ROYAL COMMISSION ON THE SANITARY STATE OF THE ARMY IN INDIA.

VOL. II.

APPENDIX.

REPORTS FROM STATIONS IN INDIA AND ITS DEPENDENCIES OCCUPIED BY BRITISH AND BY NATIVE TROOPS.

REPORTS OF INSPECTORS-GENERAL OF HOSPITALS.

REPORTS ON STATIONS IN CEYLON.

LONDON:
PRINTED BY GEORGE EDWARD EYRE AND WILLIAM SPOTTISWOODE,
PRINTERS TO THE QUEEN'S MOST EXCELLENT MAJESTY.
FOR HER MAJESTY'S STATIONERY OFFICE.

1863.

INDEX TO THE STATIONAL REPORTS.

APPENDIX TO THE EVIDENCE

TAKEN BEFORE THE

ROYAL COMMISSION APPOINTED TO INQUIRE INTO THE SANITARY CONDITION OF THE INDIAN ARMY.

REPORTS ON THE SANITARY CONDITION OF STATIONS.

QUESTIONS

HAVING REFERENCE TO THE SANITARY CONDITION OF HER MAJESTY'S TROOPS IN INDIA, AND OF THE EUROPEAN AND NATIVE TROOPS IN THE INDIAN ARMY.

To which Answers are required by the Commissioners from every Station throughout India and its Dependencies.

(*The Answers are to be written on the Margin opposite each Question.*)

(It is desirable, wherever practicable, that the Answers should be filled up and signed below, concurrently, by the Commanding Officer, the Engineer, and the Medical Officer of the Station.)

Name of Presidency _____

Name of Station _____

Strength (non-commissioned officers and men) of each denomination of troops and arms for which there is accommodation at the Station _____

Queen's Troops, or European Troops of the Indian Army. { Artillery _____ / Cavalry _____ / Infantry _____

Native Troops - { Artillery _____ / Cavalry _____ / Infantry _____

Date _____

Signatures _____

References to Subjects.	QUERIES.
I. TOPOGRAPHY.	1. What is the general aspect of the country surrounding the station? Is it flat, hilly, mountainous, sandy, dry, or swampy? Is there much wood, jungle, or water in the vicinity? 2. What is the elevation of the station above— (1.) The sea? (2.) The adjacent country? (3.) The nearest water, lake, river, canal, nullah, or marsh? Is there any higher and healthier ground adjoining the station? if so, state its nature and elevation above the station, with any advantages or disadvantages attending it for military purposes. 3. At what distance from the station is the nearest mountain or table-land? and state approximately the height of such higher ground above the level of the station. 4. At what distance from the station is the nearest water, whether sea, river, lake, marsh, nullah, or canal? Is the vicinity liable to overflow of water? if so, at what season, and how long does the overflow last? Is there any broken ground, or are there any ravines or water pits near the station; and what is their effect on health? 5. Is the station open and freely exposed to winds? or is it so encumbered with trees, hedges, and gardens, or surrounded by trees, or by higher ground, or by houses or walls, as to interfere with free external or internal ventilation? Is the temperature of the station raised by the buildings being exposed to reflected sun-heat? Is the station exposed to cold or variable winds; to land winds, or to the sea-breeze, and what is their effect upon health? 6. Is the surrounding country cultivated or uncultivated? Are there any works of irrigation near the station; if so, at what distance are they? Is artificial irrigation observed to have any effect on the health of the station? Is the cultivation of rice prohibited within certain limits? if so, state the limits or distance from the station to which the cultivation of rice is restricted. Is the cultivation of indigo, or the preparation of hemp or flax carried on near the station? if so, at what distance? Is there any nuisance or injury to health in consequence? 7. Is there any large city, town, or native population in the vicinity of the station, and at what distance?

References to Subjects.	Queries.
I. Topography—*cont.*	8. State generally the geological structure, surface, and subsoil of the district; and whether the station occupies new ground, or ground which had been occupied by population before the present station was formed? 9. At what depth below the surface is water usually found:—during the dry season? During the rainy season? 10. Does the rain-fall, or the water from surface springs in the district within which the station is situated flow readily away; does it sink into a pervious subsoil, and so drain off; or does it ooze out again near the level of the station; or does it lie on the surface until it evaporates? State whether there be any adjacent higher ground, the drainage from which must necessarily pass into the subsoil of the station. 11. Whence is the water-supply of the station derived; is it from river, lake, wells, marsh, or rain-fall? Is it stored in open tanks; if so, state the extent of the tank surface both within the station and within half a mile of it? State whether the tanks are generally full or dry; The nature of the plants and animals they contain; Whether any tank used for drinking purposes is also used for bathing; Whether the water tank or well is liable to pollution from leaves or other matter falling into it; whether any foul drainage or surface impurities are allowed to drain into tanks containing drinking water; Whether nuisance or malaria proceeds from any tanks within or without the station, and the best means of preventing such nuisance or malaria? 12. State the amount of the water-supply available for the station, its sensible qualities as to colour, taste, and smell; If possible, its chemical composition, its hardness or softness, its microscopic characters; and state generally whether you consider the quality of the water as good, and not injurious to health, and whether its amount is sufficient; State the means for raising and distributing it for use; also whether any better water-supply could be obtained, with any recommendations you may have to make on the subject. 13. State any other topographical points bearing on the health of the station not included in these queries. 14. By whom, and after what amount or kind of inquiry or examination as to topography, climate, diseases, sanitary condition, &c., are new stations selected, whether on hills or plains; and could you suggest any improvements in the way this service should be conducted?
II. Climate.	1. What means and instruments are available at the station for conducting and registering meteorological observations? 2. Prepare and transmit a meteorological table for as many years past as possible, arranging the facts, so far as the observations at your disposal will admit, in the following form:—

Years of Observation from 18 to 18 .

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain, Inches.*	Winds.		Days of Sunshine.	Remarks as to Cloud, Dew, Wind, Storms, &c.
										Direction.	Force.†		
January													
February													
March													
April													
May													
June													
July													
August													
September													
October													
November													
December													

The Table should contain as many observations on these points as can be obtained.

* If the rain-fall cannot be given in inches, some expression should be used to give an idea of the amount of rain, such as "Dry Weather," "Rain," "Much Rain," &c.

† In describing the force, the following terms may be used:—"Calm," "Moderate," "High Winds," "Gales," "Storm," "Hurricane," "Monsoon."

3. State generally your opinion in regard to the character of the climate, its dryness, moisture, heat, variability, cold, fog, damp, tree planting, canal irrigation, or irrigation of any kind, as influencing the climate generally; purity or impurity of the air from dust or other admixtures affecting the atmosphere over large areas of country;
Also its influence on the health of the troops, and on the kind of diet, shelter, and clothing required, and the precautions as to the amount, nature, and times of drills, duties, and exercises which the climate renders necessary;
State which are the most healthy and which are the most unhealthy months at the station; state also which are the prevailing diseases during the unhealthy months.
4. Is there any district near the station the climate of which is more conducive to health than that of the station; if so, will you state its name, distance, elevation above the station, the nature of its drainage and water supply, and generally those circumstances which appear to render it more healthy, and any reasons which may exist for or against its adoption?
5. Will you transmit a list of the stations on which you have served, with your observations on the comparative salubrity, stating which were and which were not conducive to health, or positively injurious?

References to Subjects.	Queries.
III. Sanitary Condition of Station.	1. Transmit a general map or tracing of the station, with the country round, showing the position of the bazaars, public buildings, villages, jheels, &c., to a distance not exceeding four miles, with a scale attached? 2. Transmit a plan or tracing of the station itself on a scale sufficiently large to show generally the buildings in the station, and the position and dimensions of water tanks; the position and breadth of rivers, nullahs, or canals, and of all ditches, drains, and sewers, indicating whether such drains and sewers are open, covered, or constructed of masonry, bricks, or earthenware pipes, and whether they have a free or imperfect escape or outlet; each building within the station to be designated separately, and the position of all cesspits, wells, dung heaps, ashpits, privies, urinals, and nuisances to be marked and designated upon the plan. 3. Transmit a ground plan* and a rough marginal sketch, to show the general construction of the barracks at the station. 4. Fill up and transmit the annexed form of particulars regarding barrack-rooms, guard-rooms, and military prisons:— Date of construction of barrack. Total number of rooms or huts. Total regulation number of non-commissioned officers and men.

* The map and plans should be done on thin paper, and fastened by one edge to the page.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
Total - -											
Guard Room -											
Prison Cells -											

5. State whether the windows are on opposite sides, on adjacent sides, or on one side of the rooms, and how they open.
   Whether there is a verandah on either or on both sides, to what extent, and of what dimensions.
   If so, state whether the verandah is ever occupied as sleeping quarters by soldiers or other persons.
   State whether there are properly constructed jalousies or jhilmils.
6. State the nature of the bedsteads, cots, bedding, &c. used in barracks, huts, and tents, and whether you have any improvements to suggest in regard to its nature.
7. Describe the structure and dimensions of tents used in camp, giving the cubic space and superficial area per man, and the number of men in each form of tent.
8. Describe the means of ventilation in barracks, tents, huts, and guard-rooms.
   And whether the ventilation is sufficient to keep the air pure by night as well as by day.
   State also what means, if any, are used for cooling the air for barrack rooms. Describe the structure and cost of the apparatus, and append a rough marginal sketch of it.
9. State the materials of which barracks, huts, and tents, are constructed.
10. State the materials of which floors are constructed, and whether the floors are raised above the level of the ground; if so, how many feet or inches are they so raised, and whether there is a free passage of air beneath.
11. State whether the materials and construction of barracks, huts, and tents, are suitable for the climate, and whether any and what improvement in any of these points would increase their salubrity.
    State by whom the barracks and cantonments are kept in repair; whether repairs are quickly executed, and who is responsible for the general sanitary state of the cantonment.
    State at what intervals of time the walls and ceilings of barracks are cleansed and limewashed.
12. Transmit a rough marginal sketch and description of men's lavatories or washing places, and of the baths, if any, which are in use, stating their number and how supplied with water, and how drained.
13. Send a similar description, and rough marginal sketch of barrack cook-houses, and state the means of cooking provided, the means of supplying water, and of draining away refuse water.
    Describe the conveniences for washing and drying linen, and whether they are sufficient for the wants of the station.
14. Send a similar description and rough marginal sketch of the privies and urinals, and state whether they are drained, and how their contents are disposed of.
15. In describing these buildings state particularly the manner of ventilating and lighting, and state how the barracks are lighted at night.
16. Describe the arrangements for draining and sewering the barracks; the dimensions and construction of all sewers and drains, and the distance between the barracks and the outlet for the barrack drainage.
    State if the drainage be sufficient for conveying away readily and efficiently all surface water, and the drainage from men's lavatories, baths, women's wash-houses, cook-houses, privies, and urinals.
    State whether any part of any building used as a barrack or hospital is damp, and the cause of the dampness;

References to Subjects.	Queries.
II. Sanitary Condition of Station—*cont.*	And if the drainage be not sufficient, state what becomes of the fluid refuse of the barracks, whether it is left on the surface to evaporate, whether it is allowed to sink into the subsoil, or whether it is received into cesspits. If the latter, state the position and dimensions of the cesspits, and their distance from the nearest tank or well. Their distance from the nearest men's quarters and from the hospital, and the method and times of cleansing them. State whether there are any foul ditches, and at what distance from the station. 17. Describe the general state of the surface cleansing within the cantonment and its vicinity, whether the cleansing be efficiently done, and how often; and how the refuse manure, &c. are disposed of. 18. Is the surface of the cantonment kept free of vegetation? State whether there are any old walls, thick hedges, &c., interfering with the ventilation of the station, bazaar, &c., and which could be advantageously removed. 19. Describe the sanitary condition of the bazaar as to drainage, ventilation, water supply, cleanliness, latrines, crowding, and other similar matters. State what regulations and arrangements are in use for preserving due cleanliness in the bazaar, and whether any and what improvement in the sanitary police of bazaars be practicable. State generally the condition of the native houses near the station, and whether there are any dung heaps or cesspits within them. Is any nuisance experienced in barracks from wind blowing over the native dwellings? If so, state its cause and how the nuisance could be prevented. 20. State at what distance from the station animals are slaughtered for the use of the soldiers, whether any and what regulations are in force regarding slaughtering places, how the offal is disposed of, whether nuisance is experienced in the station from the condition of the slaughtering places, and how you would propose to prevent it. 21. State the arrangements for stabling or picketing bazaar horses, and those of the camp followers generally; at what distance these horses are kept from the station and what regulations are in force for preserving the stables and picketing grounds in a state of salubrity, and how the manure is disposed of. 22. Describe the manner in which the artillery or cavalry stables belonging to the station are constructed, their position with regard to the men's barracks and hospital, their means of light and ventilation, distance of the dung heaps from the soldiers' rooms and hospital, and how the manure is disposed of. State how the picketing grounds for artillery or cavalry horses are arranged, and their distance from and position as regards the men's accommodation, and the hospitals. 23. State whether there be sufficient quarters for married non-commissioned officers and men, or whether any married people occupy barrack-rooms with the men.
Officers' Quarters.	1. State generally what is the sanitary condition of officers' quarters at the station, with any details as to drainage, ventilation, &c. State what improvements you have to suggest with regard to them.
IV. Health of the Troops.	1. State generally whether the station, the district in which the station is situated, and the adjoining native population be healthy or unhealthy. 2. State what diseases are most prevalent among its native population, especially epidemics or spleen disease. 3. State generally the circumstances to which you attribute the healthiness or unhealthiness of the neighbouring native population. 4. Name the station at which the troops were before coming to the present station, the length of time they were in their former station, and the date of leaving it, their state of health there and the diseases from which they chiefly suffered, their state of health on arriving at their present station, and the date of arrival and the diseases from which they have chiefly suffered since arriving. State whether any portion of the men's accommodation in your present station is more unhealthy than the rest; if so, state to what such greater unhealthiness is attributable. 5. State whether the troops at the station are camped out, and for how long every year, and with what result to health. 6. State whether you have been in charge of troops at hill stations; if so, name the hill stations and state generally the result of your experience of residence at hill stations on the health of troops. 7. Have you observed whether troops who have been resident for some time on hill stations are more or less liable to attacks of febrile and other diseases on returning to the plains, and will you state the circumstances which in your opinion have influenced such greater or less liability? 8. From your experience, do you approve or disapprove of selecting hill stations for troops? 9. Are there any diseases peculiar to hill stations with which troops are liable to be attacked on going to them? 10. Are there any precautions as to diet, clothing, shelter, duties, or exercises which would guard the men from such attacks and enable them to obtain greater benefit from residence in hill stations? 11. From your own experience, what seasons are best adapted for residence in hill stations? And what is the shortest period of residence which would enable troops to obtain the full benefit of such residence to their health? 12. Is there any period of residence beyond which injury is likely to be inflicted on the health of the troops on returning to service in the plains? 13. Are any and what special precautions required for protecting the health of the troops on leaving hill stations for the plains? 14. As a general rule, and provided there were no military or other reasons against it, would it or would it not be the course most conducive to the preservation of the health of troops serving in India to locate them on hill stations with short periods of service in the plains, or does your own experience lead you to consider that service in the plains with short periods of change to hill stations would or would not be equally conducive to the health of the troops? Is frequent change of station in the plains beneficial or otherwise to the health and spirits of troops and convalescents?

References to Subjects.	Queries.
IV. Health of the Troops —*cont.*	15. Is the barrack and hospital accommodation provided at hill stations or sanitaria sufficient for the health and comfort of the troops, or are there any and what deficiencies in the accommodation in those hill stations or sanitaria with which you are acquainted? 16. Have you any experience to show between what ranges of elevation above the level of the sea the most suitable sites for hill stations may be obtained? and state the height. 17. Is there any higher ground near the station at which you are at present located, which could be advantageously occupied as a hill station, if so, state its name, distance from the station, means of access, elevation approximately, and, generally, its climate. 18. In your experience have you found any particular classes of surface and subsoils for stations more healthy or unhealthy than others? and if so, describe them. 19. State what age you consider the best for soldiers proceeding to India. State what is the best period of the year for troops to land in India. State how troops are disposed of on first landing, as regards barrack accommodation, clothing, drills, duties, and marches. And state what precautions you would recommend for preserving the health of recruits on first landing in India. 20. State whether troops should be sent direct from the home depôts to India, or whether they should be sent to an intermediate station for a certain time. Whether they should be sent to hill districts on landing and gradually accustomed to the climate, or in what other way you would propose to diminish the dangers of the earlier years of service. 21. Describe the mode of transport of troops from the port to the interior by land or by water, and whether any additional precautions are required for preserving the health of the troops on the route. 22. What, from your experience, should you consider to be the number of years a British soldier should serve in India? 23. Is the manner of conducting the business of medical boards, whether at stations or at the Presidencies, such as to avoid conflict of opinion as regards invaliding, or have you any suggestions to make on this subject? 28. What time of the year do you think it desirable that invalids should leave India for home?
Diseases.	1. Are there regular inspection parades for the discovery of incipient diseases at your station, and at what times? 2. Is there, or has there been, scorbutus or scorbutic disease among the troops at your present station? If so, in what proportion does it occur to other diseases? To what is it attributable, and what preventive measures would you suggest? 3. State the proportion of cases of hepatic disease usually under treatment, the causes to which you attribute the disease; whether it is generally more or less the consequence of other diseases, and of what diseases, and any prophylactic measures which, in your opinion, would diminish its frequency. 4. State similar particulars and recommendations with regard to the occurrence of dracunculus. 5. What proportion do the constantly sick from venereal diseases bear to the total sick in hospital from all other diseases? Could you suggest any additional precautions for diminishing the liability of the soldier to these diseases? Would it be advantageous or otherwise, to the health of the army to establish lock hospitals? 6. Do troops at the station suffer from diseases of the epidemic or endemic class, such as— Fevers,—distinguishing the forms; Dysentery; Cholera; Small-pox; Rheumatism? State the proportion which admissions and deaths from these diseases bear to the total admissions and deaths. 7. State generally the nosological character of the more frequent zymotic diseases. The seasons when such diseases are most prevalent. The climatic and atmospheric conditions which precede or accompany their appearance. The sanitary condition of those portions of the station, bazaar, or native dwellings, as to cleanliness, drainage, water-supply, ventilation, and crowding of dwellings where these diseases are most prevalent. Also, any personal habits or conditions among the troops or among the native population which appear to predispose to these diseases. 8. State further to what extent the prevalence of epidemic disease is influenced by the nature of the soldiers' duties and occupations in barrack or habits on the march and in the field. 9. Have small doses of quinine been tried at the station as a prophylactic against malarial diseases? If so, state the result. 10. State any recommendations your experience may enable you to make on any of the preceding points towards the prevention or mitigation of epidemic disease at the station.
V. Intemperance.	1. Are the soldiers at the station usually temperate or intemperate? Have you many confirmed drunkards? If so, state the proportion. 2. What proportion of admissions into hospital are there from diseases— (1.) Directly? (2.) Indirectly? Caused by intemperance? Prepare a statistical table showing the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality and crime at the station. Is drunkenness *per se* punished as an offence? 3. Are distilled spirits sold at the canteens or bazaar? If so, state the quality and the probable amount consumed by each man per diem. Is spirit any part of the ration for soldiers— (1.) At the station? (2.) On march? (3.) Or in the field?

References to Subjects.	Queries.
V. Intemperance—*cont.*	If so, state its quality and amount, and whether it is a habit among the men to take a dram before morning parade: if so, state its effect on health. Is spirit ever given as a ration to convalescents? If so, state its quality and daily amount. Are any drinks other than intoxicating drinks sold at the canteen or bazaar which are injurious to health? 4. Is the consumption of spirits by troops and convalescents conducive to health or injurious to health? Is it conducive, or otherwise, to the efficiency and internal discipline of the corps? 5. Would it be beneficial or injurious to the health of the troops to restrict or abolish the use of spirituous liquors as part of the ration, and to restrict or abolish the sale of spirits in the canteens or bazaars. 6. State your opinion as to the influence on health of the use of malt liquor or wines as compared with spiritous liquors. 7. Are coffee, tea, lemonade, soda-water, and similar drinks much used at the station? And what in your opinion is their influence on health, efficiency, and discipline, as compared with spirits and malt liquors? 8. Would it be beneficial or otherwise to the health of troops on the station to suppress altogether the spirit ration, whether for soldiers or convalescents, and to substitute for it beer, tea, or coffee, &c.? 9. Would it be beneficial or otherwise in prohibiting the sale of spirituous liquors in the canteens to permit only beer, coffee, tea, lemonade, &c., to be sold to the troops? 10. Have you any recommendations to make on these points? 11. Transmit copies of the present canteen and bazaar regulations on these subjects, and state how they are obeyed.
VI. Diet.	1. State the composition of the ration— (1). For Queen's British troops; (2). For European troops in the Indian army, specifying the quantity of every substance which enters into it, and any periodical changes which it is found necessary to make. Is there any responsible inspection made of the constituents of the ration, and by whom is it made? 2. State whether a complete ration, including a due proportion of vegetables and fruit is provided for troops at the station, and what the stoppage is. Also how many meals a day the soldier takes, the times of the meals, and their nature. State what proportion of vegetables enters into the constitution of the ration. 3. State whether any improvement in the ration would be conducive to the health of the troops, whether in the Queen's or in the European troops of the Indian army. And state further whether there is any arrangement to prevent any part of the rations being disposed of by the troops. 4. Describe the means and apparatus for cooking available at the station. State whether the kitchens are clean, light, well ventilated, and sufficiently supplied with water. Whether the food is boiled or roasted, and whether the cooking is properly done and sufficiently varied, and whether tea and coffee are properly prepared for the men. State whether the men have tea, coffee, or other refreshment before a march. 5. Could gardens for the cultivation of vegetables by soldiers be advantageously established near the station? If so, under what regulations?
VII. Dress, Accoutrements, and Duties.	1. State the component parts of the soldier's dress and accoutrements at your station. State whether you consider the present dress as suitable to the climate, and for the soldier's duties by day and by night, and at different seasons. State whether you would suggest any improvements in dress in stations, either on hills or in plains, for diminishing the effects of sun, heat, cold, wet, night air, or malaria, whether as regards head dress, under clothing, body clothing, boots, socks, &c. What is the present guard dress, and what protection have men on guard from sun and wet?
Duties.	1. Would it be advisable or otherwise, so far as regards the health of the men, that they should be thoroughly drilled at home, or at some intermediate station, before being sent to India? 2. Describe the usual routine of a soldier's duties, the amount, duration, and times of drill at the station. State whether the men appear to suffer in health from drill, and what remedy you propose. What are the best hours for drills, parades, and marches? Are there any general orders respecting these? State the average number of nights the men have in bed during the week. 3. At what distance from barracks are guards mounted? How long do guards last by day and by night? State whether there are roll calls by day or night, and how often; what the effect of night guards is on health, and whether any additional precautions are requisite in performing this duty.
VIII. Instruction and Recreation.	1. Are there any, and which of the following means of recreation and instruction at the station? (1.) Ball courts. (2.) Skittle grounds. (3.) Schools with good schoolmasters. (4.) Library and reading room, and whether sufficiently lighted at night. (5.) Day-room or soldiers' clubs. (6.) Soldiers' gardens, and how managed. (7.) Workshops; (8.) Theatre; (9.) Gymnasia. Whether they are sufficient to keep the men occupied during the wet season, and during the heat of the day. Whether there is any restriction on the men as to exposure to sun and rain out of barracks when off duty, and the result to health. 2. What improvements, if any, you would suggest to increase the efficiency of the existing means of recreation and employment, or to provide others? 3. Would the institution of soldiers' savings' banks be advantageous or disadvantageous? 4. Is there sufficient shade from trees, sheds, verandahs, or other means to enable the men to take exercise without injury to health during the day?

References to Subjects.	Queries.
IX. Military Prisons.	1. Describe the sanitary state of the military prison or cells at the station, comprehending any defects in their structure, overcrowding, ventilation, or sanitary arrangements, which may be prejudicial to the health of the prisoners, with your suggestions for remedying them.
X. Field Service.	1. Transmit copies of any local regulations for field medical service not included in the General Presidency Regulations. 2. State what is the practical working of the powers of the medical officers as regards the conduct of the line of march of troops bivouacking, camping, billeting, &c. 3. Describe the practical operation of any regulations in camp for the preservation of the health of the troops, as to the selection of camping grounds, general sanitary regulations, ventilation, water-supply in tents, huts, and field hospitals. Describe what are the powers of the medical officer in these matters, and whether any and what improvements you would suggest in the plan of procedure. 4. State generally the arrangements adopted in the Presidency for field hospitals, ambulances, transport of sick, and of hospital supplies, and transmit copies of all regulations bearing on these matters.
XI. Statistics of Sickness and Mortality.	1. Forms for obtaining statistics of sickness and mortality (in so far as these statistics cannot be obtained from the records in the departments at home) among (1) Queen's troops, (2) European troops in the Indian army, and (3) native troops, will be transmitted to the Presidencies. (These forms will perhaps be most easily filled up at the offices of the medical boards and inspectors-general of each Presidency.) It will be highly desirable, for the sake of comparison with the statistics of European troops serving in India, to make up and transmit for 10 years last past, if possible, the mortality statistics (1) of the East India Company's covenanted European civil servants; (2) of the East India Company's uncovenanted European civil servants, and (3) of soldiers' wives and children. The military forms may be used for this purpose. The essential points are the following :— (*a*) the number and ages of civilians, and (*b*) civilian mortality for the same period, arranged according to the ages, sexes, and diseases. Any reliable statistical information as to the diseases and mortality of groups of native population would also be useful.
XII. Hospitals.	1. Transmit a ground plan* and a rough marginal sketch of the elevation of the hospital. 2. Describe the position of the hospital :— (1.) As regards the barrack buildings and its distance from them and from the stables. (2.) Its position with regard to the bazaar, and the houses of the civil population generally. (3.) Whether the site is open and freely ventilated, or whether there are any buildings, high walls, trees, &c., which interfere with the ventilation. (4.) Whether the site generally is healthy as to elevation, drainage, absence of malaria from river banks, marshes, nullahs, ditches, water pits, foul ground, or other nuisances. 3. State whether the water-supply is abundant and wholesome, and if not, what facilities there are for improving it. 4. Describe the means of drainage employed for removing refuse water and other impurities from the hospital, and at what distance from the hospital the outlet for the sewage is situated. 5. Describe the general structure and arrangement of the hospital buildings with respect to the following points :— (1.) To what height the lowest wards are raised above the ground, and whether there is a free perflation of air underneath the floors. (2.) Whether provision is made for conveying away the roof-water, or whether it sinks into the subsoil. (3.) Describe generally the surface drainage and guttering round about the hospital, and whether it is sufficient for carrying away the rain-fall rapidly. (4.) Describe the materials of which the hospital is built, whether the roofs and walls are double, with ventilation between, or whether the roofs and walls are sufficiently thick to keep the hospital cool. (5.) State whether the hospital is supplied with verandahs on both sides, and their breadth, and whether they afford sufficient shelter from the sun's rays. State whether the verandahs are ever used for the accommodation of sick, convalescents, or others. (6.) State the number of flats of which the hospital consists. (7.) Fill up the particulars in the following table :— Date of construction. Total number of wards. Total regulation number of beds.

Wards or Hospital Huts, No.	Regulation Number of Sick in each Ward or Hut.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.

* The plan should be done on thin paper, and fastened by one edge to the page.

