops. A fourth charge against the present system of coffee cultivation is that it is imperfect. Although there is some diversity of opinion as to details, the most advanced experts agree that great errors are committed in an agricultural sense, which have resulted in a great deal of unproductive labor from the agriculturist. The soil becomes exhausted and nothing is done to restore its fertility, while in clearing ground for coffee cultivation no allowance is made for the requirements of climate and rainfall.

[True, but almost the fault of too zealous sub-officials, but when those are properly superintended it should not be possible.—*Cor.*]

The majority of the commissions, while acknowledging the objections to a uniform price, say that there is practically no way of escaping it. All proposals made in a contrary sense must in their opinion fall when confronted with difficulties which they consider insuperable. They therefore confine their recommendation to raising the price of coffee from 15 to 20 florins in addition to giving the planters other advantages, such as facilities for growing "intermediate crops, and advances in the security of the harvest for the current year; the choice of land and the system of cultivation to be left practically free, and after five years all compulsory planting to be abolished.

Other plans than those recommended by the commission have been proposed, but are not received with favour. They include granting a bounty to planters above the purchasing price, and under certain conditions a remission of taxes.

One plan which is much advocated by the Director of Inland Affairs and approved by the Governor-General is to concentrate the area of Government cultivation to certain districts (complexen), so that they may no longer impede the development of free industry.

The Indian Government does not consider this project as regards districts feasible, although it desires to see the system of granting subventions in money on farms under Government introduced universally, even at the cost of lowering the purchasing price to 13 florins or 14 florins per picul, against which there are weighty objections. The subvention should also be granted to anyone who will plant coffee voluntarily on land and according to a system approved by the authorities. The native preferring to plant according to his own system should be free to do so, however, on the old terms.

If the cultivation of coffee is to be adopted as a national industry, the Council are of opinion that Government cultivation should be gradually restricted, and free cultivation on a larger scale encouraged, a measure which would not only increase the revenue by producing a directly taxable commodity, but appreciably advance the welfare of the people. As a beginning, the Council would like to see the principle adopted of relinquishing the system of compulsory supply, wherever it can be done without very great difficulty or increase of police precautions.—[It is also my opinion that this is a good way to lead this affair.—*Cor.*]

COCONUT PALM WEEVIL IN BRITISH HONDURAS.

(Continued from page 120.)
(From Kew Bulletin for March.)

The destruction of trees on Mr. Baber's plantation amounted to nearly 40 per cent, that on Mr. Phillips's to be about 30 per cent (1,000 out of 3,500). Other owners have lost equally large numbers. But the amount of injury has not been uniform over the different plantations; Mr. Baber believes that although the weevil was abundant in Sittee River, they had not affected his plantations at Sraengo Bight or False Sittee at the mouth of the river.

V.—FEVER.—The coconut palms of Honduras appear also to suffer from disease, and disease of an obscure kind not due to insects. It is known as *fever*, and at present no accurate account has been given of its symptoms, nor of its prevalence, so that it cannot yet be accepted as a cause of the weevils' increase, but it must be taken merely as a hypothesis to be inquired into. From the little known about it, it appears to be allied to one or other of the diseases (if, indeed, they are not the same) observed in Demerara in 1875-6, and in Montego Bay, Jamaica, in 1891. Attention has been called to it in Honduras in a recent communication by Mr. Seay to the Colonial Office of which the writer has only seen an abstract. According to Mr. Hunter, 50 to 80 per cent. of the trees attacked by the weevil show signs of the disease at the top first. This may be merely a misinterpretation of the early signs of injury due to weevil-grubs before they have been noticed in the trunk, but the statement is of importance and should be confirmed or refuted.

VI.—OTHER INSECTS.—Another question for consideration is the possibility of other kinds of insects aiding or preceding the weevil in its work of destruction. There is no evidence whatever that such is the case in Honduras, if we except another species of weevil, but it is not so elsewhere. The Indian weevil shares its responsibility with two other beetles, *Xylotrupes gideon*, Linn., and *Oryctes rhinoceros*, Linn. both quite distinct in appearance and allied to the chafers. The latter, the Rhinoceros, Elephant or "black beetle" of the Indian planter, is a stout cylindrical insect about 2½ inches long; the head has no snout whatever, but is short and broad with small clubbed antennae, whose ends are formed of several flat plates placed side by side. Between the eyes is a fixed horn, like that of the rhinoceros, large in the male, small in the female. The legs are very strong, with stout shanks set on the outer edge with three teeth, binder end; they are harmless, and live in heaps of teeth, and five-jointed feet. The grubs are large, soft and curved, with six stout legs and a baggy rotting vegetable matter or the manure-like inside of decayed palm trees. The beetles are the destroyers, and attack the palm at night boring in at the base of the leaf-stalks till they reach the cabbage, thus forming holes which attract the weevils. They bite through the young folded leaves which become characteristically ragged, and may kill the tree by injuring the bud. Treatment consists in the removal or destruction of the heaps of rotting matter in which they breed, and in extracting the beetles from the holes in the trees with a barbed wire or beetle spear.

VII.—METHODS OF TREATMENT.—To a certain extent reference has been made to measures adopted against the ravages of the Palm Weevil. It is now necessary to discuss them in detail, and in so doing to keep in mind the ascertained facts of its life history, and the records of this and similar infestations. These measures will be found, as usual, to fall under two heads, those designed to prevent attack upon trees hitherto untouched, and those intended to save injured plants. The former are more important, for the latter in the opinion of many experienced men do not exist.

1. METHODS OF GROWTH AND CULTIVATION.—Care should be taken in the choice of sites for new plantations, and special attention paid to the avoidance of undue proximity to a cochon ridge.

2. PREVENTION OF EGG-LAYING.—The trees should be left as far as possible in the natural state, and unnecessary trimming either of fronds or of the fibres

avoided. It may be necessary to tie up the older fronds, and if they must be removed the stalk should be cut through sufficiently far from the stem to leave the sheathing base intact. It may be advisable to tar the cut stump if it is found to attract beetles. The value of leaving the tree alone is shown by a passage in Ferguson's *All about the Coconut Palm*, which is also quoted by Ridley:—"Scores of instances might be recorded where, till the trees were come into bearing, a red beetle was never seen, but, no sooner was the land cleared and the trees trimmed, then it made its appearance and became very destructive. On one property the trimming system had been carried on for years till, indeed, more than one-third of the original plants perished, before the estate was ten years old, and they were going at the rate of three trees weekly. The work of trimming was stopped for the reasons offered above; the loss of trees continued for some time afterwards, but at the end of six months it had entirely ceased. On another property beetle men had been employed for ten years, and trees were being constantly lost; from the day that the beetles were discontinued two trees perished within the month, and not another was lost in the subsequent seven years." And W. B. L. writes in the *Tropical Agriculturist* to the same effect:—"The red-beetle [*Rhynchophorus ferrugineus*] cannot penetrate the leaf imbrication, and, when the older ones decay in the course of nature, the stem has become too hard for its operations. A tree here and there may be lost from an accidental wound or from some defect in the fitting of the leaf sheaths, but it is only where the good taste of the planter has impeded him to trim the leaves that any serious damage has been done to a field. All the leaves should be left on the tree till nature disposes of them at her own time and in her own way. Nothing that can be done to a coconut tree above ground can be anything but injurious."

All wounds, whether made by accident or by insects, on the soft part of the stem, leaf sheaths or spike, should be at once dressed with a dab of tar mixed with sand. Holes should be probed with a "beetle spear" or hooked wire to extract insects which may have caused them, and then plugged with a tuft of fibre or dry grass dipped in tar.

The parts selected for egg-laying on the stem may be plastered with lime-wash, to which, when cold, there may be added, as an experiment, a small quantity of Paris-green (a deadly arsenical poison).

Tarring the stem will probably keep off the beetles, but should be tried with great caution till its effects on the tree have been ascertained. Mr. C. T. Hunter states that he has kept away the beetles by pouring tar on the leaf-spike and the leaf sheaths; he claims for this method that it does not injure the tree and that the effects of it last for some three years. Application of tar to the leaf sheaths would probably do no harm, but may not be necessary if they themselves afford sufficient protection by being left intact. It might, however, lessen any possibility of beetles creeping in to oviposit between loosely fitting sheaths. Such a remedy ought only to be tried on a small number of trees, so that the loss may not be felt if it proves injurious. Most disastrous results have before now followed the application on a large scale of an untried method of treatment to plants. Coatings of moist clay have been found useful in similar circumstances, and a composition which has met with success in Germany is Leinweber's, and is thus prepared: Five pounds of coarse tobacco are infused in a bucket half full of boiling water and allowed to stand for 24 hours. The vessel is then filled with ox-blood and one part of slaked lime and sixteen of fresh cow-dung are added (quantity not stated.) These are well mixed and allowed to ferment for two or three days in an open tub, and then applied to the parts requiring protection. It is particularly well suited for the lower parts of the stem.

It is not supposed that the above mixture can be successfully employed in Honduras, but it is given as an example of the class of compositions found to be of service. Coarse soaps and rank oils (whale oil) have also been of use.

3. **DESTRUCTION OF INJURED TREES.**—This treatment is the one most generally recommended, but it requires caution. An attacked tree should not be hastily cut before there are unmistakable signs, by the withering of the leaves and spike, that it is doomed. About the possibility of saving injured trees there is much dispute, but a certain number do survive the first attack, especially if low down in the stem, and in India it is found practicable to attempt their cure. It is useless to cut down any infested tree, unless proper steps are taken to treat it when felled so as to make it unsuitable as a breeding place. In fact it will be probably less harmful if left standing than if felled and neglected.

4. **CAPTURE OF THE WEEVILS.**—This plan has also been generally recommended, and is in some ways preferable to the last. It is attended with no destruction of trees, and is applicable to plantations which have not yet become seriously infested, whereas the felling of palms can only be resorted to when they are already injured. There are three ways of taking the perfect insects: on the wing or when crawling about; when lurking in the crevices of the leaf-sheaths and fibre; when attracted to baits.

The best way—that by which the greatest number can be caught with the least labour—is the last. It has been mentioned in the preceding section that the stumps and soft tissues—the split cabbage—of felled palms are most suitable for this purpose, because the weevils are attracted in large numbers to the fermenting sap, and can be easily collected. It has been proposed to sprinkle the stumps with Paris-green to kill the weevils visiting them. The experiment may be tried, but will possibly defeat its object, because arsenic is an antiseptic and may check the fermentation of the sap and its attractive odour.

The beetles can be collected into buckets and killed with boiling water. If they are apt to escape from the buckets these should be furnished with a tinced iron lid sloping down to a hole in the middle, so as to form a funnel through which the weevils can be dropped. As the weevils, like many other kinds, seek shelter by day, the stumps and other baits should be visited at different times, practically at daybreak, to find out when the insects frequent them most; and the stumps will probably last longer and keep fresher if protected from the sun with a slight covering of leaves and fibre, which can be removed to get at the insects. When no felling of palms is going on, other suitable baits are mangoes or other fruit crushed and allowed to ferment. It has been suggested to cut wild palms in the neighbourhood in order to catch the beetles visiting the stumps. This is open to the objection that these palms must be carefully destroyed or by becoming breeding places they will be more dangerous than if left standing. Now the practice of attracting the weevils to fermenting mangoes cannot, however carelessly carried out, increase their numbers. The search for weevils biding in the crannies of the palms is more suitable for Indian plantations, where the trees are regularly examined to catch Rhinoceros beetles and the Palm Weevil are taken incidentally. It is simply a question of convenience and the amount of labour involved. Observations may be made to see if there is any hour when the weevils can best be taken on the trees. The females are the important sex, and any means of capture which only takes males will not limit the numbers of the next generation. One advantage of the method of capture at baits is that it can be carried out by children and unskilled labourers. Attraction, by fire, into which the weevils plunge at night, has been tried in Asia, but the Palmetto Weevil, according to Summers, does not come to light.

5. **ENCOURAGEMENT OF INSECTIVOROUS ANIMALS.**—Till the habits of the weevils' natural enemies have been more studied, not much can be done in this way, and it is unlikely that there is at present any large destruction of insectivorous birds that requires checking. Mr. Hunter in the Report ascribed the immunity of his plantations to his keeping a herd of 190 pigs. The practice of letting swine forage is well known and employed in Continental forestry. They are greedy

devourers of such large insects and grubs as they can find on the ground or by rooting. Mr. Craig, another planter, states: "in a group four trees out of 25 were not attacked, found that those four were infested with black ants. Has tried to transplant ants, but failed; says the ants feed on the eggs of the beetles. Did not understand the various stages of insect life; did not know female ants; accidentally smoked some ants out of a tree five years old; the next year it was attacked by beetles and died."

6. **THE CURE OF INJURED TREES.**—This, though little tried in Honduras, has met with a certain amount of success in India. One method is to cut into the soft parts of the tree, and extract the grubs. This requires great skill, both in observing the early stages of the injury—for it is useless to try it on a tree whose leaf-spike is manifestly dying—and in the operation itself. It is preferable not to attempt to reach the grub, but to kill it by the injection into its burrow of carbolic acid, kerosene, or Paris green suspended in water, but there is a risk of injuring the tree in this way. All wounds should be properly dressed with tar. Another plan is to apply remedies to the head of the tree, which presumably are carried down to holes made by the grubs at the base of the spike. It is questionable whether these applications are not more of a prevention than a remedy. An Indian native method of destroying them "is to hang little bags of salt over the affected parts of the tree. Water is then poured over the salt, so that the brine soaks into the borings and drives out the beetle. It is believed that the latter will never return to a tree where it has been subjected to the above treatment." The above quotation from a recent report is intended to refer to the Palm-Weevil. It appears, however, to the writer that the plan is used for the Rhinoceros beetle.

Other applications said to have met with success in some persons' hands are slaked lime, kerosene and arsenic; the latter is perhaps the best, and should be used as Paris green or London purple, stirred up in water in the proportion of about 1 oz. of Paris green and 2 of flour made into a paste, to 10 or 12 gallons of water and sprayed into the head of the tree. If the plant shows signs of injury a weaker solution should be used. Lime deserves a further trial, and nitrate of soda might be used. None of the above methods should be tried on a large scale till they are proved to be harmless to the plant. Firing the head of the tree as recommended for "fever" has also proved a cure, but the palm is greatly weakened, and a further attack is thereby invited. Perhaps the method of pouring poison into the holes is the most promising; according to Mr. Seay it has already met with some success.

LABOR ON HAWAIIAN PLANTATIONS.

Among the questions involved in the proposed change of the present Hawaiian Government by its absorption in the American Republic, and which has brought out much comment, is the labor system on our sugar and rice plantations. If we rightly understand the American law, no contract made abroad for any class of laborers is binding in the United States, and a penalty attaches for every attempt to evade this law, which is designed to prevent the importation of foreign laborers of any kind whatever, skilled or unskilled.

Laborers on Hawaiian plantations come here under a verbal promise or a written engagement to enter into a three-years' contract immediately on arrival. These contracts are generally favorable to the laborer, and in the case of the Japanese, where a portion of the wage is paid to the consul, many of them close their term of service with a handsome cash balance to their credit. In fact, they return comparatively independent to their homes in Japan, which they left as poor men three years before.

As some of the existing contracts contain penal provisions, these will, in the event of annexation, require to be changed. This might be done readily, if a small advance in wages were offered. It would seem, then, that our labor system, as thus modified, might be made to suit the new order of things, without injury to the planting interest.

The plantations employ about 20,000 laborers, of whom at the present time only 9379 Japanese and Chinese are under contract, out of a total of over thirty thousand Asiatics residing in the Islands. Besides the above, many Hawaiians, Portuguese and others are employed under various forms of service, mostly as day or month laborers.

There is another system of service now being tried on several estates, which promise to work well, being based on the co-operative plan. A planter takes a tract of, say one hundred acres, more or less, and engages to plow, plant, cultivate and harvest for one-fifth of the sugar manufactured from it, less certain small charges. He is furnished by the plantation at cost with all the necessary tools, and agrees to provide all the labor that is required to work the tract assigned to him in the best manner possible. For each laborer in his employ, while the crop is growing, he receives from the plantation, say, ten dollars a month on account. When the cane is ground and the sugar delivered in Honolulu, he is credited with one-fifth, or whatever proportion may have been agreed on, of the sugar produced from his tract, which sum is equitably divided among all who have shared in the cultivation of the cane. This plan has been tried on several estates, and has worked well for all, though experience will doubtless show how it may be improved for the benefit of all interested. It is a system that can be readily adopted on any or all the plantations. The labor question will, therefore, adjust itself to any changes that may be required whenever annexation may take place, and without much, if any, loss to the plantations, and in the end both employers and employees will be the gainers, for time will show that annexation will be a wise policy, not only for every industrial interest here, but equally so for the United States.—*Planters' Monthly*.

HOW INDIAN NATIVE AGRICULTURE

Is watched over, controlled and encouraged under the Indian Revenue system is well illustrated in the annual Report to the Board of Revenue for the North-Western Provinces, thus reviewed in the *Pioneer* :—

With the extension of the canal system, the revision of the land-revenue settlements in many districts, and the growth of local rates and cesses, the public land-revenues have greatly increased during the last twenty years. But there is no evidence that the increase of these burdens on the land is disproportionate to its increased productivity, or that their collection is attended with increasing difficulty. On the contrary, the report indicates that, except in certain limited tracts where agriculture is depressed through special causes, the revenue comes in with ease, and the severer forms of coercion are seldom resorted to. The depressed tracts lie in the Agra Division, where a rise in the subsoil level, and consequent water-logging, has thrown thousand of acres out of cultivation. Large reductions of revenue have been made in the distressed districts, extensive drainage works undertaken, and money advanced to landlords and tenants. The low-water mark of depression has evidently been passed, but debt, insufficient capital, traditional extravagance, and the belief that the State will forego its claims if pressed hard enough, retard improvement in agriculture and the collection of the revenue. The Thakur landlords of Mainpuri are thus described :—"Nearly all are heavily involved in debt or litigation, and have spent their rents in staving off the most urgent demands of their private creditors, in contesting suits, or in marriage expenses, there being quite an unusual number of marriages this year. In short, the State has come to be looked on as the least pressing of those whose demands have to be met and the one to whom payment can be deferred for a more convenient season. It is clear that no remissions or reduction can ensure the punctual payment of the Government demand when the proprietary body is determined to make default and wilfully misappropriate all assets that it can lay hands on." If this description be accurate, and its accuracy is accepted by the Commissioner and the Board the administra-

tion of the district must indeed be arduous. On one side is the Scylla of leniency: on the other the Charybdis of coercion. Elsewhere the land revenue came in easily, and the harvests and the condition of the people were generally good. It is satisfactory to notice that in districts where the land revenue has been revised and greatly raised, the demand was paid without difficulty. The returns of the Director of Land Records enable us to ascertain with close accuracy the incidence of the State land-dues and the proportion in which they stand to the gross rent. Including cesses and patwari rate, but excluding canal dues, which are virtually payments for value received, the State demand on the land amounts to 527 lakhs in the N.W. P. and 153 lakhs in Oudh, or 680 lakhs in all. The area occupied by landlords and tenants aggregates 36 million acres. The incidence of the State demand is thus Rs 1-13 per acre, being Rs 2 theore in the North-Western Provinces and Rs 1-10 in Oudh. Of the 36 million acres, 8½ millions are shown in the village accounts as paying no rent, being for the most part cultivated by the proprietors themselves. The recorded rental on the remaining 27½ million acres amounts to 1,201 lakhs. The corrected rental of the Province is, therefore, considerably more than double the State demand, including local rates of every kind.

COFFEE CULTIVATION.

CLOSE versus WIDE PLANTING.

Says our contemporary *The Queenslander* :—As a large number of the cultivators of the soil in Queensland are thinking seriously of devoting some attention to coffee growing, the following information elicited at a meeting of fruit growers at Wellington Point lately will be read with interest. Mr. Gilbert Burnett asked for information about the distance apart coffee trees should be planted, as he intended to plant a few acres. He had made inquiries through a merchant who was informed by a planter that, in Ceylon, coffee was planted 6ft. by 6ft. apart. From what he had seen of the habits of the plant in Queensland he rather doubted the accuracy of the information. Mr. Sonter stated in reply that the coffee plant required space according to climate and soil. In rich soil or flats, Ceylon coffee had been planted 15ft. apart and Liberian 20ft. apart. From his own experience here he found 12ft. by 12ft. sufficient space. Here the coffee plant wanted plenty of shelter, and if planted close it would protect itself. He found that in Brazil, coffee was planted 12ft. by 10ft. with very satisfactory results. He had plants in the Acclimatisation Society's grounds, which were sown and grew in but poor soil four years ago, 9ft. apart, and the branches of which were touching each other, and now bearing berries. Mr. Cowan said he thought the information obtained from Ceylon by Mr. Burnett was correct, because in that island coffee trees were planted principally on the hill sides and slopes, not on flats, and being so thick protected themselves. He believed in close planting as he had seen it in the West Indian Islands as on the slopes the heat was especially severe, and being closely planted the trees protected the roots by their shade. Coffee trees threw out an immense mass of surface roots.

A NEW TEA BREAKER.—We received from a Terai planter a very good account of a new tea breaker, the invention of Mr. H. Sabow, the well known Kurseong Engineer. Since using this breaker, the planter informs us, he has made 40 per cent less Fannings and Dust than with his former machine. Mr. Sabow's breaker costs Rs250—*Indian Planters' Gazette*, July 8.

THE EGGS of the Algerian locust have been found to yield a thick oil resembling honey in appearance. It burns well, and makes good soap with alkali. As large quantities of these eggs are collected by the natives in order to destroy them, it is proposed to extract the oil for industrial purposes.—*Standard*.

CEYLON HIGH-GROWN AND FINE TEAS:

A CORRECTION AND INTERESTING INFORMATION FROM MR. ARTHUR THOMPSON.

We direct special attention to the letter which Mr. Arthur Thompson (of the well-known Mincing Lane firm, Messrs. W. J. & H. Thompson) on page 180. We regret very much that Mr. Thompson should, through a misconception, have been credited with a suggestion which he never made; and the strange part is that the statement of this suggestion as a fact, originally published soon after Mr. Thompson's visit, was formally repeated by being made the text for an editorial in our *Tropical Agriculturist* of Dec. 1887, and has never, until now, been contradicted or corrected. However, we can readily see how the misconception arose in the first instance and, as Mr. Thompson explains, there is no virtue in a mark now, unless backed by undoubted quality. The testimony afforded in the letter before us to the better paying results, in the long-run, from going in for quality rather than quantity, should receive attention especially in view of the possibility of the difference in value between ordinary and fine teas being accentuated more in the future than it has been of late.

COFFEE IN MEXICO.

A syndicate of American capitalists has purchased the San Marcial coffee plantation, situated near Cordoba, in the State of Vera Cruz, (Mexico) the prices paid being \$160,000. There are 550,000 coffee trees in production on the plantation and 100,000 nursery plants of various kinds. It is stated that although Olaus Spreckels' name does not appear in the syndicate he is heavily interested in the enterprise.—*Merchants' Review*.

—An American who has recently made an extended tour through the coffee districts of Vera Cruz, Mexico, has the following opinion of its capacities: "The great bulk of these lands could be put in coffee, and when in coffee plantations their value is almost inestimable. To illustrate the value of these coffee plantations, I will take 100 acres which can be purchased for 500 pesos, or about \$375 in American money. Each acre can be planted in 1,000 trees. After the third year each tree will produce a pound and a half of coffee on an average of 1,500 pounds to the acre, or for the 100 acres, 150,000 pounds, worth \$37,500 on the spot. After five years the plantation will produce 3,000 pounds to the acre worth \$75,000 in Mexico. In the interim the spaces between the coffee rows can be planted in bananas, corn or beans bringing from this source a revenue early sufficient to maintain the property."—*Rio News*.

IS VANILLA A PARASITE?

Some time ago Mr. Geo. N. Beringer, of Philadelphia, asserted at the college there that vanilla is not a parasite, and he expressed his astonishment that such an authority as the *Encyclopedia Britannica* should have perpetrated that mistake. This touches Mr. E. M. Holmes, no doubt, for he was the writer of most of the drug-articles in the *Encyclopedia*; it also touches Mr. C. E. Hires, of Philadelphia, in respect to the fact that Mr. Beringer started his remarks from a circular issued by Mr. Hires's firm. Mr. Hires did not succumb at once, but wrote to two Mexican firms—Messrs. Montessoro & Scagno, of Gutierrez Zamora, and Mr. L. S. Silvers, of Papantla—who reply (we quote from the *Pharmaceutical Era*) that they have often cut the vanilla-plant 5 or 6 feet above the root, and that it lives from the sap of the

tree after the root is cut for two or three years, but by that time its rootlets grow down to the ground again, the plant bearing flowers and fruit during the whole time. On the other hand, when the tree upon which the plant attaches itself dies, the plant fails to propagate and will soon show decay. While admitting that his knowledge of the vanilla from the islands of the Indian Ocean is not as full and as ripe as that of this Mexican, Mr. Hires adds that all information received on the subject warrants him in stating that the cultivated and wild plants bearing fruit in these countries take their sustenance and life from the sap of forest-trees.

COFFEE LEAF-TEA.

Mr. A. J. Slaney, of the National Wholesale Tea Supply Association, writes under date June 30th, and accompanying his letter is a specimen of the leaf:—"We purchased in Thursday's Ceylon tea sales two small lots, we believe the first substitute for tea made from coffee-leaf imported into England. It does not yield a very agreeable drink when prepared after the fashion of ordinary tea, but on making experiment we find by another process it yields a highly characteristic, yet, withal, exceedingly pleasant beverage. We have decided to offer it to the trade in parcels value 5s each, containing packets made up in attractive form, giving thereon instructions we recommend for use."—*H. and C. Mail*.

BANANAS IN FIJI.

Appended is an estimate of the result of the cultivation of 40 acres of bananas in four years. After that time, if the disease appear, not at all a certainty, the returns decrease, but a good profit in cultivation can be looked for another two years. [No explanation is given of the disease.—*Ed. T.A.*]

Estimate of cost of planting and cultivation of 40 acres of bananas and returns for second, third and fourth years.

EXPENDITURE.		£
1st Year—Plants 12,000 at 40s		24
Houses ..		20
Tools, &c. ..		20
Five Labourers at £10		50
Food ..		50
Overseer ..		100
		£264
2nd Year—10 Labourers at £10		100
Food ..		100
Overseer ..		100
		£300
3rd Year— ..		300
4th Year— ..		300
Total for 4 years ..		£1,164
Freight 60,000 at 20s per 100		600
		£1,764
Profit ..		£1,236
RETURNS.		£
2nd year 20,000 at 1s		1,000
3rd year " "		1,000
4th year " "		1,000

N.B.—The only actual outlay is for the first twelve months. The second year's produce shows nearly 100 per cent on cost for the two years.

The foregoing is a very fair and moderate estimate. A sufficiency of labor is provided for, also of plants calculated at 300 to the acre as it is not desirable to plant too close. The returns are calculated at a low average, some plantations on the Rewa and Navar having cut 600 bunches per acre per annum. The present estimate is at 500 only. The price is that ruling in Levuka at present, but large contracts were made in Suva for 1s 3d and 1s 6d per bunch delivered f.o.b.—*Polynesian Gazette*, June 17.

HANDBOOK TO THE FLORA OF CEYLON:

By DR. H. TRIMEN, M.B., (London.)

F.R.S., DIRECTOR OF THE ROYAL BOTANIC GARDENS,
CEYLON*

We welcome heartily the first part of this valuable work of our learned Director. It is a work that has long been wanted, but to which very few men could or would devote themselves. Only a botanist can realize what time is required to perfect such descriptions of plants from the examination of numbers of specimens, as well as the labour or difficulty of collecting the plants. It is wonderful, though, how a trained native at last gets to recognize all the familiar plants, and with what glee he will bring his master a new specimen. The Handbook is to consist of four parts, and this one is accompanied by an atlas of 25 (quarto) coloured plates which are selections from the extensive series illustrating the Ceylon flora now preserved in the Library of the Botanic Gardens at Peradeniya. There are several thousands of these plates and they have been the work successively of three members of one Sinhalese family, employed on the Garden staff as draftsmen. The plates selected are beautifully executed as to work and colouring and correct in drawing and scientific detail and add greatly to the value of the Handbook. Being enclosed in a separate case they are easy of reference and handy for the study of any one plant. We hear they are not so delicate and reliable as to colour as the originals by the Messrs. de Alwis, but a more exact imitation would have been too expensive.

The plates for Part II are already half printed and Dr. Trimen is now sending home the MS. But, as he tells us, he is much interrupted; also he is hampered by want of books and specimens and will have to visit Kew and the British Museum before Part III can be properly done.

We can best give our readers an idea of the scope and intention of the work by quoting from the author's Introduction:—

One principal object of this Handbook is to enable observers in Ceylon to ascertain the name of any plant they may find growing wild. When this is arrived at, they are in a position to learn all that may have been written about it in botanical and other literature, to appreciate its relationships with other plants, to trace its distribution in other lands, and to intelligently investigate its properties and uses.

The analytic keys and descriptions here given for this purpose require for their use a general knowledge of the outside anatomy and structure of the principal organs of plants and of the terms in use for defining and distinguishing their different parts and modifications. This knowledge can be readily obtained from any elementary work on Botany, and is here presupposed. The descriptions are, however, as little technical as I can make them consistently with accuracy.

The book refers to Ceylon only. In the definitions of the Natural Orders and Genera it must be distinctly understood that the distinguishing characters here given for each group do not include the whole of those which belong to it, but such only as are shown by the species found in Ceylon. It is especially necessary to bear this in mind in using this Handbook for educational purposes; for it may so happen that the Ceylon members of a particular Order or Genus are more

or less exceptional, and in that case the definition given will be by no means characteristic of that group as a whole.

To a less extent this applies also to each species. My descriptions have been made wholly from Ceylon specimens, and will thus often be not comprehensive enough to cover the range of form exhibited in other countries. I have, indeed, throughout this Flora endeavoured to restrict all the information given under each species to it as a Ceylon plant only, excluding, as a rule, everything referring only to Peninsular India, Malaya, or other regions beyond our limits.

Concerning the "Plan of this Handbook," he writes as follows:—

"The sequence of the Natural Orders and Genera is that followed in all recent English systematic Flores, viz., that of Bentham and Hooker's 'Genera Plantarum.' For the species I have kept mainly to the 'Flora of British India,' with which important work it is highly desirable that this Flora should be in general accordance. When any deviation occurs from these standard books, attention is always drawn to it.

"After a diagnostic description of each Order there follows a brief Key for the rapid determination of its Genera; and fuller description of each Genus is afterwards given with a similar Key to its species. Each species is treated in paragraphs on the following plan:—

1. The Botanical Name (in Clarendon type) immediately followed (in Italic type) by a reference to the authority by whom that name was first published, with the date.

No Botanical name in the modern taxonomic sense can be of earlier date than 1753, when Linnæus first definitely published his binominal nomenclature.

The Vernacular Names when known (also in Clarendon type) follow, the letters S. and T. signifying Sinhalese and Tamil respectively.

2. References (in small type) arranged chronologically, to published books and papers where the species is treated of or noticed as a Ceylon plant, with any names (= synonyms) there given when different to the one adopted.

3. A reference (also in small type) to the 'Flora of British India' and to selected published Figures of the plant.

4. The Description (in larger type).

5. The general distribution in Ceylon and the comparative frequency (in small type); followed, in the case of the rarer species, by special localities.

The time of flowering and colour of the flowers.

6. The general range of distribution beyond Ceylon (also in small type).

Intercalated in their proper places among the species thus fully treated are certain other plants which are not natives of Ceylon, but have been certainly introduced by the agency of man, and are now met with in a more or less completely wild or naturalised state. The names of these are printed in Italic, not Clarendon, type, and the whole account runs on in a single paragraph.

The Appendices give us (a) Common Prefixes in the Vernacular names of Plants, Sinhalese and Tamil, with their English equivalents; (b) Abbreviations used in the description; and (c) a Sketch of the Climatic Regions of Ceylon.

Of course, the reader already grounded in Botany will be able to make most use of a volume of this description, and if any of our readers are stimulated by the publication of this work to commence the study of Botany, they will find the "First Book of Indian Botany" by Oliver, the clearest and most useful Handbook (locally procurable) to adopt. But to many others who may have no scientific knowledge of Botany, the publication cannot fail to be useful.

The descriptions of plants range from Ranunculaceæ to Anacardiaceæ. In order to show the style of the book we quote the description of the well-known Kina tree:—

* A Hand-Book of the Flora of Ceylon, Containing Descriptions of all the Species of Flowering Plants Indigenous to the Island, and Notes on their History, Distribution, and Uses. By Henry Trimen, M.B. (London), F.R.S., Director of the Royal Botanic Garden, Ceylon. With an Atlas of Plates Illustrating some of the more interesting Species. Part I. Ranunculaceæ—Anacardiaceæ. With Plates I—XXV. Published under the Authority of the Government of Ceylon. London: Dulau & Co., 37 Soho Square, W. 1893.

11. *C. Walkeria*, *Wight*, III. i. 128 (1840). Kina, S. Planch. and Tr. l. c. 263. C. P. 1170.

Fl. B. Ind. i. 275 (localities omitted). Wight, III. i. t. 45 (poor).

A very large tree, with a thick, straight, tall trunk and a rounded head, bark reddish-brown, thick, twigs quadrangular, glabrous; l. small, $1\frac{1}{2}$ —2 in., crowded, rotundate or obovate-oval or orbiculate, cuneate or rounded at base, obtuse, very stiffly coriaceous, lat. veins coarse, not prominent, petioles very short stout; fl. large, 1 in. diam., numerous, in axillary and terminal racemes forming together a large terminal panicle much exceeding the l., ped. $\frac{1}{2}$ — $\frac{3}{4}$ in., glabrous; sep. 4, inner twice as long; pet. usually 8, longer than sep., inner row smaller; stam. very numerous, slightly coherent at base; fr. globose, $\frac{3}{4}$ in. or rather more, apiculate, smooth, pale yellow mottled with brown.

Upper mountain zone in forests; common. N. Eliya; Adam's Peak; Ambagamuwa; Knuckles. There is a specimen from Moon in Mus. Brit. without definite locality. Fl. Jan.—April; whits or pinkish (not yellow as in Wight's fig.).

Endemic.

The well-known 'Kina' tree of the mountains, growing often to an immense size. The flowers are very beautiful and sweet-scented, and are said to be produced only once in 3 or 4 years. Wight's plate gives a very poor idea of this fine species.

Wood pale reddish-brown, hard, rather light, durable.

This is liable to very curious terminal galls which have been often mistaken for fruit; they are urceolate in form with a 2-tipped chink at the summit, and appear to be formed by the fusion and malformation of a pair of opposite leaves. They occur in other species also of this genus.

Dr. Trimen's Handbook is sure to be warmly welcomed in the world of botanists, and we trust it will have a fair sale among our countrymen here: Government officials, foresters, masters in public schools and the more observant of our planters should have it among their works of reference. An intimate acquaintance with the plant life by which we are surrounded adds much to the charm of life out here and well repays one for the labour of learning even the alphabet of Botany.

Since the above was in type, we have received from a friend, competent to treat on the subject, a very interesting analytical summary of generally useful information given in the Handbook. With this as a guide, we are making a series of extracts to embody in a second notice of a publication which really marks an important advance in the permanent and scientific literature connected with the island. Dr. Trimen's "Handbook to the Flora of Ceylon" is a work for all time.

(Second Notice.)

We now give the very interesting references to various parts of Dr. Trimen's Handbook furnished by a correspondent and to make the analysis complete, we have extracted the information in each case, so that Planters and others may be able to judge of the value of the work by the samples afforded. Our friend writes:—

The introductory part appears to me to give all that is required to make it very plain to even an ordinary reader. The Analytic Keys are so clearly given that it is very easy to tell at a glance what the Order or Genus is like. I believe it to be a most useful and interesting book for planters or other residents who wish to become acquainted with the plant life around them, giving as it so often does, such interesting particulars in a concise form, of their preparation, products and uses, as for instance the *Anemone* on page 3. There one is told that it is a pretty plant and is the only one of its genus that extends into the tropics, and persons who wish to send Ceylon plants home can learn that this is one which would not only be worth

sending, but could be successfully grown there. Another example is on (p. 93) where *Hypericum* is described as a remarkably ornamental shrub and, growing in the upper montane zone, would be a desirable plant for greenhouse cultivation in Europe; also *Hibiscus* p. 153 and the beautiful Balsam, *Impatiens Hookeriana* p. 208, and many others.

Then see the very valuable information that is given about the timber trees; and what Planter or Proprietor is there who is not interested in these. It not only enables you to find the proper and common names of the trees, but tells you the colour of the wood, whether it is hard or soft, durable, useful for building or other purposes. It also gives information when the fruit is good for food and the seeds for oil, &c., see

Michelia Nilagirica, "Wal-sapu S. (p. 15.)

"One of the best of the mountain timbers. Wood pale-brown, often somewhat greenish, fine-grained, strong and very durable. One sort is often called by carpenters 'Wal-buruta,' and distinguished from the ordinary 'Wal-sapu' by darker colour and greater weight. The 'Buruta' wood used for sleepers on the Nannu-oya Railway (see Vincent's Forest Report. par. 452 and note) was this, and not satin-wood."

Cratava Roxburghii, Lunu-warana S. (p. 59.)

"Much planted by the Tamils for the sake of its bitter leaves, used as a stomachic. Wood yellowish-white, fairly hard; used for making sandals."

Garcinia Cambogia, Goraka, S. (p. 95 and 96)

"The fruit varies extremely in the number of grooves, often as many as 12 and 13, and in the shape and depth of the lobes and their colour: one red variety is very like a large tomato. It is ripe in July, and is acid but pleasant; the rind cut into pieces and dried in the sun is much eaten by the natives, and is very palatable.

"Wood hard, fine-grained, greyish. The bark affords a transparent gum-resin."

Calophyllum spectabile, Dumba-kina, S. (p. 99)

Calophyllum tomentosum, Kina, S. (p. 101)

"This is the ordinary 'kina' of the lower hill-country, and its seeds afford orange-coloured oil, 'kina-tel' much used by the natives. Wood pale red, rather light, smooth."

Calophyllum Walkeria, Kina S. (p. 104)

Messua ferrea, Na. S. (p. 105)

"One of our most beautiful trees, and much planted, especially near Buddhist temples. The large fl. are deliciously scented, and the young leaves of an intense blood-red passing into the dark green of the adult growth through delicate shades of pink.

"The 'Iron wood' of the English. Wood very hard and heavy, dark red extremely durable."

"An oil is obtained from the seeds."

Ternstroemia japonica, Pena-Mihiriya S. (p. 108)

"Wood even-grained, pinkish-brown, rather heavy, durable; called by the carpenters in the hill districts 'Pena-mihiriya,' 'Rattota,' and 'Ratatiya.' The bark is chewed."

Eurya acuminata, Wild Tea, Eng. (p. 110)

"The habit and ionage of these species of *Eurya* are very like those of Tea, and young plants have been frequently mistaken for it, and even cultivated in nurseries. Hence the plant has acquired the name of 'Wild Tea' among the planters."

Dipterocarpus Zeylanicus, Hora S. (p. 114)

Doona Zeylanica, Dun, S. (p. 119)

"A characteristic tree of the lower hill-forests, now much cleared. The mode of branching horizontally chiefly at the top, and the preference of the tree for the crests of hills, which causes their outlines to stand out against the sky, gives the tree at a distance much the appearance of the Stone Pine of Italy.

"The timber is light, moderately hard, pale greyish-brown, durable, and greatly in request for shingles, whence the tree is often called 'shingle-tree.' It burns with a bright flame. An excellent colourless Dammar-like resin exudes from the trunk."

Vateria acuminata, Hal, S. (p. 131)

"A very beautiful tree, often planted for ornament. The stem exudes a clear yellowish (erroneously said to be 'green' in Fl. B. Ind.) resin abundantly, equal

to the best dammar. The bark is much used for checking the fermentation of toddy, and many trees are killed by being stripped. Wood light, rather hard yellowish grey. The seeds are ground into meal and eaten.

And many others in this family *Dipterocarpacee* *Hemitelia littoralis*, Etuna S. (167.)

Berrya Ammonilla, Hal-milla S. (173.)

Erythroxylon lucidum, Devadara S. (p. 191.)

"The juice of the leaves is a valuable anthelmintic and much used, especially for children."

Chicrassia tabularis, Hinlan-hik S. p. (252.)

"Wood hard, rather heavy, even, shining, brownish red, with rather large pores, durable. Much valued, and goes by the name of 'Chittagong wood' and 'White cedar' at Madras. The finely carved pillars in the audience-hall (now District Court) at Kandy are made of it."

Chloroxylon Swietenia, Buruta, satinwood S. (253.)

and others of this order *Meliaceae*.

Kokoona Zeylanica, Kokum S. (p. 270.)

"Wood pale yellowish-brown, smooth, light, readily splitting. The inner bark is of brilliant yellow colour, and is used by jewellers for polishing gold embroidery, and also as a snuff when powdered."

Schleichera trijuga, Kon S. (p. 304.)

"The 'Ceylon Oak' of the English, the foliage in the mass, especially when young, very much resembling that of *Quercus Robur*."

"The fruit sometimes bears sharp spines on its sides."

"Koenig states (in Hb. Banks) that the seeds excite vomiting; the pulpy aril is however, eaten. An oil is obtained from the seeds. Wood very hard, heavy, close-grained, pale reddish brown, strong and durable."

Sapindus emarginatus, Penela S. (307.)

and *Camposperma Zeylanicum*, Aridda S. (p. 326.)

"A handsome tree with fine dark foliage. Attains a great height in Knruwita Korale, and 6 or 7 ft. in circumference. In a few forests this is a gregarious tree."

"Wood white, smooth, rather light and soft, coarse-grained, of little use except for tea-boxes, for which it is said to be very good."

The common and useful trees, plants and shrubs that have become wild, though not indigenous, are also interestingly noted

see *Michelia Champaca*, Sapu S. (p. 15.)

"*M. Champaca*, L. (O. P. 1,023 is the well-known 'Sapu,' 'Hapu' or 'Champak' tree much cultivated in Ceylon, but nowhere native. It is considered wild in many parts of India and in Java, and is doubtless a very ancient introduction here. There are specimens in Hermann's Herbarium, and it is recorded in his Mus. Zeylan. p. 64 as 'Hapugabaha.' The very fragrant yellow flowers are produced in May, and much used for temple offerings. They are quickly followed by the fruit, which contains several somewhat angular seeds extremely like fragments of pink coral. The tree is well figured in Pierre's magnificent 'Flore Forestiere' of Oobiu Obina, t. 3.

Cananga odorata, Ilang-ilang m. (p. 22.)

"*Cananga odorata*, Hk. f. and Th., though not native, is so commonly met with in an apparently wild estate in the moist low country that it requires notice. It is a tall, quick-growing, straight tree with very large drooping strongly sweet-scented yellow flowers. It is a native of Burma, Java and the Philippines. The scent known by the Malay name Ilang-ilang is said to be obtained from its flowers. The tree is often called 'Wana-sapu' or 'Rata-sapu' by the Singalese."

Nasturtium officinalis, Watercress Eng. (p. 53.)

"*Nasturtium officinale*, Br., the common English watercress, has become naturalised in many small streams in the mountains, where intentionally introduced. The name 'Kakkuta-pala' has been given to me by Sinhalese for this, but by Moon (Cat. 13) this native name is applied to his *Anagallis esculenta* from Uva which is undetermined. The watercress is also given by Moon (p. 47) as found naturalised at Kandy."

Flacourtia inermis, Lovi Lovi (p. 73.)

"*F. inermis*, Roxb., is the Lovi-lovi, the red acid fruit of which is well known, and the tree commonly grown in native gardens; it is of Malayan origin."

Adansonia digitata, Baobab (p. 159.)

Very interesting particulars are here given of the tree.

"*Adansonia digitata*, L. (O. P. 1141). The Baobab trees at Mannar have long been well known, and are said to have been introduced by the Arabs. The tree is native to Trop. Africa. Roxburgh (Fl. Ind. iii. 164) quotes a letter from Gen. Hay Macdowell, written in 1802, describing one of these trees at Mantota (Mantai) nearly 50 ft. in circumference and stating that there were then many about that place. In 1890 I observed only a few there, on the site of the ancient city of Tirukettivaram, the largest stem measured being 48 ft. in circumference at 6 ft. from the ground. On Mannar Island itself are several dozen very conspicuous objects in the low scrubby jungle, and Mr. M. S. Crawford, c.c.s., gives the circumference of the largest stem (in 1890) as 61 ft. 9 in., whilst the tree is only 30 ft. high. The trees fruit freely, but though the seeds germinate well, no young plants are to be seen, being at once eaten off by cattle. The Tamil names for the tree are Pappareppuli and Perukka, and the Roman Catholics call it 'Judas' Bag' because the fruit contains 30 seeds. I have not seen naturalised trees elsewhere in Ceylon, but Moon (Cat. 49) gives Jaffna, and Thwaites (Enum. 28) says 'naturalised in the north.' There are specimens from Koenig in Brit. Mus. labelled by him 'in sylvis zeylanicis solo arenoso arido,' no doubt from Mannar and collected in 1781. Specimens from Gardner in Herb. Perad. are labelled 'Batticaloa(?) 1848,' and Tennent (Ceylon, ii. 627) mentions a large tree at Puttalam in 1848, which was destroyed a few years later."

"The pulp round the seeds is agreeably acid and is eaten with buffalo milk and sugar; the leaves are excellent fodder for cattle."

Egle marmelos, Beli, S. (p. 229)

Feronia elephantum.

"This is the 'Wood-apple,' of the English, the hard fruit of which is sometimes mistaken for that of the Bacl. The specific name refers to its common appellation in India, 'elephant-apple.' Pulp of the fruit eatable. Wood hard, heavy, yellowish white. Affords a good gum."

Canarium commune, Rata-kekuna S. (p. 240)

"*C. commune*, L., the Java Almond, *Rata-kekuna*, S., is not infrequently found as an introduced tree; it is a native of Malaya generally. The fruit is considerably larger than in *C. zeylanicum*, and the seeds form a good substitute for almonds."

"*Canarium Zeylanicum*. Whole tree fragrant when bruised. Abundance of a beautifully clear fragrant balsamic gum-resin, like the Elemi of commerce, flows from the bark; it is much used for fumigation, and also burnt for light in houses, mixed with sand. Hermann who spells the name 'Kakuriahaha,' notices the flow of gum Elemi. The oily seeds are eaten. Wood rather light and soft, even-grained, white."

Anacardium occidentale, Caju S. (p. 317)

"*Anacardium occidentale*, L., Cashew nut, is so completely established in the low country, especially in sandy ground near the sea, as to have all the look of a native tree. There are specimens in Hermann's Herbarium. The Sinhalese call it 'Caju,' an adoption of the name used by the Portuguese, who no doubt introduced it. The Tamil name for the edible part is 'Montirisa.' It is figured in Bedd. Fl. Sylv. t. 163. Its native country is Tropical America and 'Acaju' is the native Brazilian name."

and *Moringa pterygosperma*, Murunga S. (p. 327)

"*Moringa pterygosperma*, Gaertn. (*M. zeylanica*, Pers.) is much cultivated in native gardens and appears semi-wild. There are specimens in Hermann's Herb. (Fl. Zeyl. n. 155), and it is figured in Burm. Thes. t. 75. Well known as *Murunga*, S. and as 'Horse-radish tree' by the Euglish. The long fruit is much eaten in curries and the root is a good substitute for horse-radish, the seeds afford an oil. Native of Northern India. *Moringa* has a remarkable floral structure and forms of itself the small order *Moringaceae*."

Again it tells you what plants to seek for that are useful for food, medicine, dyes and various other economic purposes, such as *Coscinium fenestratum*, Weni-wel S. (p. 41.

"The wood is of a bright yellow colour, and is valued as a bitter tonic by the Sinhalese. It has been exported to England as a substitute for Calumba root and called 'false calumba' (see W. J. Hooker in Pharm. Journ. Oct. 1852). A yellow dye is also obtained from it."

Berberis aristata, Barbery Eng. (p. 49.)

"Wood yellow, hard. The root bark of this species is much used in India as a bitter tonic in fevers and an extract from the wood is there well known as 'Rasant,' and is found a valuable local application in chronic ophthalmia."

Nelumbium speciosum, Nelun S. (p. 51 & 52.)

"This is the Cyamus or 'Sacred Bean' of ancient Egypt, but is usually called the 'Lotus' by Europeans in the East. It does not now grow in Egypt. A great ornament to the tanks, often covering many acres with its curious leaves and fruit and magnificent flowers. The large seeds are an article of food."

Capparis Zeylanica, Kattoddi (p. 61.)

"The leaves vary greatly in width, but the varieties based on their forms are connected by intermediate states. The coloured patch at the base of the upper petals may be either yellow, pink, dull purple or crimson, or either in combination as seen at different stages of growth. Some of Hermann's specimens are doubtful. The green fruit is sliced, dried, cooked and eaten."

Trichadenia Zeylanica, Tolol or Titta S. (p. 75.)

"A little known forest tree, now become scarce through extensive clearing. The leaves of seedling trees or young shoots are sometimes very large and deeply palmately 7-fid. The wood is useless. An oil is obtained from the seeds and used in skin diseases and for burning."

Portulaca oleracea, Genda-Kola S. (p. 89.)

"An abundant weed in cultivated ground throughout the country. Fl. all the year; yellow. In all tropical and warm countries. The Purslane, a common potherb. The fls. are open only for a few hours in the morning, and *P. quadrifida*, Hin Genda-Kola S. (p. 90.)

"Extremely common in cultivated ground in the low country, extending up to 3,000 ft. Fl. all the year; lemon-yellow, open in the middle of the day only. Throughout tropical Asia and Africa, a common weed. Variable; in dry places often very small with the stipular hairs very long and shaggy."

Garcinia Cambogia, Goraka S. (p. 95 & 96.)

"The fruit varies extremely in the number of grooves often as many as 12 or 13 and in the shape and depth of the lobes and their colour; one red variety is very like a large tomato. It is ripe in July, and is acid but pleasant; the rind cut into pieces and dried in the sun is much eaten by the natives, and is very palatable. Wood hard, fine-grained, greyish. The bark affords a transparent gum-resin."

Doona trapezifolia, Yakahalu S. (p. 121 & 122.)

"Easily recognised by the fine small raised reticulation of the upper surface of the leaf. The name 'Yakahalu' is applied, with different prefixes to several other species of this family in South of Ceylon. This is called 'Beraiya Yakahalu' in S. Prov. There appear to be several varieties recognised by the natives and possibly more than one species are confounded here. The fruit of the Ambamuwa tree (2200 ft.) is shorter and has smaller fruit-sep. than as above described. The fruits are dried, pounded and made into flour for food and are largely consumed when they can be got, but are said to be produced only every seventh year. It was abundant in the S. Prov. in 1887."

Vateria acuminata Hal S. (p. 131.)

"A very beautiful tree often planted for ornament. The stem exudes a clear yellowish (erroneously said to be 'green' in Fl. B. Ind.) resin abundantly, equal to the best dammar. The bark is much used for checking the fermentation of toddy and many trees are killed by being stripped. Wood light, rather hard yellowish grey. The seeds are ground into meal and eaten."

Hibiscus Abelmoschus, Kapukinissa S. (p. 156.)

"Moist low country; rather rare and doubtfully native Colombo (Moon); Kandy; Badulla; Ritgam Korale. Fl. September; bright yellow with a purple centre. Found wild or cultivated in most Tropical countries. The seeds have a very strong odour of musk but I do not know that they are used in Sinhalese medicine,

though they have a reputation in Persia and Arabia: *H. esculentus*, L. is commonly grown as a vegetable and met with half wild in native gardens. Its capsules are the 'Vandakkay', T. so much used in Ceylon cookery."

Eriodendron anfractuosum, Imbul S. (p. 161)

"Low country up to 2,000 ft., very common but nearly always planted and I doubt if really a native. Fl. Jan.-March; creamy-white, faintly scented. Apparently found in Tropics of both worlds; native of Malaya (?) Though each seed appears to have a separate investment of cotton, this is quite unconnected with the testa and really arises from the inner side of wall of the capsule and from the central axis; it ultimately becomes separated from these and is then a mere stuffing round the seeds. This material is called 'Pulun' or silk cotton and is largely used for stuffing cushions and pillows; of late years (under its Malay name 'Kapok') it has become an article of export on a rather large scale, chiefly to Queensland. A bright red resinous gum is afforded by the stem."

Murraya koenigii, Karapincha S. curry leaf S. (p. 221)

"Low country, especially in dry region; rather rare. Badulla; Maturata. Very much cultivated. Fl. Dec., August; white, scented. Also in India. This is the familiar 'curry leaf,' a constant ingredient in curries and mulligatawny. Its scent is pungent and slightly aromatic. Wood hard, close-grained, smooth, pale brownish-yellow, durable."

Samadera indica, Samadara S. (p. 231)

"Moist low country, in forests; rather common. Galle; Kalutara; Hewasse; Ohilaw. Fl. March; pinkish-yellow. Also on the Malabar coast of S. India. The whole plant is very bitter and the bark, root and fruit are all used as febrifuge medicines. An infusion of the leaves is a good insecticide and destructive to white ants. Wood light, soft pale yellow."

and *Azadirachta indica*, Kohomba S. (p. 244.)

"This tree is generally known by its Portuguese name 'Margosa.' In India it is called 'Nim.' Wood moderately heavy, very hard, dark red with large pores. The bark is astringent and bitter and used as a febrifuge and tonic. The oil from the seeds, Kohomba-tel is a universal external application for rheumatism, &c., and as an insecticide. Thw. states that the juice of the leaves which is very bitter, is used as an anthelmintic for cattle. Stands drought well and much planted as an avenue and roadside tree in the Jaffna district.

Also it tells which are to be avoided as dangerous and poisonous as

Anamirta paniculata, Titta-wel S. (p. 40)

"The seeds are very bitter and poisonous, and are known as 'Oocoulns indicus' in pharmacy and in trade; they do not appear to be used in Ceylon."

Lydocarpus venenata, Makulu S. (p. 75 and 76)

"The fruits are used as a fish-poison having narcotic properties; and it is said that these are sometimes communicated to the fish so killed. The oil from the seeds is employed in skin complaints. Wood yellow, moderately hard."

Cullenia excelsa, Katu-boda S. (p. 162)

"This is known as the 'Wild Durian' and it very closely resembles that Malayan fruit tree, *Durio zibethinus* L., in foliage and the structure of the fruit; this, however, has not the disgusting odour of the Durian, nor is it edible. Wood light, rather soft, pale yellow."

Oxalis violacea, (a dreadful weed) (p. 197)

"*O. violacea* L. This I take to be the name of the species which has become a very troublesome weed in some parts of the hill districts in cultivated ground, increasing very rapidly by no means of its numerous bulbils. It is a native of the United States and already recorded in Moon Cat. 36."

Cansjera Rheedii, Eta-mura S. (p. 259)

"Low country in both dry and moist regions; common. Mannar, Koening (Mns. Brit.) Fl. Jan. Feb.; pale yellow. Also in India, Malaya, China and Trop. Australia. The leaves are finely wrinkled and greyish-yellow when dry. Three women at Galle are said to have been poisoned by this plant eaten accidentally with vegetables."

and *Leca sambucina*, Burulla S. (p. 297.)

"It also gives interesting and useful notes of any special peculiarity as in the stamens of the *Berberis* (p. 49) also the scot. in."

"*Berberis aristata*. The stamens are irritable and bend over the stigma if touched at the base."

Gynandropsis pentaphylla, Wel-la S. (p. 58.)

"A common weed in all tropical countries. Develops when bruised a very strong and peculiar scent."

Xanthophyllum javescens (leaves), Palala S. (p. 84.)

"Most low country; rather rare. Kalutara; Passum Korak; Ratuapua; Colombo. Fl. March; pinkish-white. Also in S. W. India, E. Bengal, Burma, Sumatra and Java. The Ceylon plant is *X. virens* Roxb. which is reduced to a variety of *X. javescens* in Fl. B. Ind. The leaves frequently present large circular pores scattered over the under surface."

Portulaca Wightiana, (p. 90 and 91.)

Calophyllum bracteatum, Walu-Kina S. (p. 102)

"The dimorphic leaves give this tree a very singular appearance. The smaller leaves appear to be of the nature of persistent bud-scales and to mark periods of less vigorous growth. Thwaites' name *bracteatum* refers to the conspicuous bracts of the inflorescence; not as thought by Planch. and Tr. (l. c.) to the dimorphic leaves."

and *Semecarpus marginata*, The remarkable horny border to the leaves—(p. 320)

"Very unlike the rest of the species in habit; the horny border to the leaves is also very remarkable. The receptacle of the fruit is sweet and edible."

The short notes on the meaning of some of the names are specially interesting, for instance *Solomon* (p. 83) commemorates King Solomon, the earliest of known botanists, also see *Carria speciosa* (p. 111.)

Dedicated to the Hon. afterwards Sir) W. O. Gair, F.L.S., Senior Puisne Judge of Ceylon in 1846.

Wissadula (p. 146.)

"From the Sinhalese name 'Visaduli' which has been very variously applied. Hermann (in Par. Bat. Prod. 309) gives it for this; but in Mus. Zeyl. 11 refers it to *Knoxia zeylanica* which also represents it in his Herbarium. But at p. 42 of Mus. he applies the name to some parasitic or epiphytic plant and Moon (Cat. 60) gives it to *Cymbidium bicolor*. I find the name is in use still, but for the little prostrate weed, *Centipeda orbicularis* (q. v.) 'Wissadula' = poison, and Hermann explains it as meaning the pain and inflammation caused by the bite of the cobra; 'duli' is a very fine powder."

Grewia microcos (p. 177.)

"*Microcos* is Burman's translation of the names 'Kocurilla,' 'de Kleine Coocos,' given by Hermann (who has also 'Kohukirilla') for this plant apparently referring to the small hard stone of the fruit, suggesting a miniature coconut."

Huyonia Mystax (p. 189.)

"From the resemblance of the curved woody tendrils to a pair of moustaches."

Feronia (p. 228.)

"One of the deities to whom the ancients dedicated forests."

Dysoxylum (p. 247.)

"From the disagreeable scent of the wood and bark of *D. alliaceum* of Java, the first species described. Our species does not possess it."

Leca (p. 297.)

"Commemorates James Lee nurseryman of Hammer-smith who by his 'Introduction to Botany' (1760), brought the Linnæan system into England. Died 1795."

Gleniea (p. 305)

"Named in commemoration of Rev. S. O. Glenie, Colonial Chaplain and Archdeacon of Ceylon, F.L.S. He resided at Trincomalee from 1859 to 1871, where he made large collections and sent them to Thwaites for determination and incorporation in the 'Euemeratio.' Died 1875."

and *Delima* p. 5.
"From *delimare*, to polish or smooth, from the use made of the rough leaves; the native name has the same meaning."

The arrangements of the Zones, makes it specially easy to fix the locality of the various plants. I find the book more interesting and instructive the more I go into it.

THE GOVERNMENT DAIRY, COLOMBO.

The Government Dairy at the School of Agriculture is now in full swing and this morning (August 1st) milk was supplied from it for the first time to all the hospitals and asylums in Colombo. It was hoped that this supply would have been begun last month, but on account of opposition on the part of natives who did not relish the idea of the contract being taken out of their hands, difficulty was experienced in getting together the full complement of cattle to give the requisite yield. The total quantity of milk required for the six institutions—four hospitals and two asylums—is about 135 quarts, of which the General Hospital with the Planters', Anthonisz, and Seamen's Wards attached, takes, we believe, between 80 and 100. With the number of cattle in stock at the beginning of July it was of course impossible to overtake the requirements of Government and it was therefore arranged that in the meantime a partial supply should be sent out and entry upon the full contract be postponed till August in order that those in charge of the dairy might have an opportunity of gradually bringing the stock up to the necessary number. This they have succeeded in doing. The "corner" proved ineffectual and a week ago the purchases were completed. There are now 45 cows at the dairy. As is already known 21 of these were brought down from Bombay in accordance with the arrangements made by Mr. C. Driberg, the Principal of the Agricultural School on the occasion of his visit to India. They are of the Surat breed and were selected through the instrumentality of Mr. Mollison, Superintendent of Farms in the Bombay Presidency who is considered to be one of the best authorities on dairying in India. They are all capital milkers, three of them being exceptionally good, giving as much as 15 bottles a day. The Indian cattle give on the average about 9 bottles, whereas native animals only give about 3 bottles. The stock also includes five pure Singalese cows, and the result of feeding them with gingelly ponac will be looked forward to with interest, for, as a rule, their food consists of grass only. Every attention is given to the dieting and health of the cattle under the supervision of Mr. Lye, the Colonial Veterinary Surgeon, who has taken a great deal of personal interest in the starting of the dairy which he visits daily. The food of each cow is weighed and given out according to scale, and the yield of milk which each gives is entered in a book. This register is submitted for Mr. Lye's inspection at every visit so that he may be able, after examining the animals to give instructions as to whether their diet should be lowered or increased. Whenever a cow shows the slightest symptom of ill-health in any way it is at once removed from the building where it has been stalled along with the others to the shed at some distance off where it is treated until thoroughly recovered.

The cows are milked at 3 o'clock in the morning and 1 o'clock in the afternoon. The milk is first passed into a pail through a strainer so as to ensure its being perfectly clean and is then weighed on a patent recorder, the estimate being we understand, 2½ lb to the quart, and the result entered up at once. Having been weighed the milk is poured into a graduated tank where the

exact quantity required by a customer is measured and put into the churn in which it is conveyed to its destination and which is secured by means of a Yale lock of which duplicate keys are kept, one at the dairy and the other at the hospital or asylum. When the milk is taken from the cows in the afternoon it is passed from the graduated tank through the refrigerator, the result of which is that it keeps better and is not so liable to give way when it has to be taken a long distance to the customer; and when the milk is sent out in the afternoon a wet canvas jacket is put over the churn which is thus kept nice and cool. The refrigerator consists of a tank with a series of tubes fitted below. The milk passes from the tank to the vessel in which it is to be removed over these tubes which are so constructed that not a drop of milk is spilt as it trickles over them. Through these tubes an effluent of water is continually passing and so the milk is cooled. Hitherto the milk supplied to the hospitals has been tested by means of the lactometer, but now we believe this practice is being discontinued. It seems that the lactometer is not altogether reliable, because it has been found that the specific gravity of milk varies with the temperature, and that in the case of milk that has been taken any distance, unless it is at once brought down to some standard temperature, the lactometer test is of no value. According to the lactometer the standard specific gravity is 1030 or 60 degrees, but milk that has been skimmed will show a higher specific gravity than pure milk with the cream. Where we believe the lactometer is of most value is in testing two samples of pure milk. With the milk which is over after the hospitals have been supplied, butter is made and of splendid quality indeed, judging by the specimen which one of our representatives was shown today. This butter is for sale to private individuals and we should think there would be a good demand for it. From the separator the cream is put into one of the Speedwell crystal churns and there manufactured. This churn is a very efficient apparatus and consists simply of a glass jar with lid thoroughly scoured placed on a swinging frame which is made to revolve by turning a crank. Now supposing the butter in stock shows signs of giving way it need not be allowed to run to waste; but made into what is known in India as ghee which is very extensively used amongst the Hindus we believe as a concomitant of rice. This is very easily accomplished, all that is required being to subject the butter to heat for a length of time until it has become thoroughly clarified and then allow it to cool when it is ready for sale.

Of the 45 cows there are four or five uncalved, the number of calves at present being about 30, and all doing well. We have previously given a general description of the building in which the cattle are housed but we may mention that it consists of 70 stalls, 35 on each side; the space allowed for each cow which has its name displayed on a board at its stall being 4 ft. The sanitary arrangements can only be described as admirable. The stalls are strewed with oir dust which absorbs all liquid matter and a man is kept constantly on the premises for the purpose of keeping them clean. Manure is at once removed outside and afterwards taken to the adjoining fields. The place is frequently scoured with water and presents a remarkably tidy appearance. No offensive matter being allowed to lie about, there are no bad smells, and from a sanitary point of view there seems nothing left to be desired. A drain passes along the stalls and all that goes into it is at once carried outside

into a tank. Mr. Rodrigo, who was formerly one of the assistant masters in the Agricultural School, has been appointed manager of the dairy. He has been specially trained at the School for the work and Mr. Driberg gives him a high character as a very willing worker. Of course the administrative part of the work devolves upon Mr. Driberg and the duty could not be in better hands.

The idea of starting the Dairy originated we believe with His Excellency the Governor who had been impressed with the success of similar institutions in the West Indies, and we trust that he may witness complete success in Ceylon.

SUGGESTIVE READING FOR CEYLON TEA PLANTERS.

JOKAI (ASSAM) TEA.
(*Financial News.*)

DIVIDEND MAINTAINED NOTWITHSTANDING A BAD SEASON.

At the thirteenth ordinary general meeting of the shareholders of the Jokai (Assam) Tea Company, Limited, the Chairman, Mr. J. Berry White said: Gentlemen,—The report and accounts which we present to you today would, in most concerns, be considered very satisfactory ones, but I am bound to say that we feel more or less disappointed that the results are not better than they have proved. At the end of October I felt almost certain that the gross receipts could not be under 150,000 notwithstanding the short out-turn. We were working under many advantages, with the lowest rate of exchange and the lowest rates of freight ever known; whilst, on the other hand, we had at that time sold nearly a moiety of the crop at the highest average price to which we had ever attained. My expectations were, however, cruelly upset. The early closing of the season—nearly a month before the normal time—reduced the yield to fully one-eighth under the estimates, and after the commencement of the New Year the market value of the high-class teas, which we produce, fell quite 25 per cent. This falling off in the quantity of the crop was almost universal throughout all the tea districts of India, excepting in the Dooars, but it was probably more felt in Upper Assam than in other portions of the country. Notwithstanding the adverse climatic influences, I have no doubt that we would have made the full quantity had it not been that we gave orders that fine plucking should be pursued in those divisions which hitherto had given more consideration to quantity than quality. The shortness of the crop enhanced by over 20 per cent. the cost of production, which amounted to 10.65d per lb. against a little over 8d for the average of the previous five years. Still, if the cost of production was an extreme one, so was the selling value, as we realised 1s 1.19d per lb. being the actual highest average attained for ten years. The profit per lb. was also above the average, being more than 2.3d. Our gross profit on the season's working was a little less than £30,000, which, after paying the usual dividend of 10 per cent, &c., leaves a balance of £3,926. I had hoped that we should have been able to have added materially from the profits on the sale of the crop to the reserve fund; but, for the reasons which I have given you, this is impossible. But the premium on the issue of the capital necessary to pay for the Witon estates has put us in possession of £9,041 for this purpose, and the whole of this we, of course, place to reserve, bringing that fund up to £39,041. The estimates of expenditure for next year have been very carefully arrived at, and I have every hope that the crop estimated for will not only be attained, but that it will exceed three million lb. The estimated cost of production (8.3d) is, I admit, a high one. I am connected with two other properties, which produce their teas for under 6d per lb., but then the produce from these

estates rarely realises more than 8d per lb., against our average of about 1s. In making these calculations we have taken 1s 3d as the rate of exchange. This may be slightly exceeded, but if so, it will be very little, as we have already enjoyed a lower rate for the first six months of the year, and if the measures today announced by the Government of India fix the exchange at 1s 4d, it will give us an average of about 1s 3d for the year. We have a considerable area of young plant, which will give a greatly increased yield this year. The old tea at Dikom, with its improved cultivation, is also expected to make an increase, and we have received a cable that the total quantity actually made up to the 15th inst. was 33 per cent, ahead of last year.

GOING AHEAD VERY FAST.

The increased area of cultivation last year was 246 acres, and we have partly cleared and made arrangements for putting out another 120 acres during the current season. We then proposed to stop further extensions for some years. The fact is, we want a little breathing time. We have been going ahead very fast, and these new extensions although they will be by far the most valuable portion of our property in the future, are at present a heavy drag on revenue. The saw mills have made a profit of over £800, a fair return on the capital expended; but the advantages are not to be regarded as a mere profit realised, as indirectly we derive considerable benefit from having our own mills. We are about to transfer them to Bordesbam, one of our gardens on the North bank of the Brahmapootra, as there is a want of soft wood in the forests close to Bokel. We have at that place over six square miles of splendid timber, and the mills were set up there with a view to utilising it. At Bordesbam we have an abundance of this timber on the shelving banks of the Subansiri, sufficient indeed to supply all the tea boxes required for the whole of India for some years. We have imported during the year over 1,500 coolies. Our labour force has thus been well maintained there being nearly 12,000 actually on the books, which, with casuals, gives an average of nearly 1½ coolies for every acre in bearing, and of 1 coolie for every immature acre. With regard to dwellings, hospitals, and water supply, the coolies on our estates are now far better off than their European masters were 25 years ago. We naturally looked for a great improvement in the health of the coolies, and in this we have not been disappointed, although, unfortunately, during the past year we suffered much from cholera, and even more from influenza. The report contains the usual information as to the course of the market, and the statistics of teas from all countries. The first fall occurred after Christmas, and was undoubtedly produced by the shortsightedness of growers and importers in forcing immense quantities on the market, quantities so large that the trade were unable to taste or value them. Then, owing to the distrust and uncertainty created by the introduction of the Home Rule measure, the wholesale merchants in Belfast and Dublin ceased to hold stock in any quantity. This for the most part affected fine teas only. Further, many supporters of the new Government were identified with the cry for "a free breakfast table," and dealers and grocers believing that this would be carried out in the Budget, held only sufficient stock for their requirements from week to week. There has been no change in the public taste for Indian teas and no falling off in their consumption, as the deliveries were 111½ millions, being nearly 10 millions higher than the highest figure ever before recorded. As usual, this increase was gained at the expense of the China article which, in the same year, fell to 60 millions. Although the Wilton estates were only acquired during the year under review, it was yet an accomplished fact when we met you last year. The result of their working has proved much more profitable than even I anticipated. At the close of the season, in November last, we concluded the purchase of a small garden, which lay between two of our Wilton properties. We would not have thought of purchasing it had it not

been for its situation. Although we got it in a terribly bad order and with very few coolies, I have no doubt whatever that under our system of working, it will give a profit from the first. I pointed out last year that our expenditure on Block account was nearly £9,000 in excess of capital then called up. To meet the sum required for the purchase of Tengakbat and for extensions we have made since, we determined on issuing the remainder of our uncalled capital. This we did in April, and the proceeds still leave our Block £10,000 more than the paid up capital. This we have taken temporarily from reserve, and will make good whenever any additional capital is authorised.

THE AUTHORISED CAPITAL EXHAUSTED.

We have now exhausted our authorised capital of a quarter of a million, all in ordinary shares. We have given the subject of future increase of capital much thought, and consider that any future increment should be in the form of preference shares. I have no doubt that we could place our preference capital, bearing 6 per cent, at a premium of from £1 to £2 per share, although I would advocate its being offered to the existing shareholders at par. But the time has not yet come. We would only need it in the case of some property offering for sale and the acquisition of which would be as desirable as, say, the Wilton estates. We have no keen desire to add in any way to our present area. Turning to the accounts, you will see that Bokel and Takai give us a gross profit of about £3,500, which is much less than in the previous three or four years, so that the change from general to fine plucking told most unfavourably in this division. The same may be said of Muttuck, which only gives a small profit of £1,200. Dikom left us the handsome profit of over £8,000. Jamira, owing to special causes, barely covered its expenses. I now learn from independent sources that the property is now in first-class order, and I am confident that its working this year will be as satisfactory as formerly. Panitola and Hukaupuki yield nearly a half of the income made by the company, as has been the case for some years past. This is particularly gratifying to me, as these estates were formerly for the major part owned by me, and although a loser by the transaction, it is highly satisfactory to know that the shareholders who accepted my estimate of the property have gained largely by doing so. Tippuk yielded a moderate profit of about £4,000, which is much less than it should do; but it was worked under considerable disadvantages, which will not recur. Joybing shows the very small profit of under £1,000; but this is more apparent than real. Since we purchased this place four years ago we have nearly doubled the cultivation, and the present working revenue is saddled with a number of charges which more correctly should have been charged to Block. The working of Subansiri has been thoroughly unsatisfactory, showing for the second year, a considerable loss. I am quite satisfied that the property is a valuable one, and will repay us handsomely in coming years; but since we have held it, it has suffered from a succession of misfortunes. I have little doubt that this year it will turn the corner. No blame attached to the management, in which we have every confidence. We have, in co-operation with a number of other large tea companies, representing more than a quarter of the entire crop of Indian tea, put £5,000, of which half is paid up, in Bate's Wharf, where our tea on arrival is warehoused, and which is one of the most valuable properties in the City. It was acquired on such advantageous terms that our investment could already be sold at much above cost, and it will most probably double in value in a few years. The next two investments made out of a portion of the reserve I cannot speak so favourably of. They are really advertisements for the purpose of extending Indian tea on the Continent and in the United States. They have succeeded in some measure in effecting their object, and it is only indirectly or remotely that we can expect to derive any benefit from them. With the same view we have recently given about £1,000

for the purpose of representing Indian tea at the Chicago Exhibition. In all these matters we have acted in concern with the majority of the other tea companies. Some years ago when it appeared that there was a possibility of the rupee going to 1s 10d or higher, it having actually touched 1s 9d, we purchased two lacs and 31,000 Indian rupee paper. The public funds of the country in which one's operations are carried out form the most suitable means for investing a reserve, and it was a mode of insuring against any extreme rise in the value of silver. The action just taken by the Government of India in the adoption of measures to steady the value of the rupee has caused a considerable rise in value in this stock and at the price we gave for it yields about $3\frac{1}{2}$ per cent. In conclusion, the Chairman said he entirely disagreed with the opinion expressed by the *Standard* that morning to the effect that the action of the Indian Government with regard to the rupee would adversely affect tea planters and other producers in the country. He regarded this as a very statesmanlike move on the part of the Government. They were bound to do what they had done or they would soon have been landed in bankruptcy—at any rate there must certainly have been a tax imposed upon some of the industries to make up this existing deficit, if this course had not been adopted. (Hear, hear.) He moved the reception and adoption of the report (Applause.)

The resolution was seconded by Surgeon-General A. C. C. De Renzy, C.B., and carried after a brief discussion, and a final dividend of 5 per cent. was then declared, making 10 per cent for the year.

PROVINCIAL ADMINISTRATION IN CEYLON IN 1892.

THE CENTRAL PROVINCE.

In respect of extended cultivation we find the following remarks:—

It is satisfactory to note that there has been considerable extension—estimated for the Kandy district by the Ratemahatmayas at 687 acres—in the opening of land for tea by natives. I cannot say what may be the quality of the leaf—which is generally sold to some neighbouring European planter—but the gardens which I have seen appear to be carefully and well cultivated.

The Ratemahatmayas also report 700 acres of new land—mostly in Lower Dumbara, Harispattu, and Lower Hewaheta—opened in cacao. As regards these latter figures I do not pretend to guarantee them as correct. The plantations are individually so small and so scattered that it must be very difficult to compute their acreage. In Lower Hewaheta I saw some very fine cacao planted by Chetties and Tamils on extensive portions of old abandoned coffee estates; but elsewhere all that I have seen are small patches, which I fear only serve as pretext for the possession of stolen produce.

And this information can be supplemented from Mr. Saxton's Report as follows:—

CULTIVATION.—The product which is making the most notable strides in this district is cacao. The Matala climate and soil have been shown to be most suitable for its cultivation, and clearings are being made in many places. At Marnkona, Nugapitiya, Ratwatta, Warakamure, Tenna, Kadnwela, in Asgiri korale, close to Matala, and in other places land is being bought freely for cacao by European planters. Natives are induced to sell their gardens and chenass, and frequently their paddy fields for the hard cash offered to them. They are planting it themselves in all available places, and it would seem likely that the Matala and Asgiri valleys will in a few years be almost a sheet of cacao. Seed is distributed amongst them occasionally from the Botanical Gardens, Peradeniya. The output last year was perhaps less than was estimated, as the autumn crop was a very late one.

The cultivation of tea is also extending, chiefly at Ratwatta, Mandeniya, Nagolle and Aluvihare.

I have already noticed the applications for tanks in the Kandapalla korale for paddy. Paln Rotawewa, Pahalawewa, and Kuda Dissawagewewa having new clearings under them, and the gradual improvement of the tanks leading to small patches of new asweddumas, for instance, at Henayala Puakpitiya, and under Bambaragaswewa.

CEYLON TEA IN AUSTRALIA:

REVIEW OF THE PAST SEASON'S TRADE.

The Melbourne *Argus* has a very interesting Review of the past season's Trade in Tea and one which ought to be deemed extremely satisfactory to Ceylon, though there are warnings given and lessons to be learned which ought not to be lost on our planters. First of all it is pointed out how great is the need for "federation" among the Colonies—at any rate for a fiscal and Customs Union—from the point of view of the Tea Trade. New South Wales abolished its duty on tea, just as Victoria re-imposed the duty, while Queensland put an extra duty on packet teas—all these movements disturbing the trade almost as much as the financial panic. It says well, however, for the soundness of business on the whole that only one failure in the tea trade has been reported. Sydney, it is stated, is in a fair way to supersede Melbourne as the most important tea import and re-export market in the Southern Colonies and the New South Wales dealers are doing a largely increased business since the tea duty was abolished. The sources of supply are next considered and the great change which has taken place within a few years, since the time when Melbourne blenders began using $\frac{1}{3}$ th of Indian or Ceylon tea to $\frac{2}{3}$ ths of China kinds. Now 2-5ths of the requirements are supplied by India and Ceylon and the *Argus* reviewer anticipates that during the ensuing twelve months the supply may be drawn in equal proportions from China and from India and Ceylon. Now then is the time in our opinion, for the Ceylon Tea Fund Committee to make a strong bid for an even larger share of the Australian tea trade. It is distinctly stated that the drinkers of "India and Ceylon" teas can never go back to China's. What an argument this affords to so distribute samples and multiply agencies of Ceylon teas as to gather in, practically, the whole custom of the Austral Colonies for our teas. Many people think that £10,000 spent in such work in Australia would produce better and speedier results than £100,000 spent at Chicago. Be that as it may, while there can be no drawing back from the latter, it behoves planters to consider the immense advantage of annexing the Australian tea trade. At present the capitals have practically adopted our teas; it is in the "inland trade" that China's have the pull. But then there comes the words of warning in the Review under notice, and what is said about Ceylon tea is of so much importance that we quote it in full:—

"Ceylons have come forward by leaps and bounds until, as regards quantity, they exceed Indians, but as against this advantage there has been a far too large percentage of poor rubbishy sorts, which have been a great drawback to their popularity. Not only does the make of leaf of some of these remind one of the earlier days of 'post and rail,' but the faults in curing, even in the higher grades of the others, has done much harm. The main cause of this drawback is the primitive character of the market in Colombo owing to the policy of most of the gardens in sending their fancy breaks to the local market, and their good ones direct to London. Time will correct this fault, and then we may look for a steady and increasing demand for the excellent

quality Ceylon can send in the common, medium, and fine grades. For the greater part of the season the importation of these teas was attended with satisfactory results, but for the last five months prices paid in Colombo were very high, and consequently those who held over stock for covering rates met with losses of 15 to 30 per cent. upon purchases made during the height of the excitement. Present rates are, however, reasonable, and should they continue there must be a large increase of shipments from Colombo to Australia. China, as supplying us with less and less, is now the least important, although up to the present we receive the greatest weight of leaf from it. Hardly a cbox comes from Hankow. Canton and Macao send but little congon, though still a considerable quantity of scented koolocs comes from those ports to meet the present requirements of the lower grade blends. Focbow is rapidly losing its trade in good scents and also in buds, and the choice teas of the earlier days are not now grown, or, if they are, the valued flavour and quality upon which their reputation was built no longer exist. The percentage of fine and choice kinds, imported has rapidly diminished, the supply being mainly confined to teas for price, and common kinds upon the one hand, and fair flavour to good medium panyong kinds on the other. The good old-fashioned kai-ows, souchongs, saryunes, and padraes are things of the past as far as these markets are concerned.

So, poor "Ceylon's"—poor, both in make and quality—have been finding their way to Australia, and much harm,—let the planters note this—has been done to the reputation of, and trade in, our teas. Then again here is what is said about "fine teas" and improvements in the mode of doing business:—

"One change that has gradually taken place, and this season is more particularly marked, is the falling-off in the demand for fine tea. The public, apparently, will not pay its value, and consequently really fine tea is practically unknown in the markets of Australia. The whole of the choice growths of Hankow go to Russia, with a small percentage to London, and the whole of the choice breaks of India and Ceylon go to London. Here, however, we may look for a change as the poorer a nation becomes the greater is the demand for excellence of quality in "the cup that cheers." Another change of moment is in relation to the terms of trade. Nominally they are the same as in the past, but actually they are getting closer and closer to the requirements of legitimate trade, the greater bulk of local settlements being now made upon a cash less discount basis in 14 or 30 days, as against extended terms without any cover. This is an immense advantage to all, and it seems possible that in the near future our traders may enjoy the benefit of paying net cash upon delivery of documents, and so avoid the necessary charges where a credit basis exists. These charges are at present a tax upon consignments and inflict an injury to the trade as a whole."

Let it not be overlooked that "fine teas" are again expected to be in demand. Finally here are the trade statistics for the year:—

	1892-3.	1891-2.	1890-1.	1889-90.
To all the Colonies,				
From China...	14913513	16038403	15378142	21050832
India...	3932998	5165109	4716827	3600000
Ceylon...	6000000	3750000	2812892	1532440
Total...	24846511	24953512	22906861	26182772
To Melbourne				
Fr. m China...	7665738	9032519	9448331	12137400
India...	2274050	3650518	3106201	2750000
Ceylon...	3320000	2812000	1827000	1125090
Total imports	13257788	14995057	14471532	16012400
Total exports	7020145	7580000	6720000	6770872
Total home consumption	5442248	11927372	8972000	8356800

The apparently large consumption of last season was due to heavy clearances in anticipation of an increase in duty, the accumulation of these stocks and the recent depression accounting for the falling-off in duty payments this season.

It will be observed that in round numbers the supply of the past twelve months was made up of 6 millions Ceylon and about 4 of Indian to about 15 millions of China. In 1893-4, it is expected to be say 13 millions China to 7½ Ceylon and 5½ Indian? But with a special effort on the part of our Tea Fund Committee, we do not see why even before the middle of 1894, we should not be supplying at the average rate of a million lb. of tea a month, leaving room only for half-a-million lb. of China tea in the market each month. We need scarcely say that to have 12 million lb. of Ceylon tea taken off by Australia in 1893-4 would be of very special advantage to our planters."

CEYLON TEA HAS NOT DETERIORATED.

MR. DONALD MACCAT'S OPINION.

"I have seen as much as I could in the ten days I have been here. I went all over Mariawatta, and the condition of the place greatly pleased and even astonished me. Of course, I had known the place intimately when in charge of all Reid's and Rutherford's places before they were converted into the Ceylon Tea Plantations Company, and I can safely say that the estate looks, if possible, more healthy, and the trees more vigorous, than when I knew it. I also went over East Holywood, the Scrubs, and Tillyrie, and a few other places besides. In all I found tea looking astonishingly strong and vigorous. To maintain in face of this fact that the quality of the tea in the cup is deteriorating is hardly possible. Any one could see that the soil of all these and many other estates that I saw was admirably suited to the growth of healthy and promising tea bushes, and I cannot believe that the splendid leaf I saw plucked from these estates has fallen off in any respect from that which they yielded in their earlier stages of growth.

TEA A PERMANENCY IN CEYLON.

My visit convinces me of one thing, namely, that tea is, for all practical purposes, a permanency in Ceylon. I saw a large number of our best known and most practical planters, and none of them would admit that there was any deterioration in the leaf now obtained. I did not have time to visit the Kelani Valley as I had wished, but, from what I learnt here, estates in that district and in the low-country generally are as healthy and as vigorous as they were when I left the country some years ago. Altogether, therefore, I am very pleased with what I have seen, and am more convinced than ever of the stability and future prosperity of the tea enterprise in Ceylon. It may be that when the market is slack and in times of commercial depression, such as the present, complaints may be heard as to some deterioration in quality; but I do not think the planters need be alarmed in this respect. Wherever I went I found well-equipped factories possessing abundance of withering-space where years ago insufficient machinery, cramped accommodation, and other drawbacks were the rule; and it is impossible to believe that with all these advantages, with a superior knowledge of the requirements of tea manufacture, of the necessities of the market, and with leaf plucked from trees in no way deteriorated in growth, a deterioration in the quality of the liquor has taken place."—Local "Times."