References to Subjects.	Queries.
XII. Hospitals--*cont.*	State whether the hospital is so placed as to receive the full benefit of prevailing winds. State how the windows open; whether their arrangement and construction is conducive to ventilation and coolness. 6. State the means of ventilation in use in the wards, and whether they are sufficient to keep the wards at all times free of odour or closeness. State the construction of jalousies or jhilmils, if any. 7. Describe and make a rough marginal sketch of any means of cooling the air admitted into the ward, which are in use at the hospital. 8. Describe the means of warming, if any. State at what intervals of time the walls and ceilings of hospital wards are cleansed and lime-washed. 9. Describe the position and structure of the privies or water-closets, and of the urinals, belonging to the hospital, and make a rough marginal sketch of their construction. State whether they are properly drained and supplied with water, or whether they are placed over cesspits. State whether they are offensive. 10. Describe the lavatory arrangements for the hospital, and state whether they are sufficient for the sick. 11. Describe the means of bathing for the sick, and state whether they are sufficient and convenient. 12. State what means there are of washing and drying hospital linen, and whether they are sufficient. 13. State whether the storage is sufficient and dry. 14. Describe the bedsteads, cots, and bedding in use in the hospital, and any improvement in either you may have to suggest. 15. Describe the hospital kitchen, its position with regard to the sick wards, the means and apparatus for cooking hospital diets, and state whether the means are sufficient, and whether the cooking of diets is properly done and can be sufficiently varied. 16. Transmit copies of the diet tables, diet rolls, and all other returns required for working the internal economy of the hospital, including copies of all the present forms in use for keeping the statistics of sickness, mortality, and invaliding in the corps. 17. State the provision for attendance on the sick as regards hospital serjeants, nurses, and orderlies, and whether such attendance is sufficient. 18. State generally your opinion as to the sanitary condition of your hospital, and whether any epidemic disease, hospital gangrene, pyæmia, have appeared in the wards; and if so, to what circumstances you attribute their occurrence. 19. State any other deficiencies or sanitary defects which have come under your notice as medical attendant, and what improvements you have to suggest. 20. State what provision is made for convalescents for taking exercise, and whether there is sufficient ground, suitably fenced, and shaded walks and seats set apart for their use. 21. State whether any and what arrangement or provision is made for the treatment of soldiers' sick wives and children. State whether the present arrangements are satisfactory, or whether any improvement in them be necessary. 22. Transmit copies of any special local hospital regulations enforced at the station, and which are not included in the General Presidency Medical Regulations. 23. State what powers the medical officer has practically in matters appertaining to the sanitary state of his hospital, to repairs in buildings, to change of diet, and to medical comforts within his hospital, at stations, camps, and on march. 24. State whether there be any convalescent wards, or hospital for convalescents, at the station, into which a soldier discharged from hospital might pass until he is fit for duty; or would such accommodation be an advantage?
XIII. Burial of the Dead.	1. At what distance from the station is the burial ground used by British troops, and what is its position as regards the station with reference to the prevailing wind? 2. State its area, soil, subsoil, drainage, whether decomposition takes place readily, and if the ground be carefully kept. 3. State the regulations as to burial under the following heads: (1.) The grave-space allowed and the interval between graves. (2.) The depth of graves, and whether graves are ever re-opened, and if so, how many bodies are interred in the same grave before it is considered full. (3.) How long after death is interment compulsory, 1, at ordinary times, and, 2, during epidemics? Send similar information regarding burial grounds used by native troops. 4. State whether the graveyard is ever offensive, and if so, what precautions are adopted to prevent nuisance. If there be no regulations, state the practice as regards the burial of British troops. 5. How are the dead of the camp followers or bazaar people disposed of? 6. And does any injury to the public health accrue from the present practice? 7. Could you suggest any improvements in the way of regulation or otherwise in the burial or disposal of the dead?
XIV. Reports from Presidency Directors-General, and Inspectors-General.	The Director-General and the Inspector-General of each Presidency should make up and transmit independent general reports for the Presidency on all matters contained in the preceding questions, including any additional points which they may consider of importance to lay before the Commission. The following additional information will be of importance:— 1. A list of all the stations in each Presidency, arranged according to their order of salubrity, with notes on the general sanitary condition of each. 2. A list of all existing sanitaria in the Presidency, with an account of the advantages or disadvantages of each— (1.) As places of residence for preserving health; and (2.) As places for recovery from sickness, with the diseases for which they are adapted or not adapted. 3. A list of all places within the Presidency where hill stations might be advantageously fixed for the health of the troops, or where sanitaria might be established, with particulars as to the elevation, topography, climate, means of access, distance from stations, &c.

References to Subjects.	Queries.
XIV. Reports from Presidency Directors-General, and Inspectors-General—*cont.*	4. It should be stated in what months troops usually arrive in the Presidency from England, whether any restriction for preserving their health is placed upon the men on arriving; whether there is any place of resort provided for the men, or whether they are allowed to go at large; whether there is much drunkenness amongst the men after landing, and whether much preventible disease arises from such irregularities; how long the troops remain at the port after disembarkation and before proceeding to the interior; what precautionary measures are in use for protecting their health during the voyage or journey. 5. It would be important to state the general result of experience as regards the Queen's troops and European troops of the Indian Army on the following points:— (1.) As to the best age for a soldier landing in India. (2.) As to the amount of previous service desirable before arriving in India. (3.) How he ought to be disposed of on landing, and what would be the best mode of life during his first years of service. (4.) The routine of stations, the length of time he should serve on hills and plains, and the total length of his service in India. (5.) The marriage of soldiers; the present regulations in regard to this; with any suggestions for improving such regulations. 6. Any additional recommendations or suggestions which past experience has shown to be requisite for protecting the health of troops after landing during the transit to the interior, in stations, on the march, or in camp, should be given. 7. A list of hospital equipments according to existing Presidency Regulations, for 100 or any other convenient number of men— (1.) For station hospitals. (2.) For field hospitals. With any additions or improvements in these equipments that can be suggested, and in the hospital regulations generally. Military and medical officers at stations should also add any additional information which they may think of importance, besides that required by the questions.

ANSWERS.

BENGAL PRESIDENCY.

CALCUTTA.—FORT WILLIAM.

Accommodation - { Queen's Troops - { Royal Artillery - - 80 / Infantry, H.M.S. 5th Fusiliers and 37th Regiment. } / Native Troops - { Cavalry, Governor General's Body Guard. / Infantry, the Alipore Regiment and Police Battalion. }

FORT WILLIAM. BENGAL.

References to Subjects and Queries.	Replies.
I. Topography.	1. The surrounding country is a plain covered with jungle, rice fields, native villages, garden houses, marshes, stagnant water, and low grass jungles. The fort has a circumference of 3 miles, and is surrounded by an open esplanade about half a mile wide. The adjacent country is flat and in many places swampy. There are numerous tanks in the vicinity of the station, and a considerable surface of stagnant water in the rainy season. Within the municipal limits of Calcutta there are 1,043 tanks, with a total area of no less than one 26th of that of the city. The river Hoogly, 2,000 feet in width, flows past the west of the town and fort.
	2. The elevation of the station above the sea is 18·16 feet by the barometrical measurements of the Surveyor-General. The direct distance of Calcutta from the sea is 67 miles. The station is on a level with the adjacent country, and but little more than 1 foot above the mean of high water in the river. There is said to be a fall from the bank of the river in the direction of the salt water lake. Alipore, a suburb to the S.E. of the city, is a little higher and better drained than the other suburbs. Its soil also is sandy. Balleegunge, to the immediate east of Calcutta, is open and airy, with a sandy soil, well calculated to carry off surplus water. The Howrah, or right bank of the Hoogly, is also said to be higher than the Calcutta side. There is no higher ground within a reasonable distance of Calcutta.
	3. The Rajmahah Hills are about 130 miles from the station. A spur of these hills has been proposed as a sanitarium, but it is generally considered that it would prove unhealthy. This spur, Parasnauth, is 188 miles from Calcutta, near the Grand Trunk Road, and is 4,233 feet in height. It is granitic.
	4. The nearest water is the river Hoogly, which runs to the immediate west of the town and fort. The circular canal lies to the N. and N.E. of the city, and Tully's nullah to the north. The salt water lake, a shallow brackish marsh, extending over a surface of many miles, is situated about 3 miles to the east of the city. The river sometimes overflows its banks, during the height of the rains; but there is always, after rain, much water lying on the surface in and around Calcutta, in consequence of imperfect drainage. The Drainage Committee remark that the slope of the drains is so trifling that it sometimes takes several hours to flow off. There is much broken and irregular ground in and around Calcutta, also filthy stagnant tanks and pits, which are a fertile source of disease to all who reside in their neighbourhood. The fort is pretty free from hollows for the accumulation of stagnant water; but the cunette which surrounds the fort is a cause of disease, and every effort is now being made to remedy this evil.
	5. The fort is comparatively open, being surrounded by a broad glacis; but the city is surrounded by jungle, or encumbered with trees, hedges, and gardens, which must interfere with free external ventilation. The ramparts of the fort, which are 25 feet in height, interfere with free ventilation; but this cannot, of course, be avoided. There is no doubt that the temperature of Calcutta and of the fort must be considerably raised by reflected sun heat, from the numerous white-washed solid buildings, in which the troops are quartered, and the greater part of the European inhabitants reside. The upper rooms of the barracks are as cool as any part of Calcutta. During the cold season the prevailing N. and N.W. winds are bracing and invigorating. In the hot weather the prevailing S. and S.S.E. winds are from the sea; but passing over a large tract of low, inundated, and jungly land, are comparatively unhealthy.
	6. The country surrounding the station is partly cultivated and partly uncultivated; the glacis of the fort is a sward. Much rice is cultivated around Calcutta, half a mile distant from the city, some of which requires artificial irrigation. I have no doubt that the increased humidity caused by irrigation coupled with a high temperature is productive of endemic disease. I am not aware that there is any limitation to the cultivation of rice in the vicinity of Calcutta; but there is no cultivation of hemp or indigo within some miles. Indigo is manufactured in the immediate neighbourhood of the planters' habitations, in which the smell of the "seetie" or refuse plant is at times most offensive; yet it is not considered a cause of disease.
	7. The station is surrounded on all sides by large and populous villages. The population of Calcutta is estimated at 500,000.
	8. The surface of the station is alluvial, with vegetable moulds, sands, and sandy clays. At a depth of 70 feet are found white and yellow sands, kunkar, and stiff clays. It is recorded that when digging the circular canal, numerous and large trees were everywhere found, many of them in an erect position, much below the present surface of the earth. Amongst these the natives recognised the Jack, the Soondry, the Pyen, the Gonah, and other well-known trees of the present day. A stratum of black peat, 2 feet thick, was found at a depth of 50 feet in Fort William.
	9. Water is usually found at a depth of 12 feet below the surface in the dry season, and from 8 to 4 feet during the rainy season (when it has been found as high as 2 feet below the

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	surface). These are somewhat below the mean tide level of the river at the different seasons.

10. The drainage is very imperfect, even in the city, and the rain fall flows slowly away, much of it sinking into the subsoil. A large proportion evaporates on the surface, causing increased humidity of the atmosphere. The drainage of Fort William is bad, but this is about to be remedied, and that of the lines of the Alipore regiment and of the body guard is pretty good in the immediate vicinity of the parade ground and huts, but very imperfect at a short distance all around. The country surrounding the station is a dead level, save at a few places in the suburbs, where the elevation is scarcely perceptible, though it is said to be sufficient to assist the drainage. No drainage from higher ground passes into the subsoil of the lines of the Alipore regiment, the Governor-General's body guard, or that of Fort William.

11. The water supply of the station is derived partly and principally from the river and tanks, partly from the rain fall, and partly from wells, but the water from the wells is generally considered brackish and unwholesome. The water used for drinking, cooking, &c. by the garrison is brought from a large tank on the glacis by native water carriers. This reservoir is 300 feet long, 200 feet wide, and from 5 to 12 feet in depth. It is filled by surface drainage. In addition to this there exist numerous other tanks within half a mile of the fort, having an aggregate superficies of 1,000,000 square feet. These are almost exclusively used by the natives of Calcutta. I have never known the Havildar's tank to be dry. After great droughts the water in it falls to 5 feet, but rarely continues so low as this for more than a few days. During the rains this tank is quite full, but it gradually falls to its minimum in the hot weather. The tanks contain a grassy fucus which grows rapidly, and has to be removed frequently, and also the pistia statistus. The fish found in them are carp, the Siluri family, Ramidæ in numbers, and infusoria. The natives frequently use the same tank both for drinking and bathing purposes, but no one is allowed to bathe in the tank used for drinking by the garrison. The water tank for the supply of the garrison is kept perfectly clean, and is generally free from foul drainage and surface impurities. From the well known careless habits of bheesties and native servants of all classes, it may not be unfairly assumed that water is sometimes taken from nearer and impurer sources of supply in the ditch. There are no tanks in the fort, and none of the tanks on the glacis or in the immediate neighbourhood of the fort are, in my opinion, a cause of disease; but in the city and in its suburbs there are innumerable tanks, many of them in a most filthy condition, which produce malaria.

12. The supply of water available for the station is sufficient for drinking and washing, but not for bathing. In consequence the Fort William special committee have recommended a steam pump for the purpose of bringing into the fort from the river a due supply of water for all purposes. The number of gallons per head was fixed at 30, and provision has been made for filtering 90,000 gallons. An efficient flushing volume will also be delivered at the head of the drains. The river water being unsuitable for six weeks annually, masonry tanks within the fort have been recommended, having storage space for two months' supply of pure water for drinking and culinary purposes, the quantity so stored to be calculated at 1 cubic foot per head per diem for 5,000 souls, and three-fourths of an inch per diem for evaporation.

The following table shows the chemical analysis of the Hooghly river water from off Fort point on the 30th April 1860, at low water, by Dr. Macnamara, professor of chemistry:—

Silica	0·5
Earthy carbonates	2·5
Sulphate of lime	0·3
Alkaline sulphates	1·1
Common salt	4·1
Alkaline carbonates, and little soluble organic matter	0·9
Solid residue from 40 ounces	9·4

The water was filtered before analysis; but the river being unusually low at the time the water was taken its impurities were probably at the maximum. The water is soft, and its quality good, and not injurious to health. The amount is sufficient for drinking purposes, but not for bathing. The water is raised and distributed by bheesties or native water carriers, the number of whom vary with the strength of regiments in the garrison. The proposed new arrangements for water supply to the fort are very perfect, and leave nothing to be desired. The total cost of conservancy and water supply is 134*l.*, viz.:—

	£
For bheesties and sweepers, with the cost of supervision	80
Establishment for regiment in garrison, about	54
	134

13. The drainage committee are carrying out a most efficient system of drainage, which, if successful, will tend much to increase the health of the town. Much good might be done by clearing the ground for a mile or two to the E. and S.E. of Calcutta, forbidding the cultivation of rice upon this space, and planting the outer edge with two or three rows of trees.

14. Committees for selecting new sites for cantonments, &c., consist of two military officers, two experienced medical officers, one civil officer or military officer in civil employ, and the executive engineer. This committee has authority to call for any information they may require on the topography, climate, diseases, &c., of the place proposed as a new site. As most of our army surgeons are well acquainted with military hygiene, the above arrangement would seem to be the most efficient that could be proposed.

Climate.

1. All our meteorological observations are conducted at the Observatory by the Government astronomer, who publishes the results weekly in the public papers. I am also supplied with a thermometer, barometer, and differential thermometer.

FORT WILLIAM. BENGAL.

3. The temperature of the station is high; but extremes of heat are moderated by contiguity to the ocean, rivers, and lakes. The atmosphere is generally moist. Elevation of the thermometer in the hot, and its depression during the cold seasons are not so great as up the country, and the climate is more equable, though more humid. The air at times is very offensive and impure from malaria and effluvia in the neighbourhood of Calcutta; in Fort William much less so. Even in the fort, however, the climate affects the health and constitution of the garrison, notwithstanding every care in diet, shelter, clothing, and the utmost precautions as to the amount, nature, and times of drills, duties, and exercises. In Calcutta and its suburbs the effects of malaria and a high moist temperature are evidenced in fever, cholera, dysentery, and a large proportion of glandular disease. The healthy months extend from November to March, the unhealthy are April, May, September, and October. The prevailing diseases during the unhealthy months are remittent and intermittent fevers, cholera, small pox, and dysentery.

4. There is no district near Calcutta, the climate of which would be more conducive to the health of the troops. Dr. Chevers, in his admirable article on the means of preserving the health of European soldiers in India, in the Indian Annals of Medicine, remarks that "Chittagong, Midnapore, Balasore, Buxar, and Monghya, although not so elevated as to benefit much from the protection of the lower clouds, are thoroughly open to the prevailing cool breezes, and are therefore pleasant situations. None of these localities, however, have sufficient elevation to place them above the miasmata of the neighbouring flats."

5. The following is a list of stations at which I have served. Dum-dum, the climate of which is very similar to that of Calcutta; Beerbhoom, a healthy station, elevated, well drained, and built on red kunkur or gravel; Jessore, which has a bad reputation, being surrounded by paddy fields, jungle, jheels, filthy tanks, and stagnant water, and having a river passing through it, which possesses all the characteristics of a stagnant jheel during many months of the year; Balasore, which is salubrious to Europeans, the nights being cool in the hot weather, the wind blowing from seaward, and the station raised and well drained; Moradabad, a healthy dry station with a sandy soil; Prome in Burmah, which is unhealthy for Europeans from malaria, great average heat, and considerable vicissitudes of temperature, also from extreme and long continued humidity during the rainy season; Thyet Myo, a well known station, soil a deep fine sand with a gravelly substratum, through which the rain percolates and flows off freely. In consequence of the poverty of the soil, jungle, scanty and deciduous leaves desiccated by the dry sand; Moulmein, which is a healthy place, with an undulating surface, and rapid drainage. There is a broad river on one side of it, and a low range of hills on the other; its soil is laterite.

III. SANITARY CONDITION OF STATION.

1, 2, 3. Maps of the station and surrounding country with plan of the barracks, &c., are transmitted. With the exception of those portions which pass under the ramparts all the drains are open and constructed of masonry. No pipes of any kind are employed. No cesspits, dung heaps, or ash pits are allowed in the fort.

4. Table of barrack accommodation.

DALHOUSIE BARRACKS.—Constructed in 1859.

Total number of rooms, 36 (besides two Verandahs along the North and South Faces).

Total regulation number of non-commissioned officers and men, 612 rank and file; 13 non-commissioned officers and six serjeants. (900 men have been accommodated in this barrack without inconvenient crowding.)

Barrack Rooms.	No.	Regulation No. of Men in each Room.	Dimensions of Rooms. Length.	Breadth.	Height.	Cubic Contents in Feet.	Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Windows. Number.	Height.	Width.	Remarks.

III. Sanitary Condition of Station—*cont.*	5. With the exception of a few windows in the rooms for serjeants at the end of each barrack, the windows are on opposite sides, and are as numerous as is consistent with the due apportioning of space for cots. These open outwards into verandahs. There are verandahs on both sides of the barracks, 12 feet wide, with the exception of the east and west bomb-proof which are in the ramparts. They are not intended to be occupied as sleeping-apartments; but in the hot weather many of the men prefer taking their cots into the verandahs to remaining in the wards. All the doors are one-third panel and two-thirds venetian or jhilmils. 6. The latest pattern of soldier's cot consists of a round rod iron frame with a net work of flat hoop iron for the support of the bedding. They are 6 feet 9 inches long, 2 feet 9 inches broad, 1 foot 6 inches high, and weigh about 1 cwt. They are in every way unobjectionable. 7. Tents have a double fly or top, and single kanats or sides. They are made of stout cotton cloth. They measure 20 feet by 16, and can accommodate 16 men, giving each a superficial space of 20 feet. The kanats or sides are triced up in the hot weather so as to give the occupiers the benefit of any wind that may be blowing. When shut and with the side doors only open, each man would have about 120 cubic feet of air. 8. Ventilation is effected in the barracks by numerous doors from 12 to 13 feet high at about 6 feet apart all round the wards. These secure thorough lower ventilation, whilst above openings are left at the insertion of all the flooring beams to carry off the heated upper air. These arrangements, coupled with the great height of the wards, from 17 to 20 feet, are, in my opinion, quite sufficient to preserve purity of air by night as well as by day. As the hot winds of the upper provinces are rarely experienced in Bengal, thermantidotes and kus-kus tatties are not required in Calcutta. All the barracks have punkahs pulled by natives. 9. The barracks are constructed of the best burnt bricks, set in lime mortar; the roofs of solid brick, and concrete terrace. They are plastered and white-washed. The tents have been already described. The huts for native troops are built of mud and are thatched. 10. The floors are constructed of bricks on edge, covered with square chuna flags. The basement floors of all the barracks, with the exception of the bomb-proofs, are given up for mess-rooms, canteens, skittle alleys, &c. They are never used as sleeping-apartments. 11. As far as the barracks are concerned, it would be very difficult to suggest improvements in those of Fort William. In the Dalhousie and Queen's barracks the accommodation may be considered perfect. The construction and repairs of buildings are in the hands of the garrison engineer, with the exception of such as are not likely to cost more than 5*l.*, in which case the work is done by the barrack-master. Periodical repairs of buildings are annual or quadrennial according to the nature of the work. External white washing, painting, &c., belong to the latter, whilst the internal white washing of hospitals, barracks, privies, &c., is annual. Both are provided for in regularly framed estimates, which are entered in the year's budget. Occasional repairs and emergent work are done by the garrison engineer on the authority of the brigadier commanding, who can sanction work extending to 50*l.* 12. The rooms for lavatory purposes are placed at the extremities of the barracks on each story. They have stone floors with raised masonry stands for basins. The water flows off readily into the drains surrounding the building. Plunge baths are much wanted and are included in the plans for the water supply of the fort already alluded to.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	13. The barrack cook rooms are of the most primitive kind. There is an open hearth for roasting, with two sloping side walls, to support the spit, and the chulas or native fire places for boiling meat, &c., are merely two low masonry walls, having an iron grating built in a few inches from the top, on which the charcoal is laid, the ashes falling beneath. The pot rests on the top of the low walls. Generally these are closed both behind and in front, having an opening for the removal of ashes, and the admission of air. Water is supplied by native water carriers; and the drainage is carried into the ditch. Soldiers' linen is washed by the regimental dhobies or washermen, and is accomplished out of the fort. Sufficient dhobies are supplied to each company for this purpose, and when in hospital the patients are supplied with hospital clothing, which is kept clean and in a serviceable condition by the hospital washermen and tailors. 14. The new pattern privy is now being introduced into the fort. More than half the number requisite for the garrison have been built, and the rest are in course of construction. By this arrangement all solid filth is received into iron pans placed under the seats, and emptied into iron barrel carts, which are removed at night, and their contents discharged into the river. Urinals have hitherto been made of sheet iron painted. Enamelled and cast glass urinals have been proposed and will probably be obtained from England. 15. The greatest attention has been given to the proper ventilation of the new privies. A ventilator runs the whole length of the ridge of the roof, and the sides of the building have numerous windows. The barracks are lighted at night by oil lamps under the management of the commissariat department. One light is generally allowed in each room, staircase, passage, and privy. This method of lighting being considered defective, a project for lighting the fort with gas has been submitted to Government and approved of. The requisite works have been entered in the budget of 1860–61. 16. Open masonry catch drains run along the sides of the roads in the fort and around each barrack and building. These slope in the direction of the ramparts, where they are met by intercepting drains leading to wells opposite each of the gateways. The sewage falling into the wells is conducted by sewers leading under each gateway to the level of the main ditch, crossing which in open drains it is discharged into the cunette. The open barrack drains are a little more than 100 feet from the main drains. The drainage of the fort is bad, inasmuch as it requires manual labour and the constant attention of the conservancy department. The special sanitary fort committee have recommended a thorough revision of it, and have also proposed a plan to Government for this purpose. I think the bomb-proof barracks are damp, but none of the others in which the men are located at night are so. The fluid refuse of the barracks is swept off night and morning by the garrison sweepers and water carriers, with the aid also of a fire-engine. There is no doubt, however, that a large portion of this evaporates. Only such liquid refuse sinks into the subsoil as is thrown on the ground outside the drains. There are no cesspits in the fort; the cunette receiving as it does the whole of the sewage of the fort is to a certain degree a foul ditch; but being filled twice daily by the tide it is not nearly so offensive as it otherwise would be. 17. The roads of the fort are swept twice daily, and are also watered in the hot season. All the catch drains are washed and swept down twice daily. All refuse, manure, &c., is removed by the conservancy carts, and thrown into the river. 18. All underwood is removed, and also the lower branches of trees from the surface of the cantonment. The ramparts, with numerous outhouses, &c., interfere in a measure with the free circulation of air; but this does not affect the soldiers in their sleeping apartments, which are so raised as to be above the influence of any stagnation of air from this cause. 19. The garrison bazaar is well drained and ventilated, and is supplied with water in the same way as the barracks. It is supplied with a urinal, and the native shopkeepers and others are prevented from making any filth in it. There is a special establishment of water carriers and sweepers entertained for the purpose of preserving due cleanliness in the bazaar. It is kept scrupulously clean. There are no native houses in the immediate neighbourhood of the European troops in this circle. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. Cattle are slaughtered at East Curriah, a suburb of Calcutta, about two miles east of the fort. The offal is always buried. The slaughter houses are too far distant to affect the health of the troops in any way. I have made inquiries of the natives residing in East Curriah, and they do not consider their vicinity to the slaughter houses as unwholesome. 21. The stables of the fort are at some distance, as no cattle are allowed to be kept in Fort William with the exception of those of the brigadier commanding. The horses of the Governor-General's body guard are lodged in fine airy masonry stables at Ballygunge, which is two miles east of the fort. These stables are furnished with approved means of light and ventilation; the dung is removed daily on carts. 22. When cavalry arrive in Calcutta on their way to other stations, the horses are picketed on the plain in the centre of the race course. They are arranged in lines of squadrons, and the men are encamped beside them. 23. The Queen's barrack provides accommodation for 120 married men, which would give separate rooms in the proportion of seven men per company for the present strength of the garrison. In addition to these the serjeants have separate rooms at the end of all the barracks.
Officers' Quarters.	1. Three ranges of barrack are given up for the use of the officers, viz.:— (1.) The staff barracks, which has 10 quarters for married officers. (2.) The rampart barracks, which has 11 quarters for field officers and married officers. (3.) The royal barrack (3-storied), having 28 quarters for unmarried officers. There are also five gateway houses which are occupied by the brigadier and senior staff officers. Extensive improvements are at the present time under execution.
IV. Health of the Troops.	1. The station, district surrounding it, and adjoining native population, are comparatively unhealthy. The mortality of troops garrisoning Fort William has been always high, though I am confident that a great reduction will take place when the sanitary arrangements now in progress are completed. [The fort is generally unhealthy.*] 2. The most prevalent diseases among the native population are fevers, cholera, dysentery, and small-pox. The usual sequelae of fevers and dysentery, viz., enlarged spleen and fatal diarrhœa, are remarkably prevalent.

* This reply and the subsequent replies within brackets are taken from another unsigned report on Fort William, received from Calcutta.

FORT WILLIAM. BENGAL.

IV. Health of the Troops —*cont.*	3. I attribute the prevalence of these diseases to,—rank, exuberant growth of jungle, filth, stagnant water, foul drains, bad drainage, unwholesome drinking water, and nuisances of various kinds. 4. The troops in garrison have been constantly changing during the last year. Her Majesty's 37th regiment came from Ceylon in 1857, and has lately arrived from Ghazeepore. The regiment was unhealthy on landing in India, and has suffered much since. At Calcutta they were attacked with cholera, and at Ghazeepore with fever, cholera, and dysentery. This regiment has lost 257 men in Bengal. The 37th regiment is a very unhealthy one, and a very large proportion of the men have enlarged spleen and liver. It is believed that the greater part of this disease was contracted in Ceylon. The 5th regiment of Fusiliers has lately arrived from Allahabad, where they enjoyed good health in the cold weather, but suffered much from fever and cholera in the hot season. The bomb-proof barracks are not quite so healthy as the others. This is owing to their being built on the ground, and to the lateral ventilation not being equal to that of the other barracks. Till lately also, the privies attached to them were an offensive nuisance. [The bomb proof barracks, as also the lower floors of all the others, are unhealthy. This is attributable to inefficient ventilation and the vapours from the drains.] 5. The troops in garrison are never camped out, but troops arriving at or leaving Calcutta, are frequently lodged temporarily in tents pitched on the glacis of Fort William during the cold season. 6. I have never been on the hills; but from an examination of those who have had large experience of hill stations, I have arrived at the conclusion that the climate is beneficial to the weak and to men suffering from functional disease, but useless or even hurtful in organic disease. The climate is believed to be prejudicial in inflammatory disease, in continued and remittent fevers, in gout, and rheumatism, dysentery, diarrhœa, and cerebral affections, also in syphilis, and in cachexia. 7. I am of opinion that troops returning to the plains from a hill climate, are not more liable to febrile and other diseases, than those located on the plains, if proper care be taken to avoid all great and sudden changes, and to insist on the troops wearing flannel. 8. To the healthy the climate of the hills is invigorating, after the relaxing and oppressive heat of the plains, and impending attacks of disease are generally warded off by the prophylactic agency of a hill climate. In the plains there is a tendency to the impairment of the muscular and nervous energy, and the general tone of the system is lowered. On the hills the healthy and temperate would seem to enjoy vigorous health. With proper precautions, therefore, I entirely approve of selecting hill stations for troops. [I approve of hill stations for troops.] 9. At Kussowlee, Subathoo, Simla, and Dugshai, the troops are liable to an obstinate and troublesome form of diarrhœa, called the "White purging," which often causes serious losses in regiments stationed at those places. Epidemics of croup and diptheria occur in the higher ranges. The natives suffer much from hill colic, and are sometimes visited by the mahanurree, a malignant fever of a typhus character accompanied by external glandular swellings. [Troops at hill stations are liable to be attacked with diarrhœa and lung affections.] 10. I understand that every precaution is taken with troops in hill stations. Flannel belts are worn; the men are kept from exposure to wet and from the use of improper articles of diet, and are encouraged in athletic exercises, and in healthy recreations. 11. From October to June [from October to July] is said to be the best season for residence in hill stations; but to obtain the full benefit of the climate for sick and convalescents, two cold seasons are recommended, or from October of one year to March of the next. Troops should reside in hill stations for not less than one year, in order to obtain full benefit to their health; but the period of such residence must, of course, depend very much on the nature of the ailment. 12. I am not aware that any period of residence on the hills is injurious to the health of troops, on their return to service in the plains. 13. On leaving hill stations the troops should descend to the plains gradually, halting for two or three days half-way down. Great care should be taken to prevent the men throwing off their warm clothing suddenly, or drinking cold water when heated. The use of flannel is also to be insisted on. [Light clothing, avoiding exposure to the sun, and temperance above all.] 14. I am of opinion that it would be more conducive to the health of troops serving in India to locate them on hill stations with short periods of service in the plains. The longer they enjoy the invigorating influence of a hill climate, and the less they are exposed to the debilitating effects of the plains, the better. Frequent change of station is liked by the troops, and they generally enjoy good health on the march in cold weather, if not harassed by forced marches, nor allowed to stray in villages on the route for drink, &c. As far as health is concerned, change of station depends very much upon the salubrity or otherwise of the places to which they are removed. [The course most conducive to the preservation of health would be to locate them on the hills, only bringing them to the plains during the cool season.] [Frequent change of station in the plains is beneficial if the change is effected during the cool season.] 15. I understand that the barrack and hospital accommodation provided at hill stations is amply sufficient for the health and comfort of the troops. 16. Experience shows that the ranges of elevation most suitable as sites for hill stations are from 4,000 to 8,000 feet above the level of the sea, if removed from sources of miasmata, possessing good natural drainage, thorough ventilation, space, and freedom from local causes of disease. 17. The Rajmahal hills are about 130 miles from Calcutta; but their elevation is insufficient for the formation of sanitaria. They are also covered with jungle, and are said to be deficient in water supply. 18. Low, marshy places, ground subject to inundation and saturated with moisture as in many places in lower Bengal; rich soils, the upper part of which is composed of leaves and other vegetable matters undergoing decay, and tenacious clays which prevent water passing through them, are the most unhealthy class of soils for the formation of stations. [Sandy or metallic soils are more healthy for stations than others, as Meerut, Umballa, Ferozepore, &c.]

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	19. I should say from 18 to 23 years is the best age for soldiers proceeding to India, and they should land there in October or November, as it gives them the benefit of the cold season, and gradually introduces them to the hot one. Leaving England in July or August there is a gradual transition from the cool temperature of England to the heated atmosphere of India. Drafts for Her Majesty's corps go to Dum-Dum on landing, and those for the Indian Army to Barrackpore. They have excellent barracks at both those places, and are under instruction during their detention. They are sent up the country either by the river steamers or by bullock train. Personal cleanliness, temperance, exercise morning and evening, the careful prevention of exposure to the sun, and occupation of mind when confined to barracks during the day, are the precautions to be observed by the recruit on first landing in India. [22 years of age. Should arrive from November to March.] [Drafts are now detained in Calcutta only till such time as arrangements are completed for dispatching them to their destination. The necessary precautions on arriving in India are to avoid exposure to the sun, abstinence from spirits, moderate use of animal food, and not too much drill.]
	20. If drilled at home, and sent to India at the proper season, I feel certain that the proportion of sickness amongst the recruits on landing in this country would be greatly reduced. Gradual acclimatisation by short residence in an intermediate station would be advantageous. I think it would tend to reduce disease if troops on landing here were sent to a good hill station during the first hot season. The most stringent measures should be adopted to restrain intemperance, the use of crude fruit and vegetables, and to prevent undue exposure to the sun, and excessive physical exertion. [Troops should be sent to hill stations on first arrival.]
	21. Troops are transported from the fort to the interior by large, airy troop boats towed by steamers, and by bullock train. In the former the space provided for each European soldier, woman, or two children, is not to be less than 6 feet by 2. Separate hospital accommodation is provided for every detachment of 50 men and upwards. These boats have venetianed windows extending down both sides, and separated from each other by only a few inches of wooden post. The bullock train is composed of covered carts and waggons drawn by bullocks, four men being allotted to each cart and six to a waggon. These start from Ranegunge, to which place troops are conveyed by rail. Doolies are also supplied for men who may be taken sick on the journey, and there are road hospitals, with a medical officer, &c., attached to each, at short distances all the way up to Allahabad. [They are mostly sent up country by bullock train.]
	22. The number of years a British soldier should serve in India depends upon constitution, habits, idiosyncracy, &c. I have seen many soldiers whose constitutions were quite worn out by the climate after 15 or 16 years service, and I have known others who were active, apparently healthy, and quite fit for further effective service after double that period of residence in India. He would serve longer if allowed a furlough to England for 2 years, after 8 or 10 years [ten years] service in India.
	23. Difference of opinion will sometimes occur at invaliding boards, but in such cases the votes of the majority decide the question. [The majority decide in particular cases.]
	24. Invalids should never be allowed to quit India before January, in order to avoid the chill piercing winds of March in England. [November till February.]
Diseases.	1. There is always a surgeon's weekly inspection parade at this station for the discovery of incipient diseases.
	2. The admissions into hospital from scurvy are almost exclusively of seamen from merchant ships. On the arrival of the British troops during the mutinies, a small proportion of the soldiers was admitted from scorbutus, which was attributed to an insufficient supply of hermetically closed fresh provisions. This disease is attributable to overcrowding, and a diet which is deficient in the variety and quantity of the principles essential to the healthy constitution of the blood. We have numerous examples which establish the fact that this disease does not occur in well ventilated ships, when the troops are supplied with untainted recently salted meat, fresh biscuits, sufficiently hermetically sealed provisions, milk, potatoes, and lime juice, with fresh fruit and vegetables when procurable.
	3. In the general hospital the proportion of hepatic disease to total sick is about 9 per cent. Hepatic disease in this country may be caused by exposure to heat, to sudden atmospheric changes, and by indulgence to excess in spirituous liquors. Fatty degeneration and abscess are frequently found in cases of chronic dysentery. The frequency of this disease would be lessened by temperance, and by making the men wear flannel and flannel belts. [In India hepatic disease bears a very large proportion in comparison with any other class of disease, and is attributable to climate and mode of life. The means of warding off this disease are moderation in the use of articles of diet containing hydro-carbonaceous elements, avoiding exposure to the sun, cleanliness, mental amusement, and exercise.]
	4. I know of no well authenticated instance of dracunculus having been generated in this neighbourhood. Cases of this disease are sometimes admitted into the general hospital at the Presidency; but the worm is always mature, and most of the patients are sailors from Bombay. Its mode of entrance into the human body, and its subsequent propagation are involved in obscurity. [Europeans are rarely attacked by dracunculus.]
	5. The proportion of constantly sick from venereal disease to total sick in hospital is about 5 per cent. This disease might be lessened by keeping the men to their own bazaar and having frequent inspections of the women. The latter ought to be separated, and kept from all communication with the men when diseased.
	6. The following are the diseases from which the men at this station suffer, viz.:—
	Fevers.—Intermittent (of the quotidian, tertian, quartan, and double tertian types) the remittent and continued fevers. [Yes.]
	Dysentery.—Acute and chronic, with various complications. [Yes.]
	Cholera.—Bilious and spasmodic. [Yes.]
	Small-pox.—Benign and confluent. [Occasionally only.]
	Rheumatism.—Acute and chronic. [Yes.]
	The admissions from the above diseases are from 60 to 65 per cent. on the total sick, and the deaths are from 75 to 80 per cent. on the total deaths.

FORT WILLIAM. BENGAL.

IV. Health of the Troops —*Diseases--cont.*	7. The following is a statement showing the nosological character of the more frequent zymotic diseases :—

Diseases arising from depressing causes characterised at their commencement by impaired vital or organic nervous force, but generally followed by more or less re-action throughout the frame, but often more prominently expressed in one or more organs. — Periodical fevers :— Intermittent and remittent, continued, and variola.

Pestilences appearing epidemically - - - Cholera.

Diseases characterised by an unnatural state of excitement or irritation of an organ or part, followed by morbid exudations, by changes of vital power, and of organization of the affected part. — Dysentery, hepatitis, splenitis, &c.

Variola is most prevalent in February, March, and April; fever in September and October; dysentery in July, August, and September; and cholera in March. The advent of the hot weather, the change from cold to heat, the extreme humidity, the drying up of the country after the rains, and increased generation of malaria, are amongst the climatic and atmospheric conditions which precede or accompany the above diseases. The barracks for Europeans are generally kept very clean; but the neighbourhood of native dwellings is almost always filthy. In fact, a large proportion of the natives die of disease brought on by inattention to the most obvious sanitary rules. The greatest attention is paid to the sanitary condition of the barracks, and every exertion is made to remove all endemic sources of disease. Amongst the troops the great predisposing causes to disease, are exposure and drink. The natives are temperate and their personal habits are not generally provocative of disease. [Hepatitis, febris, cynanche, dysenteria, diarrhœa, cholera, during the hot and rainy seasons.]

[The barracks and fort altogether are kept remarkably clean, but the drainage is bad, the water supply not so good as it might be, and the ventilation defective. The cooly bazaar, in the immediate neighbourhood of the fort, is foul and filthy to a very great degree. The drainage is most imperfect, and the bazaar is crowded with native huts.]

[The conditions which predispose to zyomtic diseases here are overcrowding, bad ventilation, foul air, and bad food.]

8. European and native troops suffer from frequent and long-continued exertions in the field, from forced marches, and exposure to the sun, but with proper care and management, the duties of a soldier do not, in my opinion, predispose to epidemic disease in Fort William. [Predisposition produced by long continued exertion, producing great fatigue and depression. Idleness and dissipated habits.]

9. Small doses of quinine have not, that I am aware, been tried as a prophylactic against malarial disease. To those predisposed to malarial disease, I am of opinion that it would act as a prophylactic; but I fear that the system would soon get accustomed to it, and that its effects would cease, or require greater doses.

10. To prevent or mitigate epidemic disease, I would recommend the careful avoidance of predisposing causes, as overcrowding, unwholesome food, unripe fruit, bad water, drunkenness, exposure to the sun, want of cleanliness, physical and mental depression, sleeping out at nights in the bazaars, &c. [A good supply of water, free ventilation, improved drainage, and a free use of disinfectants, and the immediate removal of the contents of latrines and cesspools. Active employment for body and mind.]

V. INTEMPERANCE.

1. The troops at this station are about as temperate as those at other stations. With means and opportunity, many soldiers in most regiments will indulge too freely in spirituous liquors. The officer commanding H. M. 8th regiment reports 7 trials in 3 months for habitual drunkenness in his regiment; the officer commanding the 5th Fusiliers about 2 per cent., but the average number of drunkards to strength in European regiments in this country cannot be less than 15 per cent.

2. The surgeon of H. M. 8th regiment stated that the admissions into his hospital during the last year from diseases caused *directly* by intemperance was in the proportion of 1 to 114, and indirectly from the same cause 1 to 11. The surgeon of H. M. 5th Fusiliers gives 2 per cent. of direct admissions from intemperance, and 17 per cent. indirect. In 7 regiments serving in Madras during 1849, there were punished :

	Strength.	Punished per 1,000.
Teetotallers	671	236·95
Temperate	6,611	587·20
Intemperate	1,461	1709·78

Total ratios of sickness and deaths in the above 3 classes during the same year in six European regiments in Madras :—

	Strength.	Admissions per 1,000.	Deaths.
Teetotallers	450	1308·88	11·11
Temperate	4,318	1415·93	23·15
Intemperate	942	2148·61	44·58

Drunkenness is always punished as an offence.

3. Spirits are sold in all regimental canteens. Rum of 24 under proof, and of good quality, is supplied to the men. In H. M.'s 8th regiment, the daily consumption per man is $1\frac{4}{9}\frac{1}{1}$ drams, in H. M.'s 5th Fusiliers $1\frac{1}{2}$ drams. Spirit does not form part of a soldier's ration, but is supplied by the commissariat, and paid for by the soldier. The issue of rum before dinner is prohibited. Porter and beer are supplied at dinner time to those who desire it. Before breakfast, neither spirits nor fermented liquors are permitted to be issued. Spirit is never given as a ration to convalescents. Ginger beer and coffee are sold by dealers in those articles in the barracks, who obtain a pass for this purpose. When out in the town, the men often partake of intoxicating drinks, which are very injurious to health.

4. To men in health spirits are, in my opinion, decidedly injurious in this country. There are some conditions of the body in which the circulation is sluggish, and the nervous system weak and depressed, in which small quantities may be useful. They are the curse of the European soldier in India, causing an amount of moral evils and of physical ills, the magnitude of which would render any attempt to lessen their consumption by the army worthy of our sincerest admiration and support.

5. I think it would be most beneficial to restrict the sale of spirituous liquors to moderate quantities. The reports of the American temperance societies show that 1,000 ships sailed from the ports of that country without ardent spirits as a part of their provision, and the men on board

V. Intemperance—*cont.*	were proved to be better able to undergo the fatigues and hardships of the sea, than those in vessels where the old plan was persevered in. It is also well known that the American insurance societies insure vessels which do not carry spirits 5 per cent. lower than others. The use and abuse of spirits cannot be abolished in the army, but every exertion should be made to prevent intemperance; which is not only the bane of the soldier in this country, but a dreadful expense to the State. 6. Beer in moderation is generally considered nourishing and wholesome in this country. It is greatly preferable to spirituous liquors. 7. Tea, coffee, lemonade, soda water, &c., are used in considerable quantities in Fort William, and I have no doubt that their influence on health, efficiency, and discipline, is most beneficial when properly made as compared with spirits. 8. I think it would be beneficial to the health of the troops to suppress altogether the spirit ration, and to substitute for it beer, tea, or coffee, &c., at the option of the soldier. Not only are the direct fatal results of drink painfully numerous, but it exerts in a considerable number of instances a marked influence in predisposing to other diseases. Habits of intemperance also by undermining the constitution render them, in many instances, incapable of resisting the destructive tendency of these other diseases. 9. I am convinced that it would be most beneficial to prohibit the sale of spirituous liquors in the canteens, allowing each man a ration of beer instead. This arrangement may induce the intemperate to resort to the bazaar for bad and unwholesome liquor, but stringent measures must be adopted to keep the men inside the fort, to prevent the introduction of spirit, and to suppress its sale in the bazaars. 10. Every means should be adopted to exterminate this bad habit in the soldier, such as the diffusion of knowledge, and the production of a taste for pleasures of an intellectual kind, and the occupation of his leisure hours by amusing pursuits, &c., &c. 11. There are no regulations on the above subject in the Fort William regimental canteens, but the following rules have been established for all regimental canteens in India. 1. Each regiment is to have a canteen which is to be managed by a quarterly committee composed of a captain and two subalterns of not less than 3 years' service, under the control of the commanding officer. 2. A steady non-commissioned officer is to be appointed by the commanding officer as canteen serjeant. 3. The establishment consists of 1 canteen sergeant, at 50 rupees per mensem; 1 assistant, at 16 rs.; 1 native writer, at 12 rupees, with the number of native servants considered necessary. 4. A sub-committee of non-commissioned officers is to be appointed to act under the quarterly committee, for the more immediate superintendence of the general management of the canteen, but to have no concern in any money payment or contract. 5. Detachments when practicable, are to establish canteens. If impracticable, malt liquor or rum will be supplied daily by the commissariat agent, on requisition, and issued under the orders of the commanding officer in the presence of an officer. 6. It is very desirable that coffee should be available for the men early in the morning, both on the march and when stationary. The committee should secure a contractor who would engage to supply coffee at a fixed rate. 7. Malt liquor and rum are supplied to canteens by the commissariat, and are retailed under regimental regulations. Rum is issued at 2 rs. a gallon, 24 per cent. under London proof, and retailed to the men at 1 anna per dram. 8. The difference between the original price of the rum, and that at which it is issued, viz., 8 annas per gallon, forms the canteen fund from which the authorized establishment and charges are defrayed. 9. The accounts of this fund are kept by the canteen committee. 10. Malt liquor is issued at rs. 40·2 per hogshead, and retailed to the men at 3 annas per quart, and 6 pice per pint. 11. The maximum quantities that can be issued daily are 2 drams of rum, or 1 quart of beer and 1 dram of rum. 12. No spirits are to be issued before the men's dinner hour, nor are the 2 drams of rum per diem to be issued at the same time.
VI. Diet.	1. The ration for Queen's British troops and European troops in the Indian army is the same, and is composed as follows, viz.:—1 lb. bread, 1 lb. meat, 1 lb. vegetables, 4 oz. rice, $2\frac{1}{2}$ oz. sugar, $\frac{5}{7}$th of an oz. of tea, 1 oz. salt, and 3 lbs. firewood. Mutton, when procurable, is issued twice a week in lieu of beef, and coffee may be substituted for tea, at the desire of the soldier, in the proportion of 2 lbs. of the former, to 1 lb. of the latter. The vegetables are generally potatoes in this circle, but when these are not procurable country vegetables of good quality are substituted. The rations are always of good quality, wholesome, and plentiful. Rations are daily inspected by the regimental officer of the day, and by the regimental quartermaster. 2. The troops are provided with a complete ration daily, with a due proportion of vegetables. The stoppage is about 5*d.* The soldier has 3 meals per diem, viz., breakfast at 8 a.m., dinner at 1 p.m., and supper at 6 p.m., one pound of vegetable enters into the constitution of each ration. 3. In cantonments in the hot weather I am of opinion that the meat ration might be beneficially reduced to three-quarters of a pound. So much highly carbonized material is not required by the system at that season, and tends to the production of fatty degeneration of the liver, kidneys, and heart. The system of messing would seem to prevent the disposal of any part of the ration by the troops. 4, The means and apparatus for cooking available at this station have been described (29, 13, sanitary condition of the station). Grant's cooking stove has been recommended for use in the barracks, and I have no doubt that it will be found most effective and convenient. It has also been approved of for hospitals by the special hospital committee, as per plan transmitted. The kitchens are clean and well ventilated. The regimental water carriers always supply a sufficiency of water. The food is sometimes boiled, sometimes roasted, and the cooking is generally good and sufficiently varied. The tea is generally boiled instead of being infused; but the men prefer the former mode of preparing this beverage. It is generally the custom to have coffee prepared for the men on the line of march. They very rarely have tea, coffee, or other

FORT WILLIAM. BENGAL.

VI. Diet—*cont.*	refreshment before a march, which is generally made very early in the morning, so as to reach the encamping ground before the sun has risen so high as to be troublesome or dangerous. 5. Gardens for the cultivation of vegetables by soldiers could be advantageously established at the distance of a mile or two from the fort, but not in its immediate neighbourhood. Very stringent regulations would, however, be required to prevent the men wandering into the bazaar for drink, &c.
VII. Dress, Accoutrements, and Duties.	1. In the cold season the soldier's dress and accoutrements are the same as in England. For the hot season he is provided with cotton tunic and trowsers, a forage cap and cover. The present dress of the soldier is very suitable to the climate, and for his duties by day and by night, at the different seasons of the year. The protection for men on guard during wet is the great coat. The summer coat is made of a slate-coloured khakee, worn loose. A light handkerchief has been substituted for the stock. The men are supplied with 2 pairs of boots and 2 pairs of socks, and 2 cotton cap covers with flaps, which protect the neck and temples from the sun. Flannel is indispensable as an article of upper clothing in this country; but it should be frequently washed, or it becomes a source of disease. The soldier ought to have two flannel shirts at least.
Duties.	1. There is no doubt that it would be most advantageous to have the men thoroughly instructed in drill before coming to India. 2. The usual routine of soldier's duties is, parades for drill and exercise, and mounting guard. Drill is very seldom continued for more than 1 hour, and the men do not seem to suffer in health from it. The best time in this country for drills, parades, &c., is in the morning, half an hour before sunrise. At present the European troops in garrison have 5 nights in bed for 1 on duty. 3. Guards mount close to the barracks, and last 24 hours. There are more or less frequent roll calls by day, and by night, according as the men are absent without leave from the barracks. I am of opinion that night guards tend to increase sickness.
VIII. Instruction and Recreation.	1. The following are the means of instruction and recreation at this station:—1 ball court, 4 skittle alleys in use, and 4 others nearly finished, 2 regimental schools with schoolmasters, also a garrison school; a large library just opened for the use of the garrison, besides regimental libraries, and a library for the use of the non-commissioned staff. There are neither day rooms, soldiers' clubs, soldiers' gardens, or workshops, but, with respect to the latter, the matter has been under consideration. A theatre has been lately constructed in the barracks for the use of the men, and a gymnasium has been lately provided by order of Government. In addition to the above, cricket, foot-ball, and quoits are played morning and evening. I think the men have now the means of recreation during the wet season and heat of the day, and there is every reason to hope that these will afford them full occupation. The men are not allowed to leave barracks during the heat of the day, and there is no doubt that this restriction is a matter of necessity in this country. 2. I am of opinion that the means of recreation and employment at present in operation in addition to such as are in contemplation will be found sufficient for such soldiers as are willing to take advantage of the same. 3. The institution of soldiers' savings banks is decidedly most advantageous. They have lately been established throughout the country. 4. The ground floors of the barracks and the verandahs afford ample space for recreation and exercise during the heat of the day.
IX. Military Prisons.	1. The solitary cells are objectionable on account of their contracted dimensions and imperfect ventilation. The Fort William special committee have the subject under consideration at present, and propose to concentrate the whole of the cells of the fort in a single building, so as to diminish as far as possible the demands for guards over prisoners.
X. Field Service.	1. When proceeding on field service, medical officers are instructed to accompany their regiments in the rear into action, furnished with all instruments, dressings, and necessaries requisite for field duties; to protect their establishments by their presence; not to remain unnecessarily under fire; to select a suitable and safe spot adjacent to their regiments for the wounded, and to send in lists of casualties in killed and wounded immediately after any encounter with the enemy. 2. The recommendations and objections of medical officers as regards the conduct of the line of march of troops, bivouacking, camping, &c. are generally attended to unless weightier reasons forbid. The practical working of the power of medical officers in all such cases is always most beneficial. 3. Permanent encamping grounds planted with trees, exist along all the principal roads in this country, and the most careful attention of all medical officers is required to the application of the generally established rules relating to health and conservancy, under all the varying conditions to which the troops under their charge may be exposed. The existing arrangements on the line of march are excellent and have proved efficient. The special hospital committee have recommended the establishment of completely equipped hospitals at all the larger stations in India. 4. When an army goes into the field a field general hospital is established quite independent of regimental hospital establishments. To this are appointed a field surgeon, a medical store-keeper, assistant surgeons, an apothecary, steward, assistant stewards and apothecaries, and apprentices according to the strength of the army employed. It is also supplied with native head compounders, assistant compounders, head dressers, assistant dressers, shop coolies in the apothecary's department, and native writers, stewards, servants, bheesties or water carriers, sweepers, ward coolies, cooks, washermen, a clothier, tailors, and barbers in the steward's department. Tents are furnished at the rate of 8 patients per tent; necessary tents, serjeants' tents for subordinate establishment, tents for stores, &c., camels and elephants for the carriage of tents, and native tent pitchers or clashis; hospital clothing, hospital cots, and hackeries for the carriage of the same. The doolies and bearers for every 100 patients are, 100 doolies, 6 scidars, 12 mates, and 600 bearers. European medicines, wines, stationery, cloth for bandages, and dressing are provided, and also cooking utensils, and charpoys for natives, &c. The sick and wounded are transported in doolies, which are comfortable and easy, and admirably suited to the country. The hospital supplies are carried by elephants, camels, hackeries, and banghy-wallahs.

XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1. Ground plan and elevation of the hospital transmitted herewith.
	2. The hospital is situated at Bhowanipoor, about three-quarters of a mile S.S.E. of Fort William. The nearest stables are those of the body guard at Ballygunge, about 1¼ miles east of the hospital. The hospital is bounded on the east by a native bazaar, on the south by native houses and the European lunatic asylum, on the west by a road which divides it from the compound of the Sudder Dewanny Adawlut, and on the north by an open plain continuous with the glacis of Fort William. The site is open to the north and west, but surrounded by buildings, walls, and trees, to the south and east. As most of the walls and buildings are low they interfere but little with the ventilation, save that in the lower story which in both wings is used as godowns. The site is healthy for Calcutta, though it is not elevated above the general level. The drainage is bad; but the drains being open and swept out most carefully morning and evening, I am of opinion that no ill consequences result therefrom. An open ditch to the east of the hospital which carries off a large portion of the sewage of the great jail and of the hospital has been reported a nuisance by me, and by the surgeon of the general hospital.
	3. The water supply is abundant and wholesome. It is obtained from a tank in the hospital compound, measuring 192 by 126 feet, and 30 feet in depth.
	4. The drains are all open surface drains, made of masonry, and most of them lined with large tiles. About 100 yards from the hospital buildings the drains discharge themselves to the east into the ditch already referred to, and to the west into a large pucka drain, both of which convey the sewage to Tulley's nullah, a large canal which empties itself into the river.
	5. The lowest wards in the right and left wing hospitals are raised 12½ feet above the ground, the ground floor of both buildings being occupied as store rooms. There is consequently free perflation of air under the floors. The roof water is carried off by the drains, and none of it sinks into the subsoil within the hospital grounds. The drains and guttering are sufficient to carry off the heaviest rain fall; water lodges in several places when the drains are nearly empty, and this requires to be swept out; having but little fall the drainage is not rapid. The walls of the hospital are of brick and mortar, 3 feet thick in the centre. The centre ward has a double verandah to the south, and a single closed verandah to the north, but neither roofs nor walls are double. The roofs are flat and of thick tiles covered with masonry. They are sufficiently thick to keep the hospital cool. There is an open verandah to the south, supported on pillars and arches, and an inner verandah with same aspect, having broad arches on one side, and venetians and glass doors on the other side. There is a verandah similar to the last to the north of both the wing hospitals.
	The inner closed verandah to the south of the wing hospitals is frequently used for the accommodation of sick. The outer open verandahs are only employed as a promenade or for the patients to sit in. The centre hospital consists of two flats, and the wing hospitals of three flats each.

Table of Hospital Accommodation.

Date of construction, 1795.

Wards for eye cases -	2	23·5	9	12	5,076				6	8	4

N.B.—The dimensions in the above Table are of the first stories or flats of the wings; the second stories are precisely similar, except in height, which is 15 feet.

The hospital faces the north, and has the full benefit of the prevailing winds. The side windows are so large and numerous, that the patients may be said to live in the open air, under a roof to protect them from the sun's rays. The venetianed windows open outwards and turn back against the walls, the glass doors fold inwards. When open there is no impediment to ventilation in the entire space included in the window frame. In fact the windows are large doors opening with a few exceptions to the floors of the wards.