CEYLON IMPORTING COFFEE!—That we should come to this—it is hardly conceivable! A correspondent writes:—"A pretty large consignment of native coffee has been imported from Tillichery by a local firm for a native dealer. From Singapore a few bags of Liberian coffee have been sent to a European firm. The price of coffee has gone down considerably the last few months.—Cor., local "Times."

Correspondence.

To the Editor.

MOSQUITO BLIGHT.

DEAR SIR,—In the course of a conversation lately, on the Enemies of Tea in Ceylon, the question was started whether mosquito blight had yet visited Ceylon. Can you or any of your readers describe the appearance of this blight, and what remedies are recommended or have been found useful in the treatment of same? The T.A. does not mention it.—Yours faithfully,

ENQUIRER.

[“Mosquito Blight” is better known by the name which made it so sadly familiar to cocoa planters in Ceylon a few years ago, namely *Helopeltis Antonii*. It has not attacked tea in Ceylon yet seriously, so far as we know; but in India it is no uncommon occurrence to see a field with a luxuriant flush one day, all brown and withered the next, from a sudden attack of this enemy. The insect attacks the young shoots, sucking out the juices, so that they wither and die. Red and black ants readily prey on *Helopeltis* if they have the chance. “Enquirer” will find a great deal about the pest in past volumes of the T.A. and a short account on page 134 of the *Tea-planter's Manual*—Ed. T.A.]

PLANTING; IMMIGRANT LABOUR; CLIMATE
AND FOOD IN GERMAN EAST AFRICA;
MR. COWLEY IN DEFENCE.

Derema, Tanga, German East Africa, June 30th.

DEAR SIR,—Were it not for the expense and trouble that the German East Africa Company has already been put to in introducing conductors and foreign labourers into this Colony, and the serious injury such a letter as that which appeared in “The Ceylon Examiner” of the 25th April last is likely to do to the Company and to myself, I think Mr. Percy Braine's letter would suffice; but in view of all this I must ask you to do me the favour of publishing my reply as well; for the letter in “The Examiner” simply teems with oriental exaggerations from beginning to end.

There is not the slightest truth in the statement that “the estates are 50 to 60 miles from the coast and that it takes about a month to get here.” In proof of what I say, I can first of all produce tracings of the “whole of the cooly route” from Tanga to this, and of the “railway trace” half way, and besides these tracings I have the Agent's letter dated the 16th June 1892 stating “the conductors arrived here (Tanga) from Zanzibar on the 14th instant and are now leaving for Derema;” and to this I would add they arrived here on the 18th June, thus accomplishing the journey in the average time of 2 days, the distance being under 45 miles, and not looking at all as if they had “suffered considerably from a scarcity of good water.” So much for statement No 1.

Now, turning to the second statement that “they had suffered considerably from a scarcity of good water.” I must say they had only themselves to blame to a very great extent in this matter. Considering they were two whole days in Tanga, during which time they were careful enough to lay in a stock of tinned provisions, besides brandy, for consumption on the road, they could also have provided themselves with soda, a common enough drink in Tanga; and, supposing the soda had run dry, by exercising a little forethought, they could

very easily have got filtered water, or cold tea, not to mention coconuts. However, be this as it may, with regard to drinkable water on the road, it can be obtained in quantity at two places, and in small quantities, at, at any rate, one other place along the road; but of course to obtain it one must try a little persuasion in the shape of copper money, for no native is going to bestir himself, just for the sake of a little water even without some slight encouragement being offered by strangers.

I have brought up as many as 223 persons with me and have provided all with water, partly by carrying some, and partly by buying it for them along the road, paying a few pices for each chatty full, and had the 3 conductors only thought of all likely requirements they could have made themselves perfectly independent of any water for drinking purposes along the road, especially as all expenses for porters, drink and provisions were paid for by the estate.

With regard to the number of Ceylonese originally here, there never were 8, even if Burghers, Sinhalese and Malays are counted together. When I started I brought 1 Tamil with me, since that 1 Malay and 2 Ceylonese or Burghers followed in June, and 1 Tamil, 1 Burgher and 2 Sinhalese arrived during December, and of this lot the 3 Burghers have been the *only ones* to return.

The first of these I sent off because shortly after his arrival he complained of pains in his chest and throat, and according to his own admission he should never have left Ceylon being in ill-health before starting; the second to go was obliged to return because he had no engagement here, having been employed to bring out various products, and some men (had the Ceylon Government allowed them to go,) and the last of all to leave was compelled to do so because he was peculiarly susceptible to fever when others fell ill of it, so that it would have been nearer the truth to have said that sickness (contracted in Africa) compelled *1* to leave and not *some*, thereby leaving the impression that all 3 were compelled to leave because of the climate.

And now regarding the climate and its effect on the labourers here: With the exception of the death of a little girl of 5 years of age from acute pneumonia following an attack of fever, *not a single Javanese or Chinaman has died of fever up to the present time.* The few deaths that have occurred, and amongst the Chinese only, were due to contagious diseases, consumption and pure dysentery, some of the men being ill from the time of landing, and two deaths out of these few not occurring on the estate at all, and one of the Chinese committed suicide whilst off his head with dysentery and under the influence of opium.

On arrival here slight fever did attack a good many at first towards end of August. During September the cases of fever had dwindled down by 50 per cent., and in October there were *no* cases, and included amongst the fever-stricken ones were many cases of contagious diseases. Since October cases of pure fever have been exceedingly few and far between, the diseases imported giving us far more trouble than any fever cases, so that what business the writer has “for believing that if Sinhalese came here they would have to return within a year,” that “the attacks of fever are unbearable and carry one off within eight and ten days” I cannot conceive; nor, as I understand this assertion that there is “no proper medical attendance,” The medical officer here has been attached to the Army Medical Department both in Germany and out here—in the Hospitals—and on the march, and is fully qualified to deal with all ordinary cases such as one meets with either on

low-lying estates, or those at high elevations, and he is also able to conduct surgical operations. Besides having at hand the services of a resident Medical Officer, the Government send up here every two months a fully qualified doctor to inspect every individual cooly, all coolies being stripped and thoroughly examined in my presence and in that of the medical officer. Could we have better medical supervision under the circumstances and can any estate in Ceylon say it has any better? Should one man fail I can easily obtain the services of another Medical Officer, for an hour's walk from this another Medical Officer is stationed.

As to good and nutritive food not being supplied, this assertion is on a par with each and all of the others, there not being a tittle of truth in any one of them. Had we been supplying bad food to our coolies, complaints would have been heard soon enough; but very few complaints have ever been made, for the simple reason that if I find any bad food amongst the *tons* of it brought up here, I condemn it and it is thrown away or destroyed at once. Besides, the Governor of the district visits the estate very regularly, and any complaint of whatever kind the coolies may have to make, they are at full liberty to bring up before the Governor, and I am glad to say any little differences, mostly through misunderstandings at first about contracts, have always been arranged with satisfaction to both parties and never has there been a question about the food.

As to food for Europeans and conductors such can be had, and always is here in sufficient quantity. When I first came there was some little difficulty, but I soon knocked that on the head by arranging with a Hindustani 13 miles off to send up provisions regularly, and that source hasn't dried up yet. Putting beef aside, we get mutton, duck, fowls, fruit, such as bananas, pineapples and oranges, vegetables (perfectly fresh) grown on the estate and sold to the coolies, and really we get everything mortal man requires. Not only can food be got, but liquor also can be obtained by the conductors in small quantities. You would really be surprised to see the quantity and variety of stores we have,—clothing, food, and groceries of all kinds, worth some thousands of rupees, brought up here at immense cost and trouble, and for the benefit of those resident here.

In conclusion I may state that the two Ceylonese sent back in ill-health should have been the last of any to complain about medical attendance, from the fact that they were attended at different times by the English Doctors at the Mission, and in future I would advise the writers before putting pen to paper about other people's business, to make up their minds to stick to facts and not go in for fiction only fit to adorn the pages of their next volume on their hunting experiences in East Africa.

They might also lay in a good stock of "grit" which will enable them to withstand any little ailments and rough work that "nice and healthy" climate may have in store for them, and where the much-abused native may not only be able to "fry an egg to their liking," but perhaps be able to serve up "Crocodile as pie" or "Manyurma or Jutti Frutti Toast" whichever tasty dish may take their fancy at the end of a day's march.

The subject of Emigration from Ceylon to this is still under consideration, and you may rest assured I would not undertake the responsibility of introducing any large body of labourers into this part of the country if I thought there was danger of seeing them die off one by one from malaria; but taking the facts as they stand at present, the elevation of the estate, no part being under 920

metres=3,000 feet, and the distance we are from the low-lying plains, and the good water we have here, I see no chance of fever attacking the men seriously. If I thought that such a thing would be likely to occur, or if I find that during the next few months fever compels me to alter my opinion regarding the healthiness of the place, then I will be the first to give up the idea of introducing Sinhalese labourers or artisans until the place became healthy.

Regretting the inordinate length this letter has run to, only to be excused on the ground of the unwarrantable charges brought against the estate demanding a full explanation from me, and thanking you in anticipation for the publication of this,—I beg to remain, sir, yours very truly,
W. H. COWLEY.

MOSQUITO BLIGHT IN CEYLON.

DEAR SIR,—I see in your issue of 22nd inst. an inquiry as to whether mosquito blight has yet visited Ceylon. The answer must be a decided *yes*. I have seen fields in Ceylon covered with it, and the young flush completely spoiled. The fly does not pierce the leaf right through, but sucks the juice (as a mosquito would the blood from one's hand) from under the skin of the leaf. If closely looked at after the fly shifts its ground, it is seen that the part left is of a much paler green than the rest of the leaf, and very soon gets dark brown. On the bud and finest leaves there will be many punctures all turning black; and it is a heart-breaking sight to see whole fields without a single young shoot free of the pest. The remedy has yet to be found.
Yours
LYNX EYE.

HIGH-GROWN CEYLON TEAS—"A CORRECTION" AND INTERESTING INFORMATION FROM MR. ARTHUR THOMPSON.

38 Mincing Lane, E.O., London, July 14, 1893.

SIR,—In one of your late issues I see you have credited me with having suggested marking your high-grown teas "Ceylon-Darjeeling."

It is nearly nine years since I had the pleasure of visiting your island and when there, the chief part of my time was spent in discussing the one engrossing topic, tea; but I must distinctly disclaim being the author of such a proposal, which I feel would be misleading and unfair to both countries. High-grown teas and Darjeelings have each a distinct flavour and are as different as hock and claret, while at the same time both are highly appreciated by the various buyers.

What I have probably frequently said and still consider,—which may have led to this misapprehension,—is that the high-grown teas of Ceylon compare with other Ceylon growths as those of Darjeeling compare with the teas from other districts in India, that is, they have a fine delicate flavour peculiar to themselves; but while claiming this, I fully recognise that we do receive good fine teas from other districts in Ceylon and India, and shall no doubt continue to do so.

What a tea is marked is now of little consequence, each sample is valued on its merits, and if special marks at any one time fetch special prices, a close examination will nearly always show that there is a good reason for it.

The trade is too keenly watched to buy for a mark only, or indeed for a country, and it is not unusual to see batches of Ceylon, Indian and China teas tasted together so as to test their comparative value for blending purposes.

"Good wine needs no bush" and in the long run I believe that "quality" rather than "quantity" will best pay the producer; for while it is true, as Mr. G. A. Talbot says, "the more fine tea you send the lower the price you get for it,"—taking a "quality" crop at an average of 2d per lb. over a "quantity" crop, the net result would prove in favour of the former.

The steadily increasing extensions in all parts must also be noted:—China, whose export has been steadily decreasing the past few years,—may yet find it worth while to ship more freely and in that case the difference of value between ordinary and fine teas may be more accentuated than we have of late been accustomed to see.—Faithfully yours,

ARTHUR THOMPSON.

MORE HINTS TO POULTRY-KEEPERS.

DEAR SIR,—When cholera appears in the poultry yard, cholera can be detected by the evacuations being very white: administer to the birds attacked a pinch, night and morning, of pepsalia and another of quinine.

Another hint is that the disease called "roop" is incurable. Birds attacked should, therefore, be killed and buried as soon as possible. The symptoms of roop are difficulty in swallowing, and a sort of bad snuffles, with much shaking of the head on food being taken into the mouth.

Third hint is, use whitewash for the walls, and wood-ashes for the flooring of the sleeping rooms liberally.

MARTHA.

NORTH BORNEO COMPANY.

Kandy, August 5.

DEAR SIR,—I send the British North Borneo Company's Report and balance-sheet presented at the last half-yearly meeting of the Company.

The comparative statement of the expenditure and revenue of British New Guinea, Imperial British East Africa Company, British Bechuana Land and the British North Borneo Company is a very interesting one, and shows how the last-mentioned Company though not subsidised either by the British or Australian Government, or Missionary Society has held its own and developed a revenue in four years double that of all the other Companies put together and with an expenditure of only a third. The British Colony of Fiji has a public debt of £259,000, and the British Government has advanced that colony £126,000 on which no interest is charged.—I remain, yours faithfully,

W. D. GIBBON.

[We have quoted from the Report fully on page 185.—ED. T.A.]

CEYLON TEA IN AUSTRALIA, RUSSIA, AND AMERICA.

Talawakella, August 8.

DEAR SIR,—With reference to your Editorial of 5th instant, anent the encouragement to a further "Tea Campaign in Australasia," I would go a step further and include Russia, as well as follow up this splendid advertisement we are getting at Chicago, for I hold, unless a some well-thought-out scheme is ready to be put in practice almost before the Hon. J. J. Grinton leaves that city we might as well have had our money in our pockets. Whatever shape this effort takes, it is quite clear from our experience of America that it must not only be a determined one, but sustained for some time to come.

This being so, it is high time the subject was having attention. Mr. Rutherford's scheme of voluntary

subscriptions if it has not already had its day, (so far as it went, a good day too it has proved) is unable to cope with any plan or plans which will be worth trying. Why not therefore agree to continue the special levy made on the planters by themselves after all expenses connected with Chicago have been met? Where so much of the island's prosperity rests, Government would not object to continuing to be the medium of collecting the levy. In it, we have a perfectly equitable means of getting subscriptions which none can shirk and I should be surprised if there were a dissentient voice to its continuance. So long as the spending of it is in the hands of such a body for instance, as the existing Tea Fund Committee, nothing but good to our industry can accrue.

Taking ninety millions per annum as the yearly output for the next five years and one-eighth of a cent tax on that we have a sum equal to £7,500 per annum with which to subsidise traders, advertise pure and simple, or any other scheme suitable in each case; whilst surely no one would grudge a quarter of a cent were it necessary!

No accounts have yet been published in connection with the tax so far, nor do I know if the Tea Fund Committee is in funds to allow of an immediate grant for the object your Editorial dealt with. At all events, as I find I have not subscribed for two years now I have no right to make any proposal regarding their available funds, but I should think if it were agreed to by the planters, that the levy should be continued a sum sufficient for the object you advocate could be got immediately.

It is a pity that no one has thought of moving a Resolution on the subject at the Planters' Meeting of the 11th. Perhaps it may be competent for some one to take it up, notice not having been given notwithstanding.—Yours faithfully,

JAMES SINCLAIR.

TEA DEALERS COMPLAIN.

In the report presented at the annual meeting of the London Wholesale Tea Dealers' Association there is the following:—

"Many complaints having been received of irregularities in the rates of certain Indian and Ceylon teas, especially that some Indian teas were inferior to sample; also that in some warehouses tea, after bulking, had been left on the floor for an unnecessary time before the packages were refilled, these subjects were brought under the notice of the Tea Brokers' Association, and greater care has since been exercised. Attention has been given to the reweighing of tea on leaving the bonded warehouses, and it is hoped that uniformity of practice and a correct record of the delivery weights will be kept in future. The subject of the establishment of a central sampling warehouse has been considered, and further details have been promised. Your committee await these before expressing any opinion. Instances were mentioned to your committee of parts of breaks of tea only being offered in public sale, when it was generally understood that the complete parcels were submitted, and the attention of the Brokers' Association has been directed to the subject with the view of having fuller particulars specified in the catalogues. It has been found that wood in a green state is frequently used in Indian, but still more often in packing Ceylon teas. The sap from the wood, when it comes in contact with the lead, produces an acid which seriously affects the tea. The Indian and Ceylon associations have been fully advised of this, and, recognising the justice of the case, have taken steps to insure only seasoned wood being used in future."

PLANTING IN CENTRAL AMERICA
AND MEXICO.

An ex-Ceylon planter writes:—"That was a very interesting letter of Forsyth's about coffee planting in Guatemala and Mexico, it should tempt many of our young capitalists to try their luck there. Still these Republics are not over safe places with their frequent insurrections; there is one on now in Nicaragua."

LONDON REPORTS ON TRAVANCORE
CEYLON PRODUCE.
TRAVANCORE TEA.

(From *Patry & Pasteur, Limited, July 5th, 1893.*)
Venture was the only estate in sale this week, and sold as under.

CINCHONA REPORT.

(From *Chemist and Druggist.*)

London, June, 29th.

CINCHONA.—The fortnightly bark-auctions this week were of very small extent, six catalogues comprising the whole of the supply which amounted to:—

	715 of, which	521 were sold
Ceylon cinchona	400	208
East Indian cinchona	44	44
Javan cinchona	46	46
S. American cinchona	1,205	819

The assortment of bark was fairly satisfactory one considering the small quantity offered, the total supply representing about 104,000 oz. (2,900 kilos) sulphate of quinine, or an average of, say, 2'3 per cent. The Indian barks included about 200 bales of old stock, imported in 1886 and 1887. For most of these only a fraction of 1d per lb. was obtainable, and about one-half was bought in. offers of ½d per lb. being refused for low mixed chips. There were a few parcels of good renewed red and grey shavings from Ceylon, but the Indian barks were very poor. Yellow bark was scarcely shown at all. The tone throughout the auctions was quiet, but there was no further decline on the low rates of the last preceding sales, and the unit remains upon an average from 11-16ths d. to ¾d per lb.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim and Amsterdam works	49,820
Agents for the Auerbach works	23,690
Agents for the Frankfort o/M and Stuttgart works	22,030
Agents for the Brnnswick works	21,989
Agents for the American and Italian works	21,139
Agents for the Paris works	12,780
Messrs. Howards & Sons	2,970
Sundry druggists	21,782
Total quantity of bark sold	175,000
Bought in or withdrawn	105,616

Total quantity offered ... 281,616
SOUTH AMERICAN CINCHONA.—A recently-imported parcel of 46 bales cultivated Bolivian Calisaya in good but somewhat irregular quills sold at 4½d per lb. for sound, and at 3½d to 4d per lb. for country damaged bark.

The following are the exports of cinchona from Ceylon during the periods between January 1st and June 5th:—1893, 2,099,831 lb.; 1892, 2,875,845 lb.; 1891, 2,417,611 lb.; 1890, 3,890,902 lb.

The exports of cinchona from Java during the ten months from July 1st to April 30th are given as follows:—

	1892-93	1891-92	1890-91	1889-90	1888-89
Government plantation	533,034	536,877	484,087	445,940	723,491
Private plantations	5,917,999	6,140,017	5,718,577	3,709,648	2,989,780
Totals	6,414,833	6,676,694	6,202,664	4,155,588	3,713,271

THE CINCHONA SUPPLIES.

A telegraphic report from Java states that the shipments of cinchona bark from that island during the month of June reached the unusually large figure of 900,000 Amsterdam lb. This brings up the total for the Java season 1892-3 (July 1st to June 30th) to 7,900,000 Amsterdam lb., which is the heaviest crop on record. Add to this that the shipments for the first half of the present year amounted to 4,000,000 Amsterdam lb., an unprecedented figure for that period, and that the average quality of the bark is steadily, if slowly, improving, and it will be seen that the sudden decline of 25 per cent at last week's public sales in Amsterdam was by no means unjustified. The unit value for Java bark is at present equal to only ½d. per lb., London terms and it is possible that this drop may have the effect of driving up to some extent the enormous flow of the bark supplies from Java. The Ceylon shipments are gradually dwindling, but the deficit from that island does not balance the excess of the Java exports. Our London stock on July 1st is returned at 37,944 bales only, against 45,310 in 1892, and 53,338 in 1891.—*Chemist and Druggist.*

THE MARKET FOR CEYLON TEA IN
AUSTRALIA.

It is an encouraging coincidence that within a few days of the appearance of our strong appeal to the Tea Fund Committee to make one more special effort in Australia, we should receive a letter from a well-known ex-Rangalla planter and ex-Australian Colonist, urging the same thing on the attention of Ceylon Tea Planters. Last mail brought (along with a contribution on another subject) a private letter from "Cosmopolite" who knows the back-countries of both Victoria and New Zealand so well, and here is what he says:—"I see W. A. T. has struck the same idea as I have, about exploiting tea in Australia, namely getting it up to the stations direct. Let the squatters and the station hands once get a taste for it (UNBLENDED) and they are the real tea-drinkers of Australia." This is confirmed—it will be remembered—by the *Argus* annual tea report which distinctly stated that Ceylon and Indian tea had conquered the big towns, but was comparatively unknown in the country districts of Australia. There is here therefore, very special encouragement—in fact an urgent call—on the Tea Fund Committee to make an effort to place pure Ceylon tea before the squatters and their employes, country farmers and villagers. Unfortunately both "W. A. T." and "Capricorn"—planters in Australia—who have been writing to us about this work, will not be available to act as agents, as they are both returning to the island shortly; but we know of a third and most reliable Ceylon planter, who is going to New Zealand by the end of the year and who would be very glad to act as Agent of our Tea Fund and to lecture and show slides all through the provincial towns and villages while distributing tea samples in likely quarters. Such an opportunity should not be lost.—There is the utmost encouragement in the way the exports from India and Ceylon are now increasing to Australia, to go in and conquer the untouched field pointed out to us by Tea authorities in the Melbourne press as well as by W. A. T., A. H. D. and "Capricorn" (C. M. H.); and Mr. James Sinclair supports the movement in a letter elsewhere which, besides, pleads that Russia and America should not be forgotten, as of course they will not. Why we urge Australia for immediate attention is that the pear there seems ripe to fall into our lap with a very little additional exertion. The comparative figures for

Export so far from India and Ceylon are as follows:—

To Australia and New Zealand:

	1893.	1892.
	lb.	lb.
India (to 1st Aug.)	.. 754,455—	301,049
Ceylon (to 7th Aug.)	.. 3,596,788—	3,064,549

Total lb. 4,351,193—3,365,598

The increase is greater in proportion in the case of Indian tea and the expectation is, as we have said, that Ceylon and India should supply 10 to 11 million lb. this season against 18 to 19 million lb. from China. But if only the country drinkers of tea in the Southern Colonies got the taste for pure unblended Ceylon tea, we believe that these figures ought to be reversed before another twelve months rolled over our heads.

OUVAH COFFEE COMPANY, LIMITED.

Report to be presented to the Thirtieth Ordinary General Meeting of the Company, to be held at No. 5, Dowgate Hill, London, on Friday, the 28th day of July 1893, at 12-30 o'clock p.m.

The following Annual Accounts are now presented to Shareholders, viz.:—Profit and Loss Account for Crop 1891-2, Balance Sheet made up to 31st May 1893. crop 1891-2.

In the Directors' last report the coffee crop of the above season was estimated at about 1,250 owt., and it will be seen that the actual weight sold in London amounted to 1,109 owt. The proceeds amounted to £5,579 14s. 10d., giving an average of 100s. 7d. per owt., against an average of 97s. 10d., obtained for the previous crop. The Crop of Tea was estimated at 340,000 lb. and the actual weight sold from the Company's own estates was 334,568 lb. Besides this 255,900 lb. of Tea manufactured from leaf brought from neighbouring estates were sold. The value of all Tea sold was £26,103 4s. 1d., or an average of 10½d. per lb. as compared with 10½d. for the previous season. The weight of Cinchona Bark sold was 45,302 lb., and the value £589 8s. 9d., or 2½d. per lb., against the former year's average of 3d. per lb. Cocoa, weighing 73 owt. 0 qrs. 15 lb. realized £333s. 16s. 6d., the average selling price being 91s. 4d. per cwt. against 96s. 3d. for the former year's crop. It will thus be seen that the total value of all produce sold amounted to £32,556 4s. 2d.

The total Expenditure for the year in Ceylon and London, amounted to £29,909 7s. 1d., and deducting this from the value of the Produce, a Profit is shown on the season's working of £2,646 7s. 1d. To this has to be added the balance of £88 6s. 6d., brought forward from last year, giving a total of £2,735 2s. 7d. at the credit to Profit and Loss Account.

An interim dividend of 1½ per cent. on the capital of the Company was paid on the 14th January last, which absorbed £1,500 of the above-named sum, and the Directors now recommend that £1,000 be applied to the payment of a further dividend of 1 per cent., making 2½ per cent for the year, and that the balance of £235 2s 7d be written off the £600 at present standing at the debit of Machinery Account.

It will be remembered that the Coffee Crop of 1890-1 amounted to 2,791 cwt., and realized £13,875, while the crop of the season now under review, amounted to only 1,109 cwt., which sold for £5,579 shewing a reduction in value against the present season of £8,296.

When this falling off in the Coffee Crop is taken into account, it will be seen that the working of the Estates even to a small profit was a task necessitating the closest management, especially as the area from which the Coffee was secured was the same in both years, viz.: 914 acres, and involved practically the same labour for cultivation. For season 1891-92, the Coffee produced was little more than 1½ cwt. to the acre.

The yield of Tea from the Company's Estates showed a fair increase on that of the previous year, being 884,568 lb., against 286,346 lb. This increase was due

to a favourable season, and to the improvement of the bushes by age, as the area pinched from was about the same.

The principal difficulties which had to be contended with during the season, were the upkeep and cultivation of a large area under Coffee from which only a small crop was secured, the upkeep of over 400 acres of Tea not yet producing any leaf, and the planting up of 109 acres of Tea which last expenditure was also debited to revenue.

CROP 1892-93.

Shortly after the beginning of this season it was feared that the Coffee Crop would be a complete failure, as it was reported that the trees were looking very weak from disease, and it was doubtful whether they would be able to mature the blossom that had set. The result, however, has proved more satisfactory than was then thought possible, and it is now expected that the Crop will total about 1,300 cwt. From the reports which they receive from the Estates about this product, the Board feel that they are no longer justified in looking with any confidence for remunerative crops of Coffee, as owing to the effects of disease, the bushes have reached that stage when large areas might entirely fail to produce crop especially if the weather proved unfavourable. They have therefore decided to plant up in Tea about 200 acres of the coffee area this year, and unless any unexpected change takes place in the condition of the coffee bushes it is their intention to continue this process year by year. The Tea continues to grow well and the yield from the Company's Estates for season 1892-93 which was estimated at 365,000 lb will be exceeded. The present market price, however is very low and leaves only a small margin of profit, but it is hoped that the returns from both Tea and Coffee will be such as will enable the further planting up of Tea to be carried out without unduly curtailing dividends.

During the last eight years considerable sums have been provided out of revenue to meet the cost of planting and the various works in connection with the manufacture of Tea, it may not now be found necessary to charge up further expenditure on Tea planting to Profit and Loss directly it is incurred, but as the Capital Account was not reduced when Coffee gave out, all such expenditure will have to come out of revenue at no distant date.

The area now under Tea is as follows:—

	TEA.	acres.

SPRING VALLEY COFFEE COMPANY, LTD.

Report to be presented to the Twenty-Eighth Ordinary General Meeting of the Company to be held at No. 5, Dowgate Hill, London, on Friday, the 28th day of July, 1893, at 1-30 o'clock p.m. crop 1891-92.

In last year's Report, Shareholders were informed that the Coffee Crop of the above season was estimated at 1,300 cwt., and it will be seen that the actual weight sold amounted to 980 cwt. exclusive of Clean and Refuse Coffee. This crop realised £5,631 12s 8d, the average selling price in London being 102s 7d as compared with 98s 5d per owt obtained for crop 1890-91. The yield of tea from the Company's Estate amounted to 192,372 lb the estimate in last report being 215,000 lb and this, together with 77,920 lb brought from neighbouring estates and manufactured at Spring Valley, sold for £12,550 8s 6d or an average of 11d per lb the average selling price last year being 10½d per lb. Cinchona Bark to the extent of 30,342 lb was also sold for £295 17s 10d the average selling price being 2½d per lb or the same as last year's average. The

total proceeds from the sale of produce amounted to £18,477 19s 0d and deducting from this the total expenditure in Ceylon and London, there remains a profit of £2,171 10s 1d on the year's working. To this has to be added the sum of £2,555 14s 8d brought forward from last year, making a total of £4,727 4s 9d at the credit of profit and loss.

On the 14th January last an interim dividend of 1½ per cent was paid on the capital of the Company, and the Directors recommend that a further dividend of 2½ per cent be now declared, making 4 per cent for the year, and leaving £1,527 4s 9d to be carried forward to next account.

For Season 1890-91 the crop of coffee was 3,465 cwt., while for the year above referred to, the coffee secured all told, amounted only to about 1,100 cwt. The net proceeds from this product for the two seasons were respectively £17,237 4s 8d and £5,631 12s 8d, showing a reduction in value adverse to crop 1891-92 of no less than £11,605 12s. In the face of this great reduction in returns from coffee, the Board consider that great credit is due to the Manager for having worked the Spring Valley with such economy that a fair profit was earned.

Crop 1892-93.

The coffee crop for this season is now estimated at 1,200 cwt., but from the reports which came home early in the season, it was at one time feared that it would not reach more than half the above estimate. While the Board are glad to report the above improvement in the year's crop over the small estimate at one time given, it must be remembered that the outturn of coffee will be but little better than season 1891-2, and that it is being secured off the same area, viz. 872 acres. In view of the reports which have come to hand during the past six months the Board feel bound to take into consideration the possibility that they might at any time have to face a complete failure in the coffee crop, the trees, already weakened by disease, not having sufficient vigour to mature their crop should they have to contend with an unfavourable season. As the area of tea on Spring Valley is by no means large, the Board have resolved to plant up in tea during the present year some 200 acres of the coffee area, and about 100 acres in each subsequent season, always selecting for this purpose only such areas of coffee as are not expected to yield crop.

From Reports received during the last few months an improvement had set in in the condition of the coffee; this may or may not be only of a temporary nature, but if it is found that the improved state of the coffee is likely to be at all permanent, the instructions of the Board with regard to the extension of the tea area will be modified accordingly. The tea on Spring Valley is not yielding quite up to expectations, but from the satisfactory appearance and growth of the bushes, this is only attributed to passing conditions brought about by a not altogether favourable season, and the Board have no reason at all to doubt that a full average yield will be secured as the bushes develop with age.

The crop of tea from Spring Valley for Season 1892-93 is now estimated at 170,000 lb. and from Olanakande at 23,000 lb.

PLANTING AND AGRICULTURAL PROGRESS IN THE STRAITS.

(From Mr. Bellamy's Report on Kuala Selangor.)

With regard to agriculture in the District, I am able to report very favourably. Large tracts of land are under permanent cultivation and all the planta-

tions of young coconuts are in excellent order. I have used every effort to encourage this kind of cultivation, as the soil here is eminently fitted for the growth of the coconut palm. I feel perfectly certain that the extent of the plantations in this District is not known at head-quarters. The work of assisting the holding in the District gave an excellent opportunity to the District officer of making himself familiar with the various mankims, and I was astonished at the magnificence of some of the coconut plantations at Jeram, Permatang, and Ujong Permatang. These are a constant source of revenue to their owners, and the Penghulu work hard to induce people to open up new land for this crop. Padi planting also received great encouragement by the Government making small advances to people wishing to make ladangs. At Api-Api about 80 acres of land is under padi, and here the buffalo has been used with great success. At Sungei Brong to which place the new Beraun Road has given access, over 60 people have got ladangs, covering something between 200 and 300 acres. All these people were assisted by Government, and I am glad to report well of their work. Padi planting without Government assistance has also been carried on in Ujong Permatang, Pauchang Pedena, Bagan Nakhoda Omar, Sabak and Ijok, and good reports are received from all these places with the exception of Ijok, where the Penghulu confesses he is not a skilful padi planter. He deserves considerable credit for having made the trial. Padi cultivation, however, will never gain a sure hold in this District unless the buffaloes are utilised, and I trust that in the present year Government will be induced to make advances to the settlers to enable them to purchase these useful animals. In the old Malay times buffaloes were very plentiful here, and padi cultivation was carried on to a far greater extent than it is now. I feel sure that if the people are given the means they will raise as heavy crops of padi as the place has ever known. All the District here is suitable for padi cultivation, but the native, unaided by his buffalo cannot keep down the tremendous growth of grass and weeds that spring up in a very short time after a clearing has been abandoned. A much larger population of padi planters is needed for the District and it has struck me that, owing to the land in the interior of the State having now become so valuable for tin-mining, padi sawahs are being bought up by Chinese miners, it would be a good thing if Government were to transport the agricultural population from the interior Districts to the coast Districts, where there is no tin-mining to interfere with their padi fields. The "anak dagang's" objection to dealing with the "anak negri," or settling near him is, I believe, the reason why foreign settlers do not come to Kuala Selangor, but if they were backed up by Government they would, I fancy, willingly come here. For instance, the people from the Setapak Valley, a place much coveted by the tin-miner, could settle in this District, where they would be free from molestation, and I venture to predict their crops of padi would be quite as heavy as those raised in the interior, while they would be able to live here at a cheaper rate.

THE PLANTERS and others connected with the staple industries in British Guiana are turning their attention to the question of endeavouring to secure some of the Chinese cheap labour which will very shortly be leaving the United States en masse as a consequence of the late legislation. "John Chinaman" is unquestionably patient, persevering, very practical, and withal very cheap, but he seems not to have been altogether a success in most countries. The States will have none of him, Australia rejects him, and we believe Cuba has been endeavouring to diminish his numbers within her borders. Will Demerara do any better with him? An article in the *Chronicle* seems to regard his acquisition as only a *pis aller*, and not to be looked to as a constant factor.—*Sugar Cane*, July 1.

THE BRITISH NORTH BORNEO COMPANY'S
ANNUAL REPORT.

In our issue of the 25th ultimo we gave a report of the proceedings at the half-yearly meeting of this Company held on 4th July. We have now received a copy of the Directors' report for the year ended 31st December last from which we make the following extracts:—

PROGRESS OF THE COLONY.

The largest and most satisfactory increases in the exports will be found under timber and tobacco. The progress of the country is clearly indicated by the figures under review, shewing as they do that whilst in 1888 the total export trade, consisting chiefly of jungle produce amounted to \$25,875, it has grown in four years to \$1,762,246, the bulk of which is due to Agriculture and Manufactured produce.

A sample of block Gambier produced in the Government Experimental Garden at Sandakan under the superintendence of the Commissioner of Lands, weighing about 7 cwt., has realised a good price in the London market. The authorities at Kew, who have given the directors valuable assistance and advice in this matter, are of opinion that as there is a demand for this article for tanning purposes both in Europe and America, the experiment may be fraught with important results to the country. The reports on this shipment will be brought to the notice of European tanners, who may be inclined to embark in the enterprise. Mr. H. Walker (the Commissioner of Lands) writing to Mr. Thisleton Dyer of Kew, under date of 21st April last, on this and other planting operations, states:—"Up to the present only Chinese have taken up the cultivation of Gambier, but I can confidently assert that Europeans would do it better and get a higher price. What the trade wants is an assurance of quality and a sufficient quantity of a similar quality. I think it would be well to sell it per unit of tannin as cinchona bark is sold, with a guarantee as to moisture, &c., and if copper pans and properly constructed drying houses be used, the colour would never vary. The pepper plants are doing well. I am glad to tell you our coffee, Liberian, is doing very well. About 330 acres were planted by Europeans last year, and I believe a similar acreage will be planted this year. The reports all round are very favourable, and 12 months' plants are now blossoming. Our climate, with its well divided rain-fall, seems particularly well suited to Liberian coffee, and I never saw anything like it in Ceylon for vigour of growth or size of stem. Cocoa is doing well here, and has a remarkable stem, but it is only since my return in 1891 that any plantings of coffee &c., (of any size) have been made by Europeans, so that we do not figure in the markets. That we shall do so I have no doubt; indeed I expect this will be a great coffee country." The distribution of seed by the Government among the natives has considerably increased, and reports have been received that the appearance of the plants in various parts of the Territory is very encouraging. As the market price of this coffee shows a very large profit, this cultivation promises to become one of the staple industries of the country. All the above products are being planted by the Development Corporation, with the addition of coconuts and Manila hemp. The reports from their estates continue to be satisfactory. When it is considered that the Sumatra tobacco trade, after 22 years of prosperity, has passed through a crisis during the last two years, so severe that the result has been the closing of a large number of estates in that country, it is a matter of congratulation that so many companies have weathered the storm in North Borneo; and, now that the supply of Wrapper Tobacco is quite unequal to the demand, there is every reason to anticipate a cycle of good years and high prices and, consequently, renewed activity in planting in the company's territory. This is foreshadowed by the unprecedentedly high prices which have been realized this year in Amsterdam. On the 10th inst., some

13,000 bales of Sumatra and 2,000 hales of Borneo tobacco were offered for tender, and in spite of the absence of American buyers for the first time this season, the result as regards the following lots of Borneo tobacco was highly satisfactory, viz.:—

The New London and Amsterdam (Kinabatangan River)	335 bales, about 4/ per lb.
The Tobacco Estates Syndicate	289 do do 3/6 do
The New Darvel Bay Company (Darvel Bay)... ..	401 do do 2/11 do
The New London Borneo Company (Marudu Bay)	480 do do 2/4 do

These prices compare favourably with those obtained by Sumatra Companies, which sold at an average of about 3s. per lb., and are the more satisfactory from the fact that the Tobacco came from various parts of the Company's territory. It has been stated that although good Tobacco can be raised in North Borneo the yield per field is so small, and the cost of production so great, that it cannot be grown to pay. These theories have been completely upset this year, as Count Geloes, of the London Borneo Tobacco Company, has succeeded in producing a crop of about seven piculs a field from about 800 fields at a cost of about seventy guilders cents per half-kilo (equal to about 1s. 2d. per pound avoirdupois) which compares favourably with Sumatra where the cost of production varies from 75 to 110 cents per half kilo, or an average of about 1s. 6d. per pound. Count Geloes has rendered signal service not only to his own company but the country generally, as he has demonstrated that there is no reason why, with equally careful management, Tobacco Estates in North Borneo should not achieve the same brilliant results as have attended the enterprise in Sumatra. Too much stress cannot be laid on the fact that the cultivation of Tobacco in the Company's territory has had to pass through the same difficulties as were experienced in the early days of Tobacco planting in Sumatra. Recent reports speak very favourably of the health of the Coolies in all parts of the country; the weather also continued favourable for Planting operations, which were being pushed forward on all Estates.

In a letter lately received, Governor Creagh reports that the Timber trade was improving, owing to the advance of prices for hard wood of all sorts in China, and that the Sago trade on the West Coast is very brisk on account of the high price ruling in Singapore.

GOLD.—The Directors have instructed the Governor to carry out a systematic search for Gold, under the advice of an experienced consulting Engineer in London who, after digesting all the information put before him, is strongly of opinion that the gold fields of Borneo will be found to resemble the banket formations of South Africa.

A Scheme has been put forward by a Japanese gentleman for introducing his countrymen into the Company's territory for the purpose of planting rice, sugar, coffee, tapioca, &c., and a grant of land in Sandakan harbour, proposed by the Governor, has been approved by the Directors. If this undertaking is successfully carried out it will introduce a desirable class of colonists for the development of the country.

To those who may be disposed to contend that the progress of the Territory has been slow and unremunerative to Shareholders, it may be confidently answered that if a comparison be instituted with the progress of any modern Colony, whether under the British Crown, any Foreign Government, or Chartered Company, there is not one—with the exception of the Niger Company—that can show, without the aid of minerals, such good results in so short a time, at so little cost. For instance, British New Guinea was taken possession of in 1884, and although the Australian Government have contributed some £15,000 a year in addition to what has been spent by the Imperial Government for its administration, the trade of the country is still quite undeveloped, and but little progress has been made towards opening up the country, as shown by the comparative statement given below.

Lord Ripon in the last Colonial Report published, testifies to the value of the work which is being performed by the able Administrator, Sir William Macgregor, who is of course backed by the prestige of the British Government and the Australian Colonies. The Imperial British East Africa Company have recently issued a Report to their Shareholders, showing that in four years they have spent £378,042 of the Shareholders money, £30,000 contributed by Her Majesty's Government and £26,435 presented to them by the Church Missionary Society, or a total expenditure of £434,477, whilst the receipts for the same period amount to £45,037 from Customs, &c., and £26,080 from other sources, or a total of £71,117. British Bechnuanaland was taken possession of by the Government in 1884, and after seven years a revenue of £45,313 was secured by an expenditure of £159,545. During the whole period the Imperial Treasury has contributed by Parliamentary grants a sum of no less than £446,437.

COMPARATIVE STATEMENT.

	Expenditure.	Revenue.
	Total for 4 years (1888-91)	Total for 4 years (1888-91)
British New Guinea	... £60,000	£13,153
Imperial British East Africa Company	... 434,477	71,117
British Bechnuanaland	... 422,108	92,779
British North Borneo	... 281,564	314,126

The total trade of New Guinea for this period amounted to £98,308, whilst that of British North Borneo reached £1,483,300.

The German Colonies on the West Coast of Africa and in New Guinea, which have been established since the formation of the British North Borneo Company, are not yet making any material progress and continue to be a heavy charge on the Imperial Treasury; whilst the collapse of the German (chartered Company on the East Coast of Africa cost the Imperial Government £1,500,000 in subsidies.

Mr. W. H. Treacher, the Company's first Governor (than whom no one is more competent to express an opinion) has recently written a small book on Borneo, in which the following paragraph appears:—"The question may be asked, what has the Company done for North Borneo? A brief reply to this question would include the following points: The Company has paved the way to the ultimate extinction of the practice of slavery; it has dealt the final blow to the piracy and kidnapping which still lingered on its coasts; it has substituted one strong and just Government for numerous weak, cruel and unjust ones; it has opened Courts of Justice which know no distinction between races and creeds, between rich and poor, between master and slave, it is rapidly adjusting ancient blood feuds between the tribes and putting a stop to the old custom of head-hunting; it has broken down the barrier erected by the coast Malays to prevent the shorigines having access to the outer world, and is thus enabling trade and its accompanying civilisation to reach the interior races; and it is attracting European and Chinese capital to the country and opening a market for British traders."

After obtaining a Charter H. M. Government in 1881, the Directors took possession of an uncultivated country, inhabited by barbarous tribes, similar, in fact, in every respect to British New Guinea, to which a reference has already been made, and from which neither trade nor revenue of any magnitude could be expected, except as the result of skilful opening up and development, extending over a great number of years. A British Colony has since been successfully founded on the basis of the Charter, which has been further strengthened by the establishment of a British Protectorate creating "The State of North Borneo." Outside capital amounting to over a Million sterling has been attracted to the country. The annual revenue has been raised from \$51,000 in 1883, to \$357,000 in 1892, and the volume of trade has increased in the same period from \$590,000 to over \$3,000,000. To have carried out this work, de-

frayed the cost of administration and paid two small dividends (laying meantime the foundations of new industries and enterprises, capable of enormous extension in the near future and likely to add largely to the revenues of the Company) must generally be admitted to be a considerable and promising result from small beginnings, achieved under many discouraging circumstances.

INDIAN PATENTS.

Calcutta, the 13th July 1893.

No. 79 of 1893.—Alfred George Woodward Reid, Executive Engineer, Punjab Irrigation, Ludhiana, for raising and holding at every required height the gates used for regulating the admission of water into the minor distribution channels on irrigation canals. (Filed 20th June 1893.)

No. 133 of 1888.—Messrs. O. Bowen, A. S. Tomkins and J. Cobeldick's invention for an improvement in the manufacture of charcoal. (Specification filed 11th April 1889.)—*Indian Engineer*.

HIGH PRICE FOR TEA IN CALCUTTA.

At the tea sales in Calcutta on the 27th instant, some of the prices realised were remarkably high. The produce of the Balasun Tea Company Darjeeling, sold at particularly high rates. Thirty-four chests of Orange Pekoe were sold at Rs-10; twenty chests of Pekoe at Rs-13; fifteen chests of 1880s Coughing at Rs-12-9; and twenty chests of Broken Orange Pekoe at Rs-12-6 per lb. The Ting Ling Tea Co. Darjeeling has also done remarkably well. Amongst others were twenty-one chests of Broken Orange Pekoe which sold at Rs-9; thirty chests of Orange Pekoe at Rs-16; thirty-five chests of Pekoe at 1-0-6 per lb. The average of Balasun was Rs-5-3, and of Ting Ling Rs-13-4. Last year the best averages from these two gardens were Rs-9-2 and Rs-11-11, respectively. The best invoices are late this year and are still to come.—*Madras Mail*, July 31.

SELECTED ENGLISH PATENTS.

No. 20,964.—TEA.—J. Y. Johnson, 47, Lincoln's Inn Fields, Middlesex.—(W. Jackson; Colombo, Ceylon). Rolling Machines.—Consists in means for preventing a rise of temperature during the rolling. Air is introduced into, or drawn from, the space in which the rolling takes place by means of a fan, air pump, etc. In the arrangement shown a fan driven from the shaft which actuates the rolling surfaces is connected with perforated tubes extending along the sides of the casing and communicating with the rolling chamber.

No. 20,965.—TEA.—J. Y. Johnson, 47, Lincoln's Inn Fields, Middlesex.—(W. Jackson; Colombo, Ceylon).—Rolling Machines.—Order to facilitate the circulation of the charge of tea leaf, the under surface of the upper plate, etc. is formed with a dome-shaped or convex projection.—*Indian Engineer*.

BARK AND DRUG REPORT

(From the *Chemist and Druggist*.)

London, July 6.

COCOA-BUTTER.—At the auction on Tuesday 200 cwt. cases of Cu-bury's cocoa-butter sold at an advance of about 1 9-16ths d. per lb. on the preceding sales—viz., at from 18 3d to 18 3½d per lb.

GAMBIER.—Block gambier remains inquired for. A fair amount of business is reported, mostly for arrival, at from 18s 3d down to 18s per cwt according to position.

July 13th.

CINCHONA.—The fortnightly auctions which were held on Tuesday were among the most insignificant in point of quantity, as well as of quality, which have ever taken place in London. The eight catalogues comprised;—

	Pkgs.	Pkgs.
Ceylon cinchona ...	617 of which	548 were sold
East Indian cinchona	216 do	216 do
West African cinchona	32 do	32 do
Javan cinchona ...	28 do	do
Cuprea bark ...	153 do	153 do
	1,046	919

The assortment was an exceedingly poor one, the bulk of the lots shown consisting of low-class natural Succirubra and Ledger barks, probably containing less than 2½ per cent of quinine. The highest price realised for any lot at the auctions was 4½d per lb. The tone was a very dull one, and prices fell considerably in sympathy with the heavy decline established at the last Amsterdam auctions. A rather larger proportion than usual was bought by druggists, but the average unit cannot be placed above ½d per lb., the lowest on record. The following were the prices paid for sound bark:—

The average unit obtained at last Thursday's auctions in Amsterdam is the lowest on record in the history of the bark. The total quantity equivalent of sulphate of quinine sold was 12,383 kilos, at an average unit of 3.55 cents, but including 794 kilos at 3 cents and ranging chance up to 4.25 cents, at which last-named figure 386 kilos found buyers. The greater part of the bark offered (representing 12,728 kilos quinine) was bought in. The tone throughout the auctions was one of increasing listlessness, the unit being 0.5 cent lower at the end than at the beginning. The principal buyers were the Pharmacy Trading Company 3,218 kilos, Mr. Gustav Briegleb 3,164 kilos, Mr. H. A. O. Wischerhoff 2,655 kilos, the Amsterdam Quinine Works 1,837 kilos, and J. J. Louet Feisser 1,512 kilos. Druggists' bark were in rather better request, and fine quills were held for comparatively high prices. The next Amsterdam sale will be held on Aug. 31st. The richest parcel in the sales was one of 7 bales Ledger stem bark, testing 9.58 per cent sulphate of quinine for which 37 cents (7½d) per half-kilo was paid.

COCA-LEAVES.—There have been heavy arrivals of good bright green Truxillo leaves in Liverpool: 1s has been asked for them, but it is doubtful whether more than 10s could be obtained at present. Advices from Peru, on the other hand indicate the scarcity of cocoa-leaves, and report higher prices as likely.

PLANTING IN BRITISH CENTRAL AFRICA.

COFFEE NOTES.

(By an ex-Ceylon planter.)

Milsnji, June 20th.

Our coffee just two years planted out, has cherry ripe from November blossom. Such grand clusters, which please the eye and tell in an estimate, 10 to 15 berries!

There is evidence of an autumn crop's blossom just starting. We have doubtless an Uva climate here which was always considered the home of the coffee tree.

Mr. Johnstone, H.B.M. Commissioner, is reported to have gone down to the Cape Colony to meet Mr. Rhodes.

All is quiet now in the country. Natives are swarming here in want of work having come some hundred odd miles in search of calico. Unfortunately, they only come from a distance during the dry season after their crops are gathered; they are in time, however, for the coffee crop although not available for planting purposes.

Our rainy season is just over, and it totals up in inches about 80. During the dry season very little falls, only a few showery days per mensem.

P.S.—Please let it be known that I am not the B. who advertises for men for Africa, as I've had letters applying.—I am sending you a local Mission publication from which you will learn a good deal. H. B.

We quote as follows from the publication referred

to, albeit it is older than the letter a good deal:—

Coffee which threatens to bless or curse men with fortunes is this year crowded with berries. The season has also been a splendid one for nurseries and for planting out. The River has shown no flood and we cannot tell what is going on in the North, but the rains here could not be better.

We hear that some of those who have been helpful to the German Expedition stand the chance of receiving the decoration of the Red Eagle. At any future levee held in the Shire capital and given by his Excellency the Governor we shall see an African brilliancy of no mean lustre.

With a Civil Service for Africa; a hall of learning at Blantyre; ecclesiastical, civil, naval, military and geographical degrees, we shall soon be a community of kings and knights and professors, with not one amongst us who does not boast a spur or a hood or some other peaceful weapon of inspiring awe. And it is quite as it ought to be. We need kings for Africa and any kings going a begging may apply—only we need real kings.

The native villagers are coming down from the hills to build upon the plains, beside the streams, and beside garden ground. Local supply almost sufficed this year for coffee planting, and if settlement of villagers begins and if garden plots are judiciously arranged, there should be a local supply in almost every plantation.

We must not drive them away by the terror of armed soldiery and taxing raids: the country will soon lie to and run with willing hands the Union Jack up to the mast head.

We are almost, as far as man can promise, sure of a railway now, to connect in some way the upper with the lower Shire. Of course there are many ideas as to how such a railway ought to run. After long consideration of the subject, we hold the opinion that the old Katunga road is certainly the cheapest and we believe the best. The only real difficulty is the first Katunga hill, and this could easily be overcome by a cogged wheel and wire rope arrangement. It would take very little cutting to bring the Mbame hill into good order, and the Mtonda hill is already overcome by Captain Sclater's new portion of the road. The 3,000 feet must be got over some way, and there is not another spot where twenty times the amount of cutting and engineering, and six times the length of road would not be necessary. The Mlanje plain is a marsh in the rains, and necessitates a long journey through a malarial region.

The interlacing with railroads of the Shire highlands themselves is an afterthought in any case and will come in equally well with any route. A very slight dredging would clear the Shire and Zambesi, for they are splendid rivers. We must not discount real water resource already there, laid down for us and ready to hand by nature, because some of the natives who chance to guide the vessels are not so good as some others and the European guides are new to the work. Think of a run down to Ohindo from Chiromo being possible in 24 hours with our present means of conveyance! Think of two days from Katunga to the sea! And yet we have not touched the river channel nor the river banks, nor dredged a foot of sand, nor even learnt the river channel as we might.

I need not say that the railway will pay. Coffee in its green dress forms as good if not as gaudy an asset as gold, and the land and the people, which are the real banquet will be served well after this judicious hors d'oeuvre.

A most surprising speech has been made by Mr. Rhodes in England, and news of it has just reached us here. It is about as fine a piece of audacity as we could well have conceived. Against the reiterated pledges of our Commissioner that the country is British, and would be so, against the assurances of the Foreign Office that we are under "misapprehension" and "misconception" in thinking anything else, Mr. Rhodes says, "Our understanding with the British Government is that we shall gradually relieve it o

responsibility in the Nyasaland Protectorate," and that "the reversion of the land" is with them. The ignorant applause this evoked is said to have been extravagant, and to us falls the difficult task of enlightening the British public.

The Churches themselves have sunk about £200,000 in money; how much more in men! and this money is not lost, it is invested lawfully, under British sanction in every note of it, and is recoverable. What else means the fact that the only place where Mr. Rhodes can place his soldiers is in Blantyre. They cannot exist anywhere else. He has not lent them to us; we have rather lent him these hills for barracks; and an element of disturbance and danger has been quartered upon us against our will. There are three and a half million coffee plants (almost all of them descended from one Mission tree), and these should yield even this year their £18,000; and this is nothing to the money sunk, by Lakes' Company, by traders and planters and by others. Blantyre is the only annexable spot in the whole of Central Africa, and the annexable in it is not land, not people, but that which has been made into a property by the life and labours of seventeen years' work. Who is "the concession hunter" which Mr. Rhodes so unsparringly condemns? Who with a miserable "bit of paper" from "some wretched native" wants to "climb upon the backs of those who have done all the work" and to "reap all the profits"? Who but Mr. Rhodes himself.

Not a foot of land had Mr. Rhodes in the country until six months ago, and then it was a small holding at Chirimo bought for him by Mr. Johnston, not a share in the country until he managed to out-manoeuvre the Lakes' Company and get a share of their business. The Shire highlands are not touched by his Charter or has he a pennyworth of claim on the land.

Quinine is considered by the people almost one of their own medicines now; and they have their own ways of taking it. We heard of one patient taking it in pala (gruel.) The reader must express for himself his idea of the taste, we cannot.

From Mr. Lionel Deele we have received in great kindness the donation of £2 2s.

He is travelling through the country as a scientist for the French Government. He has a series of most interesting photos of Zimbabwe ruins, Victoria falls, and drawings of various types of African tribes.

MLANJE STATION.—Road-making in our neighbourhood goes on apace. Under contract with Government Mr. Brown is pushing on the road to the Mlanje plateau and soon the fagged-out and fever-stricken from other places will find their way by an easy route to the home-like climate of our mountain-top. Mr. Angus, on behalf of Mr. Moir, is also busy on the contract-road between Blantyre and Mlanje.

COFFEE.—Cholo,—or to be phonetically precise, Chyolo is without doubt the coffee garden of the Shire hills. The native carriers (and there is no better judge of good soil than the African) declared it to be the "home of coffee." Nowhere had they seen soil so rich nor water so plentiful as along the banks of the upper waters of the Mswazi river. To the south towards the Ruu the country becomes very rough, and the useful gives place to the picturesque. On the journey out they kept to the high road along the escarpment of the plateau. On the return journey they followed for the most part the course of the Mswazi River. Along this latter route we believe an engineer would find little or no difficulty in the way of constructing a good waggon road or even a railroad. Starting from Chirimo the route could follow the present path to Mlanje by Zoa as far as the junction of the Tuchila and Ruu. Thence it would follow the Tuchila for a short distance, and then the Mswazi by an easy gradient, till it reached the level of the Blantyre plateau at Malanduzi; thence to Blantyre, Chiradzulo and Zomba would be an easy task, and so from Zomba on to the Lake or Upper Shire. In this way the road or railway would touch the chief centres of work and trade and coffee cultivation in the Shire Hills. To carry it, as we once heard an engineer gravely propose, twice across the Tuchila River and along the Tuchila plain, would be the task of a De Lesteps.

COFFEE GROWING IN JAVA.

Reporting on the finances of Netherlands' India for the year 1893, Sir G. Bonham makes some interesting remarks on the cultivation of coffee in Java, which had been brought out by a Government commission on the subject. Referring to the difficulties a coffee planter has to contend with, the fact is stated, that, as the coffee plant only comes into bearing in its fourth year, the capital and labour expended are meanwhile unproductive, a state of things rendered particularly unsatisfactory in the case of the native, who is usually entirely destitute of capital or ready money, and consequently has to borrow if possible. To assist this class, it has for some years been the practice of the government to give special advantages for the growing of intermediate crops, i.e., crops grown between the rows of coffee plants, but this system has again disadvantages. The fact that land suitable for coffee cultivation is no longer to be found in the neighbourhood of the villages causes the crop to be looked upon as an auxiliary one where the cultivator has other resources to depend upon. During the four years that a planter derives no income from his coffee, he devotes his attention to the cultivation of indigenous crops, and ends by regarding these as his principal source of income, the coffee being entirely substantially, so that a man may plant as few as fifty trees annually, thus leaving himself ample time to grow other crops. The case of the free coffee farmer is entirely different; he plants not by tens, but by hundreds and thousands. Coffee planting is his principal business, occupying all his time and resources. To work any coffee plantations of importance he must either have large means or good credit to tide him over the four years of waiting for the first full coffee harvest.—*Gardener's Chronicle*, July 15.

THE AMSTERDAM CINCHONA AUCTIONS.

AMSTERDAM, July 6th.

At today's bark auctions 3,459 packages Java bark sold at a decline, the unit being only 3½c. (?) per half-kilo. Manufacturing bark in quill and chips brought 6c. to 37c. (=1d. to 6½d. per lb.); ditto root, 7c. to 28c. (=1½d. to 5d. per lb.); druggists' bark in quill and chips, 10c. to 65c. (=1½d. to 11½d. per lb.); ditto root, 6c. to 14c. (=1d. to 2½d. per lb.). The principal buyers were the Frankfort Quaineworks, Mr. Gustav Briegleb, the Brunswick, Amsterdam, and Auerbach Works.—*Chemist and Druggist*.

QUININE, &c.

Messrs. C. F. Boehringer & Söhne, Waldhof near Mannheim, report on 10th July:—

Quinine.—Large quantities of Bark were brought forward in the Sales at Amsterdam, and as some of the growers were obliged to realise low prices had to be accepted for the Bark. Quinine makers remain however very firm with their quotations, as the exceptionally low figures for the raw material, which cannot possibly cover the expenses of production, must prevent the growers from sending large quantities of Bark to Europe. The consumption of Quinine is steadily increasing and as soon as a few weak holders of second hand goods are cleared out, we shall see an improvement in the market.

CAFFEIN.—The raw materials is getting very scarce and we shall have to raise our quotations shortly.

COCAIN remains firm with a good demand.

COFFEE NOTES.

Mexico has recently imposed an export tax on coffee, which is estimated to yield \$331,748 on an exportation next year of 11,058,279 kilogrammes. The duty is \$3.00 per 100 kilogrammes, net weight.

An important movement has been initiated in commercial circles in the United States to secure

the abolition of the discriminating tax on Venezuelan coffee. It has been found that the tax has made no difference whatever with the Venezuelan producer, as his coffee is readily taken in Europe, while the American consumer loses a favourite brand.

A correspondent of an American journal writes:—"In the State of Oaxaca, recently opened up by the completion of the Mexican Southern railway to the city of Oaxaca, there is an unwonted stir at the present moment. Americans and Englishmen are going extensively into coffee there, and some idea of the profits now being made in this culture may be had when it is learned, as I am credibly informed, that coffee there costs 10 cents a pound to raise pick, and send to the city of Oaxaca, and is selling in that place at 27 to 28 cents, giving a net profit which should tempt the most cautious. Good native coffee, unroasted, sells in this city today at retail at 36 to 38 cents. A man with \$25,000, or a small company with from that sum to \$50,000, could start into coffee today and in a few years be paying heavy dividends. Throughout all the coffee-producing states of the republic there is a steady investment in lands appropriate to that culture. Brazil has given Mexico her golden opportunity, and it is being availed of by enterprising men here. Mexican coffee has won its way in the United States and in Europe and is no longer treated with indifference in the trade. Its market is assured for all time. It has no longer to masquerade as Mocha or take other names, but now stands on its own merits."—*Rio News.*

COCOA CULTIVATION IN SAN DOMINGO.

The production of cocoa is gradually but surely increasing in the Republic of San Domingo, and more attention is given to selection and classification than formerly. Thanks to the perseverance and good example of a young Russian gentleman (a resident in the interior, and the representative there of a substantial London firm), who has taken the trouble to go round to the cocoa producing districts, and with samples before him, shown to the country people the exact condition in which cocoa should be shipped to bring a good price in the European markets, a great deal of care is now being taken by planters to bring their produce to as high a pitch of perfection as possible, and although there is still room for improvement (according to our consul), a very creditable effort has been made, with the result that a carefully selected grade has been sold in London at £3 8s per cwt.—*Circular Report.*

WANARAJAH TEA COMPANY.

GENERAL MEETING.

The first ordinary general meeting of the Wanarajah Tea Company of Ceylon was held on the 5th August at No. 4 Queen Street, Fort. The chair was occupied by Mr. Joseph C. Dunbar and the others present were Messrs. Wm. Taylor, J. W. Vanderstraaten, D. Noble, J. Buchan, W. H. Davies, R. L. M. Brown, M. Bremer, E. B. Creasy and J. F. Baker as representing the agents and secretaries. Messrs. T. W. Hall, and F. H. M. Corte were represented by their attorneys and Messrs. G. G. Anderson, Alexander Skene, W. M. Suttler and Robert Porter by proxy.

The directors' report which was as follows was taken as read:—

The Directors have the pleasure to submit to the shareholders their Balance Sheet and Profit and Loss account for the year ending 30th June, 1893.

The accounts show a profit on the working expenditure of R7,871.53; and after writing off the preliminary expenses in full, leave a balance of R1,170.89 to be carried to credit of next profit and loss account.

The Shareholders are aware that when these estates were taken over by the Company there had been very little spent on them for some years, and they were consequently in a rather neglected

state: buildings very much out of repair, waste land and ravines grown up and encroaching on the cultivated area. This has during the year been for the most part rectified: all the coffee land has been planted up with tea, and ravines, banks, and waste land put into cultivation either with tea, timber trees, or grass.

The acreage taken over by the Company was:—

Coffee	350
Tea	541
Waste	29
Forest	214

Total ... 1,134

At end of this month it will be as follows:—

				Acres.
Tea	964
Fuel Timber, and Grass (about)	61
Forest	99
Encroachment by Newton Estate	10

Total ... 1,134

The estate having been re-surveyed, an encroachment of about 10 acres of very old standing by Newton Estate was discovered, and the proprietors of that estate have offered to pay R1,000 as compensation on transfer of the land, and this offer the Directors have decided to accept. A very substantial Factory is in course of erection, and will probably be ready for work early in October. The Directors considered it good policy, in view of the rapidly extending plucking area, to build in advance of present requirements both as regards accommodation and motive power. The Store is 120 ft. by 40 ft., with 3 floors; and the turbine is calculated to develop 40 horse-power.—By order of the Directors,

BAKER & HALL,
Agents and Secretaries.

The CHAIRMAN, in moving the adoption of the report, said it would be seen that the acreage in tea had been considerably extended. He thought that by the end of the month the land under tea would be increased by 420 acres. In addition, about 60 acres of scrub and abandoned land on each side of the cart road had been cleared and planted in timber which would add very much to the appearance of the estate. The Directors he said were determined to push on the tea cultivation as rapidly as possible, because little or nothing could be expected from coffee. Another matter he wished to mention was that he had received a letter from a shareholder who seemed to be under the impression that the factory was far too large for their requirements. That was a matter which the Directors as practical men had considered, and they thought it better that they should at the beginning build the factory and make a good job of it, as well as finish the watercourse. Of course, they did not intend to put in as much machinery just now as they might perhaps require afterwards, but in putting up the full extent of building, although it ran away with a good deal of their capital early in their career, the Directors thought they were doing the best they could for the Company. Passing on to other items he stated that a great many of the shares had been paid up in full, but there was still a sum of about R14,000 to come in of the third call. On the opposite side of the account it was shown that R240,000 of the original capital had been spent as follows:—On land R228,000, on buildings (original value) R10,000, and on machinery which was practically the machinery at Manickwatte R2,000. The sum of R15,379 had been spent in 1892-93 on new building, not on repair, and R31,832 on extension, tea, timber, and grass, and upkeep of land not in bearing. The expenditure on machinery in 1892-93 was R7,485 being the cost of piping or new factory turbine and a new sirocco

which was necessary for the factory in which they were at present manufacturing their tea. In the profit and loss account an item which might be considered rather large was that of preliminary expenses amounting to R6,700, and he explained that it represented discount on payment of calls in advance, payment of bonuses to superintendents under agreement with the vendor Mr. Corbet, legal expenses, valuation and various other items. He did not think there were any other points calling for special mention and he would therefore simply move the adoption of the report.

Mr. N. BLE seconded and the report was unanimously adopted.

DIRECTORS.

The CHAIRMAN said the next business was the election of Directors. The Provisional Directors placed their resignation in the hands of the meeting but they offered themselves for re-election.

Mr. NOBLE accordingly moved that Messrs. Thomas Maokie, J. C. Dunbar, J. W. VanDerstraten and William Taylor be re-elected Directors.

Mr. BUCHAN seconded.

Mr. CREAMY thought it went without saying that the Company were most fortunate in having such an able Manager as Mr. Taylor, but it struck him as not advisable in the interests of the Company that the Manager should have a seat at the Board. It seemed to him to be rather anomalous that as a Director he should be able to issue instructions to himself as Manager. He therefore thought it would be in the interests of the Company if Mr. Taylor did not have a seat at the Board.

Mr. NOBLE—Do you move that as an amendment!

Mr. CREAMY replied in the affirmative and moved accordingly.

The amendment however was not seconded and the Directors were re-elected as moved by Mr. Noble.

STATEMENT BY THE MANAGER.

Mr. BROWN suggested that it would be very desirable to have a statement from Mr. Taylor giving them some idea of the progress that had been made on the estate. The clearing that had been done must constitute a great factor in the development of the Company.

Mr. TAYLOR at once complied with the suggestion. As they were aware the most of the planting last year was done by seed, and he was happy to say it had been very successful. About 11 or 12 per cent covered the vacancies and those had been supplied, and the clearing was getting on, in his opinion, very satisfactorily. The extension this year, 102 acres, was already roaded and drained, and a great part of it holed, and he expected to have the planting of it finished by the end of this month. The factory, he thought, would be finished about October. After that it would be pretty plain sailing; there would be very little capital expenditure except the upkeep of the land not in bearing. He was in hopes that they would have secured the manufacturing of leaf from another estate amounting to 200,000 lb. of tea, but their factory not being ready in time that estate had made other arrangements for another year. They might possibly get some outside leaf yet to manufacture at their factory which was of course rather in advance of their present requirements. If they had not thus built in advance they would never have been done building, and they knew very well that it was better to finish their building at once than to adopt a patch-work system. It was more economical in the end and best in every possible way so to do. They had put up a more powerful turbine than they required at present but if they had put in a smaller one they would have had to discard it in the course of a few years, throwing it away or selling it at half price. He considered it very

much better that they should put in as powerful a turbine as they were likely to require and have done with it. The weeding had been very troublesome and probably would give some more trouble for the next year or so, especially where the ravines had been overgrown, but the place was much cleaner than it had been and the progress generally, he thought, was very satisfactory.

ELECTION OF AUDITOR.

The CHAIRMAN said the next business was the election of auditor. Mr. Guthrie had audited the accounts this year and he proposed that they re-elect him for the ensuing year on a fee of R100.

Mr. CREAMY seconded and Mr. Guthrie was unanimously re-elected.

VOICE OF THANKS.

This being all the business

Mr. BROWN proposed a vote of thanks to the Chairman and Directors for their services during the past year. They deserved it particularly after the very satisfactory explanation that had been given by Mr. Taylor as to the progress that had been made. It showed that they had the interests of the Company at heart, and the least they could do was to thank them.

Mr. BUCHAN had much pleasure in seconding, and the vote was cordially passed.

The meeting then terminated.

FINEST GARDEN IN THE WORLD.

Every year upwards of a million and a half of people visit the Royal Gardens at Kew. One hundred thousand have been admitted on a Bank Holiday; 50,000 on a Sunday. But very few of the thousands who roam about its 270 acres and huge glass-houses realize the splendid work done there, and its importance to the British Empire. For 120 years Kew has taken the lead in the discovery and utilization of "economic" plants, with a view to the extension of trade, the development of our Colonies, and the creation of new industries. "Economic" plants by the way, are those whose fruit, seed, fibre, sap, etc. may be turned to account. Kew has no equal, for no rival garden has half so large a sphere of usefulness. It is the centre of a hundred similar gardens in various parts of the Empire many of whose directors it has trained. All are engaged in the same work, which is something much more magnificent than growing lovely flowers to delight the eyes of visitors, or for profit. An illustration: A tanner informs the Director of Kew that the supply of "gambier," an extract from the leaves and shoots of a Malayan climber, is not equal to the demand. The price has doubled two or three times. No substitute has been discovered. Then Kew goes to work. The Director communicates with the Colonial Office, which instructs the Consul at Singapore to send seeds and particulars of the culture of "gambier" to Kew. This is done. The seeds are sown, and plants dispatched to such botanical centres as possess a suitable climate. Full particulars of growing and preparing for the market are published in the "Kew Bulletin," or elsewhere. Planters and natives are put in the way of cultivating *Uncaria Gambier*, and so the output is or will be increased, to the great benefit of the traders interested and the public. Again: A trader, say on the West Coast of Africa, is shown by the natives a sample of rubber new to him. It may be valuable or worthless. He does not know the plant from which it is extracted. He obtains specimen leaves and inflorescence, and sends them, with a sample of the rubber, to Kew. There the plant is identified with almost unerring certainty. The rubber is sent to a manufacturer to be tested. Eventually, particulars of the plant, the manner of obtaining the rubber, and its capabilities and market value, are published. Thus the trader learns whether the article is worth exporting. If it prove valuable, other traders are apprised of a commodity worth seeking.

This systematic identification, testing, and propagation are going on daily. A dozen "economic" plants may be receiving attention at one time. Kew introduced to India the cinchona, from which quinine is obtained. It is constantly studying new fibrous plants, an idea of the value of which may be gathered from the price of pineapple-leaf fibre—£60 the ton. Gums, resins, indigo, jute, coffee, cacao, and other products too numerous to mention, plant diseases, insect pests, adulterants, etc., are taken in hand with a view to extension or remedy. Whenever something new is discovered an attempt is made to propagate it for cultivation in our Colonies. Should the demand for the staple product of a colony fall off, Kew is able to suggest and supply another, indirectly or otherwise.

Much of its work, though unattractive to those engaged in it, is naturally uninteresting to the general public. That cannot be said of the inquiry into the so-called "weather-plant," the "Pateroster pea," of which much nonsense has been written. A Mr. Nowack, an Austrian, actually patented the plant, *Abrus precatorius*, with an apparatus to enable it to forecast the weather—fog, rain, snow, and hail; earthquakes, depressions likely to cause explosions of fire damp in mines, and what not, forty-eight hours in advance, for forty miles round! Such were the claims advanced.

Kew, in conjunction with the Meteorological Office, took the "Pateroster pea" in hand, demonstrating that the much-advertised "weather-plant" is not influenced by the weather, past, present or future in any way. The movements of the leaves are induced by variations of light; the downward motion supposed to presage an earthquake, is caused by an insect that punctures the stem, when the leaves droop and die. Exit the wonderful "weather-plant." The services rendered by Kew in connection with coffee have been of the greatest value. The coffee tree is a native of Abyssinia and tropical Africa. Kew has assisted to spread it over the tropical world. It has inquired into its acclimation, which is carried on to such an extent that 96,000,000 pounds of bogus coffee are said to be sold every year in the United States alone. In the Kew Museum are specimens of sham coffee-berries made of rice-flour, glucose, and water, worked into a paste and shaped in a mould. Kew has endeavoured to check adulteration by increasing the output of the genuine article.

The Royal Gardens are an advanced technical school. Each gardener is admitted for a two years' course, but it is necessary that he should have had experience elsewhere. He sees every kind of cultivation carried on in the establishment, attends lectures, and obtains instruction in scientific subjects connected with his profession. Kew men are in great request; the best receive valuable appointments as opportunity offers, and are to be found in every part of the world. Nearly all of them are in constant correspondence with their *alma mater*; the authorities foster it in every way.

Four periodical publications are issued from or prepared at Kew. The 'Botanical Magazine' has been prepared there since 1841. The 'Kew Bulletin' has been issued monthly since 1887. The 'Kew Annual Report' is, as its name implies, published yearly. The first number of a new publication, a private enterprise, has just been issued. It is the 'Journal of the Kew Guild,' an association of past and present Kew men.

The Kew roll of martyrs is not insignificant. Not long ago two promising young fellows went to the Niger to found and superintend Botanical Gardens for the Royal Niger Company. The climate killed both in a very short time. A brief history of the gardens may be of interest. In the reign of Charles II., Lord Capel had at Kew, somewhere near present chief entrance, a garden containing an orchery and the finest fruit-trees and flowers in England. It grew everything obtainable at that time. The garden was famous. In 1730 Frederick Prince of Wales obtained a long lease of the house and ground from the Capel family. To his widow Kew owes much of its present glory. She gave it its definite scientific form. It was then described as "that garden

where every tree that has been seen in Europe is at hand." George III. showed great interest in the gardens after his mother's death. During his reign the botanical, exploration, and horticultural activity at Kew had no parallel—and has not since been surpassed. No fewer than 6,746 rare exotic plants were introduced. At that time a common fuchsia, now worth 6d., fetched £5. Sir Joseph Banks, who voyaged with Captain Cook, became unofficial Director. He sent out collectors all over the world. A botanist connected with Kew accompanied Captain Cook on his third voyage. The same man, David Nelson, sailed to the South Seas in the ill-fated "Bounty" when that vessel went to introduce the bread-fruit to the West Indies, an idea which probably originated at Kew.—*Tit Bits.*

COCONUT PLANTING IN JAFFNA.

The cultivation of this palm in the Northern Province has received considerable impetus from the experimental attempts made by some native gentlemen in different parts of the Province. Till about 10 years ago the industry was exclusively in the hands of some Europeans, who opened up large tracts between Pallai and the Elephant Pass and turned them into useful and profitable estates. There was also a small area nearer Jaffna planted about the time the Pallai district was favoured by the introduction of English capital and skill. Our countrymen, who are slow to view with favour innovations of any kind have tardily begun to appreciate the advantages of the industry on a large scale and to believe in the adaptability of our soil to the growth of the palm. Those who had the capital were sceptical whilst those who had faith in the suitability of the soil had not the means. But we are glad to note that the sweets tasted by some native planters have wrought a healthy change; and the eyes of our few capitalists are now turned towards planting, though in certain quarters still lurks the idea that we should wait for a favourable opportunity to buy up an estate instead of speculating on virgin soil and waiting long for the expected return. Even the most sceptical ought not to doubt the facility with which fit lands can be procured. We learn that there are still large tracts to be had in the Pallai district where the soil has been so long tried and not found wanting.

Landed property in our district may be said to bring 4 per cent to the owner. Even this percentage is very doubtful in the case of our costly paddy fields. The little capital that finds its way into our country from parts near and far is invested in the purchase or upkeep of costly gardens worked at a loss, of palmyra lands of high value, and of paddy fields reputed to have brought many a man to the verge of insolvency. In spite of the large opening we have at a short distance from our centre, it is to be regretted that our love for proximity to home has been so inordinate as to make a capitalist ambitious of owning some unprofitable plots in his own parish. In fact the *summum bonum* of many a man has been this. Hence the congestion and property of our district, which can effectually be relieved by continuing to convert the now waste, but not sterile, lands in the Pallai district and beyond into good plantations. The man who takes to planting coconut in fit soil will find that his capital is not dissipated, the net yield of a plantation in Pachohilapalli being estimated at rates varying from 12 to 20 per cent on the outlay. He will without wasting his tortuous find labour for the destitute and homes for the homeless. It is needless to recount here several other advantages.

We would earnestly exhort our well-to-do countrymen not to wait to buy estates, already planted, but to rise above the mental infirmities of the vulgar and benefit themselves as well as their countrymen by opening up new plantations in suitable places. The construction of our longed-for railway will be expedited by the promotion of the industry, which, whilst being productive of capital and increased trade, would turn places at present uninhabited into fit habitations for our surplus population.—"Jaffna Patriot."

NOTES ON PRODUCE AND FINANCE.

TEA IN SUMATRA.—At the meeting of the British Delhi and Langkat Tobacco Company, Limited, held on Friday, Mr. J. Berry White, the chairman said that the company had lately utilised a portion of their large estate in raising other crops. "The climate and soil are," said Mr. White, "admirably suited for all these plants, the only doubt being whether labourers can be procured at sufficiently low rates to grow these crops remuneratively. We, of course, will feel our way very cautiously, and will spend very little capital on this departure until we have ascertained that we can grow these products to a profit. We have commenced with tea. We got some of the choicest variety of tea seed from Upper Assam, and this has been planted out in nurseries and will soon be transplanted on specially suitable land at Lingga, which, in my opinion, is far better adapted to the growth of tea than for tobacco. Liberian coffee already grows luxuriantly at Rimboem, and when the tea has made a fair start this will be proceeded with. Cocoa is a less hardy plant than either tea or Liberian coffee, and we do not expect to commence planting any until next year. We have engaged a skilled assistant from Java, and have recruited a number of Javanese coolies at moderately low rates of wages for the cultivation of the new products."—*H. and C. Mail*, July 7.

THE TARE QUESTION.—Commenting on the tare question, the *Grocer* says:—"We are not surprised to learn that many complaints have been made of the irregularities in the allowances for tares in some Indian and Ceylon teas, for the importers have in recent years managed so skilfully to arrange the weight of the wood and lead that any little overweight from this source has nearly disappeared, and consequently the purchaser of a few packages has little or no compensation for any short weight which may arise from an excessive tare. Of course in all cases the actual net contents of packages should be ascertained before any complaint is made, as the cooping of a package in the bonded warehouse may add to the gross and tare without affecting the net weight, but we are satisfied there have been good grounds for an alteration in the manner in which the tares have been determined, and it is comforting to what extent greater care is to be exercised in future. The subject of leaving tea on the warehouse floors for an unnecessary time after bulking is one we have previously drawn attention to, and as Indian, and particularly Ceylon, teas deteriorate so rapidly, it is highly desirable that the exposure to air should be as little as possible, for, as our readers know to their cost, they purchase from a sample perhaps submitted to them soon after the tea has arrived in London, and they are the greatest losers if the tea is not properly protected when in the bonded warehouses."

CINCHONA, COFFEE, AND TEA.—From a report which is given elsewhere it will be seen that the Wentworth Indian Estates Company, not content with its operations in cinchona, is extending its cultivation of Liberian coffee and tea. When everything else is doubtful try tea seems to be the idea prevailing, and so long as tea cultivation is not overdone there is something in it.—*H. and C. Mail*, July 21.

TEA PLANTING PUPILS IN CEYLON.

To the Editor "The Field,"
Sir,—As so many young fellows come out here as pupils to learn tea planting, without having the faintest idea of the sort of life or prospects before them, I venture to send you a few remarks on the subject, which you may see fit to publish for the benefit of intending "creepers," as the pupils are termed out here. These consist of two classes: those who have a certain amount of capital to invest, and those who have not. The prospects of the former are good; a year's training (generally costing, premium, board, and lodging, about £200) should qualify him,

provided he throws himself into his work, to manage—under the advice of an experienced visiting agent—a small property of his own, in which case a good start in life is assured him; and I believe tea is now considered to be as safe and profitable an investment as any in the Colonies, though I am personally far too inexperienced to give any opinion on this subject.

Planting is undoubtedly a healthy, open air life, up-country the climate is all that could be desired, and living is, of course, far cheaper than at home. At the same time there is heaps of work to be done, consisting almost entirely of accompanying and looking after the Tamil coolies in the field. Youngsters embarking for the Spice Isle will do well to bear this in mind.

Now a word to those of the second class who are thinking of coming out here, *Don't!* At least, don't take the step without thoroughly thinking it over.

For a young man without capital or interest in the island the prospects are at present very poor. The island is at present quite overstocked with premium-paying pupils seeking employment, and the cry is "Still they come." Most of the billets are in the gift of Companies, who, of course, generally have their own men; and when the "creeper" obtains the desired billet, it is only to find that the work is hard and the pay is small. Assistant's salaries vary from 83 rupees to 150 rupees or so a month, and when, after years of work, the "creeper" becomes a full-blown superintendent, he will probably never get more than 3,000 rupees or 4,000 rupees a year at the outside; and, though the vanishing value of the rupee may benefit the proprietor, the paid superintendent certainly suffers by it.

Ceylon, June 6.
—*Field*, London,

YOUNG PLANTER.

LIGHTNING ON TEA.

A Ceylon paper mentions that on the summit of a hill in the Kelani Valley, 60 tea bushes were killed by lightning, and it is further of opinion that this is the first occasion on which such a circumstance has happened. In Cachar, though such occurrences are not frequent, many instances are recorded, especially on plantations situated immediately under the Northern hills. Nutwanpore factory being particularly liable to these visitations, owing no doubt to the quantity of iron in the soil.—*Indian Planters' Gazette*. [We have since heard of a case in Dolosbage some years ago.—*Ed. T.A.*]

THE AUERBACH QUININE-FACTORY.

A rumour obtained currency on Change this week, and spread with great rapidity among the holders of quinine, that the Auerbach Quinine-factory was in liquidation and would give up manufacturing. This report is entirely inaccurate. All that has happened is that the factory in question is being re-converted from a limited company into a private concern, a change which will enable the proprietors to dispense with certain formalities regarding the publication of periodical accounts prescribed by the law in the case of companies. The firm, however, propose to make quite as much quinine in the future as they have done in the past.—*Chemist and Druggist*, July 28th.

THE REFUSE STICKS of the sugar cane can be utilised in making paper, and a contemporary expressed natural astonishment that in face of the present large production of sugar, which results in the constant depreciation in value of this product and *per contra* of the increasing use of paper, this industry has not been developed on a practical basis, so as to enable the sugar planters to get a better return from their plantations. The mechanical and chemical manipulation required in this industry is, we believe, of the simplest character, which only makes its neglect the more remarkable.—*Invention*.

THE CHINA TEA TRADE AND ITS PROSPECTS.

Although we do not hear much from the China ports on the subject—probably because it is too late to do much this season; yet, we must not suppose that China tea-dealers are not aware of the advantage they have with a cheap dollar. Here are two views of the Foochow Tea Trade from our latest files which show how the wind blows:—

THE FOOCHOW TEA TRADE.

To the Editor of the *Daily Press*.

SIR,—I perused with some interest the reproduction in your paper dated 21st inst. of a letter to the *Foochow Echo* on this subject from a correspondent. As if in reply, London, dated 16th June advises:—

"We hear that shipments from the North and Foochow to date are too large for our requirements; what we are to do with them we do not know; they will have to be dealt with in a most retail manner, or a ruinous scale of prices will be the result."

As I take the trade to be in the United Kingdom, Ceylon and Indian teas are the basis they work upon and China congeners, with the exception of really fine quality, are mostly used by blenders as a stopgap, the demand and price for which varies in proportion to the export from India and Ceylon being in excess or diminution of trade requirements.

This being so and the fashion having set in for Ceylon and Indian teas, I do not, unless the quality shows most phenomenal improvement on previous crops of former seasons, look to a quantity of Foochow teas, such as could be bought from 11s 7³/₄d to 15 per picul, reversing the now established order of things at home. On the other hand, if in excess and not required they may only serve to depress China tea still further and the trade all round. It would appear that if Foochow wishes to advertize her trade into some of its former position on the London market it would best be done by the exceptional quality and strength of her teas, together with a restricted export, and not by quantity even though at a low price.

It must be remembered that the same cause which brought about a demand for China congener for price at the close of last season raised Indian and Ceylon rates most materially for lower grades. It was not a revival of feeling in favour of China tea by any means the want of tea from all producing centres was felt not Foochow in particular.—Yours faithfully,

F. O. S.

Macao, 24th July 1893.