FORT WILLIAM. BENGAL.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	6. I have been in this hospital when it contained 460 patients, yet the wards were perfectly free from odour and closeness. The lateral ventilation in this building appears to me to be most effective in allowing a constant current of air through the wards. The jhilmils are broad slips of wood, which overlap each other, and can be raised or shut at pleasure. Each slip is furnished with a pivot at each end, which moves in a socket in the door frame. The jhilmils are in the usual place of panels in a door. 7. Tatties are not considered wholesome in Bengal, and are not employed in the general hospital. Punkahs are supplied for military patients, but these merely circulate the air and do not cool it. 8. The wards never require to be warmed. The walls and ceilings of the wards are cleansed and whitewashed once yearly, but in most hospitals this is done when certified by the medical officer to be necessary. 9. The privies are connected with the wards by a covered passage 61 feet in length, and 10 feet in breadth. These are airy rooms in which close stools are placed, the pans of which are removed by sweepers immediately after the patient's resort to them, unless otherwise ordered. They are all furnished with separate stairs for the sweepers and water carriers. The privies are well drained and supplied with water; they are not placed over cesspits, which are very objectionable in this country. They are never offensive with proper care. All the filth is removed to the river by means of carts, which receives the contents of the stool pans during the day, and carry it off at night. 10. The general and garrison European hospitals are supplied with hot baths, wash rooms with shelves for basins, and bath rooms on the common country plans, the water being poured over the body from native earthen pots; shower baths have also been recommended. 11. There are hot and cold baths in each wing built of masonry, also the ordinary country bathing room, in which the sick can bathe by having vessels of water poured over them. 12. There is a tank of water in the compound of the general hospital for the use of washermen, who are also supplied with all the requirements for washing, steaming, and drying hospital clothing. 13. The store rooms are sufficiently commodious for the number of sick in the general hospital, but it has been found insufficient during the last 2 years, in consequence of the large quantities of clothing handed over by troops proceeding to England, and by invalids from the upper provinces. 14. The common wooden or iron cot is used in hospital. The first is a mere wooden frame on legs, the latter is preferable, and has been already described. The former has a cane bottom, the latter one of slips of iron. 15. The hospital kitchens, which are separated from the main buildings, and at a convenient distance from them, are supplied with ranges of chulas or the common native cooking places, and with an open fire-place for roasting meat. The chula is composed of 2 low walls of brick, on which the pots rest. 16. Copies of diet tables, &c., have been forwarded. 17. The regimental hospital has an hospital sergeant, and the general hospital 2 European ward masters, but the immediate attendants on the sick are the native ward coolies. It is however proposed to introduce female European nurses in the proportion of 1 to every 25 patients. The present attendance is sufficient, but that of the European nurses would be more grateful to the patients. 18. I consider the sanitary condition of the general hospital as good as circumstances will allow. Hospital gangrene is almost unknown in its wards, and pyœmia is quite as rare. I am not aware of a single case of either disease which originated in the ward. 19. The drainage of the hospitals is imperfect, and objections have been made to the wards being too low. I am of opinion that great height of wards is not so essentially necessary in a building, the lateral ventilation of which is so great that the patients may be said to live in the open air. 20. Accommodation for 32 men in bullock ambulances for the conveyance of convalescents out upon the plain every evening for exercise is provided. The men are allowed to take exercise in the verandahs in the day time, and on the top of the hospitals morning and evening. They can also walk about the grounds, and may sit under the shade of a fine banian tree, which is situated in front of the hospital. 21. There is a female hospital. It is detached and well raised, having flues below, but being surrounded at a short distance by other and higher buildings, it is not very airy. I am of opinion that the arrangements for the treatment of soldiers' sick wives and children are most satisfactory. 22. No reply to this query. 23. All requisitions from medical officers with regard to the sanitary state of the hospital and repairs of buildings obtain the immediate attention of the local authorities. The greatest latitude is allowed to medical officers in dieting the sick soldier, and in supplying him with medical comforts within his hospital, at stations, in camp, or on the march. 24. With regard to the accommodation of convalescents at this station, the soldier is generally kept in hospital till he can be reported fit for duty, or else sent to barracks with a recommendation that he be excused heavy duties for a day or two. Convalescent hospitals would be superfluous, as the regimental hospitals possess all requirements for the sick soldier in every stage of disease. For chronic diseases there are the convalescent depôts on the hills.
XIII. Burial of the Dead.	1, 2. The burial ground used by British troops is at Bhowanipore, behind the general and garrison hospitals, and is about 2 miles S.E. of the fort. Its area is about 1,500 square feet, the soil being sandy, with a sand and sandy clay sub-soil. Decomposition takes place rapidly, but the drainage is imperfect. 3. The grave space allowed is 9 feet by 6 feet, the interval between each grave being 2 feet. The depth is 6 feet. Graves are re-opened for the interment of relatives, and each grave is supposed to be full after 4 interments. Such as are not considered family vaults are opened for interment after 3 or 4 years. The burial of the dead cannot be deferred long in this country, in consequence of the rapidity of decomposition. It generally takes place in from 12 to 24 hours after decease. The Mussulman troops are buried in the grave yard belonging to the sect in the neighbourhood, no special provision being made for the burial of native troops in this circle. Hindoos throw their dead into the river or burn their bodies.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead —*cont.*	4. The grave yard is not offensive at ordinary times. During the mutinies when the mortality was great, and the water in Tully's nullah which runs to the south of the ground, ran very high, some of the graves were inundated and became offensive; but this was checked with lime, and no effluvia has been perceptible in the grave yard since that time. The funerals of deceased soldiers take place at sun rise or half an hour before sun set according to circumstances. The accumulation of rubbish in the grave yard is prohibited, and there are rules to ensure the ground being kept in proper order. 5. The dead of camp followers and bazaar people are disposed of in the manner already described for native troops. 6. In some few instances the Mussulman burying grounds have been proved to be nuisances, in consequence of the graves being shallow and liable to be broken into by jackals. The police, however, use every exertion to prevent this, though not always with success. 7. The present arrangements for the disposal of the dead seem unobjectionable as far as European troops are concerned. The Hindoo custom of throwing their dead into the river is a serious nuisance, but cannot be prevented without interfering with the religion and prejudices of the natives.

(Signed) James Anderson, M.D.,
Deputy Inspector-General Indian Army,
Presidency Circle.

FORT WILLIAM.—FURTHER REPORT.

*** The abstract of this report is limited to points not so fully illustrated in the preceding report on Fort William.

References to Subjects and Queries.	Replies.
I. Topography.	1. Fort William, which has a circumference of somewhat over 3 miles, is surrounded by an open esplanade, nowhere less than half a mile wide. The ground is perfectly flat, and covered with a good firm turf, which remains green throughout the year. Though not swampy, water lies everywhere close to the surface. Trees, with the exception of those in the botanical garden, north of the fort, are very sparingly scattered. As to general appearance, the view from the fort is bounded on three sides by the houses of the city, and on the other by the shipping in the river, with the suburb of Howrah on the opposite bank. Of water there is abundance in the neighbourhood,—Calcutta itself having, within its municipal limits, 1,043 tanks, with a total area of no less than $\frac{1}{25}$ of the area of the city. The river Hooghly, moreover, 2,000 feet wide, flows past the west face of the fort. 2. The height of Calcutta above the sea by the surveyor-general's barometrical measurements, is 18·16 feet, and distant 67 miles as the crow flies. The fort is built on the general level of the Gangetic delta, and consequently has no command of position over the adjacent country. The elevation of the enceinte above the Hooghly during high spring tides in the monsoon is exceedingly small, while during the dry season it is never less than 7 feet. The following table shows the heights of the river according to the state of the tide and season of the year, the numbers indicating the level of the river surface below the top of the bank in each case:—

State of Trade.	Dry Season.		Rainy Season.	
	Neaps.	Springs.	Neaps.	Springs.
	Feet.	Feet.	Feet.	Feet.
High Water -	15	$6\frac{3}{4}$	$8\frac{1}{4}$	$\frac{3}{4}$
Low Water -	$21\frac{1}{2}$	$22\frac{1}{4}$	$12\frac{3}{4}$	15

The Howrah, or right bank of the Hooghly, is slightly higher than the Calcutta side, and might probably from this circumstance, as well as its better position in regard to the prevailing winds, have proved more salubrious; no very determinate opinion, however, can be given regarding this. There is no higher ground within such a distance as would render a change of location desirable on sanitary grounds; but, even did such a position exist, a change would apparently be out of the question for political reasons.

3. The Rajmahal hills, the nearest to Fort William, are not less than 125 miles distant. A spur of these hills has been chosen as a sanitarium. Parasnauth is 190 miles distant, and 4,230 feet high.
4. In addition to the river, a tidal creek, called "Tulley's Nullah," joins the river at three-quarters of a mile south of the fort. An extensive swamp, known as the "Salt Water Lakes," lies to the north-east at about three and half miles, and a circular canal between that and the city. The situation of all these is indicated on the map of Calcutta which accompanies. The committee for drainage in Calcutta remarks "that the slope of the drains is so small in "the town, and the quantity of water which falls in a short time is so great, that the streets "are sometimes flooded, and it takes several hours for the water to flow off." Upwards of 11 inches of water fell on the 21st August 1844, and 10 inches on the 22nd October 1851, and from 3 to 4 inches seem not uncommonly to have fallen in 24 hours in August and other monsoon months. In such cases a good deal of water naturally remains on the ground, but it can hardly be doubted that within the fort itself the storm waters are carried off more quickly than in any part of the city. There is no natural hollow in or about the fort, in which water accumulates or becomes stagnant. The lunette, however, which surrounds the fort, and is filled and emptied with the tide, receives the whole of the sewage; from this circumstance, and the large deposit of silt that takes place annually, its effect on the health of the garrison is manifestly injurious. Strenuous efforts are now being made to mitigate, if not entirely cure, the evil.
5. The fort is not so open as might be wished, but still the large masses of buildings requisite for the garrison and arsenal have been disposed as judiciously as the available space admitted of. The height of the rampart surrounding the fort, 25 feet, of itself interferes with the circulation of air in a measure; but this obviously cannot be avoided. With the exception of a few trees to the southward, no vegetation in the enceinte within, interferes with

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	the circulation of air nor grows to any injurious extent. The reflection of the sun's rays from the numerous buildings in close proximity in the fort naturally raises the temperature, but the extent and airiness of the barracks, and the open esplanade on all sides, each and all tend to counteract this, so far as to make probably the fort equally cool with the coolest part of Calcutta. With the exception of the heavy squalls which occur towards evening in March, April, and May, the station cannot be said to be exposed to cold or variable winds. From October to January land winds from the north-west prevail, while during the rest of the year the wind has generally a south-easterly direction. The malarious exhalations driven over Fort William by the south and east winds from the salt lakes and from the immense tract of low and jungly country called the Sunderbunds are productive of unhealthiness. 6. The esplanade surrounding the fort is a grass sward. Beyond the Calcutta suburbs there is rice cultivation to the east and north, and thick jungle succeeded by cultivation on the south. There are no regular works of irrigation near this station as water for cultivation is easily obtained (from its nearness to the surface) from tanks and wells. None of the unhealthiness of Fort William has been referred to the rice and other cultivation, which, as before mentioned, exists beyond the town limits, malarious influences being justly attributed to the uncultivated marsh and jungle lands. Cultivation, as superseding these, must be held to exercise a beneficial influence. Neither indigo nor flax is cultivated in the adjacent country. 7. The mass of the native population occupy the portions of the city on the north and north-east of the fort, and again there is a considerable collection of natives along Tully's Nullah, Allipore, &c. Merchants, Government officers, &c. have their private residences to the east and south. The total population is estimated roughly at 450,000 souls. 8. With respect to the geological structure of the surface, subsoil, &c. of the station and surrounding district we have the following from the Drainage Committee's report already quoted.—" After penetrating through the artificial soil of the surface a light blue or slate-" coloured clay occurs, becoming darker as we descend, from impregnation with decayed " vegetable matters, until it passes into a stratum of black peat about 2 feet in thickness, at a " depth in Fort William of 50 feet below the surface." This general character seems to be preserved about the district. 9. In the dry season water seldom stands at less than 12 feet from the surface of the ground, and in the rainy season at 10 feet. 10. There are no surface springs. Rain-water partly flows off, partly soaks into the ground, falling to the levels above indicated, which would appear to be somewhat about the mean tide level in the river at the different seasons. The drainage of the fort is altogether uninfluenced by that of any neighbouring locality. 11. The whole of the water used for drinking, cooking, and by the Europeans in garrison is brought from the havildars' tank, which is a reservoir of about 300 feet long, 200 feet wide, varying from 12 feet deep in the hot season to 4 feet deep in the dry, and filled by the surface drainage of the esplanade. The natives of the garrison supply themselves partly from the tanks, and partly from wells within the fort. The water from the latter is brackish. In addition to the havildars' tank on the esplanade, there exist, within a limit of about half-a-mile from the Fort glacis, several large tanks, having in the aggregate a superficies of 1,000,000 square feet. These are, however, now exclusively used by the townspeople. No water is at present drawn from the river, but a project is being digested which it is hoped when carried into execution will amply suffice for all the wants of the garrison. By this plan water, filtered, will be pumped into the fort at the rate of 30 gallons per man per diem. In the monsoon the havildars' tank is generally full to overflowing, but towards the end of the dry season, from the quantity of water drawn from it, and evaporation, its level becomes considerably reduced. No person is permitted to bathe in the havildars' tank, neither does foul drainage find its way into it; but from the smallness of the depth of water it is found impossible to prevent vegetable matter from growing on the surface. This is, however, carefully and frequently removed. The main sources of malaria, Salt Water Lake, and the Sunderbund jungles already alluded to, are irremediable; but the nearer ones of bad sewerage and the cunette in which the mud deposits are exposed at each recession of the tide, and doubtless give off noxious gases, are quite within the range of our means of prevention, and, as already mentioned, the subject is receiving the closest attention, with a view to a complete rectification of the evil. 12. For drinking and cooking purposes the amount of water from the havildars' tank is barely sufficient. Bheesties are specially employed for bringing it into the fort. For the soldiers washing, for cleaning utensils in the cook-rooms, &c., the supply exclusively drawn from the cunette just suffices for absolute requirements, but no more. From the same source is also drawn the water used for washing down barracks and drains, for watering the roads, and flushing the sewers. A good water supply is the main desideratum of the fort, the present one barely sufficing the requirements of the garrison, admitting of no plunge baths for the men, nor any proper system of sewerage. The drinking water from the havildars' tank becomes quite clear and colourless after standing a short time, but retains, however, an earthy taste. The cunette water is quite unfit for drinking, as in its present state it receives the sewage of the fort, and holds in solution all kinds of impurities. The tank water is pronounced by the chemical examiner to Government to be remarkably pure and wholesome. This might be expected, from the fact of its being rain water stored up and secured from all contamination. The river water, which is extensively used by the population of Calcutta, is also considered wholesome. Its chemical composition, as determined by the late Mr. Piddington, is as follows:—245·3 grains of silt, 188·3 of carbonate of lime; total 433·6 of solid matter, or $\frac{9}{10}$ of an ounce for the whole solid contents of a cubic foot of water. In supplying this water as proposed, all silt and impurities will be got rid of as much as possible by filtration. The present water supply and conservancy establishments may be stated to consist nearly as follow:—Bheesties and mehter, with cost of supervision, 80*l.* per mensem; establishments for regiments in garrison, about 54*l.*; making a total, including cost of conservancy and water supply, of 134*l.* A slight variation always exists, as the allowance of water carriers, &c., is proportioned to the strength of regiments in garrison. That a better supply of water can be given to the fort will be gathered from the foregoing replies. The means proposed for filtration, raising, storage, and distribution, in the project now under consideration, it would be manifestly impossible here to detail. 13. No reply to this query. 14. The selection of sites for barracks, &c. is a matter to which every attention is now given under existing regulations. It is laid down in the Public Works Code, that committees,

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	which one, and in all practicable cases two, experienced medical officers must be members, shall be assembled in all cases in which it may be necessary to select sites for barracks, hospitals, and other buildings for troops, or when it may be necessary to report on their condition in a sanitary point of view. The following instructions leave nothing to be desired in respect to this most important matter.

Extract from Code of Regulations for the Public Works Department, Cap. VIII. Sect 2. Para. 1. Clause 3.

"The choice of a site for any building requires careful consideration on the part of the engineer; but when the building is designed as a residence, especially when for a large number of human beings, this point becomes one of the utmost importance. In the case of barracks, gaols, &c., the executive engineer must therefore carefully investigate the nature of the drainage for a considerable distance round the proposed site, particularly satisfying himself that the spot (and as far as possible the neighbourhood) is not liable to flood. He must examine the position of the neighbouring buildings, cultivation, tanks, jheels, jungles, and note the direction of the prevailing winds, and the character of the country over which they blow, and must, if possible, obtain the opinion of medical officers as to the salubrity of the site, with reference to these and all other circumstances. The aspect of the buildings must also be determined, with reference to the prevailing winds and other circumstances."

II. Climate.

1, 2. *Vide* preceding report.

3. The atmosphere at the commencement of the year is generally dry and cool; it gradually, however, becomes warm towards April, from which time, during the prevalence of the south-east winds, a very sensible change takes place, the air becoming charged with moisture, and being at times extremely oppressive. This state of things prevails up to the middle of October, when the cold weather may be said to commence. The nights in December are frequently so cold as to render fires pleasant. In March and April, dust storms, followed by thunder, lightning, and rain, are not unfrequent towards evening. Abundance of dust is generally flying about during the hot weather, which further than being peculiarly disagreeable, is not supposed to be injurious. Heavy fogs prevail all over the Gangetic delta from the end of November to the end of January. Though the climate can by no means be said to be variable, cold blasts of wind frequently precede the thunder storms, which occur, as above stated, in March and April. It is also uninfluenced by tree planting or works of irrigation. The troops suffer from the relaxing effects of the damp climate during the prevalence of the south-east winds. The cold weather, unlike that of the north-west provinces, is not sufficiently bracing to set men up for the ensuing hot season. The influence of climate on the food, clothing, and shelter of men offers no peculiarity in Bengal. The precautions regarding drills, duties, and exercise are to keep men from over exposure to the sun, and too much work at one time. Duties are best performed in the early morning. The healthy months extend from November to March; the unhealthy ones being April, May, September, and October, during which the prevailing diseases are cholera, dysentery, and intermittent and remittent fevers.

4. No district exists near Fort William possessing a climate more conducive to health than that of this station.

5. The following are the stations at which the members of the committee have served:—

In Bengal proper: Fort William, Hazareebaugh, Barrackpore, Chinsurah, Purneah, Dinapore, Bhaugulpore, Tirhoot. In the north-western provinces: Cawnpore, Allyghur, Agra, Allahabad. In the Punjab: Meerut, Umballa, Lahore, and Peshawur. In Oude: Sultanpore. In Burmah: Moulmein, Thayetmew, and Pegu. In Madras: Madras and Mercara. In Central India: Kamptee and Banda. In Hymalayah: Darjeeling and Saybathoo; and in the Neilgherry Hills: Ootacamund. The simple expression of individual opinion as to the healthiness or unhealthiness of particular places not being altogether reliable, it is thought advisable to give a table of mortality compiled from Dr. Chever's articles "Health of Troops," published lately in the Indian Annals of Medical Science, which, while embracing nearly all the places mentioned by the Committee, is framed from the most authentic sources.

Table showing Per-centage of Deaths per 1,000 of Strength in the Three Presidencies.

FORT WILLIAM. BENGAL.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station.	The replies under this head are substantially the same as those of the preceding report.
IV. Health of the Troops.	1. The health of the troops in garrison at Fort William has always been indifferent, but this is in a great measure attributable to the numerous temptations existing in so large a town as Calcutta for soldiers to commit excesses. The town of Calcutta is not healthy. 2. The diseases prevailing among the native population are cholera, small-pox, fevers, intermittent and remittent, and typhoid. Spleen disease, as a sequel of intermittent fever, is common. 3. The unhealthiness of the natives is attributable to damp, brackish water, immoderate use of fruit, bad diet, overcrowding, and dirt. 4. The bomb-proof barracks are not so healthy as the others, but this is attributable to faulty privy arrangements, which are about to be completely altered. 5. The troops at this station are not camped out. 6. I have had charge of a corps in a hill station, Subathoo, and I consider a residence in the hills to be beneficial to men who suffer from debility or functional derangement of the liver, or to men recovering from fever, but highly prejudicial in cases of organic disease, more particularly that of the liver. 7. I do not think that troops returning to the plains are liable to febrile attacks in a greater degree than the men who have not served in the hills. 8. I consider that a selection should be made of men to be sent to the hills, as I do not think it benefits very many of the men. 9. Diarrhœa of a very obstinate character sometimes attacks men on their going to the hills. It is peculiar in its kind, the stools assuming the appearance of a frothy paste. Men rarely recover from this type of disease. Fever of a bilious remittent type occasionally attacks them. 10. Every precaution is taken in hill stations to preserve the health of the men. Flannel belts are worn, the men kept from exposure to wet, and prevented going down the khuds in wet weather, and use of unripe fruit, &c., is prohibited. 11. To be beneficial in cases likely to profit by residence in the hills, the winter and spring months are the best, say from October to June, but it is better to allow men 18 months from the October they go up, thus giving them the benefit of a cold season. 12. I think two years quite enough for a residence in the hills. The 32nd regiment at the adjoining station of Kussowlie suffered severely from hill diarrhœa and hepatic abscess during the third season, more so than they did during the two first. 13. The only precaution necessary to be observed for the preservation of the health of men leaving hill stations for the plains, is to take measures to prevent them getting suddenly chilled. 14. I consider that service in the plains, with one year in every four, *i.e.*, three years in the plains, and one or one and a quarter in the hills, the best course to pursue for preserving the health of troops in India. I do not think that frequent change of station in the plains is beneficial to the health of the men, and marching, except in the cold season, is very harassing to them. 15. The barrack accommodation at Subathoo was sufficient for the 2nd Fusiliers, but the sites for the old barracks were not well chosen. There were new ones building, which will, when completed, be the finest in the hills. The hospital is superbly situated, and most convenient. 16. Subathoo is under 5,000 feet above the sea level. Kussowlie and Dugshai (only nine miles from it and from each other), each about 7,000 feet. The two latter are more exposed to the keen westerly winds in winter, and have great fall of rain, and are consequently damper. The same remark applies to Darjeeling which, in my opinion, would be a better locality for the sanitarium for the greater part of the year. 17. The high land nearest to Fort William, is the Rajmahal range of hills, the elevation of which is insufficient to make any marked difference of temperature. Its distance is about 125 miles, and it is accessible by rail. The climate is damp, and the face of the country jungly. 18. I have generally found troops to be most healthy in the stations where the soil is of kunkur, or sandy with a kunkur subsoil, namely, Agra, Allyghur, Meerut, Umballa, &c. 19. I consider from 19 to 23 years of age, the best period of life at which a soldier should proceed to service in India, and the best season for them to land there is October or November, as it admits of the men getting to the most distant stations before the hot season sets in. Drafts for H.M's. corps are sent to Dum Dum on landing, those for the Indian army to Barrackpore, the first 8, the latter 16 miles from Calcutta. They are put into comfortable airy barracks, and are under instruction during their detention awaiting their turn for dispatch up the country. Recruits should be kept from getting liquor in any way, except from the canteen; they should be kept out of the sun and be made to wash, and keep themselves very clean, and to wear flannel, to which generally they are very averse. No melons, cucumbers, &c., should be allowed near the barracks. 20. There is no objection to send a corps direct to India from the home depôts; in fact, corps do better, the men being under the strict discipline of their own officers. The difficult matter is to manage drafts of different corps. With care, I consider the men are healthiest during the first portion of their service, that is, if care has been taken to keep them from liquor and exposure, and if they have been properly clad. 21. There are two modes for the transport of troops from the port to the interior, the one by flats towed by steamers, the other by bullock train. The former is one that has every comfort, the latter is the quickest method; but, as the season advances, entails great exposure. Great care is required when men go by bullock train to prevent them straggling and getting liquor in the villages, and committing excesses of all kinds. 22. A British soldier should, I consider, serve in India about 12 years. 23. Each case of invaliding brought before the Board is examined carefully by the members, and well discussed before a final decision is given. I have rarely seen a conflict of opinion; but, should this be the case, the majority would carry the question. 24. Invalids should leave India for home in January or February.
Diseases.	1. On the morning of a fixed day once every week, there is an inspection parade for the discovery of incipient diseases at this station. 2. I have not seen a case of scurvy this season; but, in 1858, it was not uncommon among the recruits sent out for the new corps raised for the Indian army. This was attributable

References to Subjects and Queries.	Replies.
IV.—Health of the Troops—*cont.*	to the length of voyage and bad constitution of the men who suffered from scurvy. I would suggest that more vegetable matter be given in the diet. 3. The usual number in my hospital of distinct hepatic disease, viz., hepatitis acute and chronic, liver abscess, and functional derangement, was about 8 or 9 per cent. of the sick. Hepatic disease in India generally arises from two causes, exposure to sudden atmospheric changes, and indulgence in spirituous liquors. Fatty degeneration is found in cases of chronic dysentery. It may be prevented, in some measure, by making the men wear flannel belts on all night duty, and keeping them from getting liquor. 4. Dracunculus is endemic to certain districts. Europeans are very rarely the subject, and it is chiefly confined to the natives. 5. I am of opinion that the number of sick from venereal disease does not exceed 4 or 5 per cent. in hospital at one time. The soldiers rarely get it in field or in their own bazaar; the mischief is done when they roam about towns on the march, or on first arrival at a large station. The women in a regimental bazaar are periodically inspected, and any found diseased are sent away. 6. The following are the diseases from which the troops at the station suffer, viz.:— *Fevers.*—Of the intermittent, remittent, and bilious types. *Dysentery.*—Acute and chronic. *Cholera.*—Bilious and spasmodic. *Small-pox.*—But very rarely. *Rheumatism.*—Acute and chronic. The admissions from the above diseases are generally from 60 to 65 per 100 on the whole, and the deaths 75 to 80 per cent. on the total deaths annually. 7. The following are the more frequent zymotic diseases at this station:—Hepatitis, bronchitis, pneumonia, febris intermittens, febris remittens, febris, sore throat, erysipelas, dysentery acute and chronic, diarrhœa, cholera, &c. The fevers prevail in the rainy season, dysentery and diarrhœa, hepatitis, and other liver affections throughout the year; sore throats, bronchitis, coughs and pneumonia in the winter and spring months, cholera from February to November. Unseasonable or sudden access of heat induces fever and cholera,—damp, fever and hepatitic affections; but the dry heat is most favourable to health. Barracks for Europeans are generally kept scrupulously clean. The natives suffer in the bazaars from the exhalations from open cesspools and cesspits, from stagnant and filthy drains, and from over-crowding. The natives are predisposed to many diseases from insufficient clothing. The changes of temperature in the 24 hours are very great. 8. There is not generally much sickness induced by the duties of a soldier in barracks. 9. Small doses of quinine have not been administered as a prophylactic against malarial disease at this station. 10. I would recommend, if an epidemic be general, the removal of men into camp from all the barracks, or from the one or more to which the epidemic may be confined in the cold season and spring, or to other buildings during the hot and rainy seasons; whitewashing the walls and floors, and looking very closely into what the men get extra in their messing from the bazaar. I would also recommend the prohibition of the use of pork and sausages,—giving the men new sources of amusement, and preventing recourse to the rum bottle to drown fear and care; having frequent inspections, the men well watched by non-commissioned officers, and that they be sent at once to hospital when any symptoms of an epidemic are apparent.
V. Intemperance. VI. Diet. VII. Dress, Accoutrements, and Duties. VIII. Instruction and Recreation. IX. Military Prisons. X. Field Service. XI. Statistics of Sickness and Mortality.	The information under these heads is substantially the same as that contained in the previous report on Fort William.
XII. Hospitals.	1. The sick from the regiments quartered in Fort William are sent into the general hospital, which consists of a centre building and two wings, in the right or eastern of which the sick soldiers are received, the centre and western buildings being kept for the public and soldiers of Her Majesty's Indian army. 2. The distance from the Fort is about a mile; there are no stables near the hospital. To the S.S.E. native huts come almost up to the boundary wall of the general hospital; but to the north and west there are no buildings. The site is healthy, though not elevated, open and well ventilated, and there are no high walls or trees which obstruct the air in any way. There is, however, an open drain, from the Calcutta Great Gaol, which passes close under the hospital boundary wall, and into which the drains of the general hospital empty their contents. This large drain or ditch seems to be very badly constructed, and it sometimes happens that the water from it flows back into instead of from the hospital drains. This, which is always a nuisance, then becomes a source of impure air, and might be the cause of disease. The attention of the local authorities has already been directed to it. 3. The water supply is abundant and wholesome. 4. The drains are mere surface drains of bricks or tiles and mortar, and are swept out perfectly morning and evening, as there is no fall—the ground being level. 5. The lower story of the hospital is not occupied by patients; the wards are, therefore, 20 feet from the ground. The surface drains receive the water from the roofs, and these with the gutters are ample for the purpose, were there only some slight slope; as it is, the water lodges unless swept away. The walls of the hospital are built of brick, are 3 feet thick, and quite sufficiently so to keep the wards cool. The verandahs are on the south side only, the breadth of which are 12 feet, and afford ample shelter from the sun's rays; but are never used for sleeping in. The centre building has but two flats, the wards three; the ground floors in the wings are used now only as store rooms. Total number of wards - - 3 The wings hold - - - 150 each } Total 420. The centre - - - - 120

FORT WILLIAM. BENGAL.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	For table of hospital accommodation in extenso, *vide* preceding Report. The position is most favourable, and the hospital receives the full benefit of the prevalent winds, the N.E. and S.W. The windows may be described as those known in England as French windows, and the arrangement seems good for purposes of ventilation. 6. The windows and doors are so numerous that no other means of ventilation are required. 7, 8. There are no means for cooling or warming the hospital wards. The walls and ceilings of the wards are cleansed and limewashed annually, but this might advantageously be repeated once a month eight feet up the wall. Note by garrison engineer:—" Regulations provide for such at the requisition of the " medical officer." 9. The privies are at the end of each building, connected by a passage with the wards, and consist of rooms in which commodes are placed and removed when dirty. A large earthen vessel in the centre is used as a urinal, and is also removed and cleansed morning and evening, or oftener, if necessary. There are no cesspits. 10. In the centre building arrangements for washing have been hitherto very imperfect, but lavatories amply large are now in course of construction. In the wings the arrangements are sufficient. 11. There are masonry baths for the use of the sick, but the slipper bath is generally more convenient. A bath room is being constructed, which will be supplied with two slipper baths and a warming apparatus. 12. Native washermen wash and dry the hospital linen, and answer very well. 13. The storage is sufficient, and dry. 14. Both wooden and iron cots are used in hospital; the latter are to be preferred. The bedding is good, made of country cloth, and stuffed with hemp. 15. The hospital kitchen is situated in a range of buildings with steward's store room, at right angles to the line of hospital buildings, and at a convenient distance from them. It is in size sufficient for its purpose, but the means of cooking are very inadequate. They consist of a line of open chulahs or square spaces enclosed on three sides with loose bricks, and open in front, and allow only of the proper cooking of boiled provisions. No means exist for roasting or frying diets, or of conveying them to the wards when done with a possibility of their reaching the patients hot, or even warm. 16. Copies of the diet rolls, &c. are herewith transmitted. 17. The provision for attendance on the sick in the regimental hospital consists of 1 hospital serjeant and 2 ward masters in the general hospital, but the sick are more particularly attended to by hospital coolies. On the whole, the attendance is sufficient. 18. I consider the general hospital to be very healthy, and am not aware of the occurrence of any hospital gangrene or pyemia having appeared or originated in the wards. 19. The hospital is imperfectly drained, like all the rest of Calcutta. 20. There are 4 ambulance carts sent every evening for the use of the convalescents; these are drawn by bullocks, and can accommodate about 32 men. There are no shady walks, but there are seats under a very large banyan tree, and convalescents can walk about the grounds or in the verandah. 21. There is a detached building, divided into 2 wards, one of which is used as a hospital by the women and children of the military in Fort William, the other by the public and civil part of the community; the arrangement is not good. 22. There are no special local hospital regulations. 23. The medical officer has no direct power except that of making a representation to either the brigadier or the superintending surgeon. Should any repairs be required of a trivial description, a memorandum is sent in direct to the executive engineer. With regard to diet, anything required or ordered in excess of the regular diet is entered by the surgeon under the head of " Extra," and forwarded in a separate statement to the superintending surgeon at the end of each month. This holds good either at the station, in camp, or on the march. 24. There are no convalescent wards or hospital at the station. Most undoubtedly the formation of such a ward at some short distance from Calcutta (as Barrackpore) would be attended with much advantage to the sick.
XIII. Burial of the Dead.	For information under this head, *vide* preceding Report.