A correspondent writes to the *Foochow Echo* as follows:—

There is a feature in our tea trade this season which I look upon as distinctly cheering. It is this, that instead of the falling off of supplies which has been going on uninterruptedly year after year for nearly ten years past, we have now an increase. This I trust will be henceforward progressive. The dwindling away was a great misfortune. Had it continued, our trade would before long have been a thing of the past.

The statistical year of the London Tea Brokers Association ended on the 31st May, and their interesting statement of imports, deliveries, and stocks for the year is now before us all. We look aghast at the figures of the twelve months deliveries of China congener as compared with those of the previous year and of other earlier years in order, but what was to be expected? How could the London dealers buy and take delivery of what was not there for them to buy? They have taken all China could manage to send them, leaving but a minimum of stock, and it is only fair to suppose that more would have been taken had it been shipped for them to take. The more we retire from the London Market, the more we may retire. We have been simply bowing Indian and Ceylon into a position we ought never to have surrendered, and probably never would have surrendered but for the high cost price which had grown up in our time of prosperity, and, so to speak, be-

came normal obliging us to be cautious and limit our shipment.

We are, however, I think, on the eve of a change—indeed it commenced, I consider, last year when the teamen "went for" the growers to cheapen the first cost, in which they succeeded, and they, as well as foreigners, made money. The growers certainly lost, but they are contented again this season, the teamen having agreed to pay them about ten per cent advance on last season's prices which they could well afford to do and yet make money, as, indeed, they have done, while as far as foreigners are concerned they have still been able to lay down their teas at the same reasonable prices, exchange having favoured them to the extent of the higher tael cost. At these prices, the shipments that have gone forward may be considered "fair merchant's risks," that is to say, there is every promise of a profit and at worst no room for more than a minimum of loss. In a word, we have, last year and this, got prices down to a level at which we may send tea freely forward to London to meet its fair share of the large consumption in the United Kingdom without being careful to heed our rivals. Whatever general trouble the adoption of a gold currency and the fixed value of the rupee in India may bring about, our tea trade will not suffer. On the contrary, it will be to our advantage, just as it will be against India and Ceylon, on the other hand, in the matter of laying down their teas, through their being handicapped in exchange.

Altogether I look upon the prospects of the Foochow tea trade as improving, but we must keep our teas well advertised by sending plenty of them—not too much at a time, which would depress prices—but spread over the season as much as possible; and, certainly, on no account allow the business to dwindle away as it has done for so many years up to the present time, if it can possibly be helped.

The point of my argument applies equally to the Australian markets. The export to that quarter of the world dropped from 21 millions in 1889 to 15 millions in 1890, thereby leaving a direct opening for the produce of India and Ceylon.

Although not apropos of my subject, I can never touch upon the subject of tea without referring to the cruel heaviness of the China export duties. More than half of the Congou settled, so far, this season, has cost from 7½ to 11s. 15 per picul, the duty on which is 20 to 30 per cent. With only a partial reduction our trade would, I do not hesitate to say, double in extent in two or three years.

ST. HELIERS TEA COMPANY, LTD.

Minutes of First General Meeting held at the Office of the Company, No. 11, Queen Street, Colombo, at 12 noon on Tuesday, 8th August, 1893.

Present:—W. H. Figg, Esq., (in the Chair); E. M. Shattock, Esq.; W. B. Kingsbury, Esq.; Stanley Bois, Esq.

Notice convening the meeting being read, and there having been no previous general meeting, it was proposed by Mr. W. B. Kingsbury, seconded by Mr. W. H. Figg: "That the Report and accounts be passed and that a dividend of 17 per cent for the past year be paid forthwith."

Mr. E. M. SHATTOCK drew attention to the falling-off in the make of recent breaks of tea, and suggested that the attention of the Superintendent and of Mr. W. S. Thomas be drawn to the matter with a view to maintaining a higher standard. The Secretaries then read Mr. W. S. Thomas' report on his visit of 11th July.

Proposed by Mr. E. M. SHATTOCK seconded by Mr. W. B. KINGSBURY:—That all the Directors be re-elected.

Proposed by Mr. W. H. FIGG seconded by Mr. W. B. KINGSBURY:—That Mr. E. M. Shattock be appointed Auditor on a fee of Rupees fifty.

The meeting concluded with a vote of thanks to the Chair.

The following was the report of the Directors:—

The Directors herewith have the pleasure to submit their first Report, which they trust will be considered satisfactory by the Shareholders, shewing as it does a profit of nearly 26 per cent on the year's working.

The crop, which was estimated to be 100,000 lb. of made tea to 30th June, only reached 89,505 lb.; but this short fall was fully compensated for by the higher average price realized—namely 48 cents.

The Directors recommend dealing with the profit as follows, viz.:—To write off the total preliminary expenses incurred in the formation of the Company, amounting to R3,449'66; to set aside the sum of R855'27, being 4 per cent on the full insured value of Factory and Machinery, in respect of depreciation thereon; to divide a profit at the rate of 17 per cent for the year; and to carry forward the small remaining balance of R62'91.

In terms of the Articles of Association, all the Directors retire, but are eligible for re-election. It will also be necessary to appoint an Auditor.

CEYLON TEA IN SOUTH AUSTRALIA.

Messrs. Drummond of Adelaide are now firmly established in Adelaide and they should be encouraged in every way. They have had great uphill work, but now their business is progressing well. A joke appeared lately in the Adelaide paper "Quiz." Major-General Downes the Commandant of the South Australian troops complained to the Manager of the Refreshment Rooms of a large railway station in South Australia as regards the wretched quality of the tea:—"Why don't you get your tea from Drummond Bros. They sell Ceylon tea and it is good." "Ah" the Manager replied "We are not all Major-General's!"—Miss Drummond a sister of Messrs. Drummond has arrived by the "Hoheuzollern" and has had the pleasure of meeting her brother here who has completely recovered from his late illness.

THE CINCHONA DEPARTMENT.

According to the report of the Director of the Cinchona Department, the absence of sunshine and drought which prevailed on the western side of the Nilgiri plateau from October till the end of February last, rendered the season unfavourable for cinchona cultivation in all the estates except Dodabetta. The crop harvest during the year was, therefore, less than the quantity disposed of. Of the bark disposed of, a large quantity was utilised for the manufacture of sulphate of quinine and solid febrifuge. Crown bark was principally used in the manufacture of quinine. A large quantity of sulphate of quinine and febrifuge was manufactured at the Nedivattam factory and supplied to the medical stores departments of Madras and Bombay, to the Mysore Durbar and to private parties. The annual output of the factory is considerably in excess of the requirements of the Government Medical Department and there will always be a sufficient quantity of the drugs in stock to meet all demands. There was a very material increase in the number of indents received from the several Collectors of quinine packets. The receipts during the year under review excluding the cost of quinine packets supplied to collectors for distribution was less than the budget and revised estimates. The decrease was due to a reduction in the price of quinine and to the Ceylon Government having discontinued the purchase of quinine from the Nedivattam factory. The expenditure of the department during the year was also less than the budget and revised estimates. The reduction in the expenditure is the result of an attempt on the part of the Director to equalize the actual revenue and expenditure.—*M. Standard.*

WENTWORTH INDIAN ESTATES CO.

GOLD, TEA AND LIBERIAN COFFEE.

The thirteenth ordinary general meeting of the shareholders of the Wentworth Gold Mining and Indian Estates Company, Limited, was held on Thursday week, at the offices, 34, Nicholas Lane, E.C., Mr. Robert Ewing (the chairman) presiding.

The Secretary having read the notice convening the meeting.

The Chairman said: Gentlemen, during the year we have been pursuing the same policy as we have done for several years past; but now you will see from the accounts that we are coming to the end of our cash resources. This has arisen, to a material extent, owing to our not being able, from various reasons, to get in the whole of our last call. We have, however, the last two years' harvests of cinchona bark on hand, which will, we expect, with the growing coffee crop, produce sufficient to carry us over the current year. We have done our best to keep the estates in proper order, and have, moreover, only taken such harvests of bark as were necessary to the well-being of the plantations. By taking a fair crop each year the estate would be self-supporting, unless prices fall below their present level. We are making extensions of tea and Liberian coffee, which we think, when they come into bearing, will add considerably to the returns from the estates. We cannot see our way to making any reduction on the debit side of the account, and it is possible the cost may be slightly larger next year, owing to the recent rise in exchange, caused by the legislative enactment. As regards the share capital, after exhausting all possible means of getting the arrears of calls paid up, and not having succeeded, we put the matter into the hands of our solicitors, and at the small cost shown in the account they succeeded in getting in a considerable amount. The shares in respect of the remainder of the calls, with the exception of a small amount, we have declared forfeited, owing to bankruptcy, death, or inability to trace the shareholders. At the same time we have, under the articles of association, a claim upon these people in respect of those calls should the opportunity of enforcing it arrive, and this will explain the cross entry in the balance-sheet of debtors for calls on forfeited shares. Since the accounts were made up a further sum of £10 has been got in for arrears, and we think that the small sum of £145 will be ultimately recoverable. In the extract we have given you from the manager's report you will observe that the Liberian coffee seems to suit our estates remarkably well, and a great feature in its favour seems to be that this species is not subject to the ravages of leaf disease. Our managers also inform us that he is now planting out 60 acres of this coffee, which, I understand, comes to maturity quicker than the Arabica, therefore we may expect some returns from this source in a year. We are going on as actively as possible with the cultivation of tea, as you will see from the report. As regards the future of the company, we think that the policy that should be adopted is to take sufficient bark to pay the outgoings each year, and when the coffee and tea extensions come into bearing it will be for the company to consider whether some plan of reconstruction should not be adopted to reduce the large amount at which the capital stands, and provide some further working capital. With regard to the position of the produce market, I will ask Mr. Labonchere to address you. I now beg to move: "That the directors' report and statement of accounts be, and they are hereby, received and adopted."

Mr. James Labonchere said:—The market for bark has not been satisfactory for the last two or three years. I can state no reason why the market has not improved; certainly the supplies of bark have not been larger than in previous years. There have, however, been certain changes of distribution. Ceylon, for instance, is reducing its production of bark, and no doubt, next year there will be a decrease, inasmuch as less bark is being imported from Central America and Java. The Java bark is very rich, and larger quantities have been sold at Amsterdam. Experience

has taught us that there generally has been a fair competition for the bark, and the prices are fairly maintained; but recently, at the sales at Amsterdam, the competition has fallen off, and, consequently, importers have not sent the same quantity. The Java importers are passing through the same crisis as we have had to pass through in Ceylon and India, and, consequently, only good estates will survive, and the bad ones will have to go to the wall. That process has been going on for a year; but the curious part of it is that, although the supply of bark is not larger than last year, the prices of bark have fallen off. For three years prior to last year the prices were 1d. per unit, 1½d. per unit, and 1¾d. per unit; but since then the price has fallen to ¾d. and ¾d., which is a reduction of 25 per cent. With such a falling-off it is hardly worth while to sell. A rise, however, to 1½d. or 1¾d. in the next three or six months may bring about a little more demand. Owing to the fall in the price of the bark we have not made a regular harvest, but have thought it better to wait until the market improves. The recent price of quinine has been 10s. and 9s. per ounce; but in 1892 it was 8½s. and 8s. The German manufacturers have combined not to sell any quinine under 10s., and I am glad to say that they are holding to their compact. I think that you have no reason to be alarmed about the price of quinine, and, although the price of bark is getting lower and lower, it will work its own cure. As regards the production of our coffee I am glad to say that it sells at a very high price. Last year, unfortunately, we had no crop, but this year we expect three or four tons, for which we hope to receive £300 or £400. As to the tea, as soon as we are able to bring it forward we can dispose of it in Mincing Lane, if it is made without machinery, at 7d. or 6d. a lb.; but if it is a better class of tea which we shall be able to produce later on, we ought to be able to get from 9d. to 1s. a lb., according to the market. The prices of tea have been fairly good lately, but we should possibly be able to produce tea and sell it at a profit even at lower prices. We have in this company, therefore, three strings to our bow—our bark, coffee, and tea—which are coming to the front. I beg to second the resolution.

Mr. E. Jones asked the amount of the assets and liabilities of the company.

A number of other questions having been asked. The Chairman, in reply, stated that Mr. Jones would see from the balance-sheet that the cash liabilities amounted to £1,141, and against that they had produced £2,820, £602 in cash and sundry debtors for £26. Sixty acres of coffee were being planted out. The report from the manager was dated March 29 last. As regarded the appointment of a new assistant-manager, the board were at present in negotiation with a young man to proceed to the estates. The board would be very pleased to consider any suggestions that Mr. Eccles might make with regard to planting other articles of produce. As regarded the production of tea, to which allusion had been made, statistics proved that the deliveries were larger than the imports. There was a good deal of room, therefore, for extensions; but he did not think they would be so large as to materially effect the supply.

The motion was then put, and carried unanimously.
—H. and C. Mail. July 21st.

THE HORTICULTURAL COLLEGE, SWANBY.

This College was founded about four years ago, with the object of promoting scientific horticulture, as well as poultry rearing and agriculture. Such an establishment was a long felt want, and the means of acquiring a practical knowledge of the best system of horticulture was out of the reach of those who wished to enter this field for the employment of labor or capital; but, at the Swanby College, young men—and young ladies also, for there are eight lady students there at the present time—are given every facility to acquire a thorough and practical knowledge of the most scientific systems of horticulture, thus fitting them to fill posts either as market garden-

ers or land owners, either as tea planters or fruit-growing colonists.

The College is situated 15 miles from London, near Swanby Junction on the London, Chatham and Dover railway, and its grounds, including orchards, glass houses &c. are 4½ acres in extent. It was formerly the residence of Sir Edward Reed, designer for the navy, and inventor of that shocking failure, the "Bessimer," the swinging saloon of which is now utilized as the lecture room of the college. There is accommodation for 50 students; and the buildings include also a lecture hall, class rooms, dining hall, laboratory and library, in addition to the private residence of the Principal. There are also farm buildings, stables, workshop, dairy, apiary and poultry runs, with glass houses and horticultural accessories adjoining. Like many other schemes this one had an uphill climb to commence with, and many difficulties had to be encountered before it could be said that the college was in a fair way to success.

The Kent County Council, however, has proved of the greatest assistance to the college, by nominating and paying for twenty students, these being first selected and subjected to an examination. Three members of the Kent County Council are on the governing body of the college, to watch over the interests of their students, but they do not interfere in the least with financial matters.

The number of students have increased, during the past few months, from 35 to 50—the full complement,—and a scheme is even now under consideration to enlarge the college by taking a house adjacent, and thus have accommodation for more students. In addition to these there are 8 young lady students, who live in a house close by, with Mrs. Watson as matron, and these attend the lectures and practical demonstrations in pruning, poultry raising &c. It has been argued by many that the study of Horticulture is not a suitable one for young ladies, but it may not be generally known that there are, at the present day, 8 lady gardeners in England, 3 in Ireland, 2 in Wales and 1 in Scotland, and these are all in the first rank of their profession. There are many ways for ladies to turn the knowledge of gardening to account besides growing for the wholesale market or retailing to private individuals. They might take situations as gardeners, or even manage their own gardens and thus save the expense of a gardener. There are many women to whom an active out-of-door-life is preferable to a life of confinement, such as school teaching or dress-making, and these, if they decide on adapting the profession of gardening, could not do better than place themselves under the care of Mrs. Watson at the College, for gardening must be systematically learned if a living is to be made from its pursuit.

Experts daily lecture in the College on many subjects, such as Horticulture, Floriculture, Botany, Zoology, Physics, Chemistry, Agriculture and Land Surveying, besides which practical demonstrations are given in pruning, grafting, agriculture &c. and I may here remark that at Swanby College, I saw the gooseberry bushes pruned in the same way as Ceylon planters were wont to prune their coffee trees, a thing I have only seen once before in Great Britain, namely, in my own garden. And I may also here remark that the finest gooseberries and the heaviest crops I have seen on any gooseberry bushes in the Island were on the bushes in my own garden and at Swanby College, from which I conclude that the system of pruning coffee has been successful when applied to gooseberries.

During the fruit season a van laden with produce leaves the College three times a week for London, and on the other three days orders are fulfilled by train, the College fruit being well known in Covent Garden. When a rush of crop takes place, and the means of despatching the fruit is inadequate, the surplus is made into jam, the boiling being done by means of a small steam engine, and the bottled fruit and jams which I not only saw but sample, needs no recommendation at my hands, as they speak for themselves.

The rearing of poultry is done principally by means of an incubator, and this is worked more skilfully and with less trouble than any incubator that I have seen. The fowls are not of any special breed being prized more for their generous production of eggs than for the length of their pedigrees.

The glass houses appear to be worked in a manner which is likely to leave a profit, for no sooner is a crop of geraniums or peaches finished than the pots in which the plants are growing are put outside, and young tomato or melon plants are substituted and these again give place to something else, so that the heating apparatus is always usefully employed in forcing something or other on the market. The grape vines are very fine and the crop when I saw it hung in huge bunches from the roof of theinery; whilst some idea may be gathered of the profusion of roses when I say that, from one glass house alone, upwards of 10,000 gloire-de-dijon rose blooms were sold in the London market this spring.

The Principal, Mr. Eliot, took over charge from Mr. Boid some eight months ago, before which time he was engaged on the Manchester Ship Canal as Resident Engineer, he having the chief section under his care, namely the lock-gates at Eastham and that portion of the embankment which has to withstand the severest strain of the tidal waters. Previous to that he was engaged in harbour works in all parts of the world, and the breakwater at East London, Cape Colony, I have heard spoken of as a far superior feat of engineering to the Colombo one, because in East London there never is such a thing as a spell of calm weather, such as you have in Ceylon during the N.-E. monsoon. Mr. Eliot appears to be as contented and enthusiastic with his life at the College as ever he could have been as an engineer, and his knowledge of surveying, building construction, &c. must be of material assistance to the students.

I left the College with the conviction in my own mind that, for young men who intend going abroad either as planters to Ceylon or India, or as fruit-growers in Australia, no better training could be given to them than what they could obtain by residence at Swanby College, and as it is only half-an-hour's run from London, parents, whose sons are preparing to go to the East, might do worse than take a run down to see the College and judge for themselves of the good that a year's training there might do their sons before going abroad.

COSMOPOLITE.

THE CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the "Ceylon Tea Fund" held at Kandy on Thursday the 10th day of August 1893 at 3 o'clock (3 p.m.) in the afternoon.

Present:—Messrs. Giles, F. Walker, Chairman Planters' Association of Ceylon; J. Anderson, Kandy and Matala West; Charles Gibbon, Hon. Secretary Northern Districts Planters' Association; W. Megginson, Chairman Ambegamuwa Association; James Westland, Chairman Northern Districts Planters' Association, C. Spearman Armstrong, Hewabeta; T. C. Owen, Kandy; Charles Young, Kandy; J. H. Starey, Kandy; R. S. Duff Tytler, Kandy; A. W. S. Sackville, Maskeliya; Hugh Blacklaw, Ambegamuwa; Thomas Smith, Chairman Dolobsaga and Yakdessa Planters' Association; H. M. Toller, Chairman Maskeliya Association; W. S. Thomas, Dimbula; S. E. Trench, Hon. Secretary, Maskeliya Association; F. G. A. Lane, Kandy; A. Philip, Secretary to the Planters' Association of Ceylon Kandy.

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the committee held at Kandy on Friday the 9th June 1893 were submitted for confirmation.

Resolved that they be and they hereby are confirmed. Read letters from Mr. T. C. Anderson on the subject of certain Exhibits at the Chicago Exhibition, and

forwarding a photograph of the sale of Gartmore Estate golden tips at £25 10s per lb.

Resolved:—"That the letters be acknowledged and thanks conveyed for the photograph."

Read letter from the Yatederia Tea Company of Ceylon Limited.

Read letter from the Manager Syndicate Boat Company Limited.

Resolved (I):—"That a copy of the letter be sent to the Chairman of the Ceylon Tea Company Limited for his information with a request that he will arrange with the Manager of the Syndicate Boat Company for carrying out the proposed alteration."

Resolved (II):—"That a copy of this Resolution be forwarded to the Syndicate Boat Company Limited."

CEYLON TEA AT THE IMPERIAL INSTITUTE.

Read letters from the Secretary Ceylon Association in London on the subject of the agreement with the Contractors and advising draft R1,441-06 on account.

Read letters from the National Bank of India Limited acknowledging payment of acceptance.

Read letters from Mr. F. R. Saunders and Messrs. Gow Wilson & Stanton notifying the transmission of a diagram showing the history of the Ceylon Tea Industry similar to one placed in the Ceylon Court at the Imperial Institute.

Resolved (I):—"That the letters and enclosures be sent to the Newspapers for publication."

Resolved (II):—"That Mr. Saunders and Messrs. Gow Wilson & Stanton be thanked for their courtesy in forwarding Diagram of Ceylon Tea as exhibited at Chicago."

CEYLON DUST TEAS.

Read letter from the Secretary London Wholesale Tea Dealers' Association received through the Secretary Ceylon Association in London inviting attention to the class of chests used for dust teas, and asking that the matter may be considered with the view to having a more suitable package adopted.

Resolved:—"That it be stated in reply that in the opinion of this Committee it is advisable to pack dust teas in half chests properly hooped."

CEYLON TEA AT THE WORLD'S EXPOSITION AT CHICAGO 1893—CHICAGO EXHIBITION FUND.

Read letters from the Colonial Secretary.

Read letter from the Special Commissioner for Ceylon at the World's Columbian Exposition.

Read letters from the Ceylon Agent of the Commissioner.

Laid on the table Official Guide World's Columbian Exposition received by the courtesy of the Special Ceylon Commissioner.

Resolved (I):—"That Government be thanked for the letters received and informed that the question alluded to in the Colonial Secretary's letter of the 1st August is having attention.

Resolved (II):—"That Mr. Grinton be asked to state with reference to paragraph 7 in his letter of the 26th June to the Colonial Secretary what steps he would advise being taken in Ceylon to assist in carrying out his views, and to add to what extent he would be willing to initiate arrangements personally and further to afford the Committee any information in his power that may bear on the question.

Resolved (III):—"That a meeting of the subscribers to the Chicago Exhibition Fund be convened at the date and place of the next Planters' Association Committee meeting to decide on the further disposal of the money.

Resolved (IV):—"That the memo. submitted by the Secretary be annexed to this minute.

CEYLON PLANTERS' TEA COMPANY OF NEW YORK.

Read letter from Mr. R. Wade Jenkins.

Read letters from the Ceylon Planters' Tea Company of New York.

Read correspondence between Mr. C. O. Mackwood and the Chairman.

CEYLON TEA IN PORTLAND, OREGON WEST COAST OF AFRICA.

Read letters from Messrs. A. B. Scott & Co.

Resolved:—"That the Committee is not in a position to avail itself of the proposals made on the subject during the present year.

CEYLON TEA IN RUSSIA.

Read letter from Mr. M. Rogivue.

CEYLON TEA IN BAVARIA.

Read letter from Mr. Wickremasinghe.

CEYLON TEA IN AUSTRALIA.

INTERNATIONAL EXHIBITION, TASMANIA.

Discussed the representation of Ceylon Tea at the Tasmanian Exhibition.

Resolved:—"That consideration of the question be deferred to next meeting.

Laid on the table and circulated at the request of Mr. John Ferguson his article in the *Ceylon Observer* on the subject of Ceylon Tea Consumption in Australia.

Read letter from Mr. Alexander Thom on the subject of pushing Ceylon tea in the North Island of New Zealand comprising beside the Auckland Province, the districts of Wellington, Hauke Bay, &c.

Resolved:—"That Mr. Thom be asked to supply the Committee with further information before next meeting of the Committee."

CEYLON TEA FUND STATEMENT OF ACCOUNT AS AT 30TH JUNE 1893.

Laid on the table statement of account as at 30th June 1893.

Resolved:—"That it be published, The Standing Committee of the Tea Fund then adjourned."

A. PHILIP.

Secretary to the Planters' Association of Ceylon.

WORLD'S FAIR AND COLUMBIAN EXPOSITION AT CHICAGO 1893.

NOTES ON PRODUCE AND FINANCE.

OCEAN FREIGHTS.—At the annual general meeting of the India Tea Districts Association, a full report of which appears in another column, a most important discussion took place regarding the attitude of the tea industry towards the ocean steamship companies. Our readers are aware that while undoubtedly there exists some divergence of views among the more powerful members of the Tea Association, there is a general feeling that the time has now arrived for the important tea industry to shake itself free altogether from the engagements with the steamship owners hitherto existing, of an onerous and onerous nature. This view has been affirmed and re-affirmed at various meetings of tea proprietors, both in Calcutta and in London. The chairman of the meeting above alluded to very properly characterised the attitude of the shipowners as one which appeared to ignore the most ordinary business principles, and he also indicated very rightly that the tea industry was bound, on ordinary principles of self-interest to organise to protect its own interests. It was accordingly decided to make a strong endeavour to obt

from shippers, representing not less than a certain proportion of the whole industry, to agree to stand unconditionally together in opposition to any one-sided or disadvantageous arrangement of the steamship companies, which might have for its object directly or indirectly to stifle free competition. It is sincerely to be hoped that this suggestion will not only command a wide support, but will result in paving the whole question on a better basis, and that the Indian tea industry will be enabled to hold its own against the increasing competition of Ceylon and China, both of which countries are at present very much more favorably treated than India in regard to freight rates.

THE INDIAN PLANTERS AND CO-OPERATION.—At the meeting of the Indian Tea Association a most important proposal, which on more than one occasion of recent years has been brought before that body, was made with a view to placing the association, so far as its financial resources are concerned on a more solid and satisfactory basis. It is suggested that, in co-operation with the Calcutta Association, the revenues of the association should in future be increased and placed on a better footing by means of the assessment which is levied in India—this being increased a little, if necessary, and that in this way the two associations may not only be strengthened financially, but may be brought into closer connection with one another. We have always advocated the strengthening of the industry by such co-operation and self-help, and we would strongly urge on our readers, so far as in them lies, to give their support and assistance to any well-conceived scheme which may be placed before them with the above object in view.

FIBRE CULTIVATION IN THE BAHAMAS.—Sir A. Shea's report to the Colonial Office says that the area of Crown land already acquired for the cultivation of the fibre in the Bahamas is about 70,000 acres, of which nearly 12,000 acres are already under cultivation in various stages of progress. From the present agencies at work it can be safely estimated that 5,000 acres per annum will continue to be added to the operations. There need be no special effort to dispose of the balance of the land now ungranted, within the prescribed limit of 100,000 acres, as the increasing experience of the value of the fibre enterprise will assure the sale of the available land in good season. None of the investors would, if they could, withdraw from the enterprise, and there is no diminution of the confidence with which it was undertaken. The small shipments that went forward in the past year satisfied every expectation on the score of the excellence of the fibre and its market value, and as shipments increase, and the article becomes more extensively known, there is little doubt that it will establish a stable position in the fibre market. It is now generally conceded that it will enter considerably into the manufacture of various fabrics, and that for some time to come but a small portion of the production will be used for rope making. Indeed the prices that have been hitherto paid indicate clearly that other uses have been found for the fibre, for the rates have gone well above the quotations for Manila.—*H. and C. Mail*, August 4.

THE GALLAHA CEYLON TEA COMPANY.

We are now in a position to be able to announce at least one proposal towards the substitution of a new Limited Company on a big scale for private proprietors in Ceylon Tea Plantations. The Gallaha Ceylon Company is to have a capital of £100,000 in £10 shares with £30,000 in mortgage Debentures bearing 6 per cent. The Company is to take over the group of properties belonging to Messrs. Chas. Strachan & Co. in the Hantane, Nilambe and Hewabeta districts, including the well-equipped Gallaha Tea Factory which we have heard described by an impartial authority as one of the best arranged and roomiest Factories he had seen in

the island. The Company also takes the Union Mills and Agency premises. Altogether, a total of 4,092 acres with 1,953 in tea and 66 in cardamoms are taken over on the following estates:—Gallaha, Kitulamule, Vedeettes, Mousakelle, New Madagama, Gourakella Group. Last year, the crop was over 500,000 lb. of tea and for the coming year it is expected to be as much as 630,000 lb., besides the leaf purchased for manufacture. The vendor Mr. Chas. Strachan takes 2,500 fully paid shares. He and Messrs. M. P. Evans and C. Hannen are to be Directors, and the valuations of the properties being made by Mr. W. D. Gibbon, the estimate is that the crops after paying 6 per cent to debenture-holders will secure 10 per cent to shareholders with a balance over, during the coming year and do better probably in the years following:

In any case, there is not likely to be any general appeal to the public to take up many of the shares; for we understand that about three-fourths of the number were almost at once subscribed for by friends of the promoters.

CEYLON TEA AT IMPERIAL INSTITUTE.

Kandy, 16th Aug., 1893.

SIR,—I enclose copy of letters from the Secretary Ceylon Association in London in reference to Ceylon Tea at the Imperial Institute and other matters.—I am, sir, yours faithfully A. PHILIP,
Secretary to the Planters' Association of Ceylon.

(Copy.)

4 Mincing Lane, London, 30th June 1893. E.C.
A. Philip, Esq., Secretary, Planters' Association, Kandy, Ceylon.

Dear Sir,—I have to thank you for your letter of 29th ultimo, confirming my action in regard to the agreement with Messrs. J. Lyons & Co. of the Imperial Institute. I am sending you by parcel post one of Messrs. J. Lyons & Co.'s advertisements. The Firm is carrying out the terms of the agreement faithfully: and the Tea supplied seems to be of uniform good quality in the cup.

By next mail I shall have to draw on you for the £100 payable on 8th proximo under the agreement.

Kindly bear in mind that on or before 31st proximo I have to give notice of continuing the agreement till June 1895. If you have not already sent instructions on this point when you receive this letter, please wire to me what I am to do. I enclose copy of a letter received from the London wholesale tea dealers' Association as to the chests used for packing tea dust in Ceylon.—I am, &c,
(Signed) WM. MARTIN LEAKE, Secretary.

TEA CHESTS.

London Wholesale Tea Dealer's Association,
4, Fenchurch Street, E.C., 23rd June 1893.

W. MARTIN LEAKE, Esq.,—Dear Sir,—Complaints have reached my Committee that the chests used for dust teas are not made sufficiently secure to prevent leakage in transit; so much so, that in some cases the Railway Companies refuse to take the tea unless it is covered with a canvas wrapping, the Consignees in many instances decline to pay the cost thereof, which therefore falls upon the wholesale dealer.

My Committee would feel obliged by the Importers considering this matter with the view of their adopting a more suitable package for this class of tea.—I am &c., Signed R. SEDGWICK, Hon. Secretary.

4, Mincing Lane, London, E.C., 7th July, 1893.
A. PHILIP, Esq., Secretary, Ceylon Planters' Association, Kandy.

Dear Sir,—I have the pleasure to enclose account showing an my transactions with Messrs. J. Lyons & Co., Ltd., owing to an error in the making up the account (an error which is now corrected) the proceeds of my

Draft on you at 7 days sight for R1,441-06, for which I ask your kind protection, leave a balance due to me of 5/ to be carried to a fresh account. I have today sent a cheque for £100 to Messrs. J. Lyons & Co. Limited, in terms of your agreement with them. If it be wished I can send full particulars of the tea purchased for Messrs. Lyons & Co. I have sent them this week a further supply of 1 chest and 2 half chests. All the tea sent has been of excellent quality and it has I hear met with general approval as served in the cup at the Imperial Institute. I have sold the above-mentioned Draft to the National Bank of India at 1-3 9-16th per rupee.—I am &c. (Signed) Wm. MARTIN LEAKE, Secretary.

BARK AND DRUG REPORT.
(From the Chemist and Druggist.)

London, July, 20th.

ANNATTO.—Two chests bright and dryish paste were bought in at 4 1/2, and two barrels seeds sold cheaply without reserve (if paying charges) at 4 1/2; 7 bags clean seeds were bought in at 2d.

ARRICA-NUTS.—Of 135 bags offered, only 25 sold—5 at 19s and 20 at the same price subject; for 50 bags good clean a bid of 17s 6d was refused, the parcel being bought in at 21s.

CARDAMOMS.—Over 200 packages of various kinds were offered, including a goodly number of fine white Mysore, and there was comparatively little demand for them, and they were ultimately only about a half sold. The principal prices obtained were: Fair bold white Mysore 2s 1d to 2s 4d (mainly subject); the finest lots were bought in at 3s to 4s. Small to medium Ceylon Mysore, pale inc. lour 1s 6d to 1s 8d; duller 1s 4d; some parcels of a bolder character 1s 8d and 2s 6d; splits 1s 3d. A fair proportion of the Malabar met with demand at 1s to 1s 5d for small to medium, and 1s 6d to 1s 8d for bold, these being chiefly brown.

CROTON-SEED.—One case sold at 20s subject. It was an old and poor-looking lot.

LONDON, July 26th.

CINCHONA.—Tuesday's bark-auctions bore off the palm in respect of insignificance, the quantity of bark offered being barely one-fourth of that shown at an average sale. There were nine catalogues, which included:—

	Packages	Packages
Ceylon cinchona	218 of which	133 were sold
East Indian cinchona	404 "	404 "
South American bark	255 "	246 "
	878	783

African or Java barks were not offered. The assortment was rather poor, and very little interest was shown in the auction, one or two firms obtaining from competition altogether. The unit remains unchanged, at from 9-16ths d. to 3d per lb., for ordinary and medium qualities.

The approximate quantities secured by the principal buyers were:—

	Lb.
Agents for the Mannheim and Amsterdam works	48,834
Agents for the Brunswick works	25,589
Agents for the Paris factory	25,185
Agents for the Frankfurt-o/Main and Stuttgart works	8,280
Agents for the American and Italian works	1,908
Messrs. Howard & Sons	900
Sundry druggists	25,479
Total quantity sold	138,155
Bought in 'or withdrawn	30,910
Total quantity offered	167,065

CEYLON CINCHONA.—Original—Red: Dull to good bright quilly stem and brnch chips 1d to 1 1/2d; dull root 1 1/2d; fair medium druggists' quill 2 1/2d to 2 3/4d per lb. Grey: Dull woody stem chips 1 1/2d; dull root 1 1/2d per lb. Yellow: fair bright quilly stem chips 3 1/2d to 4d per lb. Renewed—Dull red stem and branch chips 1 1/2d per lb.

QUININE.—The makers' quotations remain unchanged, as follows:—Howards, tins 1s 1d to 1s 2d; vials 1s 2d to 1s 3d; Whiffins, tins 1s; vials 1s 2d; Brunswick, Mannheim and Auerbach, tins 10 1/2d; Zimmer & Jobst, tins 11d; Fabrica Lombarda, tins 11d; vials 1s 1d; Pelletier, vials 1s 5 1/2d. There has been rather more demand during the last week for second-hand quinine, and sales have been made of 3,000 oz German bulk at 9d, and 25,000 oz. ditto at 8 1/2d per oz.; there are still further sellers at the latter price.

VANILLA.—The following figures refer to the yield of the Bourbon crop during the last twenty-four years:—

Year.	Kilos.	Year.	Kilos.	Year.	Kilos.
1869-70...	12,64	'77-78...	3,077	'85-86...	57,073
'70-71...	7,462	'78-79...	29,912	'86-87...	48,519
'71-72...	13,780	'79-80...	44,689	'87-88...	89,57
'72-73...	11,814	'80-81...	23,031	'88-89...	52,217

'74-75...	25,665	'82-83...	21,095	'90-91...	85,617
'75-76...	22,882	'83-84...	28,049	'91-92...	9,722
'76-77...	26,818	'84-85...	48,648	'92-93...	34,282

RHEA (RAMIE) FIBRE.
(Bohmeria Nivea.)

I have received a prospectus of the Indian Husbandry Company, Limited, which has secured 200 acres of suitable land about 90 minutes' journey by rail from Calcutta and is in treaty for about 800 acres of land close to the above.

The object of the Company is to grow and manufacture rhea, flax, jute, hemp and other products on a commercial scale.

"Rhea," it is stated in the prospectus, "is an indigenous perennial plant propagated by roots, cuttings or suckers and yields in some places, five crops in a year. Its fibre is placed in a pre-eminent position by its inherent physical properties: fineness, length, lustre, strength, lightness, durability and resistance to water, which favour its application to various textile fabrics. It is already being converted in Europe into imitation silk fabrics, handkerchiefs, neckerchiefs, ladies' scarves, umbrellas and parasol covers, waistcloth etc., etc. It stands a strong rival to the finest varieties of flax, and in canvas and sail cloth its superiority over flax is undoubted. It admits of advantageous admixture with wool as well as silk and the 'noils' or the waste of the fibre, when cut into lengths of 2 inches and mixed with cotton in the willow machine, render the yarn stronger and shining."

Mr. J. Cameron, Superintendent, Botanical Gardens Bangalore, writes to me that he has been selling Rhea roots at a nominal charge of R25 per 1,000 and that he still has several thousand in stock and could easily increase the nursery stock enormously.

In the 'Kew Bulletin,' Oct ber 1892, it is stated that "what little interest is at present being taken in extracting Ramie fibre from Bohmeria nivea appears to be centred at Belfast."

According to 'Indian Textile Industries,' November 1892, "the Bank of France will have their new issue of notes printed on paper made from it."—Indian Forester.

THE SIROCCO WORKS.

Sir,—As I was lately in Belfast, I availed myself of the opportunity to see the Sirocco Works, and think a few lines on the subject may interest you. Those who have watched the history of the Sirocco cannot fail to have been struck by the energy and striving after improvement which Mr. Davidson has shown. The evolution of the newest Downdraft from the old charcoal Sirocco is remarkable, and can, I think, only be the work of a man who invents and improves because he cannot help doing so. Mr. Davidson received the most kindly and handed me over to his General Manager, Mr. Chambers. The Sirocco Works form two sides of a private street, the offices and the bulk of the workshops being on the right side at present, though new offices and workshops are in course of erection on the other side, to which a large part of the staff will be transferred before long. Some months previous to my visit I had asked a Belfast shipbuilder about the Sirocco works, and had received the answer "When I want to show anyone a model workshop I send them there," and to an unprofessional man the praise seems well earned. As soon as one enters the shops on the ground floor, where all the heavier work is done, one notices the characteristic which runs through the whole works, that is the ingenuity and thought which has been expended on labour-saving appliances. Almost every operation in the place is done by machinery, even down to stamping out the clamps for the corners of the packing cases. So far as I saw, the only work done by hand was a little riveting in inaccessible places, fitting up the machines when made, and packing them for transport. I should like to give you a detailed account of the works; but it would take much too long to do so, suffice it to say, that I was shown the whole process of making Siroccos, from the rough sheets to the finished machine packed in cases. The principal improvement in the Downdraft this year are the extra "Tray Ports," by which a tray can be withdrawn and examined, and the leaf shaken up and re-spread when half fired, and the insertion above the trays of a perforated sheet to equalise the distribution of the hot air. I was much interested in the sifter, which has just been brought out. It is on the cylindrical system, which from previous experience rather prejudiced me against it; but I am bound to admit that the tea sifted by this machine on Mr. Davidson's own estate was not in the least grayed and was very evenly sized. The machine can be made to sift into five sorts, or by a little manipulation into any less number down to Broken Pekoe and Pekoe only, in which case it gives 56 per cent. B. P., 40 per cent. P., and 4 per cent. Dust. The machine runs so lightly that it can, I believe, be worked by hand, though at present it is fitted for power.

Another most ingenious invention, which should be a boon to planters, is the double-clinch fastener for sewing leather. Anyone who has wrestled with a blunt punch and a piece of thick cotton belting will appreciate a rivet which is merely placed on the surface of the belt and hammered through. They are being made from $\frac{1}{4}$ inch up to $1\frac{1}{4}$ inch, and the former size will do admirably for mending a broken stirrup strap or anything else when the cobbler is not handy. I should strongly advise any Ceylon man at home to turn over to Belfast and see the Sirocco Works. He will see much to interest him, and will find it a pleasant trip either via Liverpool or Fleetwood.

I was asked lately by a very large tea dealer why no one ships in metal chests now. I said planters had an idea that grocers did not like them, and was told in reply that grocers prefer metal to wooden chests, and, judging from the state in which packages leave the hands of the customs people, I can quite understand it.—Yours truly, W. B. H.—Local "Times."

INDIAN TEA ASSOCIATION: TEA BLIGHT; FIXED RUPEE: FREIGHTS, &c.

Abstract of proceedings of a Meeting of the General Committee, held on Friday, the July 21st. The Chairman stated that he had received a letter from the Hon'ble J. Buckingham, C. I. E., Chairman of the Assam Branch, stating that the Branch were intending to offer a prize of Rs500 for the best essay on the prevention of blight in tea.

Read letter of the 16th June, from Editor, *Ceylon Observer*, Colombo, asking for figures of the actual crop of 1892 and the estimate for 1893; also asking how the comparison with past years was to be adjusted now that the commencement of the season was altered from 1st May to 1st April. The information asked for had been supplied.

Read letter of 18th June, from Mr. George Seton, London, on the subject of pushing Indian Tea in Germany, and detailing for the information of the Committee, efforts he had himself made to further Indian Tea interest. Mr. Seton was to be thanked for his letter with an expression of regret that at the present moment the General Committee had no funds available for this purpose.

Considered also letters of 8th and 21st June, from Messrs. Schlochau and Levy, Berlin, with reference to the same subject, and the same answer was to be forwarded to these gentlemen.

Read letter of June 30th, from Planters' Stores and Agency Co., Ltd., drawing attention to the serious consequences certain to result to the Indian Tea interests from the artificial raising of the rupee in India, and asking whether the Committee were taking steps to place their views before the Government of India, while yet the matter was capable of some remedial action. The latter had been replied to, stating that the Committee knew of no remedial action that could be taken, and asking for the further views of the Planters' Stores and Agency Co., on the matter.

Read extract from a letter of 16th June, from Secretary, Indian Tea Districts' Association, London, stating that a form of Agreement was to be drawn up for the signature of shippers, undertaking not to accept rebate on shipments and holding themselves free to ship by any steamers available, the object being to ensure concerted action among shippers representing 40 million pounds of tea for the purpose of maintaining a fair competition in freights.

In the same letter it was stated that a large firm of buyers of Indian Tea had drawn attention to the loss occurring in chests containing dust, and suggesting that Planters should pack all their dust and small broken teas in the patent metal chests so as to avoid the dissatisfaction and complaints occasioned by the loss of weight sustained under the present system.—*Indian Planters' Gazette*, Aug. 5.

"THE TROPICAL AGRICULTURIST."

A COMPLIMENT FROM A BROTHER EDITOR WHO IS ALSO AN AGRICULTURIST.

It is no secret we believe that the Editor of the "Examiner" now resides on his "Franklands" coconut plantation in the Veyangoda district and that for a good many years he has given attention to a variety of experiments in low-country agriculture. This makes the testimony in the following letter addressed to us in the ordinary course of business all the more telling and welcome. We venture to quote as follows:—

"I have much pleasure in sending herewith Rs in advance for the *Tropical Agriculturist* for the current year. There is no payment that I grudge less than this. The bound volumes from No. 1 are among the possessions of the estate, and I should consider no estate properly equipped without the *Tropical Agriculturist*. I note that you mean to improve it in some ways; but as a repository of information bearing on Agriculture it leaves little to be desired; and is very cheap in the bargain. Will you please direct the Nos. for last year, sent herewith, to be bound."

ALLEGED DETERIORATION OF CEYLON TEAS.

Our opponent of 1891-92—Mr. F. Sutton Hawes—has returned to his preaching against Ceylon teas as may be seen by his letter given on page 205, addressed to the *Morning Post*. But it gives us great pleasure to be able at this time to publish a letter addressed to ourselves and received by the same mail from England which we regard as one of the most valuable contributions yet made to the prolonged discussion in our columns of two months ago. This discussion has evidently been attracting a good deal of notice at home. We ask for special attention and careful consideration in the case of the letter signed "Anon," (given below) because the writer if we were allowed to publish his name would at once be recognised as one of the very first authorities in the Tea Trade. The great care he has taken to discriminate between terms usually mixed up in our local discussions, and the new light he throws on the condition of our teas as a whole in the estimation of experts in the Lane, cannot fail to be regarded with interest. On the whole, we consider "Anon's" deliverance to be distinctly encouraging and fortifying to the position of Ceylon teas in general estimation. Under the shield of an authority like our correspondent, we can afford to disregard to a great extent the criticism which would have the world believe that Ceylon teas had fallen irretrievably in quality and that too in a way that was not experienced with Indian teas. On the contrary, Indian teas have passed through precisely the same experience as our adverse critics would have had us believe was peculiar to Ceylon.

THE ALLEGED "DETERIORATION OF CEYLON TEA"—THE OPINION OF AN EXPERT WHO HAS TASTED AND SOLD CEYLON TEAS FROM THE BEGINNING.

(To the Editor, "*Tropical Agriculturist*,")

LONDON, 28th July 1893.

SIR,—If it be not too late, I would like to contribute a supplement to the discussion carried on in your columns in May and June about the alleged deterioration in quality of Ceylon tea: and as I write anonymously I ought to preface my note with the remark that it has been my occupation for twenty years to taste and sell Indian tea for growers, and Ceylon tea from the first day of its introduction here.

Such a calling trains one to be careful in observation and precise in statement, if less positive than is usual with those who have not a similar experience, and I realize the difficulty of giving a direct answer to the question "has Ceylon tea deteriorated in quality?" For this reason: the term "quality" is very loosely used and needs definition. By some it is used as the equivalent of "value," and this I think accounts for the widely divergent opinions on the matter at issue.

What, then, is the professional index of "quality?" I should reply "the colour and texture of leaf after infusion." Tea makers from the beginning have been taught to watch this in order to satisfy themselves that they were working on the right lines; and no safer standard could have been given them, for the senses of sight and touch are in most men more acute and reliable than those of taste or of smell.

Trying, by this rule, to find an answer to the question, I should say that the average quality of Ceylon tea has not deteriorated, but that its character has undergone a gradual change. This change is only one of the causes of the fall in value; but it accounts for one so often hearing planters complain that though their tea is of good

quality they get poor prices. Gauged by the standard given them their teas are of good quality, though they may not have the characteristics which create high value.

The phrase "poor quality" strictly used, implies either that the leaf was in bad condition before or during manufacture, or that it has been badly treated in the making; but the term is carelessly applied to crops made from good leaf but not such as has been "plucked fine," and properly made up but necessarily of a low grade and low average value.

The criticism passed on planters and their produce on this side often arises from confounding "quality" with "value;" from mistaking a low quotation for a low profit to the grower; or from failure to understand that planters know their business, and aim at the sort of crop which seems likely to pay most. When such criticisms do not proceed from responsible advisers, given in the privacy of confidential reports, producers need not be sensitive about them, for they do not touch the trade at large.

Having spoken of a "change in character," I should like to give evidence (if you, Sir, will answer for my competence) that it appears to be neither more nor less than is experienced by Indian gardens which give up making specially fine tea and instead of that pluck freely in order to make a large crop. I think it is even less than the change which has taken place (subject to exceptions) in the entire crops from Kangra Valley, Chittagong, the Terai, and the Dooars since the estates first began to yield.

Outside certain favoured localities in Darjeeling and Assam, very little tea comes from old estates equal in character or value to the teas of 20 years ago—though much of it is still of excellent quality; and far better manipulated than it used to be.

On the other hand, each season witnesses an estate notorious for making poor tea sending some of good quality and value, due to a different policy, first in the field then in the factory.

This being so, I have grounds for assuming that if Ceylon planters should see it to be to their interest to make a different kind of crop, it is in their power to do so, and thus to dispose of the rumours that "plans are played out," "the soil exhausted" &c., which I may say are becoming unpleasantly prevalent.

It would seem to be desirable that some of the Companies which control numerous estates should try this on a limited portion of their property, as they can do so with the minimum of risk. For a precedent, I may cite the Jokai Co. of Assam, a prosperous concern, which makes choice tea on some estates and heavy crops on others, and so caters for varying requirements, and provides against fluctuations of market.

Reverting to the "change in character"—as it fell to me to handle most of the choice teas in the early days, trusting to memory, I should say that we do not now receive any with the high flavour of Rockwood, the richness of Loolcondra, the strong ripe liquor of Blackstone, or the peculiar strength of Agarsland, when those teas made Ceylon the talk of the town. Neither do we receive much tea now which shows the unmistakable outward signs of being made from specially "fine-plucked" leaf, but numerous estates make equally good quality in the strict sense of the term; for "strength" "richness" "flavour" are not in themselves essential to quality.

Whether the prices paid for choice teas in the past will ever be paid again is another matter altogether: on referring to memoranda of the years 1884-5 when such high prices were paid, I see that quotations for the best Indian teas were 6d to 9d higher than they are now, and the average value of Indian tea about 30 per cent higher than it is today.

—I am, sir, yours &c.,

ANON.

LIBERIAN COFFEE CULTIVATION IN TAVOY

The following report has been written by Mr. J. D. Watson, Tavoy, to the Director of the Department of Land Records and Agriculture, Burma:—

The investor in coffee land for the purpose of planting Liberian coffee has several choices in Burma. The superiority of forest land over *chenas*, especially if they are recent, is very marked at low elevation, this system of cultivation having very poor results on soil exposed to the hot sun and heavy rains of the plains. On the hills rich forest lands that have a free soil are much to be preferred. Much land of this description is to be found in Burma in all the districts in Lower Burma, and forest land should be selected in any case. The soil for Liberian coffee cannot be too rich, but it must be deep and friable. Shallow soil, especially if mixed with quartz and gravel, will not grow good Liberian coffee, but a sandy loam friable to a good depth; this is of great importance, and in selecting soil one must take the trouble to inspect the nature of the soil down to a depth of 2 feet at least, and, if found friable at this depth, it recommends itself. Stiff marsh or clay land should also be avoided. All land that might be water-logged, *i.e.*, retain water for a long time, should be also avoided and friable land insisted on with a natural slope to drain itself. As to lay of land, this should be undulating and not too steep as Liberian coffee is a tree that should not be exposed to wind, and shaded ground well protected at the base of our many mountains is perfection for the cultivation of Liberian variety. The steep land at the higher elevations would be suitable for *Coffea Arabica* and tea. Exposure to wind is a certain drawback to the cultivation of this variety as it is to any other planted product, but its ill-effects are comparatively small, if the land is selected with care, and the wind must be very exceptionally bad, if other conditions which I have formerly pointed out are favourable.

The best climate is undoubtedly that of the wet portion of Lower Burma (I am here speaking of what I know as I have only been once up in Upper Burma, and I cannot say what might not be possibly attained in Upper Burma in those great mountain ranges which have all the appearance of a country that would be perfection itself for the cultivation of the coffee plant and other valuable products, such as tea, cocoa, pepper, and rubber, and by appearance from what I have attained here Liberian coffee ought some day to be the king of products in Burma). A rainfall of 100 inches is sufficient for Liberian coffee, but for all that 200 inches in the Tavoy district seems to be in its favour; if the ground is well drained, this must be attended to strictly, as no coffee will stand what is termed *wet feet*; standing water in the soil rots the roots. Elevation, where aspect and exposure are favourable, from sea-level up to 2,000 feet, each elevation having its own advantages, but the higher we go the greater the necessity for good soil and shelter from wind.

Shade is most important in the cultivation of Liberian coffee until the tree once gets a good hold of the ground. In forest this can be done by only removing the small trees and scrub at first, planting at the same time as the coffee valuable trees for shade (trees that are sub-soil feeders), such as jack and the san tree, *Albizia stipulata*, and *Medeloa (Albizia etata)*, San, (*Albizia stipulata*), *Hiris* or *siris (Præru* or *Sirisu*), *Fatikolia (Margaritata odoratissima)*. All these trees are found in Burma and the Forest Department might be asked to secure seed of some and supply to intending planters. The jack tree is my favourite tree, and it can be turned to account to grow the pepper vine upon it at the same time.

When the shade trees grow up the jungle trees left for the purpose of temporary shade can be gradually cut down and removed, or allowed to rot on the ground for manure. Rotten timber mixed with the weeds and surface soil and quicklime makes a splendid manure for the coffee trees, nothing better, barring cattle-dung,

The size of the estates depends on the means of the planter. But I should recommend blocks of land to be taken up from 200 acres up to 4,000 acres; to those intending to form a company every encouragement ought to be given.

Seed ought to be selected from matured trees; this is an important point; and the seed should be thoroughly ripe and selected from the most robust trees that are well formed, as Liberian coffee is inclined to what is termed "sport," *i.e.*, you will find trees that do not cover ground well and get as it were spindly and do not throw out branches from the stem near the ground; those trees should be avoided in selecting the ripe cherry. Seed for planting into nurseries should never be dried in the sun; the sun's power destroys the germ, the life of the seed. Seed ought to be all dried for seed purposes under shade and never allowed to heat or ferment, and it ought to be kept in an open space to allow air to pass, but shaded from the sun's rays, and I prefer to cure seed in this manner with the husk on the bean, not as parchment. Should the seed be wanted for seed purposes when ripe, then by all means remove the husk and put in the seed at once to the ground without drying. This is a sound and sure plan to put into boxes or prepared beds. As to the best method of germinating seed there are many opinions. I have been most successful in the germinating of Liberian coffee seed between coir mats simply. The seed is laid in a layer on a coir mat, care being taken that the layer is a single one, and on it another mat is placed. If kept damp, but not wet, the seed will germinate freely and can be readily picked out. This method has the advantage of cleanliness. Another plan is to put the seed after the husk has been removed into coconut fibre dust into boxes, a layer of seed and a layer of coconut fibre until the box is full, and put a piece of wood in the centre of the box so that you can draw out and put in your hand to inspect how germinating progresses. This is a good sound plan and generally safe. The fibre must only be kept damp and not wet. The same method may be carried out with charcoal where experience is wanting, as if too wet the charcoal takes in the extra moisture, and gives it out again, when the bean or germ requires it; any of these three methods I fully recommend.

The formation of nursery beds is a matter which need not engage our attention much here. Sloping ground should be chosen, with water above it if possible, but in any case close at hand. The beds should be made about 4 feet wide to facilitate sowing, weeding, &c., and should be raised above the paths between them in the usual way so as to allow superfluous moisture to run off readily. The soil of the nursery should not be dug too deeply, otherwise the tap roots of the plant will reach an inordinate length before they are put out and be most difficult to deal with, but it should be thoroughly pulverised and cleared of all stones and roots. Soil with a good proportion of clay in it is better than what is gravelly as it enables the plant to be removed with earth round the roots. Soil in nurseries should be rich; it does not answer practically to make them in poor soil. As regards the distance apart at which the seeds should be planted, much depends on the class of plants and the length of time they are intended to remain in the nursery; 2½ to 3 inches apart is the most satisfactory distance: I would recommend all such nurseries to be shaded until the plant get up at least 4 or 5 inches and has six or eight leaves. Out of the rains they should be shaded right throughout the dry season here and, when the rains are well set in, the shade should be gradually removed to allow the stem or collar of the plant to harden. The importance of watering nurseries in a liberal manner during the dry weather cannot, I think, be overrated. They should be watered thoroughly after the sun is well down, say, 4-30 or 5 p. m. I object to watering in the morning for the reason that the sun is so powerful that it burns the leaves in a manner, if the water is not brushed off the leaves. No plant in fact ought to be watered in the morning in India, a great mistake which few understand. * * *

Now that I have made things clear how this variety can be planted with success in Burma, and also proved that it is to be a lasting and standing product of value, I am able to state what can be done to bring it into bearing. It can be planted fairly well at the cost of R120 per acre, and brought into bearing for R350 with care, if all that I have pointed out here is properly attended to, and bear in mind that it thrives best not beyond the voice of man, that it must have daily attention for its protection from cattle and it must not be knocked about, but tended to with care. After it comes into bearing see what a gold mine it is to be. I have pointed out already that I have individual trees bearing $\frac{1}{2}$ cwt. husk or cherry coffee per tree. Now if we will take it at Burmese measure you will understand this better. Say one basket per tree, and to take this at 8 viss per tree of husk or cherry coffee. Another thing must not be lost sight of here, *i.e.*, that the Liberian coffee contains far more percentage of husk than the Arabian, or we will call it Ceylon coffee. I point out this not to mislead any one on this important point, which has again and again been misunderstood even by expert planters who have not had experience in the manipulation of this product. Now we will take, instead of 8 viss to the tree, only 1 viss. Mind I am now speaking of clean coffee or rice coffee prepared for the shop or London market, *i.e.*, say that 8 viss of husk only produce 1 viss clean coffee. Now 1 viss of clean coffee brings at the present moment in Tavoy R2-8-0 per viss: Now we will take the lowest percentage of trees per acre leaving allowance for shade trees and roads and drains, &c., say, 600 trees per acre. See what this will bring in yearly, or again, to put it at the very lowest, put it at $\frac{1}{2}$ viss per tree of clean coffee and value it at R2 per viss, and again see what this will bring in per acre of cultivated coffee. This is about the lowest average and is the lowest amount which I have put down for information to the Government of India, which has been called for from me. I put down the very lowest, namely, 896 pounds or 8 cwt. per acre. At the present moment clean coffee in London is selling at over 120 shillings or, say, £6 sterling per cwt. See what this will come to per acre, £48 sterling. I need not say more on this point as the very lowest average recommends itself.

We will now take £48, or say R600, allowing the rupee to revert to the value of 1s. *s.d.* Now R600 will allow an expenditure of R300 per acre, and with this amount on an estate of 400 acres much could be done to bring this variety into even greater perfection and allow expenditure on building roads, drains, dams, tools, machinery of all necessary sorts for irrigation purposes; much can be done here by irrigation in the dry season. I have proved this, and this amount should allow a liberal amount for cultivation, such as manuring with cattle manure and compost, making new cattle sheds and roads for cart traffic and the purchase of pigs and cattle. Pigs could be fed on jack fruit and poonack from the rice-mills, such as paddy-dust, and after this liberal allowance the planter would have a profit at the very least of R300 per acre yearly. I do not recommend the Ceylon coffee, *i.e.*, *Coffie Arabica* to be planted below an elevation of at the very least of 2,000 feet, and it will succeed much better at 3,000 or 4,000 feet elevation. I planted 14 acres here; it gave a maiden crop and went out, *i.e.*, died right out.

You will see by this report that where the cultivation of Liberian coffee stops, Ceylon coffee begins. From 2,000 up to 6,000 Ceylon coffee can be grown with this variety, but I do not consider the conditions in Burma yet ripe for this valuable cultivation. Should planters wish to embark in this cultivation, let them do so by all means, but at their own risk. I do not recommend it for the reasons, first, of dread of the leaf disease; it I think must have a time of rest for this evil to leave the coffee or work itself out by ultimate death of the trees where it exists. Where it does not exist it will again flourish and pay well in this country, but the local Govern-

ment ought not to recommend it as the time has not come as yet to recommend its cultivation again on a large scale.

Besides, the present existing circumstances in this great country do not afford facilities to reach elevation. Take this into consideration. Where are your roads? Nowhere. At this elevation I strongly recommend the cultivation of Liberian coffee, cocoa, cardamom, cinnamon, croton oil trees, ginger, Colombo root, sapan wood, pepper, vanilla, and all manner of fruit-bearing trees for shade purposes. And above all, next to Liberian coffee, I would strongly recommend cocoa for Burma, as the soil and conditions are suitable for its cultivation.

The local Government ought to procure fresh cocoa pods for those that would give a guarantee to cultivate the same. As I have already remarked, it can be grown side by side and interplanted with the Liberian coffee as the great Liberian trees would answer for shade for the valuable cocoa.—*Rangoon Gazette.*

THE WEST INDIAN COURTS AT THE IMPERIAL INSTITUTE.

THE BAHAMAS.

The first section of the West Indian department is that occupied by the Bahamas. The exhibits are not at present numerous, being represented only by a few specimens of fibre, coral, woods, and certain seeds and species, &c. A very attractive feature in this section is, however, a collection of pictures and photographs. These illustrate the remote past, a century ago, and the present day, and serve as a picture history of the colony.

JAMAICA.

The whole of the West Indian section is installed in the west half of the intermediate gallery, the greater part of it being occupied by the Jamaica section.

The entrance to the Court is under a fine screen, the panels of which are beautifully inlaid with woods from the colony, and cannot fail to be admired by the visitors. At the entrance to the Court there are two cases, thirty feet long, largely given up to the reception, on the south wall, of coffees, sugars, medicinal drugs, a large exhibit of the rums produced in the colony, spices, &c. The large and increasing importation of these products from the island of Jamaica is well known. The island is very rightly classed as a veritable garden, and the collection in this Court cannot fail to more deeply impress the visitor with that view.

In the case on the north wall is a large collection of sugars, not less than two hundred specimens, to each of which is affixed a number. By referring to the information against that number, in the possession of the Imperial Institute authorities, the whole of the details concerning each specimen can be given—such as the estate and locality from which the sugar was imported, the price at which it can be placed upon the London market, quantity imported, &c.

The whole of these specimens will, as in the other sections, be replenished from time to time as new consignments arrive, so that it will not be a mere collection of obsolete samples, but practically a living museum, where the latest information concerning each particular product can be obtained and turned to account.

Noticeable also is the collection of turtle in various forms, as used for food and other purposes. The economic products of the colony are also shown in a number of beautifully coloured drawings, tastefully framed and arranged upon the screen at the west end of the section. This, no doubt, will be much admired.

The centre of the court is occupied by a trophy of the timbers of the colony in logs, one side simply planed and polished, which arrangement not only shows the outside of the tree, but also a cross section, and the heart-wood.

In the table portions of the case will be noticed some tastefully arranged mats, made from ferns and dried flowers. These, though not exactly an economic product, show the flora of the colony and the handicraft of the natives in the arrangement of them in a decorative manner.

The whole of the specimens in this section has been obtained and arranged by Col. Washington Eves, and comprising, as it does, some two thousand different specimens classified and arranged, it will be understood that the task has been anything but an easy one.

LEEWARD ISLANDS.

On quitting Jamaica the visitor enters that part of the gallery devoted to the Leeward Islands.

Dominica.—Among the chief exhibits of this island are the following:—Cocoa, coffee, sugar, arrowroot, starches, spices, lime juice, alum, gum, barks, fibres and rums. There are also specimens of timber.

Montserrat.—The most conspicuous exhibits are seeds, guras, barks, roots, woods, ropes and fibres; but there are also some specimens of bay and other waters, and essential oils, as well as of gypsum, and sulphate of alumina.

Antigua.—A few woods and seeds at present represent the products of this island.

St. Kitts and Nevis exhibit a small collection of arrowroot, cassava meal, and castor oil, in addition to a few other miscellaneous articles.

WINDWARD ISLANDS.

These islands follow the Leeward Islands in the West India Gallery.

St. Lucia displays specimens of wood and of rums, fibres and petrefactions.

St. Vincent is conspicuous for its display of fish oils, and essential vegetable oils. It also exhibits some arrowroot, barks, fibres, and woods.

Tobago.—Specimens of fibres, some rums, and a box of mineral specimens are the chief objects.

BRITISH GUIANA

comes next, with a comprehensive display of its products.

TRINIDAD.

The collection is small at present, the most noticeable articles being seeds, fibres, materials for paper, barks, and silk cotton. There are also exhibited some blocks of pitch from the celebrated pitch lake. A complete collection is being prepared in the island.

BRITISH HONDURAS

is the last of the sections in the West India part of the gallery. Its chief display is timber, which is exhibited in a most practical and, at the same time, attractive manner by means of an elaborate screen, which not only illustrates the use but also the decorative qualities of the woods. Its other exhibits comprise shells, seeds, beads, Indian corn, coffee, sugar, flours, pickles and rums. There are also some interesting photographs, illustrating life and scenery in the colony.—"Ceylon Advertiser."

QUALITY OF NEW "CROP" INDIANS.

To the Editor of the HOME AND COLONIAL MAIL.

SIR,—In a quotation from the *Produce Markets Review* (a usually well-informed journal), which you give in your last week's issue, the following sentence occurs:—"It seems almost certain that the supply of the higher grades of tea (from India) will be much smaller than last season, as there appears every indication of a desire to produce tea for price."

From the evidence at my disposal, I cannot see that there is any certainty whatever of this, and I would be obliged if you would give publicity to this letter; with a view to perhaps removing certain misapprehensions from the minds of your readers. It should not be overlooked that one remarkable feature regarding the Indian tea crop—applicable also, no doubt, to Ceylon—is that from month to month, owing

to conditions of weather and other causes, there always is, and probably always will be, more or less, a great divergence in the quality of the tea produced in each separate district. Happily, the effect of this in one direction or another is largely neutralised by the varied conditions prevailing in the different districts. But the fact remains that this is the case.

Another point which affects the matter of quality is that, fortunately for all concerned, there always are, and probably always will continue to be, certain districts whose forte is the production of a comparatively low class of tea at a low cost, and others the conditions of which favour the production of a high-class tea at a higher output cost, while the relative proportions given from these districts will always vary considerably.

A third factor, affecting, in a general way, the quality of the crop, is that a certain proportion of producers are, at all times, making a greater or lesser effort to produce quantity as opposed to quality, while another section are, in all probability, endeavouring to produce a smaller quantity of tea of enhanced quality.

At present, looking at the districts generally, we have no clear evidence to lead to the conclusion that the majority of planters are "going for" common teas. If anything, the evidence at my disposal leads to the belief that the majority will be rather going on the opposite tack; but we must advance much further in the season before anything positive can be said on the subject.

Recurring again to the question of quality as resulting from uncontrollable weather conditions, it is undoubtedly the case that all the districts (more or less) the first months of this season were adverse to the manufacture of good quality generally. But this is the very reason why the probabilities are all in favour of the ensuing few months (which are the largest producing months), being the reverse in this respect, and consequently that teas due to arrive here, say, from September 1st onwards, if not earlier, will show improvement, while I may say that there appear signs already in Mincing Lane of forerunners of this better range of quality.

I would merely conclude by pointing out that the above remarks have some bearing on certain points raised recently, I think in your columns or elsewhere, in a letter addressed to the Press by so well-known an authority as Mr. Francis Peek.

If my views are incorrect, I should be only too pleased to hear of anything which may be advanced by others of your correspondents on the point at issue.—Yours truly,

MINCING LANE.

August 3rd 1893.

—Home and Colonial Mail.

SILK-COTTON TREE.

In an article entitled "*Un nouveau service for estiers sous les tropiques*," contributed to the *Revue des Eaux et Forêts*, 10th December 1892, M. A. Chavegrin writes from Réunion as follows:—

"I plant out in some moist localities the wool-giving tree, *Bombax malabaricum*. The timber of this species is valueless, but the fruit capsules, which the tree produces from the age of five years onwards, contain a valuable down, for which as much as five francs per kilo is given. In certain years, when there have been no violent gusts of wind, the tree at ten years of age can yield as much as ten kilograms of woolly stuff, but this figure is a maximum which is very rarely reached."

In the *British Trade Journal*, 1st January 1893, it is stated that "the export in kapok (*Bombax* or *Eriodendron*?) in Ceylon is of very recent origin, and that, since an export trade has begun, the demand has increased so much that not only is kapok carefully collected from the trees growing wild, but great care is taken to preserve it, and plant new trees wherever the opportunity occurs. There is a large demand for the article in Australia, where it is used in the manufacture of pillows and cushions; and it is also exported to Holland and Fiji, where it is said to be used for the manufacture of cloth."—*Indian Forester*.

CEYLON TEAS.

To the Editor of the *Morning Post*.

SIR,—I left London on the 15th ult., and have only just returned. My attention has been drawn to your issue of that date, in which there appeared an anonymous letter on Ceylon tea, commenting adversely on some previous reports on the subject written by myself, under my firm's signature. In the ordinary course I should not take notice of opinions expressed by anyone who has not the courage to append his name to them, but the letter in question is so personal that I must reply to it. It is evidently written by an interested and prejudiced planter. His statements as to the teas naturally being inferior at this time of the year, because of the early pickings, &c., after the annual pruning, contradict nothing I have stated, and I again maintain that the general quality of Ceylon tea has been declining for the last two years. It is true that sometimes for a short period a few months ago the best Ceylons offering were slack of sale, but that was only an ordinary turn of the market, when there was an abundance of fine Indian tea which could be bought comparatively giving much better value to the trade and therefore until fine Ceylons fell to a tradeable price they were neglected. Really fine Ceylons, as a rule, are always saleable at good prices. He could, he says, give at least a dozen gardens from which the teas have improved in quality, but what is a dozen against the hundreds of gardens that have been sending depreciating qualities? The closing paragraph of the letter is also misleading as it was the former full fine-flavoured teas from Ceylon which gave that country such a reputation everywhere. Now the constant complaints from all consumers is that the teas are not as good as formerly. The writer has only to consult any of the large wholesale dealers or leading brokers of Ceylon teas to learn the truth of my assertions. My strictures on this article, the success of which I am largely interested in, have not been to damage, but, on the contrary, to prevent it becoming damaged in the public estimation.—Yours, &c., F. SUTTON HAWES.
14, Miacing Lane, July 21.

INDIAN TEA NOTES AND NEWS.

Our Monani correspondent writes on 29th July, 1893:—Rainfall up to date 55.10; same period last year 47.57. Most gardens now falling behind owing to unfavourable weather and blights, and those mountains of tea which we read about as having been made in the district are growing beautifully less.

INDIAN TEA DISTRICTS weather news is as follows:—Duars—clearing, but still cool, fair quantities of leaf of light quality and wanting in sap; gardens rather falling behind again. Terai—a little more sunshine but still unfavourable. Cachar—High floods still prevail and in places the young rice crops are deep under water. South Sylhet—ceaseless rain and coolies having a hard time owing to scarcity and dearness of rice. In Sibsaugor there have been heavy flushes, but wet days have interfered with manufacture. As to output over the whole of the tea districts, a writer in the *Englishman* says with regard to the comparative statement of yields of a leading Tea Firm, "The Agency is, over all its large interests, about three thousand five hundred maunds ahead of last year, which is doubtless fairly indicative of the state of matters over the whole of the North-Western tea district." "North-Western is without doubt, a misprint for "North Eastern."

The season is now getting well on and another fortnight will see many plain gardens at their half-crop day. Most of the large agency houses' yield-returns show up, we believe, fairly ahead of last season, but against this has, of course, to be set, the new area which has come into yield. Upper Assam is doing best among all the districts, but Cachar is getting on well also. Sylhet is, in spite of its large area of new tea, only on about a level with last year, and the Duars seem rather to have gone back some-

what lately. Severe landslips on the steep Darjeeling slopes have been caused by the recent heavy and continuous rains, and much tea has been buried by the avalanches and mud stones. Green fly blight is prevalent on some Sibsaugor gardens, others of which are unaffected, and making mountains of tea.—*I. P. Gazette*, Aug. 5.

CAN'T GROW TEA IN AMERICA.

IT WILL NEVER BE A PAYING INDUSTRY IN THIS COUNTRY.

THE EXPERIMENTS OF DR. SHEPARD IN SOUTH CAROLINA MORE SUCCESSFUL THAN THOSE OF THE AGRICULTURAL DEPARTMENT, BUT WE CANNOT COMPETE WITH CHINA, INDIA AND JAPAN IN GROWING TEA.

Washington, D. C., July 19.—About ten years ago the then Commissioner of Agriculture, under direction of Congress, expended a small appropriation made for the purpose of ascertaining whether the tea leaf could be grown in any part of the United States in such quantities as would warrant the fostering of the industry for commercial purposes. The result of the experiment, which was made in one of the Southern States, demonstrated that the soil was too dry, the average temperature too low, and that it would require much irrigation and outlay of much money and care to carry out the project. It was accordingly abandoned by the Government as a failure.

The trial was so thorough that the department has since expended nothing in further experiments.

Not long since, Dr. Charles U. Shepard wrote to ex-Secretary Rusk requesting his co-operation in further experimenting with the production of tea. On the doctor's request Secretary Rusk wrote to the Secretary of State to request the United States Consul at the various tea ports to send samples of the seed of the tea grown there. The seed was forwarded to Dr. Shepard which action ended whatever pecuniary interest the department had in the experiment.

Dr. Shepard selected Pinehurst, S. C. where he established an experimental station at his own expense and began the propagation of the plant. He has made a report to the Secretary of Agriculture, which will be incorporated in the annual report of the department on the progress of the plant. While he has had more success than did the department in growing the leaf, and is quite hopeful of better results, it is plain that the conditions are such that as an industry, tea-growing in the United States can never be profitably conducted in competition with China, India and Japan.—*Brooklyn Standard Union*, July 19th.

PICKINGS WITH A LOCAL APPLICATION.

In an article on "THE POISONING OF THE FUTURE" in the *New Review* for July last, Dr. Squire Sprigge referring to poisoning by vegetable alkaloids mentions the following facts as being in favour of this method of poisoning, viz., the smallness of the fatal dose, the obscurity of the symptoms produced, and the impossibility of obtaining chemical proof of the presence of the alkaloid in the body. Against these he puts the difficulty of obtaining the drug, possibly the great difficulty of administration, the notoriety that will attend the purchase, and the impossibility of all questions of accident, and most questions of suicide. Now in Eastern countries the difficulties attending the adoption of vegetable poisons practically vanish, since poisoners of men or cattle do not use the alkaloidal extracts of poisonous plants but parts of the plants themselves. It is to be hoped that the reproach against science of not providing satisfactory tests for vegetable poisons will be absent before long, at any rate it behoves our chemical and physiological students to work at the subject of vegetable poisons if they would be benefactors of mankind and

are anxious to secure for themselves a niche in the temple of fame.

Would that our prize day orators would seek to emulate ZOLA in delivering to our boys such deep and wise words as that author embodied in his address to the Paris Students' Association—the authentic text of which has just been published. Here is a specimen: "Labour! remember that it is the unique natural law of the world, the regulator which leads organized matter to its unknown goal. Life has no other meaning, no other *raison d'être*; we only appear on this earth in order that we each may contribute our share of labour and disappear. One can only define life by that motion which is communicated to it and which it transmits, and which after all is but so much labour towards the great final work to be accomplished in the depths of ages. Why, then, should we not be modest, why should we not accept the respective tasks that each of us comes here to fulfil, without rebellion, without giving way to the pride of egotism which prompts men to consider themselves centres of gravity, and deters them from falling into the ranks with their fellows?"

The word *cigar* is said to owe its origin to the fact that when the Spaniards smoked their cigars they did so in the orchard or "*cigarral*," so called from its being the abiding-place of those soothing sleep-producing insects, the balm crickets: Hence "*cigarro*" a small roll, "*cigarron*" a large roll, and ultimately *cigar*.

Here is an AMERICAN RECIPE which is worth a trial by our local architects. It is described as a durable white-wash which retains its brilliance for many years, and those who have tried it say there is nothing of the kind that will compare with it, either for inside or outside walls. As a recommendation it may be mentioned that it is being applied to the White House at Washington.

Take one half-bushel unslacked lime; slack it with boiling water, cover it during the process to keep in the steam. Strain the liquid through a fine sieve or strainer, and add to it a peck of salt previously dissolved in warm water, three pounds of ground rice boiled to a thin paste, one half pound of powdered whiting, and one pound of clear glue which has previously been dissolved by soaking it well, and then hang it over a slow fire for an hour in a small kettle within a larger one filled with water. Then add 5 gallons of hot water to the mixture, stir it well, and let it stand for a few days covered from dust. It should be put on hot, and for this purpose it can be kept in a kettle on a portable furnace. It is said that about a pint of the mixture will cover a square yard on the outside of a house. Fine or coarse brushes may be used, according to the neatness of the job required. It answers as well as oil paint for wood, brick, or stone, and it is cheaper. Colouring matter, of any shade or colour, may also be mixed with it.

Ceylon ANNATTO would seem to be hard to beat, and the credit of extracting the dye and oil from the seed most successfully, must be given to Messrs. Borron and VanStarrex. The *Kew Bulletin* referring to the annatto sent from the Andaman and Nicobar Islands, remarks, "upon submitting samples to Messrs. Fullwood & Bland, the well-known annatto makers, they reported that both the seeds and prepared dye were valueless in the English market. The fact is," continues the *Bulletin*, "that Ceylon now supplies annatto dye of such excellent quality, that other countries can scarcely compete with it, except when prices are exceptionally high."

THE MOCHA TEA COMPANY OF CEYLON.

The ordinary general meeting of the Mocha Tea Company of Ceylon Limited was held at the registered office No. 6 Prince Street Colombo. Mr. F. W. Bois presided and, there were present—Messrs. F. G. Bois, H. G. Bois, W. Moir, V. A. Julius, W. H. Kingsbury, H. Tarrant, G. Vanderspaar, R. Webster, and S. E. Tenoh. The notice convening

the meeting was read after which the minutes of the last meetings were confirmed.

The CHAIRMAN then moved the adoption of the Report and in doing so said that the Report was satisfactory and did not require much comment. He gave particulars of the profits and working expenses of the two estates Mocha and Glentilt, the tea of the former realising 57 cents per lb. and the latter 51½, the profits per acre being R109½ and R90½ respectively. The estimate for next season was 250,000 pounds, and if the prices continued as in last year the prospects would be satisfactory. He mentioned that out of the reserve fund R20,000 had been devoted to the purchase of Government stock.

Mr. KINGSBURY seconded and the Report was adopted.

On the motion of Mr. Tarrant seconded by Mr. Webster a dividend of 11 per cent was declared. Mr. JULIUS proposed and Mr. KINGSBURY seconded the re-election of Messrs. J. N. Campbell, F. W. Bois and W. B. Baring as directors.

The CHAIRMAN proposed and Mr. Vanderspaar seconded the election of Mr. W. Moir as Auditor.

On a question by one of the shareholders whether any percentage of profits was given to the Superintendents, the Chairman said that it has been decided by the Directors to give them a bonus of 20 per cent on their salary, but if it was suggested to give them a percentage on profits the matter would be considered.

With a vote of thanks to the chair the meeting concluded.

The following is the Report of the Directors:—

Your Directors have now to submit their Report and Accounts for the year ending 30th June last and trust they will be considered of a satisfactory nature.

The purchase of the Glentilt Estate was completed in accordance with the special resolution passed on 13th June, 1892, and confirmed at a subsequent meeting on 14th July, 1892; and it is a source of gratification to the Directors that it has proved a valuable addition to the Company's property.

The capital of the Company has been increased to R500,000, in accordance with a special resolution passed on 14th July, 1892 and confirmed on 16th August 1892; but only 808 shares have been issued, all of which are fully paid, and represent a subscribed capital of R404,000.

Notwithstanding the unfavorable yield during the first six months of the period under review, the crops from the two Estates—Mocha and Glentilt—now belonging to the Company, have resulted as follows, which compare favorably with the estimates referred to in the last Report. The yield of Tea, which is the only product which need be enlarged upon, is equal to 363 lb. per acre on the area in bearing. The average net price realized is cents 54·48, and the average cost, after deducting expenditure on Capital account and produce other than Tea, is cents 27·07 per pound.

The net profits for the year amount to R82,094·94, which is equal to 20·32 per cent upon the capital. To this falls to be added the small balance remaining after the payment of dividend to 30th June last, making R82,168·77 available. Out of this your Directors have already paid an interim Dividend of 5 per cent. amounting to R20,200, and have transferred to Depreciation Fund R6,400, Reserve Fund R10,000, leaving R45,568·77 still to be dealt with. It is proposed to pay a further dividend of 11 per cent. making 16 per cent. for the year, which will absorb R44,440, and carry forward the balance of R1,128·77.

The prospects for the season on which we have entered are satisfactory, and the estimate of crop and expenditure will be framed on a safe basis.

At the last General Meeting held on 15th August 1892, all your Directors retired, and were re-elected; but as the Articles of Association provide that they retire at the First Ordinary General Meeting to be held in 1893, they now do so, but being eligible offer themselves for re-election.

The meeting has also to appoint an Auditor. By order of the Directors, J. M. ROBERTSON & Co.

VARIOUS AGRICULTURAL NOTES.

FIXATION OF NITROGEN.—At a recent meeting of the Académie des Sciences, M. Gain (according to a London paper,) read a paper on the influence of humidity on the warts or nodosities growing on the roots of vegetables. These nodosities are known to be the seat of bacteria which fix atmospheric nitrogen, and hence the growth of such vegetables improves the soil instead of exhausting it. M. Gain finds that the nodosities are much more numerous in moist soil than in dry, and have a somewhat different form. It follows that the fixation of nitrogen by the bacteria must be more active in moist than in dry soil.

TEA-GROWERS in India and Ceylon—says the *Indian Agriculturist* of July 29th,—have been raising a note of alarm as to the consequences of cheap silver and a dear rupee in their competition with China in the tea trade, and no doubt had the rupee been sent up at a bound to 20d., there would have been some ground for apprehension; but an advance of about 1½d in the rupee, the equivalent of 3d. on a pound of tea, cannot place Ceylon and India planters at any disadvantage in regard to China, seeing that the ordinary fluctuations in the market price of tea frequently amounts to as much and more. Besides, Ceylon and India have not carried on a war with China in teas for price, but in a leaf for quality; and no matter what silver may decline to, these countries need not fear the competition of China, unless at the same time the markets of that country improve the quality of their tea. This is the pronounced opinion of tea experts in Mining-lane, who point to recent proclamations of the Chinese authorities once more denouncing the markets of and dealers in *li tea*, i.e., rubbish, in support of their matured opinion and belief in British grown-teas being able to hold their own.

COFFEE GROWING IN BURMA.—Mr. J. D. Watson, an old Dimbula planter, has submitted to the Director of Land Records and Agriculture, Burma, a very interesting, not to say glowing, report on the prospects of coffee cultivation in Burma. Speaking only of Lower Burma, and more especially of Tavoy, Mr. Watson is of opinion—says the *Pioneer*—"that coffee will ultimately become one of the staple products of the country. For the comparatively low-lying districts he recommends the Liberian variety, and, in addition to practical hints on cultivation derived from his own personal experience, he has drawn up an estimate of cost and probable profits, which is well worthy of attention. Liberian coffee, says Mr. Watson, can be planted fairly well at a cost of R120 per acre, and brought into bearing for R350 with adequate care and attention. After it comes into bearing, it is, he adds, a veritable gold mine. As the result of a calculation, Mr. Watson arrives at the conclusion that the planter should make an annual profit of R300 per acre."—This is just the sort of bait that does harm to a good cause. No doubt J. D. Watson writes in good faith, but he is one of the very sanguine ones, as his letters to the *Tropical Agriculturist* show. We would just ask from how many acres has Mr. Watson—and he has now been a good many years in Tavoy—netted R300 per acre or even half that amount for himself or his employer? We reprint Mr. Watson's Report—which is a long as well as instructive one in its details—on pages 202-3. We observe that at the lowest he counts on 8 cwt. clean coffee from 600 Liberian trees per acre, and that this would sell at £6 per cwt. so giving £48 per acre gross! He converts this into 600 rupees at no less than 1s 8d per rupee (1), takes half for expenditure—and *hay presto* the thing is done with a balance of R300 of profit!

TEA SUPPLY.—Remarkable changes in the source of the world's tea supply—says the *Indian Agriculturist* of July 29th,—have taken place during the last thirty years, and are still going on in the continued displacement of China tea, and the rapid increase of the supply from Ceylon and India. These changes are strikingly shown by the figures given below:—

	1862	1872	1882	1892
China	80	111	114	34
India	—	17	51	110
Ceylon	—	—	—	63

It took from 1862 to 1884 for the Indian production to reach about the stage that in Ceylon occupied the period between 1880 and 1892. In other words, to attain a production in Ceylon of about 63 million pounds occupied 12 years, while to attain much the same production in India took a period of 22 years. The maximum consumption of Chinese tea in the United Kingdom was in 1879, when it reached approximately 125 million pounds. The consumption in the year 1892 was reduced to about 34 million pounds. Between 1879 and 1892 therefore, the production of Chinese tea fell off 91 million pounds; and between the same years the production of Indian and Ceylon, British-grown tea as it is termed, increased about 136 million pounds.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for September:—

Vol. V.]

SEPTEMBER, 1893.

[No 3.

OCCASIONAL NOTES.

WE mentioned some time ago that we were favoured with the loan of some American implements for trial, through the kindness of Messrs. W. H. Davies & Co.

These, viz., the "Planet, jr.," double-wheel hoe, the single-wheel hoe with cultivator and rake and plough attachments, and the standard horse-hoe and cultivator combined have now received a fair trial. While we do not hesitate to say that the last mentioned is rather too cumbersome an implement for our cattle, the two former are undoubtedly excellent little machines easily worked by a man, and doing effective work which saves much time. The great point about these is that they are moderately priced and are admirably adapted for garden cultivation.

We note with pleasure that the idea of a Zoological Garden for Colombo has been revived. We trust the matter will not be allowed to drop out of sight, and that Colombo will not be long wanting in one of the most interesting and entertaining institutions of a city.

The present want of rain is telling badly on all forms of vegetation in the country. In the Colombo district there is a dearth of fodder for cattle, as the cultivated and natural grasses are fast dying out for want of moisture.

We hear of two or three projects for starting dairies on an approved system. We wish them all success, and do not hesitate to say that if the concerns are properly managed, they will yield handsome returns.

Nothing practical has yet come out of the discussion on the "Dairies' Supervision Act of New South Wales." It is to be hoped that the matter of controlling the dairies and cattle sheds of the city will be carefully considered in all its bearings, so that a workable ordinance will before long be the result.

It has been recommended that the Colonial Veterinary Surgeon should supervise the slaughtering of cattle in Colombo and inspect the meat before it passes into the markets. Any proposal with the object of ensuring an improved meat supply deserves to be heartily supported.

Cattle disease was prevailing in August in the Negombo and Mirigama districts. The Veterinary Surgeon visited both these infected areas.

The School of Agriculture reopened, after the Midsummer holidays, on the 21st August, and work will be carried on now till the Christmas holidays without a break.

TREATMENT OF LIQUID MANURE.

Dr. J. H. Vogel recommends the following for fixing and preserving the readily decomposable nitrogen compounds occurring in urine:—The liquid manure is allowed to collect in a suitable vessel, and sulphuric acid is then added sufficient to fix the contained nitrogen. When the vessel is full, the liquid manure is carted to a place prepared for its reception by heaping dry mould (or peaty soil) on to a concrete floor to a height of 20 inches. The spot should be protected from rain by a light roof. About 1 cwt. of mould may be conveniently used for every 56 gallons liquid manure. Whilst the vessel employed is filling again, which will take, say 14 days, the saturated mould should be turned over with a spade every

third or fourth day. This can easily be done in 14 minutes for half a ton of mould. After from 8 to 14 days the mass will be completely dry, and will contain, in a non-volatile form, all the fertilising compounds of the liquid manure.

When the vessel is full again the liquid manure is once more poured on the same mould, and this is dried again in the way described while the vessel is refilling. The procedure is repeated till the mould has absorbed as much as possible. It should stand five or six soakings. In experiments made last year, 2 cwt. peat litter absorbed 480 gallons horse urine between 21st May and 1st August.

The advantages of the method are—(1) Preservation of the easily decomposed nitrogen compounds in liquid manure. (2) The manure need not be used at an inconvenient time. (3) The resulting manure is comparatively concentrated (e.g., the liquid manure produced in a whole year by a single horse can be stored up in a space 39 inches square), and can be carted with little expense. The more bulky stable manure can be used for the land nearest the farm, and can be easily preserved by keeping damp and strewing small quantities of kainite or carnallite upon it. (4) Any sulphuric acid added in excess re-acts on the mould and converts its insoluble nitrogen compounds into a soluble form.

Dr. Vogel is continuing his work on this subject, and is particularly anxious to determine whether the drying process will go on as well in winter as summer. The German Agricultural Society have made a grant of £2,000 to be expended during the next four years on research, conducted by Dr. Vogel, to determine the best ways of preserving manure.

The subject of the conditions under which loss of nitrogen in farmyard manure takes place is of the highest interest to every farmer. The results of some experiments recently carried out are worth citing. It was found in comparative experiments that the loss of nitrogen by fermentation is greater when the manure is left to ferment in the stable or byre, than when it is removed and left in a heap by itself, this being due to the more rapid fermentation of the urine which takes place in the former circumstances. The loss is greater in summer than in winter.

The experimenters (Müntz and Girard) have found that this loss is considerably reduced by the substitution of peat for ordinary straw litter. It is also reduced when dry earth, rich in humic substances, is used, the efficacy of this latter substance as a litter being in proportion to the amount of humic matter it contains. Thus the difference of loss, in a stable containing 16 horses, between straw and peat was as much as 15 per cent. of nitrogen—the loss of nitrogen when straw was used being 63·6 per cent., while with peat it only amounted to 48·3 per cent. The difference between straw and dry earth was even greater. In a sheep-fold, with 25 sheep, the loss amounted to 50·2 per cent. when straw was used; on the other hand, when dry earth was used, the loss was reduced to 25·7 per cent.

These results are distinctly in favour of peat as a litter, and confirm experiments carried out by other investigators on the same subject.

Among these we may mention some extremely interesting ones made by Dr. Bernard Dyer, of London, some years ago, the results of which appeared in the *Mark Lane Express* (7th October, 1889). The experiments were carried out with peat-moss litter, as compared with straw. From them Dr. Dyer concluded that in every respect peat-moss was superior to straw as a litter. It absorbed about three times as much liquid as the straw did, and its power of retaining this liquid was very much greater. Both these properties are of great importance in a litter. It further absorbed and retained more nitrogen than the straw, and produced a richer manure.

To return to Müntz and Girard's experiments, in summing up their results the learned experimenters suggest that where peat is not readily accessible, the best plan would be to supplement the usual straw litter with a little earth, rich in humus, sprinkled on the top of it. This is, of course, purely in the interests of the conservation of nitrogen. The question of cleanliness in stable or byre has also its claims to be considered. There is a further point to be urged in supporting the use of straw substitutes for the purposes of litter, and that is the value of straw itself as a fodder.

TRAVELLER'S JOTTINGS.

One is particularly struck while *en route* to Anuradhapura with the apparently wild growth of *Cassia fistula* (the Sinhalese *Ehela*) which lightens up the roadside in the month of August with its golden blossoms that have been compared with the laburnum. Among the other common and striking trees in the neighbourhood of the ruined city are the Kon (the Ceylon oak) *Schleichera triguga*, which in that part is a veritable giant of the forest, palu (*Mimusops hexandra*) and wera (*Hemicyclia sepiaria*), *mimusops elengi* (*Moonamal*) and *Diospyros ebenum*, the ebony tree. These are all valuable timbers, and the first three bear fruits that are much appreciated by the natives.

I was pleasantly surprised to find the cattle of the country in such good condition. The reason of this may be that the animals are allowed to roam at large and find fodder anywhere it can be got at. The native breed has, I observed, become a good deal mixed, also owing probably to the fact that the cattle have no restraint whatever placed upon them, being secured neither by day nor night. But what is to be regretted is that the males are not kept under control, and only desirable animals allowed to go with the herds of cows. No attempt whatever is made at selection in breeding, and it is most to be regretted that young bulls are permitted to run about with the rest of the animals.

It struck me that the vicinity of the ruined city would not be so bad a place for a cattle-breeding station, now that some of the ancient lakes of the district have been restored. By means of irrigation cultivation during the rainless hot months, a grass and cattle farm ought to do well. Further up towards Tammankaduwa the

pasture lands are reported to be of exceptionally fine quality, and may perhaps be still more suitable for such an object.

One cannot but wonder and feel indignant when he sees the manner in which cattle manure is wasted in these parts. In the lowcountry the value of farmyard manure is now being fully appreciated by the natives, who, knowing that there is a ready market for the stuff, take care to store it after a crude fashion. In some places not far from Colombo I have heard of as much as R1.25 having paid for a load of dung. But in Anuradhapura manure seem to be looked upon as a nuisance to the possessor of cattle, since he cannot dispose of it for money. One sees heaps thrown about with other rubbish, and I was told it is not uncommon to burn the dung in order to get rid of it in some way, and why is this? Is there no cultivation in the neighbourhood? Well, there are some large stretches of paddy land—but altogether not very much cultivation to speak of near the tanks. The explanation I was given for the neglect to use the dung was that the lands are so fertile that they did not need manure!

Indeed, the reviving capital of the ancient Sinhalese kings is sadly in want of some little instruction in the arts of agriculture and rural economy, the knowledge of which, like its marvellous engineering skill, would seem to have been buried with ruined temples and palaces.

LUCERNE.

The cultivation of lucerne is the subject of an interesting paper by the Principal of the Government Agricultural College of South Africa, where lucerne is considered the queen of perennial fodder crops. As we believe that, with an increasing interest in dairy farming, lucerne is destined to be one of the fodder crops of Ceylon, a statement of the methods of cultivation of the plant in the Cape will not be without value. It forms a green fodder and hay which is most wholesome and useful to dairy cows as well as horses, it resists drought, and, last but not least, it improves the soil on which it grows. We quote as follows:—

"The European farmer is as a rule very particular in selecting land for lucerne culture, and he is in one sense correct, since the duration and productiveness of the crops depend chiefly on the nature of the soil. I have, however, found by experience that in this climate a soil which would not be considered a 'lucerne soil' produces quite a fine crop. But it will be understood that on a loamy soil containing a fair amount of lime with a rich permeable deep subsoil the duration and yield of a lucerne field is very much more accentuated than in places where the soils contain less lime and have not such a subsoil. The cultivation of lucerne is, however, also profitable where the natural conditions are not so favourable, though under such circumstances it may last as long and may require some manuring to insure a proper start and vigorous growth. In spite of the fact that lucerne does not require much moisture it thrives best when it gets a fair amount of rain every month, and where the local rainfall is under 1½ in. to 2 in. per month it should obtain a good

wetting once after each cut. Heavy rains are rather injurious, they favour the growth of grass to too large an extent and the lucerne is easily suppressed by it.

"There are two essential points which must not be lost sight of in growing lucerne—the necessity of deep cultivation and of keeping the land free from weeds. Lucerne is naturally a deep-rooted plant, and it is imperative that in preparing the soil for lucerne sowing, it should be loosened to a great depth. Such an operation obviates the application of manure and at the same time serves to keep weeds off."

It is advised that manuring where necessary should be done some time before the sowing of the seed:—

"The application of manure may, however, be dispensed with entirely on a great many soils, and in almost all instances where lucerne is sown on new land, manuring may be considered as unnecessary except when sown in very shallow soils. If the subsoil is of the proper description the lucerne derives its mineral food from a great depth, the roots having been found to penetrate into the soil to a depth as great as from 5 ft. to 10 ft. and even further. In the Museum at Berne the root of a lucerne plant is exhibited measuring 50 ft. in length. In many instances some manuring with lime and ashes will prove very useful; this can easily be comprehended when it is considered that a hundred pounds of ash of lucerne plants contains, according to a series of analyses, as much as 34.9 lb. of lime and 21.9 lb. of potash. Ashes, it may be remarked, also tend to check the growth of weeds.

"There is considerable difference of opinion regarding the time and method of sowing lucerne and the quantity of seed required per acre. At Stellenbosch, I found by experience, it is best to sow lucerne during April and May (autumn) broadcast in beds 5 in. to 6 in. broad at the rate of 15 lb. to 20 lb. per acre. This method will prove satisfactory in many other parts of the colony, notably in the Western Province. Sowing in spring can also be recommended if there is no danger of late frosts and of the earth-fly destroying the young tender plantlets. It is true that the autumn sowing affords a chance to the growth of weeds, but the crop will have the full benefit of the moisture in localities where winter rains are prevalent, and besides a full cut is produced early in the ensuing spring. Wherever the land is clean enough to allow of broadcast sowing it should be preferred to sowing in rows, more food being produced by broadcasting the seed, and the plants in consequence of being more closely crowded together will be more tender. Thick sowing is generally preferred to thin sowing; in France, where lucerne culture is an old and important part of farming, as much as 35 lb. of seed per acre is sometimes sown. I found 15 lb. to 20 lb. ample here, and in Australia some sheep farmers, who have laid out lucerne pastures, have successfully sown only 2 lb. to 3 lb. of seed per acre. The seed should be of a bright yellowish brown colour and smooth. Seed a year old is preferred to quite fresh seed, as the former does not contain such a large percentage of hard grains as the quite fresh article. The seed should not be covered too deep. The covering is best accomplished by means of light wooden harrows or

inverted heavier harrows. The practice of dragging a stout sapling to which are attached a number of small branches over the land will also serve the purpose. Sometimes the seed is merely pressed into the soil by rollers, and when a large area has been sown grass-seed harrows will render good service in covering the seed. At Oudtshoorn lucerne is sometimes sown along with barley. This practice has the advantage of requiring only one preparation of the land for two crops, and the lucerne further enjoys some protection. In spring sowing, particularly in localities where the spring is dry, this method of sowing lucerne mixed with a cereal crop is not advisable.

The principal attention required by young lucerne is the removal of weed with a cultivator if sown in rows or by hand if sown broadcast. It is a work which may be inconvenient to many growers, but it must be done to insure success, for lucerne is very easily suppressed by weeds in the early stages of its growth. As there is nothing so fatal to lucerne as a sward of grass, which is almost as pernicious as dodder, old lucerne fields should be subjected to a thorough harrowing after the last autumn cut and before the growth sets in again in spring. Such a system of cultivation keeps down weeds and loosens the ground, thus allowing the air to penetrate into the soil. Well-rotted manure, and in particular compost to which lime has been added, may at the same time be applied as a top dressing where manuring is necessary. Sometimes a fungus shows itself early in spring, causing brownish and blackish spots to appear on the leaves, which finally drop off. The only thing to be done in this case is to cut and feed the lucerne when the disease first becomes manifest. As the season advances the disease disappears altogether. Plots showing the symptoms of the presence of dodder should be cut off and the infected spots treated with a strong solution of sulphate of iron. The slugs sometimes found on lucerne may be killed and driven off by dusting quicklime over the crop.

"One of the important questions to be considered in laying out a field for lucerne is its duration and the number of cuts which may be expected per annum in the locality selected. Lucerne will not last longer than five years where the soil is shallow, deficient in lime, and sometimes water-logged. On suitable soils it may last from fifteen to twenty-five years and even longer. I have seen a lucerne field at Graaff-Reinet which is supposed to have been in existence for about seventy years; the soil there is, however, of the best quality to an almost unlimited depth. It appears that this bed of lucerne has resown itself, it being sometimes cut after some seeds had ripened and fallen to the ground. Lucerne may be cut in this country from five to nine times per year, each time before being in full flower. During midsummer it may be cut at intervals of about a month. The yield, which is at its best during the third year of its growth or during the second in poorer soils, is simply astonishing to a European farmer. Out of a plot of two and a half years' standing above 8½ tons of green lucerne were cropped per acre at one cut, yielding above 2 tons of hay. This is of course exceptional, but 4 to 5 tons of hay per acre may annually be expected in most localities and on soils of

average quality, in many places much more. That means two or three times as much hay as is obtained from one acre of oats, the nutritive value of lucerne hay being besides much higher than that of oat hay. When cut at the proper time, some time before flowering, green lucerne is an excellent food stuff, rich in albumen, and most suitable for dairy cattle. When cut whilst flowering, during which time the stems become harder and tougher, lucerne adds to the flesh rather than to the milk. Good lucerne being so very rich in composition it should always be fed along with some poorer food, such as straw, green maize, grasses, and root crops. The hay, properly cured, is almost as valuable as the green stuff, and forms a forage which is much relished by horses, sheep, and cattle. To give some idea of the richness of lucerne I may mention that the ratio of nitrogenous to non-nitrogenous nutriment in lucerne, hay or green fodder, is about as 1:3.2, whilst that of maize is about as 1:9.5, that of good oat hay as 1:6.5—1:7, that of millet as 1:7.1—that is, there is more of the valuable albuminous matter in lucerne than in any other fodder plant.

"It is often fancied that lucerne cannot stand depasturing. In a moist climate there is some truth in this assertion, but extensive experiments conducted in Australia, where several thousands of acres of land have been sown with lucerne, and where the area under lucerne for the purpose of pasturing is extending largely, have shown that the plant is suitable for grazing sheep. In other countries, too, where stable feeding has become a necessity, it is the usual practice to depasture lucerne in autumn instead of cutting it once more before winter sets in.

"It is a recognised fact that the prosperity of several districts of countries such as the south of France, the north of Italy, some parts of California, Hungary, &c., depend upon their lucerne fields to a great extent. It suits the natural conditions of these countries better than any other fodder plant, being a crop which is exceedingly productive and rich in composition; it at the same time restores fertility to soils, and is a great factor in the production of manure on farms, besides being a never-failing source of food for dairy stock and other farm animals."

A FEW NOTES ON FODDER. II.

1. As is well-known it is in dry districts that cattle suffer most for want of sufficient fodder. But in many of those parts where even very severe droughts occur, there are periodical rains which fall more or less regularly when the monsoon sets in. At this season a surplus quantity of grass may be grown on the waste lands with a little extra trouble, and can be stored up as hay or ensilage, if cattle-owners will only care to do it. This no doubt will be looked upon as a novel practice, and there are many among our village farmers who will consider it hardly worth their while to take so much trouble on account of their cattle. But those who do will be amply rewarded in the better condition and yield of their animals, not to mention the amount of suffering they will save them from.

2. Again in the neighbourhood of some parched and sterile places there are to be found well-

watered fertile spots like oases in a sandy desert. Grass and other fodder crops may be abundantly grown in these fertile places, throughout the year or in rotation with the paddy, so as to supply forage to the cattle both there and in the dry districts around. For instance, in the North, a few miles from Mullaitivu, we come across a fertile spot called Taniuttu, which derives its name from a perennial stream by which it is watered. The vegetation here is in a very thriving condition, and the place contrasts favourably with the dry and sterile look of the town of Mullaitivu. The flora on the banks of the stream is characteristic of comparatively cold places, and bears a striking resemblance to that of some hilly districts in the centre of our Island. At Mullaitivu cattle suffer from a scarcity of food during the dry season, and sometimes when the drought is unusually prolonged, they are well nigh starved to death. Now, why should not cattle-owners of this place take advantage of the close proximity of the fertile and well-watered village for growing a large quantity of fodder for their starving cattle?

3. Where natural irrigation is not available in the vicinity, recourse may be often had to artificial irrigation for growing fodder crops. Now, that there is a fair sprinkling of tanks, why should not a part of the immense tracts of land under them be set apart for growing food for cattle? And indeed even where such easy irrigation is unavailable, some have found it profitable to grow fodder by irrigation from wells by means of the 'picottah,' or 'well-sweep,' though on a small scale. For example, in the Mission compound at Nellore, there is a nice little plot of guinea grass grown in this way. The tall, luxuriant growth of it shows that much might be done by this method of irrigation.

4. Besides straw and grass, there are various other kinds of forage used in the districts with scanty rainfall; and the great avidity with which half-starved cattle, being compelled by necessity, gorge themselves with any trash they come across, has become proverbial in the North. But there is also a variety of wholesome stuff with which they may be fed.

(1.) The browse of various trees and shrubs is one of this class. The live-fence trees such as *Erythrina Indica*, *Inga dulcis*, &c., which are so common, are very serviceable to cattle in this way; and considering the fact that they also form strong, durable fences and are useful for shade and shelter in addition, the usefulness of live fences cannot be too highly spoken of.

The leaves and tender twigs of some common big trees are also sometimes eaten by cattle; and certain varieties of browse are reputed to have medicinal properties too. Thus the margosa leaf which is freely eaten by cattle in some parts, is said to have a tonic action, while the erythrina leaves serve as a laxative when taken in considerable quantities. But there are several kinds of browse to which cattle do not take very kindly until they are specially trained by degrees to eat them.

(2.) The leaves and stalks of the maize and the straw or hay of the inferior cereals, such as 'kurakkan' (*Eleusine corocana*), 'Varagu' (*Panicum miliaceum*), 'Tiuai' (*Panicum Italicum*), 'Shami' (*Panicum miliare*) are also used for feeding cattle in Jaffna and some adjoining districts.

(3.) The bran of paddy is given to cows and cart-bulls. When given to milch cows mixed up with tepid water, it is said to increase their yield of milk.

(4.) The mesocarp of the tender palmyrah fruit is also said to have a similar effect. By way of explanation it might be mentioned that all the palmyrah fruits do not mature and ripen on the tree. Many of them drop down when they are tender, i.e., in the *nonku* stage, being shaken off by the wind or partly injured by squirrels &c. They are then gathered, and after the refreshing juice in the 'eyes' of the *nonku* is sucked up and drunk by children, who, by the way, are extremely fond of it, the tender fruit is sliced up into thin bits and served to the cows.

There are several other kinds of food which are given to cattle in the dry districts of the North-East, but as they are of minor importance, it is not necessary to mention them here, but I trust that these few lines will awaken some little interest in the subject of fodder. The natural grass in the South-West and centre of the Island is generally so abundant and unailing that most of the village cattle-owners there complacently regard it as a sufficient food for all classes of cattle at all times and seasons; but it is in the dry parts of the North where protracted droughts occur, that the necessity for raising artificial forage is seen. When we remember that all the meat, dairy products, and labour of cattle come to us as the result of feeding, the importance of growing sufficient food for cattle will not be undervalued, and I have been induced to write these notes in the interests of starving cattle, after seeing the careful feeding on scientific principles practised at the Government Dairy, and the laudable attempts of the Superintendent of the School of Agriculture to introduce fodder crops into the Island.

E. T. HOOLE.

ZOOLOGICAL NOTES FOR AGRICULTURAL STUDENTS.

We now come to the fourth class of Annulosa, and perhaps the most important group of animals so far as the agriculturist is concerned, viz., Insecta. The Insecta may be defined as articulate animals in which the head, thorax, and abdomen are distinct; there are three pairs of legs borne on the thorax, the abdomen is destitute of legs, and a single pair of antennæ is present in most there are two pairs of wings on the thorax; respiration is carried on by means of trachæa. The natural orders of insects which possess the greatest interest to the agriculturist are Coleoptera, Hymenoptera, Lepidoptera, Homoptera, and Diptera. The termination *ptera* is derived from the Greek *pteron* a wing, while the prefix refers to some peculiarity of that organ.

The life-history of many insects may be illustrated by that of the butterfly. The female lays eggs which produce caterpillars (or larvæ). When full grown these choose a place of security, or in some cases spin a cocoon in which to change to the chrysalis (or pupa) stage. In due time the outer coat of the pupa cracks

and from within it comes the mature winged insect (imago). The change from the grub-like larva to the imago takes place during the quiescent period or resting stage represented by the pupa. After pairing the female lays eggs and dies. Then the whole cycle of egg, larva, pupa, and imago, is repeated.

This is termed "complete metamorphosis," and it includes, as mentioned, the quiescent pupa stage. It takes place in the case of the following orders of insects: Coleoptera, Hymenoptera, Neuroptera, Lepidoptera, and Diptera. In some orders, however, the pupa stage is absent; the larva is then much like the adult form which is reached after many moultings. This is the case with the Homoptera, Heteroptera and the Orthoptera.

To the order Coleoptera or "sheath-winged" insects belong the beetles. The front wings are hard and act as a protection to the membranous hind wings. Beetles have biting jaws. The insects of this order pass through a complete metamorphosis. The larvæ are usually fleshy grubs, the mouths being furnished with jaws; they are mostly 6-legged and often have a fleshy proleg at the end of the tail. Weevils are a group of hard beetles provided with snouts, their larvæ are legless grubs. What are known as lady-birds, are useful beetles which destroy plant lice. Wireworms and cockchafer grubs, which live in the soil for years, are very troublesome. To this order also belong, beside the wireworm and cockchafer, the turnip fly, the mustard beetle, the bean seed beetle, the turnip gall beetle, the nut weevil and others.

The Hymenoptera or membrane-winged insects have usually four membranous wings which have few veins, though often furnished with scattered bristles. The abdomen of the female frequently has a conspicuous ovipositor or egg-laying apparatus, which is also used as a borer or is developed as a sting. The Hymenoptera pass through a complete metamorphosis. In some species the larvæ are legless (existing as a maggot or grub), and live in a nest stored with dead insects or pollen; in others they possess up to 10 or 11 legs, and feed on leaves, or stems in galls. The latter are specially destructive to crops.

The true stinging insects such as wasps, bees, and hornets belong to this order, and most of the parasitic insects (such as gall flies) and the true ants are also included in it. The galls on the oak tree is due to the marble-gall fly.

To the Lepidoptera or scaly-winged insects belong butterflies and moths, of which the latter are the more numerous. They possess four wings which are usually covered with delicate vari-colored scales. The organs of the mouth are adapted to sucking, and the insects pass through a complete metamorphosis. The larva is worm-like with usually 5 to 8 pairs or less (occasionally none) and is furnished with biting jaws (caterpillar). The following are the differences between butterflies and moths; butterflies have antennæ or horns with knobs like a drumstick, the antennæ of the moths have no knobs. Butterflies when at rest raise the wings so that they meet back to back; moths at rest keep their wings spread out so as to cover their bodies. Butterflies usually fly by day, moths at night or twilight.

The Homoptera or similar-winged insects have wings of the same texture throughout, either leathery or membranous. The wings when at rest are held slanting over the back like a steep roof. Though four wings are usually present, there are only two in some species and none in others. The mouth or beak is adapted for sucking. The antennæ are generally short. The larvæ are much like the mature insect and there is no quiescent stage. The Homoptera are terrestrial insects and are all injurious to vegetation. With the Heteroptera (dis-similar winged)—an order including the plant bugs and certain water insects—they make up the division called Hemiptera (half-winged). The Homoptera are well illustrated by the aphides or plant lice which include some of the most destructive insects known. Vegetables, hops, vine (attacked by the Phylloxera), fruit trees and corn are all subject to their attack.

Diptera (two-winged) have only one pair of wings which have few veins and are naked. This is the order of the true flies. In place of the hind wings are a pair of balances or poisons; the mouth is furnished with a proboscis for piercing or lapping. The larvæ are usually wormlike, legless maggots with a soft retractile head of no definite shape, though sometimes there is a hard head with jaws. The house-fly and blow-fly are familiar examples, and one of the most destructive root pests is the leather-jacket, which lives in the soil like the wireworm. The ox warble fly, horse bot fly, gad fly, forest flies, sheep's nostril fly, sheep tick and mosquitos are all dipterous insects.

As before mentioned the above five orders include the most important plant pests. The Orthoptera (right-winged) have four wings, the outer being leathery rather than horny as in Coleoptera, and slightly overlapping; the hind legs are fitted for leaping, the jaws for biting. The larvæ live on land and there is no resting stage. Cockroaches, crickets, grasshoppers, and locusts (so destructive to vegetation in some countries) belong to the order, as do the walking-stick and leaf insects.

Neuroptera (nerve-winged or net-veined) have four wings, generally with numerous hollow veins and either naked or hairy. The worm-like larvæ have six legs and are provided with jaws. They are mostly aquatic and with few exceptions pass through a pupa stage. Dragon flies, may flies, and the well-known termites or white ants are examples of Neuroptera.

HORSE-BREEDING. II.

We have all heard of the horse-breeding farm at Delft which is said to have produced very good animals at one time. Another place where a few animals are bred is the Massalwala near Beruwala. Moist soil and undrained lands are the worst places for animals to live in and far less to breed. The Beruwala land is thus totally unfit to be a breeding station, and could only have been chosen owing to so large an expanse of flat country being available, and from the fact that there is also a good growth of natural grasses in the locality. The place was probably originally a resort for cast-off horses, which, having bred under natural conditions, set a precedent for a

crude form of breeding whereby foals of the very poorest quality were got.

Now if there is sufficient encouragement for carrying on this method of breeding in so unfavourable a spot, surely it should both pay and prove in every way a success to breed horses in suitable localities and under favourable circumstances.

One may venture to say that it would pay any moderate capitalist to go in for horse-breeding in the Island, without the least aid from Government.

Even if the idea of adopting horse-breeding as an independent industry be put out of consideration in a country with such a grateful soil and climate, where very few would care to venture in any new enterprize unless driven to it under severe pressure, still the subject is surely deserving the serious attention of coconut planters, both small and great; I mean those who possess from a few acres to thousands. Even in the smallest garden one or more mares could be profitably kept. Serviceable Indians need not cost more than from R100 to R150, and they should not require much for their keep, for they need not get their paddy and gram so long as they are left to graze in the estate, and the most they would require in the way of additional expenses would be some straw and a shelter, except when in foal a little feeding for a few weeks. The animals may, moreover, be put to some use in a coconut estate, which would amply pay the little extra care and feed.

As a matter of course the item on which something will have to be spent is on the keep of a stallion; this is the most important point in the success of the whole industry, though some may think that the method followed at Massalwela aforementioned would be ample.

The cost of a serviceable stallion would range from two hundred and fifty rupees to thousands; and the more the outlay on a stallion the better the quality of the progeny, and hence the profits. It has been estimated by Indian authorities after the experience of many years, that in this country a stallion could profitably serve fifty mares in a year, though I believe they make more use of a stallion in England. So a single stallion, if obtained, would be ample for a whole district, and a small charge from those who keep the mares would amply repay its cost and keep.

There is no reason why some system like the above should not prove successful, and perhaps lead to altogether a new industry and a new source of profit which may eventually be shared by the native cultivators themselves.

W. A. D. S.

THE CLOVE TREE.

The English name clove is said to be derived from the Spanish *Clavo*, and the French *Clon*—the names of the spice in these languages—from the resemblance which the dried buds bear to nails.

A peculiarity of the clove-tree is that every part is aromatic, but the greatest strength is found in the bud, which is the "clove" of commerce. The finest quality of cloves are dark brown in color with full, perfect heads, free from moisture.

In the cultivation of the clove, the first thing to be done is the starting of the shoot. The seeds are planted in long trenches and kept well watered until after sprouting. In the course of forty days the shoot appears above ground. They are carefully watered and looked after for the space of two years, when they should be about three feet high. They are then transplanted, being set about thirty feet apart, and are kept watered till they become well rooted. From this time the young trees require only ordinary care, though the best results are obtained when the ground about the trees is well worked over and kept free from weeds.

The growth of the tree is very slow, and five or six years are required for it to come into bearing, at which time it is about the size of an ordinary pear-tree, and is usually very shapely. It is a pretty sight to see a young plantation just coming into bearing. The leaves, of various shades of green tinged with red, serve to set off the clusters of dull red clove buds.

As soon as the buds are fully formed and assume this reddish color the harvesting commences, and is prosecuted for fully six months at intervals, since the buds do not form simultaneously, but at odd times throughout the said period. The limbs of the trees being very brittle, a peculiar four-sided ladder is brought into requisition, and the harvesting proceeds apace.

As fast as collected, the buds are spread out in the sun, until they assume a brownish color, when they are put in the storehouse and are ready for market.

A ten-year-old plantation should produce an average of 20 lbs. of cloves to a tree. Trees of 20 years frequently produce upwards of 100 lbs. each.

Zanzibar, as is well known, is noted for being the principal source of the world's supply of cloves. The industry received a serious check there in 1872, when a great hurricane swept over the Island. It is said that at least nine-tenths of the trees were destroyed at that time, so the larger part of those now standing are of new growth. It is reported from there that the present season, commencing with July 1889, is very favourable, and that the crop will exceed that of any previous seasons. It is expected in all probability to amount to 13,000,000 lbs., averaging a local value of 10 cents per lb. Besides the clove buds, the stems are also gathered, and form an article of commerce, commanding about one-fifth of the value of cloves, and having about the same percentage of strength. To this circumstance is traceable the fact that ground cloves can frequently be purchased in the market at a lower price than whole cloves.

GENERAL ITEMS.

A new patent, called the Disc churn, has been awarded the Silver medal at the late Royal Agricultural Society's Show. It is described as a simple contrivance which is likely to revolutionize butter-making. The principles which are employed to produce butter from cream seem to set at naught the rules which have hitherto been observed in modern dairying. Temperature is disregarded, and the speed of the churning

has no other effect than to make the butter-making a longer or shorter process; the faster the handle is turned, the sooner the butter comes, is the maxim of the Disc; and the quality and the quantity of the butter are the same whatever the speed. The machine and the process are so simple and ingenious that a description of them, as given in the *Ayr Advertiser* is worth giving:—A very simply constructed box, open at the top is fitted with a narrow wooden disc which is levelled so as to come to a knife-like edge. The disc is placed vertically in the box, and is made to revolve by means of a handle which is geared to cogs to acquire speed. Over the wheel, and fitted on to the top of the box, is a wooden cup some three inches in width with hanging boards. As the disc revolves a thin layer or film of milk is picked up and dashed with great force against the lid or cup. The working of a natural law prevents the butter from being worked beyond the granular stage, for when once the cream becomes butter it no longer adheres to the disc, but dances about in the butter-milk as the liquid is disturbed. The washing of the butter is easily effected, as when the butter milk is drawn off and clear water is substituted, a few revolutions of the disc are sufficient to clear the grains of the fluid matter, while the brining or salting becomes effective in a similar manner. The butter is easily removed, and the scalding and cleaning of the churn is as simple as the cleaning of a bucket. It is said to be possible to make the box of glazed earthenware or porcelain, when a foul churn would be almost an impossibility. It will thus be seen that the process is very simple, and the value of the machine is best realized when it is known that from three to eight minutes are sufficient to produce the butter.

The utilization of skim-milk is a matter of great economic importance under the developing system of separation by cream separators. The Royal Agricultural Society invited Mr. Rehenstrom, expert in dairy science to the Swedish Government to visit the Show to exhibit his machinery for making human and cattle foods from the solid constituents of skim-milk. The following is a description of the process:—By means of a steam exhaust the milk is brought into a pulpy consistency and is subsequently subjected to pressure which gets rid of moisture, and the solid matter can be dealt with as required. Cakes of a highly nutritious nature composed of the solid milk and grain are combined to constitute a horse fodder. Calf foods, coffee, coffee and cocoa mixtures, and an unlimited variety of palatable foods are made, and when it is remembered that all that is good in milk (except the fat) is retained, it is certain that there must be much that is valuable in them. Food that has a milk foundation must be good for the young animals, and the makers state they can produce the articles so cheaply, that compared with foods of a similar value they are able to find a good profit.

A thorough test, however, is necessary as to the practical value of the discovery.

Within the past few years, says the *Auckland Weekly News*, much attention has been given to okra (*Hibiscus esculentus*) as a fibre plant in the Southern States of America. Mills are said to have been erected in England, Germany and France by a Mr. Sadow, for working up the raw material, which he says he can produce at $\frac{1}{2}$ d per lb. This information we have gleaned from American sources, and it may of course be overdrawn. But one fact is patent, and it is a valuable fibre plant, and its production, cost and value are worthy of careful enquiry.

No. 16 of the Imperial Institute series of Handbooks issued by the Indian Government reproduces the information in the Dictionary of Economic Products regarding *Kamela* dye, the powdery substance obtained as a glandular pubescence from the exterior of the fruit of *Mallotus Philippinensis* (*Rottlera tinctoria*), the Sinhalese hamparila, and the Tamil kapila-podi. Regarding it Dr. Watt says: "Even at the present day *Kamela* dye cannot be said to have obtained the position in European countries which its merits deserve."

When you are ready to plant, says a correspondent of the *Practical Farmer*, put your corn in a sack, hang it and give it a thorough smoking. With seed that had been smoked no damage was done by the ant-worm and other vermin, and as far as I could judge not a single kernel was disturbed, while the corn which was planted without smoking on adjacent ground was badly damaged.

As an instance of the ease with which weeds may be introduced, the following will be of interest to agriculturists. A box containing Smyrna fig cuttings is said to have been brought over to Australia; these plants on identification were found to be *Hypecum procumbens*, *Vesicaria utriculata* and *Artsemisia campestris*,—the plants appearing for the first time in the colony. As they were known to have the character of noxious weeds, prompt steps were taken to destroy them at once, so as to prevent the possibility of their spreading in the country. It is not an uncommon experience to find a few weeds among flowers and vegetables, the seeds of which have been imported from abroad.

Chickens are often observed to become stupid, go to sleep, and appear to sleep themselves to death. Some style this the "sleepy disease," which often destroys the chicks rapidly, especially in warm weather and in a warm climate. The so-called "sleepy disease" is nothing more or less than *lice*. Whenever a chicken droops without any apparent cause, examine the head closely for the bloodsucker, and rub two or three drops of sweet oil on the head of each chick twice a week.

ROBERT BOYD TYTLER, Esq.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XIII.]

COLOMBO, OCTOBER 2ND, 1893.

No. 4.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

ROBERT BOYD TYTLER.*

EARLY LIFE.

F “a wise son knows his own father” it is but meet and right that the modern planter should desire to know, and learn a lesson from the life of the late Robert Boyd Tytler, emphatically the

father of coffee and cacao *cultivation* in Ceylon. Specially educated and trained for a tropical agriculturist, practical, shrewd, energetic and conscientious, Mr. Tytler would have made his mark in any walk of life. That he devoted the first-fruits of his experience and active life to the interests of Ceylon, was indeed a fortunate circumstance for the island, which at the time, so specially needed guidance in planting matters. And now though gone, upwards of ten years ago, the result of his life and labours may yet be seen in a body of highly-trained planters, whose energy, intelligence and integrity will compare favourably with that of any agriculturists in the world.

It may be said that while yet a baby, “Bobbie” was expressly set apart for a planter. Born in the village of Inverurie, 16 miles North-west of Aberdeen, on the 27th July 1819, he received the name of *Robert Boyd* after a cousin of his mother, which proved a fortunate thing for all concerned, and must have often led the parents to think that after all there's something in a name. Had the boy's name been plain *Peter* or odd *Obadiah*, ten to one, Ceylon would have never seen him. Mrs. James Tytler's uncle was minister of Crimmond, consequently the boy's name-father was “a son of the manse,” already well-known as a keen and successful man of business, deeply interested in eastern trade, particularly in the planting prospects of Ceylon.

THE MANSE.

The manse had now no children to enliven it, while James Tytler had a quiverful of a round dozen. What so natural and so proper that that the manse should adopt one, and that this one, should be the bright little embryo planter now verging upon 8 years of age. Bobbie was a decided acquisition to the manse. Especially appreciated by the two ladies, who charmed by his quaint humour, would listen amusedly to his naive recital of village life. “And can you sing?” said Miss Boyd, one day after calling him in from the garden to amuse some lady visitors. “Hoot ay”! said he, and clearing his throat at once proceeded. But the first line proved enough. “Stop” they all shrieked at once, and the astonished Bob received such a lecture on the impropriety of his song as he never forgot to his dying day.

THE SCHOOL.

It was now considered high time to send the boy to school, and to school he forthwith went, and so set himself to master the mysteries of *Mc'ulloch*, *Lindley Murray* and *Gray* with a success which, while it delighted the dominie, astonished the good folks at the manse. At this same school Tytler made the acquaintance of several youths with whom he afterwards came in contact in Ceylon. Amongst others, Reid, Webster, &c., all of whom were distinguished in after life by their splendid *peermanship*, alas! now almost a lost art.

Even at this early age R. B. T. made his mark, and it is said left it on more than one of the boys.

THE GARDEN.

At 12 years of age he was removed from the public school, and bearing in mind the life and work for which he was destined, his studies were transferred to the Gardens of Philorth, the seat of Lord Seafield. Although it was understood he was sent there as a sort of supernumerary apprentice—in something like the position of a modern “creeper”—yet he had to begin at the beginning, taking his turn with the others, and he had reason to remember his first afternoon's work.

In those days it was the fashion—and for all I know may be so still—that every lout who called himself a journeyman gardener, thought he was entitled to inflict all sorts of practical jokes on the

* By “OLD COLONIST,” with a few additions by the Editor.

green hand, and the tender years of the new arrival were no protection for him; rather the reverse.

The work in hand was wheeling manure along a steep walk, and the others took care that Bob's barrow was filled to the overflowing, but he was too proud to give in, and pluckily kept his turn. Again and again they filled the barrow with double the quantity that they themselves attempted to lift, but Bob only set his teeth and manfully came in up to time. At length they so contrived to build up the barrow with wet muck, that his utmost strength could only wheel it along the level. In attempting to take the hill, his poor little legs tottered beneath him, and in pure vexation of spirit the tears came to his eyes. "What a ——— shame!" said the voice of one behind him; who had taken in the situation. "Let me take that barrow," and as Bob relinquished it, he saw that the voice came from the kind-hearted Forester, and as he walked behind the powerfully-built man, he made two resolves. The first being, that if ever he became an influential man, he would reward that Forester or those belonging to him; and the second was that he would yet be upsides with his persecutors, both of which laudable resolutions he literally carried into effect. Thrashing the journeyman gardener before he was two years older, and in after years when he had become a prosperous proprietor in Dumbara, two of the Forester's sons were amongst his most capable and liberally-paid managers. Meanwhile, young Tytler became an adept in "the Art that doth mend Nature," and as soon as his three years' apprenticeship were completed, he was sent out to continue his studies in Jamaica.

JAMAICA.

He reached Kingston when only 15 years of age, and for the next three years led a very active and highly-interested life, partly on the Blue Mountains, studying the coffee tree; partly on the plains learning the art of sugar-making. But it may here be said, that he never took kindly to sugar planting; his speciality now—and for many years after—was *Coffee*.

The lively young Scot soon became a special favourite in Jamaica, was an active Militia-man, and generally took a keen interest in all the social affairs of the little colony, so that it was not without much regret that his friends at Kingston bade good-bye to him at the end of three years.

CEYLON.

A larger and more promising field, however, now lay before R. B. T. Coffee-planting in Ceylon was only as yet in the experimental stage: the experience he had gained in the only spot where the tree could be said to be cultivated, was much required. True, a considerable export, amounting to about 30,000 cwt. per annum was already being shipped from Colombo. Albeit, the planters were but groping in the dark, under the shade of massive trees, and the lanky long-drawn coffee plants were already pining for more light.

For a few weeks only did our young planter pay a visit to his native Aberdeen. "And how did he look on his return from Jamaica?" the writer asked of the only remaining brother the other day.

"Look! (he said) Better than any o's; but the only thing I can distinctly remember is, that he gave me his watch to hold till he ran round the race-course, *two miles in 10 minutes!*" In 1837—Mr. Tytler being then 18 years of age—landed in Colombo, and was without much delay forwarded to Dumbara, in which rich and beautiful valley he was destined to play so important a part. For

a time his attention was confined to sugar, and it was said that this was the only time in Ceylon when sugar showed a profit; but it was never congenial work, nor were the surroundings at this time in Dumbara very congenial to the new arrival, and it was not without a considerable feeling of relief that he ultimately got a commission to explore the surrounding mountain valleys, in order to select the most suitable land he could find for coffee. He had previously given the benefit of his experience to the planters in the vicinity of Dumbara, and the West Indian system of cultivation was universally adopted, perhaps rather too literally, for although the benefit from entire absence of shade became speedily apparent, it was not a lasting benefit, and suitable and necessary as its absence may be on the misty hills, a modified shade is unquestionably beneficial both for coffee and cacao in low, hot and dry localities.

PIONEER.

It was as a pioneer on the mountain zone that R. B. T. first really distinguished himself. To him is due the merit of selecting the famous Kelebokke Valley, and some of the finest properties in Matale East, in both of which districts he did admirable work, not merely as a selector but as a practical planter, contending with difficulties such as the present race of planters could scarcely conceive possible.

WRITES.

While working here as a pioneer planter, Mr. Tytler began to make his presence felt in the island generally. Not only was his work executed in a manner to call forth the admiration of those who saw it; but in his spare moments he dropped letters to the *Observer*, which for terseness of language, commonsense and fearless hard hitting, Colombo had not before been accustomed to receive "from the hills."

At first Colombo merchants were not disposed to put up with this youngster's advice on coffee curing and copper-bottomed clippers, and more than once a dignified attempt was made to silence the obnoxious scribbler, the only result being a retort more "outrageously" plainspoken than before. To those who only know the modest Colombo Agent of today there is no use trying to picture the effect of such exasperating conduct upon the mercantile grandee of the 40's and 50's. Occasionally it seemed to bode badly for the prospects of R. B. T.; but by-and-bye even Colombo merchants came to appreciate his worth, and work much more than he could undertake came to him unsought.

BECOMES A V. A.

For some time he took up his residence in Kandy acting as agent and adviser for a number of absent proprietors, and always with the most satisfactory results to those directly interested.

PALLAKELLIE.

To become a resident proprietor in his beloved Dumbara was, however, the aim of his life and acme of his ambition as a planter, and this he ultimately accomplished by acquiring the abandoned estate of Pallakellie, also holding shares in the adjoining properties of Rajawella, Ambecotte and Gangawatte.

On Pallakellie he built and formed his unique demesne, which for many years has been the admiration of all visitors. 'Twas here he became best known to Ceylon during the middle and latter years of his planting life; here he received distinguished travellers interested in tropical agriculture

here he entertained, as no other planter could entertain, all and sundry, from the Queen's representative down to the humblest coolie, and all were alike welcome to his table and the best he had upon it. It was from here he was chosen Chairman of the Planters' Association and became member of the Legislative Council, a position he deliberately aimed at and steadily worked up to.*

It was here the writer periodically paid him a passing visit, and generally found the patriarch surrounded by a bevy of his favourite coolies, singing extempore songs and ever ready to laugh

"At all his jokes,
For many a joke had he."

Meanwhile, the estates were giving bumper crops, and everything he touched seemed to prosper. Pallakellie itself seemed a curious experiment by one who came to teach pruning and the clearing away of shade, *but it succeeded*; and nothing could exceed the beauty of the coffee as it grew like large patches of glossy shrubbery in a noble park. For some ten years the average crops on the Dumbara estate had equalled 10 cwt. per acre. Wealth accumulated, and the people did *not* decay, prosperity indeed only stimulated our friend to greater exertions and still more liberal giving.

DRY CYCLE.

But the time at length came when the prosperity of Dumbara received a serious check, a cycle of dry seasons set in and the crops became more and more uncertain. The trees indeed blossomed as of yore, and the bright red cherry too followed in abundance; but alas the bean did not mature, and only floated like chaff in the cisterns. Dumbara, with all its rich soil and genial sunshine, could not be got to grow fully-developed fruit without reasonable moisture, and how to supply this too-evident want now exercised the active brain of Mr. Tytler.

IRRIGATION.

The Mahavelliganga rolled past. What so natural to suggest itself as that these muddy waters, carrying the riches from the hill estates, should be utilized in moistening the thirsty lands of Rajavella. And now comes the interesting story of the gigantic Waterworks, a story unfortunately too long for the space at my disposal, works ably conceived and admirably carried out.

We have looked upon the elaborate make-shifts of the Egyptians for the conveyance of water, seen the stupendous aqueducts of the ancient Incas; but nowhere in the world have we seen such powerful force-pumps in use, as those erected by Mr. Tytler. In the erecting of these works, Mr. John Brown—since so well known as the pioneer of Uva Companies—first made his mark as Engineer and Colonist under Mr. Tytler's auspices.

A huge turbine supplied by water from the river gave the motive power, by which a continuous stream of about 1,000 gals. per minute was carried to the crest of a ridge 500 feet above the pumps. On the crest of each minor-ridge the main pipe was

furnished with stop-cocks to let out the water, which was conducted by surface drains to each line of coffee and every coffee tree. But carefully thought-out and faithfully-executed as these costly works were, it must be admitted they did not prove a financial success. Magical as the effect at first seemed to be, it was found that the water percolated rather too readily through the open subsoil, and although it refreshed the coffee for the time, it did not even with liquid manure added, sufficiently sustain the trees to enable them to carry the crop to maturity.

That coffee will thrive and prove eminently productive under irrigation, is of course well known, and we have seen it bearing very abundantly where *rain was never known to have fallen*, but only on perfectly flat land, regularly irrigated *at night*, and these conditions were not present or very practicable in Dumbara, so that the success of the costly waterworks was far from being such as Mr. Tytler and his many friends could have wished. In short, the irrigation works proved his first serious loss; but nothing daunted, his ever-resourceful brain was next directed to a study of the chemical composition of the soil, the gradual impoverishment of which he now saw with growing concern. This was a study of years, the result of which we will come to later on.

TAKES A TRIP HOME.

Meanwhile (1857), Mr. Tytler prepares to take a trip home, a visit which Aberdeen well remembers. He was then in the prime of manhood (38); weighed 18 stone! but ever active, hearty and cheerful to a degree. The burly frame of the broad-chested planter became familiar on the Castle Gate, and a welcome sight at all public meetings, while his cheery salutation on the streets was enjoyed by gentle and simple alike. There was something so intensely sympathetic, and at times so child-like in voice and laughter, that he invariably won the hearts of all with whom he came in contact. But this was not the whole secret. He was passionately fond of giving—enough of itself to insure unbounded popularity in Aberdeen—liberal to a fault, though surely a fault that leant to virtue's side. The boys thought so; would double round corners, change bonnets, and do as they did in the days of dear old Dr. Kidd. But in this case it was not to get a double blessing *but another sacrifice*, or even a "fite penny" as R. B. T. would call the florin with which he delighted to astonish the recipient.

Most unselfish of men! He cared nothing for money, as *money*, and looked with the greatest contempt on the poor creatures who accumulated it for the sake of hoarding:

"You see what the Lord thinks of money by the sort of people he gives it to keep"—he used to say.

THE VOLUNTEER FIASCO.

It was at this time that the famous Volunteer movement broke out amongst the Ceylon planters, and when he threw his celebrated letter like a bombshell in their midst, it caused intense excitement. He ridiculed the movement as an impossibility and an outrage on commonsense, could see nothing in it but "an idle vapouring of undignified playing at soldiers," that "the planter was paid for duties which no man of honour would neglect for the purpose of volunteering," that "proprietors at home who were already torturing their ingenuity how to get the two ends of high expenditure and short crops to meet, would derive little consolation from seeing in the *Observer*, that their Superintendents were zealous Volunteers!" Finally, he recommended his friends in Matale to

* No more popular Chairman ever presided over the Planters' Association, and to the last, the sight of "R. B. T.'s" gigantic "topee" with its famous pug-gery, making for a P. A. meeting was a sure sign of a successful gathering with abundance of humour to season the business speeches. As M. L. C., Mr. Tytler was all too short a time in office, and the Governor, Sir Henry Ward (who most warmly appreciated his ability and good qualities) greatly regretted that he had not his (Mr. Tytler's) co-operation in the Legislature for a longer period.—*Ed. T. A.*

"give the *kepi* to the kangany, take opening medicine, and put their feet in warm water!"

The letter gave mortal offence to many, and for weeks the *Observer* was inundated with fierce, fighting letters in reply. "Who cares for R. B. T.'s impertinence" was the burden of the comments upcountry. "It will only stimulate us to persevere" said "B. W." ("Backwoodman" or W. Abercrombie Swan) and so said Matale generally. Grand old Crüwell was particularly savage, though the time soon came when he generously relented, as I see from a letter addressed to R. B. T. beginning "My dear old boy, Glad to see you fist which I should like to shake very much again." As for the Matale Volunteers, they in a few months wisely disbanded, and sought the shelter of their own pulping-houses. From all of which, we can only surmise, that if a few plucky R. B. T.'s were now to arise, it might fare badly with that grotesque body of Don Quixotes, yecept "the Mounted Fut."

RETURNS TO CEYLON.

Mr. Tytler returned to Ceylon about 1862, in order to carry out certain experiments with reference to the special manure he was now having prepared. He was not a man to do anything by halves, and certainly no man ever went more patiently and systematically to work to ascertain the exact requirements of the coffee tree in the shape of sustenance, for day after day he would sit studying the different groups of trees. Here under the sloping rock a vigorous tree bearing at the rate of 15 cwt. an acre; there within a few yards a tree planted at the same time from the same nursery, year after year with only a few beans; what is wanting in the one case which the other has got? Here said Mr. Tytler "are certain conditions, these they are wanting; let us but ascertain what these are, and the difficulty is kraaled."

SOMBREORUM.

Carefully he had the heavy bearing tree lifted up with half a ton of the soil in which it grew, not forgetting portions of the sloping rock above, and all was packed away in huge cases. The same was done with the unfruitful tree, and home he went with his cases to the eminent chemist Professor Brazier of Aberdeen University. The writer accompanied Mr. Tytler on this occasion, and well remembers the eagerness, care and thoroughness with which the whole matter was gone into. The ultimate result was "*Sombreorum*," his remarkable letter of April 1866, addressed to the *Observer*, and something was said about a sealed packet to be opened when all Ceylon was again bearing bumper crops. Many planters now set confidently and zealously to work to apply the elixir. There was much real enthusiasm and not a little chaff. The Volunteer letter had not been quite forgotten, and two Matale men put their heads together and hammered out the following specious parody on

TULLOCH-GORUM.

O, Sombreorum's my delight,
In it gude qualities unite;
And ony Dori wha shows spite,
May puku copee smoor him!

* Times, are greatly changed since the "fifties"—one of the chief objections then was the difficulty of moving about and getting together a decent number of recruits; roads and railways have altered that, as time has also brought us a heavier military tax, of which the success of our Volunteers may justify us in claiming a reduction.—*Ed. T. d.*

Glad and busy coolies a',
Glad and busy, glad and busy,
Glad and busy coolies a',
Wi' plenty coffee o'er them.

Ower a' the totums that I ride
Baith "bones" and "poonac" I have tried;
And o'er guano I have cried
And even cattle orum!

They're puir and feckless at the best,
Puir and feckless, puir and feckless;
They're puir and feckless at the best,
Compared wi Sombreorum!

HEMILEIA VASTATRIX.

Nevertheless, the effects of *Sombreorum* were very striking, the mixture had unquestionably a potent fertilising and sustaining power, and for some years gave promise of a revival of coffee crops, wherever applied. Alas! these hopes were but short-lived, and were destined to be more completely shattered than any previous promises, by the appearance of the new and unlooked-for enemy *Hemileia Vastatrix*, an enemy which baffled the scientist, rendered worthless the experience of forty years, and ultimately brought irretrievable ruin upon nearly every coffee planter in Ceylon. No single individual suffered more from this calamity than Mr. Tytler.

THE AGE OF 10 %

It is true he still had his pet product *Cacao* to fall back upon, a product he had been carefully nursing and acclimatizing for 20 years, but to thoroughly establish this in the place of coffee, still meant five or six years. How to get over this interval was the difficulty; and with the income from coffee reduced from £5,000 or £6,000 a year, to less than nothing, and compound interest accumulating at 10%, the prospect was not encouraging. The age of 5% block loans and 50% reduction in the cost of production (which depreciated silver practically means to the planters) had not yet come, a fact which men who marvel at Mr. Tytler's inability to surmount the difficulty, would do well to remember.

THE COMING STRUGGLE.

R. B. T., naturally the most sanguine and cheerful of men, began to give way under the growing load. He found the pillow indeed a hard one, and frequently when sleep forsook him would rise up, look once more at the unconscionable balance piled up against poor king coffee by those who had most profited by his generosity. And as often would he seek and obtain comfort from the only Source he implicitly believed in, and few who met his cheery smile on the morrow could dream of the agony he had passed through during the night-watches.

HIS CHARITY.

And yet, it was not for himself that he grieves,—“not so much for the planters as the poor patient wives and helpless bairns dependent upon them.” “O man,” he would write, “I am dowie, I continually am, I cannot rise out of it, and the only cure would be a return to coffee of its former capacity for crop-bearing. I am aware that my own prospects, bad as they are, might be envied by many, and I am not unthankful, far from it, only dowie and wae, and no small degree of that comes from thoughts of others. God help us all! “There's that poor widow Mrs.—; my heart bleeds for her; could you convey the enclosed

to her *without mentioning any name*. I am impelled to send it by Unseen dictation."

The enclosure was a £20 note, and it might not be out of place now to take a passing peep at the home of the poor young planter's widow, whose half-broken heart still fondly clung to the hills of Ceylon.

It was the November term; the grey granite city looked cheerless and cold, and few were abroad in the slush, except what Tytler playfully called the Platypus, *i. e.*, a beast with a bill!

Poor Mrs.—heard the door bell ring, felt assured it was a demand for the rent, her legs trembled beneath her, she sank down on the stair and uttered a brief prayer. Again the bell rang, and she opened the door to find her prayer fully answered.

This I know to be only a sample of R. B. T.'s religion, and the grief he felt at the downfall of coffee was chiefly the grief of having to discontinue these generous acts of real Christian charity.

THE GLOOM DEEPENS.

Early in 1882, he wrote after his last visit to Ceylon:—"There is now no longer any doubt about the gravity of affairs. What to do is the question asked on every side. What's the use of foreclosure? and who's to buy if put up for sale? I incline rather to the view of restricted upkeep doing its fatal work by degrees, and how fatal that will be in Ceylon soil and amongst coffee *planted as the bulk of it has been*, there's none can conceive better than *yourself*. Whole sweeps of districts, and even districts themselves, will drop out of existence as coffee producers, and then the poor owners, *their wives and families?* (Oh! good Lord help them!) What *will* become of them in such a country I do not know; mortgages will drop very heavily, banks and firms will go down, and then? Why I fear except for *Cacao* it will be gloaming in Ceylon."

It will here be noted that there is not a word about tea, the profitable cultivation of which has since been rendered *possible* by the depreciation in the value of silver.

CACAO THE HOPE OF THE FUTURE.

I have already alluded to Mr. Tytler's experiments in cacao cultivation. He was the first to *plant out* this famous tree in Ceylon. His "Chocolate Watte" at the Kondesalli corner, was for years one of his favourite show spots on Pallakellie. He invariably spoke of it as "*Chocolate*," in order to distinguish it clearly from the somewhat confusing name of *cacao* (really pronounced *kakow* in its native home of South America). At first, the tree had many enemies in Ceylon, the worst of which proved the dry scorching winds. To provide against this, and with a view to further extensions, Mr. Tytler had been for years steadily planning and planting belts along the ridges. He was opposed to shade, but after a visit to the West Indies in 1879, he became convinced that a moderate amount of shade was beneficial for cacao. The soil of Dumbara is well adapted for its growth and the climate admirably suited for the preparation of the product, but there is much more moisture in the warm shady valleys of Ecuador and Amazon, where the tree is indigenous.

VISIT TO TRINIDAD.

In the winter of 1879-80, Mr. Tytler paid a visit to the islands of Trinidad and Grenada for the

purpose of further studying the growth and manipulation of cacao. In Trinidad he found much to interest and surprise him in the vigour and fruitfulness of the gigantic trees, albeit growing in a soil much inferior to the average of Ceylon, but in a climate even hotter and much moister than Dumbara. So long as this soil is kept shaded it will bear abundant crops; remove this, and it would be reduced to sterility for years. In the matter of curing the cacao it soon became evident that there was little to be learned from the Trinidad planter, who indeed has got very much to unlearn before he produces good marketable cacao. We have nothing in Ceylon to compare to the massive cacao trees in Trinidad, but the curing of the crop here is primitive, slovenly and filthy to a degree, quite accounting for the low prices of the article when compared with the carefully prepared cacao from Ceylon. In after years the writer had occasion to follow in the footsteps of his friend, through Trinidad and Grenada, and was gratified to hear him frequently spoken of as "the G. O. M. of Ceylon," for by this time—though only 60 years of age—he looked quite an old man, the cares of recent years having already told upon him.

LAST VISIT TO CEYLON.

Once more, after his visit to the West Indies he returned to Ceylon full of schemes for the future, and sanguine of cacao as ever he was of coffee. Probably many will think he was *over sanguine*, but here again the fault surely leant "to virtue's side," for the world has ever been much indebted to her most sanguine men. Early in 1882 he wrote in great glee from Pallakellie:—

"Cacao in Dumbara is something magnificent. During the first stroll, I let my cheroot out three times, absorbed in the spectacle! 800 acres Palli. The last sold at 115/6 against Trinidads at 90/, and with 8 cwt. per acre, *clear profit*=100/p. cwt. *Mind you, we take a trip round the world two years hence, to celebrate my freedom from debt!*"

HOPEFUL TO THE LAST.

In May 1882, just a month before the end, he writes:—

"Palli Cocoa selling at 116/. Caracas 93/. Keep me going for only two or three years, and—harroosh for all debts paid!"

To the last he firmly believed in the recuperative powers of his Ceylon properties. "With fair play between man and man, the uttermost farthing will soon be paid."

Those now most interested, may at any rate, well congratulate themselves upon the forethought and perseverance of R. B. T. on leaving one of the most valuable properties in Ceylon, where thirty years before he found an abandoned coffee estate.

VALUE OF ESTATES.

Yes. Ye who shake your heads and talk about the depreciation of Ceylon property, *remember this*, that in 1852, R. B. T. purchased Pallakellie at the then current value of £1,500 with 5 years to pay it in, and after gathering crops to the value of fully £150,000, he leaves to his fortunate creditors a property valued at £60,000! This applies to the single estate of Pallakellie, and does not include his one-third of the Raja group, and the whole of Hoolankanda.

The end came in June 1882, at the critical age of 63. His father William Tytler died about

the same age, a period, which it will be observed, carries off very many.

R. B. T. did not expect it; indeed, during the past year he frequently wrote:—"I have 15 or 20 years yet; let us seriously consider whether it is to be in Tasmania or New Zealand."

But it was otherwise ordered. The call came rather suddenly at last, and the closing scene was comparatively brief.

In a certain sense—in the most important of all senses—few men could have been better prepared for the change. Albeit, as he painlessly, silently and calmly crossed the bourne, there seemed to me an expression of slight surprise that the journey had come to an end so soon.

So ends the succinct, graphic word-picture by R. B. T.'s old friend, to be developed some day, we hope, into an adequate biography of this 'fine old Tropical Planter all of the olden time,' from whose life-work and varied experiences for 51 years—from his 12th to 63rd year—so many valuable lessons may be pointed for the young tropical colonists of the present age. But we cannot deny ourselves or our readers the pleasure of quoting from further MSS, which "Old Colonist" has forwarded with his essays, and we feel sure these extracts will be pardoned for the further insight they give into the character of Mr. Tytler. First, in his letter to us with the above notice, "Old Colonist" says:—

"Bearing in mind that I was writing for the T.A., I have not—as I would have otherwise so much liked to do—dwelt (scarcely touched) upon the most notable and interesting side of his character, viz., R. B. T. as an Evangelist. His tact in preaching to the motley crowds on Castle Gate or the Fair; how he was attacked by a burly mason who said he "didn't believe in a Deevil." Have you not read said the ironical R. B. T., "Believe in the D—l and thou wilt be saved" "Na," said the man stopping to think a bit, and then the correct version took hold of him. He followed T. home, ever after to be fast friends. How with a volley of oaths the cobbler in Gallow Gate ordered him (T.) out of his shop, as he didn't want any hypocritical—s there; but T. never turning a hair, coolly took to examining the cobbler's work: "Man, that's fine work! I like the hand-sewn—." "Get out o' this ye—" howled the cobbler, but T. only continued to turn over the boot. "Much better than pins or sprigs," ending in getting his foot measured, and the savage soiler becoming a sincere disciple!

"Again one would like to tell how T. brought his religion into all the affairs of life. He wasn't the man to throw it off with his Sunday cloth-s. 'O Lord give us good crops and fair prices' was his form of asking 'daily bread' in Ceylon, and you remember the apt petition about 'crimping,' when G. M. interjected 'Speak for yourself T.' Such traits as these, and gems from the marvellous flow of grim humour have yet to be recounted when the opportunity occurs, but I quite recognize that the place for all this is not in the T.A."

Under date, Aberdeen, 24th May, 1879, R. B. T. writes to his friend:—

"It was you, was it not; wrote that scrap in the *Weekly Free Press* on Sleep? You old rogue! Sleep is coming back to my pillow since Palli is coming so to the front with Cacao. Possibly 3 years hence my account will shew large credits per annum—no bad sudorific with a good 'night cap' to promote saporific sweating off the effects of astonish-

ment at finding one's self with more money than one can possibly manage. Then, (when this 'next year' comes,) I am to requisition you to join me in a cruise to Manitoba, thence to Colorado, thence Hawaii, Fiji, New Zealand, and Tasmania (not forgetting Cyprus or Zululand) to prospect."

Later on, 26th February, 1882, we have another characteristic letter:—

"It seems an age since we exchanged hails. I know I am owing you a letter, yours to me being our last, so here's a square. How are ye—and *Thou's da*? We are as usual. I am *pech-pechin*? Aye 'grappet, and doonhadden.' Oh, me—mu!!! *Coffee*—say 'KAUFHY'—(and give it a good deep groan.) You see it *transforms*! not one letter of the proper word. It has got to this. There's not one comfort such as there *used* to be 20 years ago when all was roseate in the future sky. Fact was we then LOOKED FORWARD. Now alas we look back, and *present!* My wonder is that I am still upheld. It is purely and surely to God's providence alone that this is attributable. Yet—cacao looms hopefully ahead and may carry a poor fellow through. Do write me something, and soon—for I am wae.

"What a grand success is John Ferguson's *Tropical Agriculturist* idea! It promises (or indeed is already) to be a most valuable production to the entire world.

"When are you coming this way? I am wearying for a crack? What a winter. It's no *winter* at all, and, best of all, there's oceans of rain in Doombere. Never seen such floods—and soil soaked. But for disease it would be a red-letter year there. What about Boustead and his Ceylon affairs—or Byrde—or our old friend Willie Smith, or any body?—There's been no snow at all here! Now on the verge of February."

"Dumbara and rain" reminds us of the two photographs Mr. Tytler had taken in Colombo to present to his friends:—one represented him looking downcast and weary almost sulky as if ill-used and had for superscription "Dumbara in dry weather—R. B. T." The other, representing a cheery, laughing open countenance, he entitled "R. B. T. with rain in Dumbara." The portrait we are enabled to present with this notice represents the natural man in his prime, and does justice to his well-developed, well-balanced head, and the firm, intelligent, self-reliant nature revealed in his countenance. One important omission from "Old Colonist's" narrative has reference to Mr. Tytler's happy marriage in 1848 with the youngest daughter of the Rev. Charles Gibbon, D.D., the Parish Minister of Lonmay, Aberdeenshire, Miss Annie Grace Gibbon, who still survives him, and who was in every sense a worthy helpmeet and companion to her husband. Mr. Tytler was the friend and generous supporter of every good work that was ever brought to his notice in Ceylon, and no one appreciated him more than Dr. John Murdoch, the apostolic founder of the Sinhalese Tract Society and of the Christian Vernacular Education Society of India, lifelong friends as he and Mr. Tytler were. No one could be in his company long without realizing the original as well as masterful character and the many varied as well as good qualities of

ROBERT BOYD TYTLER.

He was indeed as a Planting Colonist, one of whom it may be said:—

— take him for all in all,
We shall not look upon his like again,

AN UNIQUE COFFEE PLANTATION (OR GARDEN OF 15 ACRES).

The visitor to what are commonly termed "the planting districts" of Southern India is not surprised to see Coffee growing more or less luxuriantly, be he in certain parts of Mysore, in Coorg or the Wynaad, or on the Nilgiri Hills; but the visitor to Bangalore is not usually aware that he may see coffee thriving and bearing plentiful crops within but a short distance of "the city of beans." Yet such is the case. Climatic difficulties have been overcome, and the growth of the coffee shrub from the seed to the heavily-laden plant weighted with ripe berries may be as satisfactorily observed near Bangalore as on the larger plantations which are to be found in other parts of Southern India. Experience has shown that, as regards rainfall, the distribution rather than the quantity that falls during the year is of the greatest importance in the cultivation of Coffee. In Mysore and Coorg, owing to the lengthened periods of drought that occur, elaborate arrangements, which are the result of many years of experience and patient study, have been made for shading the estates with carefully selected varieties of trees which are either left standing when jungle is cleared or are systematically planted and annually lopped and regulated in accordance with the requirements of the Coffee below them. The class of soil, its physical condition and inherent fertility have each an important bearing on success in coffee cultivation; the most favourable conditions being usually found in forest land where the manurial wealth of ages has been accumulated by the dropping of the fruit, leaves and bark of trees, and by the decay of a luxuriant undergrowth. Art, however, has learnt to assist Nature. What may be termed an unique example of the truth of this is visible at Bangalore, where that enterprising gentleman, Mr. Meenatchee Iyer, now Acting Judge of the Mysore High Court, has solved the problem of growing coffee, at a fair altitude it is true, but in a climate where a low average of rainfall is accompanied by heat which would be considered by many planters fatal to the development and fruition of the coffee shrub. Mr. Meenatchee Iyer's successful experiment, which affords a new example of the potentialities of irrigation, has been rightly described as of the utmost importance to the State of Mysore. We have reason to believe that recent progress has been watched and criticised by many coffee planters; and there is a possibility that the example set will be followed by other enterprising gentlemen, Europeans and Natives, who having witnessed what has been done at Rochdale Park within three miles of Bangalore, on level ground, will try to emulate the efforts of Mr. Meenatchee Iyer, able lawyer, wise councillor, good Judge, and—as is now shown—successful pioneer in a new branch of coffee cultivation.

While in Bangalore last week a representative of this paper took an opportunity to visit the estate referred to. The courteous proprietor showed him over the whole place, giving most interesting particulars of his experiments and experiences, and entering upon explanations which showed that he had made a careful study of books on coffee cultivation, had received and availed himself of useful hints from experienced planters, and had followed the growth of the estate with a zeal and enthusiasm which in themselves mark him out as a man who deserves to be successful. Knowing the age of each batch of plants, acquainted with the minutest detail of cultivation, from the nursery to the full grown and fruit-bearing shrub, Mr. Meenatchee Iyer has throughout conducted on business principles an experiment which some of his friends perhaps regarded at the outset as unpractical. Apparently, however, he still regards his coffee plantation as an experiment; at any rate, he is still anxious to hear the opinions expressed upon it by more experienced planters. In this connection it need only be said here that excellent as is the general condition of the coffee, there is reason to believe that some few improvements will be introduced from time to time. For

instance, there is room for criticism in respect of shade trees. The trees used are mentioned elsewhere; but it is open to question whether they are the best that are available. In Mysore there is every facility for obtaining other varieties of excellent shade trees, and with few exceptions those belonging to the *Ficus* tribe are the best, although the *Gerrulligay* or *Nogga* (Canarese for "yoke"—*Cedrela toona*) is greatly used to fill immediate and temporary requirements.

The following details of the Rochdale Park estate will probably interest our planting readers:—

FIRST EXPERIMENTS.

Nine years have passed since Mr. Meenatchee Iyer started a coffee plantation in the vicinity of Bangalore with a view to see how the shrub would succeed under irrigation. He started with 170 plants. They turned out well, but it was some time before he added to their number. At the outset he had been warned that the coffee might do well for two or three years, but would then, in all probability, die away. Predictions of this stamp were falsified, however, and in course of time 1,500 plants were added to the original 170. This second batch comprises trees which are now four years old, having been planted three years ago after having spent one year in the nursery. Another batch consists of 2,500 trees, now three years old, *i.e.*, planted two years ago. There are also 2,500 trees planted 14 months ago and now about 2½ years old. This year, within the last three months, Mr. Meenatchee Iyer has planted 9,000. He states that he has now a total of about 18,000 plants, on 15 acres of ground. How thoroughly the oldest of these have falsified pessimistic prophecies, is shown in the fact that at nine years of age they are so strong and healthy as to give good promise of flourishing for another twenty years at least. The estate stands about 3,020 feet above sea level. The shrubs are planted 6 feet apart. The soil in which they stand is mostly red earth, but it is sandy at a little distance below the surface and is strengthened by the addition of a mixture of red earth with tank silt. At the present time it is decidedly hard, so much so, that an experienced planter recently declared that, but for irrigation, no coffee could grow in such soil. It does grow, however, and this despite other conditions not exactly favourable to its success. The average annual rainfall in the locality is not more than 30 inches. In normal seasons, the minimum temperature is 58°, the maximum 90°, as recorded on an upstairs verandah of the proprietors's house, which stands within the plantation.

THE IRRIGATION SYSTEM.

The most interesting feature of the experiment is, of course, the irrigation of the soil, which renders the property almost wholly independent of blossom showers. The system employed is for the most part that of drawing water from wells, by means of *piccottahs*, but three of the wells on the plantation are provided with *kappillas*. These are seldom used except in the hottest weather when the level of water in the well is so low as to render raising by means of the *piccottah* difficult. There are altogether 7 wells used in connection with the coffee, but Mr. Meenatchee Iyer has a total of 18 wells for coffee cultivation and other purposes. The 7 wells were not constructed specially to aid coffee cultivation; they were originally intended for sugarcane and coconuts, which were formerly grown on the land. The supply of water from the seven is, however, more than enough for the coffee. In fact, the proprietor considers that he has "a luxury of wells." He thinks that the 15 acres could be irrigated by 4 wells. Of the seven now in use, one is 39 feet in diameter, three are 20 feet in diameter, and three are under 20 feet. The deepest is 35 feet, another 25 feet, another 20 feet, another 13, another 11, and the rest 6 to 7 feet. Irrigation is practised during the hot weather, and when the spring goes below 20 feet from the surface of the well the *kappilla* is used. A common method is usually made with irrigation

in January. During that month the plantation is watered once a fortnight; during February once in ten days. In March, April and May until the monsoon sets in, the irrigation proceeds once a week; but it is entirely stopped when the monsoon sets in. The above months are the dry months of each year, rain does not usually fall until about the beginning of May; hence the need of irrigation. It should be here added that the cost of the 7 wells used for irrigation of coffee amounted to from R8,000 to R9,000. This is, however, regarded as excessive, the wells having, as has been said, constructed for other purposes. Mr. Meenatchee Iyer is of opinion that four wells, such as he deems requisite to irrigate his present coffee land, could be constructed at a cost of something like R5,000.

METHOD OF CULTIVATION.

From the feature which establishes the claim of the Rochdale Park Estate to be regarded as *sui generis*, we pass to details of cultivation, &c., more familiar to our planting readers. We understand that all the seed used is obtained from Mr. Chisholm's estate in Coorg, and that a fresh supply is obtained every year at a moderate cost. The seeds are planted in the usual nursery. When the seedlings are three months old, they are transferred to pots, still within the nursery, and here they are kept until they are from 6 to 9 months old and about a foot high. They are then planted out in pits of 2½ cubic feet dug 6 feet apart. Before the seedlings are planted a little manure and earth are put in. There is no special season for planting out, for if it is the dry weather irrigation is available to keep them alive. It is found, however, that, as a rule, plants put out in July and August in the rainy season, require less irrigation subsequently than those planted in the dry season. No particular system of weeding is adopted. Once in two years the plantation goes through a process of digging similar to what takes place in an apple orchard. When the ground is first prepared for planting the whole is dug up. Then the pits are made, the digging process being repeated at intervals of two years after the seedlings have been planted. Two years after planting, picking commences; it continues for 6 months from July to December. Picking in July, August and September is light, but for the two subsequent months it is very heavy, a rich harvest succeeding the monsoon blossom. During the last two months about 20 maunds of coffee has been picked, and it is estimated that ten times this quantity will yet be gathered this season. The fertilisers available are horse and cattle manure and oil-cake. Very few cattle are kept upon the estate, but two pairs of bullocks which are available for the *kuppilla* are, of course, useful also for manual purposes.

SHADE.

In regard to the important matter of shade, Mr. Meenatchee Iyer states that he does not expect his shade trees to afford protection until his coffee shrubs have yielded two or three crops. This takes about four or five years. Shade trees are planted along with the coffee seedlings, and by the time that the former are in a condition to serve the purpose for which they are intended, the coffee is from four to five years old. The shade trees used are that known locally as the *Houlogay* and the *Grevillea Robusta*, or silver oak, which are also employed to form wind belts. The former is the *Acrocarpus flavinifolius*, the wood of which resembles that of some of the cedar tribe.

COST OF UPKEEP.

The cost of the upkeep of the estate is stated to be between R170 and R180 per acre per annum, including manure* which costs about R600 a year, and supervision, which costs about the same.

* Cheap labour and garden cultivation which could scarcely be given to an appreciable area, say 100 acres or more.—Ed. T. A.

YIELD.

Last year the experimental trees yielded 10 maunds, the yield having increased from 6 maunds in the previous year, and 6 maunds in the year before that. At the present time there are 2,500 plants of three years old from time of planting, which yielded 20 maunds last year in the virgin crop. From these very trees a yield of 1½ tons may now be expected according to experts' estimates of the crop on them. Out of the other 2,500 trees at least 1 ton is expected, though this will be their virgin crop. Approximately, a ton is worth £100 in the London market. A fair virgin crop can, according to Mr. Meenatchee Iyer's experience, be gained after two years, the yield being probably 3 to 4 cwt. an acre. He has, as will have been seen, only a limited area under cultivation, and his experience is not therefore great, but the figures which he has given will, we believe, be found very interesting to planters of much longer experience. To the particulars already given we may add some more regarding output and price. Last year, the proprietor informs us, he had about 30 maunds, and this he sold locally, at R16 per maund;* peaberry at R18. He states that the demand is so great locally, that for the last two months retail dealers have offered to give him a large advance in order to secure the crops at market rate. Nevertheless, he is thinking of trying the London market this year.

DISEASES.

Leaf disease and borer have had to be contented with. When trees are attacked by the former, constant irrigation and heavy manuring are resorted to, with considerable success. Bored plants are simply extirpated by being dug up and burnt.

REMARKS.

In conclusion, we may observe that Mr. Meenatchee Iyer has 7 or 8 acres of land fit for coffee, besides that which is already planted with it. He finds it difficult to give reliable information as to the cost of similar land in the same part of the country. Dry land in the immediate neighbourhood of Bangalore may be obtained at R100 an acre; wet costs about R200 an acre. He has tried coffee under coconuts, but this proved unsuccessful, the reason given being that the coconuts, which are surface feeders, choked the roots of the coffee. Mr. Meenatchee Iyer is of opinion that 1 ton an acre is a poor average, but he remarks that if coffee is to be tried under irrigation, the planter must be sure of his water-supply. He objects to planting coffee below tanks, because it is not likely to succeed there unless an efficient system of drainage is arranged for.—*Madras Times*.

INDIAN TEA NOTES AND NEWS.

Our Darjeeling correspondent writes on 31st August:—We have just passed through perhaps one of the most sunless months known for some time and what with the cold week I have already mentioned, crop has been very short, and most gardens here, instead of hoping to pick up on what they have left are only too anxious to keep up with what they made at the same time last year. September will open fairly well in these parts, as sun has been rather more frequent the last two or three days and some heavy rain fallen which has done the world's anything but good but will probably keep that dreaded pest mosquito blight off for some time yet, as it generally appears in these parts, on the lower elevations, about the middle of September if it is at all d.y. Rainfall is still some 20 inches behind, but the soil is soaked to as much as it can hold.

The reports from the Terai are to the effect that there is good tea weather, alternate sun and rain, and the gardens are flourishing freely.

During the last week the weather at Kurseong has been cold and wet, but there is little to complain of in regard to output.—*Indian Planter's Gazette*, Sept. 9.

* But this is equal to far less than £100 a ton; not ½rd unless parchment coffee is meant in the instant, and clean coffee in the other.—Ed. T. A.

CEYLON MANUAL OF CHEMICAL ANALYSES.

A HANDBOOK OF ANALYSES CONNECTED WITH THE INDUSTRIES AND PUBLIC HEALTH OF CEYLON FOR PLANTERS, COMMERCIAL MEN, AGRICULTURAL STUDENTS, AND MEMBERS OF LOCAL BOARDS.

By M. COCHRAN, M.A., F.C.S.

(Continued from page 157.)

CHAPTER VI.

CINCHONA BARK AND COCOA.

SPECIES OF BARK—CEYLON SUCCIRUBRA BARK, NATURAL AND RENEWED—INDIAN BARKS—MATTAKELLIE ESTATE LEDGER BARKS—WEIGHT OF, AND PERCENTAGE OF QUININE IN CEYLON BARKS ANALYSED DURING THE YEARS 1885 TO 1891 INCLUSIVE—COMMERCIAL ANALYSES OF CEYLON BARKS: SUCCIRUBRA, OFFICINALIS, CALISAYA LEDGERIANA HYBRID AND MIXED BARKS—ANALYSIS OF SULPHATE OF QUININE MANUFACTURED BY THE INDIAN GOVERNMENT—COCOA OR CACAO—PREPARATION OF SEEDS FOR MARKET—CEYLON COCOA—TRINIDAD COCOA-NIBS—COCOA-NIBS VARIOUS—ASH OF COCOA-NIBS AND HUSKS—COMMERCIAL COCOAS—AGRICULTURAL ANALYSIS OF CEYLON COCOA SEEDS—PROPORTION OF NIBS AND HUSK IN SEED—PROXIMATE ANALYSES OF COCOA NIBS—ALKALOIDS IN COCOA-NIBS—NITROGEN, PHOSPHORIC ACID AND POTASH IN COCOA CROP—COMPARISON OF THE IMPORTANT CONSTITUENTS OF PLANT FOOD REMOVED FROM THE SOIL BY TEA, COFFEE AND COCOA CROPS RESPECTIVELY.

CINCHONA BARK.

Various species of cinchona bark are cultivated in Ceylon on a commercial scale, viz., Cinchona Succirubra, Cinchona Officinalis, Cinchona Calisaya, especially the Ledgeriana variety, and several hybrids. The amount of Succirubra grown hitherto has been more than that of all the other species put together.

The following are examples of the analyses of Ceylon Succirubra bark, both natural and renewed:—

Analysis of Ceylon Succirubra Bark.

	Natural Bark.			Renewed Bark.
	Per ct.	Per ct.	Per ct.	Per ct.
Cryst. Quinine Sulphate ...	1.03	1.39	1.62	3.67
Quinine75	1.03	1.20	2.73
Cinchonidine ...	1.79	4.54	1.95	3.85
Quinidine ...	—	.36	—	.27
Cinchonine60	.08	.31	.08

In the sample of renewed succirubra, the amount of Crystallised Quinine Sulphate is high. The great bulk of Ceylon renewed Succirubra contains only from 1.8 to 3 per cent of crystallised quinine sulphate.

The following analyses of Indian barks by Mr. Broughton quoted from Mr. T. C. Owens' Cinchona Planter's Manual shew the effect of renew-

ing the bark of Cinchona Succirubra under moss:—

	Age of trees 8½ years.	
	Natural.	Moss renewed 18 months.
Total Alkaloids ...	6.36	6.39
Quinine ...	1.36	3.21
Cinchonidine and Cinchonine ...	5.00	3.18

Sulph. Quinine Cryst.90	2.30
Cinchonidine ...	4.03	3.03

The following analyses, quoted from the same source as the last, shew the effect of renewing officinalis or crown bark:—

	Age of trees 8 years.	
	Natural.	Renewed 2 years old.
Total Alkaloids ...	3.61	5.83
Quinine ...	2.34	3.34
Cinchonidine and Cinchonine	1.27	2.49
Cryst. Quinine Sulphate ...	2.10	3.13
Cinchonidine Sulph.	1.44	2.60

Examples might also be quoted shewing the amount of crystallised sulphate of quinine to be larger from the natural than the renewed bark; but such cases are rather exceptional. As a general rule the amount of crystallisable quinine is considerably larger in renewed than in natural bark from the same trees, particularly if the bark has been renewed under cover.

The highest results obtained in the analyses of Ceylon barks which have come under my notice were those of individual trees from Mattakellie of the Ledgeriana variety, submitted to the Messrs. Howard of London, for analysis and report. The following were the analytical results:—

Analysis of Mattakellie Estate Ledgers. (HOWARD.)

	p.	c.												
Quinine Sulphate Cyst. ...	12.8	9.6	12.3	9.2	12.3	9.2	12.3	9.2	12.3	9.2	12.3	9.2	12.3	9.2
Quinine Alkaloid ...	8.6	6.4	8.6	6.4	8.6	6.4	8.6	6.4	8.6	6.4	8.6	6.4	8.6	6.4
Cinchonidine ...	7.3	—	7.3	—	7.3	—	7.3	—	7.3	—	7.3	—	7.3	—
Cinchonine	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Quinidine	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Cinchonine	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Quinidine	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Renewed Ledgeriana bark does not exhibit the like increase on quinine which is shewn by renewed Succirubra and Officinalis barks.

The following commercial analyses of Ceylon cinchona barks are interesting as shewing the average richness in quinine sulphate of bark analysed by Mr. C. E. H. Symons and the author between April 1885 and December 1891. I give

also, approximately, the weight of bark represented by the samples analysed each year:—
Commercial Analyses of Ceylon Cinchona Bark.

	Approximate Weight of lots Analysed.	Anhydrous Sulphate of Quinine.	
		Per ct.	Per ct.
April to Dec. 1885 ...	2,611,530 lb.	1.58	1.85
Jan. to Dec. 1886 ...	2,643,186 ,,	1.50	1.75
Do 1887 ...	2,100,981 ,,	1.83	2.14
Do 1888 ...	2,914,100 ,,	1.84	2.15
Do 1889 ...	2,127,985 ,,	2.05	2.40
Do 1890 ...	2,572,733 ,,	2.28	2.68
Do 1891 ...	2,609,832 ,,	2.28	2.68

The following are commercial analyses shewing the maximum, minimum and mean richness of the different kinds of cinchona bark analysed by Mr. Symons and the author during the year 1891:—
Commercial Analyses of Cinchona Succirubra during the year 1891.