(Signed) M. Smith, Brigadier,
Commanding Fort William.
R. B. Kinsey, F.R.C.S.,
Late Garrison Surgeon, Fort William.
Robert H. Sankey, 2nd Captain and Brevet Major,
Offg. Garrison Engineer.

Dated 19th June 1860.

XII. Hospitals.	1, 2. The sick from the regiments quartered in Fort William are sent into the General Hospital, which consists of a centre building and two wings; in the right or eastern of which the sick soldiers are received; the centre and western buildings being kept for the public and soldiers of Her Majesty's Indian army. The distance from the fort is about a mile. No cavalry being quartered in the fort, there are no public stables. To the south and east native huts come up to the boundary of the general hospital, but to the north and west there are no buildings. The site is open and well ventilated, and there are no high walls or trees which obstruct the air in any way. The site is healthy, though not elevated; but there is an open drain from the Calcutta great jail which passes close under the hospital boundary wall, and into which the drains of the general hospital empty their contents. This large drain or ditch seems to be very badly constructed, and it sometimes happens that the water from it

References to Subjects and Queries.	Replies.

XII. Hospitals—*cont.*

flows back into instead of from the hospital drains. This, which is always a nuisance, then becomes a source of impure air, and might be the cause of disease. The attention of the local authorities has been already directed to this.

2. The water supply is abundant and wholesome.

4. The drains are all open surface drains constructed with bricks or tiles and mortar, and are supposed to discharge their contents on one side into the drain above alluded to, and on the south side into a similar drain about 100 yards south of the hospital inclosure. The ground being almost level there is no fall, and the drains are therefore swept out perfectly, morning and evening.

5. The lowest wards occupied are raised 2 feet above the ground, and there is free perflation of air underneath. The surface drains receive the water from the roofs, and it does not therefore sink into the subsoil. The surface drains and gutters are ample for carrying away the rain-fall, were there only some slight slope; as it is the water lodges unless swept away. The hospital walls are built of bricks; they are 3 feet thick, and quite sufficient to keep the wards cool. The verandahs are on the south side only, are 12 feet, and afford ample shelter from the sun's rays. They are never used for sleeping in, and have not hitherto been used for the accommodation of sick, convalescents or others. The centre building has but two flats, the wards three. The ground floors and wings are used now only as store-rooms. The total number of wards is three, the wings holding 150 each, and the centre 120 making a total of 420.

The position of the hospital is favourable, and the hospital receives the full benefit of the prevalent winds, the north-east and south-west. The windows may be described as those known in England as "French windows," and their arrangement seems good, and conduces to free ventilation.

6. The windows and doors are the means of ventilation, and these are so numerous that no other method is required. Each window is supplied with Venetian doors outside the glass, and all so constructed as to be opened or shut at pleasure. The jalousies are constructed in the usual way, and may be opened or shut as required, except in certain rooms intended for the reception of insane or violent patients in which the jalousies are fixed.

7, 8. There are no means of cooling the air admitted into wards at present, and no apparatus is required for warming the wards. The walls and ceilings of the hospital are cleaned and lime-washed once a year, but this might be repeated with advantage once a month, 8 feet up the wall.

9. The privies are situated at one end of each building connected by a passage with the wards, and consist of rooms in which commodes are placed. These are removed when dirty. A large earthen vessel in the centre is used as an urinal, and is also removed and cleansed morning and evening, or oftener if necessary. There are no water-closets, nor are these used in India; the entire removal of all filth to a distance being considered the best plan. There are no cess-pits. The night-soil is received in a cart morning and evening.

10. The arrangements for washing in the centre building have hitherto been very imperfect, but lavatories, amply large, are now in course of construction. In the wings the arrangements are sufficient.

11. There are masonry baths, but the slipper bath is generally more convenient for the sick.

12. There is a small pond or tank in the compound or inclosure, and there are conveniences for the native washermen who wash the linen. These means have hitherto been found sufficient.

13. The storage is at present neither sufficient nor dry, but the want of space is entirely due to the fact of a large quantity of old clothing and hospital furniture being stowed away in storage intended for the general hospital alone. For the hospital itself the space is ample.

14. Both wooden and iron bedsteads are in use in hospital. The last are much to be preferred for cleanliness, in fact, those with iron bottoms are as good as can be wished, but the patients generally prefer those with rattan bottoms. The bedding is good, and is made of country cloth stuffed with hemp.

15. The hospital kitchen is situated in a range of buildings, with a steward's store-room at a right angle to the line of the hospital, and at a convenient distance from them. It is in size sufficient for its purpose, but the means of cooking are very inadequate. These consist of a

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	line of open chulas or square places, enclosed on three sides, with loose bricks, open in front, and allow only of the proper cooking of boiled provisions. No means exist either for roasting, or properly frying diets, or of conveying diets so treated to the wards with the possibility of their reaching the patients hot or even warm. It is understood, however, that to remedy this defect a plan exists for furnishing to the hospital a stove on an American pattern to supersede the existing chulas altogether, this having been most favourably reported on by a committee. 16. Copies of diet rolls, &c., have been transmitted. 17. There is one hospital serjeant in the regimental hospital, and there are two ward coolies in the general hospital. The sick are more particularly attended to by hospital coolies. Nurses are not employed to attend, but if required orderlies are sent from the regiments to which the sick belong. In the civil hospital the juniors of the subordinate medical department, attend particularly to such cases as are considered to require it. On the whole the attendance is sufficient. Since writing the above, nurses have been sent in the proportion of one to every 25 sick. These are not Government servants, but are paid from funds furnished by the benevolent. 18. I consider the general hospital to be very healthy, and am not aware of the occurrence of any epidemics in it. 19. The deficiencies have already been pointed out, but to recapitulate, they consist,—1st, in imperfect drainage which depends on inattention to the fall, all the drains seeming to be on one level; 2ndly, in the very bad accommodation for the reception of female patients all being necessarily received into one ward in which it is impossible to class the cases, and where women in labour, of necessity, are treated in the common ward; 3rd, since the garrison of Fort William has lately been formed of more than one regiment, or in consequence of several detachments being present there, very great inconvenience has been experienced by the members of the subordinate medical department. The quarters provided in the general hospital being calculated only for the accommodation of the usual establishment and for those attached to one regiment; should the present state of things continue, either two or three would have to live in quarters intended for one, or other buildings must be constructed. The remedies for the above deficiencies are too obvious to require any suggestions. There is also an evil of considerable importance. The walls of the three buildings seem to have settled after construction, and consequently the lower story is on the level of the general surface, while the brickwork which ought to slope from the wall to the drain inclines from the drain to the wall. Much more efficient fastenings are required for both doors and windows, as hardly a gale occurs without several being blown violently open and the fastenings broken or rendered useless. As these storms are accompanied with heavy driving rain, something more than inconvenience is experienced in the ward when this occurs. 20. Four ambulance carts are sent every evening for the purpose of affording the means of exercise for convalescents; these are drawn by bullocks, and can accommodate about 32 men. There are no shaded walks, but there are seats under a very large banyan tree, and convalescents can walk about the grounds or in the verandahs. 21. There is a detached building divided into two wards, one of which is used as a hospital by the women and children of the soldiers in Fort William, and the other by the public and civil part of the community. The arrangements for sick women and children are not good, as sometimes there is much crowding. More privacy is desirable, and detached rooms ought to exist in which women in labour can be received. At present all cases must be accommodated in the common ward, which is an arrangement not conducive either to health or comfort. 22. No diet tables, diet rolls, &c., are used, except those contained in the code. 23. The medical officer has no direct power in matters appertaining to the sanitary state of the hospital, except that of making a representation to either the brigadier or superintending surgeon; or should any repairs be required of a trivial description a "memo," is sent in direct to the executive engineer. With regard to diet, anything required or ordered in excess of the regular diet, is entered by the surgeon under the head of "extra," and forwarded in a separate statement to the superintending surgeon at the end of each month, and this holds good whether his charge be at a station, in camp, or on the march. 24. There is no convalescent ward or hospital at the station, but most undoubtedly the formation of such a ward at some short distance from Calcutta (as Barrakpore) would be attended with much advantage to the sick, and probably the expense would not be great.
XIII. BURIAL OF THE DEAD.	The information regarding the burial-ground has been derived from the undertaker who has been attached to the hospital since 1856. 1. The burial-ground is about 500 yards from the general hospital, and a mile from the garrison of Fort William. It is to the south of the fort, and south-west from the hospital. 2. Its area is 724,535 feet, and its soil is sandy. There are no drains within the burial-ground, but a large drain runs close on the north side, and is in fact the boundary in that direction. On the south runs Tolly's nullah, and on the east is another large dry drain, and the public road. On the west are the huts for coolies selected by the Emigration Office. Decomposition takes place readily, and the ground is kept in good order. 3. The grave space allowed is 9 ft. 6 in. by 5 ft. 6 in., with an interval between the graves of 2 ft., the depth being 6 ft. from the surface. Graves are re-opened after the expiration of three years when no marks or tombs are put over them. Family vaults are re-opened when required for the interment of any of the family, and no special time is fixed in such instances. Every grave, however, is supposed to be full after three or four interments; the last coffin, therefore, is only three feet from the surface. I am not aware that interment is compulsory at any time. The rule seems to be that it take place within 24 hours after death, and this is so fully acted up to that compulsion is not required. 4. The graveyard was slightly offensive in the years 1857 and 1858, when the mortality was very great. The garrison chaplain seeing such the case, sent down two carts of lime to be strewn over the graves, after which the smell subsided, and since that time there has been no offensive odour perceptible. The cause of the smell was owing to the rapid decomposition caused, probably, by the water from Tolly's nullah, which flowed into the burial-ground, and lodged in the graves. At all times interment very rapidly follows the death of a British soldier, and generally 12 hours is the time allowed to keep the corpse, but I am not aware of any particular time being fixed by order or police regulation.

XIII. Burial of the Dead —*cont.*	5. The Mussulmen dead are taken away by their friends, and buried in their own cemetery at Gobra. The Hindoo portion of the population when dead are taken to the river side and burnt 6, 7. No injury arises to the public from the present practice. The burial-ground of the Mussulman population is about 2½ miles distant, and the ghat for the Hindoo people is about 3 miles south on the banks of Tolly's nullah.

I. Topography.	1. The country surrounding the station is alluvial, with abundance of rich tropical vegetation. It is flat, with occasional low marshy ground, and a moderate quantity of wood and jungle. The river Hooghly runs towards the south, and there are a few marshy or watery flats or jheels of no great size in the vicinity. 2. The elevation of the station above the sea is about 23 feet, but it is on the same level as the adjacent country. The river Hooghly in level is about 5 or 6 feet lower than the left bank on which the station lies. There is no higher or healthier ground in the neighbourhood. 3. The nearest mountain lands are the Rajmahal hills, rather less than 120 miles off. A spur of these hills, on which it was proposed to erect a sanitarium (Parisnauth) is upwards of 4,000 feet above the level of the sea. 4. The nearest water is the river Hooghly, which forms one boundary of the station, the sea being about 80 miles distant. There is no overflow from the river, nor to any important extent from the tanks in the station. No ravines or broken ground of any importance exist near. 5. Although there is a great deal of vegetable growth in the neighbourhood, it is not so extensive as to interfere in any material degree with the ventilation of the station, and as all the buildings are thatched, they expose but little surface of masonry to the effects of the sun. The S.W. monsoon, laden with moisture from the sea, sets in during April, and continues till about the end of May, when calms alternating with high easterly winds are frequent; clouds collect, and the rainy season begins, continuing up to the middle of October. The station, however, is never really exposed to cold winds at any period of the year. 6. The surrounding country is principally cultivated. No works of irrigation are in the vicinity of the station, nor has artificial irrigation had any perceptible effect on the health of the inhabitants. The growth of rice is prohibited within the boundary pillars of the cantonments, and no cultivation of indigo or hemp is carried on near the station. 7. The town of Serampoor opposite, on the right bank of the river, is the only town of any size near the station. 8. The geological structure of the cantonment is formed of delta deposits, having a loose spongy surface soil with sandy or clayey subsoils. The present European barracks are built upon the site of the old native infantry lines, which had been in existence many years. 9. Water is found during the dry season at a depth of about 12 feet, and during the rainy season at about 8 feet, below the surface. 10. In several situations within the cantonment boundaries the rain-fall does not thoroughly flow out until the rainy season ends,—it is renewed before it has time to run off; generally, however, it sinks into the subsoil or drains off into the river with sufficient freedom; in some places, however, where, probably, a retentive clayey subsoil would be found, the surface soil is always wet and swampy all the rainy season. No drainage from any higher level sinks in the subsoil of the station. 11. The water supply is obtained from tanks, wells, and river, but principally from the first-mentioned source, being stored in open tanks; but I cannot state the extent of tank surface. Before the commencement of the rainy season they often get low, and the shallower ones become nearly dry, but during the rains and cold weather they keep full. I cannot myself furnish any information as to the nature of the plants and animals contained in the tanks, nor can any medical officer now at the station. No tank used for drinking purposes is also used for bathing, yet the water is often polluted by the falling into it of decayed leaves from adjacent trees, No drainage impurities are permitted to get into the tanks, and I do not think either malaria or nuisance has ever been observed to proceed from them. 12. The large tanks of the station furnish a never-failing supply of good water, which is pure, and without taste or smell. The water from the tanks and wells was forwarded by me to the chemical examiner at Calcutta, and the following is his analysis:— "The tank water is very pure," an imperial quart evaporated to dryness leaving only 2·7 grains of solid residue. Total solid residue - - - - - 2·7 grains Consisting of—Earthy carbonates - - - 1·02 „ Silica - - - - - ·38 „ Saline soluble matter, chiefly chlorides, with a little sulphates and carbonates 1·3 „ The well water contains a large quantity of solids; an imperial quart yielded 12·0 grains of solid residue. Total solid residue - - - - - 12·0 grains Consisting of—Earthy carbonates with a little sulphate of lime - - - - 6·46 „ Silica - - - - - ·44 „ Soluble saline matters, chiefly chlorides, with a smaller proportion of carbonates 5·1 „

BARRACKPORE, BENGAL.

I. Topography—*cont.*	Both waters contained a little organic matter. The water is distributed in skin bags by bheesties or water-carriers, and no better supply could be obtained. 13. No reply to this query. 14. To the question, as to after what amount of inquiry or examination as to topography, climate, &c., new stations are selected, I can only say that, in my opinion, medical officers have not so often been consulted on these points as is desirable. It seems to me that, conjoined with one officer for reference and guidance as to the military requirements of the new station, the committee for determining the site of a new cantonment ought to be exclusively medical, the education, observation, and experience of medical officers peculiarly fitting them for such duties.
II. CLIMATE.	1, 2. There have never been, with the exception of hospital thermometers, any instruments for meteorological purposes at this station, and I am therefore unable to give any satisfactory meteorological table such as is here required. I would say generally that according to thermometrical observations the temperature in the hot season ranges from 82° to 104° in the shade; in the rains from 80° to 96°, and in the cold season from 54° to 80°. The mean temperature would probably be about 79°. The rainy season, as I have before said, usually sets in about the end of May and ends about the middle or 20th of October. Within this period there are often considerable intervals without any rain, during which the temperature is close and oppressive. In the middle of October the wind usually changes to north, the atmosphere clears, the nights are calm with heavy dews, and there are occasional dense fogs in the morning. 3. The climate I consider a moist, warm one, with little variation of temperature. I do not conceive that any peculiar effect from what irrigation exists in the neighbourhood can be observed. So far as experience yet goes, it seems a moderately healthy station for European troops, not so much so for native troops. Drills cannot be carried on in the rainy season, except to a limited extent, on the roads, for the parades are then mere swamps. In the hot weather the early mornings only are suitable for parade duties, for the evenings are generally sultry and oppressive. In the cold weather time should be allowed for the sun to drive away the dew from the grass, which is, in the mornings, frequently heavily laden with moisture. The most healthy months are from the beginning of November till perhaps the middle of July; August, September, and October being the most unhealthy months. Diarrhœa, dysentery, cholera, and fevers of the remittent and intermittent type, are then the prevailing diseases. 4. I am not aware of the existence of any healthier district near the station. 5. The following are the stations at which I have served, with my opinion as to their comparative salubrity, *Mhow* and *Neemuch* (central India), are both healthy stations, with an occasional year of rather severe febrile, remittent and intermittent, disease after the rainy season. *Loodiana.*—Formerly a hot and healthy European station; but latterly subject to frequent returns of intermittent fever, which although seldom fatal, sapped the strength from the frequency of their return. After repeated inquiries and several committees on the subject, no satisfactory cause for the change could be discovered. *Jullundur.*—In my experience a hot but healthy station. *Deyrah Dhom.*—An equable temperature and healthy in the station, as also in its immediate vicinity only. *Barrackpore.*—I have already spoken of. *Dinapore.*—I was only a few months resident at; it was moderately healthy. *Peshawur.*—Is an unhealthy station for both Europeans and natives. Few escape the intermittent fevers (often of a low reducing kind) that prevail there, and the frequent returns of which shatter the constitution, and lay the foundation of grave organic disease of the abdominal organs. *Ferozepore.*—A moderately healthy station, but very hot and dry. *Lucknow* (old cantonments).—A moderately healthy station.
II. SANITARY CONDITION OF STATION.	1, 2, 3. Plans of the station, adjacent country, &c., are transmitted. The drains are all open, and nearly all of earth. The excreta are now ordered to be carted away, and cesspools are done away with entirely. The drains vary in depth from a few inches to 6 feet, and in breadth from 1 foot to 12 or 15 feet. 4. Table of barrack accommodation. Date of construction - - - - - - 1858 and 1859. Total number of rooms or huts - - - - 85 rooms, besides 30 small rooms for non-commissioned officers. Total regulation number of non-commissioned officers and men - - - - - - 960 single, and 120 married men.

Guard Room. Prison Cells.	Is a portion of a small barrack, in every way similar to the larger kind. An estimate for these is now before Government on standard plan. 5. The windows are on opposite sides, opening from the middle to each side. There are open verandahs from 10 to 12 feet wide on one side, and an enclosed verandah on the other side, the whole length of the barrack; but they are never used as sleeping quarters for soldiers or others. The windows are jalousies, and in some cases the doors also. 6. The bedsteads are wooden frames, with hoop iron bottoming, the bedding consisting of blankets, sheets, and cotton-stuffed quilts. 7. The common double-poled new pattern tent used in camp contains 16 men. 8. With regard to ventilation, the temporary brick and iron frame barracks have free communication with the verandahs for nearly three feet from the roof downwards. Those in the barrack square, Nos. 1, 2, and 3, have ventilators in the apex of the roof at equal distances. With open doors, the ventilation is generally good and sufficient in the hot weather and rains, as also in the cold months. No means of cooling the air of barrack rooms exist at this station. 9. Some of the barracks have thatched roofs, others being thatched and covered with tiles. Some are built on brick and mortar pillars, while others are constructed on iron frames, the sides being built of bricks in mud cement. 10. The flooring is of twelve inch tiles laid in bricks over rammed earth, and varies in height from 2 to 3 feet, but there is no passage of air underneath. 11. The materials used in the construction of the barracks are suitable, the buildings being very temporary and semi-permanent. They are kept in repair by the Public Works Department, and the walls and ceilings are whitewashed once every six months; autumn and spring. 12. Each barrack has a wash-house, but at present there is no bath; an estimate, however, has been submitted for one. 13. The cook-houses have been formed out of old bells of arms. Water is supplied by bheesties, a small drain carrying away the refuse. The washing and drying of linen is performed by washermen, generally outside the station. 14. The privies and urinals are supplied with pans and tubs, the contents of which are daily removed. The cesspools have been filled up. 15. The ventilation of these buildings has been already described. The barracks are lighted at night by lanterns, six per company. 16. There are only surface drains and no sewerage, filth of all kinds being constantly removed to a distance in carts. The drainage is sufficient, however, to carry away all surface water, &c. I have never observed any appearance of dampness in any part of the barracks or hospital. No cesspits of any kind exist in the station. 17. The cantonment is traversed by large open drains, not lined with masonry, extending from the parades through the barracks and compounds of officers to the river. Some of them open into a large tank on one side of the Government House and park, the overflow of which also escapes into the Hooghly. These drains in the rains soon become choked with rank grass and weeds, and do not always allow a free circulation. Further remarks on this subject are contained in letters appended to the Report. 18. This is the only vegetation not kept down at this station, and I have no doubt that evil results from it. The refuse and manure, &c., are daily removed to a distance in conservancy carts, four of which are employed for the purpose. The drains from the privies, &c., are open and kept clean. A barrel cart is kept at each latrine, &c., in which the filth is carefully removed. No old walls or hedges of consequence exist in or near the station. 19. The bazaar is clean, tolerably drained and ventilated, and not overcrowded. Water is obtained from the adjacent tank, and the management of the bazaar is in general unobjectionable. A light tax is levied on the inhabitants for the payment of an establishment of sweepers, and police are instructed to apprehend all people whose premises are not kept in a properly clean state. The exteriors of the houses are generally clean and in tolerable repair. Dungheaps and cesspits are not permitted within them. No nuisance is ever experienced in barracks from wind blowing over the native houses. 20. Animals for the use of the soldiers are slaughtered outside the cantonments, behind the Sudder bazaar, by which all nuisance is avoided. 21. No reply to this query. 22. The artillery stables are three long sheds, supported on wooden pillars, and open on all sides. Their situation is about 150 yards to the north of the barracks, the hospital being at a great distance. The manure is removed daily in carts. 23. No reply to this query.
Officers' Quarters.	1. The officers live in detached houses, flat roofed and thatched. Their sanitary condition is good, and the drainage and ventilation sufficient. No improvements are required.
V. Health of the Troops.	1. For Europeans (excluding epidemic causes), I consider Barrackpore healthy, but with regard to native troops, the duties, diet, &c., injure the health of the up-country soldiers. It was found that the mortality among native troops, and the number of men who required sick leave to return to their homes in the third year of residence, were so large that latterly they were relieved every two years. The adjoining native population are moderately healthy. 2. So far as my experience goes, I may observe that the epidemics that occasionally visit all stations are not more severe at Barrackpore than at neighbouring cantonments—rather less so indeed. The prevailing diseases among the native population are intermittent fevers, dysentery, both chronic and acute, splenic enlargements, and epidemics of cholera; elephantiasis is also common. 3. No observation to make in reference to this query. 4. Her Majesty's 53rd were last at Allahabad, where they had been only three months, during which time they suffered rather severely from fever and cholera. They left it in August, and arrived here in September 1859, since when the regiment has been very healthy. An European recruit depôt for the Indian army, necessarily varying very much in strength, is also at this station. These men are sent up from shipboard, and, ignorant of the evils of exposure, liquor, unwholesome food, &c., they suffer much more than older soldiers. Bowel complaints, including fatal dysentery and cholera, are very frequent during the rains. I do not think, after careful inquiry, that any portion of the men's accommodation is more unhealthy than the rest.