	Rough Sulphate.	Impurity.	Dryage.	Anhydrous Quinine Sulphate.
	Per ct.	Per ct.	Per ct.	Per ct.
Maximum ...	5	16	3	4.05
Minimum ...	1.70	41.2	5.5	.94
Mean ...	2.90	35.44	4.81	1.78

Commercial Analyses of Cinchona Officialis during the year 1891.

	Rough Sulphate.	Impurity.	Dryage.	Anhydrous Quinine Sulphate.
	Per ct.	Per ct.	Per ct.	Per ct.
Maximum ...	8.54	5	3.5	7.83
Minimum ...	2.23	32.6	5	1.43
Mean ...	3.86	18.43	4.37	3.06

Commercial Analyses of Cinchona Calisaya Ledgeriana during the year 1891.

	Rough Sulphate.	Impurity.	Dryage.	Anhydrous Quinine Sulphate.
	Per ct.	Per ct.	Per ct.	Per ct.
Maximum ...	6.75	5	3	6.22
Minimum ...	1.08	18	4	.85
Mean ...	4.38	5.79	3.41	3.99

Commercial Analyses of Hybrid Cinchona Bark during the year 1891.

	Rough Sulphate.	Impurity.	Dryage.	Anhydrous Quinine Sulphate.
	Per ct.	Per ct.	Per ct.	Per ct.
Maximum ...	5.73	5.3	4.5	5.18
Minimum60	5.0	4	.54
Mean ...	3.35	23.4	4.34	2.58

Commercial Analyses of Mixed Bark during the year 1891.

	Rough Sulphate.	Impurity.	Dryage.	Anhydrous Quinine Sulphate.
	Per ct.	Per ct.	Per ct.	Per ct.
Maximum ...	4.64	8.9	4	4.06
Minimum ...	1.42	23.2	5	1.04
Mean ...	3.03	28.11	4.68	2.08

In the above analyses, rough sulphate means sulphates of crude alkaloids from sun dried bark extracted in the process for estimating the quinine.

Impurity indicates the sulphates of alkaloids other than quinine, together with a little coloring matter in the rough sulphate.

Dryage indicates the loss in weight sustained by the bark when dried in the sun. Anhydrous quinine sulphate indicates crystallised quinine sulphate deprived of its water of crystallisation.

The following is an analysis of a sample of the crystallized sulphate of quinine manufactured by the Indian Government in 1892:—

	Per cent.
Water of crystallization and moisture ...	6.80
Sulphate of quinine (anhydrous) ...	91.95
Sulphates of other cinchona alkaloids ...	1.25
Ash
	100.00

This article contains a very high percentage of anhydrous sulphate of quinine, the water of crystallization being much below the theoretical quantity. This absence of the full complement of water would not interfere with its efficacy as a febrifuge. Other analyses of this product will be found in the Appendix.

COCOA OR CACAO.

The plant *Theobroma Cacao* of the natural order Bythneriaceae yields the cocoa of commerce. It is grown in the West Indies, Central America, and now also in India and Ceylon, and parts of Africa. The tree is indigenous to the West Indies and Central America. It attains a height of from 12 to 20 feet usually, but is found much higher. It bears fruit at 3 years old, and its productiveness increases to the age of 8 years. The seeds are contained in pods, the length of which, as given by different writers, is from 5 to 12 inches long, and the number of seeds from 20 to 50. The diameter of the pods is from 3 to 3½ inches. The size of the seeds is from 7 to 9 inches long by .39 to .58 inch broad.

The seeds having been removed from their pods may be prepared for the market by simply drying them; but their value is increased by a preliminary fermentation, by which a good deal of the harsh disagreeable flavour of the raw seed is got rid of. Fermentation also darkens the color, and the beans that have been so treated throw off their outer coatings or husks more readily after the process of roasting.

In Ceylon the cocoa chiefly grown is the Caraccas variety; but the Forastera is also cultivated. A Ceylon Estate owner resident in London, who has been in communication with chocolate manufacturers and also with brokers who deal in cocoa, supplies the following information, which, as bearing directly on the

Ceylon Cocoa.

The following analyses of Ceylon Cocoa, grown on Anniewattie estate in 1892, are by Mr. R. R. Tatlock, City Analyst of Glasgow and Chemist to the Glasgow Agricultural Society:—

Agricultural Analysis of Cocoa Seeds.

	Per cent.
Moisture	5.12
Lime20
Potash	1.25
Phosphoric Acid	1.21
Nitrogen	2.20
Ash	3.35

Proportion of Nibs and Husk in Seed.

Nibs	92
Husk	8
	100

Proximate Analysis of Cocoa Nibs.

	Per cent.
Moisture	4.81
Fat	56.50
Albuminoids	13.87
Alkaloids95
Ash soluble in water	1.05
Ash insoluble in water, but soluble in hydrochloric acid	2.37

According to the above analysis Ceylon cocoa nibs are richer in fat and albuminoids than any of the other analyses quoted. The alkaloids, one of which Theobromine gives the name to the plant, are also higher than in all the most recent analyses. The following table shows the amount of alkaloids obtained by Dr. Bell in several varieties of cocoa nibs:—

Alkaloids in Cocoa Nibs.

Cocoa.	Theobromine. Per cent.	Theine-like Alkaloid. Per cent.
Guayaquil54	trace
Grenada91	..
Surinam78	.02
Trinidad59	.25
„ Husk	1.02	.33

It is worthy of remark that the husk contains a larger percentage of alkaloids than the whole seed.

The following results according to Dr. Bell have been obtained by other Chemists. Tucker obtained .38 to .66 of Theobromine, Hassall from .47 to .78 per cent, and Muter .9 per cent. Payen, Playfair and Lankester report 2 per cent, and Mitscherlich 1.5 per cent.

The agricultural analysis of the seeds by Tatlock enables us to calculate the amount of important ingredients removed from the soil per annum by a crop of the seed; thus, taking an average crop of cocoa seeds at 300 lbs., the nitrogen, phosphoric acid and potash removed from the soil will be as follows for one and two years respectively:—

	One Year.	Two Years.
Nitrogen	6.6	13.21
Phosphoric Acid	3.63	7.26
Potash	3.75	7.50

It will be interesting to compare here the amounts of important ingredients removed from the soil by equal weights of tea, coffee and cocoa.

Important constituents of plant food removed from the soil by 1,000 lbs. of Tea, Coffee and Cocoa respectively.

Plant-food.	Tea lbs.	Coffee in Parchment lbs.	Cocoa lbs.
Nitrogen	48.8	14.6	22.0
Phosphoric Acid	7.6	2.7	12.1
Potash	25.2	13.5	12.5
Lime	5.7	1.9	2.0

It will be seen from the above that, for equal weights, the tree crop is the most exhausting of the three as regards the nitrogen, potash and lime, removed from the soil, while Cocoa is the most exhausting as regards phosphoric acid. If on the other hand instead of basing our calculations on equal weights of the three crops, we take average crops, the following table will show the respective amounts of plant food in lbs. removed from the soil by tea, coffee and cocoa:—

Important constituents of plant food removed from the soil by average crops say, 400 lbs. tea, 500 lbs. coffee and 300 lbs. cocoa per acre.

Plant-food.	Tea 400 lbs.	Coffee in Parchment 500 lbs.	Cocoa 300 lbs.
Nitrogen	19.52	7.3	6.6
Phosphoric Acid	3.04	1.35	3.63
Potash	10.08	6.75	3.75
Lime	2.28	.95	.6

The above table again shows that tea is the most exhausting of the three crops as regards all the ingredients except phosphoric acid, in respect of which cocoa exceeds it.

Cocoa Pods Analysed as a Manure.

The following analysis was undertaken by the author to ascertain the proportion of fertilising constituents contained in cocoa pods after the removal of the seeds. The analyses was made at the instance of a local firm. The pods when received were partially decomposed, being quite black in color:—

Mixture	Per cent.
Dry Matter	76.00
	24.00
	100.00

Analysis of Dry Matter.

*Organic Matter	Per cent.
†Ash	94.34
	5.66
	100.00

Containing Nitrogen	Per cent.
„ Lime	2.85
„ Potash65
„ Phosphoric Anhydride89
„ Silica07
„ Undetermined	2.04
	2.01

Percentage Analysis of Ash.

Silica	36.10
Lime	11.48
Potash	15.64
Phosphoric Anhydride	1.20
Undetermined	35.58
	100.00

Cocoa pods are thus very slightly richer than Ceylon cattle manure No. 2 in respect of nitrogen, much poorer in potash and lime, and very much poorer in phosphoric acid of which they only contain a mere trace.

Analyses of the leaves of the cocoa plant are still required, and also an estimate of the loss of leaf per acre per annum to enable us to calculate the amount of plant food removed from the soil by cocoa cultivation. Judging from the analysis of the seed an ordinary coffee manure should meet the wants of this plant, nitrogen and potash in the average crop being somewhat less than in coffee, and the phosphoric acid (which in coffee manures generally is added so much in excess of the theoretical dose) greater. The quantity of manure per tree will of course be greater than in the case of coffee, but not necessarily the quantity per acre.

(To be continued.)

MANGOSTEENS IN THE PLANTING DISTRICTS.

The mangosteen is a very difficult fruit tree to propagate and bring to successful bearing even in the low-country. We have known of trials of young plants in Colombo with every care given, again and again fail. Kalutara seems to be the district in which they best succeed. We are surprised however, to learn of the tree growing and bearing freely in Western Dolosbags on Gang Wariy plantation at an elevation we suppose not under 2,500 feet above the sea. Mr. Drummond has two trees in bearing and they are fine specimens and are giving a splendid crop this year, the fruit being of first-class quality as we can testify through Mr. Drummond's kindness. An orchard of mangosteens or even of oranges in these "steamer" days would be a little fortune in itself!

TEA AND "HELOPELTIS."

Writes a proprietor:—"Helopeltis is something we must try to keep down, and in the meantime out of the newspapers, as they won't find us a remedy."

This is going a little too far! For instance, how were Dr. Trimen's most practical and timely suggestions to be made known save through the Press—and again what could be more useful news than the hints about the appearance of the eggs of *Helopeltis* given by us the other day.

At the same time, we can quite understand how multiplied discussion may be regarded as magnifying the evil to the imagination of outsiders, and also there is the risk of creating a scare about any little difference in appearance of the tea bushes or leaves. A case of this kind occurred the other day: a gentleman sent us some tea leaves to ask what ailed them or attacked them. We referred to Dr. Trimen who is of opinion that there is nothing beyond a scorching of the sun which has dried them up and turned them suspiciously brown.

On the other hand, we feel sure that the series of letters or extracts we append will only do good by their publication as showing that in some Ceylon tea districts, the insect has not made its appearance at all. But first we may give a letter which affords a really good practical hint about how to "catch and kill" the enemy:—

HOW TO CATCH HELOPELTIS.

To the Editor "Ceylon Observer."

DEAR SIR,—Dr. Trimen telling planters to catch and kill *helopeltis*, puts me in mind of Mrs. Glasso's receipt for hare soup "first get your hare." Your correspondents talk of bottles and match-

boxes to hold those caught, but none tell you how to capture. I tell you a plan I find answers. Get a green wand cut from any tree 15 to 18 inches in length. Peel, to make it white, smear all but 6 inches of thick end with jack milk and arm your podian with this and send him forth. Every insect he touches with it will stick and show his assiduity at *vellayatu* with 5 p.m.—B. B. B.

From typical districts North of Kandy, here are the reports made to us:—

"I have nothing to add to the information already published *re Helopeltis*, but can only support the idea of stamping it out by collecting. Unless the *Helopeltis* is more apparent in one place than another, I think the usual gangs of pluckers or pruners ought to be sufficient to do all the collecting. If the coolies are shown what is wanted and promised a cent per so many insects or grub, according to the extent of the pest, it will be found that they will work harder perhaps than if they had no *Helopeltis* to collect. The price to be paid should be fixed for two or three days and if they bring many without much trouble the price should be reduced, the coolies wont object, so long as they earn from 4d to 6d a day extra."

"I must say I do not know much about *Helopeltis*, but that it has been with us for years, attacking cinchona and cocoa before tea was planted; here the higher fields of tea from 3,500 to 4000 feet are mostly pestered, bushes nearest the jungle being preferred, little seedlings under the bushes are attacked just as often as the big trees. So far the attacks have been slight not doing much harm. It checks the flush a little, but as the leaves do not fall off I do not think it can do permanent injury.

"Another pest does much more damage, this insect rules a line on either side of the midrib of the leaf, and then eats along the under surface from the midrib to the ruled lines, the result is the whole bush looks puckered, the flush shrivelled and coming into the factory quite red when the attack is at its height. It begins anytime from February to July and on tea a few months from pruning, the attack lasting on each field for about 2 months. This is the third year we have had it. The bushes recover rapidly and seem none the worse a month afterwards. I send (enclosed) a few leaves to let you see what it is like, it is nearly away or I should be able to send better samples. I call it the 'Ruler' for want of a better name. I have heard it called the tea louse. This year we have had red spider, *Helopeltis*, ruler and scale bug; but we are quite happy, all the estates in the district doing better than last season."

Then from Kandy, Mr. Gibbon writes:—

"*Re Helopeltis* in tea I have had no trouble with it in any of the estates I visit. Dr. Trimen tells us and others corroborate his testimony that it is the same pest that did such serious damages to our cacao some years back. Cacao planters in the course of two years so reduced their numbers by systematic destruction that now they scarcely do any harm. The planting of suitable shade and shelter belts no doubt considerably facilitated the destruction of the pest as regards cacao. There is the difficulty of shading tea in its checking flush, but I understand a great deal might be done in the way of shelter belts on the tea estates in the low country where the pest has been most troublesome. The coolies are most expert in catching the *Helopeltis* when money inducements are offered."

From districts South of Kandy:—

"I know nothing of *Helopeltis*, don't know the gentleman when I see him. I have just returned from a tour in the district and no one here has seen anything of the kind on tea. Will let you know, if he does turn up."

"I have never seen a *Helopeltis* and I note with satisfaction that Dr. Trimen only warus those whose properties are below 3,000 or so. The tea in which I am interested high runs; I had some little black bug on tea grown near willows, but that disappeared when the willows were removed.

"Black grub bothers me by eating off the shoots of the tea seed at stake and in the nursery. We also have a very small fly at times that destroys the young buds of cinchona, grevilles &c., but it does not touch the tea. These are our only insect pests. Frost is what I suffer from: I lost the flush this year for 2 months off 2-3rd my acreage. The price of tea is as surely and steadily falling as was the case with cinchona only not so rapidly.

And finally from Uva:—

"I am thankful to say that as far as I know, we have no *Helopeltis* on tea in these districts. I trust it may keep away. At present prices we can hardly support a pest!"

NOTES ON PRODUCE AND FINANCE.

CHINA BRICK TEA TO RUSSIA.—There is no great change in the volume of the export trade in brick tea from China to Russia overland. A new feature is worthy of notice, however. A form of brick tea termed tablet tea has been introduced, and has become popular. It is made of the finer kinds of tea dust compressed into small cakes like the well-known chocolate Menier cakes. Its extreme profitability and freedom from deterioration would seem to recommend it for the use of travellers or for troops on the march. Over 1,000,000 lb. of this article were exported last year.

TEA, COFFEE, AND THE CHOLERA BACILLUS.—In an article dealing with the question, "What the cholera bacillus thrives on," a writer in *Nature* says:—"As regards the behaviour of the cholera organism in tea, it is interesting to note that in a three per cent. infusion of black Chinese tea they are destroyed within 24 hours, while in a four per cent. infusion no trace of them could be found at end of 60 minutes. Friedrich has confirmed the results of other investigators on the bactericidal properties of coffee, finding two hours' immersion in a six per cent. infusion of this material sufficient for the destruction of these organisms. We take it for granted that there was nothing special about the black Chinese tea, and that a three per cent. infusion of black Indian or Ceylon would have done the business in quicker time."

COFFEE PLANTING.—Coffee planting has had its "ups and downs," and of late years the latter have predominated; but the prospect is rather brighter in India. According to recently published statistics, the total yield of coffee in India, in the year 1891, amounted to no less than 39 million pounds. This is a very considerable advance upon the yield of the preceding year, which was only 22 million pounds.

THE CHICORY FRAUD.—The consumption of coffee in the British Isles is hampered very considerably owing to the chicory dodge, which continues to flourish notwithstanding the occasional raids made by the legal authorities. The *Daily Telegraph*, in calling attention to this, says:—"English people will drink almost anything as coffee, if a shop-keeper tells him that it is Mocha. As a rule the majority of purchasers do not know the taste of coffee at all, for the simple reason that the real article has never touched their palates. For example, Albert Green, of Harrow Road, who has a shop in a good position in a poor neighborhood, sells "coffee" at 1s 4d and 1s 6d per pound. The public should understand that they cannot buy, retail, real coffee at these prices. They must pay at least 1s 8d per pound for pure beans, and even more for the scarcer sorts, which are dearer but are really no hotter. An Inspector entered Mr. Green's shop and bought a pound at 1s 4d, and when he told Mrs. Green, who served him, that it was for analysis, she said, 'If I had known that I should have given you pure coffee.' The force of her remark

may be gathered from the fact that the article sold was adulterated with fifty per cent of chicory. Think for a moment of the profit made from such stuff. You can buy first-class and really pure coffee retail for 1s 8d and yet in a pound sold at 1s 4d there is 50 per cent of chicory! And sold to the poor! Those who know the taste of coffee would hardly drink such stuff for nothing; and those who are ignorant of it ought not to be driven away from the real article to suit the avarice of dealers who ought to know better. Green was fined £3 with 12s 6d costs."

THE BAHAMA FIBRE INDUSTRY.—The fibre industry has worked wonders for the Bahamas. A complimentary dinner to Sir Ambrose Shea, K.C.M.G., Governor of the Bahamas, was given on Wednesday evening last week at the Imperial Institute, Mr. Herman Lescher, of the Bahamas Fibre Company, in the chair. Sir Ambrose Shea said that it seemed more like a fable than an accomplished fact that a colony which five years ago was in the throes of depression should now be running a course of progress that bid fair to give it a distinct place in the roll of prosperous dependencies. Nor was this transformation more remarkable than the agency through which it had been accomplished. It seemed hard to conceive that a plant long known in the colony, and regarded as a pestilent weed, should be found to contain one of the finest fibres in the world, that was to lay the foundation of a future of unexampled prosperity for the colony. When first he was convinced of the value of the product, he invited the attention of outside capitalists to its great attractions, but never without an admonition that a personal examination on the spot should precede any outlay, and he was unaware of any instance in which enquiry failed to satisfy the parties that an investment was a safe and conservative measure. The plant was of unfailing growth; it resisted the influence of droughts; the fibre is the best that can be seen in England; labour in the colony was moderately paid; and there was no necessity for a reserve fund, as renewals are so inexpensive that the cost is fairly chargeable to the current account. The progress of industry was satisfactory, and already some cultivators had reached the harvest stage and the exports would now be an annually increasing quantity. It was felt wise to place a limit on the production and the Crown land allotments were consequently restricted to 100,000 acres for ten years, which area might now be said to be disposed of. At half a ton to the acre this quantity would yield 50,000 tons; but some years must pass before this issue is reached, and meanwhile it would be a process of steady progress to that result. At a bottom price of £20 a ton the value of the production would be £1,000,000 annually, as against about £120,000 a year, which had hitherto been the amount of exports from the colony of fruit and sponge, which were its only resources. Mr. D. Morris, of Kew Gardens, who spoke as an expert upon the character of the plant, and not as a commercial man, referred to the judgment that had been formed at Kew Gardens of the Bahamas plant and its fibre, which they considered most emphatically to be the best of its kind that had come under the notice of that institution.—*H. and C. Mail*, Aug. 25.

UVA PLANTING REPORT.

Badulla, Sept. 8.

The WEATHER during the past month has been dry, with a high wind. There have been one or two good showers however, and there has been no drought this year. I have not seen a coffee bush drooping.

It has in consequence been a particularly good year for TEA, which has not only not shut up, but has continued finishing well right through the dry months. Tea is looking as well now as it did in June, and there is not nearly as much red spider as usual. A large acreage has been pruned during the past two months and the earlier pruned fields are coming round fast.

COFFEE has had one moderate blossom for the coming season's spring crop, and there is a small spike for a further blossom now forming on high coffee. Wood is still immature however and there is none of the 'bristly' look, coffee in these districts at this season used to have—with spike. Higher coffee will do much better however in coming years than seemed probable a few weeks back. Bug is showing up again and is doing harm in patches on low coffee—but at present the attack is not general and I do not fancy will prove as disastrous as the attack we had last year.

I do not think HELOPELTIS is present in any numbers on tea in this district. Odd trees here and there have all sorts of curious diseases, some of which may be due to Helopeltis. But I have not seen the animal yet and I have not seen any field of tea look other than vigorous and well. Should helopeltis be sufficiently considerate as to breed at certain fixed times it will be a comparatively easy matter to wage war with it.

COFFEE NOTES.

The people of the United States in 1892 consumed, per capita, 6.54 pounds of coffee, and 1.37 pounds of tea. Coffee is imitated there in many ways, besides being adulterated, and when the price of coffee is high the substitutes are largely purchased by poor people.

A Santos telegram of the 15th says that the receipts of coffee during the week had been 26,000 bags, and the sales 30,000 bags. The stock on that date was 116,000 bags.—*Rio Nes.*

SISSAL FIBRE IN THE BAHAMAS:

DINNER TO SIR AMBROSE SHEA.

A dinner was given at the Imperial Institute the other evening to Sir Ambrose Shea by the Directors of the Bahamas Fibre Company (Limited), of London, in testimony of His Excellency's services as Governor in bringing an important industry into existence and converting the Colony from its former condition of great depression into one of fast growing prosperity and importance. The chair was taken by the Chairman of the Bahamas Fibre Company, Mr. Herman Lescher, and there were present, besides the guest, the Earl of Denigh, Mr. Austen Chamberlain, M.P., the Count de Torre Diaz, Sir J. Somers Vane, C.M.G., Mr. John Fleming, Judge T. A. Thompson (Bahamas), Mr. D. Morris, C.M.G. (of Kew Gardens), Mr. Willard Brown (of New York), Mr. J. W. Knowles (secretary of the Bahamas Fibre Company), and about forty other gentlemen of prominence in the commercial world, and more or less interested in the industry. When the loyal toasts had been disposed of the Chairman gave the toast of the evening, and referred to the remarkable services rendered by Sir Ambrose Shea, who out of depression had by his own efforts lifted the Colony into a proud position of progress and independence. Sir Ambrose Shea thanked them most heartily for the kind words spoken on his account. He, of course, valued them all the more as he knew they were the friendly recognition of successful endeavour, which had opened a new field for safe and promising investment of English capital, and was also fast bringing to the families of thousands of peasants comfort and brightness of which they had no previous experience. It seemed more like a fable than an accomplished fact that a Colony which five years ago was in the throes of depression should now be running a course of progress that bids fair to give it a distinct place in the roll of prosperous dependencies, nor was this transformation more remarkable than the agency through which it had been accomplished. It seemed hard to conceive that a plant long known in the Colony and regarded as a pestilent weed should be found to contain one of the finest fibres in the world, and was to lay the foundation of a future of unexampled prosperity for the Colony. When first he was convinced of the value of the product he invited the attention of outside capitalists to its great

attractions, but never without an admonition that a personal examination on the spot should precede any outlay, and he was unaware of any instance in which inquiry failed to satisfy the parties that an investment was a safe and conservative measure. The progress of the industry was satisfactory, and already some cultivators had reached the harvest stage, and the exports would now be an annually increasing quantity. It was felt wise to place a limit on the production, and the Crown Land allotments were consequently restricted to 100,000 acres for 10 years, which area may now be said to be disposed of. At half a ton to the acre this quantity will yield 50,000 tons; but some years must pass before this issue is reached and meanwhile it will be a process of steady progress to that result. At what was deemed a bottom price of 20s a ton the value of the production would be 1,000,000 annually, as against about 120,000 a year which had hitherto been the amount of the exports from the Colony of fruit and sponge which were its only resources. Although his term as Governor of the Colony was now about to expire, he should remain for another year as Lord Ripon thought it undesirable that he should for the present be separated from the supervision of the important interests it had been his good fortune to have called into existence.

The Earl of Denigh proposed "The Visitors," coupling therewith the name of Mr. Austen Chamberlain, M.P. He paid a high tribute to the Governor's remarkable career and its far-reaching beneficial consequences. Mr. Austen Chamberlain, in responding, said he had twice visited the Colony, and could speak from observation on the spot of the Governor's phenomenal and successful efforts for its advancement. For himself, he had every confidence in the future of the Colony and in the industry in which he was largely concerned. Mr. D. Morris, of Kew Gardens, who spoke as an expert upon the character of the plant and not as a commercial man, referred to the judgment that had been formed at Kew Gardens of the Bahamas plant and its fibre, which they considered most emphatically to be the best of its kind that had come under the notice of that institution. He had known of its existence for many years, but it had never been practically dealt with until Sir A. Shea went to the Colony, and made it the splendid success to which it had now attained.—*Colonies and India.*

TRAVANCORE AND CEYLON TEAS.

Considering the nearness of the two tea-planting countries of Travancore and Ceylon to each other, it is a remarkable fact how very much the ways and means of production and general arrangements differ, and this is the more extraordinary when it has to be borne in mind that the Tamils from Madura, Tinnevely, and Tencasy, etc., supply the whole or practically the whole of the labour in both places. The principal and most self-evident fact is that Ceylon being a colony under the British Government; whilst that of Travancore is under a Native Government. Ceylon has also the advantage of the port of Colombo, and having almost daily communication, i.e., daily vessels sailing for and arriving from Europe. The railway also which goes from Colombo right through the principal planting districts is an enormous boon. Tea picked on a Saturday can be made and packed by the Monday and be on the high seas on the Wednesday. Whilst with Travancore, tea can at the quickest not be got on board under ten days, and that is rare; in fact, unless you ship by P. I. boats from Alleppey at the rate of 40s and 45s a ton of 40 ft., you often have to wait weeks for a direct steamer from Cochin, rates for which are 32-61 for 50 ft. But, given these advantages to Ceylon, there are a huge number of considerations on the Travancore side. The Ceylon planter is famous the world over for his push and go, and rightly so. But it is obviously absurd that the smart man should always go to Ceylon and the duffer to India. The fact is, in Ceylon the planting interest is the interest of the whole island. Without it Ceylon would be of but

minor importance, so though the planter is taxed, he is encouraged; railways and the best roads in the world are made for him; he is represented in the Legislative Council, and his grievances and needs attended to. He forms Associations, and the whole planting community being comparatively close to each other, the Associations are of real good, and are conducted on a business system utterly free from the amateurish element which though less now by far than it was 20 years ago, still permeates the whole of Southern India from Government to individuals.

Ceylon exports now 80,000,000 lb. of tea a year Travancore 3,000,000 lb. at the most, and yet there is nothing to prevent Travancore sending 40,000,000, and at a cheaper rate than Ceylon. But the Government of Travancore, though it tolerates the European planter, does not hanker after his presence. It has a nice comfortable little surplus yearly, and does not at all see to opening up its masses of unequalled forest, which are now practically valueless to European enterprise. It has grand opportunities of a fine harbour at Quilou, and, railways to benefit the whole country, and it likes to talk of these things, but it does not do much more. So the planter who comes is treated well, but not encouraged. He can get land, but it is troublesome. He is given roads but grudgingly, and the meagre sums of R150 and R100 a mile are allowed for upkeep. *Per contra* and on the same lines he is not taxed, or hardly at all, and he is hampered by no medical or other expenses; but fancy, if Travancore were opened up to the European with its miles of forest, if shipping arrangements were facilitated and good roads cut through the old and new districts, and railways touching the feet of the hills constructed, but not only tea but cocoa and Liberian coffee would be cultivated along the whole chain, as would the other tropical products, all of which thrive in that little State far more luxuriantly than elsewhere. Planters would of course be taxed, but if this were done fairly, none but the most shortsighted could object, and Travancore would find itself in very truth the richest of Native States. But the present system prevents this. Twenty years ago in coffee planting it was far worse, but even now the good done by associations is trifling compared with what it might be. The head branch is the South, though that section turns out less tea than the Central. Still it does hold an annual meeting and publish an annual report of its proceedings. But of the others, what can he say? A meeting every year or 18 months, a unanimous carrying of two or three petty motions, and a good breakfast is about all it means, and all this could be altered if Government set the example and offered inducements for new men. New blood is a *sine qua non* in everything, and if the new blood is set going, why it will probably have a dash and go on it, that can but do good and stir up the older members. Another drawback which, however, is vanishing was the large number of small proprietors, who quite overbalanced the firms who held estates. At one time everyone indulged in his own fads, the distance from estate to estate kept opinions from being ventilated, and so on ten places at least five different systems would be pursued. But hard times and low prices have done much to alter this, and in many places there is as much system as on a Ceylon plantation, and as much care is taken to keep up the average prices and keep down the expenditure, so far at least as is compatible with good cultivation.

Now, among the advantages a Travancore planter reaps over a Ceylon one are, first, the soil, which is far richer everywhere. Than there is a superabundance of firewood, the grass-land grows excellent tea, and is practically unlimited and is broken up everywhere with pieces of forest, and besides this grass-land gives wonderful conveniences for manuring, and herds of cattle can be kept at a nominal cost, and in the spring months when they come up from the plains in thousands to graze, they can be induced with little trouble to camp close to the land which requires manuring. In this matter the Government helps, and it remits the grazing tax for cattle which come up and camp on or near an estate. In this way the cost of manuring with Travancore

core planters is reduced to a minimum, which is far from being the case in Ceylon. Labour is cheap, averaging 4 annas a head all round, and abundant especially in Peermaad. In that district there is not an estate which has not more than it wants almost, many places having to send away 25 per cent of those who come up; this, of course, means that advances are practically nil. Moreover labour can be got up and sent down very much as is required! We believe that this is not the case in the south, but probably the difficulty there is temporary. The average yield for Peermaad was just 400 lb. an acre, which beat Ceylon we fancy. Rice is cheap, tea can be put f. o. b. at Alleppey for 4 1/2 annas allowing for manuring the whole place every three years i. e. one-third a year, and when machinery is properly started and going this will be reduced. Travancore backwaters, which run miles inland give cheap transport and if railways run from the foot of the hills this would be cheaper still. Ceylon will always have the pull in shipping and probably in capital. But it rests with the Government in the first place and with planters themselves in the second to bring the exports of Travancore as much to the front as those of Ceylon are at the present time.—*Madras Times*, Aug. 20.

TEA NOTES AND NEWS.

Writing on the progress of Ceylon teas in the United States, a correspondent says some of the orders received cannot be executed owing to scarcity of the teas required in the market. "I saw," he says, "some parcels of Broken Pekoe which had realised only 8½d., whilst Pekoes of the same mark had brought 8½d. and Pekoe Souchongs 7½d. On casting my eye down the broker's catalogue I noticed that the grades were in these proportions:—Broken Pekoes 45 per cent; Pekoes 30 per cent; and Pekoe Souchongs 25 per cent. Now if the proportions of these had been reversed they would in all probability have been properly graded, as it was, it precisely bore out what had been said by Mr. Lipton's Agent, that teas are being overgraded. The worst of this practice is that country dealers, seeing sales of Broken Pekoe effected at 8½d., fail to see why they should pay 1s. which is frequently asked for what is really a fine tea worth all the money. I mean *fine in favor*, not fine in make merely, for a tea may be made anything."—*Indian Planter's Gazette*, Sept. 2.

NETHERLANDS INDIA.

COFFEE IN EAST BORNEO AND JAVA—TOBACCO IN EAST BORNEO.—PEARL SHELL FISHING.

The Sultan of Cote in Netherlands East Borneo has gone heavily into coffee-growing there. He has been enterprising enough to lay out a plantation of the Liberian variety which now begins to bear. The Sultan has since ordered machinery for his own use to facilitate preparing the berry for market.

In Java, the estimates of the Government coffee crop this year show every prospect of the outturn proving shorter than had been expected. Successive estimates point to steady diminution.

The *Sourabaya Courant* calls attention to successive failures in tobacco cultivation in Netherlands East Borneo owing to the soil proving unsuitable for that line of enterprise.

Arrangements for despatching a man-of-war to the Aru islands to check contraband fishing by pearling parties from Australia will, in all likelihood, be hastened by news of alleged high-handed proceedings by them in that group. For instance, one of them threatened to shoot down a district officer who had objected to his fishing for pearl shell without a license from Netherlands India Government. At Batavia, a pearl-shelling venture was being promoted at the date of last advices under the style of the Netherlands India Pearl Fishery Company with a capital of a quarter of a million of guilders. It has not been started yet, but the promoters hold out prospects of a dividend of 53 per cent yearly on the capital. The waters around Banka are to be its field of operations.

—*Straits Times*.

AREA CULTIVATED ON CEYLON
PLANTATIONS.

In the two years which have elapsed since the statistics of our Planting Enterprise were last compiled, a considerable addition has been made to the area in cultivation. So far as we can judge from figures which are now being finally checked, the total amounts to less than 20,000 acres, or to give the exact figures before us, 19,164 acres. We are not prepared to say how much of this should be credited to different products—tea and cacao especially. Indeed, as regards the former, it is very likely that when our tables are complete we may find that tea has to be credited with more than 20,000 acres, and for this reason. Simultaneously with the expansion of tea in many districts during the past two years, there has been a contraction of the area under coffee and perhaps cinchona. No doubt in most cases, tea has taken the place of the older staples; but there are not a few fields given up in the older districts which have not been replanted. We quite expect therefore to see the increase under tea exceed the total aggregate addition when making allowance in the latter for the extent once under the older staples but no longer cultivated. Meantime, it is safe to speak of 20,000 acres as the addition to our tea area since August 1891.

Of the distribution of this additional planted extent according to districts, we can speak a little more definitely. One-tenth of the whole, or about 2,000 acres, has to be credited to the Kelani Valley district, and in this case of course we know that the addition have been made on fresh land, generally virgin forest land. Matale West and Pangwila districts come next, if we couple them together with about another 2,000 acres of additions either to existing plantations or in new places. We take these two districts together, because they really indicate the same new and important expansion of industry in the Valley north of Katugastota and Wattagama, which promises to give us more than one "Mariawatte," besides valuable properties under cacao. It is significant of the attention once more given to the older districts and of the new lease of prosperity which seems falling to them that such well-known divisions as Pussellawa, Kadugannawa and Kurunegala, can each show an appreciable increase in the area cultivated. The first-named has 1000 acres more than in 1891, indicative of the activity displayed in planting up tea in the valleys and hillsides South of Gampola. Kadugannawa has been freely entered on, though long treated as an almost wholly abandoned district, and we find an addition of 600 acres to the cultivation; while Kurunegala has begun to raise its head again with its important cacao and coconut fields and we find additions here aggregating no less than 800 acres. Before leaving the older districts we may mention that Rangalla, Allagalla, Hewsheta Lower and Nilambe have each got a few hundreds of acres added to their record; while more notable are the cases of Dolosbage which has added 800 acres to its tea fields and Upper Hewsheta which has increased its planted extent by no less than 1,400 acres—all tea of course. Reverting to low-country districts we find an addition of about 500 acres to the Kegalle-and-Polgahawela district and

surprising to say not much more added in the two years to the planted area of the Kalutara district.

If we turn to the higher districts, our record of cultivation would seem to compare somewhat as follows:—

District.	Total cultivated.	1891.	1893.
Dimbula	„ „	acres...45,420—	45,747
Dikoya	„ „	„ „ 28,034—	29,269
Maskeliya	„ „	„ „ 18,508—	18,818
Lower Dikoya	„ „	„ „ 6,771—	7,368

Total „ „ 98,733—101,202

An addition of 2,500 acres in the two years in the case of these important districts cannot be considered much; but as respects tea, the process of superseding coffee and cinchona fields with the new product has certainly gone farther. If we now turn to Uva we have to face the division of Badulla into two districts:—Badulla with 11,227 acres under cultivation and Passara with about 5,664 or together 16,891 acres against 15,424 for both, two years ago. Haputale and the other divisions including Udapussellawa show little or no change: what may be lost in coffee has been gained in tea. The only district which has to be entered as altogether abandoned this time is Lower Walapana, and this arises very much from the transfer of Maha-Uva to the Udapussellawa or Upper Walapana division. Finally, we may notice that the "low-country districts" not separately classified, such as Amblangoda, Hanwella, Heneragoda and Veyangoda, show a total addition to cultivation of no less than 3,000 acres. Altogether progress during the two years has been steady though it may be regarded as slow when compared with "the rush into tea" of the previous years.

A HANDBOOK TO THE FLORA OF CEYLON, &c.

By Henry Trimen, M.B., F.R.S. With an Atlas of Plates. Part 1. Ranunculaceæ—Anacardiaceæ. 8vo. Pp. 327 (Dulau & Co.)

Botanists have been long waiting for a flora of Ceylon. Gardner, and especially Thwaites, laid the foundations of such a work, whilst the successive volumes of the *Flora of British India* have comprised Cingalese plants, as well as those from other parts of our great Indian dependency. A separate Flora of Ceylon is, however, a great desideratum, especially to residents in the island, and this desideratum Dr. Trimen is specially well qualified to supply. In plan this volume follows the lines of the *Flora of British India*, the descriptions of plants being in English. No name earlier than 1753, when Linnaeus first definitely published his binominal nomenclature, is accepted. The adopted names of species are followed by reference to the author who first described them and the date of publication. Synonyms are duly recorded, and references given to the literature of the subject, and to the local and general distribution of the plants. The coloured plates comprise a selection from several thousand figures, made under the direction of successive Directors of the Botanic Garden by three members of one Singhalese family—De Alwis. A sketch of the climatic regions of Ceylon is given, and the island shown to be divided into three main regions, distinguished by varying amounts of rain and temperature, viz., the dry low country region, the moist low country region, and the montane or hill country. Four-fifths of the island belong to the first region, where the vegetation is mainly that of peninsular India. The moist low country region, though occupying less than one-fifth of the area, is the best known, and the most interesting. Dr. Trimen assigns to it a limit in altitude of 3,000 feet,

all above that being included in the montane region. This district has a rainfall of from 75 to 200 inches in the year, chiefly in May and June. A short dry period occurs in the first quarter of the year, and again in August and September. This wet tropical region is the home of the bulk of the endemic species and has a strong Malayan affinity. The montane region above 3,000 feet, up to 8,296 feet on Peduratalagala, is wholly in the moist region, and south-west of the centre of the island. The descriptions seem to be particularly clear, and the typographical arrangements excellent, so that the work of the student is greatly facilitated.

No doubt when the work is completed, an index and a map will be provided. The volume is so indispensable to all those concerned with the Flora of Ceylon that we hope succeeding volumes will be speedily issued.—*Gardeners' Chronicle*, August 3rd.

THE COCOA MARKET: FALL IN PRICES.

(From a Correspondent.)

London reports the absence of American buyers and the troubled state of business on that Continent as the cause of the tumble down of cocoa rates. Good Ceylon marks were offered before the mail left and were returned as there was really no market. It is always a bad time of the year this for cacao, and our low quotations—95s—contrasts not unfavourably with some of our rival's highest!

SULPHUR, A REMEDY FOR RED SPIDER.

A well-known planter writes:—You are wrong in supposing (see *T.A.*) that sulphur is no longer used as a remedy for "red spider" in Darjeeling. The gentleman you mention as having tried it without success, now imports large quantities annually to be used as an "anti-rust" or "epider."

[Flowers of sulphur is the great remedy in gardens and conservatories in England. We have good reason to believe that "Red Spider" can never be such a pest in Ceylon as it is in some of the Indian tea districts.—*Ed. T.A.*]

CEYLON TEA IN AMERICA.

In contrast with M. Rogivue's experience in Russia in building up a tea trade equal to a demand for 200,000 lb. to 300,000 lb. per annum already, may be put that of a well-known ex-Ceylon tea planter in America who gives a piteous account of how "Ceylon tea has ruined" him! We need not quote names—to say that Philadelphia was his headquarters is sufficient and he got, we fear, very little aid indeed from the Ceylon Tea Fund. This is how he writes in a letter before us addressed to a friend in London:—

I am no longer in the business, having failed absolutely in the attempt to introduce, unsupported Ceylon tea in America. There have been opportunities when Ceylon could have helped me instead of letting me drop out of their minds. There is no one in this country who has worked harder and faced debt and starvation in the interests of Ceylon as I have done, and had I not been naturally musical and received an education in the art which stood by me, I would have been lost in the thankless and discouraging attempt to make a stand for Ceylon in this country. The little capital I had was lost before I had been two years in the business and twice I lost my business and started again.

Even now I own the oldest brand of Ceylon Tea in the country and am known to every one in the Tea or grocery business in Philadelphia as associated entirely with Ceylon Tea. I lecture at my own risk. I advertised grocers who would handle it at my own cost and loss. I stood up for it, more like a bull alone

in the Spanish arena to be killed, than anything else I can think of. I laid the way in Phila for the Ceylon Planters' Tea Co. who today are selling to nearly all my best customers. When Mr. May wanted my good word, he got it in New York when at my own expense I made a special visit to him. He promised to do great things as "I was just the man he wanted." He went to England and kept me waiting for months in hopes of some results. He was two months in New York before he wrote to me and when he did, he meant nothing and did nothing*. I could stand up today before the Retail Grocers' Association and let them say who has fought for Ceylon Tea. What has Ceylon tea done for me? Absolutely ruined me. It will take me years of teaching to repay what I owe on Ceylon tea.

There was a time when a little assistance from the Ceylon planters would have established me in Phila, I had gathered together a loyal circle of customers, but not enough to make a living. I know one thing, there is a face missing in the city which reflected Ceylon Tea wherever it was seen for five solid years. Years that I would not go through again for ten fortunes. It was a reign of terror to me, and it is a wonder to me today that I am what I am, of sound mind, with prospects of living once again.

EILA TEA COMPANY.

GENERAL MEETING.

The ordinary general meeting of the shareholders of the Eila Tea Company of Ceylon, Ltd., was held this forenoon at the registered office, Colombo. Mr. F. W. Bois presided. The report and the accounts (given below) were adopted and a dividend of 10 per cent declared. Mr. Stanley Bois who retired according to the articles of Association was re-elected as a Director.

Mr. E. M. Shattock was elected Auditor.

REPORT.

Your Directors beg to submit their report and accounts for the year ending 30th June last, which, notwithstanding a short fall on the estimated crop, are of a satisfactory nature, and afford encouragement for the future of the Company.

Work in the New Factory commenced on 1st November, and since that date 120,000 lb. Teas of uniformly good quality have been manufactured. The average nett price for the year shows an advance of no less than 12 cents per pound over last season.

The working profit is equal to 16 per cent on the Capital of the Company; but your Directors think it expedient to write off R10,000 from the cost of the Factory and Machinery. The balance available is therefore R22 815 30; out of which it is proposed to pay a dividend of 10 per cent and carry forward R315 30.

The estimate for the new season is 190,000 lb. to cost 22½ cents per pound in Colombo, exclusive of expenditure on capital account. It is proposed to plant up further 105 acres of forest, which, with the extensions recently completed, will make 150 acres of young Teas.

In terms of the Articles of Association, Mr. Stanley Bois retires from the Direction; but, being eligible, offers himself for re-election.

It will also be necessary to appoint an Auditor.

By order of the Directors,

J. M. ROBERTSON & Co., Agents and Secretaries,
Colombo, 15th August, 1893.

* No doubt Mr. May hoped his Exhibition negotiation was going to lead to great things; but both he and his lieutenant would now respond to 'Philadelphia' by saying,—“And see what Ceylon tea has done for us!”—Pineo, Arthur, Murray alas! all in the same boat: the man who is to make Ceylon tea pay in America has evidently yet to appear.—*Ed. T.A.*

ENEMIES OF TEA:

MOSQUITO BLIGHT OR TEA BUG.

There is no call for alarm, or even uneasiness, at the heading of our article. No cultivation is without its enemies and the minor pests affecting tea have long been the object of inquiry in India, while in Ceylon they have also from time to time been noticed by our planters. We direct special attention to the timely and important letter of the Director of the Royal Botanic Gardens, and we trust Dr. Trimen's advice will, at once, be taken, by a systematic campaign being started for the extermination of *helopeltis antonii* from the Ceylon tea districts now affected by it. Our cacao planters got a pretty intimate acquaintance with this insect pest in 1833-4-5, and only by the cultivation of shade trees were they able to get rid of the attacks of the enemy though its numbers were greatly reduced by following Dr. Trimen's counsel "to catch and kill them." Shade cannot be thought of in the case of tea, and therefore, there is nothing for it, but to set a campaign of capture and extermination on foot throughout the tea districts referred to. We may be told that only isolated estates are affected by this "tea-bug"; but as was the case with cacao-fields when once examination and search for the insect take place, it is very possible that it may be found more generally prevalent than is at present realized. To enable tea planters the better to judge for themselves, we quote from the *Tropical Agriculturist* the portions of Dr. Trimen's Report dated 9th September 1884—written primarily for the benefit of cacao planters—that more particularly bear on the description and identification of the insect:—

Helopeltis itself belongs to the true Hemiptera, being a member of the tribe *Cuspidæ* all of which are destructive to plants (one especially so to raspberry fruits) and are partly characterized by their comparatively active running habits of the genus, several species have been described by naturalists of which the present insect *H. Antonii* Lynt, is the best known. In the adult state this can scarcely be mistaken for any other insect, and may be recognized by the following description. The narrow body is less than $\frac{1}{2}$ inch (6 mm.) in length, but the greyish wings project beyond the abdomen and thus increase the length to nearly $\frac{1}{2}$ inch (8 mm.); the thorax is brownish-red in colour and ends in a slender red neck, from its centre arises the singular erect rigid pin-like process which gives the genus its scientific name (*hilos*—a nail). The head is small and black, and a characteristic feature are the antennæ quite $\frac{3}{8}$ inch (10 mm.) long spreading, 4-jointed, and curved. On turning the insect over, the abdomen is seen to be black, but in the female this is crossed about the middle by a broad band of white. The formidable beak or proboscis, fully 2 mm. long, can be seen beneath the thorax, to which when not in use it is pressed. The insect is long-legged and active and can fly well, but so far as I have seen does not make any long flights.

Before arriving at the imago state, the *Helopeltis* passes through several stages, but the changes (as in all the bugs) are not so complete as in most insects. When first hatched it is about 1-24th inch (say 1 mm.) long, pale yellowish olive in colour and semi-transparent, the eyes and some internal parts showing red. During its progress through the larval stage it sheds its skin several times, and the little empty sloughs are commonly found on the cacao. The olive colour is maintained through these changes, and the insect is easily recognized by the thoracic spike which is soon developed, the long antennæ, and the long legs which raise the body well off the surface; the abdomen is soft and pointed and turned up at the end. Rudimentary wings are present in the pupal stage but are not matured for use until the final change from this to the perfect insect. Though thus

unable to fly, these immature creatures run about pretty briskly and their appearance is decidedly ant-like; apparently their whole existence is passed on the cacao plant where they were born.

I regret that my opportunities and leisure have not permitted me to trace out the whole life history of the insect. I do not know the time occupied from egg to imago nor how long the latter lives. I find that the female contains from 8 to 12 eggs, large for the size of the insect, and of a peculiar long flask shaped form provided at the truncate end with two filaments half its length. I have not succeeded in seeing the actual deposition of the egg, but I have detected two *in situ*, one attached to a punctured cavity in the leaf-stalk; and the other in the tender shoot at the foot of a leaf-stalk these were milk white with a tough skin. After a careful search I have not discovered more than these two and my knowledge on the point is thus very defective; so far as it goes it corresponds with that of Van Gorkom in Java who says that (in *Cinchona*) the eggs are laid in the ends of twigs and in leaf-stalks but are quite hidden and very difficult to find.

The little insects commence to suck the plant at once, and they continue to do so throughout their lives. Apparently they specially feed at night, and the amount of injury a single one is capable of effecting can be seen by any one who will place on in a cage with a fresh shoot for a night and examine the shoot in the morning. The underside of the mid-ribs of the very young leaves is also a favorite position for the punctures. It may be presumed that the perfect female insect does some damage also by the deposition of the eggs.

The difficulty, however, of detecting the immature *Helopeltis* is well-known, so much so that both in Java and Assam as now here, it is difficult for planter to believe that such serious mischief is wrought by a foe so nearly invisible. I therefore requested the superintendent to initiate systematic catching of this insect, which he consented to do. The results obtained corroborated my belief that *Helopeltis* is really far more abundant than it appears to be. During the first two days, indeed, though six coolies went over 220 acres, only 311 specimens resulted; but so soon as the boys learned how to find the insect, the numbers increased. Thus by the end of ten days 2,011 had been bottled, and in the forty-one days ending with August 31st, as many as 25,000 individuals (the greater proportion being immature ones) had been captured and destroyed.

Then as regards the remedy and in view of further investigation we quote:—

As regards remedies, I have but one to recommend, that is to catch and destroy the insect. Nothing else that can be suggested is so direct and radical as this. The cooly boys employed should be instructed to go over the trees, one by one in order, carefully and exhaustively; the larvæ and pupæ of *Helopeltis* being unable to fly are caught easily enough when once seen, and even the perfect insects are not quick to escape. No doubt, a promised reward for the largest "bag" at the end of the day will stimulate the search. The superintendent of the estates to which this report refers is of opinion that the practice has been of very great benefit; and indeed it was evident on my last visit, that the latest "flush" of young shoots, brought out by recent very slight rains had passed through the critical period, and has "set" without much damage during the time that the systematic catching of *Helopeltis* was being pursued. If the attacks of this insect ceased, I believe that the trees would to a great extent recover. This experience here, so far as it goes, perfectly agrees with that in Java, where the attacks of *Helopeltis* on cinchona produce almost precisely the same effects as here on cacao. By constant watchfulness and the capture of all the individuals that can be detected, the pest has in the Government plantations been kept under and in some nearly abolished.

Did we possess more certainty as to the precise positions where the eggs are laid and a ready means of detecting their presence, a timely removal

of the parts of the tender shoots affected before hatching had occurred could be confidently recommended. Unfortunately the first indications we get are the brown stains showing that the young *Helopeltis* is already at work. The investigation of this point is to be strongly recommended to those in a position for observing it.

There is thus made available, sufficient information to enable every tea planter who should take part in the "tea-bug campaign," to begin and carry on operations leading to the extermination of the pest. Our senior nine years ago, thought that the aid of the magnesium light might be called into requisition at night on cacao plantations for the capture of the immature but destructive "cusses" at night. But cooly children can evidently give a good account of large numbers of the enemy if set systematically to work, during the day. On Mr. Kerkhoven's tea estate in Java, they were regularly captured and "given to the dogs to eat." We trust in the case of Ceylon that the catching and killing process may result in the practical extermination of the pest. It must be remembered that we have here not a fungus, but an insect to deal with—and an insect too of an appreciable size, so that there is nothing *prima facie* to prevent such a united campaign as we now advocate, under Dr. Trimen's advice, being fully successful in banishing "*helopeltis antonii*," "tea bug" or "mosquito blight" from every tea-field in Ceylon.

COFFEE-TEA.

The Lords of the Treasury will have to get the British Tariff revised, and a new heading—Coffee-tea—introduced if this sort of thing, about the preparation of coffee leaves as tea, goes on. The *Lancet* is one of the most influential journals in the world on dietetic matters and when it speaks so highly of "Coffee-tea" as in the following report, we may be sure a demand for the product will follow and there will be planters ready to meet it. Ceylon, however, we fear, can never do much in this way, unless the very leafy Liberian variety be taken advantage of for crops of leaves as well as, or in place of, berries. The Coffee-tea shown by Messrs. J. A. Hadden & Co. was, we learn, from Middleton estate, Dimbula.

(From the "*Lancet*," Aug. 5th.)

(JAMES A. HADDEN & CO., 25 FENCHURCH-STREET, E.C.)

In a recent article on the merits of Indian and Chinese teas we were led to remark that mankind would seem to have instinctively selected as the bases of common beverages amongst the plants at his disposal only those of seeds, fruit, or leaves of which contain that interesting body caffeine or theine. It by no means follows, however, according to a short investigation that we have recently conducted, that man has selected that part of the plant which yields the greatest abundance of this alkaloid. He has done so, it is true, by choosing the leaves of the tea plant and of the maté plant of Paraguay and the nut of the kola plant, but it would appear that in the case of coffee he has arrived at a wrong conclusion, at least as regards the theine-containing portion. The coffee berry or seed contains but a feeble portion of theine, but of course there are other principles present which together make coffee a wholesome and agreeable beverage. According, however to a recent analysis we have made, the dried leaves of the coffee plant are nearly as rich as regards theine as is tea itself; moreover, they contain a smaller proportion of tannin than the stronger teas of India and Ceylon. Two specimen parcels of coffee-tea, which really consists of the dried leaves of the coffee plant, have recently been submitted to us by the above firm, and we have devoted some time to an analysis and an examination which a product of this unique character demands, presenting

as it does certain novel features which may assign to it an important place amongst the beverages available for the use of man. The samples we have submitted to analysis formed part of a recent experimental consignment grown in the district of Ceylon called Dimbula, at an elevation of from 3,500 ft. to 8,000* ft. On examination one proved to be a small broken leaf and the other a whole leaf sample. Both presented very closely the characteristics of tea as regards appearance and aroma. The infusion made in the same way as ordinary tea, had an agreeable aroma and a full-bodied, smooth, though bitter flavour, in which there was a suggestion of tea; it was entirely destitute, however, of that delicate roughness characteristic of a real tea infusion. The taste was, in fact, somewhat insipid, but not disagreeably bitter. The specimen of small broken leaf yielded the best liquor on infusion in regard to body, flavour and aroma. The following analysis of both specimens is very interesting as showing that the dried leaves of the coffee plant contain almost as much theine as does tea, whilst the tannin, which does not appear to be identical with the tannin of tea, is distinctly less. Sample 1, whole leaf: theine, 2.66 per cent; tannin, 7.14 per cent; extract, 39.45 per cent; moisture, 7.60 per cent; mineral matter, 6.10 per cent. Sample 2, small broken leaf: theine, 3.20 per cent; tannin, 6.66 per cent; extract, 34.40 per cent; moisture, 7.09 per cent; mineral matter, 5.50 per cent. Although the flavour of the infusion yielded by coffee-tea compares unfavourably with both that of the coffee and of tea, yet in view of the restorative and refreshing properties which it must possess on account of the excellent proportion of theine it contains it might be advantageously used by many individuals, and especially by those who are not able to tolerate coffee or tea.

THE UDUGAMA TEA AND TIMBER COMPANY,

Which is being formed with a capital of R400,000 will, it is proposed, acquire Udugama, Gunnedomine, and Saumares estates, the cost of the property being set down at R260,000, machinery R50,000 and cultivation, working expenses &c. R40,000. The total acreage of the three estates which are from 18 to 24 miles from Galle, is 4,710, 377 being tea, 149 areka, 66 coconuts, 1,339 virgin forest, and 2,779 chena. At present it is proposed to issue 7,000 shares of the value of R350,000 and an estimate has been prepared showing profit at the rate of 13 per cent on the called up capital. The profit on the making of tea (for others as well as the estates in the Company) is estimated at R10,000, on the making of chests R25,000, on timber R12,000, and on rents, jungle sticks &c. R1,000. The vendors have signified their willingness to accept in part payment of the purchase price 1,560 fully paid shares of the value of R78,000 and the balance in cash.

WYNAAD PLANTERS ASSOCIATION.

Proceedings of a General meeting held at Poothacoolie Bungalow, Friday, 11th August, 1893.

CINCHONA.—Read letter from Baron von Rosenberg, President of the Kannan Devan Planters' Association suggesting that statistics should be collected and published with a view of proving that the present low price of bark is not warranted by the statistical position of the article.—Resolved that the Honorary Secretary write in reply that in the opinion of this Association the collection of such statistics would involve a great deal of trouble and is not likely to have any practical result.

* A mistake for 5,000 or at most 6,000 feet.—Ed. T.A.

CEYLON TEA IN RUSSIA, AMERICA & C.

Undoubtedly pioneers who endeavour to introduce our teas into foreign countries have to battle against many adverse influences. It has not as yet been shown that any of those who have thus endeavoured to secure Ceylon interests, have found the results to themselves financially satisfactory. Very recently, it has been made plain how discouraging to the parties concerned has been such an attempt with regard to America, where efforts have been made by pioneers who certainly deserved, although they have not obtained, a full measure of success. In France, Germany, and other Continental countries but little has been effected up to the present date, at all events not to the extent which can have repaid the time and labour expended by individuals. The opening of new markets for our teas is, however, a necessity of the time, and one that in our planting interests must be encouraged in as liberal a spirit, as is possible.

None of the enterprising persons who have set themselves to the accomplishment of this object on the Continent of Europe, have rivalled in success the Tea Fund's recognized agent in Russia. And yet the field M. Rogivue attacked was, perhaps, one of the most unpromising that could have been selected. True it is that throughout that Empire the population is essentially a tea-drinking one. The infusion is in every Russian household the established drink, and on every sideboard there stands the samodvar in readiness to supply the craving of every visitor. But then custom of centuries of growth has led to the formation of certain tastes and of prejudices which could not easily be overcome. The trade in tea was in the hands of a few firms of long establishment and of ample financial means. These seem to have set their faces strongly against any new introduction that might disturb the commercial relations they had formed, and M. Rogivue soon found, when he first applied to these firms, that they were determined to oppose him in every possible way. They had established a strong influence in high political quarters, and brought that to bear with great effect in opposition to the efforts made by M. Rogivue. With but very limited means at his command, that gentleman found that unless he could commence work as a retailer he had no chance of inducing a demand in Russia for Ceylon teas. Foiled in his attempts to do this in St. Petersburg, he transferred his exertions to the ancient capital of Moscow, and radiating thence as from a centre he has now succeeded in establishing a large number of agencies, and has carried his warfare into the very heart of the enemy's country at Nijni-Novgorod. All this has not been done without a great amount of personal labour and of financial risk, and M. Rogivue now complains to our London Correspondent—whose report will be found on page 229—that he has not for this as yet reaped any reward for himself, and that his prospects of ultimately doing so are cramped by the narrowness of his resources and by the want of adequate help from Ceylon tea planters who are, with himself, interested in the development of his business. It may readily be understood that hesitancy is felt out here as to granting direct financial assistance to a business which in the first place is certainly one of private aim. But there is a side-issue which in fairness to M. Rogivue we think cannot and should not be overlooked. Quite independently of the amount of Ceylon tea now sold through his agency in his establishments throughout Russia—and this is no inconsiderable quantity—he has succeeded in making Ceylon tea a felt want

in many a Russian household. His success in this respect has stirred up the Russian tea merchants to the consciousness that they must endeavour to meet the consequent demands, and accordingly, we are assured that month by month the exports of Ceylon tea from London to Russia have shown a steady increase.

We are not quite clear that the whole credit of this result should be given to M. Rogivue's Agency. Undoubtedly some part at least of this result is due to other, though we admit, much more limited and temporary agencies. For instance, the visit of Sir Graeme Elphinstone to Russia did some good in making the name and quality of Ceylon tea known. Then again, we ourselves had communications with the St. Petersburg Correspondent of a well-known London journal, whose friendship we made at Vichy so far back as 1887 and both in St. Petersburg and Moscow we are aware that the said Correspondent did some service for Ceylon tea by distributing samples among his friends and causing an inquiry to be made for it at the stores. Then again as to M. Popoff's visit to Abbot'sford, so far back as 1890-91 and his interest in Ceylon tea, that could scarcely be due to extraneous influence.

Nevertheless, we are quite prepared to admit that each and all of these efforts and agencies are not to be compared in importance with the work done by M. Rogivue and for this reason, that his own figures of his sales last year, and estimate for the current season, show the large and increasing business developed solely by himself. It is the importance of this business in itself that has caused some leading Ceylon planters to indicate that surely M. Rogivue has got aid and start enough,—that he has now only to go on and win a fortune out of an established, ever-growing trade? Be it remembered too, that all the Tea Fund Committee promised, or that M. Rogivue, originally asked in the way of aid, has been scrupulously fulfilled. What then has caused the fresh demands—preferred too almost by way of complaint? We cannot help thinking that—as London tea men think—the lavish way in which planting money has been devoted to Chicago, is responsible for these and other demands specially urged on the Tea Fund. And with some show of reason we are bound to say. For, M. Rogivue and other claimants for aid, may well argue,—‘If the Ceylon tea planters are able to spend £20,000—£25,000—£30,000? (albeit, a goodly portion of this comes out of the general revenue) on an Exhibition in a coffee drinking country, surely they may well spend a comparatively paltry £500 or £1,000 more on such a grand field as tea-drinking Russia, and in aid of one who has already given of his time and expenditure of private means, so freely?’ We most firmly agree in the logic of such an argument, and if we saw the means available—and had the power to grant it—M. Rogivue would have £500 twice over to do further justice to his tea crusade in Russia, while a similar amount would also at once be devoted to still further develop the demand for our teas in the back-country of the Australian Colonies,—a more promising field even than Russia—assured as we should feel, in both cases, of an immediate return in an increased demand for our teas.

But then the financial position of the Tea Fund in Ceylon and the means of the planters to further supplement it, must be taken into consideration: With the fall of late years in the average

price of his product, and the risk of exchange going against him, the self-imposed Chicago tax of ten cents per lb. which is likely to last through all 1894, may in itself, be considered no inconsiderable burden by the Ceylon planter. The Tea Fund has no great balance at command, and except by calling on those proprietors who have hitherto most unfairly escaped contributions to it, there is no means that we can see of supplementing its income. The thought of laying any further burden on the tea planter, beyond the Chicago tax and Tea Fund contribution, before 1895, may at once be dismissed as impracticable, and therefore however deserving M. Rogivue may be of further aid,—however encouraging the Russian and Australian markets may be for the distribution of further samples,—all that can be done must be according to the very moderate balance available to the Tea Fund Committee.

All this has, of course, a bearing on the further proposal in the Chicago Commissioner's letter about following up his splendid advertising work at the Exposition. We see no hope in looking to the community as a whole: the poorer members are really doing more already than they can perhaps well afford. It must only therefore be through the voluntary co-operation of our wealthier tea proprietors that anything can be done of the nature suggested by Mr. Grialinton; and the same may be true of M. Rogivue's work. If he wants shareholders in his business, it is possible that some big Ceylon tea-growers who would wish to have a special market for their produce in Russia, might, on such terms, advance capital. On the other hand, it would be well, perhaps, to get the opinion of London firms now engaged in exporting Ceylon tea to both Russia and the United States, as to whether the business might not be allowed to develop after a normal fashion, on the close of the expenditure of the taxation already guaranteed to the end of next year for America, and of such aid as the Tea Fund can now afford to M. Rogivue.

To sum up, our advice to the Committee of the Tea Fund is to devote what they can spare to Russia and the Australian back-country in about equal proportions, and to point out in respect of America that the tax already pledged is the utmost the planting community as a whole can do in that direction. If once the Chicago debt were paid off, a good deal more might be accomplished.

NOTES ON PRODUCE AND FINANCE.

INDIAN TEA IN PERSIA.—Mr. E. O. R. Thompson, the English Consul at Meshed, in a report to the Foreign Office, says:—"The statistics show that during the past year British trade improved all round and Russian trade declined. For this we have to thank the cholera, and the rigid quarantine enforced, in consequence, by the Russians, for many months. The total value of the British tea imports via the Persian Gulf amounted to 953,556 tumans (£245,782), as against 753,110 tumans (£198,187) for 1891-92. The amount of green tea imported was considerably greater than in the previous year, the figures being 660,230 tumans (£169,290), against 478,750 tumans (£125,987) for 1891-92. Most of this green tea comes from China to Bombay, and is despatched thence to Persia. The amount of black tea imported was also greater than during the previous year, the figures being 95,325 tumans (£24,442), against 80,715 tumans (£21,241) for 1891-92. Nearly the whole of this black tea is Indian."

TEA CULTIVATION IN THE UNITED STATES.—The *Chicago Evening Journal*, which contains a long account of the work performed by Mr. Blechynden on behalf of Indian tea at the World's Fair, also gives particulars of the experimental tea culture by the

United States Department of Agriculture, and has a great deal to say about adulterated tea. It says:—"The department of Agriculture is pushing experiments with tea culture in South Carolina, and the forthcoming annual report will give a glowing account of the prospects of this industry in the United States. Last summer," says the *Journal* quoting from the *Washington Star*, "the first pickings were taken from plants that sprouted in 1889. The product, submitted to expert tea tasters and merchants, has been pronounced excellent and readily marketable at a high price. It is declared to have a character distinct from the teas of any other country. There is reason to believe that it can be grown with profit on a commercial scale. Not requiring special curing for export, like Chinese and Japanese teas, the leaves can be dried for domestic trade, and sold in bricks like other herbs. Ten years ago the Department of Agriculture attempted to grow teas in South Carolina. The effort was abandoned without a fair trial, as is now believed, and it is being resumed. At the request of Uncle Jerry Rusk the Department of State issued requests to consuls at the tea ports for seeds of the best teas. Experimental gardens have been established near Summerville, S.C., where plants of Japanese, Chinese, Formosa and Assam hybrid varieties are under cultivation. The first season's crop was 38 lb. of the cured article per acre. It takes 4 lb. of fresh leaves to make 1 lb. of cured tea. It is expected from that 400 lb. to 500 lb. per acre of fresh tea can be raised yearly. In China the cost of picking is 1c. per lb. of cured tea. The cost in South Carolina is 6c. a lb."

COST OF AMERICAN TEA.—On account of this difference in the price of labour, American teas can only compete with high-priced imported grades. "It is estimated" (says the *Evening Journal*) "that the cost of raising a pound of tea in South Carolina is 20 cents, in addition to the rental of the land. If successful this new field for agriculture enterprise will furnish an easy outdoor occupation for many who are unequal to rougher employment in the fields. Taking an average, every man, woman and child in the United States consumes twenty-one ounces of tea per annum. Just half of it comes from China, 42 per cent. from Japan, and the balance from India and other British possessions. The first plant of this species grown in South Carolina was set out by Michaux, the French botanist, in 1804, fifteen miles from Charleston. During the latter half of this century people in that section have cultivated little patches and larger gardens of tea, which have produced crops of a fine flavour, though usually not strong enough to satisfy many drinkers. It is believed, however, that the failure of pungency has been due to defective curing. Many families in that part of the country today grow what tea they require for household use. A Fayetteville (N.C.) man writes that half a dozen bushes furnish his family of six persons with more tea than they can consume. His wife prepares it by heating the leaves in an oven until they are wilted squeezing them by hand until the juice is expressed from them, and finally drying them again in the oven. The tea is then fragrant and ready for use."

ADULTERATED TEAS.—Immense quantities of trashy and adulterated teas are—says the *Evening Journal*—sold in the markets of the United States. One method of sophistication is to introduce leaves of other plants. This species of cheat is readily detected by means of the microscope. The tea leaf possesses so marked a character of its own, in respect to its veins and serrated edges, that it cannot be mistaken. What is called "the tea" in China is an imitation usually containing fragments or dust of the genuine leaves, foreign leaves, and mineral matters, held together by a starch solution and coloured by a "facing" preparation. Tea is sometimes falsified by the addition of spent or partly exhausted leaves—in other words, old leaves dried for use second-hand. This is a fraud difficult to prove, though weakness of the beverage may cause it to be suspected. Sometimes teas are treated with catechu to increase their apparent strength. This can only be

discovered by chemical tests. The teas exported from China and Japan are nearly always "faced" with some mixture to impart a colour or gloss to the leaves. The preparations employed for this purpose contain Prussian blue, tumeric, indigo, and plumbago. Damaged and imperfect leaves are treated in this way to improve their appearance. The substance most commonly used for black teas is plumbago—black lead.—*H. and C. Mail*, Aug. 11.

CEYLON TEA IN RUSSIA.

LONDON, Aug. 11.

My last letter mentioned that there was a prospect of my having an interview with Mr. Rogivue before this my next writing. It unfortunately happened, however, that the delay in my receipt of that gentleman's note before alluded to prevented my reply to it from reaching him before he had started on his return journey to Russia. He had left a request with his London agents, Messrs. Malcolm, Kearton & Co., of 17 Fenchurch Street, that my letter, when received, should be opened by them, and that they would endeavour to see me and discuss with me the circumstances of his enterprise in Russia. Mr. Piper of that firm accordingly made an appointment with me and gave me the opportunity desired by me of gaining more extended information than I had possessed of the situation of affairs. It was known to me that Mr. Rogivue had expressed himself a feeling that he had not received from Ceylon the acknowledgement of and support to his services rendered to it that he considered he had a right to expect. Mr. Piper explained to me what the nature of those services has been. Upon this topic it is hardly necessary for me to enter, for recent communications by Mr. Rogivue that have appeared in your own columns will have made you very fully acquainted with all that he has accomplished towards introducing your teas into the great empire of the Tsar. On my stating to Mr. Piper my belief that there was no disposition in Ceylon to underrate those services, but that I could readily understand how it might be difficult for the public bodies there to vote assistance to an enterprise undertaken primarily for the saving of a private interest, that gentleman remarked:—"You seem scarcely to realise all that Mr. Rogivue has achieved. It is not only that he has been gradually working up a business for himself that may in the end prove remunerative and that he is even now disposing on his own account of a very considerable amount of Ceylon tea, but that what he has done has been the means of breaking down the opposition felt by the tea trade throughout Russia to the introduction of a competitor with the classes of teas in which they have an established interest. Probably you have no idea of the increasing extent to which Ceylon teas are now being exported from London to Russia. I have not the figures at hand, but will obtain them for you very shortly. I can only say at present that the trade is becoming a very large and important one. This is solely due to the fight Mr. Rogivue has fought during the three years of his residence in Russia. When he first went there he met with every kind of opposition, both from private parties and officials. In spite of this he has literally forced Ceylon tea into consumption and demand, and that so successfully that the Russian tea firms are now obliged to hold supplies ready to meet this. Is that nothing to have done on behalf of Ceylon? And you must remember that from this increasing trade Mr. Rogivue himself derives not a penny of benefit, while the Ceylon

planters obtain from it a great advantage. Mr. Rogivue has therefore rendered a public service to Ceylon quite apart from the serving of his own interests, and he feels, naturally as we think, that this service has not met with the recognition that it should have done."

On my asking how Mr. Rogivue thought that recognition could best be afforded, Mr. Piper replied that, in his opinion, that gentleman should distinctly state what he thought the Tea Fund could do to assist him in the development of his business. "He wants," Mr. Piper continued, "to greatly extend the number of his distributing agencies. This necessarily demands either a considerable first outlay or a large extension of credit. This last we have already ourselves afforded to him to a very considerable amount. But we feel Mr. Rogivue is a man thoroughly to be trusted, and we do not therefore object to helping him as far as we possibly can. We buy largely for him in the London Markets, and here you see an invoice showing that during his recent ten days' visit to England we purchased on his account for shipment to Russia £800 worth of Ceylon tea. But this is a trifle to what could be disposed of if either his capital were larger or his credit wider." My next remark was that probably the Ceylon Tea Fund could send Mr. Rogivue supplies on good terms of credit if it was asked to do so. Mr. Piper replied that "this suggestion would hardly meet the case. Mr. Rogivue told us when recently here that the nature of his present business is such that he cannot foresee either the amount or character of his demands beyond a month or so in advance. If he wired at a considerable expense to Ceylon he could not get tea thence under three or four months. Therefore, you see, he must buy in the London market. The larger volume of his business is of course in teas costing here from 7d to 8d per lb., but we have orders from him which we have long been unable to execute for teas at 2s 6d the lb. There are none of these to be bought at present. The Russian families will have the cheap tea for their own consumption, but when they go to the stores to purchase these they always buy a proportion of the finer teas to give to their guests. Mr. Rogivue says he should lose the latter trade if he did not supply the demand for the cheaper sorts. You ask how for the prices charged by him for Ceylon's correspond with those asked for the other teas sold in Russia. Well, they are about even throughout all grades. You see the enormous duties charged tend to bring the prices for all sorts to a comparative level. It cost Mr. Rogivue nearly £90 for the duty upon the £30 of tea with which he was supplied by the Ceylon Tea Fund when he first went to Russia, and it is the payment of this heavy duty upon the late grant of tea made to him that hampers his financial position. Mr. Rogivue while in England lately saw Mr. Whittall, and I believe that gentleman promised that he would write to the Tea Fund urging that further support should be accorded to him. Mr. Whittall feels that a very good work has been done on behalf of Ceylon, and that Mr. Rogivue is entitled to that assistance which will enable him to himself reap some benefit from the exertion he has made." I think the above account describes pretty fully all that Mr. Piper told me on behalf of his client. It seems to me that the development of the export of Ceylon tea to Russia must in all fairness be attributed to Mr. Rogivue, and that had he not gone to Russia that market would have been at the present time quite closed to you. So much has been said to me in many

quarters in praise of your agent in that country, of his energy, his trustworthiness, and his determination not to be cowed by the most serious obstacles placed in his way, that personally I feel a pleasure in putting his case before your readers with all the strength of conviction felt by myself in the good the exercise of those qualities has effected on behalf of Ceylon. It is the hope of many of us here that some way may be devised of enabling him to extend those benefits while at the same time legitimately serving his own interests.—London Cor.

THE DESTRUCTION OF FLIES AND GREEN BUG.

The subjoined letter and its enclosure is published in the *Gazette* for general information:—

By His Excellency's command, J. A. SWETTENHAM,
Acting Colonial Secretary.
Colonial Secretary's Office, Colombo, Aug, 17th, 1893.

The Assistant Government Agent, Matara, to the Government Agent, Galle.

No. 735. Matara Kachcheri, July 31st, 1893.

Sir,—I have the honour to annex copy of a report No. 1,158 of the 23rd instant from the Mudaliyar of the Weligam Korale, and to suggest that it be published for general information.

2. I believe that in the use of these sprayers and "London Purple" is to be found a remedy for the fly that is so destructive to paddy in the Kandyan Provinces, and possibly for green bug on coffee as well.—
C. J. R. LE MESURIER,
Assistant Government Agent.

Report referred to.

The Mudaliyar, Weligam Korale, to the Assistant Government Agent, Matara.

No. 1,158. Teijjawila, July 23, 1893.

Sir,—In continuation of my letter No. 1,142 of the 20th inst. I beg to submit for your information the highly successful results obtained by the use of the sprayer to destroy "godavellus," and the general feeling of gratitude among the cultivators, particularly those of the fertile paddy tracts of the Malimada division, where the sprayer was lately used, that a remedy has at last been discovered to avert what has been the curse of the cultivator from "time immemorial."

The godavella was hitherto believed to be indigenous to the soil. The introduction of the sprayer has now brought the information that instead of its being so, it is a kind of caterpillar that comes from an egg that is laid by a moth that flies about during night from place to place.

These insects generally appear about three days after sowing, in such numbers that the tract literally swarms with them, two or three of them attacking each paddy plant. If left unheeded the tract is converted into such a complete waste within seven or eight days that a second sowing is required. Flooding the tracts where water was available for that purpose was the only remedy known, and where this was not possible the more primitive methods of "polgehima" (coconut throwing) and "ankeliya" (horn pulling) and their connected feasts were resorted to, by which it was expected to propitiate the deities from whom this pest was supposed to be a visitation. The belief in such methods was maintained by the mere coincidence that as the period of these ceremonies drew to a close the godavellus, in the course of nature, disappeared.

The first attempt to devise a more practical way of destroying them was made at your suggestion early in 1892. This was to sprinkle with the hand—like seed being thrown in sowing—a solution of one part of kerosine oil to sixteen parts of water over the attacked tracts which had been previously flooded for the purpose. After a few hours the water was drained off, and the insects were found dead

or were swept away dying with the ebbing water. I tried this in several large tracts in Aparekka in the Welleboda pattu, but although the results were satisfactory it had its drawbacks in the manner of sprinkling, which was necessarily slow, and in the fact, too, that the solution could be used only in flooded fields, or there was the danger of damage to the crops. The sprayer removed the former, while the insecticide (London Purple) supplied this harvest has removed the latter. We have now an unfailing remedy, obviating, too, the often impossible necessity of flooding, to take the place of the pristine methods of "polgehima" and "ankeliya" of our forefathers.

Early in July there was great apprehension in Malimada, Uninduwela, and Kaduwa, some of the finest paddy tracts in the Province, owing to the appearance of godavellus in denser swarms than before, even prior to sowing, wherever a field was seen above water. This occurred just about the time the amunas were to be broken for sowing. I deferred sowing for another week for fear of the insects getting into the fields when the water was drained off, and reported the state of affairs to you. The sprayer with the insecticide was sent. It was freely used in the parts of the tracts referred to, which were not flooded by the amunas, and the effect was even better than was expected. The insects operated on in the morning were found dead at sun-turn. This was so reassuring that the cultivators, who opposed the late Mudaliyar in using the solution of kerosine oil, and who were clamorous for the retention of the amunas even longer than I wished, of their own accord opened them, and allowed my men to spray the insecticide, with the results stated. Within a few days there were no godavellus in this tract. What specially commends this treatment is that, unlike all other methods, godavellus never appear in the same tract again, and that the powder is perfectly harmless to the plant, obviating, as I said, the necessity for flooding the crops. There was a scramble for the sprayer among the cultivators when the first results were seen, and it was used here and there, so that the exact extent operated upon cannot be stated, but I put it down at thirty-five amunas.

I am so satisfied with this experiment that I would recommend that six sprayers may be supplied to my district with the necessary insecticide, so that they may be used simultaneously all over the district in future occasions—I am, &c.,

JAS. A. WICKREMATNA,
Mudaliyar, Weligam Korale.

NOTE BY THE ASSISTANT GOVERNMENT AGENT.

The sprayer is a copper vessel containing about 4 gallons of liquid. It is slung on a man's back and easily worked by him, the pump handle with one hand and the jet with the other. I obtained my sprayer from Mr. J. H. Starey, of the Eastern Produce Company, at a cost of R68.27 in Colombo.

The London Purple is used in the proportion of 1 lb. to 100 gallons of water. It costs, I think, about £2 per cwt. in London, and it is sold by the Hemingway's London Purple Company, Limited, London and New York. One pound is sufficient for about ten acres of paddy. C. J. R. LE MESURIER,
Assistant Government Agent.

BRAZIL COFFEE.

In their Market Report, dated on the 13th Augt. Messrs. Vaughan, McNair & Co., of Bahia, says: "In the superior grades of coffee, values are steadily rising, whilst the lower qualities, of which but few are bought by exporters, prices remain very steady. It is expected that most of this season's coffee will pass through the hands of the machine cleaning companies before reaching exporters. Crop reports continue of the best and a total harvest of not less than 400,000 sacks is expected. Some dealers expect fully half as much again, but we consider the figures given as being nearly correct."—*Rio News*.

THE PLANTING ENTERPRISE OF CEYLON:

IN TEA, COFFEE, CACAO, CINCHONA,
CARDAMOMS AND MINOR PRODUCTS:
EXTENT OF CULTIVATION UNDER
EACH PRODUCT IN AUGUST, 1893.
NUMBER OF PLANTATIONS AND
SUPERINTENDENTS, &c.

No tropical industry—and probably no agricultural enterprise outside the tropics—has had so much care bestowed on the compilation of substantially accurate statistics concerning its position and progress as has the Planting Enterprise of Ceylon in the products above-named and to a lesser extent in Coconuts and Cinnamon. Thirty-seven years ago it was a comparatively easy task to frame a list of the then limited number of plantations in cultivation, and to sum up a cultivation confined entirely to one product. This was done by the Planters' Association in 1856; but no further attempt was made to collate the acreage in cultivation, for thirteen years afterwards, until 1869, when the present compiler first prepared a complete "Directory" with this information. Since then at twelve distinct periods—in 1871, 1873, 1874, 1875, 1877, 1881, 1883, at end of 1885, in the middle of 1888, of 1890, of 1891, and now in the latter half of 1893,—the compilation has been carefully made and the position of the Planting Industry accurately gauged, our figures being adopted not only by planters and merchants, but by the Government and Civil Servants as the only available and reliable returns of an Industry which has been regarded as the backbone of the prosperity of the Colony. We have, in fact, at the expense of much time and labour for twenty-four years back, been doing the work which properly appertained to the Agents of the Government, and supplying information which in other Colonies and Dependencies is only to be found in official publications. However, we have had our reward in the intimate acquaintance it has given us with all the phases of the most important industry of the country and in being enabled to follow closely each successive development of new branches of that industry. Especially interesting, although involving far more trouble, has been the work of collating the statistics since a variety of new products has been added to our old staple; and never perhaps has so much pains been taken as on the present occasion to secure accurate returns of the area planted with the all-important new staple, TEA, and with minor Products, although no one can be more conscious than the compiler of the impossibility of attaining perfect accuracy. Still for all practical purposes we believe, the results derived from our tables, may be taken as reliable statistics from which to gauge the present position of industries, the importance of which as regards the revenue, trade and general well-being of this community, cannot be overestimated.

Taking first the total extent of the properties included in our Directory, namely 724,805 acres,—there is an increase of 36,973 acres on the return made up at the middle of 1891. This is owing chiefly to the inclusion of some 10,000 acres of land fit for tea-planting in native hands in Balangoda district and about the same extent added in "low country divisions," while the new district of Passara involves an addition of 3,000 acres beyond what was included in both it and Badulla formerly. Then there has been an addition of 3,500 acres, through land sales, to the Kelani Valley District, and further areas added to Panwila, Matale East and West through land opened at Ukuwela; and in other districts due to the revival of old properties

for tea, that had fallen out of cultivation and notice. In other directions, more correct returns have slightly increased or reduced the totals for each district.

Turning to the more important figures representing the area now in cultivation with tea, coffee (Arabica and Liberica), cinchona, cacao, rubber, and the host of new and old products with which experiments are being made in different quarters, we find the grand total to be 353,235 acres, or an increase of 19,282 acres on the middle of 1891. This addition of 19,000 acres may not be considered much for the two years, more especially when it is remembered that over 2,200 acres additional have been brought into cultivation, in the Kelani Valley alone, and 3,000 more in the minor Western Province "lowcountry" districts in the interval; while Panwila, Matale West and the higher districts show additions; and there is a distinct extension of cultivation in Eastern Uva if we take the Badulla, Passara, Madulsima and Monaragalla group together. But old coffee land has continued to be "abandoned" within the past few years in other directions, though much of the extent, of course, was in a semi-abandoned state for several years back, and chetty and native plantations make up a certain proportion. Still, in respect of old coffee land, a revival has come in favour of tea. In Maskeliya, a comparatively young district, our cultivated return in 1883 was lower than in 1881 by 2,000 acres, indicating how coffee had then fallen out of esteem there; but all this has now been more than recovered under tea. On the other hand, it is noteworthy that neither in Dimbula nor Dikoya has any land gone out of cultivation—and the same is true of most of the Uva districts which with the higher and younger divisions, never showed so large an area in cultivation as at present. That the total area under cultivation—after careful checking and verification of the returns—should stand so high as 353,235 acres (or over 550 square miles), notwithstanding the adverse experiences of coffee and cinchona, is matter for surprise and gratulation, and shows how widely tea has been planted and how satisfactory so far, have been the results.

Considering the efflux of planters from our shores during the period of coffee depression, no one will be astonished to learn that the total number of Superintendents fell from 1,389 in February 1881 and 1,108 at the end of 1883 to 1,079 by December 1885. Since then, however, the turn of the tide has set in steadily; for we had in July 1888 as many as 1,136; increased by June 1890 to 1,211; and by August 1891, to 1,258; while now we have the full number of 1,334 Superintendents and Assistants corresponding to 1,439 estates in cultivation out of a total of 1,949 properties. It is probable that more than 300 European planters left Ceylon in the four years, between 1881 and 1885; but a considerable number afterwards returned, while a large quota of young men "to learn tea" have been added to the number of Assistant Superintendents. Perhaps we may fairly say that our planting community diminished at the rate of sixty Superintendents or Proprietor-superintendents a year, between 1880 and 1886—and that about 260 or about 40 per annum have since been added of old colonists returned or new men from home. The total now is very nearly as high as in the height of our coffee prosperity; but it is noteworthy that the number of separate plantations has decreased during the past two years, a fact explained by the aggregation of small properties into one charge under the process which has given us so many Limited Companies among "tea" estates.

The analysis of the Cultivated Area is, however, of more practical importance than the foregoing total results. We must explain the principle on which the returns have been compiled. After giving the matter a fair trial, on a former occasion, we found it quite impossible to work out a suggestion made to us of securing returns from each estate of the number of trees (in thousands) of each product. In respect of all products, save cinchonas, we had to fall back on the old plan of acreage returns, asking for the figures representing each product whether cultivated in fields by itself or interspersed with others. We have thus obtained, as far as possible, the acreage in tea, coffee, cinchona, cacao, cardamoms, &c., planted alone; of tea or coffee intermixed, or planted with cinchona, or cacao or rubber; also of each of the minor products separately; and of tea and cinchona; cacao and rubber, &c. The total results under each head may be seen at a glance from the following:—

(August, 1893.)

	Acres.
Total extent of Tea planted by itself ..	263,200
Do of Coffee (<i>Arabica</i>) cultivated by itself ..	22,448
Do of Coffee (<i>Liberica</i>) ..	544
Do of Cinchona do ..	3,074
(besides 1,427,000 trees partly alone and intermixed),	
Do of Cacao by itself ..	13,322
Do of Coffee and Cinchona interspersed ..	3,115
Do of Coffee and Tea interspersed ..	8,789
Do of Coffee and Cacao do ..	3,006
Do of Tea and Cinchona do ..	5,409
Do of Tea and Cacao do ..	890
Do of Tea and Liberian Coffee do ..	146
Do of Cacao and Liberian Coffee do ..	566
Do of Cardamoms alone ..	4,537
Do of Rubber do ..	265
Do of Tobacco do ..	42
Do of Cotton do ..	109
Do of Other Products and some of the above mixed ..	24,071

[Some Cacao and Liberian Coffee are mixed with Annatto, Coconuts and other products.]

To arrive at a fair estimate of the total extent which may be taken to represent each product, we have, in the case of cinchona growing among coffee or tea, taken from one-third to one-fourth the acreage for the cinchona, and credited two-thirds or more to the staple. In the case of coffee and tea, or coffee and cacao, being planted together, we have divided the acreage into two equal parts. Of course, this would not be a fair criterion in every case: some planters who may have their 100 acres of tea or coffee interspersed with 20,000 cinchona trees will maintain that the tea should still be reckoned at the full 100 acres plus the cinchona. But knowing as we now do by experience that the cinchona, where it matures, does not benefit the other product, but the reverse, it is misleading to count the full acreage of the staple, in addition to a certain extent of new products interspersed. However we have left the figures in the Directory lists and in our tables as returned to us from the estates and agents, to speak for themselves, and it is possible that some may consider the tea and coffee area should be counted in full even when mixed with cinchona, cacao, or rubber. We have no doubt, however that the majority will agree with us that, analyzing the above figures in the way we have pointed out, and with a moderate estimate for the average number on cinchona trees per acre, the position of the Ceylon

Planting Enterprise at the end of August 1893 may be represented somewhat as follows:—

	Acres
Total area of 1,949 plantations and planting properties...	724,805
Do do of 1,439 plantations in cultivation with 1,334 Superintendents and Assistants..	353,285
Total approximate extent under TEA ..	273,015
Do do COFFEE (<i>Arabica</i>)..	30,096
Do do COFFEE (<i>Liberica</i>)..	2,438
Do do CINCHONA [6,909,000 trees over 2 years.]	16,286
Do do CACAO ..	4,723
Do do CARDAMOMS ..	551
Do do RUBBER ..	62
Do do TOBACCO (by European)...	153
Do do COTTON do ..	4,270
Do do GRASS (Cultivated). do of Annatto, Cooa, Vanilla, Pepper, Cloves, Plantains, Citronella grass, Divi-Divi, Croton, Castor-oil, Aloes, Cinnamon, (on the coffee, tea, or cacao plantations)...	4,425

Of Fuel, Timber and Fruit-trees, Span, Coconuts, Arecas, Nutmegs, Kapuk (on the tea coffee or cacao plantations) .. 12,835

We have 2,500 fewer acres under Coffee now than in the middle of 1891, and more than 2½ million trees fewer of cinchona. On the other hand we have an increase of nearly 23,500 acres in the staple (Tea) which is of chief interest. The cultivation of Cacao shows an increase of 3,300 acres which is very satisfactory as is also the extent added (800 acres) to Liberian Coffee, while the extent in Cardamoms and minor products has either been stationary or shows a decrease due to the great attention given to tea in the past two years. In giving 273,000 acres as the total area of tea it must be remembered that a certain proportion of clearings planted during the current south-west monsoon, are included. Nevertheless it is clear that 275,000 acres of tea will shortly be reached, and exceeded were it only through the supercession of both coffee and cinchona where these are at present intermixed with the staple, in the proportions credited this time to the latter products. We may expect indeed to see the 8,789 acres at present credited to tea and coffee, altogether tea, and so with cinchona and tea, so that we are quite prepared to find our once great staple reduced from 272,000 acres (as in 1877) to 25,000 acres by the time we make up another return; while on the other hand tea will probably be represented by 280,000 acres in full cultivation before the middle of 1894, even if there be no more new clearings.

In the returns of 1883, the considerable number of plantations with "abandoned" opposite their names, attracted attention: altogether they aggregated 53,540 acres; at the beginning of 1886 the aggregate was 40,000; but in the middle of 1888, the total of 298 "abandoned" properties stood at 69,432 acres; in July 1891 there were entered about 293 "abandoned" properties containing 73,262 acres; while now through more careful returns the total number is 324 with an area of 74,217 acres; but a certain proportion of this extent, —probably one-third—must still be considered reserve and untouched forest or chena land, and the increase is chiefly due to native-owned plantations, as well as to some properties lost sight of, being brought on our list.

Of good forest reserves mentioned in many of our district returns, though not in all, the aggregate is about 60,000, but, even if we add one-third of the

abandoned, making a total of 85,000 acres, we feel sure this is far below the actual extent of forest-land in private hands. How then is the difference between the total area of 725,000 acres and the cultivated area of 353,000 namely 372,000 acres to be accounted for? Our estimate would be that of forest land fit for tea, cacao, Liberian coffee or other products, there are counting all reserves and unopened blocks about 120,000 acres in private hands; that 50,000, acres represents the area of land once cultivated, but abandoned within the last 30 years and now growing up in weeds and lantana, and that the balance of about 202,000 acres may be put down as representing chena and patana (a good deal of both fit for cultivation,—especially in Uva, where patana land is turning out so well in tea—should prices of produce keep up) besides swamps and other utterly waste portions.

CEYLON TEA IN AMERICA.

A gentleman largely interested in tea has kindly favoured us with his views regarding the necessity for steps being taken at once to carry out the suggestion of our Chicago Commissioner for the establishment of stores in the principal cities of America. He says:—

"The efforts being made by Ceylon at the Chicago Exhibition for the introduction of Ceylon tea into America have been engaging the attention of all interested in the welfare of the colony and especially of those who are engaged in the tea industry. A large expense has been and is being incurred, the main object of which is to get an entrance for our teas into America. It was at one time hoped that through the agency of the Ceylon Planters' Tea Company much in this direction might have been done, but as this organization has ceased to exist, the question is now forcing itself on the minds of all thoughtful people—what is to be done when the Exhibition closes and the Commissioner leaves America? Attention seems to have been more forcibly drawn to this question since the receipt of recent letters from the Hon. Mr. Grinlinton. In his latest letter to the Planters' Association, that of 7th July, he puts the matter more plainly than on any previous occasion, and presses home the urgency of it in a manner that will demand the most serious attention of that body. He points out that there ought to be agencies or stores in the principal cities where purchasers can obtain supplies of Ceylon tea. He has found that grocers generally show an unwillingness to sell the tea, and this of itself is a serious obstacle that has to be surmounted. He appeals to the Planters' Association in the hope that those interested will provide the funds that may be necessary. Not only is a good deal of money required, as the experience of the old and also the new American Tea Companies amply testify, but men with plenty of energy and push are needed as well to persevere with the work in which men like McCombie Murray, Arthur, Pineo, and Elwood May have failed. It is useless for us to shut our eyes to the want of success that has hitherto attended efforts. We must face it, try to discern where these efforts have been misdirected, and endeavour to avoid in the future any mistakes that may possibly have been made in the past. As regards the finding of funds I do not know what the feeling amongst planters generally may be, but I am inclined to think that but little would be voluntarily contributed in Ceylon after all that has passed to carry on the work. The suggestion has been made that through the Ceylon Association in London funds might be obtained; but in that direction, too, I fear there will be but little inclination to find money. To me it seems that the fairest and most effectual way of providing funds would be by the continuance of the export duty at the Customs here, for as long a period as is necessary to provide the

sum required to continue the efforts to introduce Ceylon tea into America after what is now being done at Chicago is concluded. As a tea-grower myself I would willingly agree to the continuance of this levy. Assuming that by this means the money should be obtained, the next question is—by what means or through what organization are the men to be found to give effect to what is desired. A good many people may say leave this to private enterprise and let Ceylon tea make its way; but if only this is to be done we may find that we might as well have saved all the money expended and kept our Commissioner in Ceylon. That there is some fear of this I am somewhat apprehensive and my reason for this feeling is as follows. I see by Mr. Grinlinton's letters that the attitude he seems to feel himself bound to observe is that of a representative of the Ceylon Government and the Planters' Association, prevented as such by the very nature of his position, from personally engaging in any undertaking which would savour of personal gain. And whilst furnishing all the information in his power to those who desire to be made further acquainted with our Ceylon teas and putting them in the way of obtaining them, he does not seem to feel at liberty to enter into arrangements for the further permanent introduction of tea beyond providing this information and selling tea in packets in the manner he describes. Now if this is carried to its extremity we shall not find ourselves very much further forward at the close of the Exhibition than we were at the start. What is wanted now as it appears to me is that the Government and the Planters' Association should without delay give Mr. Grinlinton a free hand and let him know that his position as Commissioner need not prevent him from entering into any arrangements he deems fit in the interests of the Ceylon tea industry for the establishment of such agencies as he indicates to be necessary, using every reasonable safeguard to ensure his being honestly dealt with. So long as his hands are tied, or so long as he believes them to be so, it is obvious that we need not look for the important results we are all hoping for; but if he is given freedom of action to take such measures as in his judgment seem expedient and likely to be successful, then I think he would at once be likely to set about organizing the stores which he recommends should be established. It may be that many who have read Mr. Grinlinton's letters may not have been impressed in the same way as I have been and as I have endeavoured to describe, but I would invite attention again to these letters, and as there is no time to be lost I would earnestly urge the Government and the Planters' Association to consider well all that Mr. Grinlinton has put forward. My suggestions I submit with all diffidence because, I feel it is a very large question and one that seems to have an important bearing upon the future of our industry, seeing that exports of tea from China are increasing and that prices in Europe are declining. We are now in the month of September and the Chicago Exhibition will close at the end of October. There is therefore no time to lose and the urgency of the situation and need for immediate action goes without saying."

The tea planters of Ceylon may well cry where and when is this sort of demand on their pockets to cease? After voting £20,000 (since increased by some thousands) for a Show at Chicago which was to conquer America for Ceylon tea, they may well be taken aback at a proposal to spend still more money in order to push their teas into demand. The Customs Cess, to cover existing debt, will have to run on to the end of 1884—perhaps into 1885. To guarantee or vote expenditure, which may involve its continuance for a further *indefinite* period, is a rather serious matter. And yet what is to be done? If the inference from the Commissioner's letters and reports is, that notwithstanding the ready way in which Ceylon tea is being

drunk and sold at Chicago now, there is not mercantile or private enterprise enough to follow up the "Show" and profit by its advertisement, then can the Ceylon Courts and our tea be really said to have made a due impression and to be the *practical success* credited to them? We do not know, of course, how far Mr. Blechynden is justified in his reports; but he has stated to his Association that some Chicago Stores are eager to buy and sell Indian teas as the result of his Indian Tea-court and canvas. And again, our correspondent "T. A. O." discovered an "Imperial Company" at Detroit, already selling Ceylon tea; and surely the business of such a Company will receive a great impetus from the work of the Ceylon Courts. But will there not be the danger of setting this Company and other dealers or would-be dealers in our teas, against "Ceylon's" if they find the planters promoting rival retail Stores? These are questions which ought to be duly considered. For, it would be a thousand pities if private enterprises were interfered with and discouragement offered to the importation and distribution of our teas by native American Companies or Firms.

On the other hand, if it be decided by the planters themselves that a free hand is to be further given to the Commissioner to open one or more Ceylon Tea Stores, we should say that the best way would be to work through the Ceylon Tea Company, making Mr. Grinlinton in his private capacity, Agent for the Company and affording the necessary guarantee either from the Tea Fund Committee, or the Planters' Association as more fully representing the Customs Cess. We should much prefer the latter; because we think the Tea Fund resources are very specially required for, and are more likely to produce earlier and bigger results by being devoted to, Russia and the back-country of the Australian Colonies. Our Commissioner ought to be able now to say definitely what his Exhibition expenditure is likely to aggregate, and if he were to estimate how much would be required for two or three years to run the required Ceylon Tea Stores, the planting representative bodies would be in a better position to judge how long their "Cess" would take to cover the whole. The Government grant is, of course, only promised for the Exhibition expenditure. The Customs Cess by itself would next year, probably produce about R85,000 and in 1895 over R90,000.

SOME OF THE OLDEST TEA IN CEYLON: LOOLE-CONDURA FIELDS.

Time after time, it was our pleasing duty to inquire of worthy James Taylor as to the condition of his oldest tea fields planted between 1866 and 1869 and his reports were uniformly satisfactory. Mr. Taylor is alas no more; but the present Manager of Loole Condura (Mr. G. F. Deane) very readily responds to our wish to have information for the "Ceylon Handbook and Directory." What Mr. Deane has written, will be read with interest by all who wish well to the permanency of the tea industry in Ceylon:—

LOOLECONDURA, DELTOVA, Aug. 31.—In reply to yours of yesterday's date I am pleased to tell you that the oldest Tea field here, Assam Hybrid planted in 1863 or 1869 (20 acres), is full of vigour showing no signs of decay and up to date from 1st January last has given yield at the rate of 471 lb. made tea per acre per annum. The Tea (apparently China Jat) planted out along roadsides in 1866 now 2 years old is also flourishing and yielding well. And we infer that very little manure, and that only at intervals, has been given to this good old tea.

TEA-BOXES' SHOOKS FOR CEYLON FROM BRITISH COLUMBIA.

The start of the steamship service between Australia and Canada is, according to the *Canadian Gazette*, already suggesting new developments of Canadian trade, and Mr. J. B. Spencer, (Mr. J. A. Spence) of Ceylon, has made arrangements with the Rathburn Company, of Deseronto, for a trial shipment of shooks for the construction of tea-boxes. The wood now in use is obtained from Japan, but the Douglas fir of British Columbia, the Ceylon man says, is far superior to it.—*Pall Mall Gazette*, Aug. 5th. [We suppose the shooks are to come to Yokohama and thence to Colombo.—Ed. T. A.]

CINCHONA IN JAVA.

AMSTERDAM, Aug. 9.

A planter of Cinchona bark in Java has sent an open letter to the Chamber of Commerce in this city in connection with the report of the latter on a question made by the Minister of the Colonies, what to do to improve the deplorable condition of the article. The Chamber had advised the decrease of the Government's cultivation. In his letter the writer points out that it is urgently necessary to avoid the total ruin of the cultivation by the low prices ruling at present. According to the statistics the private undertakings will produce during the current year a total quantity of 3,482,839 kilos bark. The number of undertakings is 82, so that the average production of each undertakings is 42,486 kilos, with an average of 4 27-100 per cent. sulphas quinine. About the half of the undertakings are situated too high to enable the cultivation of any other produce, and thus these undertakings will be a total loss. Calculated at an unit value of 5 cents (which price, however, receded in the auction of July 6, last to 3-6-10 cents), the yearly proceeds of an estate producing 42,486 kilos would be f.18,141, from which is to be deducted freight and charges in Amsterdam, f.3,398, so that there is a balance of f.14,741. With this amount the working charges cannot be covered. The existing system of selling at any price, adopted by the Government, should not be maintained, or if this is impossible the lots of private importers should be offered at auction before those of the Government. Probably in this way an improvement of prices would take place.—*L. and C. Express*.

COFFEE PROSPECTS IN NICARAGUA.

An American resident of Matagalpa, a coffee district in Nicaragua, states in the *Boston Herald* that there is now in the centre of Nicaragua a forest of coffee land 300 miles long and 200 miles wide, which is not yet explored. There are three ways for a man to begin the coffee business in Nicaragua—buy land from the Indians, buy government land, or make a private purchase from a regular resident. The first way appears to be the best from the fact that in getting Indian land you have generally something with which to begin operations. The land is in condition partially; the plantations must always have some trees on them—probably 4,000 or 5,000—which give the purchaser a start. It takes five years for a tree to bear from the planting, and if you purchase an Indian plantation the trees will be from two to three years old when you purchase. Thus while your young trees are getting their five years' growth, in two or three years your Indian trees will be bearing enough to pay expenses. You can buy 100 or 200 acres of this Indian land with the trees for \$500. These plantations are commonly known as "fincas." A "finca" is a plantation for a certain purpose; that is a coffee finca would be a plantation for the cultivation of coffee and nothing else. There are banana fincas and cocoa fincas. In getting government land one has to start from the very beginning

and wait four or five years for any profit. Government land including all expenses, such as surveying, etc., cost \$1.50 per acre. In making a private purchase one must pay from \$5 to 7 per acre. If a man will promise to build a house, no matter what kind of a building he puts up, the town of Matagalpa will give him a lot. The best coffee is raised on high ground, Matagalpa is nearly 3,000 feet above the sea level, and the coffee there is considered very good quality. In that section of Nicaragua there have been planted by Americans 3,000,000 coffee trees in the last three years. Most of the men from the United States appear to be from Chicago. Many are from Milwaukee.

A man should not go there with the idea of buying land, starting a plantation and then leaving it in charge of an overseer and returning to the United States when he pleases; but he will stay long enough—say five years, until his place is in thorough working order, he can live six months in the United States and six months in Nicaragua very easily.—*American Grocer.*

WHERE THE TEA-BUG BREEDS.

A planting correspondent in writing to a contemporary, having mentioned (on the authority of Mr. P. D. Clarke) that *Helopeltis* breeds freely on a weed (*Stachytarpheta Indica*) which should be eradicated, we applied to the Director of the Gardens for confirmation, or otherwise, of this important piece of news. Dr. Trimen is good enough to write:—

“Mr. Clark is unfortunately away from home today so I cannot ask him what he knows about *Helopeltis* breeding on *Stachytarpheta*. It is possible, but not very likely. The eggs are so peculiar that when once seen they cannot be mistaken—white, with 2 long horns at one end. The insect certainly breeds on tea and on cacao and on cinchona, and probably on a good many other plants; but I should expect them to be woody plants, not herbs like *Stachytarpheta*.—To attempt to eradicate the commonest weed we have, even commoner than lantana, will give a good deal of work.”

FORMOSA AND CEYLON.

Formosa—the Beautiful Island—attracted a few years ago a great deal of attention from residents in the Far East because of the extraordinary activity of the Chinese Governor, Liu Ming-Chuan, who laid down railways, built elaborate forts, imported Armstrong guns and waged perpetual war with the aboriginal savages. Little, however, is known about it by most people in this country, and therefore a Foreign Office paper just written by Mr. Alexander Hosie, our Acting Consul at Tamei, deserves special attention, because it is a most admirable summary of the characteristics and commercial possibilities of the island and its products. Americans know more about Formosa than we do, for its particular brand of tea is greatly appreciated by them, so much so that the Ceylon tea-growers have tried in vain to imitate it.—*Daily Chronicle*, August 18. [This is quite new to us in Ceylon.—Ed. T.A.]

THE DUTCH CINCHONA-SALES.

(From our Correspondent.)

AMSTERDAM, August 10.

The cinchona-auctions to be held in Amsterdam on August 31st will consist of 365 cases and 6,185 bales (about 553 tons), divided as follows:—From Government plantations, 341 bales (about 32 tons); from private plantations, 365 cases and 5,844 bales (about 521 tons). This quantity contains—Of druggists' bark: *Succirubra*—quills, 250 cases; broken quills and chips 55 bales 115 cases; root, 57 bales. Of manufacturing-bark: *Ledgeriana*—broken quills and chips, 4,503 bales; roots, 834 bales. *Hybrids*—broken quills and chips, 646 bales; root, 78 bales. *Officinalis*—broken quills and chips, 12 bales.—*Chemist and Druggist*, Aug. 19.

RARE AND LARGE INSECT.

Capt. Whitley of the e.s. “Lady Gordon” on his last voyage round the island picked up a curious and unusual beetle visitor at Hambantota. It has been prepared and preserved by Mr. Haly who says of it:—“It is one of the large Indian Longicornes (*Cerambyridæ*) probably *Acanthophorus serrateicornis*; but I am sorry I cannot name it with certainty at present.”

COORG COFFEE IN DUMBARA VALLEY.

We have the following encouraging account from a correspondent of a coffee clearing in Dumbara:—“Coorg coffee planted here in June-July last year is at present most promising. The trees were topped at 3 feet some time back and they have spread out well and cover the ground. A great many have crop set on them and what is most satisfactory is that there is very little leaf-disease noticeable, whilst other and older coffee in the neighbourhood is being ravaged by the disease. Of course where the soil is indifferent or where plants from inferior seed have been put out, there are vacancies and sickly trees, but taken as a whole, it is a most successful clearing and quite equal to the best of clearings in the olden golden days. It was planted with cacao at the same time, so has not a fair chance.”

DELI NEWS: TOBACCO CROP PROSPECTS.

During July, says the *Deli Courant*, the weather took a dry turn, from too little rain falling, especially on the low lying estates. The drought was followed by rain in the beginning of August, and most of the planting companies consequently consider the outlook either satisfactory or favourable, though the dry weather had taken bad effect on the later planted crop. The drought, on the other hand, proved favourable for cutting the ripening crop, so that on many estates, two-thirds of the latter have been thus disposed of. The tobacco that has so far reached the sheds, comes in for much praise from the leaf being fine. The seedling disease shows itself in several places, and extensive nurseries have been laid out in consequence. The shipment of last year's crop has almost all been carried through. On several estates, preparations are in full course for next year's crop.—*Straits Times*, Aug. 22.

TROPICAL ROOFS.—The native of the interior of Ceylon—says the *Scientific American*—finish walls and roofs with a paste of slaked lime, gluten, and alum, which glazes and is so durable that specimens three centuries old are now to be seen. On the Malabar coast the flat bamboo roofs are covered with a mixture of cow-dung, straw, and clay. This is a poor conductor of heat, and not only withstands the heavy rains to a remarkable degree, but keeps the hute cool in hot weather. In Sumatra the native women braid a coarse cloth of palm leaves for the edge and top of the roof. Many of the old Buddhist temples in India and Ceylon had roofs made out of cut stone blocks, hewed timber, and split bamboo poles. Uneven planks, cut from old and dead palm trees—seldom from living young trees—are much used in the Celebes and Philippine. Sharke' skins form the roofs of fishermen in the Andaman Islands. The Malays of Malacca, Sumatra and Java have a roofing of attaps, pieces of palm leaf wicker work, about three feet by two in size and an inch thick, which are laid like shingles and are practically waterproof. The Arabs of the East Indies make a durable roof paint of slaked lime, blood and cement. Europeans sometime use old sail made proof against water, mould, and insects by paraffine and corrosive sublimate—for temporary roofs.

MR. JOHN HUGHES AND TEA ANALYSES.

The delay that has attended any decision by the Planters' Association about securing the services of a Chemical Expert for the purpose of locally analysing teas, reporting on fermentation, &c. will not have to be regretted should it result in a full prior understanding of the nature and scope of the services he would be expected to render. For there is no doubt that what would be required must necessitate a stay in the island of considerable length and of consequent costliness. If examination into all the questions to which answers are required is to be made at all, it must be made with a thoroughness which alone could give value to the results sought to be attained. It appears from what our London Correspondent writes us on this topic by the present mail that inquiries have been addressed by our local Association to Mr. Hughes by which it is sought to ascertain details as to the course that gentleman would recommend. To these queries the well-known Analyst finds it difficult to succinctly reply. It is, he declares, impossible to wholly foresee how far it might prove desirable to carry on the experiments to be made; and in many respects he thinks the questions put can best be solved here by experienced planters rather than by himself. He has suggested, however, that a safe preliminary step might be for himself to personally make some fifty analyses of samples of tea to be selected and forwarded to him by the Association. These samples, Mr. Hughes presumes, would include teas from estates of varying elevations and of differing conditions of manufacture. With the results to the analyses of these, carefully tabulated, the Association Committee would have before it a tolerably good index to the work which in the future should be carried on locally. Mr. Hughes has given a price for this preliminary work, and we think it should be undertaken with as little delay as may be possible. For although many among us differ as to the mode of procedure to be followed, all, we conceive, unanimously agree in attaching value to a more intimate knowledge of the chemistry of tea than is at present possessed by us. Earlier communications of Mr. Hughes to the Planters' Association having led to no results, he communicated the data of his last experiments—made voluntarily and gratuitously—to ourselves rather than run a further chance of their being ignored by the body most concerned with them. Such a course, however complimentary it may have been to this journal, we hope will not in the future have to be followed. As Mr. Hughes observed, he had no personal interest to serve in making the analyses he favoured us with. But he deemed that in ignoring the subject as it had done, the Association shewed itself hardly alive to the importance of the investigation he suggested, and therefore, he took it up *con amore* in the hope of awakening general interest in the subject. That he has been successful in doing this is evident from the wide comments upon the articles we have published made by the Indian newspapers. More especially has the subject of "stalk in tea," to which Mr. Hughes prominently directed attention, attracted the notice of our *confreres* on the other side of the water, and no doubt his communications generally will prove to be fruitful of results.

During the course of recent conversation with Mr. Hughes by our London correspondent, the latter touched upon a point which we believe to have an important bearing upon the question of the permanence of tea and the necessity or otherwise for returning to the soil the constituents of which it is deprived by the growth of the plant. It will be recollected that Mr. John

Roberts, while assigning a high value to the experiments detailed by us, declined to accept them as conclusive unless he could be informed as to the character of the samples of soils upon which they were conducted. Were these "he asked," "taken from the surface," which had been greatly exhausted by prior coffee cultivation, or from the depth at which the tea-bush seeks its nutriment." This question Mr. Hughes confesses himself to be unable to answer. He has in his possession at large number of such samples sent to him at different times, but without that full classification and description that would enable him to satisfy Mr. Roberts' objection. It is precisely such a cause for doubtfulness that we should desire to see removed by those whom we hope to see entrusted with the duty of selecting samples, both of soils and teas, for Mr. Hughes' further proposed experiments. As we have said, Mr. Hughes, expert as he is, has hitherto been working voluntarily on our behalf, and could only make use of such material as he had at hand. If commissioned for further investigations by our Planters' Association, the above difficulty—one that undoubtedly reduces the value of his previous work—must no longer be allowed to operate. A further matter that received mention by Mr. Hughes was a suspicion expressed by the Association that the samples of tea analysed by him might not have been of pure Ceylon tea: that indeed he might have been supplied with blended teas. Mr. Hughes gives us the assurance that the method he adopted for securing these left little or no chance that so fundamental an error could have been made, and we think, therefore, that it may be assumed that he worked upon data that were fully correct. At the same time, all future experiments should certainly be made upon teas specially selected and sent to him under the *ægis* and seal of the Planters' Association of Ceylon.

(From a Correspondent.)

LONDON, Aug 18.

My recent efforts to see

MR. JOHN HUGHES.

were unsuccessful until the present week. I was anxious to learn from him whether he could give me the information desired by Mr. John Roberts as to whether the Ceylon estate soils on which he had experimented had been taken from the surface or from the depth at which the tea tree feeds. Unfortunately this was a point on which Mr. Hughes could not satisfy me. He is in possession of very many samples of soil, but without knowledge of the depth from which they were derived. Under these conditions, certainly the objection taken by Mr. Roberts as to forming definite conclusions on Mr. Hughes' analyses must be held to stand. What is now wanted is that these experiments should be repeated on data that would be authoritative, and which should, some of them represent the stratum in which the deep tap root of the tea tree seeks nutriment. On my asking Mr. Hughes whether he had heard anything from your Planters' Association, he replied that he had done so in the forms of queries as to what he thought should be done in the way of further investigation on the spot by an imported chemical expert. He had replied, he told me, in the sense that he could not formulate advice on the insufficient data at present possessed. He had made the experiments he had done to satisfy his own views and to awaken the Association to the importance of results that might be obtained. The letter of the Association, he further said, cast some doubt upon the genuineness of the teas with which he had experimented.

It contained, indeed, a suggestion that these might have been blended teas, and that upon such data his conclusion might have been wholly incorrect. This Mr. Hughes assured me he felt to be impossible. He had exercised the greatest care in obtaining his samples, applying for them to a firm the three members of which were his personal friends, that firm deals in China, India, and Ceylon teas, and each of the three partners has one of three as his speciality. Consequently he was content with their assurances that they had selected for him perfectly genuine and unmixed samples, as the partners had no more interest in one description than in another. However, he had, as requested by the Association, quoted a price for the analysis of fifty new specimens to be selected and sent home to him by that body. He had suggested that these should embrace samples of different kinds, having special regard to elevation and varying conditions of manufacture. He thought that when these further experiments shall have been made we shall be possessed of sufficient data upon which he could advise as to further work to be done locally; but he remarked that the last, to be efficient, must occupy a considerable time, and that the cost of them must be somewhat heavy. Therefore he should counsel further delay before this expense was incurred. Mr. Hughes thinks that Mr. Roberts' view as to the virginity of the despoiled soils of Ceylon estates can hardly be maintained, or at all events that it is generally held that that of the surface is richer than that at greater depths because it has the benefit of all vegetable decay. My reply was that it seemed to me that this could scarcely apply in such cases as those wherein the surface soil had been for years drawn upon for constituents which had not been returned to it, and I still hold this to be a correct view. It is one, however, that can scarcely be determined without

ANALYSES.

being made of the upper and lower soils taken from the same locality, and this should certainly form part of the work that Mr. Hughes suggests should be carried out as preliminary. During the course of our conversation it was pointed out to me that when writing you on the subject of the experiments made as to the quantity of stalk in different varieties of tea I had fallen into error in saying that Mr. Hughes had sorted out the stalk before infusion. This he told me it would be quite impossible to do. It was only after the expression arising from infusion that it was possible to separate the stalk from the leaf. My error, however, in no way affects the conclusions drawn. It was further remarked to me that the Association seemed to think the analyst had shown it some neglect in having communicated the results of his last work to yourselves instead of to its Committee, but Mr. Hughes explained that his previous communication had met with but scant attention, and that to fulfil his purpose of awakening interest in the subject he could not have done better than in asking yourselves to oblige him with free and full ventilation of it. His work had been gratuitously done, and he was at liberty to seek his own channel for publicity. If specially retained and paid, of course he would be bound to communicate only with the Association.

A PECULIAR DISCHARGE OF LIGHTNING.

To the Editor, Nature.

I should like to add to the many recent accounts of lightning discharges the following particulars of which I have not yet seen any published account.

On the afternoon of Wednesday, July 26th during a storm at about 5-30, a blue flame was observed by some of the inhabitants of Epping to approach and shatter the chimney of a house upon the hill, occupied by Mrs. Brown and family at the time.

An examination of the interior of the house shows the discharge to have passed chiefly by the bell wires which are fused, down one corner of a room upon the upper floor, breaking the back of a chest of drawers near, and setting the wall in the vicinity on fire.

On the ground-floor the discharge seems to have taken two paths to earth, viz. down the corner of a front room by means of some metallic damp-proof paper, and in the kitchen adjacent by means of some wooden cupboards, the doors of which were much broken and thrown across the room.

Mrs. Brown, who was seated in the front room, states that a few seconds before the house was struck she noticed what appeared to be a darkened space, surrounded by a crimson fringe of flame in the corner (perhaps a brush discharge), and her son in the kitchen at the time testifies to having seen a similar thing previous to what appeared to be the bursting of the luminous mass, which occurred with a loud report filling the house with smoke and the usual accompanying smell of ozone. The walls are much damaged, and the polarity of a small compass in a drawer of side-board nearest the path of discharge was reversed. I considered the apparent forewarning of the brush discharge of sufficient interest to justify this letter.

MONKEYS AND COCONUTS.

Among the presents given to the Shah of Persia by British traders in the 17th century were some monkeys; and this is how they were caught:—

"We took coconuts from the trees, cut a hole that the hand of one of them might go in, which they finding thrust in their hand, and could not withdraw it unless they drew it back empty, which their covetous nature permitted not, ensnaring themselves thereby."—London *Athenaeum*.

PLANTING NOTES FROM COORG.

Aug. 18.—Although leaf disease has shown up in patches, coffee is, on the whole, looking extremely well. A very good plan of helping trees to tide over the disease consists in giving them a small dose each of some quick acting manure, like nitrate of soda, &c., and following it up by a renovation pitting &c. I noted some trees treated in this way last year which have not had a return of the disease this season.

Owing to the success as regards crops which has attended the constant renovation pitting and applying of manure round the stems of the trees on one set of places in North Coorg, this work is coming into general favour and large acreages in Santikrppa are being pitted. It is likely, I am afraid, to supersede digging. This style of work is more in consonance with the practice in orchards at home, where a trench is dug some distance away from the trees to prevent injury to the fruit producing fibres, and the coarse roots producing roots are bared and served, manure being applied all round the trees between the trenches and the stems. This treatment forces the trees to crop heavily. The only danger from constant renovation pitting is increased borer.—*M. Mail*.

PLANTING IN NETHERLANDS INDIA.

CINCHONA.

At a recent meeting of Cinchona planters held at Batavia, it was decided to restrict the output of bark owing to the glut of unsold bark in the markets in Europe. It was also resolved to ask the Government to lessen the load of taxation on cinchona planters. Stress was laid on the need for the Government to limit sales of its stock of bark in Europe, and to stop collecting bark on its plantations until better times set in.—*Straits Times*, Aug. 22.

VARIOUS AGRICULTURAL NOTES.

THE SYLHET TEA COMPANY AND CEYLON ESTATES.—We do not think we are betraying any secret when we say that Mr. A. Y. Buchanan has come out to represent the Sylhet Tea Company in Ceylon, and to see what prospect there is of any large extent of land or estates being secured for that Company. He has already paid a visit to Dimbula and Dikoya, and left this afternoon for Rakwana via Ratnapura. Mr. Buchanan will see many changes in all the districts he visits since he was last here, but we should think that he would experience great difficulty in securing such a large block of tea or tea land in one locality as he is reported to be after on behalf of the Company he represents, unless he is willing to pay a very high price for it indeed.

THE TROPICAL ENGLISHMAN.—That the active habits of the Englishman (or Britisher) preserve him from the effects of a tropical climate has long been the belief of those who have had experience in both the East and West Indies; now it receives scientific explanation and endorsement from the pen of Dr. Eijkman, of Batavia who discussing the question of "Tissue Change in the Inhabitants of the Tropics," says that they are all, especially European settlers, disinclined to bodily exertion and limit muscular work to only necessary movements. It is only the Englishman, he says true to the customs of his country, who is more or less an exception to the rule.—*English Mechanic.*

TEA AND CACAO IN FARTHER UVA.—It is cheering to hear of the progress recently made in developing tea and cacao fields in Eastern Uva. The long-neglected Moneragala district is in a fair way to come to the front after an important fashion, if only Government complete the outlet by bridging certain streams. Already cacao is doing so well that applications are in for all the remaining available forest land and there are no drawbacks now save a ready means of getting to the railway station and the stern repression of the native thieves of pods and prepared produce, who would fain imitate their Matale brethren. As there is little or no native grown cocoa in Eastern Uva, the making holders of such produce accountable for its possession would speedily put a stop to the thefts complained of, which are chiefly from and by the tavelam men, perhaps in collusion with store-keepers.—In respect of tea, the really wonderful results got from patena-land in Uva must arrest attention. In the Passera and neighbouring districts, 500 to 600 lb. made tea from young fields on very ordinary patena, is a regular experience and it is quite evident that there is special encouragement to extend the cultivation of both products in the Principality.

NORTH EAST MATALE, Sept. 4th.—We have had so much wind lately that the wonder is we have have been getting any flush at all, and compared with last year we are getting even more than we did then. Thanks are due to Dr. Trimen and your other correspondents for the interesting description of the new enemy to tea and for their suggestions as to how we should get rid of it should we see the slightest symptoms of its presence. I shall be on the look-out for it and let you know the result. This proposed method of gathering the *Helopeltis* reminds me of when I was Sinna Dorai on an estate in 1871. I was known amongst the coolies in that district as the "Poochi Dorray" from the fact of my taking the trouble of collecting every day at 4 o'clock, all the coffee borers the coolies brought me and for which they were paid a half-penny each at the commencement, and gradually the number was raised until we got I

think ten for a penny. The coolies got so used to catching them that they spotted the branch with the borer before the leaves showed the slightest decay, broke off the twig with the borer in it, rolled it up in his cloth, and went on with his work. At 4 o'clock the coolies were as busy as wood-cutters chopping up their branches and twigs, hammering them with stones or breaking them with their teeth to get out the pooches alive. They then brought them to me spread on a leaf or leaves to enable me to count them and see them put into old salt bottles. Each collector received a ticket stating the number gathered, the date, and my initials. The tickets were cashed every Saturday. The coolies were delighted with their poochi "kassie," which got for them little luxuries they would otherwise have had to go without.

CEYLON TEA IN AUSTRIA.—A contemporary is anxious to know when we visited Austria. We were in Vienna not in the Spring of 1892, but in September 1891. Austria got 74,426 lb. of Ceylon tea direct in all 1891 and 93,793 lb. in 1892. So far this year, the direct export has fallen off most miserably—less than 4,000 lb. against over 80,000 lb. to same date last year. But it is quite possible that this means a diversion of the trade to the London market. M. Rogivue's friend who had taken up the Vienna business seemed well pleased with his prospects; but he found it more convenient to buy in London; and in regard to Carlsbad, several London dealers in Ceylon teas, to whom we poke, were we know, going to try that market.

A LADY AGRICULTURAL INVESTIGATOR.—The tea planters of Ceylon are as much interested as any body of agriculturists in the investigation taken up by Miss O'Brien, who was recently awarded one of the Scientific Research Scholarships; for she proposes to investigate the question of the nitrogen supply of leguminous and other plants. Miss O'Brien has had a brilliant career. Her earliest education was received at the Friends' Schools, in Ackworth and York. After teaching for some time at the latter institution she gained an open scholarship of £25 for natural science at the Aberystwith College in 1890, and took her B.Sc. (Lond.) degree last year, with honours in both botany and zoology. In the former subject she was third in order of merit, and was alone in her class. Miss O'Brien, who is the daughter of Mr. Thomas O'Brien of Liverpool and she is to study under Professor Vines at Oxford.

INSECTICIDE: SUCCESSFUL EXPERIMENTS ON "PADDY FLIES" IN MATARA.—Last Government *Gazette* contained interesting correspondence in reference to experiments made in the Weligam Korale with the well-known insecticide "London Purple" sprayed on the paddy for the destruction of the flies often so damaging to that crop. The experiment has been made under Mr. Le Mesurier's direction and the Mudaliyar reports entire success. There is ample encouragement now to try the same experiment in other grain-growing districts and Mr. Le Mesurier suggests that as a remedy for green bug in coffee the mixture so sprayed might be effective. We should expect Mr. Stacey (who seems to have put Mr. Le Mesurier in the way of this experiment) to have given it a trial on coffee; indeed we have some recollection of a trial of "London Purple" some years ago on some Ceylon plantations, but that may have been for the leaf fungus? Planters are now not troubled with too much coffee, and we think one of the Uva proprietors might well give a trial to the sprayer and mixture on fields affected by green bug and report the result for the general benefit.

Correspondence.

To the Editor.

TEA CULTURE IN AMERICA.

RAISING PLANTS FROM CEYLON SEED.
Summerville, U.S.

DEAR SIR,—Through some mishap my copy of the June number of your most interesting journal has failed to reach me: please send me another in its place.

I am very much pleased with what I have read of Ceylon; I liked Ceylon's exhibit at Chicago; I read your journal with pleasure, and have just raised at the stake and in nurseries fully 15,000 seedlings from one maund of Ceylon tea-seed.—
Yours very truly. CHARLES U. SHEPARD.

WILD COFFEE SEED AND FODDER PLANT.

London, E.C., Aug. 11th.

SIR.—Today I enclose for you a few grains of a wild coffee from East Africa which I am planting; the flavor is good and it fetches a high price.

The "Polygonum" you see so much written about, I have grown for years, and some of the Indian planters who have been to Sydenham have ordered cases of the roots not only to grow for fodder but to hold the land up by the side of streams. They saw my cows eating the foliage. Even in this dry season it is 9 feet high. I must send you a leaf and a few roots.—Yours faithfully,
THO. CHRISTY.

[The "wild coffee" seed packet, we shall send to the Peradeniya Gardens for inspection and trial.—Ed. T.A.]

COCOA PLANTING IN THE PANWILA DISTRICT:

SPLENDID PROFITS—BEATING TEA OR COFFEE.

Marakona Estate, Ukuwela, 17th August.

DEAR SIR,—Notice in the papers many Planters and some Magistrates dwell on natives getting such large crops on small acreages. If they had seen as much of native holding or small estates, as I have from 1860 onwards, especially from 1871 to 1875 when visiting nearly all coffee gardens from Kadugannawa to Maturata and Kotmale, Matale East, North, South and West and over all Dumbura, as I can even now prove from my travelling notes then made, they would not make such remarks. In fact they would (as I did) find that working the soil, with the help of weeds and rain trenches did give them good crops, more in many cases than some of our best estates.

What do you think of Frankland Estate, Wattegama, visited by some old Planters when not even grass would grow as also Mr. Surveyor Spencer can testify that all shook their heads and thought I could not grow anything there. Yet last year I reported a good crop, and now have the pleasure to state that my cocoa crop this year from 15 acres in full bearing realized R7,350
Upkeep of 30 acres (15 not in bearing) 2,040

Profit ... R6,310

A profit of R354 per acre for bearing cocoa! Come and see then you will believe. Where are these witty folks who can write about Holl-or-away. Let

them master their profession and prove themselves able to show such results and then they can sing—"cock-a-doodle do"—I trust to make this estate of a large acreage as paying as Frankland's.

J. HOLLOWAY.

THE VIGOUR OF THE TEA PLANT.

12, Great Tower Street, London, E.C., Aug. 18.

DEAR SIR,—In your remarks contained in the *Observer* of 11th July, respecting my opinion about the vigour of the tea plant as developed in Ceylon, I fear there has been some slight error in the allusion to a remark attributed to me, that it "cannot become exhausted for centuries."

As nearly as I can remember I said, that I thought it would be a considerable time before there could be any signs of exhaustion, but I would scarcely have ventured to extend it to "centuries."—Yours obediently,

J. HENRY ROBERTS.

[We put a query at "centuries" in noticing the report at the time, feeling sure that Mr. Roberts had been misapprehended by our London correspondent.—Ed. T.A.]

ENEMIES OF TEA.

Colombo, Aug. 21.

DEAR SIR,—Enclosed we hand you two tea leaves received from the Superintendent of one of our estates and shall feel much obliged if you can tell us what sort of disease it is.—Yours aithfully,

per pro BOUSTEAD BROS.,
E. CAVE BROWN.

[The tea is suffering from an attack of red spider—the white specks on the brown, withered leaves indicating where the eggs of the insect have been adhering to the leaf. We quote as follows from the "Tea Planter's Manual":—

"The red spider is a very diminutive insect, reddish colour on the back, and white on the under part of the body. It lives and feeds on the sap of the leaf. Its eggs resemble white dust or very fine soot. The eggs have a very slight adhesive coating, by which they adhere to the leaf; the numbers that are to be found on the leaves are sufficient to extract all sap, after which they wither, showing in bad cases a resemblance as if the leaf had been scorched by fire, leaving white stains. The red spider, as I have generally seen it, is worse on tea without shade on flat land, but bushes along the slopes of hollows where jungle is growing, are rarely bad with it."

Curiously enough on opening the *Gardener's Chronicle* received by this mail, we find the following reference to a remedy which is said to be discovered in England, red-spider being a great pest on hops, vines and in the garden generally. Here is the paragraph in question:—

"RED SPIDER."—A correspondent sends us a printed copy of Miss Ormerod's favourable remarks on some Hop leaves which had been very effectively treated with a wash of his invention for the eradication of "red-spider." Any really efficient and to plants non-injurious means of lessening the numbers of these troublesome acari or mites—total eradication is out of the question—would prove a great boon to gardeners, if it should be found as cheap and as easily applied as flowers-of-sulphur. Perhaps the inventor of the remedy will kindly furnish us with a small quantity for the independent testing of its alleged powers.

We shall be on the lookout for any further report; but the great difficulty is to apply any remedy on so large a scale as is required on a tea plantation. However, the great consolation in the

case of Ceylon, is that red-spider detects moisture and ought therefore to be quickly disposed of by a good shower of rain and fortunately for us, no Ceylon tea districts are without well distributed rainfall throughout the year.—Ed. T.A.]

HABITS OF COCONUTS.

Nilgiris, Aug. 21st.

SIR,—I have perused with great interest the various articles and letters on coconut planting in your columns. I should be greatly obliged if "W. H. W., or, W. J." or any other experienced planter could inform me (1.) If proximity to the sea is essential to the success of coconut plantations. (2.) If not, what approximate rainfall do they require?—I am, sir your etc., CREIGHTON.

[Some of our best Ceylon coconut plantations are 20 to 30 or more miles inland, with an average annual rainfall under 100 inches, perhaps as low as 70 inches.—Ed. T.A.]

THE TEA BUG: A WAR OF EXTERMINATION IN CEYLON ADVISED.

Peradeniya, August 26.

SIR,—The serious damage done in Assam tea gardens by the tea bug or "Mosquito Blight" (*Helopeltis theivora*) is only too notorious, and I have always dreaded lest it should be introduced to Ceylon where another member of the genus (*H. antonii*) has already been so mischievous to cacao. Owing to several complaints of "Mosquito Blight" on tea on some estates in the lowcountry, I have been recently examining the insects concerned and find that the *Helopeltis* sent me from these estates is not the Assam one, but our old enemy the native *H. antonii*.

At present the attacks of this insect are not of very great importance; tea is no doubt a new diet to it, and it has not as yet taken to it with avidity; but no certainty can be felt that this state of things will continue. On the contrary it appears to be increasing in abundance and it is highly probable that it will find the tea-plant much to its taste and so rapidly multiply on it as to become a serious pest. I therefore feel that an effort should be made at once to check its progress.

Our experience with cacao comes in useful. In my report on this pest to Government (printed in *Tropical Agriculturist* for October 1884 pp. 327-9) the good results of the systematic catching of the insect are described; and it has been found that where carried out vigorously and thoroughly, the practice has had the effect of very greatly mitigating the damage done to the trees. I feel therefore confidence in strongly advising a similar proceeding on tea-estates while the pest is still manageable, thus anticipating a time when it may have assumed proportions rendering remedial efforts ineffectual.

To be of any real use, however, the attack must be a general and concerted one, and worked unanimously for the common good. I am not aware that *Helopeltis* extends beyond the limits of the low-country, but I think I am justified in earnestly advising immediate action on all estates below 3,000 ft. elevation. There is no occasion for any alarm, the measure recommended is a precautionary one, and offers a reasonable chance of checking the progress of this extremely destructive insect.

There is little difficulty in catching *Helopeltis*, and it should be captured in all its stages. The fully-developed flying insect can be caught in a hand-net, and in the wingless larvæ stages it can be picked off the plant by hand. These larvæ must

not be overlooked as they do as much damage (or perhaps more) as the perfect insect. They considerably resemble long-legged yellow ants and run very rapidly; cool boys quickly get into the way of securing and bottling them.

As regards the egg, I have not as yet had the opportunity of examining them on the tea-plant, but in Assam those of *H. theivora* are laid in the tender young shoots, and were found by Mr. Wood-Mason of the Calcutta Museum, especially in the spaces between the "pekoe" and next two or three leaves. No doubt those of *H. antonii* will be found to occupy the same position; they do so on cacao, being found particularly just below the bases of the young leaf-stalks. They are of considerable size (about 1.24-h inch) and, though white, are not conspicuous, being buried in the twig; usually, however, the two terminal bristles protrude and so show the position. In my cacao report (para 12) I recommended that wherever detected such shoots should be removed and burnt or buried, and a similar course should be followed with tea. The eggs will not be found in badly sucked twigs, but in those little or not at all so attacked.

In Java, another species of *Helopeltis* (*H. Bradyi*) was at one time very injurious to cinchona, but there also systematic and continued catching practically exterminated the insect.

I therefore strongly urge upon all interested in our tea-industry to combine in a vigorous effort for the suppression of the Ceylon *Helopeltis*, and the prevention of its development into an unmanageable pest.

HENRY TRIMEN, (Director R. B. G.)

ENEMIES OF TEA: HELOPELTIS BAD IN THE LOWCOUNTRY.

Lowcountry, Aug. 29.

SIR,—I am very pleased to see your Editorial in *re* Enemies of Tea, as I think many planters are inclined to stand still knowing they have the pest of *Helopeltis* on their estates, through the fear that by trying to catch them it may become known that they are doing so, and, in their ideas, thus depreciate the value of their estates. Now I consider this should at once be exposed, as it is quite antagonistic to the interest of proprietor or company to ignore a known evil, and one and all should co-operate in strenuously doing their level best to exterminate any enemy of our staple industry. When taken in time we can overcome it, and no one until they try, knows the number of flies that can be brought in daily by their pluckers, without reducing their plucking average to any extent; and as every female fly brought in means 8 to 10 eggs besides the individual fly the game is indeed worth the candle. I thought I had none on this estate, but to co-operate with a neighbour I started my pluckers on the hunt and I am now destroying daily from 1,500 to 2,500 mature flies; some of my neighbours are more than doubling that. Should we then, Sir, be doing our duty to our employers, if we calmly sat down and ignored the presence of this pest? I trow not. Let us have the courage of our convictions and eradicate the *Helopeltis*.—Yours, A PLANTER.

THE ALLEGED DETERIORATION OF CEYLON TEA—AN INDIAN PLANTER TO THE RESCUE.

Naduvatum, Nilgiris, S. India, Aug. 29.

DEAR SIR—May I ask you to allow me just this once to call the attention of my brother planters to most important facts which are not

obscure or doubtful, but are the mature results of the closest observations and investigations of our European Scientists. To one or two of these facts, I shall have to draw special attention in answering the present inquiry regarding the deterioration of Ceylon teas. What then has chiefly led to the falling-off in quality of Ceylon teas? I reply the same causes that led to the ruin of coffee! I will endeavour to be as explicit as possible.

We know how the deciduous trees in England shed all their leaves in Autumn, leaving them bare and leafless. Then in Spring those bare trees renew their branches with innumerable young shoots. Now I ask: "From whence comes the sap that supplies those young shoots to the leafless trees?" Someone hastily replies: "Why from the roots of course." Now Mr. Editor one of the thoroughly certified "facts" that I referred to, is that no leafless tree, bush, or plant is able to draw up a single particle of nutriment from the roots (not to mention the assimilating process) until that tree, bush or plant has again become clothed with foliage. It would monopolize too much of your space were I to explain how this is, but shall be glad to give a full explanation if required. Now I merely mention the fact. Where then does the sap come from that supplies those young shoots to the bare branches? Why from the same place that it went to in the previous Autumn when the green leaves emptied out their contents before they fell dry and sapless to the ground. That is from the store-house of the bark of the trees, where the sap lay stored up all Winter until set in motion again by the genial influences of Spring. To make this more evident. What happens after we have stuck out cuttings from tree, bush or plant? Young shoots appear on these cuttings. Where does the sap come from that supplies these young shoots? Not from any roots, because the shoots appear generally before there is any development of root on the cutting. The sap then evidently could only have proceeded from the bark. But now I think I hear the exclamation:—"What on earth is this fellow aiming at, and what connection is there between deciduous trees and tea bushes?" Well *festina lente*, I am working up to the point. If we examine a tree, after pruning, we find the bare branches in the same condition as deciduous trees in autumn, namely leafless. Now I ask where is the nutriment to come from that will clothe those bare branches with fresh foliage in the spring? Do I hear the answer: "Why from the same source as the deciduous trees get it of course?" Now I come to fact number two, which is that no tree, bush or plant can provide or store up any nutriment for its future requirements *during the growing period*; for all the sap, and nutriment, is then thrown forward to the growing points to form new growth and none reserved for the future requirements of the tree or bush itself. When the growing season comes to a close and the tree or bush seems to have relapsed into a dormant state, then only is the time when the storing-up of sap in the tissues is actively proceeding.

Now how is it with the tea bush in Ceylon? With the forcing climate of Ceylon, the tea bush is kept in a perpetual state of growth with only a very few slight checks occasionally. But when the growing season is supposed to have come to an end (as it ever does in Ceylon) and the over-taxed tea bush is beginning to rest and recuperate its forces by storing up sap in its tissues and bark, round comes the pruning knife and off goes all the foliage, leaving the denuded bushes in a state in which no storing of sap is possible. Thus the

poor tea bushes are starved and robbed. Every tea planter knows, or ought to know, that tea manufactured from the flushes of bushes which were allowed to retain their foliage through the dormant season, is incomparably superior in quality to tea made from bushes that were pruned in the usual way. The reason of this lies in the facts I have described. This then Mr. Editor is one of the chief causes of the deterioration in Ceylon tea. There are other causes such as a prolonged dry season being necessary for the thorough process of nitrification and aeration of the soil &c.; but I will not trouble you with this point now. I may add that with the climate of India, the tea has various sufficient intervals of rest from active growth (when the tea bushes are not flushing) to permit of the storing-up of sap in the tissues of the bushes.

By-the-bye, to those who are acquainted with such elementary facts as that the process of nitrification is only possible in the topmost twelve* inches of the soil, it is amusing to hear the earnest assertion of your London correspondent and others that tea can appropriate nourishment by its deep tap-root!—Enough for the present.

—Yours faithfully,
J. MCKENZIE.
P.S.—* Correction dated Aug. 30th.—"I meant to say that the process of nitrification is confined to the topmost eighteen inches or two feet of soil—according to the texture and composition of the soil."
—J. McK.

[We take it that when Mr. Mackenzie wrote the above letter, he had not seen the communication from one of the first Mincing Lane authorities on tea controverting the common notion that Ceylon teas had deteriorated in quality, though they had in value (as a whole) through the far greater quantity produced and more especially of the lower grades. Ceylon can (and does) produce as good teas as ever it did in certain quantities which the planters concerned judge to be equal to the demand. We are obliged to our present correspondent, however, for his suggestive remarks about sap, the sea ons, and the process of nitrification. Our best means of re-assuring Mr. Mackenzie as to his fears for the Ceylon tea plant is to point to the report of the manager of Luole Condura which he will find in next issue of the *Tropical Agriculturist*, where he shows that his tea-bushes 25 to 27 years old, and which have been regularly cropped, are as vigorous as ever they were and are now yielding at the rate of close 500 lb. made tea per acre. Mariawatte field too, near 14 years old, still looks luxuriant after giving annually over 1,000 lb. per acre ever since it came into full bearing. Let Mr. Mackenzie come and see our Ceylon Tea districts and he will be comforted as to their condition and feel that too much is made by Mr. Hawes and others of the "deterioration" cry.—Ed. T.A.]

THE SAP THEORY AND ALLEGED DETE- RIORATION OF CEYLON TEAS.

5th Sept.

DEAR SIR.—On looking over your issue of 4th inst. my attention is directed to a letter on the "Deterioration of Ceylon teas." Now, I am too young a planter to give my views on the "supposed" deterioration of our tea, but I cannot refrain from expressing myself on the botanical aspect of your correspondent's letter.

As regards his "sap" theory, it is simply quixotic. To say that the sap elaborated by the leaves is stored up in the bark, might have received credence in a by-gone age, before experiment demonstrated that it descended to the roots between the cambium

layer of the wood and the inner tissue of the bark. There is no word of its remaining in the bark! The ascending sap on the other hand creeps up from the roots chiefly in the prosenchymatous cellular constituents or soft cells in the fibro-vascular bundles of the wood. It is true that in Spring absorption is much greater than transpiration and so the water is stored in the stem—not the bark, mark you!—to meet the immediate demands of expanding buds and cell life generally. The causes of this upward flow of "crude sap" are manifold, e.g., Endosmotic action through the absorption of fluids by the root; capillarity and imbibition in or between the fibro-vascular bundles; pressure caused by tension of elastic cell walls on their contents or by increased temperature, expanding the air in the cells and so causing the fluid to move in the direction of least resistance. The "genial influences of Spring" are very potent factors, e.g. the swaying of trunk and branches in a March wind.

Many more causes might be given; but if your correspondent will refer to any standard work on Botany, I doubt not, but that he will modify his views.—Yours faithfully, YOUNG PLANTER.

THE CHINA TEA TRADE.

DEAR SIR,—I enclose a leaf of the *N.-C. Herald* of Aug. 18th:—

Increase present season.. 5,762,290

See the vast importance of Russian trade in tea compared to America. Note also the increase of shipments to the Bombay market though during the past two months exchange has been all against shipping to India though in favour of shipments to England, which, however, show a decrease of over 4 million lb.—Yours truly,

MERCHANT.

[Yes, for Shanghai alone: not so for Foochow and other ports.—Ed. T.A.]

TEA SEED OIL.

Lunenburg, Sept. 8.

DEAR SIR,—I am obliged to you for the kind note you have inserted in your valuable journal re tea seed oil. I am sending you in a bigger phial of the same oil. This quantity has been extracted from a lb. and a half of tea seed which was considered not very good by Mr. N. D. S. J. From one lb. of good seed it has been found experimentally that a little less than a pint of oil can be obtained. Kindly show or give this or part of it to any one who may feel interested I would also ask you to try it in a lamp. This ought to find its way to the London market soon and give Ceylon a chance. Some of the planters here are trying it themselves—Yours very truly,

WALLACE.

[We shall send the sample to London for report.—Ed. T.A.]

PLANTERS AND THEIR ENEMIES.

DEAR SIR,—Referring to a letter by your correspondent "Planter" which appeared in your issue of the 31st ult., "Planter" must entertain curious ideas regarding his brother planters—or those he comes in contact with must differ widely from the true representative body—when he is led to write of them: "I think many planters are inclined to stand still knowing that they have the pest of Helopeltis on their estates through the fear that by trying to catch them it may become known that they are doing so and thus depreciate the value of their estates." Is "Planter" "a new chum!" that he seems to know so little of "the acts of the planters?" Have they not ever vented the attacks of every enemy that made its appearance since bug made its inroads on the coffee in the fifties. Volumes might be made from old *Observers* on black bug, white bug, green bug, cockchafers and all the other enemies of coffee enumerated and scientifically dealt with in the *Observer* by Nietner down to that most fearful of all pests, leaf-disease, that completely routed the coffee planter. "Calmly sit down," says your correspondent, "and ignore the presence of this pest." No, I think it is the other way. A neighbour of mine has been on the war-path for a week and only found one fly. Taking a number of estates about here, the average elevation I suppose to be about 1000ft. Helopeltis has hardly made an appearance—and every Planter seems alert to stamp it out before it can do any appreciable damage. Personally I have just seen enough to convince me that it had made a faint attempt at colonisation on this estate but could not find a single fly. Nature, I believe had forestalled me. Whenever I found marks that I supposed to be Helopeltis,—a spider was there and had her net spread. As you wisely remark there is no cause for alarm we have got an insect and not a fungus to contend with, and grevilles which are now being largely planted amongst the tea may be some protection.—Yours, &c.,

ANOTHER PLANTER.

THE DUTCH MARKET.

AMSTERDAM, August 22.

All the analyses for the cinchona-bark sales on August 31 have been completed now. The manufacturing-bark contains 25 tons of sulphate of quinine, or 4.75 per cent. on the average. About 4 tons contain 1 to 2 per cent.; 54 tons 2 to 3 per cent.; 103 tons 3 to 4 per cent.; 135 tons 4 to 5 per cent.; 125 tons 5 to 6 per cent.; 59 tons 6 to 7 per cent.; 27 tons 7 to 8 per cent.; 3 tons 8 to 9 per cent.; 3 tons 9 to 10 per cent.; 1 ton contains 10 to 11 per cent.; and 1 ton 12 to 13 per cent. sulphate of quinine.—*Chemist and Druggist.*

LIMITED COMPANIES AND THE VALUATION OF TEA PROPERTY.

Our correspondent "Tea Planter" raises a very important question in the letter on page 257. The subject of it, he says is one which Editors ought to discuss and he thinks as much responsibility rests on us in connection with the formation of local Limited Liability Companies as there does on the conductors of "Financial" and other special newspapers at home. Therein, we beg to differ. Before we could venture to set ourselves to discuss the *pro's* and *con's* of each plantation or other Company that might be brought forward, we should have to add an expert to our staff and devote far more space and attention to the subject than the circumstances of the case would warrant. In most instances, we can only profess a general acquaintance with the subject and the application of common-sense and unbiassed judgment, and we must still look to critics like "Tea Planter" and others, to enlighten us and the general public where cases are supposed to arise of unreliable valuations or exaggerated prospectuses. The illustration afforded by our correspondent of two valuations (we suppose made at short intervals?) differing so greatly as £75,000 and £105,000 is a very serious one and carries us right away back to the speculative days of coffee and the inflation caused by cash credits. Certainly any business which is the outcome of inflated valuations of tea or other property ought to be condemned by every right-minded person in the community, and we quite agree with "Tea Planter" that—other things being equal—Limited Plantation Companies in Ceylon whose capital stands at no more than £30 per acre for tea in bearing are much to be preferred to those rated at £40 to £50. But, at the same time, would it be fair or right to condemn the latter simply for this reason? There are tea properties up and down the country which would be extremely bad bargains at £30 an acre; but as "Tea Planter" well knows there are others, whose proprietors would laugh the purchaser or Limited Company to scorn, who ventured to approach them with an offer of £40, and in some cases we know, of even £50 per acre for their full bearing tea. "Tea-planter," however, enters into crop figures and anticipated profits per lb. and when he asks us if it is reasonable to count on 25 cents profit per lb. of made tea, per annum, we have no hesitation in saying that only very exceptionally good, or heavy bearing, tea would justify such an estimate. We have no doubt that such a rate of profit has been, and will yet be realised in Ceylon; but with the certainty of increasing production and the uncertainty about new markets and prices keeping up, we do think it to be an extreme rate of profit to put before the public for any concern on a large scale. In saying so, we have no particular Company or plantation in view: if "Tea Planter" has, he ought to send us the prospectus or valuation and tell us all he knows, so that we may make further inquiry and see whether a good case is made out for giving further counsel or even warning, in the interests of the good name of the Tea Planting Industry of Ceylon.

NEWS FROM THE CENTRAL PROVINCE: PLANTING AND OTHERWISE.

(Notes by "Wanderer.")

Sept. 5th.

CEYLON TEA IN AMERICA.—We now have Mr. Grinlinton's strongly expressed opinion backed up by Ceylon planters who have lately visited America and have a large stake in Ceylon tea property, that we must at once take measures to supply the Americans with the tea we have at such great expense forced on their notice. The Ceylon Government and the Planters' Association through their Tea Leaf Fund must subsidise some large Company to be managed by Mr. Grinlinton in America for some time at any rate, which will have depôts in some of the principal cities where Ceylon tea, black or green, may be supplied.

There is the CEYLON TEA COMPANY under the patronage of the Ceylon Planters' Association, and in which Ceylon planters, proprietors, managers, assistants and even conductors are shareholders. Why should not the capital of this Company be raised to R100,000 and be the channel by which the Government and Tea Fund can further advertise Ceylon Tea. This Company has as its Agents one of the leading agency firms in Colombo, Messrs Whittall & Co. I trust the Chairman of the Ceylon Tea Company and the Chairman of the Planters' Association will take prompt steps to put the Ceylon Tea Company in a strong position and not allow the present shareholders' money to share the fate of the American Tea Company, Messrs. McCombie Murray, Arthur Pinco, &c.—A Company and a Company only can meet Mr. Grinlinton's requirements. Why not the Ceylon Tea Company?

TEA down 1d per lb. shows the Ceylon planter that his only hope is to have new outlets for his tea. China it appears has not thrown up the sponge, so Ceylon must continue to advertise, advertise, advertise the purity of its tea, the excellence of its preparation, and the iron its soil contains. Mr. Grinlinton can be left with safety to do that for us in America if he gets money, Mr. Rogivue in Russia if he gets support as well as promises, and the present campaigners in Australia and New Zealand, to the latter of which Mr. Thom goes as a fresh agent—by timely subsidies and parcels of tea.

Indian Tea has increased its exports to United Kingdom from .. lb.
1st May to 19th August .. 2,700,000

Ceylon Tea from ..
1st June to 31st August .. 4,300,000

Ceylon Tea has increased its exports to Australia and New Zealand from 1st June to 31st August .. 800,000

Cocoa.—Those interested in this cultivation would do well to mark the following figures:—

Total Ceylon exports from 1st January to 28th August 1893 .. cwt. 24,456
Do. Do. 1892 .. 14,564

Increase 9,892
or over lb. 1,000,000.

a jump of 30 per cent in the exports of cocoa in the first 8 months of the year is somewhat alarming—but when we study the movements of stock in London and Continental countries, it becomes more so.

In London and Liverpool, stock 1893 Aug 1st 1893 .. bags. bags.
89,338 86,372
Havre .. 42,630 38,452
131,668 124,824

The coming year in Ceylon is not expected to be so heavy as last year, but it is too soon to make any reliable estimates.

CATTLE DISEASE (foot and mouth) has been troublesome in the Dikoya and Maskeliya districts. How thankful we ought to be for our railways!

ROADS are generally considered to be somewhat starved. Too much of the work of metalling and graveling has to wait for suitable weather. MacBride is a veritable Micawber in the way of waiting for something favourable to turn up.

HELOPELTIS IN TEA.—Dr. Trimen's advice is like himself, sensible. Let planters in districts where it is troublesome, which at present is in the low country, use every effort to catch the insect. Thank goodness it is not a vegetable fungus.

WEATHER very uncertain, except that we have more constant windy weather than we care for.

COCONUTS.—It is amusing to read in the August *Tropical Agriculturist* of the editor of the "Catholic Messenger" (an old coffee planter, I believe) warning the natives of Ceylon to have another horse ready in case the coconut *nag* can be ridden no longer. Native organs have always been taunting the European planter that he puts too much trust in tea. The "Catholic Messenger" proves that the tea bush is less liable than the coconut tree to disease. "Over production may be the downfall of the tea bush, not disease," says our Catholic friend, but over-production may kill coconuts for I have heard W. J. confidently assert that if coconut planters, European and native, properly cultivated coconuts, the present cultivated area would produce double what it now does. What about prices in that case!!

VEGETATION poisonous to Cattle. The article in the supplement to *Tropical Agriculturist* or magazine of "School of Agriculture" is almost as gruesome reading as Mr. Clark's "Clockwork Coolie." It is bad enough to have one's cattle poisoned by *Datura* leaves being mixed with grass, but to be poisoned eating beef of an animal whose life had been slowly terminated by eating such food is too-too.

Advice to **CACAO PLANTERS** is given in this same number and that is never to take seeds for a nursery or stake planting from a pod which grows on the branch but on the stem.

CACAO CULTIVATION AND CROPS IN CEYLON.

When coffee began to fail in Ceylon, it was remarked how the crops became alternate ones—how a very poor export was followed by a better one and so on, although every pair showed a steady decline on the total of the preceding two years. Now, we do not think it has been noticed how in the case of our cocoa crops and exports, the experience from almost the outset of the enterprise has also been one of alternate crops, and these have prevailed even before and after the severe visitation of *Helopeltis Antonii* some years ago. The difference in the case of cocoa is, that each pair of crops shews a rise on the preceding, we are glad to say. Here are the exports for ten years with a regular alternation:—

Cocoa.	Cwt.	Cocoa.	Cwt.
1883...	4,166	1888...	13,159
1884...	9,606	1889...	19,054
1885...	7,247	1890...	15,981
1886...	14,855	1891...	20,532
1887...	16,301	1892...	17,327

Moreover the export for 1893 will fully maintain the alternation with, however, a considerable bound forwards; for already the export is about 25,000 cwt. and ought to be at least 28,000 cwt. by the end of the year,

As regards the area planted in 1877-78, it was 500 acres; in March 1881 this had increased to 5,460 acres, and this area in three years by December 1883 had increased by 4,500 acres, making 10,000 acres. Up to 1884, the growth and promise were all that could be desired, and proprietors of cacao clearings were deemed fortunate men; but about the middle of 1884, after a prolonged drought, the appearance of the cacao in several districts was so lamentable that Dr. Trimen was called on to report, and he found the chief enemy to be a sucking bug (*Helopeltis Antonii*), which lives on the tender young tissues of the plant. The only remedy was systematic catching and destruction of the larvæ, but it was also clear that an exceptionally dry year, and a wrong system of cultivation in the open in place of under shade-trees had increased the virulence of the attack. Where cacao has been grown from the first under shade, it has suffered very little from insect attack. Shade trees are now being grown everywhere. As a consequence, however, of the attack referred to, the planting of cacao was for a time stopped, and the total area covered by December 1885 was only 12,325 acres or 2,300 acres of extension in the two years. Then our figures gave no more than 12,000 acres in July 1888; and 12,900 acres for Augt. 1891. Among the natives in some parts of the lowcountry, in Matale, Uva, Kegalla, Kurunegala, and Dumbara districts, there was a good deal added to garden cultivation, but the rush into tea, and the long time taken by the cacao tree to mature, kept back the European planters. Nevertheless, in the two years up to August 1893, about 3,400 acres have been added and from the area now planted (16,286 acres) we trust we may look for an export of 60,000 cwt. (or say 6,720,000 lb. as the Trinidad people count it) by the time all is in full bearing. For 1893, the export is likely to be between 25,000 and 30,000 cwt. Now that the railway is opened to Haputale we expect to see cacao culture gradually extended in Uva: in Monaragala district it flourishes well and the Government Agent for Uva reports (1893) "abundant land available" there and in other lowlying parts. Of cacao planted alone, the area returned now is 13,322 acres; of coffee and cacao planted together we have 3,006 acres, besides 516 acres of Liberian coffee and cacao. At present cacao cultivation is chiefly confined to the Dumbara valley (about 4,200 acres); Kurunegala, Kegalla and Polgahawela (about 2,700 acres); Matale North, East and West (over 4,800 acres); about 1,000 acres in Uva; nearly 1,600 in Panwila; and 250 to 400 acres each in Alagala, Kaduzarnawa, Dolosbage, Hantane, Nilambe, &c. In Matale the Assistant Agent says, "the Matale and Asgiri Valleys will soon be one sheet of cacao" and with this and Uva and other parts in the lowcountry, there should be no difficulty in covering a good deal more than 25,000 acres of suitable land with this product. But it is of slow growth, and more liable to enemies than the favourite tea and the planting of it therefore advances much more slowly. Shelter and good soil are indispensable: even in the Dumbara Valley, the trees never grow when exposed to wind or on poor patches.

An experimental cacao clearing of 13 acres has been formed near the Walawe river in the Southern province on a large block of 800 acres taken up for low-country products by Mr. Pol-Carew.

Cacao was supposed to be first introduced into Ceylon in the time of the Dutch, and Bennett states that he got ripe pods early in the present century, before 1820 certainly, from trees planted by a Dutch gentleman. Indeed Dr. Trimen mentions that as early as 1819 "chocolate pods" were

being sold for seed from the old Botanic Gardens at Kalutara, and the distribution continued after removal to Peradeniya in 1821; but he (Dr. Trimen) believes the introduction took place by Moon early in this century, 1816-19 (see *T. A.* Vol. X.) In 1833, many seeds were sent out, and in 1843 plants were sold at the rate of 4s a dozen. Bennett thought the soil of the Northern Province and of the district of Kalutara well suited to this product, suggesting that lines of plantains should be planted between the cacao. The cacao was certainly cultivated in Peradeniya Gardens so far back as 1824, in Moon's time, and has been grown there ever since. It is said that Governor Wilmot Horton introduced a case of Trinidad cacao plants about 1834-5, which were grown at the Pavilion, Kandy, and also at Peradeniya Gardens. From a tree in an Army Surgeon's garden in Kandy, the late Mr. R. B. Tytler got seed which he utilized on Pallakellie estate, in the Dumbura Valley, the trees being intended for ornamental purposes around his bungalow. The trees flourished bearing fruit which was allowed to fall to the squirrels until 1872-3, when a gathering being made of the pods and the seeds prepared, a sample was sent to London and valued at 70s per cwt., and then Mr. Tytler began its systematic cultivation. The 48-years old trees at Pallakellie are still vigorously bearing fruit.

INDIAN PATENTS.

CALCUTTA, the 24th Aug. 1893.

Specifications of the undermentioned inventions have been filed.

No. 34 of 1893.—William Carey Leechman, of 92, Sinclair Road, in the County of Middlesex, England, Meichaut, for an improved preparation of tea and the process of making the same. (Filed 26th July 1893.)

No. 161 of 1889.—William Alfred Gibbs, of Gilwell Park, Seward-stone, in the County of Essex, England, Gentleman, for improvements in or connected with furnaces and apparatus for the production of hot air and for drying coffee, withering and fishing tea, and for other drying purposes. (From 23rd Aug. 1893 to 21st Aug. 1894.)

Whereas the inventions of the undermentioned inventions have respectively failed to pay within the time limited in that behalf by the 4th Schedule to the Inventions and Designs Act (V of 1888) [or within the further time allowed under section 8, sub-section (4) of the Act] the fee hereinafter mentioned, it is hereby notified that, under the provisions of section 8, sub-section (2) of the said Act, the exclusive privilege of making, selling, and using the said inventions in British India and of authorising others so to do has ceased:—

No. 60 of 1883.—Mr. B. C. Schumacher's invention for an improved method of winnowing and cleaning rice and other grain seeds and berries and apparatus therefor. (Specification filed 15th May 1889.)—*Indian Engineer*, Sept. 2nd.

TEA IN THE CENTURY DICTIONARY.

The following from the latest Dictionary is worth quoting in a tea-growing country:—

"TEA-TREE (te-tree), *n.* 1. The common tea-plant or tea-shrub. Sea tea 1, 2.—2. A name of various myrtaceous and other plants, chiefly of the genera *Leptospermum* and *Melaleuca*, found in Australia, Tasmania, and New Zealand. See phrases below. Very abundant and conspicuous, especially in New Zealand, is *L. scoparium*, the broom tea-tree, known also as *tea-scrub*. It is an erect rigid shrub, or in the mountains prostrate, from 1 to 12 feet high, forming dense thickets, with leathery sharp-pointed foliage, covered for two months with abundant small white blossoms. Its wood though small, is hard and useful

for tanning, etc. *L. lanigerum*, the Tasmanian tea tree (found also in Australia), is a somewhat larger, very abundant shrub or tree, with a hard even-grained wood. The leaves of both are reputed to have been used by Captain Cook or early colonists as tea, which may account for the name, but the native Australian name of the former is *ti*. *Melaleuca uncinata*, the common tea-tree, is a shrub, or sometimes a tree from 40 to 80 feet high, with hard, heavy, durable wood, widely diffused in Australia.

"Even the grass itself is not indigenous, all these hills [in New Zealand] having till recently been densely clothed with a thicket of *tea-tree*, which is a shrub somewhat resembling Juniper or a gigantic heather-bush, its foliage consisting of tiny needles, while its delicate white blossoms resemble myrtle. It is called by the Maoris *manakau*, but the settlers have a tradition that Captain Cook and his men once made tea of its twigs; hence, they say, the name. It is, however, noteworthy that this plant is called *ti* by the Australian blacks, so it is probable that the name was brought rather by some colonist from the sister isle.—*C. F. G. Cumming*, in *The Century*, XXVII. 920.

"African tea-tree. See *Lycium*.—Bottle-green tea-tree, an evergreen myrtaceous shrub, *Kunzea corifolia*, of Australia and Tasmania.—Broad-leaved tea-tree, a myrtaceous shrub or tree, *Callistemon salignus*, of Australia and Tasmania. Its wood is very close-grained, hard and heavy.—Ceylon tea-tree, *Eleocharis glaucum*.—Duke of Argyll's tea-tree. See *Lycium*.—Prickly tea-tree. Some as *naambarr*.—Red scrub tea-tree, the Australian *Rhodanthe trinervis*, a myrtaceous shrub or tree. Also called *three-veined myrtle*.—Swamp tea-tree, *Melaleuca squarrosa*, of Australia and Tasmania, a shrub, or sometimes a tree, with hard heavy wood, the bark in thin layers. *M. armillaris* is also so called in Tasmania.—Tasmanian tea-tree. See def. 2.—White tea-tree, *Leptospermum ericoides*, of New Zealand, a shrub, or a tree 40 or 50 feet high. The wood is hard and dense.

"Tea-urn ('tē'urn), *n.* A vessel used on the tea-table for boiling water or keeping water hot: it differs from the tea-kettle chiefly in having a faucet or cock instead of a spout, so that it has not to be moved or tipped for drawing hot water. "At the head of the table there was an old silver tea-urn, looking heavy enough to have the weight of whole generations in it, into which at the moment of sitting down a serious-visaged waiting-maid dropped a red-hot weight, and forthwith the noise of a violent boiling arose."—*H. B. Stowe*, *Oldtown*, p. 294.

In reference to the "Ceylon tea-tree," (*E. glaucum*) we applied to the Director, Royal Botanic Gardens, for an explanation and he has kindly informed us that General Hay MacDowall was, apparently, responsible for the name which was adopted from him by Roxburgh. But "all about" the tree we find in Dr. Trimen's "Flora" page 272 as follows:—

E. glaucum, *Pers. Syn.* i. 241 (1805). Neelan S. Piyari, Perun-Piyari, T.

Schrebera albens, Retz. Obs. vi. 25. *Celastrus glaucus*, Vahl, *Symb. Bot.* ii. 42. *Moon Cat.* 17. *Thw. Eum.* 73. *C. P.* 1227.

Fl. B. Ind. i. 623. Wight, *Ill.* t. 71 (*E. Roxburghii*). Retz. Obs. vi. t. 3.

A small tree, much dichotomously branched, bark warty, thick, brownish-grey, twigs slender, young parts glabrous; l. opp. 2-3 in., variable, oval or roundish-oval, acute at base, obtuse, often twisted at apex, shallowly serrate-oreate or entire, glabrous, rather coriaceous, g'aucous, reticulate, petiole ½ in. or more, stip. minute, triangular; fl. under ½ in., numerous, in very divaricate, axillary, or extra-axillary, paniculate, dichotomous cymes, ped. long, glabrous; sep. almost distinct, rounded; pet. oblong, obtuse, distant; stam. much shorter than pet., anther roundish; disk obscurely lobed; drupe ovoid, ⅓-½ in., apiculate, glabrous, stone bony.

Var. β . *moutanum*, *Thw. Enum.* 73. *C. P.* 2520.

L. less glaucous; fl. much larger, ½ in.; fr. larger ½ in. Dry country; common, especially near the coast. Var. β . lower montane zone, from 3000 to 4500 feet;

rather common. Dimbala; Deltota; Huna-giria. Fl. all the year; pale yellowish-green. Also in India and Malay Archipelago.

Wood hard, heavy, close-grained, smooth, reddish-brown.

First noticed by Koenig, whose specimens are in Mus. Brit. Moon gives the name 'Bat-bik' for this.

The leaves vary extremely; in the dry region they are frequently found strongly serrate, and this form is called 'Karukku-vaychchi' by the Tamils. It is this which Roxburgh records (Hort. Beng. 18) as 'Ceylon Tea,' under which name it was sent from Ceylon to the Bot. Garden, Calcutta, by Gen. McDowall (see Roxb. Fl. Ind. i. 639).

TANNIN AND THEINE IN CHINA AND INDIAN TEAS.

The London *Lancet* reports in its issue of July 1st the results of an investigation of China and Indian teas, based on the constituents of tea as it is ordinarily made and presented to the drinker.

The results to which these experiments have led may thus be generalized:

1. There is an important difference in the amount of tannin but not of theine in these China and Indian teas. The China teas contain from 5 to 6 per cent of tannin and the Indian teas average of 10 per cent. In both the theine amounts to practically the same—averaging 8.4 per cent.

2. Distilled or softened water to which carbonate of soda has been added, dissolves the tannin more rapidly, but effects no increase in the amount of theine dissolved; the practice of adding carbonate of soda to the water, therefore, is not to be recommended. Moderately hard water used the moment it reaches boiling point effects just as rapid a solution of the valuable principle theine as distilled water, whilst the objectionable tannin is not so rapidly dissolved.

3. China teas may safely be left to infuse for a longer period of time than the Indian teas; for the former even fifteen minutes may be allowed without fear of dissolving an excess of tannin, but for the latter not longer than five, or at the most seven minutes is advisable.

4. Tannin, of course, imparts astringency to tea; but this constituent is not wholly concerned in producing an infusion of the desirable body and strength, for the theine and tannin together amount to only one-fourth of the total extractive matter present, except in some instances of Indian teas, which are particularly and undesirably rich in tannin.

5. The best results are obtained when the tea is powdered immediately before use. The flavor is then exquisite, complete extraction of the theine is insured and provided the infusion is allowed to stand for only five or seven minutes, a minimum of tannin is dissolved and no sacrifice of body or strength is perceptible. The remarks in section 2 also apply here.

The Indian tea No. 4 used in this investigation was obtained by private purchase; the China teas were supplied by the Russian-China Tea Company, which has been established with the avowed object of supplying Chinese plantation teas in the United Kingdom as imported into Russia.—*American Grocer*.

BARK AND DRUG REPORT (From the Chemist and Druggist.)

London, Aug. 17.

At the drug-sale today remarkably little business was done—in fact, buyers appeared to be at a premium. Brokers came and brokers went, but in nearly every case without effecting sales, and catalogue after catalogue was gone through with apparently only a slender transaction of business.

ARECA-NUTS.—Of 137 packages 33 sold, without reserve, at 10s 6d to 13s. This was apparently for very old stock, being more or less wormy. Another parcel of 4 bags was sold at 8s.

CANELLA-BARK.—Eight bales of good pale bark, considerably broken, were bought in at 30s.

CARDAMOMS.—There was a limited supply offered, and nearly the whole was sold at good prices, considering that the quality was just about average. One parcel of fine plump and white Mysore sold at 2s 9d; split of about

equal size and colour 2s 1d to 2s 6d; small to medium, white, sold at 2s, and the smallest at 1s 4d; natural brown fruit fetching 1s 5d to 1s 9d. Of the few cases of Malabars offered all s 1d; medium in size and colour at 2s 1d, and low brown at 1s 3d. Seed sold at 1s 4d.

KOLA-NUTS.—At the sales 35 packages were offered, but only 2 s 1d at 4d; the remainder were all bought in.

ESSENTIAL OIL.—At the auctions today there was a large variety of oils offered, but business was especially stagnant, and there being no demand everything offered was bought in.

AREA PLANTED WITH TEA AND OTHER PRODUCTS.

We are now enabled (after a greater expenditure of time and labour than we care to think of), to present our readers with the all-important main results of the compilation and analysis of the returns for our Estates' Directory, now finally closed.

Those are as follows, and we include a comparison with the results arrived at two years ago:—

CEYLON PLANTATIONS IN TEA, COFFEE, CACAO, CINCHONA, CARDAMOMS, &c.

	Results in July 1891.		Difference.
	Acres.	Acres.	
Total area of Properties ..	657,832	721,865	Incr. 36,973
Do Cultivated ...	331,963	354,235	do 12,272
In Tea ...	248,565	273,015	do 24,450
Do Coffee (Arabian) ...	36,753	30,066	Deer. 6,687
Do do (Liberian) ..	1,933	2,438	incr. 505
Do Cacao ...	12,000	16,266	do 3,266
Do Cardamoms ...	4,865	4,723	Deer. 142
Do Cinchona trees... 9,175,000		6,900,000	do 2,166,000

An increase of 19,282 acres to the area covered with tea in the two years may be considered moderate when compared with the "rush" of the previous years. But as there is about 7,000 acres of tea beyond our total, intermixed with coffee or cinchona, which before long will, we fear, be all tea, it is safe to speak of 280,000 acres as representing the Tea Industry of Ceylon towards the end of 1893. The increase in cacao and Liberian coffee is very satisfactory.