IV. Health of the Troops —*cont.*	5. The troops are never camped out unless when marching in relief to other stations. 6, 7, 8. I have never been in charge of troops at hill stations, but I do not think that a long residence in such stations renders troops more or less liable to attacks of febrile or other diseases on returning to service in the plains. I approve, however, of the selection of hill stations for troops. 9. Troops going to hill stations are sometimes subject to diarrhœa, of tedious or intractable nature, which is not, however, frequent. It occurs at the commencement of the rainy season. 10. I have not had sufficient experience of hill stations to speak of the precautions necessary to be observed by troops on going to those stations. 11. The periods best adapted for residence in such stations are the hot and rainy months, and so far as the end of November. 12. I know of no period of residence beyond which injury is likely to be inflicted on the health of troops on returning to service in the plains. 13. I know of no precautions necessary to be specially observed by troops leaving hill stations for the plains. They sometimes leave the hills too early in the winter. 14. With winter service in the plains, and residence on the hills from the end of April till November, I have little doubt Europeans could be kept in the healthiest condition they are capable of being in India. I do not consider that service in the plains, with short periods of change to hill stations, would be nearly so conducive to their health, but I consider change of station on the plains would be beneficial both to health and spirits. 15. I cannot reply to this question, in reference to the accommodation on hill stations, as I have not seen a hill station for many years. 16. I cannot say what are the most suitable ranges of elevation for hill stations. 17. There is no high ground in the neighbourhood of the station which could be advantageously occupied as a hill station. 18. I cannot say truly that I have any experience to show what particular class of surface and subsoil is most suited for stations. 19. Soldiers proceeding to India should always be from 21 to 25 years of age, and should land there during the winter months, *i.e.*, after the 1st of November. With regard to the disposal of troops on first landing, I have had no experience of any value, having always until recently served at up-country stations. The recruits of Her Majesty's depôt here are generally sent from Calcutta in carriages. They have good barrack accommodation and very little drill while here. The precautions I should recommend for preserving the health of recruits on first landing in India are, great attention to diet, particularly care as to modes of cooking, restriction as to exposure in the day time, and in the use of native fruits, beverages, &c., anxious and unremitting attention to ventilation, and to avoid the crowding of barracks; evening drills, except in the cool months, occupation at trades, and moderate recreation. A staff of experienced commissioned and non-commissioned officers should be specially appointed for this service. 20. I see no reason why troops should not be sent direct from the home depôts to India. The general directions I have noted above are all which I should recommend. I do not think residence at hill stations on landing would accustom troops to the plains' climate, or, except in the case of sickly men, enable them to bear it better. 21. In the cold season the men are conveyed from the port to the interior in carriages, by railways, and occasionally partially by regular marches. In the rainy season, and till the beginning of winter, steamers on the river convey large portions of the troops. The great objects to avoid are passive exposure to the sun, the use of intoxicating drinks, and overcrowding in the flats of the steamers. 22. The number of years a British soldier should serve in India should be about 15; or 25, if it were possible to keep him temperate. 23. I have no objection to make, or suggestions to submit, as to the manner of conducting the business of medical boards. 24. It is desirable that invalids should leave India for home in the cold weather, or so as to arrive in England about the middle of May or June—not before.
DISEASES.	1, 2. There are regular weekly inspection parades for the discovery of incipient diseases. There has been no case of scorbutus, or scorbutic disease, among the troops at this station. 3. I do not think hepatic diseases are so frequent at this station as in up-country cantonments. There have not been more than 2 per cent. of cases treated. In up-country stations the temperature is higher during the hot weather, colder in the winter months, and alternations of temperature are more marked. The latter I conceive to be the more frequent cause of hepatic diseases. Intemperance and exposure to solar influence are also fruitful causes. I do not believe that it is *frequently* the consequence of other diseases, and I think the use of flannel, temperance in eating and drinking, and avoidance of exposure to the sun, the best prophylactic measures. 4. Dracunculus is not a disease that occurs in this part of India. 5. The proportion of venereal diseases at Barrackpore is rather less than at other stations, and is about 13 per cent. to total sick from other diseases. Lock hospitals would be of some use, but not nearly so much as in Europe. The practical difficulty would be to induce native women, unless under very aggravated circumstances, to enter them. 6. The prevailing endemic diseases are, continued, remittent, and intermittent fevers, which are most prevalent towards the end of the rains, and in the middle of the hot weather—intermittent the most frequent. These fevers are not often attended with local complications. Dysentery is a frequent and dangerous disease. Cholera in an epidemic form is not uncommon. It prevailed in this station in July last, and among the recruits was rather fatal. Small-pox is rarely met with. Rheumatism is frequently treated. The proportion of admissions from these diseases to the total of other diseases is about 600 to 1,000. Proportion of deaths from ditto to those from other diseases 3 to 1, *i.e.*, in 1,600 cases about 600 would be from the above-mentioned diseases, and 1,000 from all others. Out of the former 3 would die to 1 of the latter. 7. The fevers generally are of an uncomplicated character. Cholera, as here developed, presents the usual terrible and fatal characters, and the same may be said of dysentery. Intermittent fevers are the most prevalent of any form. Fevers prevail most in the hot months, previous to the rains; dysentery and cholera in the beginning of the hot weather, and about the middle of the rains, when the weather is hot and steamy, and the heat is not

Reerences to Subjects and Queries.	Replies.
V. Health of the Troops —*cont.*	much mitigated by heavy rains. Great and close heats, without any occasional high winds, precede and accompany the appearance of these diseases. These diseases are not more prevalent in one part of the station than in another. Crowding in barracks, bad ventilation, intemperance in eating and drinking, occasional sun exposure, want of occupation and recreation, predispose European soldiers to attacks of cholera, fevers, dysentery, hepatic disease, &c. Among the natives it is caused from their low *physique*, they being inhabitants of a moist, warm country, and their generally poor diet renders them ready victims to most epidemic diseases. 8. I regard crowding in barracks (particularly at night), rum, and want of employment and amusement, as the three great causes predisposing the soldier in India to attacks of epidemic and other diseases. 9. Small doses of quinine have not been tried as a prophylactic against malarial diseases at this station that I am aware of. At other Indian stations (Loodiana and Peshawur) I have frequently tried it for that purpose. In intermittent fevers of short standing it was frequently useful in the intervals; but in those of long standing, and when given to those who had not previously suffered, and residing in a district well known to be malarious, I never felt satisfied that it was useful. In epidemics of dysentery and cholera I believe it would be beneficial; but I have never used it on a sufficiently large scale to speak with confidence on the subject. 10. In order to prevent as much as possible the prevalence of epidemic disease I should recommend the moving of soldiers into camp, if possible, and giving them ample breathing room in their tents when there, thinning as much as practicable the numbers sleeping in each building, and a free use of lime and charcoal. I have faith in the prophylactic use of quinine in epidemics of cholera, fever, and dysentery. Less use of liquor, and improved dietary generally, with the careful avoidance of unripe and native sour fruits, and bad ginger-beer and other bazaar beverages, which are sometimes most deleterious. Exciting the men's minds cheerfully is, of course, if practicable, a powerful means of prevention, and if united with change of scene, is doubly useful. Elevation of the barracks eight or more feet from the ground floor at this station, particularly where the drainage is not good, would be a preventive to disease.
V. Intemperance.	1. Liquor is too easily procured at this station; and I fear that a good deal of intemperance exists. I cannot state the proportion of confirmed drunkards, but they are rather a large number. 2. The proportion of admissions into the hospital from diseases caused directly by drink is from 14 to 15 per cent.; from indirect causes, I have no data to state satisfactorily upon. The same may be said of the numbers admitted with diseases contracted by habits of intemperance, neither can the other officers in medical charge of the troops at this station assist me in ascertaining. Drunkenness, *per se*, is punished as an offence. 3. Rum and brandy are sold at the canteen; two drams a day are allowed from canteen. Spirit is part of the ration for soldiers; but it is not compulsory to take it. On the march beer is not often to be had, and rum is consequently more drunk. The canteen is not open until 12 noon, so that liquor is not, or ought not to be, procurable from that source. Spirit is not usually given to convalescents; beer is frequently; ginger beer, lemonade, and soda water are sold at the canteen or bazaar; the two former are often not very wholesome. 4. The consumption of spirits by convalescents and troops, in my opinion, is injurious. I do not think it is conducive to the internal efficiency of the corps. 5. If the use of spirits were entirely abolished among European troops, I am firmly persuaded the mortality among them would be *extraordinarily* diminished. Improvements should be made in dietary, &c. 6. The use of malt liquor is, in my opinion, much less hurtful than spirit; beer and porter in moderation, although by no means essential, are not injurious, and are generally prized by the men. 7. Coffee, tea, lemonade, soda water, and similar drinks, are much used at the station; they are far less injurious than spirits, or even malt liquor. 8. The suppression of spirit in the ration would decidedly prove beneficial to the health of the troops, whether convalescent or otherwise. It would, however, cause or tend to excite discontent; for even the prejudices of well educated men are difficult to overcome. 9. The prohibition of the sale of spirit in the canteens would be beneficial to the troops. 10. I have nothing further to recommend than I have already done, viz., employment, recreation (two most difficult things to secure on a large scale in India); good tea, coffee, milk, a little more variety and improvement in the quality of the food generally; more attention to cooking and cooking vessels. 11. The following is a copy of the Barrackpore Suddur bazaar regulations:—

Sale of spirits in cantonments.—Any person not amenable to articles of war, or camp follower, selling spirits, &c. without licence, to or for the use of soldiers in cantonments, liable to fine or imprisonment.

295. If within any military cantonment, or within any limits around the same to which the provisions of this Act shall be extended by an order of Government to be publicly notified, any person not amenable to articles of war, or any sutler or camp follower, shall knowingly barter, sell, or supply, or offer or attempt to barter, sell, or supply, any spirituous liquor, wine, or intoxicating drug, to or for the use of any European soldier, or to or for the use of any European or Eurasian being a camp follower or a soldier's wife, without a written licence from the officer commanding at the station, or from some person having sufficient authority from the commanding officer to grant such licence, the person so bartering, selling, or supplying, or offering or attempting to barter, sell, or supply, such spirituous liquor, wine, or intoxicating drug as aforesaid, shall be liable, on conviction before a magistrate, to a fine not exceeding fifty rupees, or in the discretion of the Magistrate to imprisonment, with or without hard labour, for any period not exceeding one calendar month. Act XVIII. 1853, Sec. 1.

In the case of a second conviction liable to increased fine or imprisonment, and spirits may be confiscated.

296. If any person convicted of an offence under Section 1. of this Act shall be convicted under that section of an offence subsequently committed, he shall be liable to a fine not exceeding one hundred rupees, or to imprisonment with or without hard labour for any period not exceeding three calendar months; and in such case any spirituous liquor, wine, or intoxicating drug, within such cantonment or limits, which at the time of the commission of such subsequent offence shall belong to, or be in the possession of such person, shall without further proof, be deemed to be in the possession of such person for the purpose of being supplied to European soldiers contrary to the provisions of this Act, and shall be liable to be seized and confiscated. Act XVIII. 1853, Sec. 2.

BARRACKPORE. BENGAL.

Camp followers, &c. having, &c. more than one seer in cantonment, liable to punishment.

297. If any camp follower, or military pensioner, or the wife or widow of any soldier, camp follower, or military pensioner, shall within such cantonment or limits remove, convey, or have in his or her possession, any quantity of spirituous liquor, or wine exceeding one seer or quart, without a permit, to be signed by the officer in command, or such other officer as may be appointed by him to grant permits under this Act; every such person shall be liable upon conviction to a fine not exceeding fifty rupees, and for any subsequent offence to a fine not exceeding one hundred rupees, or to imprisonment, with or without hard labour, for any term not exceeding three calendar months. Act XVIII. 1853, Sec. 3.

References to Subjects and Queries.	REPLIES.
VI. DIET.	1. The composition of the ration for Queen's British troops consists of mutton once a week (generally on Sunday), beef on other days; meat, 1 lb., bread, 1 lb., rice, 4 ozs., tea, $\frac{5}{7}$ oz., sugar, $1\frac{3}{7}$ oz., salt, 1 oz., potatoes, 12 ozs., onions, 4 ozs., wood, 3 lb. for cooking, coffee, as a substitute for tea on alternate days, $1\frac{3}{7}$ oz. In most up-country stations mutton is supplied twice a week to the troops; but in Lower Bengal, sheep are not so easily procurable. An inspection of the constituents of the ration is made by the orderly officers, and captain of the week, and quarter-master, and one corporal and a private from each company. 2. Fruit does not form a part of the ration; vegetables always do, according to season. Breakfast is taken at 8. 30 a.m., dinner at 1 p.m., and tea at 5 p.m. The men generally take coffee early in the morning at their own expense. At this station the mangoes grown in the Government park are given to the European soldiers gratis, and are much prized, although the quantity is small in proportion to the large number of recipients. 3. Fish in many stations might be allowed; a larger and more varied supply of vegetables might be supplied if public or soldiers' gardens were successfully encouraged. It is not believed that any portion of the rations is disposed of. 4. The common means of cooking are the native fire-places or chulahs; Grant's cooking apparatus has been experimented with a good deal, but not altogether with satisfactory results. The kitchens at the station are old, small, and ill-ventilated and lighted; the food is both roasted and boiled. The cooking is frequently ill done, particularly for those who require it done the best, namely recruits, who are without experience in such matters. Old soldiers have a more varied cookery; but still there is great room for improvement. Some means of converting recently slaughtered and frequently tough meat into tolerably tender and palatable food is much required. The troops do not usually have tea, coffee, or other refreshments before a march; most regiments send their cooks on ahead, and have coffee prepared at a halting place. 5. I think gardens for the cultivation of vegetables by soldiers might be advantageously established, but the time they can safely work in them is so exceedingly short that a great deal must necessarily be left to native coolies and gardeners.
VII.—DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldier's dress and accoutrements at this station consist in hot weather of a suit of cotton dust-coloured clothes—in the cold of the red serge tunic and cloth pantaloons. They have 3 flannel shirts and 2 abdominal belts; a helmet covered with cotton, slightly padded, with a good curtain over the back of the neck. I consider that no improvement can be made in the dress, as it is suited to the climate. On guard the men wear the cotton clothing in summer, and in winter the cloth suit, with woollen socks, flannels, and ammunition boots in wet weather.
Duties.	1. The troops, particularly cavalry, should be drilled preparatory to leaving home, as drilling to the extent that is necessary to make a recruit know his duty often in this climate sends the less robust or less temperate into hospital, when if done in England it would strengthen him. 2. There is a parade every morning during the year, weather permitting; duration about an hour. The men do not suffer in health from drill. In cold weather, the parades are twice a day. The best time for drills and parades in the summer months and in hot weather is before sunrise, and in cold or winter months after. For marches, in the cold weather, early in the morning an hour or two before sunrise; in the hot weather, marching about sunset would be what I should advise. The average number of nights the men have in bed in is 5. 3. Guards are mounted close to barracks at this station; they last 24 hours (from sunrise to sunrise), except mess-guard, which mounts only at sunset. There are check roll-calls day and night, twice at night and twice during the day at uncertain hours.
VIII.—INSTRUCTION AND RECREATION.	1. The means of recreation and instruction consist of a skittle-alley for each company, one school, a good library and reading room, lighted at night, and used as a day-room, or soldier's club; but there are no ball-courts, no soldiers' gardens, workshops, theatre, or gymnasia. There is not sufficient means provided to keep the men occupied during the wet season. During the rains and in the hot season, they are not allowed to appear outside their barracks from 9 A.M. to 6 P.M. 2. The erection of fivescourts, a theatre, gymnasia, swimming baths, the public reading of good biographies, travels, novels, &c., employment at trades of various kinds, and instruction in them to those untaught, clothes, accoutrements, barrack furniture of all kinds to be manufactured in the regiment, watch-making and mending, printing and paper making, bread and biscuit baking, and several other trades might be encouraged, with considerable effect, and prove great improvements. 3. In connexion with workshops for employment as already suggested, savings banks would be still more advantageous than they undoubtedly now are. 4. There is no sufficient shade in this station, but in many others there is far less.
IX.—MILITARY PRISONS.	1. In the military prison at this station there are no cells. The mainguard of H.M.'s Regiment is part of one of the barracks; it is well ventilated and is not usually overcrowded. The same arrangement exists for the prisoners of the Royal Artillery. For the depôt of H.M. Indian army the main guard is a small detached building, low, close, and ill-ventilated. There are no solitary cells.
X.—FIELD SERVICE.	1. I am not aware of any local regulations for field service which are not included in the Presidency Regulations. 2. The suggestions of medical officers are generally attended to by commanding officers, but as far as I have observed they are seldom consulted with regard to the conduct of line of march, troops bivouacking, camping, &c.

References to Subjects and Queries.

Replies.

X. Field Service—*cont.*

3. Medical officers are never consulted in the selection of camping grounds on the line of march. Space of ground for encampment is generally set apart at each halting place; at these places there are always good wells; grain, wood, and other bazaar supplies, are stored and supplied.
4. Field hospitals are established when requisite in war time, conducted upon the general principles laid down for the regulation of European regimental hospitals. There is a medical storekeeper for each hospital; and bazaar, and other commissariat stores are supplied on indents; diet and servants are also supplied by the commissariat. A surgeon is appointed in general charge, with as many surgeons, and assistant surgeons, and medical subordinates as may be deemed necessary. Doolies have been found the most comfortable and least injurious vehicles for the transport of sick, and hospital supplies are conveyed on camels, carts, &c. according to circumstances; ambulance carts have occasionally been used, but I have had no experience of them. The general regulations for the establishment of field hospitals are laid down in the Bengal code of medical Regulations. Chapter XXIV.

XI.—Statistics of Sickness and Mortality.

1. There is no information under this head.

XII.—Hospitals.

1, 2. A ground plan, together with a rough marginal sketch of the elevation of the hospital, has been transmitted; it is situated west of the line of barracks, and at a convenient distance from them. The bazaar is about 100 yards west of it; the houses of the station are south of it and lie between it and the river Hooghly. The hospital is open and freely ventilated and unobstructed by high buildings or trees, &c. The site is generally healthy.
3. The water supply is from a good tank close to the hospital, and it is both abundant and generally wholesome.
4. Drains of masonry receive the rains from the roof, the refuse water &c., and convey it into the river. They are open and quite sufficient for the purpose.
5. The hospital consists of a large iron-framed building, 411 feet in length by 38½ feet in breadth; the height at the centre of the roof is 23 feet 8 inches. There is a fine verandah on the south side 11½ feet wide, extending along the whole front, and round the east and west ends. On the northern side, there is no verandah; the floor of the building and verandah is raised on masonry pillars 3 or 4 feet, and is planked over. At the east and west ends there are two rooms, 19 × 18½ feet, used for dispensary and other purposes. The hospital is constructed for 150 beds, 60 on each side, and 30 in the centre between the iron pillars. Air freely enters under the planked floor. There are no division walls, the hospital being one immense hall. The compound or enclosure in which the hospital stands is large, well drained, and cleanly kept, traversed by good drains, and surrounded by a brick and mortar wall 4 feet high, topped to about the same height by an iron wire-netting, sustained by iron posts let into the masonry. These drains are sufficient to carry away all rain and refuse water rapidly. The hospital is built of iron, with single walls, and the roof is of grass thatch. The roof and walls are well constructed and of sufficient thickness. The doors are only closed by jhilmils, they are not glazed. Verandahs are not used for the accommodation of the sick, convalescents, or others. There is one flat only, which constitutes the hospital.

Table of Hospital Accommodation.

Date of construction, 1859.

Total number of wards - - - - - 3
Total regulation number of beds - - - 150

Wards, or Hospital Huts. No.	Regulation No. of Sick in each Ward or Hut.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		ft. in.	ft. in.	ft. in.				ft. in.		ft.	ft. in.
3 wards	50	135 2	38 6	10 6 at sides. 3 6 in centre.	90,465	1,809	86	1 6 to 1 11¾	28 windows 12 doors	4 9	2 6 4 6

The hospital is so placed as to receive the benefit of prevailing winds. Venetian doors open out of the hospital wards into the large southern verandahs; corresponding doors are on the northern side, open ventilating spaces also extend all along the roof tree.
6. The above arrangements fully ventilate the building, as it is never close or offensive. The doors are not glazed, but closed with jhilmils or venetians.
7. No means are employed for cooling the air in wards.
8. No means of warming are required. The walls and ceilings of the hospital wards are cleansed and lime-washed annually as a rule, but oftener if required by the medical officer.
9. The privies are behind, and on the northern side of the hospital. Iron urinals, containing charcoal, which are emptied daily, are used. The place is divided into 13 compartments, and is fitted with wooden seats. The soil is at once removed and placed outside cantonments. The filth is cleared away daily in barrel carts; the privies are never long offensive.
10. The lavatory consists of a long room attached to the northern side of the hospital, 30 feet by 12. There are two bath rooms, and one urinary room. They are clean and well ventilated.
11. There is a large full-length wooden and a small hip-bath. Earthen dishes are used for ablution.
12. There are no particular means for washing and drying hospital linen. Dhobies, or washermen, form part of the regular hospital establishment; they wash and dry the clothes, &c., at a distance from the hospital.
13. The storage is insufficient; the bedding and clothing has to be kept partially in the verandahs of the store-room, and gets injured by wet or damp.
14. The bedsteads are of wood of the ordinary size, with iron-hoop bottoms. The bedding consists of native tow stuffed into coarse cloth; this is easily removed and renewed when soiled, but is apt to get into hard lumps by use.

BARRACKPORE. BENGAL.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	15. The hospital kitchen is a building divided into two rooms, each 40 feet in length by 12 in breadth, and 11 in height. It is large enough for one regiment. It is also close to the hospital and sufficiently convenient and adapted for hospital requirements. 16, 17. An hospital serjeant is provided for attendance on the sick, also a sick orderly, generally the patient's comrade, when the case is serious; there are beside native hospital ward coolies for general attendance upon the sick, and these are increased in proportion of one to six men when numbers increase. A female native nurse and a female native sweeper is provided for a regimental hospital, and increased as occasion may demand for attendance in the female hospital. 18. The European hospital here is a good one; no epidemic disease, pyæmia, or hospital gangrene has ever appeared in it. 19. The hospital requires better store rooms for clothing and bedding, detached rooms for infectious diseases, insane or delirious patients, ophthalmic cases, &c. The cook house is also too small. At present a private house in the vicinity is rented for a female hospital; it is in several respects unsuitable, and a female hospital is desirable. 20. Except the large verandah to the south there is no special provision made for convalescents taking exercise. Weakly men, on the requisition of a medical officer, are taken out for air and exercise on government elephants, and when the weather is cold it is not unusual to send out convalescents under non-commissioned officers for a morning and evening walk. 21, 22. There are no special local hospital regulations. 23. The medical officer has practically complete power in matters of diet, comforts to sick, &c., and also in hospital repairs, when he can show that they are essentially necessary for the benefit of the sick. 24. There are no convalescent wards or other extra accommodation in the hospital, and I can see no very clear advantage from such accommodation.
XIII. BURIAL OF THE DEAD.	1, 2. The burial ground used by British troops is in front and on the right flank of the parade ground; the prevailing wind blows from the station over it; its area is from 360 feet by 250 feet, equal to about two acres; in the higher portions the soil consists of a friable alluvium, in part of the lower space it is clayey, and the rest of a sandy alluvium; the drainage is merely surface, through small channels left in the wall that encloses the ground. During the rains, the ground in the lower part is thoroughly permeated with water, so that open graves are nearly filled, and that by water to a certain extent polluted by the adjacent graves. Decomposition seems to be rapid in its progress, and there is no desiccation. 3. The grave space is six feet long by two feet wide, and from one to two feet between graves in the dry season, but in the rains more than double these dimensions have to be allotted, or the graves kept ready dug would fall in; they are from 4½ to 5 feet deep, and are never re-opened for fresh interments. There is no regulation as to the time allowed for interment after death. In India, if the death takes place in the morning the interment takes place the same evening, if later in the day the following morning is appointed. 4. Since the occupation of the station by European troops the burial ground has occasionally been very offensive, especially in the height of the rains. In sickly periods it is necessary to have several graves ready before hand, and in the rains these become filled with water, not merely surface water, but from the porous nature of the soil, by which there is a perfect communication between all the subterraneous fluids, and there is consequently a pollution of the water in the open graves by contiguity with the corrupting contents of the closed ones. In the dry season this is not felt, in the wet season it can scarcely be avoided. The regimental surgeon names the hour at which the burial shall take place, and puts it on his death report, a copy of which is sent to the chaplain or priest, and one to the commanding officer. 5. Some of the dead of the camp followers and bazaar people are buried; the greater number, being Hindoos, are burned, or scorched and thrown into the river. 6. No injury accrues to the public health by the present practice. 7. A new burial ground on the left flank of the parades, and in a suitable position closer to the European hospitals. The one now in use has been examined, and is about to be enclosed.

(Signed) J. B. HEARSEY, Major-General,
Commanding Presidency Division.
F. ANDERSON, M.D.,
Officiating Deputy Inspector General,
Barrackpore Division.
J. ELIOT, Captain, Executive Engineer,
Barrackpore Division.

Date 2 July 1860.

EXTRACTS of a LETTER, No. 3616, dated 27th July 1861, addressed by the QUARTERMASTER-GENERAL of the ARMY, BENGAL PRESIDENCY, to the OFFICER COMMANDING PRESIDENCY DIVISION, having reference to QUESTIONS not properly answered on the SANITARY STATE of the INDIAN ARMY for the STATION at BARRACKPOOR.

Sanitary Condition of Station.
Further Answer, vide *letters annexed.*

17, 18. The remedy for these evils seems to be with the local authorities, and I request you will inform me whether the drains could not be kept open and the jungle cleared away if bildars were employed whenever found necessary. Other stations in this country are drained in a similar manner without any pernicious results being experienced.

Military Prisons.
Further Answer, vide *letters annexed.*

1. Are no better arrangements being made for these prisons, and are no other buildings authorized for guard rooms, prisons, and cells than those referred to in the reply, which seem unsuitable in every way?

Hospitals.
Further Answer, vide *letters annexed.*

21. I beg you will inform me if the want of a proper building near the European hospital for female patients has ever been brought to the notice of Government in the Public Works Department.

Hospitals.
Further Answer, vide *letters annexed.*

19. Are any arrangements authorized, or have any been recommended, by the local authorities for increasing the store rooms?

HEN. ROBERTS,
Major, Deputy Assistant Quartermaster-General of the Army.

References to Subjects and Queries.	Replies.

To Captain Maxwell, Deputy Assistant Quartermaster-General, Barrackpore Division.

No. 350.

Sir,

Sanitary Condition of Station.

17, 18. In reply to an inquiry of the Quartermaster-General of the Army, conveyed in his letter No. 3616, dated 27th ultimo, respecting the open cutcha drains of this station, I have the honour to state that about a dozen coolies having, at the commencement of the rains, been put on, and paid out of the Grazing Fund, the drains are now kept free of vegetation and falling leaves.

Hospitals.

19. With respect to the European hospital store rooms, I have to remark that since the date of my observations on the subject, in reply to the questions of the Royal Sanitary Commission, the recruit depôt hospital has been removed into another building, and the store rooms for clothing and bedding and the cook house afford now sufficient accommodation.

21. A female hospital is certainly desirable, if the women of the regiment, battery, and depôt, are to be with their husbands in the customary proportion. When the European hospital was first built there were no women and children with the troops at this station, and the want of a female hospital was not then felt.

Two rooms of a small size for cases requiring to be detached would also prove a most desirable addition to the large European soldiers' hospital.

F. Anderson, M.D.,
Officiating Deputy Inspector-General of Hospitals.
J. B. Hearsey,
Major-General Commanding Presidency Division.

Deputy Inspector-General's Office, Barrackpore,
August 14, 1860.

From the Executive Engineer, Barrackpore Division, to the Deputy Assistant Quartermaster-General, Presidency Division, Barrackpore.

No. 220.

Sir, Barrackpore, August 16, 1860.

Military Prisons.

1. With reference to the inquiry made by the Quartermaster-General of the Army in his letter, No. 3616, dated 27th July 1860, regarding guard rooms, cells, and prisons at this station;

2. I have the honour to state that the small barrack in which the quarter-guard of Her Majesty's 6th regiment is located is specially for that purpose, and is not a portion of the accommodation of the men.

3. With reference to the artillery and depôt, I some time ago reported that *neither* has any of the subsidiary buildings allowed. I imagine the delay in giving orders on the subject arises from the uncertainty as to the permanency of the location at this station of these two bodies, one letter from the Quartermaster-General, dated 19th September, last year, stating that it was not necessary to have any artillery here, and the last distribution of troops in this division, stating that half a battery should be here.

4. The Quartermaster-General's and Deputy Inspector-General's letters are herewith returned.

J. Eliot,
Captain, Executive Engineer, Barrackpore Division.
J. B. Hearsey,
Major-General Commanding Presidency Division.

To the Quartermaster-General of the Army, Head Quarters, Presidency Division.

No. 823.

Sir, Barrackpore, August 23, 1860.

With reference to your letter, No. 3616, of 27th July, drawing attention to certain remarks made in the questions and answers issued by the Royal Commission on the Sanitary State of the Indian Army, I have the honour to forward the information called for in the accompanying letters, as per margin, from the Deputy Inspector-General of Hospitals and the Executive Engineer of the division under my command.

J. B. Hearsey,
Major-General Commanding Presidency Division.

No. 350, dated August 14, 1860, from the Officiating Deputy Inspector-General.
No. 220, dated August 16, 1860, from the Executive Engineer.

DUM DUM.

Accommodation	European Troops	Artillery	1 battery.
		Cavalry	200
		Infantry	1 regiment.
	Native Troops	Infantry	200

I. Topography.

1. The country surrounding the station is fertile and rice-producing, with numerous villages, embosomed in thick woods of bamboo, mango trees, banian, tamarind, and other large tropical trees. The country is flat, the soil parched and dry in the hot weather, and swampy during the rainy season. There is much wood, not jungle, in the vicinity, and plenty of water.

2. The station is 18 feet above the level of mean tide, and 9 feet only above spring tides, while during the months of June, July, August, and September, the south-west monsoon, causing the water in the Bay of Bengal to rise 7 feet, places Dum Dum only 2 feet above the level of high flood tide. The ebb and flow of the tide is then visible in the ditches in the immediate vicinity of the station. The sea is 84 miles distant. The nearest lake is the Calcutta Salt-water Marsh, the closest point of which is 2 miles south of the station.

DUM DUM. BENGAL.

References to Subjects and Queries.	REPLIES.
I. Topography—*cont.*	The marsh is 9 miles long and 4 miles broad. The nearest river is the Hoogly, 3¼ miles in a westerly direction. The nearest canal is the Calcutta Circular Canal to the south-west, and the nearest Nullah is the Noweye nullah, 2½ miles in a north-easterly direction. There is no higher or healthier ground adjoining the station.
	3. The nearest mountain is the hill of Parisnath, 121 miles distant, with an elevation of 4,463 feet above the sea. It is on the grand trunk road leading to Benares, and accessible at all seasons. The temperature on the summit is fully 12° F. lower than that of Calcutta; delicious water is found close to the top, and it seems very desirable to carry out a plan now in contemplation, of establishing there a small sanitarium for soldiers serving in the immediate part of India. The table-land at the foot of Parisnath stands 1,000 feet higher than this station.
	4. As but little rain flows off, the vicinity of the station is under water during the whole of the months of July, August, and September. There is no broken ground, or ravines, or water pits near the station.
	5. The station is tolerably open and exposed to the monsoon winds, but, perhaps, some portion of the houses, with gardens and hedges, owned and occupied by natives in the vicinity, might with advantage be cleared away. None of the houses inside cantonments interfere with the ventilation. The temperature of the air in the immediate vicinity of the barracks is raised somewhat by reflected sun's rays, but certainly not the temperature of the station generally. The station, as a general rule, is not exposed to cold or variable winds, but is under the influence of the N.E. and S.W. monsoons; the latter is the sea-breeze; neither have any prejudicial effect on health.
	6. The surrounding country is highly cultivated. There are no works of irrigation in the neighbourhood, but the rice crops are under water for several months. The cultivation of rice is prohibited within the limits of the cantonment, but is permitted up to the boundary pillar, all round the station; the land being private (native) property and in no degree subject to military authority. Neither indigo, hemp, nor flax are cultivated in the vicinity.
	7. The nearest large city is Calcutta, about seven miles distant, but an extensive native population exists in the immediate vicinity of the station.
	8. As regards the geology of the district, Dum Dum is situated upon the great Gangetic Delta. The soil is alluvial, and has been pierced to the depth of 480 feet, showing the following sections:—

Surface soil	10 feet.	Sand	120 feet.
Blue clay	25 „	Clay	159 „
Peat	80 „	Sand	480 „

The ground occupied by the station was not previously the site of a village, but was covered with jungle.

9. Water is found at a depth of 9 feet during the dry season, and 1 foot during the rainy season.

10. There are no surface springs in the district. The rain-fall is very partially drained away, the greater portion being absorbed in the very porous soil of the Delta. Much is evaporated and none oozes out after absorption in the ground.

11. The water supply for the station is derived from wells and from open tanks. It is stored in numerous open tanks; the extent of tank surface being as much as 25 acres within the station. I am unable to state the extent of tank surface within half a mile round. Some of the tanks have water in them all the year round, but many of them get dried up before the month of April, and there is often a dearth of water just before the rainy season commences. No tank used for drinking water by Europeans is also used for bathing. Both tanks and wells are liable to suffer from leaves falling into them at certain seasons, and require to be cleaned out from time to time; but no foul drainage or surface impurities are allowed to drain into tanks containing drinking water. No nuisance nor malaria, so far as I am aware, proceeds from any tank here, or in the immediate neighbourhood.

12. The amount of water-supply available for the station is abundant, and it is generally clear, well tasted, and free from any particular smell. The following is its chemical constitution:—

Tank Water.

In 40 oz. there are:—

Solid residue	2·8 grains.
Silica	0·2 „
Earthy carbonates	2·0 „
Alkaline chlorides with a small quantity of alkaline sulphates and carbonates, and a trace of organic matter	0·6 „

Well Water.

In 40 oz. there are:—

Solid residue	6·6 grains.
Silica	·8 „
Earthy carbonates	1·8 „
Alkaline chlorides	0·8 „
„ sulphates	0·3 „
„ carbonates and trace of organic matter	2·9 „

The waters are filtered before analysis.

It is not in my power to state the microscopic characters of the water. It is generally soft, but the well water contains a considerable quantity of silica. I consider the water-supply sufficient and not injurious to health. It is raised and distributed for use by native water carriers in leather bags. No better water-supply could be obtained. I think as a general rule all tank water ought to be filtered, and in each barrack there should be several common filters, which should be carefully looked after. Such filters are used in hospitals always, generally in barracks; but they should be made imperative, and some one should be appointed to attend to them.

13. I am of opinion that rice culture is permitted too close to the station on all sides; but, of course, beyond the cantonment pillars the officer commanding here has no power to prevent the owners of the soil from planting or sowing what crops they will. Much of the land would be under water during the rainy season under any circumstances.

References to Subjects and Queries.	Replies.
Topography—*cont.*	14. The manner of selecting sites for stations varies very much in different cases, the opinion of medical men being frequently totally disregarded. In this very station, and at Barrackpore, barracks have been built within the last two years without ever consulting the medical authorities; and very recently at Dum Dum entirely new arrangements were made regarding all the hospitals, by a committee not containing a single medical officer in its number, and the reports were sent in to the Commander-in-Chief without the result of the Committee's deliberations being even communicated to the Inspector-General of Hospitals, or the Deputy Inspector-General.
II. Climate.	1. The only meteorological instruments supplied by Government are thermometers, and of the thermometer only has any regular register been ever kept. 2. I am unable to furnish a table of sufficient accuracy to be worth recording. The Calcutta observations may be considered applicable, except that the temperature is 1 or 2 degrees lower at Dum Dum than at Calcutta. 3. The climate of Dum Dum, as of all Lower Bengal, is very moist. The weather is never very cold as in the north-west provinces, and never so hot, dry, and trying, even in the hot season, as up country. There is a thick mist nearly every morning hanging over the station for a month before the hot season commences. There is no dust at any time sufficient to render the air impure, or other admixture affecting the atmosphere unfavourably. I do not consider the climate as ordinarily unhealthy for troops, if proper precautions are used. The times of drill, &c. must be made to depend on the season here, as in all parts of India; so must the dress used by the men, it being essential that they should wear clothing at night which is utterly unsuitable for the day. I deem it more desirable here than up country that they should sleep in storied barracks, and not on the ground floor, where practicable. The healthiest months are November, December, and January. The most unhealthy from my experience are June, July, and August. Cholera, dysentery, and fevers are the prevailing diseases during the unhealthy months. 4. There is no district near the station the climate of which is more conducive to health than Dum Dum. 5. I have served at Gyah, Dinapore, Ghazeepore, Benares, Mirzapore, Allahabad, Mynpoory, Gwalior, Seepra, Augur in Malwa, as well as in Calcutta and at Dum Dum. Not one of them is, in my opinion, absolutely unhealthy, and I consider that Benares, Mirzapore, Mynpoory, Augur in Malwa, and Dum Dum ought all to be healthy for European troops if due precautions are used. Any station will prove unhealthy where too many men are put into the barracks. I consider over-crowding to be the chief cause of disease all over India, and want of attention to drainage.
III. Sanitary Condition of Station.	1. 2. 3. Plans. 4. Date of construction of permanent barracks { 4 built in 1813–14. / 1 enlarged and added to, 1858. / 1 built in 1858–60. } Total regulation accommodation, non-commissioned officers and men—1,649.

The following Table gives the details :—

III. Sanitary Condition of Station—*cont.*	5. The windows are on opposite sides of the rooms. The lower portion of each window to a height of 2½ feet is not provided with hinges, but fixed to the window frame. The upper 5½ feet portion opens on the outside in two leaves. All the permanent barracks have verandahs on both sides; 12 feet wide and 15 feet high in the old barracks; 12 feet wide and 18 feet high in the new barracks. They are closed outwardly by venetian windows opening outwards. There is a series of open arches between each verandah and the centre room or ward. The verandahs are supposed only to be used for the men to take their meals in, the centre room being reserved for sleeping. But practically the verandahs (one at least) are too often used for sleeping in, owing to want of room in the centre ward, and the inevitable consequence of such crowding is an outbreak of sickness. The jalousies or jhilmils are properly constructed, and of exactly the same kind as those used by officers and civilians in India generally. 6. Wooden cots are used in barracks. Each soldier has issued to him one cotton settringee (a carpet) the size of the cot; 2 cotton sheets; 1 quilt of double chintz, 7 feet 4 inches by 4 feet 9 inches, and one good country blanket, to measure when double 7 feet 4 inches. 8. For ventilating the barrack rooms, besides opposite doors and windows, there are close to the ceiling of all the lower stories circular holes 9 inches in diameter, both in the interior and exterior walls, and round each beam a space is left to assist in carrying off the foul air. In the upper stories regularly constructed ventilators, with glass windows capable of opening, are placed at short intervals all along the roofs of the new barracks. Those in the old ones are tiled louvres. But there are in addition holes 2½ feet in diameter pierced about every 40 feet all along the roof in the verandah, and covered over with earthenware pots (gumlahs); between the latter and the roof the heated air escapes. The ventilation was quite insufficient, especially at night, when the barracks were overcrowded; but with the numbers who have lately occupied them, and are to do so in future, I believe there is no ground for complaint. No special means of cooling the air are used, except ventilating openings and punkahs, which when properly used are a great relief to the men. 9. The permanent barracks are all constructed of solid masonry. The iron framed barracks have walls of masonry outside, and are roofed with a thin layer of thatch (6 inches), covered with the common bazaar small tile. All these buildings leak badly, but there is reason to suppose that either a proper thick thatch or larger tiles of an improved character will eventually be substituted. 10. The floors of the permanent barracks are raised 3 feet, and are formed by laying 1½ feet Chunar stones over flues of brick work. The air passes through the flues, iron gratings being placed on each side to prevent the entrance of animals. The iron-framed barracks have floors of wooden planking well raised, like the former, and on arches, with iron gratings also to keep out animals. There is thus a free passage of air beneath. 11. As regards character of materials, the present roofs of the iron-framed buildings are, as stated above, totally insufficient, but may be improved. I think it would be advantageous to have wooden flooring elsewhere in place of tiles or flags, but frequent repairs of portions will be required. The Barrack Master performs all petty repairs, and applies for the aid of the Executive Engineer when any new work is required. Repairs are executed with fair celerity. The senior Medical Officer at the place is ex-officio sanitary officer, and it is his duty to report to the commanding officer whatever he sees amiss, and also to make suggestions. The commanding officer is responsible to the higher authorities, and under him the barrack and conservancy departments. Walls and ceilings are repaired and whitewashed once a year by the Executive Engineer. But the Barrack Master may at any time be called upon to whitewash the walls to the height of 6 feet, if necessary as a sanitary measure. 12. There are lavatories supplied with water from stop cocks (there appear to be no baths.) Metal basins are used for washing. 13. The cookhouses are fitted up on one side with a number of little walls parallel to each other, 1 foot high and about 4 inches broad, placed together so as to allow a kettle, pot, or pan to rest on the edge of each, while the fire is lighted underneath. Water is supplied by water carriers, and a drain runs all round the building to carry away the refuse water. The pans are of copper, and are tinned on the 1st and 15th of every month; if this is not carefully done, they are apt to fall into a dangerous state. A large tank is set apart for washing linen, which is done by washermen, dried in the sun, and prepared by the washermen at their own homes. There is plenty of washing and drying room. 14. The privies consist of iron pans, the contents of which, together with the urine from cesspools connected with the urinals, is carried away daily in covered carts, and buried outside cantonments. 15. The means of lighting the barracks at night are sufficient. 16. There are no covered sewers for draining the barracks. All the drains are open, and vary greatly in breadth and depth. They are all at a distance of 6 feet from the walls of the buildings, the interval being a tiled platform, sloping towards, and joining the drain. The whole of the drainage passes by the main station drain into the salt-water marsh. The drains are not defective, but the fall is so slight that in the rains especially, the surface water and the drainage from the men's lavatories are not readily nor efficiently carried away. The drainage from cookhouses, privies, and urinals is removed daily in filth carts, as already stated, and buried in pits outside the station. Every privy has a cesspit about 2½ feet in diameter and about 5 feet deep, lined with solid masonry, and having a wooden cover. None of them is within 70 yards of a drinking tank or well. The floors of most of the under stories of the barracks are damp, particularly in the rainy season. This is owing chiefly, I believe, to the large quantity of moisture absorbed by the Chunar flagstone, of which the flooring consists. It is to be regretted that the floors were not made a foot higher from the ground than they are. 17. A cart and men are maintained about the station to keep the surface clean, &c. A separate cart goes round the officers' quarters. The cleansing has been effectually done of late. Up to the end of the last rains, the conservancy was totally unequal to the wants of the cantonment.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	18. By this agency the surface is kept free of vegetation, but additional aid will be required for the purpose during the rainy season. 19. The bazaar is not crowded, and there is nothing to complain of as to drainage, ventilation, cleanliness, or water-supply. A cart and six sweepers are kept up for the bazaar, and go their rounds regularly morning and evening. The sanitary state of the bazaar generally is satisfactory, but I would make vaccination compulsory on every resident old and young. The native houses generally near the station are kept pretty clean and have no dung heaps nor cesspools within them. No nuisance is experienced from wind blowing over native dwellings. 20. Only one slaughtering place is allowed, about half a mile to the south-west of the station. It is a thatched structure, but a solid masonry one has been sanctioned. No nuisance proved from the present one. The offal is chiefly disposed of with great rapidity by beasts and birds of prey. The remainder is carted off and buried. 21. There are very few bazaar horses which are picketed behind the houses of their owners. Refuse straw and grass are burned and dung is carted away. 22. Stables lately occupied have been temporary ones only. The proper picketing ground for artillery and cavalry horses is about half a mile from the hospital to the north-east, and more than a mile from barracks. 23. There are no regular married quarters. Either a barrack is divided for them into sets of temporary quarters, or, if under the same roof with unmarried men, the quarters are completely separated from the latter. I have never known married people occupy the barrack rooms with unmarried men.
Officers' Quarters.	1. The officers live in detached houses, all in satisfactory sanitary condition. The most desirable houses are those with upper stories, but there are only few of them.
IV. Health of the Troops.	1. I consider the station as healthy for European troops so long as they are not crowded in barracks, and other measures of precaution are observed. The native population here, as in other parts of Bengal, suffer much from sickness in the hot weather and end of rainy season. 2. The most prevalent diseases among the native population are small-pox and cholera in the hot weather, and fever, often accompanied with spleen disease, in the end of the rains. Cholera is now endemic in this part of the country, and has been epidemic this season, carrying off thousands all over Lower Bengal. 3. As regards small-pox much requires yet to be done to propagate vaccination. As regards fever and cholera the lowness and dampness of the native huts, affording as the huts do, insufficient protection from the rain, must be considered the great causes of sickness. Also the poorness of their food, eked out occasionally with insufficiently cooked vegetables, and fish in a state of putrefaction. 4. The troops at the station are young recruits from England, or time expired soldiers, or invalids from all parts of India, except a battery of Royal Artillery, which arrived here a few weeks ago in excellent health. I consider all the permanent barracks at this station as about equally healthy. Certain temporary barracks, which were occupied by troops last year, proved to be in the last degree unhealthy, owing to defective ventilation, leaky roofs, and insufficiently raised floors. But having been condemned by all the Medical Officers, these barracks will, it is understood, be pulled down or converted into stables. The lower stories of all the permanent barracks are more or less damp, and therefore not so healthy to live in as the upper stories. 5. Troops are not usually camped out. 6. 7. I have never been in charge of troops at hill stations. 8. From what I have seen of the beneficial change produced in the health of officers by a residence in the hills, and judging from the appearance of soldiers after being some time at a hill station as compared with their looks in the plains, I highly approve of selecting hill stations for troops. 9 to 13. (Hill stations.) No experience. 14. As regards change of station on the plains, when a regiment is healthy and the amount of duty moderate, I see no good to be gained by frequent change of station, that is, more than once in 2 or 3 years; but when a regiment has suffered much from sickness, and the men get out of spirits, they should be moved at the end of the year, or even earlier in particular cases. 15. 16. No experience. 17. There is no ground near the station that could be occupied as a hill station. 18. I have not arrived at any positive conclusions as to the comparative healthiness or otherwise of particular soils or subsoils. 19. The best age for a soldier proceeding to India is from 21 to 24 years. The best period for troops landing in India is November and December. Troops landed between 1st April and 31st August are certain to be decimated by sickness. On landing, some recruits are sent up country at once, while others are detained here for a considerable time. During the last 3 years the station has been so crowded at times that it was not possible to observe any general rule, and men were put up in the best way possible, and suitable clothing supplied as soon as possible. On landing, men should be put at once under charge of officers and non-commissioned officers who know the country. They should be strictly confined to barracks during the heat of the day, and prevented from poisoning themselves with unripe fruit and vegetables, and country liquors in the bazaars. They should also have suitable clothing immediately. 20. With reference to the question, as to whether recruits should be sent direct to India or not; as far as regards recruits merely, if thoroughly drilled at the home depôt, I think they may just as well be sent direct to India, provided it is so arranged that they arrive at the proper season of the year. With respect to entire regiments, it would probably be advantageous to send them for a time to an intermediate station, perhaps to the Mediterranean. If landed at the proper season, the sooner recruits are sent to their respective regiments the better. They will be better cared for there than at any depôt in the hills, or elsewhere. As regards entire regiments, sending them to the hills in the first instance might have the same effect as sending them to an intermediate station like the Mediterranean.

DUM DUM. BENGAL.

IV. Health of the Troops—*cont.*	21. Troops proceeding to the interior from the port either march by daily stages of about 10 miles each, or are transported by steamers as far as Allahabad (500 miles), whence they march, or they are sent 120 miles from Calcutta by railway, and thence in covered carts, drawn by relays of bullocks, 26 miles in 24 hours, travelling only by night, and resting during the day in specially constructed barracks at each resting place. At each such place there is a Commissariat Officer, who serves out the rations as soon as they arrive. There is also a Medical Officer, to attend to any who are sick. In a year or two more troops will be conveyed by the railway to all stations of most importance. When sent up country by steamer, more care should be taken than is often shown, to prevent overcrowding. 22. I think 10 years should be the utmost limit of a soldier's service in India. Men of strong constitution, however, if after that period allowed to visit Europe, and do duty at the home depôt for a year or two, might return to India, and do a few years more valuable service. 23. As regards medical boards, differences of opinion do arise at times, and cause great inconvenience. But, on the whole, I think boards act harmoniously, and, admitting the evils of the existing system, I am not prepared to suggest a better. 24. The best season for the embarkation for England of the bulk of invalids seems to be from the middle of February to the 15th March. But, in cases of fever, dysentery, &c., occurring in patients at stations near the port of embarkation, many lives may be saved by immediate change to sea, whatever the season of the year.
Diseases.	1. Health inspections are held not less frequently than once a week, either in the morning or just before sunset. 2. There is no scorbutus at this station. 3. Not prepared to give a definite reply as to the amount of hepatic disease, as the men are recruits. The things to be principally guarded against for diminishing the frequency of this disease are exposure to the sun and the drinking of ardent spirits. 4. Dracunculus is very rare here, scarcely ever among Europeans. Drinking, and bathing in shallow tanks, at the end of the rains, appeared to have produced the complaint in cases of native soldiers, which I have seen in Central India. 5. Comparatively few of the patients treated here for venereal disease have contracted it at this station. But here, as at other places, it seems highly desirable to establish Lock Hospitals. 6. The prevailing epidemic diseases are, common continued fever, in the hot season and rains; remittent fever and various types of intermittent fever later in the season. The troops suffer much, and often with great severity, from dysentery, acute and chronic. Many men die of it every year. Sporadic cases of cholera occur at all seasons, and the disease is very apt to become epidemic, when the strictest rules for preserving health are not observed, especially on first arrival in the country. Small-pox is rare among Europeans. Soldiers often suffer from rheumatism in the latter part of the rains, especially if sent on night duty insufficiently clad. As regards the proportions borne by these diseases to the total diseases, taking the average of the last two years, among the men under my medical charge (Bengal Artillery Recruits), the admissions from fever, bowel complaint, cholera, small-pox, and rheumatism conjointly were 57·23 per cent. of the total treated, and the deaths 98·95 per cent. of the total deaths from all causes. The following table gives the particulars for each disease :—

	Admissions, Per-centage.	Deaths, Per-centage.
Fevers	29·89	6·25
Bowel complaints	15·96	26·04
Cholera	10·22	66·66
Small-pox	none.	none.
Rheumatism	1·14	none.
	57·23	98·95

There was, however, a severe epidemic of cholera in the second year.

7. The nosological characters of these diseases differ very much with the seasons. Cholera and common continued fever, with occasional cases of small-pox, prevail in the early part of the hot weather. Remittent and intermittent fevers occur mostly in the rainy season, particularly in the latter part of it. Last year we had a violent epidemic of cholera in the month of August.

As a general rule cholera shows itself in seasons of great drought, and so does common continued fever. The other types of fever, again, are most severe where the fall of rain has been above the average. As a general rule I have observed that seasons in India are unhealthy generally whenever the fall of rain is considerably above or below the average.

Excepting that the native houses are insufficiently raised from the ground, and at best usually made of very flimsy materials, there is little to say against their sanitary condition. They are often too crowded and the prejudices of the natives lead to the direct propagation of any epidemic which may occur. As stated elsewhere, natives live very poorly, especially in this part of Bengal, and huddle together so as to be predisposed to catch any disease that prevails.

8. Special precautions require to be adopted for each particular epidemic. When any such prevails, more than ordinary attention must be paid to the soldier's food and clothing, and the degree of exposure to the weather to which he is subjected.
9. Small doses of quinine as a prophylactic have been used in particular cases and found useful, but have not been administered to the troops here generally.
10. As a means of preventing or mitigating epidemic disease at this station, the great object is to prevent crowding, and to have as many men sleep in the upper story of the different barracks as possible.

V. INTEMPERANCE.	1. The soldiers at this station are usually temperate. There are not many confirmed drunkards; but I am unable to state the proportion. 2. I am unable to state accurately the proportion of diseases arising from intoxication, but among the Bengal Artillery recruits during the past year, out of a total of 850 admissions from all causes, there were 2 from delirium tremens and 10 from ebrietas. Drunkenness *per se* is punished as an offence.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	3. Spirits are sold both at the canteen and bazaar, the latter being often of a most injurious description and frequently drugged; sometimes with datura. It is not however permitted to sell spirits in the bazaar to European soldiers, and the person doing so is subject to heavy punishment; still it is done. Spirit never forms part of the ration, either for healthy men or convalescents, and it is not a habit among the men to take a dram before morning parade. Quantities of noxious trash used to be sold in the bazaar under the name of ginger beer and lemonade. I have traced many cases of bowel complaints directly to the use of such drinks. Trash was likewise often hawked about the barracks early in the morning under the name of coffee, which was most prejudicial to health. The consumption of spirits by troops or convalescents is injurious to health. It is most prejudicial to discipline. 5. Spirituous liquors are no longer issued as part of the rations. The soldier has to pay on the spot for all liquor of whatever sort he gets in the canteen. I think the sale of spirits should be totally abolished in the canteen and bazaar. 6. I am convinced that the more the use of malt liquor or wines can be substituted for spirituous liquors, the better it will be for the health of the men. The moderate use of malt liquor, and in some cases wine, I believe to be most beneficial in many instances. 7. Coffee, tea, soda water, lemonade, and ginger beer are much used at the station, the two latter in the bazaar of inferior quality. All can be had good at some of the canteens. The use of such drinks when good of their kind is likely to be beneficial so long as it really causes a diminution of the quantities of spirits and malt liquor consumed. But men and women too, newly arrived in India, are apt to drink too much both of one and the other. 8. I believe it would be beneficial to suppress the spirit ration where it is still issued, and to substitute beer, tea and coffee, the latter of good quality, which at present is often very much the reverse when bought by the men from hawkers irresponsible for what they sell. Old soldiers do not purchase such stuff, but recruits new to the country are readily imposed upon. 9. It would be decidedly advantageous to prohibit the sale of spirituous liquors in the canteens, and to permit only beer, coffee, tea, lemonade, &c. to be sold, exceptions being made in special cases. At the same time the spirituous liquor sold in the canteen is harmless when compared with the native spirits, always too easily procurable in the bazaars, and until very lately in Dum Dum perhaps above all other stations, excepting Fort William. No native grog shops should be permitted within four miles of any cantonment, and the penalties on selling it to Europeans should be made very heavy. 10. As is already the practice in the provisional battalion, I should insist on having really good tea, strong coffee, and wholesome lemonade always available at the canteen. They should not be allowed to be sold in the bazaar except, perhaps, by one or two specially licensed natives, who should be liable to very heavy fines or imprisonment if guilty of selling inferior qualities. Some such rule does exist here, but it is not carried out with sufficient rigour in all cases. 11. The more important canteen regulations are the following:—Canteen open daily from 12 noon to 1 p.m., to issue malt liquor only (1 imperial pint per man), and again from sunset till gunfire p.m., for the issue of rum and malt liquor. No country-made liquor except that issued by the Commissariat is allowed. Rum is sold at 1 anna (= 1½*d.*) per dram, and malt liquor at 1½ anna (= 2¼*d.*) per imperial pint. No one is allowed more than two pints of malt liquor daily; the second pint being issued after sunset, and one dram of spirits, or two drams of spirits and no malt liquor. Malt liquor to the extent of 1 imperial pint per woman may be taken from the canteen, at the dinner hour only, for the wives of soldiers who obtain permission to receive it from the Commanding Officer. No person admitted to the canteen but men of the regiment, and gambling entirely prohibited. There do not appear to be any bazaar regulations peculiar to Dum Dum.
VI. Diet.	1. The following is the ration for European troops of the Indian army:— Bread - - - - 1 lb. Rice - - - - 4 oz. Sugar - - - - 2½ oz. Coffee - - - - 1⅗ oz. } alternately. Tea - - - - ⅘ oz. } Salt - - - - 1 oz. Fuel - - - - 3 lbs. Meat - - - - 1 lb. { mutton 4 times a month, beef at other times. Vegetables - - - 1 lb. { potatoes commonly; when scarce or bad, some native vegetable is substituted. The Quartermaster and Officer of the day both inspect the rations every morning, and are responsible for their quality. The Commanding Officer and Surgeon inspect both these and the cooking apparatus from time to time. 2. A complete ration as above is provided for the troops at this station. The soldier commonly takes three meals a day: breakfast about 8 a.m.; dinner between 12 and 1 p.m.; tea at 5 p.m. Most of them have a small portion of their allowance of meat dressed for breakfast, while some purchase eggs, and keep all the meat for dinner. 3. I think it would be an improvement in the rations if mutton could be given more frequently. The quantity of animal food seems rather too much, and I am of opinion that it would be better if once a week the men were allowed only good broth, with extra vegetables and bread. The soldier here never disposes of his rations. 4. The kitchens generally are pretty clean, light, and sufficiently ventilated, and are supplied with water by water carriers. The cooking arrangements have been already described. Whether the rations are roasted or boiled usually depends on the taste and wishes of the men. Where there are old soldiers, the cooking is tolerably good and varied. Men of less experience do not fare so well. Tea and coffee when served up are often not so good as they should be: the servants often managing to elude observation, and purloining some