LONDON REPORTS ON TRAVANCORE CEYLON PRODUCE.

TRAVANCORE TEA.

(From *Patry & Pasteur, Limited*. Report of the Colonial Markets for the Week ending Aug. 16th, 1893.)

The 452 packages offered were not attractive, and prices ruled in favor of buyers.

Correspondence.

To the Editor.

CRITICISM OF THE VALUATION OF SOME
CEYLON PROPERTIES AND PROSPECT-
USES BASED THEREON.

DEAR SIR,—Sales of Ceylon property at high rates to public Companies are a matter for congratulation to the sellers. If, however, the expectations of the valutors and promoters are not realised and the shareholders consequently disappointed, will not the credit of the Colony in the home markets be seriously injured?

It may be an unpleasant task, but it is a duty on the part of every editor whose journal is connected with the Colony's industries, to give his honest opinion in regard to the stability and prospects of any public Company that is floated, a rule invariably adhered to by financial journals at home.

A very few years ago Ceylon investors "stank in the nostrils" of home capitalists and were connected only with disastrous failure with the result that many a struggling proprietor—to whom a few thousands of rupees or pounds to tide him over temporary difficulties would have meant salvation and comfort in his old age,—was unable to raise a single penny and was ruthlessly "sold up," his property in many instances only realizing a few rupees; and he forced to begin the struggle of life again at the bottom of the ladder, a broken-hearted man in middle life.

It entailed another serious loss to the Colony. Properties which had, up to a certain point, been carefully cultivated and from the same cause suddenly abandoned, were, after being neglected for a time, mamoty weeding was resorted to, and surface soil washed away, with the result that many estates which were splendid coffee properties, have through this ill-treatment, turned out very indifferent tea gardens, hardly more than paying their way now. The most successful Companies in Ceylon today are those whose capital account is small, and crops large, and the premier Company in every respect the "Ceylon Tea Plantation Company," has (I speak from memory) a capital of about £30 an acre; and although it made only 2½d per lb. of profit on its made tea last year, it paid a very large dividend.

The Standard Company is another instance of some of the finest estates in Ceylon, having a capital of only about £30 an acre.

Wannarajah will have even less than this capital when in full bearing, and although there may be a long wait, fine results are assured. The Yataderia and Yatiyantota Companies are other instances of small capital and large profit; while I do not think you could give a single instance of a Public Company with large capital either in India or Ceylon that has given good returns for the last 4 or 5 years. These reflections have been caused by the floating of two Companies, and with the figures given I cannot for the life of me see where the dividend is to come from, as to earn it a profit of something like 25 cents per lb. will require to be made, or 33 per cent more than the Ceylon Tea Plantations Company made last year, and about two and a half times what Mr. Christie told the Kandy Meeting he was making with exchange at 1s 4d.

The other Company is not yet before the public, but the properties were valued by two different Visiting Agents who took very different views as

follows: (I give the proportions but not the amounts;) Mr. A. valued the properties at £74,650; Mr. B. at 105,000! in both cases valuation was made with a view to float a Company in England.

Now, either the first man shamefully undervalued, and by sale at his figure the present owners would have lost heavily, or the second man made an excessive valuation, and if floated the shareholders will have their fingers severely burnt, I take the latter view, and hope it won't float, as although at this figure it will pay the sellers largely, it will later on injure the credit of the whole community in Ceylon if it fails to pay reasonable interest to the English shareholders.

We have quite enough public Companies connected with the Colony,—whose shareholders in England year after year wait vainly for the dividend which never comes, and whose sole function seems to be to pay good fat fees to Directors and Agents, without wanting to increase their number. And I write this in the hope that the Editors of all the Ceylon papers will have the prospect of each public Company carefully scrutinized as it appears, and if necessary call on the promoters and valutors to explain any point that is not clear and to show where the dividend can be reasonably expected to come from, before they recommend their readers to take up a single share.

By doing so they will promote the floating of all solid Companies and help the free flow of English capital into the island and assist their readers in investing, while at the same time they will do a grand work in a sitting to exterminate any "cats paw" schemes which are put before the public.

TEA PLANTER.

THE ALLEGED DETERIORATION OF
CEYLON TEAS, AND THEORIES IN
EXPLANATION THEREOF.

DEAR SIR,—In your issue of the 4th inst., a correspondent writing from the Nigiris has offered an explanation, based on his scientific knowledge, of the deterioration of Ceylon teas. I am not at present concerned with the question of fact whether Ceylon teas are deteriorating or not, but I should like to say a few words with regard to the scientific explanation offered by the correspondent referred to above, and the criticism on that explanation or theory by "A Young Planter" in your issue of the 8th inst. Discussion and criticism when carried on in a proper spirit, with the object of edification, I believe to be desirable, and it is with a view to elucidating as far as lies in my power, some of the scientific points bearing on plant life, and specially of plant-nutrition, which have been brought out in the discussion between your Indian correspondent and his Ceylon critic, that I am persuaded to write on this subject. Your correspondent from the Nigiris has written a long and no doubt carefully-thought-out letter which proves that he has been a student of the physiology of the plant. In the second paragraph of his letter he refers, for analogy, to the case of the deciduous trees of England that shed their leaves in autumn, and asks, whence comes the sap that supplies the leafless trees with young shoots in the spring time? His answer (to quote his own words) is: "Why, from the same place that it went to in the previous Autumn, when the green leaves emptied their contents before they fell dry and sapless to the ground. That is from the store-house of the bark of the trees, where the sap lay

stored up all the Winter until set in motion by the genial influences of Spring."

With reference to this "Young Planter" writes as follows:—"To say that the sap elaborated by the leaves is stored up in the bark, might have received credence in a by-gone age, before experiment demonstrated that it descended to the roots between the cambium layer of the wood and the inner tissue of the bark."

Now if your Indian correspondent made a slight slip in using the word "bark," when he might in a general way have said "stem," his Ceylon critic has certainly been very hasty in the making the statement he has done. To begin with he has misunderstood what Mr. McKenzie (the writer from the Nilgiris) intended to convey, for Mr. McKenzie in the passage from his letter quoted above, did not intend to describe the behaviour of the sap in dicotyledons during the ordinary periods of growth, but its behaviour in deciduous trees during Autumn and Winter when growth is arrested. If Mr. McKenzie was wrong in saying that the descending or elaborated sap (for that is the sap meant) was stored in the bark, "Young Planter" is quite as wrong in saying that it "descended to the roots." In concluding his letter "Young Planter" writes thus:—"But if your correspondent will refer to any standard work on Botany, I doubt not that he will modify his views." Now, as I shall probably be credited with little authority if I gave an opinion, as my own, on the question at issue, I have decided to follow the advice offered by "Young Planter" and not only refer to standard works on Agriculture and Botany, with which my library is fortunately well furnished, but also to quote from them, and thus settle the matter. Warrington in his "Chemistry of the Farm," writing on plant development, says, "In trees plant food is stored up at the end of summer in the pith, the pith rays, and in the layer between the wood and bark. The leaves which fall in autumn have lost nearly all their starch, albuminoids, phosphoric acid and potash, these having been transferred to the stem. By the action of the sun in spring-time the new buds swell, the sap rises, the starch and other matters deposited in the wood during the previous autumn are re-dissolved, and employed for the production of new growths." This very clearly indicates that the sap in autumn and winter is in the case of deciduous perennial dicotyledons, stored up in the tissues immediately in contact with the wood and surrounded by it, viz., the pith, the cambium, and the medullary rays. So that, as I said before, if Mr. McKenzie erred slightly in saying that the sap was stored in the bark, which lies outside the cambium layer, "Young Planter" was very far out in insisting, at least in the case of the trees referred to, that the sap goes down to the roots. In the case of biennials it is true, to quote Warrington again, that "towards the end of summer there is a storing up of concentrated plant food in the root or stem to serve for the commencement of growth in the following spring. In a biennial root crop, the turnip, for instance, the root attains a great size in autumn, the leaves dying after transferring to the roots their most important constituents. The next season the root throws up a flower stem, and the store of matter accumulated during the previous autumn is consumed in the production of seed." In the potato the store house is the stem and not the root. But Mr. McKenzie was referring to the deciduous trees of England (and by analogy to the tea plant); not to biennials. And even referring to ordinary circumstances of growth it is incorrect to say that the elaborated sap descends "to the roots"

"as "Young Planter" puts it. The fact is that "the elaborated sap forms downward and cross currents varying in direction and intensity according to the requirements of the growing tissues and their conformation." It is difficult to understand what purpose could be served in the plant economy by the sap collecting itself in the roots alone. I am here reminded of Dr. Master's warning in his work on "Plant life":—"It is necessary," he says, "to guard against the still prevalent fallacy attaching to the use of the word 'sap.' That term was first employed when it was imagined that a regular circulation of fluid took place in plants from root to leaf and from leaf back to root—just as in animals the blood courses from the heart to the capillaries, and back from the capillaries to the heart by the veins." This is a warning which I cannot help thinking is applicable to "Young Planter's" case. These are the only points bearing on the "theory" of Mr. McKenzie. "Young Planter" gives further information on the medium through which the ascending and descending saps flow, but is obscure when he says that the latter descends "between the cambium layer of the wood and the inner tissues of the bark." Still further, he states that in spring "water is stored in the stem,—not the bark, mark you!—to meet the immediate demand of expanding buds and cell life generally," but no reference was made to spring storing, but only to storing during winter when there is cessation of growth analogous to that produced by tea pruning. Lastly the causes of the upward flow of the crude sap (a subject which Mr. McKenzie did not wish to burden your columns with a dissertation on, as having no direct bearing on the question at present at issue) is taken up.

Mr. McKenzie's communication in my thinking is a most interesting production and he works out the analogy between the wintering tree and the pruned tea bush with much ability, at least from a scientific point of view. I shall watch the treatment of the subject from a practical standpoint with much interest. The last paragraph of Mr. McKenzie's letter is, however, an unfortunate production. I should hardly have expected him to be astonished or rather amused to find it said by your London correspondent that tea can appropriate "nourishment" (the italics mine) in spite of the fact that nitrification is only possible in the topmost twelve or (as afterwards corrected into) eighteen inches or two feet of soil, according to texture and composition.—Yours truly,

AGRICULTURIST.

HELOPELTIS AT HIGH AND LOW ELEVATIONS.

DEAR SIR,—I was first introduced to *Helopeltis* some 7 years ago at an elevation of 6,000 feet.

I was sceptical as to its identity until the microscope and Col. Money were brought to bear on it when I had reluctantly to confess its existence.

It did but little harm however, and I am glad to say I have not seen the slightest evidence of it for years, so I think there need be no fear of its becoming troublesome at the higher elevations.

I doubt its general prevalence in the low-country as I have not yet seen any appearance of its presence on an estate 20 miles east of Colombo. J. F.

COFFEE IN BRAZIL.—The bureau of American republics is informed that the Committee of coffee factors of Brazil, appointed to estimate the coffee crop available for exportation from that market, ratifies the estimate already published of 2,700,000 bags as the maximum export from Brazil for 1893. This is a large decline from previous crops,

THE CULTURE SYSTEM IN JAVA.

[From Worsfold's Visit to Java.*]

Towards the end of last century, the British Colonial Government succeeded the Dutch East India Company in the administration of Java. During the period antecedent to the British Occupation, the revenue of the Government was derived from two monopolies: (1) that of producing the more valuable crops, and (2) that of trading in all products whatever. Meanwhile the mass of the natives were left entirely to the mercy of the native princes, by whom they were subjected to all manner of exactions.

The financial results of this state of things were seen in the fact that in 1810 the gross revenue of Java was only three and a half million florins,† a sum wholly inadequate to the requirements of administration.

During the five years of British occupation (1811-1816) Sir Stamford Raffles was Lieutenant-Governor. He at once introduced reforms. The native princes were displaced; the village community, with its common property and patriarchal government, was modified; a system of criminal and civil justice, similar to that in force in India, in which a European judge sat with native assessors, was introduced; the peasants were given proprietary rights in the soil they cultivated; and complete political and commercial liberty was established. An inquiry into the nature of the respective rights in the soil of the cultivator, the native princes, and the Government resulted in establishing the fact that of the subject territory the Government was sole owner of seven-tenths. Of the remainder, two-tenths belonged to the Preanger Regents, and one-tenth was occupied by private estates, chiefly in the neighbourhood of Buitenzorg and Batavia. In order to teach the natives the western virtues of industry and independence, Raffles determined to introduce the Ryotwarree system. The property in the land vested in the Government was handed over to individual peasant proprietors. In return for his land each proprietor was made individually and personally responsible for the payment of his land tax, and his land was liable to be sold in satisfaction of his public or private debts.

Before the English administration the peasant had paid—(1) a land rent for his rice lands to the native princes, amounting to a sum equivalent to one-half of the produce of sawah (irrigated) and one-third of legal (unirrigated) lands; and (2) a tax of forced labour to the Dutch Government, which took the form of unpaid labour in the cultivation of the produce for export. Raffles abolished both, and in place of them he established a fixed money payment equivalent to a much smaller proportion of the produce of the land than had been paid before to the native princes alone.

The Dutch regained their East Indian possessions by the Treaty of London. On their return to Java, they restored the village community with its joint ownership and joint liability, and abolished all proprietary rights of the natives in the soil, only allowing ownership of land to the Europeans. They contend that this attempt of Raffles to apply Western Principles to an Eastern society had already proved disastrous. The peasants, on the one hand, had not acquired the habits necessary for the successful development of their holdings, but, on the other, through their inability to pay the land rent, were becoming hopelessly involved in debt to the Chinese and Arab money-lenders. The broad fact, however remains that during the short period of British rule the revenue rose from three and a half to seven and a half million florins, and the population from four to five and a half millions.

As the old monopolies from which the chief part of the revenue had formerly been derived had been abolished by the policy of unrestricted commerce introduced by Raffles, it was necessary to find some

other method of raising money. It was decided to retain the land tax as a basis of revenue; but, in order to make it more profitable, a return was made to the original principle of land tenure under native rule, by which the cultivator paid one-fifth of his labour and one-fifth of his produce in return for the usufruct of the land. One day of gratuitous labour in seven (the European week) was substituted for one day in five formerly given to the landlord. In certain districts, namely, those of which the Dutch became possessed by treaty and not by conquest, this contribution in kind and labour was paid to the native princes, and not to the government. On private estates, again, as the Government had parted with their feudal rights in alienating the property, a tax of three-fourths per cent. on the estimated value of the property was substituted. This tax, called *verponding*, was at most equivalent to one fifth of the net yearly income.

As before, the produce due from the peasants cultivating Government lands was commuted into a money payment assessed upon the rice crops; but this payment was made, not by the individual peasants, but by the *vedanas*, or village chiefs, on behalf of the whole community. Beside the land tax, an additional source of income remained in the profit arising from the sale of coffee, grown either by the Preanger Regents and sold to the Government at prices fixed by treaty, or on the coffee plantations established by Marshall Daendels, which were now restored.

These two methods of raising revenue were resorted to by the Dutch upon their return to the island, and continued in force during the period 1816—1833. They were wholly inadequate. Whether the Dutch were right or not in characterising Raffles' reforms as a failure, it is certain that nothing could be more desperate than the state of the island in the years immediately preceding the introduction of the culture system. At the end of the period 1816-1833 both revenue and population seem to have become stationary. The mass of the natives were becoming so impoverished that they ceased to be able to keep a supply of domestic animals and implements necessary for the cultivation of their lands. Apart from the princes, there was no class, merchants or tradespeople, possessing any wealth that could be taxed. Not only was the revenue stagnant, but, owing to a war with the sultans of the interior, a debt of over 35,000,000 florins was incurred by the Government. In a word, the colony seemed likely to become an intolerable burden to Holland. It was at this crisis that General Van den Bosch proposed the culture system as a means of rescuing the island from its financial and social difficulties.

The immediate object of the culture system was to extend the cultivation of sugar, coffee, and other produce suited for European consumption; its ultimate object was to develop the resources of the island. This latter was, of course, the most important. Van den Bosch saw that the natives would never be able to do this by themselves. In the first place, they were still organised on the patriarchal model in village communities; and, in the second, owing to the tropical climate and the extreme ease with which life could be sustained in so fertile a country, they were naturally indolent and unprogressive. He therefore proposed to organize their labour under European supervision. By this method he thought that he would be able both to raise the revenue and to improve the condition of the peasants by teaching them to grow valuable produce in addition to the rice crops on which they depended for subsistence. Van den Bosch became Governor-General of Java and its dependencies in 1830. Before leaving Holland he had made his proposals known, and obtained the approval of the Netherlands Government. He took with him newly appointed officials free from colonial traditions, and his reforms inspired such confidence, that a number of well-educated and intelligent persons were willing to emigrate with their families to Java in order to take up the business of manufacturing the produce grown under the new system. Upon his arrival in the island, a

* A visit to Java. By W. Basil Worsfold. London, R. Bentley & Son, 1893.

† 12 florins=£1.

special branch of the Colonial Administration was created. The first work of the new department was to found the sugar industry. It was necessary to supply the manufacturers with both capital and income. Accordingly a sum amounting to £14,000 was placed to the credit of each manufacturer in the books of the department. Of this sum he was allowed to draw up to £125 per month for the expenses of himself and his family during the first two years. From the third year onwards he paid back one-tenth annually. Thus at the end of twelve years the capital was repaid. The manufacturer was to apply the capital so advanced to the construction of the sugar-mill, which was to be fitted with the best European machinery, and worked by water-power. Free labour, and timber from the Government plantations, was supplied; and the customs duties upon the machinery and implements imported were remitted. The building of the mills was supervised by the *controleurs*, the officials of the new department, and had to be carried out to their satisfaction. The department also undertook to see that the peasants in the neighbourhood of each mill should have from seven hundred to a thousand acres planted with sugar-canes by the time the mills were in working order. In Java, as in other Eastern countries, the landlord has the right of selecting the crop which the tenant is to plant, and therefore the peasants saw nothing unusual in this action of the Government. The *controleurs* ascertained, in the case of each village, how much rice land was necessary for the subsistence of the village, and they then ordered the remainder, usually one-fifth, to be planted with sugar-canes. At the same time, they explained that the value of the crop of sugar would be much greater than that of the rice crop, and promised that the peasants should be paid not only for the crops, but also for the labour of cutting the canes and carrying them to the mill. When, at the end of two years, the mills had been built and the plantations established, another advance was made by the department to the manufacturers. This was capital sufficient to pay for the value of the sugar crop, estimated, as it stood, for the wages of the peasants, and generally for the expenses of manufacture. This second advance was at once repaid by the produce of the mill. At first the department required the manufacturer to deliver the whole amount of produce to them at a price one-third in excess of the cost of production. Subsequently he was allowed the option of delivering the whole crop to Government, or of delivering so much of the produce only as would pay for the interest on the crop advance, together with the instalment of the original capital annually due. Working on these terms, large profits were made by the manufacturers, and there soon came to be a demand for such new contracts as the Government had at their disposal.

As for the peasants, they were undoubtedly benefited by the introduction of the system. While the land rent continued to be calculated as before, on a basis of the produce of ricefields, the value of the sugar crop was so much greater than that of the rice, which it partially displaced, that the money received for it amounted on the average of twice the sum paid to Government for land rent on the whole of the village land. Moreover, although the estimated price of the crop was paid to the *wedanas*, or village chiefs, the wages for cutting and carrying were paid to the peasants individually. The value of the crop, the rate of wages, and the relation between the peasants and the manufacturers generally, were settled by the *controleurs*.

In 1871, when the culture system was in full operation, there were 39,000 *bowas*, or 70,000 acres, under sugar cane, giving employment to 222,000 native families, and ninety-seven sugar mills had been started. One-third of the produce was delivered to Government at the rate of eight florins per picul,* and the remaining two-thirds were sold by the manufacturers in open market. In the five years 1866-1870 the Government profit on sugar amounted to rather more than 25,000,000 florins.

Subsequently the cultivation of coffee, indigo, cochineal, tobacco, pepper, tea, and cinchona was added to that of sugar. The system pursued was not identical with the case of all produce. Cochineal, indigo, tea, and tobacco were cultivated in a manner similar to that adopted for sugar. But in the case of coffee, cinnamon, and pepper it was not found necessary to have any manufacturers between the *controleurs* and the peasants. Of these, coffee, the most important, is grown on lands having an elevation of from 2000 to 4500 feet. Each head of a family is required to plant a certain number of trees in gardens (the maximum was fixed in 1877 at fifty a year), and to keep a nursery of young trees to replenish the plantations. These gardens and nurseries are all inspected by native and European officials. The process of harvesting the berry is similarly supervised, but after that is accomplished the peasants are left to dry, clean, and sort the berries by themselves, and are allowed to deliver the crop at the coffee stores at their own convenience. Finally, private persons contract for periods of two or three years to pack and transport the coffee to the central stores at the ports. Of the coffee produced on Government account, one-fifth only is sold in Java, and the remainder is sent over to Europe and sold there.

The culture system was so successful as a financial expedient, that between the years of 1831 and 1875 the colonial revenue yielded surpluses to Holland amounting to 725,000,000 florins. This total seems the more remarkable when we know that from 1838 onwards, the colonial revenue was charged with 200,000,000 florins of the public debt of Holland, being the proportion borne by Belgium before the separation of the two countries, which took place at that date.

In 1876, however, the long series of surpluses ceased, and they have since been replaced by deficits almost as continuous. These deficits are due to three well-ascertained causes: (1) the Achin war, (2) public works, (3) the fall in the price of sugar and coffee. In order to show that this remarkable change in the financial fortunes of Java is in no way due to the culture system, it is necessary to go somewhat more into detail.

(1) Before the outbreak of the Achin war in 1873, the average expenditure of the Colonial Government for military purposes was 30,000,000 florins annually. During the period 1873-1884 this expenditure rose to an average of 50,000,000 florins, and the total cost of the war during that period amounted to 240,000,000 florins. Since 1884 the expenditure has been reduced by confining the operations of the troops to such as are purely defensive; even then the average annual expenditure has reached 40,000,000 florins.

(2) Since 1875 the construction of railways and of other public works, notably the harbour works at Tanjong Priok, the port of Batavia, has been undertaken by Government. Since the cost has been paid out of current revenue, and not raised by loans, these works have necessitated a further annual expenditure of 8,000,000 florins. The total sum spent in public works between the years 1875-1884, amounting to 75,000,000 florins, is almost exactly equivalent to the deficit incurred during the same period.

(3) In suffering from the competition of France in sugar, and of Brazil in coffee, Java has not been peculiar. The British West Indian colonies are at the present time most disastrously affected by the bounty-fed sugar industry of France, and Ceylon is only just learning how to compensate itself for the diminution of its coffee export by the introduction of a new industry—tea.

As for the general progress of the island, it is sufficiently indicated by the fact that since the date (1831) of the introduction of the system, the population has increased from six to twenty-three millions, and the revenue from thirty million florins to one hundred and thirty-two.

Although the culture system has yielded such satisfactory results, it has been gradually abandoned since 1871.

* The picul=135 lb.

The reason for this change of policy is the feeling that the system, though necessary originally to develop the resources of the island, is at variance with the best interests of the natives and hinders the introduction of private enterprise and capital. Increased commercial prosperity is expected to compensate for the loss of revenue caused by the withdrawal of the Government from the work of production. In the meantime, it has been found necessary to impose various new and direct taxes. The most important of these is a poll tax on the natives, which has taken the place of the personal services formerly rendered by them on the Government plantations. Originally imposed in 1871, it yielded two and a half million florins in 1886. Another compensating source of revenue is the growth of the verpoeding. As already mentioned, this is a tax of three fourths per cent. on the capital value of house property and industrial plant. It is assessed every three years, and therefore is an accurate test of the growth of private wealth invested in the colony. In the fifteen years from 1871 to 1886, the amount yielded by this tax showed a growth of seventy-five per cent.

It is not necessary to detail the various steps by which the Dutch have carried out this policy of abandonment. It is sufficient to note the general result.

Today all industries, with the exception of coffee, opium, and salt, are free. In the production of the two latter, opium and salt, the Colonial Government maintains a complete monopoly; in the case of coffee they compete with the planters. The extent of the shares respectively taken by the Government and private enterprise in the trade of the island is exhibited by the following returns for 1889:—

	IMPORTS.	EXPORTS.
	Florins.	Florins.
Government	13,009,445	33,072,175
Private persons ..	160,375,326	164,590,439
Total	173,384,771	197,662,614

The Government still produces two-thirds of the coffee crop. In 1889 the amount produced respectively by the Government and the planters was 578,000 and 356,000 piculs.

Of the two chief industries of the island, sugar and coffee, the exports in 1890 amounted in value to fifty and fifteen million florins respectively. To these must be added two new industries—tea and cinchona bark. The former is only in its infancy, and is confined to the immediate neighbourhood of Soekaboemi, the head-quarters of the planting interest in Java. Here there are two important estates, Sinagar and Parakan Salak, which are from 12,000 to 15,000 acres in extent. The latter industry is especially hopeful. In 1890 the area of cinchona plantations was 22,500 acres, and 6,000,000 pounds of bark, containing four per cent. of sulphate of quinine, was exported. This amount is equivalent to half the world's supply for the year.

Of the import trade it is not necessary to say more than that the most important item is that of the various cotton goods, coming mainly from this country, which serve the natives with material for clothing suitable for their tropical climate. It is also important to remember that there are a quarter of a million Chinese residents in the island, by whom all the retail, and part of the wholesale, trade is conducted.

Last year (1891) the administration of Java was the subject of severe criticism in the Netherlands Parliament. The complaints were chiefly directed against the conduct of the Achin war, the opium monopoly, and the continued interference of the Government in the coffee industry. The reply of Baron Mackay, the colonial minister at the Hague, was in substance as follows:—

The Achin war, he said, was the result of unavoidable circumstances, and neither the Colonial nor the Home Government could be regarded as responsible for the loss of revenue involved in it. He added, however, that "excellent results were

expected from the blockade system" now adopted, and that there were already signs that the Achinese would before long be brought to terms. With regard to the sale of opium, he assured the States-General that "every possible means were being taken to reduce the sale of the drug, and to remedy its evil effects." He frankly recognised the importance of the question of coffee-culture, but at the same time urged the advisability of maintaining the system for the present. It was not certain, in the first place, that the existing system could be changed with advantage; and, in the second, "no product in the immediate future could be looked for to replace coffee as a source of revenue."

Undoubtedly the resources of Java are at the present time subjected to a heavy strain. On the other hand, it must not be forgotten that (1) the burden of the Achin war may be at any time removed, and (2) all public works are being paid for out of current revenue without recourse to loans. There is, therefore, no reasonable grounds for supposing that the present financial difficulties of the Colonial Government are more than temporary. A glance at the balance-sheet of the island for the year 1889 shows to what an extent the difficulties are due to an increasing sense of responsibility towards the natives, and to an intention to eventually open all the industries of this singularly fertile island to private enterprise.

HEADS OF REVENUE AND EXPENDITURE FOR 1889
IN MILLION FLORINS.

Revenue.		Expenditure.	
Taxes	40	Instruction ..	10
Monopolies	31	Army and Navy ..	40
Sale of produce (of this coffee contributes 37, sugar 2)	49	Public works (of this railways cost 10)	20
Other sources (railways, school fees, etc.) ..	14	Administration, etc.	60
In round numbers ..	134		130

When the natives have been educated and the industries of the island free from unnatural restrictions, financial and commercial prosperity will return to Java.—*The Sugar Cane.*

THE "TROPICAL AGRICULTURIST."

(From a Proprietor.)

I wonder how many planters know what they lose in not subscribing to your wonderful publication? The cost is absolutely nothing, compared to the convenience of having in a bound book all that is interesting and necessary in the literature of their calling. Information culled from a thousand sources, price lists of all produce sold locally and home advertisements not seen elsewhere, and a hundred other things necessary for them to see and to know. The *T. A.* is, in fact, a convenient file of useful information daily arising and permanently preserved.

TEA, CINCHONA AND HELOPELTIS.

(From an Old Planter.)

We are having a good deal of damage done to tea by helopeltis, especially in fields where there is also cinchona growing. Cinchona seems to have a greater attraction for the insect than tea, and so have other fruit and jungle trees, so it is to be hoped that, with abundance of other food, it will not develop any extra fondness for tea. Judging from the damage done and the small number of insects we can catch, one helopeltis must be capable of injuring a large number of young shoots.

CHINA TEA EXPORTS.

Our Special Telegram today shows that during the past fortnight the exports of tea from the Far East to the United Kingdom have been increased by only one million lb., bringing the total for the season so far, up to 40 million lb. According to our telegram at the same date last year this means a comparative increase of four million lb.; although compared with 1891, there is still a falling-off of two million lb. In other words during the fortnight Aug. 29th to Sept. 13th just past, the exports of China Tea to Britain have been only 1 million lb. against 1 million lb. in the same period of 1892. This looks rather like the practical closing of the China Tea Season and the comparison, according to our *Special Telegrams* (substantiated up to mail dates by those sent to Messrs. W. J. & H. Thompson) would run as follows:—

TOTAL EXPORTS TO UNITED KINGDOM :		
Season 1893 to 15th Sep.	=	40,000,000 lb.
Do 1892 do	"	36,000,000 "
Do 1891 do	"	42,000,000 "
Do 1890 do	"	40,000,000 "

But here again comes the Hongkong Price Current with its contradictory information. The copy dated 30th Aug. in its table makes the comparison as follows and we can only leave the figures with our readers, pending the explanation which we have called for from our Far East Correspondent:—

EXPORT OF TEA FROM CHINA AND JAPAN TO UNITED KINGDOM.			
Season 1893-94.			
	China.	direct	Grand total.
Total to date 30th Aug..	38,042,583	38,108	38,080,691
Same time in 1892, ..	24,289,490	192,618	24,482,108
" 1891, ..	31,124,379	107,272	31,231,651

How is it possible that the London Brokers should be misinformed if there were really an excess of 13½ million lb. tea and would our Ceylon tea prices be reported *firm* if such were the case?

TECHNICAL AND INDUSTRIAL EDUCATION.

(Communicated.)

We read in the *Bombay Gazette Budget* that, at the instance of the Industrial Association, the Poona Municipality has undertaken to prepare a comparative statement of the occupations of the population of the city with a view to ascertain what industries are common, and which require the aid of higher technical education. At the industrial conference held at Poona this month, local Municipalities and District Boards were induced, through the agency of the Industrial Association which received the sanction of the Government to the co-operation of district officers, to send representatives from the various districts. We read further that it is contemplated to include the subject of rural industries, in the program of the annual agricultural conference at Simla, with a view to their improvement. The Chairman of the Poona meeting dwelt forcibly on the necessity of fostering existing industries and reviving those which have perished. Says the *Bombay Gazette*, in this connection: "Everyone must heartily concur in the hope that the Indian industries will receive a new and a large development, for if man cannot live by bread alone, a nation cannot hope to prosper by agriculture alone, though for every nation the culture of the soil is the most indispensable of its industries."

The facts brought out in the above reference to the movement in favour of native Indian industries are well worth the serious consideration of those who are connected with Technical Education in Ceylon. The suggestion that a comparative state-

ment of the occupations of the people should be drawn up is an excellent one, and might well be acted upon in Ceylon, with a view to ascertain to what extent higher Technical Education can help native industries. That such aid is possible and necessary no one can for a moment deny. We constantly read, in accounts of Ceylon, of the buried wealth of the island, in the form of fibres, dyestuffs, tanning materials, oils, gums, resins, and other natural products, only waiting to be developed. We would here quote the following passage from an address by the Right Hon. A. J. Balfour on Technical Education. He says:—"I venture to lay down no general rule about the advantages or disadvantages of Technical Education. I believe it to be of vital importance in some places and some industries; I believe it to be nearly useless in any form in which it is likely to be applied in other places and other industries. Each case must be considered on its own merits, not simply in the light of vague generalizations, but with a close scrutiny of the practical mode in which any proposed reform would work." These are very suggestive words. There is no doubt that Technical Education is a desideratum in Ceylon, but have the authorities in Ceylon given the subject the "close scrutiny" it calls for, so that it may not be "nearly useless in any form in which it may be applied"? Have they discovered the particular industries which require the aid of such education, and which are likely to benefit thereby? Or have they "simply considered the subject in the light of vague generalizations?" These are questions for serious consideration now that a Technical School is about to be started in Ceylon. If an attempt is to be made to develop the dormant industries of the Island, and utilize for economic ends its many valuable resources, as yet but little recognized, and the value of which has been only imperfectly realized, some such measures as those suggested for India must be energetically adopted.

An adequate knowledge of the native industries and the details involved in their pursuit, is of the first necessity, and a comparative statement based on careful inquiry, such as was applied for by the Industrial Association of Western India, would tend toward securing this. In fact an Industrial Museum at the Technical School would be a most desirable instrument towards the same end. The aid of District and Provincial Officials and *Gramarakshasamagams* can with advantage be sought with the same purpose. Forest officers might also be invited to contribute much of the invaluable information which they would be able to give, regarding the undeveloped raw products of the Island. And if a Conference for deliberation the subject of Technical Education with a view to the development of existing and latent native industries, be arranged for, we should then, then only, be in a fair way towards discovering the right direction in which Technical Instruction for Ceylon should tend.

THE KALAWEWA COLONISATION SCHEME.

Report of Mr. R. W. Ievers, Government Agent of the North-Central Province.

The Report of March 26th last (sent with letter No. 90) gives the history of the experiment up to that date. Subsequently fourteen families arrived from Jaffna, who were sent to me by Mr. Assipillat. For these colonists I had houses ready in a healthy site, which had been cleared some years previously, and I allotted them land under Balawewa. But partly from sickness which occurred among them and partly from natural disinclination to work, after repeated warnings to them, I was obliged, in December to discontinue Government aid, and soon afterwards these people returned to Jaffna. The following extract* from my Administration Report for 1892 supplies the general history of the experiment, and the accom-

* Appendix A.

panying extracts* from my official diary give details of my inspections and my notes thereon. I personally visited and inspected the colonists and their lands in every month in 1892, except March, July, and October. The total expenditure † to date has been R2,576.20. But from this must be deducted the money paid for the paddy, which will be sold and refunded to Government (about R600,) and the value of some gingerly sown on the lands cleared (partly sown and abandoned) at Bataluwewa. The tools procured will also be sold and the proceeds credited to Government. When the account is finally made up the expenditure will probably be about R1,800, and of this the advances to the ten families who remain will be hereafter recovered.

The *Sinhalese* settlement (of Etawirawewa villagers) below the Yoda-ela proved a failure. These people cleared a considerable extent of land, and put up houses. When, however, they heard that lands adjoining theirs had been sold to Mr. Silva, they at once abandoned the place and went back to live in their own wretched village, where they have barely enough for subsistence. It is difficult for any but those who live among these people to understand their peculiarities. Here, people practically starving were given ample land and sure water, and all the elements of agricultural prosperity; yet they abandoned the land from some prejudice regarding their future neighbours. In the same way, one would suppose that natives of Jaffna—such as the men who came here, who have no land of their own, and cultivate almost as the slaves of landowners, and who, after working from morning to night, can only expect one full meal a day—would be satisfied with their prospects of independence and property. The land cleared by them is a valuable one, and being so improved will readily sell at a price considerably above the present. There has been no expenditure by Government on account of these *Sinhalese* villagers.

The restoration of Maha Illippallaws, to which I referred in my former report, is proceeding; and I have arranged that when sufficient work has been done on the embankment of the tank by the settlers, a sluice for irrigation should be supplied to them. The proposal of some capitalists from Jaffna to take up land under Kalawewa came to nothing, as they obtained land on easier terms than I was able to offer them, at Kanakarayanaklam, in the Vavuniya District.

In my Administration Report I have referred to the sale of 1,200 acres adjoining the land on which the Tamil families have settled, to Mr. Silva, a *Sinhalese* gentleman of the Negombo District, who is a solvent purchaser, and has command of a full labour supply for opening up the land.—R. W. IVERS, Government Agent. Anuradhapura Kacheheri, April 7, 1893.

TEA AND COFFEE IN AMERICA.

The blockade and bombardment of the commercial capital of Brazil means, at the very least, a great disturbance of trade. The important coffee trade of Rio is certain to be very seriously interfered with. For a time there will be no exports, and yet the markets in the United States and Europe are by no means heavily stocked. Indeed, the year 1893, judging by the best statistics available, was in any case to be a year of short supply, following a season of good crops and the prospect a few months ago was of coffee generally being in keen demand towards the end of this year. The consumption on the Continent of Europe for the four years 1889-92 averaged a total of 410,717 tons; but 1892 itself showed that 422,801 tons were called for. This, apart from about 12,000 tons required for the United Kingdom (against 15,000 tons consumed some years ago). Then the United States used up as its average annual supply from 1889 to 1892, as much

as 240,667 tons; but for last year required 255,000 out of an import of 260,876 tons. This makes a consumption of between 8 and 9 lb. of coffee per head of population in the United States.

How different the consumption of tea in America! Of our present staple there is in the U. States, scarcely $1\frac{1}{4}$ lb. per head used, against about 6 lb. for the United Kingdom and between 7 and 8 lb. in Australasia. In 1892, America got over 83 million lb. of tea of which not more than *one per cent* or about 800,000 lb. could have been Ceylon Tea. There is therefore immense room for an increased consumption of our staple product even in the present American consumption. But still more, is there room—as we want specially to point out today—for taking advantage of the critical period which may now possibly be overtaking the American coffee trade. Brazil supplies about 55 per cent of the entire coffee supply of Europe and America and between Rio and New York the trade in coffee is very large. As already stated, this year's coffee supply from Brazil, as well as from Java, India and the East generally, was expected to be short; and although Mexico and Central America are rapidly coming to the front as coffee growers, it was not anticipated that they could fully make up the deficit. With coffee getting dearer and scarcer after this fashion, we may fairly expect many in America to be ready to give attention to tea when they find it cheap and abundant, and especially if the refreshing beneficial character of the beverage properly infused from pure Ceylon and India teas, is rightly brought before them. Not for a long time therefore, has there been so favourable a season throughout the United States for getting at the mass of consumers (of coffee, tea and cocoa) with our good teas. But if in addition to scarce and dear coffee under ordinary circumstances, there is added for a certain period (even for a few weeks) an entire suspension of the coffee import trade from Brazil, what can the people of America do in self-defence, but turn to and drink tea? The bombardment and blockade of Rio and the consequent disturbance and stoppage of business, may therefore, quite possibly, have very important consequences in creating and stimulating a special demand for Ceylon and Indian teas. We hope our Chicago Commissioner will be on the alert to read "the signs of the times." If once our American cousins were got, even for a few weeks, in view of a coffee famine, to try our pure refreshing teas, it is quite likely that many of them would continue to buy tea and come gradually to substitute it altogether for coffee. Elsewhere will be found an extract from the American *Grocer* showing that two months ago there were complaints about coffee becoming dear and scarce, and also that the consumption in the United States was by no means keeping up to the old ratio. When on the top of this, there comes the present outbreak at Rio, we may depend on the New York coffee importers having difficulty in supplying their customers and on many of the grocers turning their attention to the substitute in which a good, large and profitable business can be done, namely the *NEW CEYLON TEAS*—so freely advertised of late in the Eastern States by the defunct Company—and which, along with *INDIAN TEAS*, have been made so special a feature at the World's Columbian Exposition. Here then is a grand opportunity in our opinion for pushing the sale of our teas, and we trust Ceylon planters will very emphatically support their Chairman in the proposal he is about to make for the establishment of Chicago, and perhaps New York, Tea Agencies through the medium of Mr. Grinton.

* Appendix B. † Appendix C.

LONDON REPORTS ON TRAVANCORE
CEYLON PRODUCE.
TRAVANCORE TEA.

(From *Patry & Pasteur, Limited*, Report of the
Colonial Markets for the Week ending
August 23rd, 1893)

The chance of a good market for this class of tea was very severely handicapped by the over abundant supply of low medium, both from India and Ceylon, but although prices appear low, they are quite equal to those paid for similar kinds in the other markets.

The kind of tea buyers look for and expect to find in Travancore is that possessing thick coloury liquor, for which they are always prepared to pay a good price.

COFFEE PROSPECTS.

Messrs. I. A. Rucker & Bencraft report on August 31st—Messrs. G. Trinks & Co. cable from Rio this week, "Weather unfavourable for the future crop. There is too much rain, and up to the present there is only poor flowering." There is a unanimous belief current that the 1894-95 crops will be very large, and therefore a telegram such as the above at present attracts little attention; but may possibly yet prove to be of some importance. After nearly three years of more or less bad times, once we turn the corner we should anticipate a decided revival in trade. The important question is, are we getting within measurable distance of that revival. Since the issue of our last, there has been a distinctly better feeling about, futures are dearer, and spot coffees are steady to advance from the recent lowest point. Moreover, the feeling generally current in commercial circles is more hopeful, and there appears to be a growing opinion that we have seen the worst.

COFFEE AND TEA IN AMERICA.

"The people of the United States in 1892 consumed per capita 6.54 pounds of coffee and 1.37 pounds of tea. Coffee is imitated there in many ways besides being adulterated, and when the price of coffee is high the substitutes are largely purchased by poor people."—*Bradstreet's*, Aug. 19.

TEA SEED OIL.

A gentleman with extensive experience in China and East who is at present on a visit to Colombo informs us that tea seed oil is regularly used in Hongkong and the Southern parts of China as an illuminating oil. It will not however burn in a cold climate.

ARE WE A NATION OF TEA-
DRUNKARDS?

We are a nation of tea-drinkers; we consume about 5½ lb. of the leaf per head annually, which when made into a beverage, produces about thirty-seven gallons of tea. The question (says the *Hospital*) is beginning to arise—Are we a nation of tea-drunkards? For not only are we yielding with all the weakness of the inebriate to the diseases of nerve and stomach which excessive tea-drinking brings in its train, but we are developing that indifference to quality which is the crowning mark of indulgence, the point of severance between the gourmand and the connoisseur. Tea has always been popular in England, even when its price was enormously high, and when a moralist condemned its consumption as a "filthy custom," to be explained only by the growing wickedness of the nations. This gentleman, Mr. Henry Savile, writing to a friend, speaks with indignation of those who "call for tea, instead of pipes and bottles after dinner, a base unworthy Indian practice, and which I must ever admire your most Christian family for not admitting." What would this old-fashioned Christian of 1678 say to our modern temperance societies and their endless tea drinking? But, indeed, it almost seems as if a new temperance would have to arise to lead a crusade against our favourite beverage, and reformers should petition parliament to increase the duty on tea. By far the larger part of the tea we drink now is the product of India and Ceylon. From a pound of Indian tea you can make 7½ gallons of infusion; from a pound of Chinese tea only 5 gallons. The consideration is likely to weigh with the average house-keeper, who appreciates an immediate effect on her purse more than a remote effect on the digestion of her household. The result is that nearly 75 per cent of our tea is of Indian and Cingalese growth. These teas are, moreover, cheaper than the China leaf, and as they are thus doubly tempting, they have attained a dangerous popularity. We drink more tea than our parents; we take it oftener, stronger, and of coarser quality. The results are less obvious than those of alcoholic intoxication, but not less serious; and, in truth, the time may be not far distant when the earnest disciples of the new temperance will plead with us with tears in their eyes, give up this accursed tea, and take to cocoa, or even to beer."—*St. James's Gazette*, Sept. 1. [What is the 5½ lb. per head of tea drunk per annum in the United Kingdom to the 7 to 8 lb. in Australia, and where will a finer healthier people be found?—Ed. T.A.]

DRUG REPORT.

(From the *Chemist and Druggist*.)

London, Aug. 31.

CALUMBA.—Of 339 bags offered today 120 sold at 11s per cwt. for brown mixed sorts, partly stalky, dull and slightly mouldy, and 8s for very common. A lot of fair bright yellow root is limited at 30s per cwt.

COCA-LEAVES.—South American leaves are very dull of sale, fair bright green broken Truxillo being bought in at auction at 1s 3d, good thick brownish Huanoco at 1s 4d per lb. Four small bags from Colombo were also shown, and two of these dark thick brown damaged leaves sold at 1d per lb.

CROTON-SEED.—Twenty bags of very small seeds from Ceylon realised 25s per cwt.

CUBEBS are neglected; 70s was suggested as the price for 4 bags small brown shrivelled berries, and of another lot of 14 packages from Bombay, 4 sold at 70s per cwt for good brown small mixed; for a less desirable lot a bid of 62s was rejected.

GOVERNMENT PLANTATIONS IN CEYLON.

(From the Administration Report on Forest Conservancy for 1892.)

The work done in the different Provinces was as follows:—

WESTERN PROVINCE.—The creepers in the Polonnaruwa jak chena were cut, but I am unable to say at what cost.

CENTRAL PROVINCE.—The strip plantations at Nanuoya are doing well, the trees planted in 1890 and 1891 being particularly healthy, notwithstanding the attacks of elk which do much damage to the young plants. The young trees in the plantations of 1890 are larger than most of those in the plantations of 1889. This is partly due to the large number of failures which there were in the former, and to the large number of standards which were left. There is no doubt that where few standards were left the growth of the young plants has been very much more vigorous. To make a fair comparison between the two systems, however, the annual girth increment of the standards should also have been taken into consideration. It will be interesting to see whether in another twelve or fifteen years' time, when it is estimated the first fellings can take place, the outturn will be larger in the areas containing numerous standards or in those containing few.

The following measurements were taken by the Forester, Nawara Eliya:—

Species.	Year of Planting.	No. of Trees measured.	Average Girth.	Average Height.
<i>Eucalyptus globulus</i>	1889	7	7.82	25
Do	1890	9	9.03	26
<i>Acacia decurrens</i>	1889	3	8.87	30
Do	1890	2	7.75	24
Do	1891	5	5.10	13
<i>Eucalyptus robusta</i>	1891	5	6.40	16
<i>Acacia melanoxylon</i>	1891	4	2.69	9

Eucalyptus robusta and *Acacia decurrens* have proved to be the best growing trees on these clearings; *Acacia melanoxylon* grows slower, and *Eucalyptus globulus* does not seem to thrive. This may be due to the roots reaching slab rock, the covering of soil appearing to be thin.

In the Nawara Eliya plantations the blue gums planted in 1888 average 17 in. in girth and 40 ft. in height, and the *Cryptomeria* of the same age 6.67 in. in girth and 14 ft. in height in the Kachcheri clearing, while in the nursery clearing the blue gums of 1888 only average 12.04 in. girth and 23 ft. in height. In this clearing the average girth of *Acacia melanoxylon* of the same age is 6.25, and the average height 20 ft., while *Acacia decurrens*, also of the same age, attains an average girth of 23.67 in. and height of 40 ft. The *Eucalyptus robusta* planted in 1891 has not done quite so well as at Nanuoya, as it averages only 4.62 in. in girth and 14 ft. in height. These plantations are getting on very nicely, but are somewhat expensive, as the area added during the year and the upkeep of former plantations cost upwards of R73 per acre.

The Galle Railway fuel plantations have given rise to much discussion and correspondence during the year, owing to the large number of vacancies in all the clearings. I have made allusion above to some of the causes of failure, and as special reports have already been submitted to Government by Captain Walker and by myself, there is not much need for me to dwell at length on the causes of failure. It may however be said that where the soil proved to be suitable, supplies were put in, nearly 20,000 plants being used. These are doing well, excepting some seedlings taken from the adjoining clumps of forest and planted on Penrhos, which were not able to stand the sudden change of surroundings and withered. On Blackwater field *Grevillea*, *Acacia melanoxylon*, and *Eucalyptus robusta* are doing best; on Dekinda *Grevillea*; while on Penrhos *Grevillea*, *Cassia siamea*, *jak*, and *Adenanthera pavonina* are growing well. The Mapakauda field is still very bare and wants re-stocking. The plantations

of the Central Province has cost up to date R53.35 per acre, but if the revenue obtained from areas planted be deducted, this cost is reduced to R33.29.

EASTERN PROVINCE.—The teak chena cannot be called successes. Most of them especially the more recent ones, consist of sheets of illik erasa with scattered teak poles. The granting of such chena has been abandoned, and I think that the efforts of the Forest Department should consist in fully stocking these areas with teak trees or other quickly growing species, which will fight successfully with the invading grass. Twelve acres were taken up departmentally near the Tumpalancholai rest-house, but the success was not very great. I have received no measurements of growth from this Province.

NORTH-WESTERN PROVINCE.—In this Province all the plantations are doing well, except the portion which was taken up at Puttalam for teak. This was unsuccessful owing to failure of the monsoon. The plantation of teak and jak at Kumbalpola, 10 acres in extent, is doing well, and has only cost R525 in three years, while that of Sundapola which is equally successful, and which now covers 89 acres, has cost less than R3,000. This plantation is chiefly of teak and jak, but also contains other species, such as satin, margosa, and the large-leaved mahogany, while the place is full of self-sown seedlings of *innmidella* (*Melia dubia*) and also of jak, for the forest contains a number of wild jak trees. The plants are put in partly in well-cleared strips and partly under shelter of the forest, which has however been considerably thinned. It will however be necessary to make further thinnings, as the young plants are growing far too lanky and spindly. I think these would benefit by being topped.

The large-leaved mahogany supplied by Dr. Trimen is doing very well indeed, the saplings being straight and sturdy. Mr. Feers, the late Assistant Conservator, and Mr. Felsinger, the Forest Ranger, deserves great credit for the efficient manner in which this plantation has been made.

At PUTTALAM 9 acres were added, but they were only very partially successful. In this case the old system was no longer adhered to of making a clean felling of the jungle and planting over the whole area, but strips 15 ft. broad were cut 45 ft. apart and planted, each with three rows of plants. However, the monsoon failed and a great number died. The remainder, which were growing on the outside rows on the strips, were saved by the shade which they obtained from the adjoining jungle. I found that the strips had not been cleared sufficiently well, and left instructions to leave no overhanging trees. The older plantations are doing well, the last one made by Mr. Armitage at the end of 1891 being particularly successful. The thinning which the late Asst. Conservator, late Forester, and myself made at the end of 1891 in the 1885 plantation has done much good, many trees which showed signs of suppression having thrown out new leaders. A similar operation was carried out in the 1886 plantation by the Assistant Conservator, the Forester, and myself shortly after the close of the year, but fewer trees were taken out, as the plot had been maltreated by Mr. Gordon-Cumming while Forester. I have not been furnished with any measurements, and cannot therefore state the average increase in girth for the plantations of different years. The cost of plantations in this Province has been up to date R40.17 per acre, or if the value of timber sold and granted free be deducted only R31.80 per acre.

PROVINCE OF UVA.—Judge's Hill plantation. This has probably been the most expensive plantation in the Island. Half an acre has been added during the year, and its total extent is now 24.5 acres. The knoll on which it is situated was originally covered with mana grass. The soil is poor, and the prison labour, which was at first lent for this work, was not regular, and unable to cope successfully with the weeds which kept springing up. No drains were cut, and in one place there must have been considerable scum. Here, the plantation is still not quite stocked; elsewhere, the plants are doing fairly well,

especially near the high road. The cost of this plantation up to date has been over R190 per acre.

ELLADALUWA PLANTATION.—Of the 27.5 acres added during the year, as shown in form 5, only 2.5 acres were fully stocked; the remainder was only cleared and holed. This plantation is a decided success, the sapu especially showing up very well.

HAPUTALE PLANTATION.—This is only 4½ acres in extent, an attempt to enlarge it having failed. It consists of *Ecalyptus robusta* with a few *Aacia melanozylon*, the latter being suppressed by the former. The younger trees have formed complete leaf canopy and are doing well.

BANDARAWELA PATANA PLANTATION.—This was abandoned during the year, the land being wanted by the Railway Extension Department. Two new plantations were started by order of the Governmet Agent at Bandarawela, one near the railway tank and another near the depôt. The land was only cleared and holed, but no plants put in. I do not put any faith in scattered small plantations. The cost of plantations in Dva amounts up to date of R102.05 per acre. Appendix B shows the measurements taken in the different plantations by the Assistant Conservator.

PROVINCE OF SABARAGAMUWA.—Para Rubber Plantations. A small addition was made to the Edangoda plantation, and 21 acres were added to the Yattipowa plantation. This addition was however not fully planted up before the end of the year. The delay was mainly due to the contractor, who put off clearing the jungle until the rains came on, with the result that the wood had all to be collected and removed before anything could be done in the way of planting, and by that time the season was over. The seed procured for this piece was therefore put in a nursery and will be planted in 1893. At Edaugoda the trees planted in 1890 are over 20 ft. high on an average, and look moderately healthy. They are, however, as yet far too lanky for their height, notwithstanding the amount of light which reaches them; and it is to be hoped that during the next few years they will develop in girth rather than in height. The same remarks apply to the young trees of 1891 planted at Yattipowa, which are liable to be knocked over by wind. It is evident that this trec requires shelter from wind, and a good soil. At Yattipowa the growth on the tops of the knolls is very poor, and Mr. Lewis and I have agreed that it will be advisable not to plant them with rubber trees in future.

At Enangoda the plantation was extended 10 acres above the road with the object of ascertaining whether jak can grow on ordinary jungls land. The experiment has been a success so far except where cattle has been able to get at the young plants. Should this plantation continue to be a success, there is no reason why hundreds of acres of poor obena land adjoining the Kalu-ganga should not be planted up. There is now a very great demand for this valuable timber, and it is to be feared that unless steps be taken by Government to satisfy this demand the gardens near Colombo and Moratuwa will be stripped of their fruit trees.

A small attempt was made by the Assistant Conservator to plant hal and nedun on the low ground in the Para plantations, and it has been made apparent that both of these trees require some shelter to start with. Hal was only moderately successful, while nedun was a total failure. It is worth noting that some natural seedlings of nedun, which had sprung up on the edge of the jungle, and were separated from those planted only by a few yards, are doing well. Sundry experiments were tried by the Assistant Conservator with the object of ascertaining the effect of light, shelter, and total exposure on young seedlings, with the result that he has come to the conclusion that most young plants indigenous in the wet zone require shelter to start with.

The teak plantations of GABELLA had to be abandoned. Not one of the plants survived a second year. It is evident that the soil was not favourable to this species.

The cost of plantations in this Province up to date is R78.84 per acre, or, after deducting revenue obtained from the acres planted, over R70.27 per acre.

IMPROVEMENT FELLINGS AND CREEPER CUTTINGS.

—Small improvement fellings have been made here and there, but without any system. As I have stated before, I am very anxious that this work should be started, but Assistant Conservators do not show particular zeal in this respect. Perhaps some of them, like the Assistant Conservator, Central Province, consider that improvement fellings should invariably be paying concerns, and that it is not worth while attempting any, unless it gives an immediate return. If such fallacious ideas are allowed to prevail, the forests will benefit very little from having special officers appointed to look after their welfare.

The area in the Kalugala forest, Kurnnegala District, over which creepers were cut in 1891, is reported to show marked improvement. In the Eastern Province 150 acres of the halmillla forest of Verana were cleared of creepers at a cost of R236.76, or R1.58 per acre.

Experiment in Exotics.—No new exotics were tried this year. The Deodar plants at Nuwara Eliya have failed, and *Pinus longifolia* is coming up well only in the nursery. At Bandarawella it was a failure.

CEYLON, INDIA AND CHINA TEAS IN AUSTRALIA.

(From Rowbotham & Co.'s Monthly Tea Market Report.)

SYDNEY, Aug. 31st, 1893.

CHINA.

The "Guthrie," with the first shipment of the new season's China teas, arrived on the 3rd instant, and the month's business has been chiefly confined to the disposal of her cargo. About 22,000 packages were printed for the first sale on the 8th. Although only a few lots were eventually passed in, there was a great want of animation in comparison with past years. Bidding was slow and hesitating, and buyers appeared undecided as to their intended operations. Irregular prices were the natural result. Several lines have been turned over since the sale at a fair advance, and similar bids refused for others. A bold, consistent buyer would have done a good day's business for himself, and made a considerable difference to the sale; but the present general state of trade is undoubtedly a check on speculative enterprise even when the prospects are most favorable. The liquor value obtained for the prices paid is about the same as last year, but the make of leaf is much inferior. There is also a much larger proportion of dust than usual. This is specially noticeable in the finer grades; and although it has doubtless improved them in cnp, it has, in several instances, seriously depreciated their local market value. Referring to the laid down cost, in comparison with last season, we do not see that any advantage has been reaped on this side from the fall in exchange, and we rather incline to the view that, taken all round, the teas have cost more than they did last year, and that results, so far, have not been satisfactory to importers. The bulk of the shipment consists of Panyong and Ching Wo kinds. Kaisows seem to have been avoided. A few Padraes were shown, but not of the finer grades.

INDIA.

ARRIVALS.—"Mombassa," from Calcutta 416 packages.

Some small shipments ex "Mombassa" and the mail steamers have arrived, and met with ready sale; the greater portion of them being Darjeelings with more strength and more color in the cnp than is usual with the early pickings. Prices have ranged from 7½d for useful whole leaf pekoe souchongs to 1s 3d for fine, true flavored orange pekoes.

CEYLON.

ARRIVALS.—"Victoria," from Colombo, 700 packages "Ormuz," from Colombo, 650 packages.

These have been arriving in smaller quantities, and have not had so much attention as heretofore. The advance in Colombo during the past three weeks is equivalent to as much as 15 per cent on teas costing 9d and under; and, if the present rates continue, the trade will have to accommodate themselves to a higher range of prices.

We quote fair pekoe souchong, 7½d to 8½d; pekoes, 8½d to 9d; fine pekoes, 9½d to 10½; broken pekoes, 9½d to 1s 4d.

Season	Same period last season.	lb.	lb.

NORTH BORNEO DEVELOP. CORPN.

(To the Editor of the *L. and C. Express*.)

SIR,—As Mr. J. G. T. Hassell, secretary of the above-named company, in your issue of 9th ult., does not mention why it is I am no longer in the company's employ, and as inferences detrimental to me may be drawn from his remark, I wish it to be known that the company dispensed with my services for want of funds and their inability to keep me on, and not for any fault of mine, as the accompanying letter from Mr. Fryer shows, and that after I had done all the hard work in opening out and planting up their estates, though when engaged I was led to believe the company was in a flourishing condition, which subsequent events have shown they were not.

My letter in your issue of 2nd ult. was written in the interest of the public in general, the shareholders, and of British North Borneo.

Had Mr. Fryer the sprouting coconuts Mr. Hassell says he was in want of, he would not even then be anywhere near the "about 1,000 acres in all under cultivation," as there are not more than 600 acres in all of the company's land filled, and about 150 acres of that not cleared.

Time, and that in a few months, will show whether I or Mr. Fryer and Mr. Hassell are right with regard to Manila hemp and sugar. As to coconuts it is a far cry; but all the same I am aware they pay in the end, if properly planted, not stuck about promiscuously anywhere, as has been done on the company's land.

I certainly have a firm faith in coffee for Borneo, and that it will yet be an important coffee-growing country, and I sincerely trust I may yet see the company's land taken up for that purpose by experienced and practical men. Coffee will certainly pay if properly managed, and I state this with over seventeen years' practical experience as a coffee planter; and had the company and Mr. Fryer gone in for coffee only his and their "visions" of wealth and prosperity for the country would to a certain extent be justified.—Yours faithfully,

Labuan, July 19, 1893. J. HAMILTON HUNTER, Sandakan, Dec. 27, 1892.

My dear Hunter,—It is with considerable regret that I have to tell you that at the end of three months from this date your services will no longer be required by this company. In sending you the annexed three months' notice of the termination of your agreement, while telling you that as matters are at present you must consider it as final, yet I am not without hope that this company may largely extend its operations at some future time, in which case I would give your application for another en-

agement the first consideration. As to when this may take place I am not in a position to say at present.

I may take this opportunity of expressing my satisfaction of your work on the Byte and Weston Jervis Estates, especially with regard to the large acreage of coffee planted up there under very trying circumstances.—Yours very truly,

(Signed) W. B. PRYER, Manager.
(True Copy.) J. H. Hunter.

NOTES ON PRODUCE AND FINANCE.

JOHORE TEA.—A contemporary, referring to the natural products of the soil of Johore, and the means taken by the Sultan to develop them says:—"Especially in regard to tea has the soil proved efficacious, giving it a delicious aroma and flavour that to the taste of many connoisseurs placed it ahead of the original Assam, or the now famous Ceylon tea. The Sultan of Johore is now in America attending the Chicago Exhibition where he has sent numerous samples of tea. It is expected than an important market for Johore tea will be found in the United States." There are a great many expectations about the market for tea in the United States, and it is to be hoped the Sultan will not be disappointed.

INDIAN AGRICULTURE AND ITS IMPROVEMENT.—The complete report of Dr. Voelcker on the best means of improving Indian agriculture has been received by the Government of India, and forms the subject of a circular addressed to the several local Governments. It is stated that in 1889 Dr. Voelcker was sent out by the Secretary of State "to advise as to the best course to be adopted in order to apply the teachings of agricultural chemistry, and in order to effect improvements in Indian agriculture." His preliminary recommendations led to the appointment, in October last, of an agricultural chemist, who takes the position of the expert asked for by the Government of India. In his detailed report, Dr. Voelcker makes numerous recommendations for the improvement of agriculture, many of them covering the same ground as those of the Famine Commission of 1880, which have been only partially carried into effect. The Government state that they still adhere to the principles of a comprehensive scheme based upon the report of that commission, issued in 1881, but that they desire their chemist and the provincial Agricultural Departments to take part in a organised system of enquiry before any schemes of agricultural improvement on a large scale are attempted. The enquiry is to include a systematic analysis of soils, water, manures; the collection of information relating to existing agricultural practices throughout India, and the best means of improving them; and the consideration of the directions in which experiments can best be applied. In order to obtain a sufficient discussion of the whole subject the Government have invited the local Governments to send representatives to a conference at Simla, to be opened on Oct. 2nd when the principal proposals of Dr. Voelcker's report will be specially considered.

THE INDIA COUNCIL AND SILVER.—Bar silver for immediate delivery has been in strong demand for India and China, and the price is 3½d. As, however, indicating the course of the market in the near future it may be remarked that the metal was offered for delivery at the end of September at 3¾d and into October at 3d. Last week the India Council sold nothing, but they had little opportunity, for there was practically no demand. On Wednesday they offered forty lacs, and more than forty lacs were applied for at a price slightly over the exchange of the day, but they refused to allot.—*H. and C. Mail*, Sept. 1.

KEW BULLETIN of Miscellaneous Information for August has for contents:—St. Vincout Arrowroot; Palping Liberian Coffee; Fibre Investigations in the United States; Decades Kewones, VI.; Henecquen Hemp in Yucatan; Californian Fruit Industries; Plant industries in the Caucasus; Miscellaneous Notes.

MINERAL OILS AS FUEL:
IN TEA FACTORIES IN THE NEAR FUTURE;
AND THE COST.

We have been much struck by the advance made of late years in the use of mineral oils for fuel for the generation of steam. More particularly has this been the case in connection with the Chicago Exposition. There, these oils are the sole fuel employed for the large batteries of boilers which supply the steam required to give motion to the many mechanical exhibits. Throughout Southern Russia nearly all the railway lines, as well as a large proportion of the local steamer enterprises, are similarly served, and have been so, we understand, for a good many years past. These facts, as well as many others that could be quoted if necessary, suffice to assure us that the difficulties in the efficient burning of oil for the purposes mentioned have been overcome. Those difficulties as generally experienced were serious, and it seemed hopeless at one time to expect that they would be surmounted. The feeding of the oil in the shape of spray has, however, resulted in a success that has led to the widespread adoption of the system, and as we have above indicated, the latest development of it is to be seen at Chicago.

Now, every year is bringing about among ourselves an increased scarcity of fuel for estate factories, especially in some of the older districts. The manufacture of tea makes a far greater demand upon our restricted and rapidly diminishing fuel supplies than did the processes connected with the curing of coffee. To a very great extent, also, the treatment of the bean produced the fuel—coffee husk—required for steam generation. No such compensatory result attends the manufacture of tea, and a scarcity of fuel is now felt in not a few upcountry localities that have hitherto been tolerably well supplied. It cannot be very long, we should say, before the augmenting cost of wood fuel must cause many planters to look about for a substitute. The objections that when writing some years ago on the subject of fuel for estate purposes, we advanced to the adoption of mineral oil, have now been largely removed by inventive progress; and there can be little doubt that ere very long, several of our upcountry factories will become dependent for their fuel on imported oils. While this prospect is developing itself, we find ourselves face to face with the imposition of an increased duty on this material. Now every year has shown that to meet competition, every means of economy must be practised both in the cultivation and in the preparation of tea. If, as we anticipate, the use of mineral oils on estates in large quantities becomes a necessity in the early future, how will our planting industry be affected by the increased duty to which we have referred? Already, as we know, and even with the restricted purposes for which mineral oils are now used in this island, this increase in the duty has led to considerable dissatisfaction. How much more will this be increased when such fuel becomes a necessity vital to the well-being of our present chief industry? We cannot ourselves say how far the present scale of taxation would apply in the case of such oils as might have to be imported for heating purposes only; but we presume that these must come under the classification on which an increased duty has recently been laid. There can be no doubt that if what we think is likely to occur in the future should take place, the present clamour against recent fiscal legislation will be increased to a point which must ensure its abrogation. We are aware that some estates

have already in part resorted to the use of coal fuel in consequence of the failure in the supply of wood. Even at the present low scale of shipping freights the price of coal laid down on some estates amounts to £4 per ton, and this rate in one or two instances has been exceeded. It may not be long before the existing rates of freight may become seriously higher. They may even be approximately doubled. Is it likely that when such an increase occurs the use of coal as an estate fuel can be maintained? With large ships specially built for the transport of the liquid fuel it is certain that the use of mineral oil will be less expensive than that of coal. All that is needed to adapt furnaces for the consumption of oil is, as we read in the scientific journals, a very inexpensive internal arrangement of bricks and mortar and an almost similarly inexpensive arrangement of tubing. The change therefore would not involve a first expenditure likely to deter tea planters from making it. But if a high rate of import duty is to be maintained, not a few planters may find themselves cut off from the use of a fuel which alone seems to promise them a road of escape from difficulties that may become embarrassing in the near future.

THE OLDEST CEYLON TEA ESTATES COMPANY AND WHAT IT HAS DONE.

We believe the Yatiyantota Tea Company Limited to be about the oldest connected with our staple industry. It commenced operations at the end of 1884 and during the year 1885 and 1886 planted 400 acres forest with Tea. The following dividends have since been paid:—

	per cent.
On 1888 working 22
1889 25
1890 25
1891 40
1892 30
1893 .. (interim)	.. 15
	157

and the following sums have been set aside from profits to credit of an 'Extension Fund':—

From 1889 working account ..	R6,500
" 1891 13,500
" 1892 7,500
	R27,500

It should not be overlooked that during the incubation period the shareholders got no interest on their capital, but they have been amply repaid since.

The paid-up Capital of the Company now is R100,000. It owns 1,440 acres of land (Polatagama plantation in the Kelani Valley) whilst 669 acres are planted with tea. Mr. Geo. Maitland is the efficient manager; Mr. Chae. Young, Inspector of the Estate, and Messrs. Whittall & Co. Agents. The oldest of our Tea Companies certainly reflects credit on the Industry and Colony.

TEA AND HELOPELTIS.

A mid-Dimbula planter writes:—"I am pleased to say that I have seen no signs of the pest on this estate nor have I seen any on other estates that I have travelled through in this district. I have not been to Kadugannawa lately, but my conductor there tells me he has seen nothing to disturb the flush on the trees."

FOREST CONSERVANCY.

Among the many Administrative Reports furnished to Government, there is perhaps none more generally interesting to the community than that of Mr. A. F. Broun, Conservator of Forests. Some years ago, Mr. F. D' A. Vincent afforded us a taste of what a first-class Anglo-Indian Officer could do in the way of investigating, and then preparing a valuable Report where a free hand was afforded him. We are in no danger in Ceylon of incurring the penalty which has fallen on certain lands from the ruthless destruction of their forests and *malgre* Sir Arthur Gordon and the *Spectator*, even had there been no Order from Downing Street shutting off from public sale all forests at an altitude over 5,000 feet, this island in the pathway of the two monsoons, and with its moist climate on the mountain zone, could scarcely run the risk which has been incurred by some other Colonies less favourably situated. As it is, our planters in the higher districts have, of their own accord, set to with their usual energy to plant up their reserves, their waysides and bare places with useful timber or fuel trees and in some districts we have a process of re-forestation going on of a most interesting character, apart from the Forest Department altogether. But that does not affect the very important work of the Forest Department in its various branches as related in the Report before us. The Conservator has really entered on a notable work in this little island and one that is bound to produce much good fruit if he is only allowed to carry it on steadily and judiciously. But alas! even in respect of Forest Conservation, there must needs be wheels within wheels and a vast amount of red-tape to be overcome. It is quite pitiable to read Mr. Broun's account of how his efforts to push on with the duties assigned to himself and his Staff are baffled by certain public servants who choose to be obstructive. In a previous Report we were told that at the rate the work was progressing it would take "400 years to reserve the valuable forests of the island if they still exist by that time." This time Mr. Broun reports a rather better rate of progress, though still unsatisfactory. Here is a specimen of the Conservator's experience and of the treatment meted out to him and his staff:—

I beg to place on record that many forests are reserved or proposed to be reserved without the slightest reference to me. The Hon. the Government Agent, Western Province, whenever he wishes to have an acre set aside for reservation, always refers all the papers for my opinion, but as regards the forests in Sabaragamuwa I know nothing until I see the notice in the Government Gazette. In a section of the amended Forest Ordinance it is stated that the Conservator may, as regard reserved forests, be invested with powers of a Government Agent and made directly responsible with the administration and working. It seems rather strange then that the officer who may be most interested in the management of these areas should have no means of expressing his opinion as regards the advisability or otherwise of reserving them.

In a report to Government submitted towards the end of 1891, I stated that there were, especially in the Northern, North-Central, and Eastern Provinces, vast tracts of forests which were practically free of rights, and the settlement of which need not be delayed by waiting for detailed surveys. I am very eager to have these areas reserved, as the framing of even the roughest working plans cannot be made for undefined and unsettled areas. I have received proposals from different Provinces, and I hope that Government may take the matter in hand.

In paragraph 14 of my annual report for 1890, and in paragraph 10 of that for 1891, I mentioned that a piece of land had been taken up within the Haputale reserved forest without my knowledge, and that the land had not been excluded from the reserve. So far from anything having been done, an additional piece was taken up, and now a number of buildings have been erected within the reserved forest without any attention being made to the provisions of the Forest Ordinance. All these encroachments have been countenanced by the Government Agent, who is *ex officio* the Chief Forest Officer for the Province! A very bad example is set to private persons when the very officers whose duty it is to see the law duly carried out expose it to such ridicule. It is impossible for officers of the Department to take a real interest in their work when those who should really help and advise them do their best to make a farce of the laws which should enable them to protect their forests.

The dealings between Assistant Conservators and Government Agents have been satisfactory in seven out of the nine Provinces. Of the other two the less said the better. In order to regulate these relations, and to define exactly the duties of the Assistant Conservators, Government issued a circular, which was meant to be obeyed, but which was set at naught by the Hon. the Government Agent, Western Province. The result is, as far as I am at present concerned, that the office accounts are in such a state that I am unable to obtain the annual forms necessary for my annual report. I am therefore unable to state how far the Province itself has derived benefit or otherwise from the *régime* which is now in force. I may however be allowed to doubt that a system which necessitates constant appeals to Government from one side or the other can be beneficial.

What would Governors Sir Henry Ward or Sir Hercules Robinson—to mention no more—do, if such a Report came before them? It is scarcely necessary for us to describe their action, but we venture to say there could be no further complaint of the kind?—We have already laid before our readers one of the most interesting portions of Mr. Broun's Report in the description he afforded of the several Plantations undertaken by his Staff under his direction. There is further interesting remarks in reference to "Natural" as well as "Artificial" Reproduction, and the foundation is being laid for the collection of a vast amount of most useful information respecting the very valuable property of the Crown and public in the Ceylon Forests. We must, however, reserve further details, merely giving the Value of the Province sold by the Department in 1892:—to Public Departments R272,165; Private Purchasers R197,099—total R480,885. There were besides free grants of Forest Produce: to the Chicago Exhibition for instance, and the Stock to depôts at the end of the year was valued at R229,931. In 1891, after defraying all the charges and the cost of the Establishment there was a deficit of R31,170; in 1892, the deficit was only R13,178—so that for 1893 we may expect the Forest Department to be self-supporting, while the work of Forest Conservation and Reproduction (in Plantations and otherwise) cannot fail to be a very profitable one to the Colony as time rolls on.

TINPLATE MAKERS AND THE TEA TRADE.

The suggestion is being revived in some quarters for the employment of tea chests in the tea trade made of tinplate instead of lead-lined wood as at present. In this connection it is pointed out that the Ceylon and Indian tea trade continues to grow a

the expense of the Chinese business—a matter not at all unsatisfactory to British tinplate makers. During last year the imports of East India tea into this country increased by twenty-two and a half million pounds, while the consumption of the Chinese and Japanese leaf declined by eighteen million pounds. Herein is encouragement for the tinplate makers to renew their efforts to get the Indian tea exporters to take up with metal instead of wooden chests. It has been proved over and over again that the metal articles are stronger, lighter, and more durable than the Chinese timber productions. We know of no sufficient reason why the Indian exporters should continue to send their orders for packing cases to Japan instead of to South Wales and the Midlands, and we should greatly rejoice to see a radical change in this direction.—*Money and Trade.*

CINCHONA BARK AND CUBEBS FROM JAVA.

CINCHONA.—The detailed figures relating to the exports of cinchona from Java during the season which closed on June 30th last have just been received. They show the following result:—

Season.	Govt. Plantation		Private Plantation		Total
	Amster- dam lb.	Amster- dam lb.	Amster- dam lb.	Amster- dam lb.	
July 1, 1892	Jne. 30, 1893	645,124	7,309,966	7,955,090	
do '91	do '92	605,792	7,181,075	7,786,867	
do '90	do '91	553,255	6,323,561	6,876,816	
do '89	do '90	541,481	4,579,787	5,121,268	
do '88	do '89	815,506	3,599,625	4,415,031	

CUBEBS.—The exports of cubebs from Java during the last five years (seasons from July 1st to June 30th) have been: 1892-3, 3,244 piculs; 1891-2, 2,207 piculs; 1890-1, 1,378 piculs; 1889-90, 1,853 piculs; 1888-9, 883 piculs.—*Chemist and Druggist.*

CINCHONA BARK.

Sept. 7.

A meeting was held on July 27th, at the office of one of the firms in Batavia (Java) interested in the exportation of cinchona, to consider the question of restricting the exportation of bark from the island until prices shall become more remunerative. Rather over one-third of all the Java planters were represented at the meeting, and it was in principle agreed to restrict the shipments for the present year to 75 per cent. of the estimated output of the plantations, and to send a memorial to the Government asking them to fix a minimum below which no Government bark shall be sold at the Amsterdam auctions; to suspend entirely the harvesting of cinchona at the Government plantations for the present; and to remove all the special taxes upon cinchona plantations which are now in force. A further meeting, this time of the Planters' Association, was convened for August 10th, at which the matter was to be further discussed.

At the bark-sales on Tuesday, Mr. David Howard proposed, and Mr. Tabor, of the firm of W. H. Cole & Co., seconded a motion, that it shall in future be permissible to advance bids on single lots of cinchona bark by $\frac{1}{2}$ d, and on whole bales by $\frac{3}{4}$ d per lb. at a time. The object of this alteration is to make the London bidding resemble somewhat more closely that of Amsterdam, where advances are made by 10 or 20 at a time. Some further discussion arose as to the desirability of getting the brokers to offer manufacturing barks by larger parcels than is now the case. At present the rule is to break the parcel up in lots of about 5 bales each, whereas in Amsterdam the whole parcel, often aggregating 80 bales or more, is offered in one lot. On this subject, however, no definite agreement was arrived at, though some brokers appeared to be willing to adopt the change if it should be generally acceptable to the sellers.—*Chemist and Druggist.*

EASTERN AGRICULTURE.

(Continued.)

In his Report on the "Improvement of Indian Agriculture" (a volume of over 400 pages) Dr. Voelcker does not accept the general idea which prevails in England and even in India, that the system of the natives is on the whole primitive and backward. He believes that while in some parts of the country, Agriculture is capable of improvements by the application of Science or otherwise, in other parts, the cultivators are best left alone. Speaking of the Indian ryot, Dr. Voelcker says,—he keeps his land free from weeds, he is ingenious in devising means of watering his crop, he knows the different qualities of soil and their capabilities, he is an excellent judge of the exact time to sow and to reap, he knows the necessity of rotation and of letting his lands lie fallow, and he is an adept at raising mixed crops. The modifications of existing circumstance,—says Dr. Voelcker,—should be effected by measures taken by the people themselves, and by the Government, whose special business it is to test and introduce the applications of modern science which are suitable for India, and to diffuse a knowledge of scientific principles among the people. Prejudices of race and caste, in his opinion, constitute the main difficulty in the amelioration of Native Agriculture where it is capable of improvement, but he is encouraged to believe that these prejudices can be overcome by the spread of education. Dr. Voelcker strongly advises that means should be provided whereby practical effect can be given to the teachings and recommendations of the Agricultural Department. He remarks that if it is necessary—though he does not admit the necessity—that European officials should take part in the administration of the Agricultural Department, then these officials should receive instruction in Agricultural methods, particularly as carried on under native conditions.

There is another erroneous idea which is commonly prevalent, and that is that there is no difference between the native Agriculture of India and that of Ceylon (we mean Sinhalese Agriculture). It need hardly be said that this view is held only by those who have never travelled in the neighbouring Continent, or had an opportunity of seeing the cultivation of the land as practised by the Indian ryot and comparing it with the methods of the Ceylon gojiya. We do not by any means intend to make injurious comparisons between the two with the object of pillorying the much-maligned gojiya, or holding him up as an incarnation of apathy and ignorance. So far from doing this, we are inclined to follow Dr. Voelcker's example and say that there is as much to be commended in the Native Agriculture of Ceylon as in that of India. But it would be absurd to say, with a knowledge of Indian Agriculture as practised particularly in the Madras, Bengal and Bombay residencies, that Native Agriculture has arrived at such a stage of advancement in Ceylon as it has in India.

The struggling on in the face of difficulties created by the absence of water and manure with extraordinary patience, referred to by Dr. Voelcker, is characteristic of the Indian ryot. No one who has seen the "hard-labour" involved in supplying water to plants in the arid regions of the Deccan will for a moment think of placing the ryot and the gojiya upon the same platform, when it is remembered that no effort is made to irrigate by means of wells when the rains fail, or to utilize the manure that is available to him, by the Ceylon cultivator,

[What a paradise Northern and North-Central Ceylon would present to a settlement of such ryots, overcrowded as they are in many parts of India, if the Indian authorities would bear part of the expense, at any rate, of the restoration of a tank or tanks for their use.—Ed. 7. 4.]

Here is how Dr. Vosloker sums up his estimate of the ryot:—"at his best the Indian cultivator is the equal, and perhaps the superior of the average British farmer, while at his worst his state is due to absence of water and manure, and he struggles on in in the face of the difficulties thus created with extraordinary patience." This is indeed high praise and from a high authority. Practices of rotations of crops, mixed cultivation and other matters in which Dr. Vosloker credits the Indian ryot with a superior knowledge, are unknown methods to the Sinhalese goyiya, whose cultivated crops, if we except paddy, are as poor in number as they are in the extent of their growth. There are of course exceptions to the rule, in the cases of a few enterprising and energetic natives of enlightened views, and the pity of it is that these should be only exceptions. It behoves the Government of this Colony to ponder over the opinion of Dr. Vosloker, the eminent Chemist to the Royal Agricultural Society of England, as to its duties in relation to Eastern Agriculture. There is much that can be done in the way of rousing up the Sinhalese cultivator and encouraging him to put his heart and soul into his work, by introducing to him new and paying crops and instructing him in methods of which he lacks a knowledge; and this we say is the duty of Government to do in a systematic and whole hearted manner if it is to have any good effect. The half measures and economic policy adopted by the Government in its weak attempt to improve Native Agriculture in Ceylon have done more to bring ridicule upon Agricultural Education than any else.

A FINE BANIAN TREE.

At Behron, seven miles north-east of Madhapur railway station, there is a very fine banian tree, which appears to be very little known, although it is one of the largest in India.

The following measurements taken about two years ago, will no doubt be of interest to some of our readers.

Circumference	1,200 feet
East to west	403 "
North to south	378 "
Longest branch	159 "

Total area covered 2½ acres. In this are 236 other trees, the whole forming a shady grove of respectable size.—Indian Engineer..

THE CINCHONA SUPPLIES.

A telegraphic report from Java states that the shipments of cinchona bark from that island during the month of June reached the unusually large figure of 900,000 Amsterdam lb. This brings up the total for the Java season 1892-3 (July 1st to June 30) to 7,900,000 Amsterdam lb, which is the heaviest crop on record. Add to this that the shipments for the first half of the present year amounted to 4,000,000 Amsterdam lb., an unprecedented figure for that period and that the average quality of the bark is steadily, if slowly improving, and it will be seen that the sudden decline of 25 per cent at last week's public sales in Amsterdam was by no means unjustified. The unit value for Java bark is at present equal to only \$1 per lb., London terms, and it is possible that this crop may have the effect of drying up to some extent the enormous flow of the bark supplies from Java. The Ceylon shipments are gradually dwindling

but the deficit from that island does not balance the excess of the Java exports. Our London stock on July 1st is returned at 37,944 bales only, against 45,310 in 1892, and 53,338 in 1891.—New York Drug Reporter.

PORTLAND CEMENT MANUFACTURE IN CHINA.

Considerable quantities of Portland cement are manufactured at a place called Tongshan, about 80 miles from Tientsin. Consul Brennan says that the raw materials used at the Tongshan works are mountain limestone, fire clay, marl, and a rough kind of China clay, all of which are found in the immediate neighbourhood of the works. The fuel used is hard furnace coke, made on the premises from the local bituminous coal. The process of manufacture is somewhat more elaborate than that adopted in the Thames works, much greater care and attention being necessary to ensure the production of good Portland clinker. The limestone and clays have first to be reduced to an almost impalpable powder. Their respective analyses being ascertained, it is then passed through the brush mill, from whence it is pumped into the "backs," to be eventually moulded into bricks for burning into cement in the kilns. The greatest possible care has to be exercised at the washing part of the process, by reason of the limestone and clays being so variable in quality as it is delivered into the works, an analysis of the slip being necessary every half-hour or so. Owing, however, to the different densities of the raw materials used, they settle down in the "backs" in their distinctive strata, and before the brick moulding can be done, it is necessary to thoroughly turn over the "slurry" with the shovel, and tread it well under foot in order to obtain a uniform mixture. The bricks are then transferred to the drying ovens, and in due time taken to the kilns for conversion into Portland cement clinker. Nothing but true clinker is ground at the Tongshan works. The resulting Portland cement is of great density, viz., 158 pounds per bushel. The present output is 300 tons per week, and that is the limit of the capacity of the works. It is all used at the various works of the Imperial Government, viz., harbours, forts, Yellow River Embankment, railways, arsenals, &c., very little finding its way into the hands of private consumers. There is every probability that the demand will soon be largely in excess of the existing works. The cement is guaranteed to yield a tensile strain of 400 pounds per square inch, after having been immersed in water for seven days; and as a matter of fact, it invariably tests much higher. Every day's work is tested in the following manner:—The man in charge of the grinding draws a sample from each pair of millstones every half-hour. At the end of the day the whole is mixed uniformly and taken to the testing-room. It is there tested for fineness, and twelve test briquettes are made from the same, 23 per cent. of water being used in gauging the cement. After standing in the moulds for 24 hours—note having been made of the time occupied in "setting"—the briquettes are each marked and placed under water for seven days, each being examined from time to time for any signs of blowing or shrinkage, the usual glass test being adopted as well; at the expiration of this time they are taken direct from the water and tested for tensibility and compressibility in patent cement-testing machines. If the cement passes the tests it is handed over to the storekeeper for delivery. At the time of delivery it is again sampled and tested, and a record of each test is kept. For some considerable time difficulty was experienced in obtaining cement of uniform quality. It was no easy matter to get the ignorant Chinese coolie to understand the absolute necessity of accuracy and carefulness in every stage of the process. No reliance, whatever, could be placed upon the native foreman, nor any assistance excepted from them, their ideas being so gross and crude as those of the coolie. But by dint of perseverance and keeping to one set of men, something like a system has been established

and the work technically proceeds with the utmost satisfaction, the output being as uniform in quality as it is possible to obtain anywhere. The fuel (furnace coke) employed in the kilns was also a great source of trouble at first. In order to effect its combustion, a very free passage of air is necessary; but unless the greatest care is exercised at this stage of process, the heat produced is so intense that complete fusion at once takes place at the very bottom of the kiln, thus shutting off all draught—in other words, the decarbonisation and subsequent fusion of the upper layers of the kiln are arrested. By the introduction of air passages throughout the depth of the kiln this difficulty has been completely overcome, and the even and uniform clinkering of the entire mass is now effected with great regularity, 48 hours being sufficient for a 90-ton charge. Owing to the severity of the winter, it is impossible to do any mixing for four months in the year, so that the output is limited to about 9,500 tons per annum. The works are in full swing 16 hours a day, including Sundays.—*Journal of the Society of Arts.*

QUININE CONSUMPTION AND THE SUPPLY OF CINCHONA BARK:

IS DEMAND TO EXCEED SUPPLY?

In summing up the information at our command in reference to the production and export of Cinchona Bark from different countries, the requirements of manufacturers and the latest statistics of the production and consumption of Quinine,—the fact is borne in upon us that the price of Cinchona Bark must ere long advance considerably unless Java planters choose to throw away their virtual command of the situation. So far as we can learn there are now seventeen manufacturing of quinine and alkaloids in the world; but of these the German factories are by far the most important. Last year there are authentic figures to show that Germany exported very nearly 8 million ounces of quinine and quinine salts, a quantity which even if made chiefly from Java bark (averaging close on $4\frac{1}{2}$ per cent), South American reaching to 7, with an admixture of Ceylon and Indian of about $2\frac{1}{2}$ per cent, must have required from 12 to 13 million lb. of bark to give so large a yield. In estimating the annual output, we have only ventured to put 400,000 lb. (6,400,000 ounces) of quinine down for the five factories in Germany; against 60,000 lb. for four factories in the United States (a good deal of the bark in America and England and specially in Spain is used in the form of "decoctions"); 51,000 lb. for two manufacturing in England; 30,000 lb. for two factories in France and the same for two in Italy (Genoa and Milan); 10,000 lb. for one in Holland and 8,000 lb. for India, making a grand total of 558,000 lb., although probably the round ten million ounces of quinine may be turned out in a busy year like the present. By far the greatest consumers are the people of the southern States, and America altogether requires close on $4\frac{1}{2}$ million ounces of quinine a year; while Russia, Southern and Middle Europe generally, and India come next in the list of consuming countries.

For the present year, we make out that no less than 21,200,000 lb. of bark must be used up (including requirements for bark decoctions, druggists' show bark, some for brewers in place of hops, &c.), of which Germany is credited as requiring 10 million (probably below the mark), rest of European factories 5, England $2\frac{1}{2}$ and America 3. But it is difficult to see where all is to be got, even when we put down Java for an export of 9 million lb. of her rich bark (to average this year $4\frac{1}{2}$ per cent), and

allow for some of the rich South American barks running up to 7 per cent; but only a very limited quantity. Ceylon and India are not likely to export more than 7 million lb. between them and this would leave over 5 million lb. to be got from South and Central America. Now of late years the South American exports from wild or indigenous trees have fallen very low indeed. Bolivia and West Africa have sent certain quantities of good bark to Europe from cultivated trees. But it is very doubtful if bark cutting from indigenous trees can be resumed at the present miserably low prices. No doubt a certain quantity does still find its way to the coasts and to Europe, through the work of men who cannot well abandon their old vocation altogether. We have allowed in our Estimate of Production about $2\frac{1}{2}$ million lb. for Bolivia, Peru, Ecuador, Colombia, New Granada &c., besides about one million lb. from cultivated plantations in Bolivia and West Africa. These, we cannot help thinking to be liberal estimates, and yet they do not enable us quite to cover the demand. So far as we can judge indeed, only large drafts during 1892-3, on existing stocks of bark, in London especially, have enabled the quinine manufacturers to get all they required up to date, and unless our information is a good deal out as to manufacture and consumption of quinine,—which we cannot admit, because the best local authority generally agrees in our figures,—there ought really to be a better time approaching for the holders of cinchona bark. Our advice to planters is certainly to hold back their bark, or delay any harvesting, in the well grounded expectation of 'good times coming'—at any rate of better prices than the miserably inadequate quotations of bark prevalent for many months back.

SCARCITY OF COFFEE IN THE UNITED STATES.

Brazil furnishes about $54\frac{1}{2}$ per cent of the world's requirement of coffee, taking the average exports for five years as a basis of computation.

It is apparent that any decrease in the Brazil supply below a crop permitting of minimum exports of 6,000,000 bags, or $54\frac{1}{2}$ per cent of the world's total supply, means high prices until other producing countries extend their area under coffee to an extent great enough to produce and export an average of at least one-half of the world's requirements—unless Brazil has other years of exceptional yield, as in 1891-92, when the receipts at Rio and Santos went 1,388,200 bags beyond the yearly average.

Coffee culture is being pushed in Mexico, Central America and the United States of Colombia, but new plantations have not yet reached a point where they are able to push exports abreast of Brazil; and until that time is reached, high prices must rule. Consumption has not increased since 1836 as much as it should in view of the increase in population and the prosperous condition of the United States. It requires the stimulus of low prices and exceptional prosperity to advance coffee consumption in the old time ratio of about 9 per cent. per annum.—*American Grocer*, July 16.

COFFEE NOTES.

The government of Costa Rica has repealed the export duty on coffee which was established by decree of May 29th, 1890 and December 29th, 1892, to aid in the building of the national theatre at San José. In lieu of that duty an increase of one cent per kilogramme has been ordered to be made in the wharfage dues incurred by all foreign merchandise imported in Costa Rica. This new arrangement will take effect July 1st, 1893. The increase in wharfage dues is to be used for the same purpose—that is, the completion of the theatre.—*Rio News*, Aug. 8th.

OUR "TROPICAL AGRICULTURIST" GALLERY.—A planter expresses his great satisfaction with the portrait which accompanies the September issue of our *T.A.* It is in the style in which we hope all future portraits are to appear, though the execution must depend to some extent on the faithfulness and clearness of the photograph placed at our disposal. The colotype of Mr. R. B. Tytler which goes with this issue is one of the best portraits of this "father of Ceylon planters" we have ever seen, and does him full justice—showing Mr. Tytler as he was in his prime and at his best, in the Colony.—Another planting correspondent expresses great satisfaction with the notice given of our deceased senior which accompanies the portrait in the September issue.

QUININE AND THE PEOPLE OF INDIA.—The Indian Government are certainly not failing in their duty to the people in respect of the cheap and free distribution of quinine. Not only is all the bark harvested in the Sikhim Government Gardens and a great deal of that at the Nilgiris manufactured into a febrifuge for local use; but the importation of quinine within the last few years has nearly doubled. Thus in 1889-90, the total imports for India was 15,119 lb. while in 1892-3 it was 32,158 lb. (and over 30,000 in each of the two preceding years). This means 514,528 oz.—an appreciable quantity when added to Mr. Gammie's manufactured article; but still, what is the total of both for a year among 300 millions of people. The United States—mainly in the Southern States—for one-fifth the population consumes five times as much quinine!

"KEW BULLETIN."—Three numbers are before us—those for April, May, June and July. The articles on Economic Botany and Tropical Horticulture are very serviceable to experts, but the general reader will feel greater interest in the miscellaneous notes which give an idea of the current work at Kew. The descriptions of new plants, Orchids, &c., render the *Bulletin* indispensable to the systematic botanist. It is interesting to learn that the first head gardener at the famous garden of Buitenzorg was trained at Kew. His name was James Hooper, who on the recommendation of Sir Joseph Baks joined the Embassy to China under Lord Amherst, and was appointed to Buitenzorg in 1817, and remained there as head gardener till 1830, when he left Java for his health, but died before reaching Europe.—*Gardeners' Chronicle*.

INTERESTING FACTS ABOUT SIROCCOS.—The first shipment to Mauritius: It may interest our readers to know that Mr. Harris, the local representative of Messrs. Davidson & Co., is about to ship by the next B. I. steamer a 4-tray sirocco to Mauritius to the order of Mr. A. J. Carson, the Superintendent of the Government Gardens, formerly on Cannavarella, Badulle, and well-known to many old residents in that district. It would appear from this that the "experimental garden" of the Government of Mauritius must be much larger than we had any idea of. There can be no doubt, we take it, that Mauritius can grow tea, for it has a very forcing climate and a fertile soil; but whether labour can be obtained cheap enough to make the enterprise a success is another matter. Questioned on the subject of siroccos today, Mr. Harris said:—"How many siroccos have we in work in various parts of the world? Well, it would be difficult for me to give the exact figures, but, roughly speaking, there are 650 now at work in Ceylon, and there are, I think, just about 2,200 of various kinds of siroccos in India, so that taking Java into consideration there cannot be far short of 3,000 altogether—not a bad record?"

TEA SEED OIL.—It is well-known, of course, that the tea seed is very juicy and oleaginous, and a likely product to yield a useful oil freely; but we can find no reference in any of the books at hand, to the manufacture or use of, or even experiments with, tea seed oil. We are obliged to our correspondent "Inquirer" for sending us the first phial specimen we have seen of this oil and an expert to whom we have shown it, writes:—"I am glad to see a sample of tea seed oil, I don't remember if this oil has any special qualities to give it a price in the market, over and above the level of about £20 per ton. This is about the price any simple, non-medicinal oil, would be sure to command in the London market. Here we know nothing of the uses to which oils are applied, and there would be no local market for this oil until London declared what it would give for it." Who can tell us anything further about tea seed oil? Has any one had it tried in England? The specimen phial can be seen at our office.

FIBRE-EXTRACTING MACHINE.—It would require a much more definite report than that which Mr. D. Morris was enabled to give on "Weicher's Fibre Extracting Machine" before we should feel confidence in its practical success. We have so often hoped for a great success and been so often disappointed. The Lieutenant Governor in ordering the report to be reproduced from the "*Kew Bulletin*" for June in the *Government Gazette* has caused an account of the well-known *Sansevieria Zeylanica* to be reproduced from the "*Ceylon Almanac*" for 1855! This is going back a long way. Our file of the *Tropical Agriculturist* has much later information, including an account of a series of Colombo experiments made in the time of coffee depression, with a number of Ceylon-grown fibrous plants *S. zeylanica* among the rest. In summing up the chapter on "Fibre Plants" in the *Agricultural Review* for our "Handbook," we have just been writing after noticing the great Mexican industry and trade in "Sisal Hemp," that "when tea becomes less profitable, attention will be given to fibres and other new products." Dr. Trimen has told us nothing about his Peradeniya plants of "Sisal" (*Agave rigida* var. *sisalana*) since his Report of 1890—are they still thriving?

TEA IN CEYLON: QUANTITY AND HIGH PRICES.—Mr. George Beck is the fortunate owner of two first-class tea plantations in Dimbula in the cropping and working of which the best mode of combining good heavy crops with high prices in the London market, has been exceptionally well illustrated. Mail after mail for a long time back Henfold has stood in the select list of high averages in the London Brokers' reports, while the quantity of tea made per acre as we learn from the proprietor, is so abundant as to be equal to, if not above the average for plantations of the same altitude. Mr. Beck, we find, attributes some importance to his system of regular pruning every six months or so of one-third his acreage; but we suspect even more is due to the fine soil on Henfold and St. Regulus and still more to the exceptionally good jât of the tea. Indeed the seed of a good deal of the latter was specially imported as only one remove from "indigenous," and therefore we may take it that in addition to good management and careful preparation, Henfold with its good soil owes its pre-eminence very much to the fine jât of its tea, not only in yielding heavy crops per acre, but also a superior quality of tea—a quality which as Lane experts declare, combines strength and flavour to an exceptional degree.

THE PRUNING OF TEA ON HENFOLD ESTATE.—Mr. Beck send us a correction of our remarks as follows:—

"You did not understand what I told you about the system of pruning on Henfold. We prune one-third of the acreage every six months, that is to say two-thirds yearly."

A NEW USE OF EUCALYPTUS LEAVES.—Have blue-gum leaves been at all tried in Ceylon for the use thus mentioned in the *Pioneer*?—A small demand for eucalyptus leaves for cleaning locomotive boilers continues to exist in the North West Provinces. Last year the Saharunpur Botanical Gardens supplied forty-six maunds, while the Lucknow gardens were indented upon to the extent of sixty-three maunds for various railways. Whether or not, therefore, the treatment eventually proves to be a successful solution of this much-discussed difficulty, it would seem to be still considered sufficiently promising to be worth experiment.

"SANSEVIERA ZEYLANICA."—We can scarcely believe that the Director of the Botanic Gardens was consulted as to the republication in the *Government Gazette* of Mr. W. O. Ondaatjes crude remarks on this plant so far back as 1853. The botanical name of the plant is not even correctly spelt in that paper, but for that matter we find there is a slip in the name in the "Kew Bulletin"! We should say when any subject of this kind came to the front, or under the notice of the local Executive, that the Colonial Secretary should at once refer the papers to Dr. Trimen, F.R.S., who would take care that the latest information within his extensive knowledge, was made available and in a really serviceable form.

"QUININE IMPROVING"—Is the heading of an article in the *New York Drug Reporter* of August 7th which winds up as follows:—

For several weeks past the position of quinine abroad has acquired considerable strength, values being higher and the tone decidedly firmer in all the important markets. This improvement has had due effect here and holders have this week been doing business on a slightly better basis and the feeling is more sanguine than has been the case for a long time. The improved position of quinine has been approaching gradually, as our market reports will show, and with the increased demand for goods which is now developing, greater activity and steadier prices will doubtless prevail.

COFFEE CULTURE NEAR BANGALORE.—The *Madras Times* has a long description of what it calls "A Unique Coffee Plantation," situated near Bangalore, belonging to a Native Judge of the Madras High Court. But as the low cultivation only extends over and 51 acres Mr. Meenatchee Ayer has only 7 or 8 more acres available, his experiment should be more properly termed a horticultural one and when we mention that regular irrigation from wells over the area and manuring almost from the beginning are features of the Judge's experiment, it may be seen that the whole has little bearing on coffee culture under ordinary conditions and on the area that would alone make it worth the while of Europeans or capitalists generally to take it up. With cheap labour, water, manure and money to spend, Judge Iyer can no doubt do wonders on his 15 acres. In Ceylon, men have experimented sometimes at an outlay of a rupee a tree and got 50 cents (8 annas) back! Still, we are bound to say that the Judge is not so extravagant, for he limits his expenditure apparently—if he counts everything?—to R180 an acre; but this course he does not include the cost of the Irrigation Wells confessed to be R5,000 to R9,000. As to returns,

20 maunds (1,680 lb.=51 cwt.) are reported from 2,500 trees 3 years old, and this year they are to give 1½ ton. The trees are put 6 feet apart in holes dug 2½ feet cubic. The detailed account is in its way interesting, which we give in full on page 223.

AGRICULTURE IN NATAL—is of interest to us here, because of its mingling of the products and industries peculiar to temperate and sub-tropical regions. Here, for instance, are tea, sugar and coffee exhibits at the Maritzburg Agricultural Society's Show discussed along with live-stock, poultry-rearing, fruit-growing, &c. The president of the above Society has issued a very interesting report which states in reference to the recent show that tea, sugar, and coffee were not exhibited as they should be. It then goes on:—

"I have already spoken to several leading coast planters, who have promised to assist us. Several gentlemen from the adjoining States have also promised to compete next year. The number of entries received was 1095, forming a record in South Africa. We had not only the entries, but the exhibits, which are the test of a show; a thousand entries may be good, but a thousand good exhibits are better. All classes, except sheep, were well represented, and the quality is year by year improving. Several exhibits in sheep from the Free State did not arrive, being prevented by the compulsory dipping required by our Seah Law. We have now reduced the debt on the yard to £750, for which we are paying 7 per cent. Farming generally throughout the colony, I do not think has had a good year, but sugar-planters are having a glorious time and are making about as much money as they could wish. Coffee is again looking up, and the tea industry is an established success; but the up-country farmers have had much to contend with through diseases in stock, and very low prices for their produce have prevailed throughout the year. Farming, however, is being carried out generally on improved lines, and farmers are realising that it is better to go in for less, and so do that well. Improved breeds of stock, better cared for, and improved methods of cultivation are annually becoming more popular. Crushed mealie cob and winter oats form splendid food in winter, and no farmer should lose an animal from property, but produce plenty of butter and milk, and have fat stock for sale early in the spring. I heard of a farmer selling spring lambs four months old at 17s. each; this should pay. Wattle-planting is still being proceeded with on a large scale, and even at present prices should pay well in favourable localities. Poultry-rearing is an industry that has yet to be carried out successfully in Natal. I think it is about the only produce upon which there is yet no duty in the Transvaal. The steamship companies would take large quantities of eggs and poultry if there was a reliable supply. Fruit culture should also pay in the midland districts. It is an absurdity that a single tin of jam should be imported into a country where sugar is made and tons of fruit are allowed to rot. After visiting farms in the Cape Colony, I was more than ever convinced of the value of lime for stock. I believe the great value of the Karoo veld, which looks so barren, is the great quantity of lime in the soil. I trust that easier means will be available for farmers to test the soil. I believe most farmers are practically groping in the dark, not knowing what manures are necessary for their lands, or what crops they are most suited for. Stock-stealing is a great nuisance, but district responsibility has been enforced with good effect. This punishment and a smart detective force will do much to lessen this evil. Fencing has now become so generally erected that farmers wonder how they ever managed to do without it. Farmers should do their best to encourage industries. What the farmers want is population to feed, and so long as we import everything where is that population to come from?"

PLANTING OF SHADE TREES.

The following is a tabulated statement of the number of shade and fruit trees actually growing, all of which have been planted since this meritorious work was begun in 1890:—

Province.	Shade-giving Trees.		Fruit Trees	
	Ingasaman.	Margosa and Suriya.	Iron Barkl (Grevillea).	Various kinds.
Western ...	361	31	..	591
Central ...	2,162	823	1,314	1,078
Northern ...	3,404	10,926	..	1,202
Southern ..	1,944	10	..	558
Eastern ...	4,496	1,307	..	505
North-Western	1,553	14
North-Central..	3,252	1,540
Uva ...	3,306	392	..	202
Sabaragamwa..	329	579
Total..	20,807	13,489	1,314	6,269

The protection thus afforded the weary traveller will extend over many miles of principal roads. The trees have been planted 60 feet apart and alternately on each side; unfortunately, as recorded in the Director's report of 1891, the enemies of shade tree planting are many and among them man is still the greatest. It is very discouraging to see the havoc wrought by the scoundrel who, passing along the road with a *catty* or knife, deliberately cuts down a young sapling, leaving it on the roadside as evidence of his wanton misconduct. But for such misconduct shelter to travellers would already be an accomplished fact and conduce greatly to the public comfort.—*Report of the Director of Public Works for 1892.*

PULPING LIBERIAN COFFEE.

The cultivation of Liberian coffee is extending in many parts of the world, especially in Java, the Straits Settlements and the West coast of Africa. Information respecting this coffee has been given rather fully in the *Kew Bulletin* ('88, p. 261, and '90, pp. 107 and 245). In the *Kew Bulletin* for '92, pp. 277-282 there is given a detailed account with the actual yield of several estates in the Malay States showing that Liberian coffee can be successfully established at elevations much below those suited for Arabian coffee and further that crops of 9 to 12 cwt. per acre can be obtained from trees after the third or fourth year. In some countries difficulty has been experienced in preparing Liberian coffee for the market. Inquiry has often been addressed to Kew on the subject, and it is desirable to place on record such facts as have been obtained after careful inquiry amongst persons possessing the necessary experience.

It is well known that when the Liberian coffee is ripe the pulp investing the beans is never soft as in Arabian coffee. It is generally of a tough fibrous character, and offers considerable resistance during the process of pulping. This circumstance has discouraged many people just starting, and after vainly trying to overcome the difficulty, they have given up the cultivation of Liberian coffee as impracticable. It would appear, however, that if rightly managed there is no special hindrance to be overcome. The first point to be attended to is to pick the cherries when perfectly ripe, and when brought in they should be passed through a simple machine called a "sizer," in order to obtain two or three lots of cherries of similar size. Cherries of unequal size cannot be successfully treated. That is well understood by everyone who has had experience with Liberian or indeed any coffee. When the cherries have been sized they are then to be passed through the "pulper." There are special pulping machines prepared for treating Liberian coffee fitted with an adjustable "breast" suited to different sizes of cherries.

There are other and larger machines combining both a sizer and pulper in one. A machine of this latter kind made by John Gordon & Co. of London is described as follows:—

"The machine is provided with a rotary screen and an elevator; it is also fitted with a patent adjustable breast, having removable working parts made of steel.

"The hopper is divided into two unequal parts, and the coffee berries are delivered into the larger division with a constant stream of water, the water being absolutely necessary to float the coffee over into the machine and to carry off the pulp and skins. The coffee berries which owing to difference in size, pass through the machine unpulped are discharged by the screen into the elevator and delivered by it into the smaller division of the hopper, and thence they pass into a separate channel of the breast, which should be adjusted to the size of the berries thus brought into the machine by the elevator.

"The working of the machine is simple, and the only part which requires care is the breast, and if this be carefully fixed and its channels intelligently regulated, no difficulty whatever will be found in obtaining good results always provided that the coffee be ripe and freshly picked."

A smaller machine capable of being worked by hand is also made by the same firm. The makers attach great importance to certain points considered essential in regard to Liberian coffee. These have already been briefly alluded to. They say that "in order to obtain good results, it is imperative that the coffee be ripe, freshly picked and fed into the machine with a constant stream of water."

Further information on the treatment of Liberian coffee is contained in the following correspondence:— Messrs. John Gordon & Co., to Royal Gardens, Kew, Dashwood House, 9, New Broad Street, E.C., 6th May 1893.

Dear Sir,—We thank you for your favour of yesterday, and shall be very pleased to forward copies of our catalogue to the addresses you have kindly favoured us with. We have supplied pulpers for Liberian coffee to Java, West coast of Africa, and mostly to the Malsy Peninsula. One firm there, Messrs. Hill and Rathbone have had six or seven pulpers; they have also our peelers and separators. You may know that we sent Mr. Hart of the Botanical Gardens, Trinidad, one of our small pulpers with which he obtained very good results.

It is quite imperative that water be used in pulping, and where it is not obtainable the only course we fear, is to dry the coffee in the cherry, when it can very well be peeled only this takes some power.—Yours truly, (Signed) JOHN GORDON & Co.

D. Morris, Esq., Royal Gardens, Kew.

Messrs. John Gordon & Co. to Royal Gardens, Kew, 9, New Broad Street, London, E.C., 10th May 1893.

Dear Sir,—We are obliged by your favour of yesterday, and we now beg to inform you that our peelers and separators will treat Liberian equally as well as ordinary Arabian coffee, and that as far as these machines are concerned there is no difference in construction. It is only in the operation of pulping where difficulty has been found, necessitating a special pulper.—Yours truly, (Signed) JOHN GORDON & Co.

D. Morris, Esq., F.L.S., Royal Gardens, Kew.—*Kew Bulletin.*

PRUNING.

(From a Practical Horticulturist.)

The following article on pruning refers more to fruit-bearing trees and especially to apples and pears; but the parts I have underlined (*Italics*) shows it is not good as a rule to prune too hard, and the concluding part that occasionally it is necessary to cut back hard, which I believe is the correct thing with tea say 3, 4 or 5 years as the case may demand:—

Professor Taft of the American Pomological Society says:—A good pruner begins his work with the figure he wishes the plant to assume, in his mind's eye. He is able to give a reason for every thing he takes off and everything he leaves on. His object is three fold, viz:—the removal of dead or dying wood, the curtailment of redundant branches, and the removal of one portion of a tree to effect the development of another, either in branch or fruit. The first of these objects presents no difficulty and demands no skill, decay is easily perceived and amputation carried out. Moreover this can be done at any time. The second requires a knowledge of plant physiology and a practical acquaintance with the peculiarity of growth in the different varieties, while the third will tax the judgment of the pruner most of all. Plant development is produced by the formation of new cells inside the structure, by means of materials obtained from without by the organs of respiration (leaves) and of absorption (roots) and pruning should be carried out in a manner to direct these materials, where they will produce a maximum of beneficial effect, with a minimum of injury. *The injury arises from the size of the wound inflicted and the extent of the leaf surface sacrificed.* It is for this reason that the system of pruning recommended consists in pinching off shoots or rubbing off buds, before they put on a fibrous or woody habit when their removal will require the help of the knife or the saw. When surplus or rampant growth is thus removed, an increase of food materials is directed to the branches and leaves retained, and these accordingly assume a hardier and more robust growth. *The removal of large branches, however carefully performed, is a blow against the health and life of the tree, and directly or indirectly injures it.* Curtailment of the leaf surface, causes a proportionate diminution of growth and development, as well as injury from moisture escaping and interfering with the free circulation of the sap at the extremities. A vast divergence of opinion exists as to the proper time to prune. It is conceded as a general rule that for growth you should prune in the autumn and for fruit in the summer. *Never prune when growth has started; it checks both the rise of the sap and its proper direction.*

Pruning is sometimes done to give figure and symmetrical proportion to a tree. Thinning out some straggling branches will thicken up those left, as these latter will receive a larger supply of sap, and as elongation of branch is the result of development of the internodes of the bud, some little distance from the extremity, the removal of the bud checks elongation and the internodes set about producing lateral shoots as an alternative. When certain proportions of a tree are not making proper growth, they may be cut back severely, and then the remaining buds in that place grow with greater vigor, because the sap flows more freely through new and tender growth than through a hard, compact old, structure. This is the reason why a tree cut down and allowed to spring up from the root will be larger and straighter and smoother, than similar trees not so treated.

THE PINE HILL ESTATES COMPANY, LIMITED.

The Gazette contains the memorandum of Association of this Company formed to acquire the Pine Hill estate, situate in the District of Kotmale, and containing in extent one hundred and forty-seven acres more or less, and the Wavahena estate, situate in the district of Pundalwoya, and containing in extent one hundred and forty-two acres more or less; to improve, plant, clear, cultivate, and develop the said estates and any other lands that may be purchased, leased, or otherwise acquired, as coffee, tea, cocoa, or coconut estates; and to manufacture tea leaf, copperah, oil, poonac, coir, fibre, yarn, rope, spirit from toddy drawn from the coconut trees or from the water of the nut, desiccated coconut, compost manure, and (or) other raw products. The nominal capital of the

Company is one hundred and sixty-five thousand rupees, divided into one thousand six hundred and fifty shares of one hundred rupees each, with power to increase or decrease the capital. The memorandum is signed by Messrs. Lionel P. Fisher, Kandy; J. Roydon Hughes, Dimbula estate, Kotgala; Stanley H. Dyer, Dimbula estate; Harold A. Johnson, Queensberry, Kotmale; Roland J. Trimen, Loona-galla estate, Rangala; Robert E. France, Madakelle estate, Madulkele; F. M. Mackwood, Colombo. The articles of Association are also signed by these gentlemen.

SCIENTIFIC INDUSTRY IN INDIA.

A deal of wise counsel, both on broad lines and in detail, is offered to the Government of India in Dr. Voelcker's report, but it teaches two lessons in particular, which are none the less important because they lie beneath the significance of his advice as a whole, and are given prominence only here and there on occasions when it would appear the learned Doctor found it impossible to restrain his opinion. One is the necessity of getting the right men for scientific work; the other is the necessity of making all scientific inquiry in India subservient some practical purpose. At first sight these principles of administration would seem almost axiomatic, but observation of the policy hitherto adopted toward scientific inquiry by Government will convince most people, as it has convinced Dr. Voelcker, that they have been very largely lost sight of. England is a little country, and her agricultural interest is not the controlling one in the disposal of the taxes. Yet it is found worth while to have all scientific inquiry connected with agriculture in England made on lines most likely to lead to comprehensive results, by men best qualified to make them. Dr. Voelcker, coming from a country where this goes without saying, is naturally surprised to find a different system prevailing in India, where the interests concerned are far vaster and the problem of the ryot's future looms more threateningly every day. Dr. Voelcker is a chemist, and therefore naturally has the indignities done to chemistry particularly before his eyes when he writes: "Another instance of the way in which no encouragement is given to scientific study is seen in the system by which appointments are made to the position of Chemical Examiner. Instead of selecting for these posts men, who have been carefully trained in chemistry, and more especially in analytical chemistry, the appointments are generally given to men who have had nothing more than the class instruction in chemistry, and the test-tube experience of the ordinary medical student." Dr. Voelcker in thus writing may not have had before his mind that the greater part of the Chemical Examiner's work is to act as specialist for the Criminal Law: to conduct *post mortem* examinations of men and animals, to detect and pronounce as to poisons and generally to deal with the ghastly exhibits sent up by the police are duties which make it obvious why the post should have been almost invariably entrusted to medical men. From the view of the agricultural chemist the arrangement is no doubt inadequate: though Dr. Voelcker is careful to add that the Indian Chemical Examiner does his duty conscientiously and as well as could be expected of him; on the other hand if these appointments were to be filled with experts of Dr. Voelcker's school, a far louder cry would soon arise as to the uselessness of men of science who could not tell the difference between strychnine poisoning and tetanus. The fact is that one man cannot fill two places. However, this is not the only branch of science which the Go-

vernment of India finds adequately covered by the degree of M. B. In a spirit of good nature, optimism and fancied economy, scientific appointments of all sorts are bestowed by Government very generally upon gentlemen of the medical profession, who have shown themselves to possess a taste for research in any particular direction, quite apart from the question of previous special training. The result are doubtless in many cases praiseworthy and as satisfactory as they could possibly be under the circumstances; but in the absence of any responsible scientific department who should supply the necessary criticism, Government must often be at a loss to ascertain what it really gains or loses in scientific investigation by this method.

It is largely as the result of such a policy, that we have in scientific circles in India a pronounced aversion to all practical application of the services of officers thus engaged. The true amateur is always an enthusiast for pure theory for the sake of his pursuit; he considers his time, as the exponent of a lofty abstraction, comparatively wasted in exploiting the uses to which he and it might be harnessed; he would dwell in the pure ether of discovery and be content with the rewards of the Zoological, the Linnæan, the Royal Microscopical Societies, who welcome him as one coming from the Oriental unknown, with his hands full of shells and beetles. It is only the trained specialist who will admit that economic investigation is the executive side of science and of an importance entirely equal, or who will grant that the man who makes two blades of corn grow where one grew before, is at least as great a benefactor to his fellows as the man who introduces them to a new species of bacillus from which he is unable to protect them. But Government finds its suggestions in the direction of economic work met in a spirit of resistance. A certain amount of it is accomplished, by the exertion of *force majeure*, but it represents only a fractional part of what should be done, and might be done, with the right organisation. Anyone who knows anything of the working of the Revenue and Agricultural Department is aware that it is like getting water from a stone to extract economic facts from the free and independent Indian scientist, who is practically allowed to prescribe his own orbit; while, if the request were for a paper on the stridulating capacity of the sea-anemone, that same Indian scientist would sit up all night to make beautiful his paragraphs.

Without the slightest desire to decry scientific effort, which has for its single object to add another name, another description, to the world's perceived phenomena, it must be said that India is comparatively speaking, as yet too poor to pay for it. Such work is the luxury of wealthy civilisations. America has very properly her Lick Observatory and England her Archaeological Galleries. India's chief business is now, and will be for generations to sanitate her villages, to teach trades to her people, to increase the yield of her fields, to improve all means of communication and to defend her borders. Each one of these directions for activity presents its special and admitted claim upon an impoverished exchequer; and in view of such paramount necessities it is not quite reasonable to tax the ryot for the price of original research among the coleoptera of Tibet, or a classification up to date of the flora of Borneo, while his own interests remain where they were five hundred years ago, in so far as any scientific attention has been bestowed upon them. The country needs all that science can do for it, but it should have recourse to such help with a strictly practi-

cal aim in view. Nothing, however, can be achieved without organisation, and organisation is incompatible with anything but the scientific service, recruited from among practical men and attached to the Revenue and Agricultural Department, which Dr. Voelcker recommends. That is only the initial step, but until it is taken we shall have what we have now, chaos, and an indefinite assortment of beginnings, pleas for grants in furtherance of this or that worthy object of "more extended research," and an occasional echo of applause from the Asiatic Society.—*Pioneer*.

AN INDUSTRY FOR INDIA.

An account in a recent issue of the *New York Sun* of an American Bamboo Furniture Factory comes in time to emphasise the remarks of Captain Beauclerk at the recent Industrial Conference at Poona regarding the neglected industries of India. New York imports bamboos from China and India, as America has not so far produced canes of a kind suitable for the work. They arrive in sailing vessels at low freights, as they pack very closely, and by the aid of suitable tools and machines, and with high-priced labour, furniture and blinds (chicks) are made in the most thorough and artistic manner at prices that defy Chinese or Japanese competition. When we think of the very low price at which Chinese chicks may be bought in the Bombay bazaars, and the still lower price of the locally made article, we can realise how thorough must be the system of the American workshops that can produce them at such a price. There are sixty varieties of bamboos known to manufacturers, and their joints vary in length from one inch to five feet apart. The colours range also from a very pale yellow through every shade of brown to black, giving a wide range of natural shades. A splitting machine is employed for preparing the wood splints that are used for the blinds and they are cut of uniform thickness and width from bamboos that have been softened by steaming or hot water. A loom of simple construction is employed to weave the blinds, of which good hemp or cotton yarn forms the warp, and the splints the weft. There is room here for artistic effect by the introduction of dyed splints as in basket work. In the construction of furniture the canes are bent or straightened by a steaming process that makes them almost as soft as leather, and when cooled and dried on moulds their shape is as permanent as that of the Austrian bentwood furniture now so well known. A hot iron, skilfully applied, provides all the necessary decorations on the surface of the cane which, with good workmanship and design, provides a great variety of household goods that are light, cheap, and very durable. The factories of Brooklyn produce chicks, screens, fret-work, baskets, fancy boxes, parasols, chairs, tables, stools, flower-stands, flower-pots, settees, hat-racks, cabinets, buckets, bottles, easels, whatnots, &c., and the American bamboo industry produces goods to the value of 800,000 dol. per annum. There is so far in Bombay no bamboo industry worth the name. Matting that will last one season is largely used as a protection against the rains, but no attempt is made to execute any permanent work in bamboo on account of its very perishable nature. This is due to its use in the green unseasoned state, and to the habit of indiscriminate cutting that ignores all rules and seasons for the work. When cut full of sap nothing but special treatment in a chemical bath or water seasoning will prevent them from being at once attacked by the bamboo weevil and perforated in all directions, for the sugar sap of the wood. It is, therefore, useless to employ them in anything that has to last, so the basket-makers about Crawford Market, and the chair-maker in Forts Road, whose work is all of the very poorest quality, represent our bamboo industry at present.

Here there is an excellent industry literally abegging while the cotton manufacture is congested and the building trade is hampered by the high price of ground in Bombay. In Bareilly there are several factories for bamboo furniture owned by natives and doing a thriving trade in the North-West Provinces. Their work is rough in finish but is fairly good and cheap, but railway freights fix the limit to which they may be sent in any direction for sale and that limit is a very long way from Bombay. The pattern of chair most in use in our city and indeed, all over India came to the country long before the Mutiny. It is clumsy, heavy and has arms that are always too high. It demands at least twice the labour that would suffice for a well-designed chair, and its joints are a hiding place for bad fitting. Such, however, is its persistence as a type that it might fairly be accorded the honour of caste. It is this chair that the bamboo article should replace, and if the man who first undertakes the enterprise understands design, and is a finished craftsman in addition, he will never have cause to regret his venture. There is no lack of information available on the subject. A work entitled "Japanese Homes and their Surroundings" is largely devoted to illustrating the uses of bamboo among the Japanese, and is full of valuable information regarding the thousand and one uses to which the most ingenious people in the world apply this giant grass. France, Holland and England have now large factories for the production of bamboo furniture, and Germany and Austria are doubtless equally well provided. England also makes a specially designed class of furniture for export, which by the aid of patent fittings will dismount and pack in the smallest compass. Bombay, both as a market for the raw material and for the sale and export of the finished article, is exceptionally well placed, and we hope she will not long have to bear the reproach of neglecting her opportunities in a legitimate industry like this. It is a pity that the uses of the bamboo are not taught in any of the technical schools established in India by the Government. Its qualities, natural history, and applications are ignored in all official text books. Its tensile and transverse strength are not published anywhere, and yet were all the useful, nay, valuable information regarding the bamboo put in print, it would require a larger volume than the well-known Roorkee book of specifications. In neglecting the bamboo as we do we are letting one of the most valuable of our raw products run to waste.—*Times of India.*

LARGE INDUSTRIES IN THE MADRAS PRESIDENCY.

From the return of industries of the Madras Presidency during the year 1892 we find that there were four bone-crushing factories, one in the Coimbatore district, belonging to Messrs. Stanes & Co., where 126 tons of bone were crushed, valued at Rs. 7,000; the Bolur works in South Canara, where 175 tons were crushed, valued at Rs. 9,108; and the Mally works and Messrs. Arbutnot & Co.'s works in the Malabar district. Of Coffee Works 31 have been returned, viz., 13 in the Madras district, 2 in Coimbatore, 5 in South Canara, and 10 in Malabar. Some of the works carry out in conjunction with coffee-curing, ginger and pepper-curing and cinchona-baling. Most of the works are owned by European firms, the largest, taking the figures furnished by the firms, being Messrs. Volkart Brothers, at Tellicherry, where 6,720,000 lb. of coffee were cured, valued at Rs. 40,000; the other principal ones being Messrs. Pierce, Leslie & Co.'s, at Tellicherry, with 3,552,080 lb. valued at Rs. 21,202; in South Canara the Jeppo Coffee Works, with 2,755,200 lb., valued at Rs. 15,49,800; Bolur Coffee Works, with 1,926,644 lb., valued at Rs. 11,18,141; and Messrs. Alston, Low & Co.'s at Mangalore with 1,363,748 lb., valued at Rs. 7,77,680; the large increase in the output at all these factories in the South

Canara district is stated to be the result of good coffee crops. The Coffee Works of Messrs. Stanes & Co. turned out 1,384,992 lb., valued at Rs. 27,000. Three new works belonging to Natives were opened during the year. The number of persons employed daily varied from 900 in the Jeppo Coffee Works to 15 on a Native Establishment in South Canara. The Cement Works of Messrs. Arbutnot & Co., at Madras, manufactured 22,400 cwt., valued Rs. 44,800. 182 persons find employment in these works daily, which is increased to 206 daily from January to March. These include the number of persons employed for lime burning and manufacturing tiles and bricks. Of cotton presses and cotton weaving establishments other than Mills, there were 51 in operation in the Presidency during the year, viz., 3 in Kistna, 2 in Cuddappah, 4 in Anantapur, 8 in Bellary, 2 in Trichinopoly, 12 in Tinnevelly, 11 in Coimbatore, 6 in South Canara, 2 in Malabar, and 1 in Kistna. The largest of these is Messrs. Milligan & Co.'s Press, at Tuticorin, where 7,776,500 lb. of cotton, valued at Rs. 17,08,300, 732,300 lb. of cinchona, valued at Rs. 83,075, and 4,000 lb. of waste yarn, valued at Rs. 560 were pressed. Next comes the newly-started press of Messrs. Ralli and Brothers, where 8,123,000 lb. of cotton were pressed, valued at Rs. 68,290. Of the other large presses are Messrs. Volkart's United Press Company, Tuticorin, where cotton cleaning, pressing, and shipping were carried on. The output was 7,500,000 lb., valued at Rs. 15,000,000. There has been a decrease in the working of this press owing to the fact of Messrs. Ralli and Brothers, who were pressing their cotton at this Press, having started a press of their own. The Fort Press, Tuticorin, had an output of 2,169,500 lb. cotton, valued at Rs. 49,207; 43,200 lb. of Sena, valued at Rs. 888; 68,650 lb. fibre at Rs. 13,730, and 15,000 lb. cullies at Rs. 2,247. The new Bejar Company (Limited), Tuticorin, pressed 4,150,000 lb. cotton, valued at Rs. 9,06,089. Messrs. R. P. Gill & Co.'s Cotton Press in the Kistna district, gave an output of 3,396,500 lb. valued at Rs. 7,81,264. A mill for pressing cotton with seeds at Mangalagiri in the Kistna district, and owned by Nar-Ha Mangayya pressed 3,470,350 lb., valued at Rs. 8,293.

Of the 5 cotton presses 7 were newly opened during the year, of which the Tinnevelly Cotton Press Company (Limited) was started in place of the Tuticorin Cotton Press Company, which was abolished on 15th May 1892. Four presses in the Bellary district did no work during the year, as there was no cotton crop on account of failure of rain. Another press in Trichinopoly, belonging to Messrs. Framji & Co., did not work during the year. The Tuticorin Press Company at Virudapatti ceased to work early in the year 1892. Nine presses are returned as having been worked by steam-power. Of Flour Mills one is returned, viz., the Government Bakery at Wellington, where 354,577 lb. was the output, valued at Rs. 27,701. There were three Ice Factories at work during the year in the Presidency two in the town of Madras, the South Indian Ice Factory, which re-started during the year, and the Madras Ice Manufacturing Co. Limited, and the third, the Maharajah's Ice Factory, in the Vizagapatam district. The Madras Ice Manufacturing Co. is a Joint Stock Company, with a capital of £15,000 its output was 787 tons, valued at Rs. 43,049. The South Indian Ice Factory had an output of 750 tons, valued at Rs. 37,500, and that of the Maharajah's Ice Factory 18 tons, valued at Rs. 2,509. There were 4,703 Indigo Factories and vats in operation during the year, viz., seven factories, all in the Jaujiam district, six in the Parlakemidi taluk, and one in Chicacole taluk, and 4,696 vats, 29 in Vizagapatam, 40 in Godavari 872 in Kistna, 793 in Nellore, 1,050 in Cuddappah, 236 in Anantapur, 11 in Bellary, 468 in Kurnoor, 349 in Chingleput, 290 in North Arcot, 468 in South Arcot, 28 in Tanjore, 29 in Trichinopoly, and 33 in Salem. There were 6 iron and brass foundries working in 1892, one in the Godavari district for the manufacture of sugar-cane mills where 33 miles were turned out, valued at Rs. 840, another iron shop in this district was closed during the year. Messrs. Massey & Co.'s iron works at Madras had an output of 7,892 cwt., valued at Rs. 69,060 the Iron Basin

Foundry (Gopal Naicker & Co.) turned out 863 sugar-cane mills, valued at R23,345. There was a Steel Manufactory at Kolitalai, the Ashley Works at Coonor, and the Basel Mission Mechanical Establishment in South Canara. Of Mineral and Aerated Water Manufactories 38 are returned. There were 16 Tile Manufactories, viz., 13 in South Canara and 3 in Malabar, 5 Sugar Factories, and 11 Tanneries. —*Madras Times*, Sept. 21.

CEYLON AND WHAT REMAINS OF HER COFFEE ENTERPRISE:
HOW THE 30,000 ACRES STILL UNDER CULTIVATION ARE DISTRIBUTED.

In 1877-78, coffee reached its maximum area of cultivation in Ceylon with the aggregate close on 280,000 acres. Six years later, and no less than 100,000 acres of this extent had either been abandoned or practically superseded by cinchona, tea or other cultivation. Six years later still, in 1890, the area under coffee was returned at no more than 54,000 acres, and now in 1893 it has sunk to 30,000 acres exclusive of about 2,500 acres under the Liberian variety. So great a transformation in agricultural enterprise within a period not exceeding half-a-generation—as such is reckoned in temperate zones—has surely never been witnessed in the world's history before.

It is of interest at this time to know over what districts in Ceylon the 30,000 acres that remain of the old staple—coffee *Arabica*—are distributed. North as well as South of Kandy, in districts that were once the stronghold of the coffee bush, scarce an acre now remains! For the Knuckles, Rangala, Dolosbage and Nilambe districts, for instance, no return whatever is made by a single planter,—under coffee the record is absolutely nil. It is no better in Ambagamuwa and Lower Dikoya; while only a very few acres appear for Kelebookka, Hunasgiriya, Medamahanuwara, Puscellawa, Ramboda, the Hewahetas and Kotmale. Dumbara, Hantane, the Matales and Pundaluoya show a little more; but altogether in the Kandy districts proper, between Ramboda and Matale and Dolosbage and Medamahanuwara, once the mainstay of the coffee enterprise, with perhaps 100,000 acres under cultivation, the total under coffee now does not exceed 3,500 acres!

We now come to the three higher districts between Adam's Peak and Great Western, which could fifteen to sixteen years ago show over 80,000 acres cultivated with coffee. Here is the return for the present day:—

Dimbula	3,633	acres coffee
Dikoya	2,820	" "
Maskeliya	397	" "

Total 6,850 " "

We now come to the Principality—to Uva and its allied districts—in which, for our purpose today, we include Maturata as well as Udapussellawa, and although compared with the maximum return fifteen or even ten years ago, our figures show a woeful decrease—still, it is a matter of satisfaction that so much good coffee remains especially in Haputale, and still more that in place of every acre superseded, we have full compensation in flourishing tea or cacao. Uva could at one time boast of well-nigh 50,000 acres of coffee. Here is now the record with some extra districts:—

Haputale	8,432	acres coffee
West	570	" "
Badulla	3,853	" "
Pasara	1,550	" "
Madulsima and Hewa		
Eliya	1,558	" "

Monaragala	164	acres coffee
New Galway	293	" "
Udapussellawa	2,727	" "
Maturata	694	" "

Total 19,841 " "

Or let us say 20,000 acres which is equal to two-thirds of the whole coffee extent in the island. Moreover we are glad to learn that in certain parts of Uva, (as in Dumbara) successful clearings with the old staple are being established, while the greatest care is being taken of the fields that remain. When during the present year, Uva planters have sold their coffee as high as R15.25 per bushel, it is scarcely to be wondered at that this should be the case.

As regards Liberian coffee, the 2,500 acres cultivated are chiefly distributed between the Kurunegala, Kegalla and Polgahawela, Matale North and West and certain lowcountry districts; but there is no reason why a considerable extension should not take place. We hope to hear of further experiments being made with the Nalkanaad-Coorg and the Mysore-hybrid coffees, as also with the hybrid between the Liberian and Arabian kinds reported some time ago to have been established in the Peradeniya Gardens.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for October :—

Vol. V.]

OCTOBER, 1893.

[No. 4.

MEANS OF IMPROVING NATIVE AGRICULTURE.

IN another column we publish a report sent in by Mr. Samaranyake, Agricultural Instructor, on a ploughing demonstration at Dedigamuwe near Hanwella. The fact of a native cultivator voluntarily applying for the services of an instructor, and expressing his anxiety to see something of the so-called new system of cultivation by the improved plough, is a significant one. The village which was the scene of the demonstration is situated some 18 miles from Colombo, and it may be mentioned that the owner of the field which was ploughed offered to pay all the expense involved in the transport of implements, buffaloes and operatives, and the upkeep of the two latter while at work. We have never advocated the system of forcing the "Cingalee plough," which was specially designed by Howard and Sons for Ceylon, on any and every description of land in the Island. There are numerous types of ploughs which have been designed for different soils and conditions of culture, and it would be absurd to try to argue that Howard's "Cingalee Plough" can totally replace the primitive "Cultivator" of the goyiya: but at the same time we do maintain that there is nearly in every case in native agriculture the opportunity of conveniently and satisfactorily improving the soil by the use of a more effective implement than the so-called native plough. Where the "improved" implement comes in is in replacing the slow and tedious though efficient work of the "mamotie" (the digger or "earth-chisel") and curtailing the monotonous repetition which of

necessity occurs in the use of the native one-tined cultivator. The turning up of the soil in paddy land at such times when it is free from water, and under circumstances when no objectionable subsoil is worked up, is a most desirable operation. And even where it is not advisable to turn over, a more effective stirrer or subsoil plough is surely to be preferred to the impotent native implement, when the latter is not being used for mud stirring. Some two years ago an Agricultural Show was held at a village called Dalugama, under the auspices of the local *Gramaraksha Samagama*, where an improved plough of native make was exhibited, and elicited much curiosity and interest. The implement was subsequently sent to the School of Agriculture through the kindness of the Committee of Management. The special qualities of this "Dalugama Plough" are that it is light and simple in make. The native workman who made it evidently intended to strike a medium between the (perhaps too highly) improved "Cingalee Plough" of Howard and the real Sinhalese implement, and he has succeeded well. The "Dalugama Plough" which has been used for a considerable time at the School has proved to be well suited to the needs of the native cultivator. As applications have been made for the purchase of the implement, we have already addressed the Secretary of the *Gramaraksha Samagama*, at Kelaniya, enquiring whether the maker of the exhibit at the late Show could turn out a few ploughs for us, and at what price. We remember being told at the time of the Show that the implement cost a very moderate sum.

Another thought that has been suggested by the recent ploughing demonstration is, that in addition to the urgent necessity there is for providing an itinerating inspector for Agricultural Instructors, there is also the need for providing means by which an instructor, with (if necessary)

some students to help him, can be dispatched, free of cost in the first instance, to various agricultural villages, with the object of demonstrating such processes as it may seem desirable to introduce into the cultivation of the land as practised by the natives. With a properly organised system for the improvement of native agriculture, not merely by introducing new methods for the preparation of the land, but in very many other ways which we have before referred to, we are confident that much can be done for the goyyias of Ceylon, which will tend to materially ameliorate their generally-wretched lot. The first necessity in organizing such a system is a thorough acquaintance with the present practices and future needs of the people in different villages, the conditions and capabilities of the soils, the facilities obtainable in the districts, and many other circumstances. And we are convinced that without the preliminary knowledge which we have indicated as essential, any attempts at administration for agricultural improvement must be weak.

OCCASIONAL NOTES.

We hail with pleasure the appearance of the first volume of Dr. Trimen's new work on the "Flora of Ceylon," which, from the exhaustive manner in which he deals with the subjects, will have a wider interest than botanical works ordinarily possess, for not only will the Botanist but also the Forester and Agriculturist find a valuable handbook in the work of our Director. Without intending to give support to the doctrine of evolution in plants, we make the following quotation from Dr. Fream's work on Agriculture in support of our opinion:—"In the botanical classification of plants, the attempt is made to arrange together those plants whose structural characters most nearly resemble each other. In this way natural groups are formed, the members of which may, it is quite possible, have sprung, in some period of the remote past, from a common ancestor. Plants which are allied to each other usually require the same kind of food. They are often liable to attack by the same kinds of insects, and fall a prey to the same kinds of fungoid and other parasitical pests. Hence the use to the grower of learning the relationships of plants."

Mr. Manchanayake writes from Kuala Lumpur:—"I send a parcel containing some seeds, and two specimens of 'Ginseng' root. It is a most difficult matter to get the seed of the latter plant. There are different names for the product of different countries. For instance, there is the 1st quality Korean and 2nd quality Korean, 1st quality Japan and 2nd quality Japan, each distinguished from the other. Of the two specimens sent, the smaller and darker one, with the accompanying leaves, is the 2nd quality Korean, while the other is 3rd class Ginseng and is not very dear. The first quality of the root is not found in any of the markets here. The Chinese assert that they have never seen Ginseng seed, and they claim extraordinary properties for the substance. They say that the plant is never cultivated but grows wild in the hilly parts of the Corea, China and Japan, though a tax is levied on the collecting of it. I am told, with what truth I can't say, that about an ounce

of good Ginseng is sold for from 15 to 100 dollars, and sometimes more. I procured the specimens sent with much difficulty. A Chinese friend of mine, who has lately come from China, promises that he will make enquiries about the possibility of procuring seed, and let me know."

The curious buffalo-head-like seeds sent by Mr. Manchanayake, and which he describes as from a plant growing in water, and furnishing a food after they are boiled, are those of *Trapa Bicornis*, before referred to in the pages of the Magazine. The other seeds are of the well-known and delicious lichi fruit.

Everything has gone well with the Government Dairy since it was started. The daily output of milk has now reached about 260 bottles, that is a little over 40 gallons.

The Veterinary Surgeon's report for 1893 is an interesting production, in that it describes in a fairly exhaustive manner the two most fatal diseases which attack stock in Ceylon, namely the so-called "Murrain" and "Kandamale." The former Mr. Lye terms *Pneumo Enteritis Contagiosa Bovis* or cattle-typhoid, a specific malignant and highly-contagious fever, chiefly affecting the intestines, and also the lungs and stomach. The latter which our correspondent W. A. D. S. is inclined to set down as a form of anthrax, is described by Mr. Lye as *Pharyngo laryngitis contagiosa*, an acute malignant febrile disease characterised by elevation of temperature and dyspnoea, associated with swelling of the internal and external structures of the throat.

The following is the curative treatment recommended by the Veterinary Surgeon for "Murrain":—Either of the following mixtures to be administered at the first indication of the disease:—

- | | |
|----------------------------|----------|
| (1) Sulphate of Quinine .. | 1 drachm |
| Nitrate of Potash .. | 2 do |
| Sulphate of Magnesia .. | 8 do |
| Powdered Aconite leaves .. | 2 do |
| Water or gruel .. | 1 pint |

To be given twice daily.

- | | |
|------------------------|----------|
| (2) Carbolic Acid .. | 1 drachm |
| Chlorate of Potash .. | 2 do |
| Sulphate of Quinine .. | 1 do |
| Water or guel .. | 1 pint |

To be given twice daily.

The treatment recommended for "Kandamale" is:—

- | | |
|--------------------------------------|-----------|
| (1) Internally. Nitrate of Potash .. | 2 drachms |
| Chlorate of Potash .. | 2 do |

To be well mixed and placed on the animal's tongue twice daily, or to be tied in a little muslin bag and secured in the mouth by means of a cord passed round the horns; and where possible inhalation of steam should be tried.

(2) Externally. Powerful counter-irritants, such as mustard or mustard and turpentine mixed, so as to form a thick paste, and thoroughly rubbed in; if hot water can be procured the throat should be well bathed before the irritant is applied, or the throat should be scarified with a knife or hot iron, and the juice of powdered chillies well rubbed into the excoriations thus made,

W. A. D. S. writes from Bombay:—Under the Civil Veterinary Department of India experiments are being carried on to show the superiority of the horse in agriculture over cattle, and a course of lectures, with suitable demonstrations were made a few weeks ago at one of their breeding farms, Babugar, in the North-Western Province. From an account of the operations described in a paper read before the Bombay Veterinary Association at its last meeting, by an officer who was delegated to attend the lectures, it appears that the work is carried out systematically, and all operations in the farm of about a thousand acres are done by horse-power. The work mainly consists of ploughing and the raising of water for irrigating the fodder crops. The promoters of the scheme are said to be convinced of the feasibility of replacing the bullock in India by the horse for agricultural purposes. No doubt the horse would do better work, and with the use of that animal there will be a possibility of more readily improving the methods of tillage &c. now in vogue. But the question is whether the ordinary ryot will be able to purchase, or to maintain horses for his farm work, when he finds it difficult to maintain himself or to keep the enduring bullock who does not entail on him much care or expenditure. Besides, what is he to do with all the cattle he possesses now? Perhaps he will be required to sell them to the butcher or continue to breed them for beef. It will, however, take a long time to convert the Hindu to the idea of meat-eating or cow-killing, and the scheme on the whole would seem to have been undertaken without taking into the least consideration the conditions of the country or its people. These attempts at innovation are no doubt undertaken with good intentions, to better the condition of the ryot and to confer on him a boon, but they appear on the other hand to stand in the way of possible and more desirable improvements.

A PLOUGHING DEMONSTRATION.

At the request of the Police Vidana of Dedigomuwe in Hewagam Korale, two students and myself were ordered to go with two iron ploughs and the pair of buffaloes belonging to the School of Agriculture to plough a field there. We started on the 11th September at 2 p.m. On our way thither many enquires were made as to the object of our journey and the information was given. A number of persons expressed their anxiety to see our process of ploughing. We reached our destination about 10 p.m., and were kindly received by the village headman, Don Saranaris. On the following morning we were taken to the field about two acres in extent, and found there a gathering of nearly two hundred people who had come to witness the ploughing.

We noticed that the soil was of good quality and free from much grass, but it had become hard and cracked by the drought that prevailed, so we found it rather difficult to plough. We nevertheless managed to plough over an acre during the two days we were there, and both the headman and the spectators expressed themselves as agreeably surprised at the work done by our ploughs.

The soil of this field and others in this locality is a clay loam but stiff and difficult to work. We noticed that several pieces of land had been ploughed with the ordinary native ploughs to no good purpose, as the furrows were little more than an inch deep.

We took advantage of the number of people present to explain the benefits of thorough ploughing and turning over of the soil in land of that description.

Some of the people to whom we spoke inquired about the price of the ploughs; and the headman, at whose instance we were sent on this occasion, handed me a letter addressed to the Superintendent of the School of Agriculture applying for an implement. I hope that one may be secured soon, so that it may reach the village while our recent visit is yet fresh in the memory of the villagers.

At the earnest request of Don Saranaris I left the two buffaloes and the ploughs in his charge for a few days, in order that he may complete his ploughing, and started back to our school on the 14th instant.

PETER SAMARANAYAKA,
Agricultural Instructor.

18th September, 1893.

JOTTINGS FROM A TRAVELLER'S DIARY.

ON THE CULTIVATION OF GINGELLY IN THE ANURADHAPURA DISTRICT.

Gingelly is one of the most important chena products in this district. Its cultivation is systematically carried on in two ways, viz., either as a separate crop in a chena cleared exclusively for the purpose; or as a second crop after the kurakkan has been gathered in. The first method is called *yalkanne*, and the second is called *maskanne*, signifying respectively the *yala* season and the *maha* season during which the chenas are cleared.

As regards the first method: A suitable piece of land is selected and the jungle is cut down about the beginning of February and burnt and cleared about the end of March. The seeds are sown about the beginning of April. Mamoties are sometimes used whilst sowing the seeds in order to scrape the ground and to pick up the partially burnt twigs &c. that may be found scattered about the land. By this process the seeds are sown evenly and the plants grow well; but as this method requires much labour and time, the seeds are often simply scattered about and the partially burnt twigs &c. are picked up and thrown away when the rains set in.

As regards the second method: the chenas for the cultivation of kurakkan are cleared in August and the seeds sown in September. The kurakkan crop is usually gathered in November, but as other products such as chillies, melons green gram &c. are also sown with it, the chenas are carefully fenced and guarded until about the month of March or April. In such chenas, with all the stubble of kurakkan still remaining, the gingelly seeds are sown in the month of April.

and the cattle let in to graze and trample the land. After the stubbles of kurakkan &c. are thus fairly trampled down, the chena, on which the gingelly seeds were sown, is set on fire, and when the rain sets in the fence around it is mended and the gingelly crop is carefully tended.

In about a month or six weeks the gingelly plants begin to flower, and in about 3 months the foliage leaves will drop off and the capsules (fruits) will also dry up and assume a yellow colour. The plants are then cut down with a scythe and heaped up in a suitable place in the chena in a vertical position with the tops pointing upwards. After a few days the capsules burst under the heat of the sun; during midday, when the sun is very powerful, the seeds are shaken off the capsules. The seeds thus separated are put in bags and carried home.

The oil is extracted in the following manner:—The seeds are first of all winnowed in order to get rid of any rubbish that they may contain and afterwards soaked in water for a day. The soaked seeds are then taken and pounded gently in order to remove their outer covering. The pounded seeds are afterwards put into a vessel containing water and squeezed with the hands until the husks are all washed off. The cleaned seeds are then dried in the sun until they assume an oily appearance. They are next taken and well pounded in a mortar until reduced to a pulpy mass. A small quantity of hot water is also sprinkled on the seeds whilst being pounded, and when thoroughly pounded the oil is easily squeezed out either with the hand or by the aid of a *peha* pressed between two poles. Large quantities of oil are extracted by the aid of chekkus.

MAN AND BEAST. I.

It is with domesticated animals that man has to do most, though he not unfrequently comes in contact with others of a wild nature in his daily life. In considering the subject of this paper, however, I shall confine myself to the domesticated animals, and particularly to the animals commonly found in Ceylon.

The relation which man bears to animals is manifold. First and foremost, the mainstay of the cultivator in the tropics is the animals which help him to till the land, convey his produce to the market, and supply manure to fertilize his field. Secondly, animals are a source of food supply, even among tribes who strictly adhere to so-called vegetable food. Milk is an indispensable article of diet, be it the milk of the cow, the buffalo, or the goat. Butter, cheese, ghee and curd, as secondary products of milking animals, are also used to a great extent, while mutton and beef as well as pork are largely consumed articles of diet. Thirdly come what may be called the luxuries (though not in the strict sense of the word), viz., the wool from the sheep and the hide from the buffalo and ox, which are made use of in the manufacture of wearing apparel. The horse and the ox convey man from place to place in more or less comfort, whilst the elephant replaces them under some circumstances. The

value of these and other animals for military purposes is admitted. Fourthly come the dog and the cat, both pets kept in the house, but the former on many occasions also as a useful servant and a guard.

The importance of these animals is so great, that they have in fact become indispensable to man. There is, however, another serious aspect which is not sufficiently considered, but is of vital importance. These animals are liable to bring much trouble, suffering and loss to man, not through their own fault, but under quite natural circumstances. They are like all other living bodies liable to disease, and some of these diseases it has been found out are communicated to man with disastrous results, and no one can deny the importance of an acquaintance with at least the more common dangers which we are liable to contract through our domesticated animals. Very often a timely knowledge of these helps to prevent much misery and loss.

Taking first the ox, let us enquire what are the diseases which it is liable to convey to us. Of the diseases of the above description in the ox may be mentioned anthrax, foot and mouth disease, tuberculosis, actinomyosis, rinderpest, pleuropneumonia, and skin-diseases.

Anthrax is common in India among cattle, sheep and horses, to say nothing of pigs and poultry. It is a rapidly-progressing disease, and the flesh from an animal which has suffered from anthrax could in many instances be distinguished by the dark appearance of the blood. One of the forms of this disease in Ceylon is commonly known as *Kandamala*, manifested by the rapidly swollen condition of the throat and the tongue. This disease is communicable to man, through inoculation, and if a person happens to touch the parts of an animal dead from anthrax, and be so unfortunate as to have an abrasion on the skin, he is liable to suffer from carbuncular boils. Even the hide of the animal after several months is liable to communicate the disease, and numbers of such sad fatalities are recorded among workmen in wool manufactories and tanneries. The meat from an animal dead of anthrax, when consumed, is liable to bring on typhoid fever.

Foot and Mouth disease is more common in Ceylon, and is easily made out, at least in its later stages. The milk from foot and mouth diseased cattle is liable to cause aphtha (sore mouth) and diarrhoea in those who consume it, especially in the case of children and those with a weak constitution. The consumption of the meat brings on various diseases of the stomach in man.

W. A. D. S.

Bombay.

(To be continued.)

BY HIGHWAYS AND HEDGES.

Referring to *Paspalum scrobiculatum*, "Dutch millet," the Sinhalese *amu* and Tamil *varagu*, known in India also as *koda millet*, Professor Church says:—"It is said, apparently with truth, to be at times the cause of vertigo, and is

not considered to be as digestible as *Setaria italica* (Tana-hal); the stems afford an inferior fodder. Koda is boiled and eaten in the same way as rice, or else is parched and ground, the meal being made into a kind of pudding. The alleged comparative indigestibility of this grain cannot be attributed to its percentage of fibre, which is usually low, but must be owing to some constituent or some condition of the grain which ordinary chemical analysis does not reveal." This grain is not uncommonly grown in Ceylon in the native chenas. Dr. Lindley, in his *Vegetable Kingdom*, speaking of injurious grasses, says, "and a variety of *Paspalum scrobiculatum*, called hureek in India, which is perhaps the ghohona grass, a reputed Indian poisonous species, said to render the milk of cows that graze upon it noxious and drastic . . . The meyna or kodro of India, a cheap grain, regarded as wholesome, is another species." Another allied species, *P. dilatatum*, is indigenous to sub-tropical parts of North and South America, and has been naturalised in Australia. It is said to be an excellent forage grass that keeps green during dry weather, being a perennial and growing tall like Dutch millet. In Ceylon we have besides many, three other varieties: *P. Conjugatum*, *P. Filiculme*, and *P. Royleanum*.

Concerning *Eleusine Egyptica*, crowfoot or finger grass, the Sinhalese *Putu-tana*, the *Agricultural Gazette* of N. S. Wales says:—Its herbage is rich and succulent, and is much relished by all herbivora, sheep being particularly fond of it. All pastoralists agree that it is a most nutritious grass. It yields abundantly during the hot months, and is recommended for systematic cultivation. According to Dr. Watt, the seeds are eaten by the poorer classes in India, especially during times of scarcity, and it is generally considered to be a very nutritious fodder grass for cattle, being both fattening and milk-producing.

Egle marmelos, the bael or beli tree, sometimes called the Bengal quince, besides yielding a wholesome and nutritious fruit, which is also much valued as a medicinal agent, produces a good gum-like arabic; a yellow dye is obtained from the rind of the fruit, the unripe rinds being used with myrabolans in calico-printing and tanning; moreover it furnishes a yellowish white, hard aromatic wood used for pestles of oil and sugar mills, naves and other parts of carts, and for agricultural implements. Almost every part of the tree is used medicinally, and the flowers yield a sweet scent.

Panicum distachyum (two-spiked pannick grass) is an indigenous growth in Ceylon, which Australian agricultural authorities say is worth disseminating in those parts of the country where it may not already be growing, and conserving where it already exists. The grass would seem to be more suited to moist lands; and cattle are very fond of it.

The marram grass, the seed of which was first introduced into Victoria by the Government botanist, Baron von Mueller, in 1883, and by him entrusted to the Borough Council of Port Fairy

for experiment on the barren shifting sand hummocks fronting the coast line of Port Fairy, has been proved to be the most effective sand stay ever planted. Practical evidence of its value can be seen in the miles of sandhills now reclaimed by the marram plantations, sown under the direction of Mr. S. Avery, the park ranger. So complete has been the reclamation of the lands, that where a few years ago not a sign of vegetation was to be seen, there now exists a succulent grass, eagerly devoured by cattle, and growing to a height of four feet. Marram grass is practically indestructible—burning, cutting, or eating off only makes it thrive—whilst in exposed, shifting sand it propagates as surely as in the most sheltered position. The grass for transplanting has been supplied by the Port Fairy Borough Council, not only to the Governments of Victoria and New South Wales, but to numerous municipal bodies and private individuals in all the Australian colonies, New Zealand, and Tasmania; and in no single instance has it failed to thrive.

The Botanist to the Department of Agriculture, N. S. Wales, referring to *Anthistiria avenacea* (tall oal grass) says:—It will stand a phenomenal amount of dry weather, but this may be accounted for by the fact that its strong roots penetrate the earth to a great depth. I can highly recommend the grass for systematic cultivation, either in the coastal districts of the interior. From its rich succulent herbage, if cut before the flower stems are developed, it should make capital hay. I think, if the grass were cultivated for a few consecutive years, it would yield a grain large enough to be classed amongst the cereals we at present cultivate. We have in Ceylon the closely allied *A. cymbaria* (Karavuta-mana, Sin.), *A. arguens*, *A. cilatu*, *A. tremula* (Pini-baru-tana), *A. heteroclitu* and *A. prostrata*, so that the Australian species may reasonably be expected to thrive here.

ADVANCED AGRICULTURAL SCIENCE.

Mr. John Hunter, lecturer on Agricultural Chemistry in the Edinburgh School of Agricultural Science, and examiner in that subject at the University, read a paper on the Chemistry of the Soil before the Royal Physical Society. We were aware that Mr. Hunter, with whom was associated Mr. McAlpine, the distinguished botanist, was long and deeply engaged in researches in agricultural chemistry, but the theories and discoveries which both he and his co-worker have for many years been laying before their students, were for the first time put forward before a representative gathering of scientists a few months ago. We need make no apology for giving a summarized report of the paper as embody some new, and it will probably be thought, startling theories and discoveries, which will no doubt have their full share of criticism.

At the outset, Mr. Hunter remarked that his sole reason for bringing this communication before the Society this evening was that the recent and important advances in agricultural science—an advancement in which he presumed to think Mr. McAlpine and he had played no inconsiderable part—had been opposed by men

occupying conspicuous places, and he had therefore embraced this opportunity of laying his views before a learned society for discussion. He regretted that the opponents of the advancing science had not, although specially invited, put in an appearance, because it was important, in the interests of science, and of its students, that the truth be known; and if this Society should express an adverse opinion of his position, he would be only too glad to accept their verdict. Mr. Hunter then proceeded to discuss the commonly obtaining doctrine of retention of plant food by silicates and oxides, and, in passing, referred to Professor Way's doctrines of the order of absorption of oxides by silicates in the soil. The tenor of his remarks was to show that certain truths had been established by the practice and experience of the forefathers who tilled the soil, and that the many ravines had been bridged over by scientists who were impractical and ill-fitted for the task, with the result that the foundations were now being demolished, even in the face of unbecoming opposition from quarters where only encouragement ought to have been expected. He then proceeded to show that a sterilised soil, *i.e.*, a soil in which germ life had been destroyed without in any way altering its purely chemical composition or constitution, was practically unretentive, while the same soil in its normal state possessed its retaining power; therefore they were entitled to assume that the retention of the essential constituents of plant food was not to any material extent due to purely chemical interchanges, but was rather due to the biological condition of soils—to germ life—that in fact, a germless soil must be an unfertile soil, unless they could grow their crops in soils under water-culture conditions, which was for the present impossible. Mr. Hunter then discussed the commonly described doctrines of capillarity in soils; this theory implied the for-ever-existing multitudinous tubes, bringing water from the subsoil. He asked the question, How was it possible for water to be rising through water-pipes by capillarity in soils whose drains—natural or artificial—were acting as exhaust pumps at the lower ends of the capillary tubes? He then referred to the opinions of physicists in regard to capillarity in organic matter, and said that physicists who had expressed opinions upon this point had yet to learn that decomposing organic matter in the soil was germ occupied, and that many of the conditions exhibited by soils, which had been ascribed to physical phenomena, were almost wholly accounted for by those biological conditions which are inseparable from decomposition of organic matters in soils. Again, he asked, How could scientists account for the occurrence of different compounds of iron existing in the subsoil as compared with the surface soil, if those much-lauded capillary water-pipes existed? It is generally conceded that in the subsoil we have ferrous salts, which are generally described as soluble; while in the surface soil of fertile land the iron is in the ferric state and insoluble. If capillary tubes exist which perform this wonderful function of bringing water from the subsoil to the surface, they must—in virtue of the well known laws of diffusion—bring ferrous salts to the surface, and that is just what even the

advocates of capillarity deny; therefore, his opponents should fight their own doctrines first before attempting to assail his.

A capillary soil Mr. Hunter described as a water-logged soil, and only serviceable for conversion into a skating rink or curling pond. He then referred to the recently-introduced theory of soil mulching or hoeing, by which the capillary tubes were broken, and evaporation from the surface or upper ends of the tubes prevented. If the water pipes were non-existing, then this theory was absurd, but even supposing this kind of capillarity were a reality, the evaporation must only be prevented by a breaking of the continuity of the mass, whereby conduction of heat would be lessened, but most certainly not because the tops of water pipes were broken, for the duration of the fracture would be measurable by seconds; moreover, soils and plants—whether the lower plants or germs, or the higher plants—required aëration, and that is incompatible with the capillary tubes described in every text-book on agricultural science which he had perused. The subject of *drainage* was then referred to, and in this connection Mr. Hunter pointed to the composition of the atmosphere, or ordinary air, as compared with that of the soil atmosphere, the former containing 0.02, or take it as .04 per cent., while soil atmosphere contained, it might be 30 to 60 or more per cent. of carbon dioxide. This carbon dioxide of the air was invariably claimed as the great soil solvent—the provider of foods to plants; but how could even .04 per cent. in the air be considered so potent, when in the soil so enormously greater a proportion existed? Soil organisms he claimed to be the providers of foods to plants, and the high proportion of carbon dioxide in soils was a product of the life's work of those germs, and that unless drains—natural or artificial—were in the soil to drain away this carbon dioxide, no ordinary plant could live, because, while these plants can be grown to perfection under water-culture conditions in water, they could not grow in an atmosphere of carbon dioxide, therefore the primary functions of drains in soils was the removal of 'carbonic acid.'

The *selective powers of plants* were next dealt with, and Mr. Hunter showed that grass seeds sown on different soils might produce a crop containing 10 per cent., or it might contain 40 per cent. of silica in the ash. How did this agree he asked, with the obtaining doctrines of selection? That fact was of itself sufficient to annihilate the present theories, but the most convincing proof of all was the leguminosæ which were employed, as the most convincing proofs of powers of selection in plants. Mr. Hunter emphasised, without any hesitation, that the composition of the leguminosæ was in no way due to selective power, but was wholly ascribable, or nearly so, to the symbiotic growths on the roots—growths which, he believed, were first described by Mr. McAlpine, and as 'wart-like excrescences,' and that long before Hellriegel, Wilfarth, or any other worker in this department had been heard of.

Mr. Hunter then dealt with soil organisms, and spoke of those which he and Mr. McAlpine had isolated; and in this connection he referred to the efforts which a number of workers had been

making to identify the nitrifying organism by growing them in ordinary culture media, while all the time Mr. McAlpine and he had this organism growing and working, and their observations upon this point at once suggested the necessity for certain conditions of the surface soil as regards composition, &c., which were of primary importance in rational and successful agricultural practice. He then pointedly referred to the enunciated doctrine, that 'iron was a salifiable base of service in nitrification,' and in language which was more than convincing showed that that was a huge blunder made by a more or less great authority—'principally less'—who knew nothing whatever of the subject,—the living plant was itself a living contradiction of this absurdity. In the course of the lecture Mr. Hunter referred to the experiments made by Mr. McAlpine and himself with soil organisms—some of which he characterised as the prime ministers of the soil—and referred to the power possessed by a number of those they had isolated of breaking down *silicates*, a power which had for the time being caused them to conclude that many of those changes in the soil which had been credited to purely chemical interactions were wholly due to the *life* in the soil which was inseparable from fertility.

THE DAIRY.

A Dairyman gives the following hints:—Feed up, breed up, and weed out your herd till there is no possibility of further improvements in the quality and quantity of your milk. Feed the cows at regular hours with a well-balanced ration, and never put down more at a meal than each one will eat. Exercise in moderation in a good paddock with sufficient shelter from sun, wind and rain.

Keep each cow in milk for ten months, and let her dry off for two months before calving.

Do not let the cows become poor. It pays better to keep them in good condition than get them into good condition, and fat that is lost is lost for ever.

The separator will save all the butter that is in the milk, and will pay for itself in extra butter within six months upon 100 gallons a day.

It pays well to use the best dairy appliances and methods. Milk should be cooled quickly immediately it is taken from the cow. It will keep much longer, and any bad flavours in the milk will be modified.

Lucerne should be cut some hours before feeding the cows.

A curious and repugnant form of cruelty to cows is being practised in order to "prepare" them for the show yard. A farmer in Scotland (and there were others also charged with a similar offence) was fined £5 "for placing a board underneath the udder of a cow and pulling the said board upwards by means of a rope thrown over the rafters whereby the animal was made to rest its weight on the udder, which was well stocked with milk, and was thus subjected to severe pain and suffering." This was done in order to put the milk vessel into proper shape, that is to prevent it from hanging down. It was

further elicited in the course of the trial, that the udder had moreover been blistered to raise up parts in which the udder was deficient, and this added to the cruelty of the application of the board. No one will for a moment regret that the authors of these atrocities were prosecuted and fined. Another owner is reported to have been fined £2 10s. for inserting plugs of wood into the teats of a cow in order to distend the udder with milk.

Bran is a valuable food for certain purposes. It supplies the material for making bone, and this is needed by old animals as well as young, for it is known that the bones of an old animal are replaced to some extent during the whole of its existence. It is also an excellent flesh-producing food, and it provides the elements of milk except the fat. Bran has all the needed elements of nutrition for the sustenance of life in the proportion required, but it is deficient in the fat needed for butter. Thus, alone, it is not a suitable food for the dairyman.

Coir-dust when sprinkled on the floors of cow-houses, helps to keep them clean and sweet. The dust is an excellent absorbent of liquid manure, and at the same time is a deodorizer. The only drawback in the use of coir dust is when the liquid manure is required for application to herbaceous crops, such as cultivated grasses and the like, which are liable to die out owing to the dust taking so long to decompose, and tending, in a manner, to smother the plants. In the case of perennial trees, such as the coconut, the same objection would not stand in the way, and in fact the use of coir dust for soaking up liquid manure would greatly aid the distribution of the latter over the land. Coir-dust could at one time have been got for next to nothing. A year or two ago we paid only 6 cents for a cart load, delivered, but now the price asked is 25 cts. The practice of spreading the dust over coconut land is becoming quite common among land-owners.

"The Thistle" is the latest patent in milking machines, of which there are now a great number. It is the invention of Dr. Shiels of Glasgow. The principle of the machine is the combination of pulsation with motion for closely imitating the action of the calf's lips and tongue, which produces the pleasant sensation that causes the cow in a natural state to let down her milk. The milk is moreover said to flow twice as fast as when the teats are manipulated with the hand, and is got in a perfectly clean and pure condition. Many cows can be dealt with at the same time. The great point in reference to these milking machines is their proper regulation, so that no injury follows their use from allowing their action to go on beyond the proper limit, and the greatest care has to be exercised by those who have the control of these artificial milkers.

Prof. Wright of the Glasgow Technical College, in the course of a lecture on the "Care of Farmyard Manure," pointed out that ordinary farmyard manure contained 75 per cent. of water and only 25 per cent. of solid matter. Of the 5 cwt. of solid matter in each ton of farmyard manure

only about $\frac{1}{4}$ cwt. was of real manurial value. In fact, all the valuable constituents in a ton of farmyard manure only amounted to about 31 lbs., viz., 12 lbs. of nitrogen, 12 lbs. of potash, and 7 lbs. of phosphoric acid. The nitrogen was, of course, the most valuable part, and as the largest proportion of it was contained in the liquid part of the manure, special pains should be taken to see that no part of the liquid manure was allowed to be wasted. The lecturer argued strongly in favour of all cattle courts and dung steads being roofed over, so that no waste of manurial substances should be incurred through washing with rain-water. He also argued that when the manure was made up into large heaps in the field, it should be covered with a coating of earth to prevent nitrogen escaping.

GENERAL ITEMS.

Another suggestion to preserve eggs is to pack them in salt after wiping with vaseline to which salicylic acid had been added. By this means eggs are said to keep in good quality for over 3 months.

An enterprising firm in Cairns, Australia, has recently sent a trial shipment of Banana meal to London. The following are some particulars regarding it:—"We dried by heating steam pipes, but found the process slow and expensive, 80 per cent. of fluid having to be evaporated to secure 20 per cent. of solid. The packing and drying is an exceedingly tedious and expensive item. We are convinced it would take 8 to 10 dozen bananas to produce 1 lb. of meal or flour. We have found 3 table-spoonfulls to make a vegetable dish of most agreeable porridge. We sell at 10s. 6d. per dozen lbs."

The Hon. Alfred Deakin, writing on Irrigation in Egypt, thus refers to the agriculture of the country:—

The principal products are cotton, wheat, barley, beans, maize, sugar cane, rice and clover. In the Delta, those grown in summer are cotton, rice, sugar cane, melons, cucumbers, and clover. During the floods the maize, cotton, rice, and sugar cane are cultivated. The winter crops are wheat, beans, barley, and clover. The common rotation is a first year of cotton and clover, the second year of maize, wheat, and clover, and a third year of maize, beans, and clover. Cotton is too exhausting to the soil to be grown every year. It could be grown every second year if the water supply was larger, but the present practice is to grow it every third year only, or, what is the same thing, not more than one-third of a farm is put under this crop in each year. It is by far the most profitable product in Egypt, an acre being worth from £15 to £25, as against £7 for rice, £5 for wheat, and £4 per acre for fodder, beans, maize, or lentils. In Upper Egypt, wheat, flax, and beans are chiefly sown; while, by the use of sâkiyehs and shadoofs, millet, cucumbers, and melons are grown in summer. Their relative value may be

partly estimated from the exports of 1885, of which the chief are:—

Cotton	£7,706,399
Cotton seed	1,439,191
Beans	696,669
Sugar	579,312
Wheat	149,356
Rice	129,716
Skins	119,061
Gum	97,671
Wool	55,524
Lentils	41,054
Maize	27,352

The food of the country, which is grown by irrigation, of course does not appear in this return. Some fruit is grown, a great deal of forage, and a great variety of vegetables. Trees are comparatively rare in the Delta; but larger estates are sometimes planted with figs, mulberries, acacias, and sycamores, while the growth of other varieties, notably of the weeping willow, myrtle, elm, and cypress, are now being encouraged. Numbers of date palms are grown upon its borders. Large estates are reckoned to return a profit to their landlords, taking one year with another, of £5 per acre; those of moderate size, also with hired labor, £4 10s. per acre; while the Fellâhin, in their own plots and with their own family labor, gain as much as £6 10s. per acre; irrigation here, as in France and Spain, favoring the small proprietors.

The results of experiments by M. E. Gain with a view to ascertaining the effect of a moist soil and a moist atmosphere on the development of plants, have established the fact, viz., that dry air and a moist soil are favourable, and moist air and dry soil are very unfavourable to the production of flowers.

As a preventative against insect and fungoid pests, plants should be allowed plenty of room when being put into the ground. If, after some time, it is found that the trees have not sufficient ventilation, the branches will require judicious thinning and shortening. All wood removed from the tree should be collected and burnt at once, more especially if the tree is infested. The operation is best performed after the fruiting season is over.

Prof. Wagner, Director of the Agricultural Research Station, Darmstadt, thus concludes a lecture in which he has exhaustively answered the question, "How are Nitrogen and Phosphoric acid to be obtained in the cheapest way?"

"We have undoubtedly found a satisfactory solution of the question which we selected for discussion, which was, 'How are Nitrogen and Phosphoric acid to be obtained in the cheapest way?' And the reply is: That, at the present time, cultivation of leguminosæ, Thomas slag, and potash salts are the three most powerful levers, by the combined action of which we must endeavour to raise to the highest possible magnitude the yield of the soil, as well as the clear profit obtainable by cultivating fields or meadows."

 In consequence of the non-arrival of the supply of portraits of No. IV. of the Planting Pioneers of this Colony, we are forced to postpone its appearance till the December Number.

TOBACCO.

HE tobaccos of commerce are the prepared leaves of several species of nicotiana, a plant belonging to the natural order solanaceae.

The tobacco plant is cultivated in the Northern and North-Western provinces of Ceylon, also to a small extent

in the Central Province.

Many analyses of tobacco have been made in the laboratories of the French State factories. In an article in the *Encyclopaedia Britannica*, the following results of these analyses are given:—

Nicotine, a liquid volatile alkaloid from 1·5 to 9 per cent.

Essential Oil.—According to Schlossing an important element in the flavour of tobacco, although its proportion is exceedingly small.

Malic and Citric Acids (anhydrous) 10 to 14 per cent.

Acetic Acid.—Very little in fresh leaves, but, after fermentation as in snuff, about 3 per cent may be found.

Oxalic Acid 1 to 2 per cent.

Mucilaginous substances, including pectic acid, pectose and pectine, 5 per cent.

Resins, fats, and other bodies extractable by ether, 4 to 6 per cent.

Sugar, little in the leaves, more in the stems; in the fermentation it disappears.

Cellulose 7 to 8 per cent.

Albumenoids calculated from the nitrogen not present as nicotine, nitrates, or ammonia, about 25 per cent.

Mineral matter from about 16 to 28 per cent. The following represents the average amount of nicotine in cigars, smoking tobacco and snuff:—

Proportion of Nicotine in Tobacco.

(Quoted from Dr. Frankland's "Agricultural Chemical Analysis.")

Nicotine varies from	...	1·5 to 9	per cent.
„ in cigars from	...	1·5 to 8	„
„ in Havana cigars from	...	1·8 to 2·2	„
„ in smoking tobacco	„	2·2 to 2·5	„
„ in snuff from	...	2 to 3	„