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	of what is given them to prepare. It is impossible to have good tea while it is all boiled in one great cauldron. Before march men often have tea or coffee; but much depends on the Commanding Officer and Surgeon of each particular regiment. 5. I do not think the climate of this part of Bengal admits of soldiers' gardens being established for the cultivation of vegetables.
VII. Dress, Accoutrements, and Duties.	1. The soldiers' dress and accoutrements are exactly the same as in England, excepting that during six months in the year they wear Khakee tunic and pantaloons (cotton) in place of cloth. I think the present dress is quite suitable to the climate when common discretion is used in adapting it to duties and seasons. I have no improvements to suggest. Commanding Officers, however, cannot be too careful in seeing that each soldier has the proper supply of flannel and other under-clothing. The guard dress varies according to the season.
Duties.	1. I am of opinion that it is highly advisable, as regards the health of the men, that they should be thoroughly drilled at home before being sent out to India. When drill has to be learned in this country, recruits are very apt to be ordered out on parade earlier and kept there later than is at all compatible with health. Besides, if they have learned steady and obedient habits before quitting England, they are less likely to expose themselves unnecessarily in the sun when off duty in this country. 2. The usual routine of duties varies with the number of troops. Since coming to Dum Dum I have never known men to suffer in health from drill. For drills, parades, and marches the men should not, if possible, be kept out later than one hour after sunrise, or turn out more than an hour before sunset. There are no general orders here about these. The strength has varied here so much that it is impossible to say how many nights a week the men have had in bed. 3. Guards are mounted at distances varying from 50 yards to half a mile or three-quarters of a mile. The men composing the different guards go on sentry for 2 hours at a time, night and day. Commonly there are 4 roll calls in the day, and 1 at night, the hour being constantly varied. I have however known it necessary to have roll call every 2 hours by night as well as by day, in the case of some disorderly recruits and others, for a week or 10 days at a time. Unless men are sick already when they go on duty, I do not think night guards, if they do not recur too frequently, injure the health of the men, if they are suitably clothed.
VIII. Instruction and Recreation.	1. The means of recreation and instruction consist of a fives court, several skittle grounds, and there is a school with a good schoolmaster. There is at present no proper library and reading room, but it is proposed to have one for the whole garrison. There is no day room nor soldiers' club. One for the garrison is in contemplation. There are no soldiers' gardens, workshops, or gymnasia. There is no theatre, except a barrack room occasionally used. These means are totally insufficient for occupying the men. In cold weather the men have many ways of amusing themselves, but in the hot and rainy seasons, reading, when they can read, is practically their only amusement. A very few work at their trades in barracks as tailors and shoemakers. The men are not allowed to go out in the daytime; the hours to which they are restricted varying with the season of the year. In the hot weather men are forbidden to go outside between 9 a.m. and 5 p.m. Exposure to the direct rays of the sun at this station is invariably detrimental to health, especially in the case of men lately arrived from Europe. 2. As regards improvements: workshops where men could carry on their trades would be a boon to the industrious, and the great success which lately attended the opening of a small museum containing models of various kinds, and specimens of native produce and industry; different kinds of armour, electrical machines, &c., all illustrated by a series of plain, practical, but interesting lectures, seems to show that soldiers are ready to avail themselves of any means of rational amusement in the evening, in preference to spending all their time in the canteen. 3. I think the less money that is put into the soldier's hand the better. Every inducement should be given to him to leave his pay in his officer's hands, and savings banks might be very useful. He should not be allowed to draw for more than a certain limited sum at any one time, unless the captain is satisfied as to the way he proposes to spend it. 4. Excepting a few skittle alleys, the men have no means here of taking exercise during the day in the hot and rainy seasons, and even to reach the skittle alleys they must expose themselves to the sun.
IX. Military Prisons.	1. The sanitary state of the cells is satisfactory, and I have not observed imprisonment in them to be prejudicial to health. Only some months ago, when the station was full of troops, there were occasionally so many as three prisoners in one cell, which, however unavoidable, was in itself objectionable. Fortunately it was the cold season, and the periods of imprisonment were short, so that no ill effects followed. I have usually found the cells clean and well ventilated.
X. Field Service.	Not in a position to answer the questions satisfactorily.
XI. Statistics of Sickness and Mortality.	No information.
XII. Hospitals.	1. Plan. 2. The hospitals are situated about three-quarters of a mile from the permanent barracks, and about half a mile as the crow flies from the temporary barracks, and stables hitherto occupied by the Royal Artillery. The hospitals are at the N.E. of the station; more than a mile from the bazaar, but within one-eighth of a mile of some of the native houses outside cantonments on the north. The site is on the whole open and freely ventilated, and generally healthy.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	3. The water-supply is wholesome, but not abundant, especially in the hot months. An additional well is now being dug, which will, it is hoped, always afford an ample supply in future. 4. The water from the lavatories is conveyed away by the same drains which carry away the roof water. That from the kitchen with other impurities flows into a pit, which is cleaned out daily, and the contents of which, like those of the privies and urinals, is carried off by the filth carts every morning. 5. The wards are raised 3 feet above the level of the ground, and there is a free perflation of air underneath the floors. The roof water is conveyed away in open drains (after reaching the latter through baked earthern spouts) to the main drain out of the station. The drains run all round the hospital, and are constructed on the same principle as those round the barracks. The hospital drains all have a considerable drop where they meet the main drain, consequently the forcing back of the drainage in the station generally does not affect them. As regards materials, one of the hospitals is iron framed, with a covering of thatch. The others have the usual flat "pucka" roof. The roofs and walls are all single, and sufficiently thick to keep the hospital cool. The walls of all, excepting the iron-framed hospital, are of solid masonry. The main hospital has a 12 feet enclosed verandah on each side. So has the female hospital. The native hospital has open verandahs, affording sufficient shelter for natives, but not for Europeans, who have occupied it of late. With the aid of matting, however, the sun is excluded. The iron-framed hospital has at present no outer verandahs, but is to have them added immediately on the east, south, and west sides. The enclosed verandahs are used for accommodating sick whenever the centre wards are full. The hospitals are one-storied buildings, well raised off the ground on brick arches. The following table shows the ward accommodation :— Total regulation number of beds, 390.

Wards.	Regulation Number of Sick per Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.

The hospitals are so placed so as to receive the full benefit of prevailing winds.

The jhilmils open outwards, the glass doors inwards, their arrangement and construction being conducive to ventilation and coolness.

6. For ventilation, besides the numerous doors and windows, there are in the main hospital large ventilating skylights, running the whole breadth of the centre ward, at intervals of 20 feet. They are 4 feet high and 6 feet wide, with glass sides, on hinges, which can be opened or closed at pleasure. There is also a sufficient supply of punkahs, which are in constant use from about the 1st April to 1st November.
7. There are no means of cooling the air, except punkahs, which are in use night and day, during the hot season, and afford much relief to the sick.
8. No means of warming required.

The ceilings and walls of the hospital are whitewashed once a year with two coats. The walls, to a height of 6 feet, can be whitewashed and cleaned as often as the Medical Officer in charge deems it necessary to call on the barrack master to do so.

9. The main hospital has a privy and urinal, both in one, at either end, 20 yards distant and connected with it by a covered way. In each is a series of copper pans set in stools, and their contents are emptied directly into the filth cart every morning.

The iron-framed hospital has also a privy and urinal at each end, connected with it by a covered way. The construction is the same as the barrack privy. The filth removed is carried 1½ miles distant.

10. There are two lavatories, like those of the barracks, opening out of the north verandah of the main hospital, and sufficient for the sick. The lavatories of the iron-framed hospital

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	are connected by a covered way. The native hospital latterly used by the artillery has no lavatory; the men wash in the verandah, but hereafter they are to be accommodated entirely in the main hospital. 11. There are two rooms out of the verandah of the main hospital for hot, warm, and shower baths. There is the necessary boiler and cistern. 12. The hospital linen is washed at a tank adjoining the hospital and dried in the sun by the washermen, who "do the linen up" at their own houses. 13. The storage is sufficient and dry, or will be so on the completion of certain repairs and improvements now in progress. 14. The hospital cots in use are 3 feet high, $2\frac{1}{2}$ feet wide, and $6\frac{1}{3}$ feet long. The framework is of wood, and the bottom either of cane or of crossbands of iron. The bedding, *i.e.*, the mattress, pillows, and bolsters, are of "Kharooa," a coarse kind of red cotton cloth, stuffed with tow. It has been decided to introduce iron bedsteads shortly, with closely cross-hooped buttons; mattress of coir covered with English ticking and tree cotton pillows. When these come into use there will be no just cause of complaint. Each patient has also two sheets and a country blanket, or two if necessary. 15. The kitchen of the main hospital is about 40 yards to the north of the wards. That of the iron-framed hospital is within 20 feet The cooking apparatus is the same as within the barracks. It is sufficient, but the cooks are not highly paid, and of the worst description, therefore requiring constant supervision. When the hospital is not overcrowded considerable variety of fairly cooked diets can be obtained. 16. The diet tables, &c. are those of the Bengal Medical Code. 17. The sick are nursed under a hospital serjeant and native "ward coolies," who fetch water and make themselves generally useful. When sick men cannot quit their beds, one or two comrades are allowed to attend them, and to make the ward coolies do their duty. When the medical officer and his subordinates and the hospital serjeant are vigilant, patients rarely want for proper attendance. 18. I consider the sanitary condition of the hospitals as satisfactory. No epidemic has appeared in the men's ward. Cholera showed itself in the female hospital two years ago, when it was overcrowded. The ventilation at that time was imperfect, but has since been greatly improved. It appeared also that some animal having got under the floor of the hospital through a broken grating, and perished there, was at the time referred to as a probable cause of sickness. 19. I know of no deficiencies or sanitary defects requiring removal which are not in the course of being remedied; many improvements have been carried out during the last two years, through the instrumentality of Medical Officers. 20. There are good dry walks and seats for convalescents for morning and evening use, but there are no trees or shady walks about the hospital. There is a light and easy ambulance waggon, drawn by two bullocks, for giving convalescents an airing 10 at a time. 21. There is a female hospital, where the families of soldiers are attended by their regimental surgeon. There is no matron at present, but two native female attendants. Diets and medicines are prepared and supplied as for the men's hospital. I think every considerable station ought to have a matron for the women's hospital, to act under the surgeon. She ought to be an experienced nurse, and capable of assisting at confinements. 22. There are no local hospital regulations. 23. I believe that in stations the surgeon has practically now-a-days (especially when supported by his Commanding Officer) every necessary power in matters appertaining to the sanitary state of his hospital, repairs of buildings, diets, medical comforts for the sick. He has great power also in camp and on the march, but its degree there must depend on circumstances. 24. A convalescent hospital or wards are not required. In the event of an epidemic, it would be better to send the recovered men away altogether for a time.
XIII. BURIAL OF THE DEAD.	1. The burial ground is about a mile N.E. from the barracks, the prevailing winds being N.W. and S.W. No inconvenience is ever felt from the graveyard. 2. The old burial ground being full, a new one was lately consecrated. Its area is 3 a. 3 r. 30 p. It adjoins the old one. The soil and subsoil are those already described. There is little drainage possible, and there are no funds for laying out or keeping the ground. The new one is, however, to be laid out with care on a plan by the Chaplain. 3. The grave there is $2\frac{1}{2}$ feet by 7, with 2 feet between the graves. Usual depth 4 feet. Never re-opened as a general rule, though it has happened. There is no positive regulation as to times of burial, either at ordinary times or during epidemics. Natives always dispose of their dead a few hours (within 12 hours) after death. 4. Graveyard never known to be offensive, and no precaution required to prevent nuisance. The usual practice is to bring soldiers 6 or 18 hours after death, generally at sunrise or half an hour before sunset. The coffin is conveyed in a cart. 5. The Hindoos throw their dead into the Hoogly. The Mahommedans bury them in two or three burial grounds, near the station. 6. I am not aware that any injurious consequences result from the present practice. 7. I think, as an improvement, that a small sum might be allowed by Government, and placed at the disposal of the Chaplain, for keeping the ground in order. During epidemic time the dead ought to be buried within 12 hours *at most* after death. I have known bodies to be kept too long, and ill effects to follow.

(Signed) J. B. DENNIS, Lieutenant-Colonel Royal Artillery, commanding at Dum Dum.
HUGH M. MACPHERSON, Surgeon Bengal Artillery.
T. M. HEYWOOD, Lieut., Assistant Engineer.

I. Topography.	1. The station is located on alluvial soil, which continues eastward throughout the country; liable to inundation from the Ganges. Westward the same description of soil continues on the right bank of the Bhagirutty river for three miles, till it reaches the raised land or platform, consisting principally of disintegrated earth, abounding in nodular limestone and fusiform iron ore. The country is flat, sandy and swampy. Water in considerable quantity, also much wood and jungle. 2. The station is 76½ feet above the level of the sea. The station is on level ground, about 3 feet below high-water mark in the river. There is higher ground, but of limited extent, three or four miles south-west from Berhampore, on the right bank of the Bhagirutty. It ranges from 50 to 60 feet above the highest flood level in the Bhagirutty river. In a military point of view it has disadvantages, being cut off by the river from the City of Moorshedabad. The valleys during the rains are full of water, which remains till December or January, and the country is considered unhealthy by the natives. 3. The nearest range of hills is the Rajmahal range, about 40 miles distant. Their heights vary from 300 or 400 feet to 800 or 1,000 feet. They are covered with dense jungle. 4. The station is on the left bank of the Bhagirutty, and is surrounded with jheels. The right bank of the Bhagirutty and the land to the north of Berhampore is occasionally liable to overflow from the river during the rainy season. All the jheels overflow during this season, or from the beginning of July to the end of September. There are many holes in and around the cantonments full of water during the rains and cold weather, and half full during the rest of the year of stagnent water and decaying vegetable matter. These holes are of no great size, and are at too great a distance from the barracks to have any injurious effect on the troops. Residents in the immediate vicinity suffer from remittent and intermittent fevers, more than those living at a distance from them. 5. The men's barracks and officers' quarters are in a square, and are as open and exposed to the prevailing winds as two native bazaars, north and south of cantonments, and the square plan of the buildings allow of. The temperature is not perceptibly raised by reflected sun heat, but the circulation of air is impeded by the causes stated in the previous answer. The station is exposed to land winds from the west and north-west from October to March, and from east and south-east from April to September. Squalls, with rain from the north-west, frequently occur in the months of April and May, and their effect is always beneficial. 6. The country surrounding the station is cultivated. There are no works of irrigation near the station. Rice is not cultivated to any extent near the station, although the cultivation is not prohibited. There is no cultivation of indigo or preparation of hemp or flax carried on near enough the station to have any injurious effect. 7. The outskirts of the town of Berhampore are contiguous to the station. 8. The surface consists of a thin crust of vegetable mould over alluvium, sand, and clay. The station is a very old one, and in all probability the ground on which it is formed had not been previously occupied. 9. During the dry season water is found about 30 feet below the surface; during the wet season immediately below the surface. Indeed the level of the station is below high-water mark, and is protected by an embankment raised along the left bank of the river. 10. The rain fall and surface water does not flow readily away. As the water in the river and jheels falls, the rain fall is partly carried into them by surface drains and by percolation, but it is chiefly carried off by evaporation. There is no drainage from any higher ground which passes into the subsoil of the station. 11. Water is derived from the river, wells, and tanks. Drinking water for European troops is chiefly drawn from wells, and that for the natives from a tank close to their lines, which is carefully guarded. With this exception tank water is not generally used for drinking. The tanks are kept as full as possible, but during the hot season they become more than half empty. The usual vegetation in tanks consists of water lilies, water bean, duckweeds, sedges, horse tails, grasses, and reeds. The usual animals are Indian carp, fresh-water shark, cuttle fish, Indian eel, fresh-water mullet, Indian jack fish, Indian frog, musquitoes, infusoria, &c. No tank used for drinking is ever used for bathing. The drinking water for the station is not liable to pollution. At the close of the rains, and during the early part of the cold weather, there is much unpleasant smell from the tanks and jheels, in and around cantonments, from decaying vegetable matter. No arrangement is made for keeping the tanks trimmed and clean, and cleaning out the long grass, reeds, and weeds, growing around their edges, which would prevent the evil. 12. The water supply is almost unlimited. The water from the wells is tolerably pure, and quite free from taste and smell when passed through charcoal, which is supplied in rude but efficient filters to every barrack. When filtered the water is perfectly good. There are no means available for ascertaining its chemical composition. It is raised in leather buckets by manual labour. No better water supply is obtainable. 13. The drainage of the station outside the barrack square is greatly neglected. The ditches dug along the road sides for the purpose are generally most uneven at bottom, and much too deep to be of much use as drains; the consequence is, that the rainfall is not carried off as

BERHAMPORE. BENGAL.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	it might be, but is left to evaporate or pass slowly into the subsoil. As it gradually dries off it leaves rank vegetable matter at the bottom of the ditches, for the sun to act upon. Although the European troops do not suffer from this cause, being located at a distance from it, the native troops do, as do all the residents out of the barrack square. 14. There are no published rules as to the selection of stations. When a new station is to be formed, a committee is nominated to report on the site by the commander-in-chief, under special instructions transmitted from head-quarters.
II. CLIMATE.	1. The meterological instruments at this station consist of a thermometer, F., an aneroid barometer, and a pluviometer. 2. The following table gives the mean of observations for three years, from January 1857 to December 1859:—

Months.	Barometer Mean. in.	Mean Temperature.	Mean Daily Range.	Mean Max.	Mean Min.	Rain, Inches.	Winds. Directions.	Winds. Force.	Remarks.
		°	°	°	°				
January -	29·94	64	25	76	51	0·06	Westerly	Moderate	Heavy dew at night, occasionally dense fog in the morning before 10 a.m.
February -	29·90	68	28	82	54	0·48	Do.	Do.	Do. do.
March - -	29·86	78	30	91	61	0·46	N.W.	Do.	Occasional squalls, generally commencing about sunset, and lasting from one to two hours, with more or less rain.
April - -	29·74	83	29	98	69	1·41	N.W. & N.E.	Do.	Do. do.
May - -	29·62	85	28	99	71	6·11	W., E.	Do.	Do. do. Frequently cloudy during the day.
June - -	29·51	87	23	100	77	6·85	E. & S.E.	Do.	Very hot and oppressive during the first half of the month. Temperature much reduced by the fall of rain during the latter half.
July - .	29·50	84	14	92	76	13·63	S.E.	Do.	Generally cloudy through the month.
August -	29·57	81	13	90	77	9·65	S.E.	Do.	Do. do.

November -	29·92	70	21	81	60	—	N.W.	Do.	Heavy dew at night, occasionally dense fog in the morning before 10 a.m.
December -	29·95	65	20	75	55	0·20	N. & W.	Do.	

3. The climate is damp. There are frequent fogs, especially during the cold weather, which however, rarely last longer than from before sunrise until 9 or 10 A.M. The heat is very oppressive during April, May, and the early part of June, but is often reduced for two or three days at a time by squalls from the N.W., which clear the atmosphere and act most beneficially on the health of the residents.

The troops stationed at Berhampore during the last two years have not been more unhealthy than at other stations. The present rules as to diet and clothing appear to be well suited to the climate. The men should be restrained as much as possible from unnecessarily exposing themselves between sunrise and sunset from April to October. Duties, drills, and exercises should be limited accordingly.

The most healthy months are December to February. The most unhealthy from August to November, when the prevailing diseases are fevers of the remittent and intermittent type, affections of the spleen, diarrhœa, dysentery and affections of the liver, and rheumatic affections.

4. I am unable to say, from personal experience, whether there be any locality more conducive to health in the neighbouring districts.

5. The following is a list of the stations at which I have served:—

Cawnpore.—Unhealthy.
Etawah.—Comparatively healthy.
Banda.—Unhealthy.
Mynpoorie.—Healthy.
Mussoorie.—Hill sanitarium.
Allyghur.—Healthy.
Shahjehanpore.—Healthy.
Naynee Tal.—Hill sanitarium.
Allahabad.—Comparatively healthy.
Futtyghur.—Comparatively healthy; might be rendered more so by prohibiting the manufacture of lac dye and saltpetre within the boundaries of or close to cantonments, and the cultivation of melons in the bed of the river near the station, during the dry season.
Berhampore.—Has not been unhealthy as compared with other stations in Bengal Proper during the past year; my experience does not extend much further back.

III. SANITARY CONDITION OF STATION. 1, 2, 3. Maps and plans.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	4. The following table gives the accommodation at the station :— Date of construction of barrack unknown, supposed 80 years ago. Total number of barracks—three upper storied and eight lower roomed.

Barrack Rooms.	Regulation Number of Men per Room.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in feet per Man.	Height of Beds above the Floor.	Doors (no windows).		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
3 Upper Roomed Barracks :		Feet.	Feet.	Feet.	Feet.					Feet.	Feet.
2 rooms each=6 barrack rooms.	52	153	22	16	53,856	1,037	70	1½ to 2 ft.	34	10	5½
4 rooms each=12 rooms.	24	108	18ft. 3in.	16	31,536	1,314	82	1½ to 2 ft.	26	10	5½
4 Lower Roomed Barracks :											
1 room each=4 rooms.	100	300	26½	16	127,200	1,272	79½	1½ to 2 ft.	88	7	4
Guard room - -	4	10	16	16	4,096	1,024	64	1½ to 2 ft.	—	—	—
Prison cells ; 24 in 2 ranges, with corridor between.	1	10	7	18	1,260	1,260	70	—	—	—	—

Four of the 24 men's rooms in each of the upper room barracks are occupied by men, and four are for messing and recreation. Thus there are only 200 men in each of the upper room barracks. All the rooms communicate with the verandahs by open doorways; the Venetian doors being all placed in the outer walls of the verandahs. These verandahs are on both sides; they are 12 feet broad and 16 feet high under the beams. In the lower room barracks there are two enclosed verandahs, 327 feet long, 11 feet broad, and 16 feet high, used for messing and recreation; and there are also two outer verandahs of the same length and breadth. Each centre room for men is divided into fifteen compartments, 8 feet high, with passage 4½ feet wide at each side. There are four lower room barracks of the same dimensions as above, divided into compartments, each 26 feet long by 8½ feet wide, for quarters for 120 married families.

5. As already stated, there are no windows, but Venetian doors opening to the ground on opposite sides of the barrack. The verandahs are never used as sleeping quarters. There are jalousies.
6. The bedsteads consist of iron laced cots on wooden frames, mattresses stuffed with hemp, blankets or coverlets consisting of cotton sewn between layers of chintz, and sheets.
7. Tents are double-poled, each pole 10 feet high, with a ridge pole between them of six feet. The length of each tent is 20 feet, and the breadth 15 feet, with accommodation for 16 men at 129 cubic feet, and 18 feet 9 inches superficial per man.
8. Barracks and guard-rooms are ventilated through the roofs, which are pierced with holes 2½ feet in diameter, and covered with earthen ventilating zumlahs. The ventilation is sufficient to keep the air pure by night and day. Punkahs are supplied to every barrack for cooling the air. They are made of long wooden frames, over which cloth is stretched. To the lower margin of the frame a double frill of cloth, about nine inches deep, is fastened. These frames are from 20 inches to 2 feet deep, and are attached by long ropes to the beams of the roof. They are swung backwards and forwards by a rope attached to one of the sides.
9. The barracks are constructed of brick and mortar, with flat and terraced roofs on saul wood beams. Tents are of canvas. Huts which are only used by native troops and camp-followers consist of mud walls, with thatched or tiled roofs.
10. The floors are terraced and tiled. Those of three upper room barracks are 2½ feet above the level of the ground. Four lower room barracks, and four barracks for married men, have the floors barely 1½ feet above the ground. The floors of these eight barracks have been lately asphalted and much improved. There are no air-flues under them, the plinth being filled in with broken brick and rubbish.
11. Probably no improvement could be suggested in the materials or construction. The repairs are under the barrack department, and are executed by the public works department on requisition. There are three kinds of repairs—annual, petty, and emergent. The commanding and sanitary officers are responsible for the sanitary state of the cantonment. Lime washing is done annually throughout, or whenever required by the medical officer.
12. Every barrack is supplied with lavatories, both for men and women. The water is supplied from the tanks and wells, carried in goat-skins by men, poured into external cisterns, and conveyed into the rooms by leaden pipes with tap-cocks. The drains from them empty themselves into the surface drains.
13. The cooking is carried on, in the usual fashion of the country, in open fire-places. The water is supplied by water carriers, and the refuse water is carried off in open drains.
    The washing and drying of linen are performed by native washermen at a distance from the station. No convenience for this purpose exists in the barracks.
14. The contents of privies are carried away in cylindrical revolving night carts, and deposited in pits about a mile from cantonments. The urinals are mere wells, and the contents pass into the soil. This latter arrangement is most objectionable, the urinals being frequently full and very offensive. The buildings are ventilated by louvre boards the whole length of the building.
15. The barracks and outbuildings are lighted at night by oil lamps.
16. The following are the arrangements for drainage and sewerage. The barracks are surrounded by open concave drains from two to three feet in breadth, and about six inches in depth,

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	These are daily washed and sprinkled with lime. All surface drainage empties itself into a large tank, a quarter of a mile long, and 320 feet broad, immediately in rear of the barracks. The drainage of the barrack square is sufficient for removing surface water. All the lower room barracks are damp, but less so since the floors have been asphalted. The dampness is caused by the level of the floor being 1½ feet lower than the highest flood level of the river. The cesspits to which the contents of the privies are carried are about a mile from the barracks, and about a mile and a quarter from the hospital. They are merely holes of a certain depth, which are filled up when necessary, and others dug instead of them. The cantonments are surrounded with jheels within half a mile, and the bazaars, looking in the stations to the north and south, abound in foul ditches with putrid water. 17. The barrack drains are cleansed by the conservancy establishment of sweepers, under the barrack department, as often as required. Manure is removed in carts, of which only one is permanently allowed, which is quite insufficient for a square mile of cantonment. 18. Cropped grass is the only vegetation within the cantonment, together with a few gardens of residents. No sanitary improvement can be made, as regards external ventilation, so long as bazaars full of jungle holes and huts enclose the cantonments on two sides. 19. Nothing can be worse than the sanitary condition of the bazaars. Conservancy establishments are kept up under the magistrates on a scale far too limited to be of much real benefit. But, were it otherwise, the habits of the natives are such that but little improvement could be hoped for without the most stringent regulations enforced, and carried out by Europeans specially employed for the purpose. The native houses are dirty in the extreme. There are either dung heaps close to them, or deep holes full of stagnant water in their immediate neighbourhood; these are the common cesspit of the house. There is no nuisance from the native dwellings unless the wind blow from the north, when there is frequently a most offensive smell from holes full of dirty water and filth, and also from the elephant and bullock sheds, which are far too near the barracks. The nuisance might be removed by filling up the holes, or at least by trimming their banks, and preventing the natives from resorting to them, also by removing the elephant and bullock sheds to a greater distance. 20. Animals for the use of the soldiers are slaughtered about 300 yards from the station. The slaughtering places are washed with lime morning and evening under the supervision of the commissariat serjeant. No nuisance whatever is experienced in the station from these places. 21, 22. There are no cavalry at the station, and no bazaar horses in cantonments, except a few in the native lines, at the end farthest from the barracks, for Europeans. 23. There is accommodation for 120 married families. No married people occupy quarters with the men.
Officers' Quarters.	1. Officers occupy hired quarters, formerly the property of Government, but sold in 1801. They are low and damp, and much out of repair. The floors, with a few exceptions, are raised only 18 inches above the ground. There are no drains under the floors, and, as a consequence, the damp is continually rising up through them. The only ventilation is by windows and doors. The proprietors should be compelled to keep these quarters in a proper state. They are not susceptible of improvement, unless a second floor could be raised on arches 18 inches or 2 feet above the present floors.
IV. HEALTH OF THE TROOPS.	1. The district and the native population are unhealthy, particularly during the latter part of the rains and the early part of the cold season. 2. The most prevalent diseases among the native population are rheumatic affections, fevers of all types, bowel complaints, diseases of liver, spleen, and lungs, cholera, and small-pox. 3. The causes of this are damp climate, rank vegetation, holes full of stagnant foul water, close to almost every house, forming the usual cesspool of the neighbourhood. Imperfect drainage. The utter neglect of ventilation, and of all sanitary measures generally, and the low level of the surrounding country. 4. The stations at which the troops served before coming here were as follows :— *European Troops.*—Lucknow for 4 months, leaving October 5th, 1859. The men suffered much there from fever, dysentery, and venereal disease. Arrived at the present station healthy on October 22nd, 1859. Since arrival the diseases from which they have chiefly suffered are fevers, rheumatism, diarrhœa, dysentery, hepatic and venereal affections. *Native Troops.*—Last station, Calcutta for 18 months. Left it December 11th, 1859. They suffered in Calcutta from fevers, dysentery, cholera, and venereal affections. They arrived at Berhampore healthy on December 23rd, 1859. Since arrival they have suffered from fevers, dysentery, rheumatism, and venereal diseases. The lower roomed barracks are more unhealthy than the upper roomed barracks, on account of dampness. 5. Troops are not camped out at this station. 6, 7, 8. I cannot speak from experience as to the effect of hill climate on troops. I have held medical charge of two of the sanitaria for civilians, and, judging from observation in them, I should most strongly approve of hill stations for troops if carefully selected. 9, 10. There are no special diseases at these sanitaria, except at Almorah, where every person on arrival is liable to be attacked with diarrhœa, but in a very mild form. It is generally attributed to the drinking water. Boiling the water and filtering it through charcoal when cool is considered a necessary precaution, and a successful one. 11. The best seasons for residence at hill sanitaria are the hot weather and rains. But invalids, for whose diseases the climate is suitable, should always remain during the winter also, if possible. The best period of residence is 18 or 20 months, arriving at the hills in March, and remaining till the following November twelvemonths. 12. There is no period of residence at hill stations which would make troops more susceptible to disease on returning to the plains. 13. The special precautions required on leaving hill stations are attention to clothing, much warmer clothing being required for the hills. Lighter clothing is required when near the foot of the hills; but the chief precaution to be taken is not to allow the men to obtain country spirits, a precaution more necessary than it appears at first sight. 14. I consider that service in the plains, with a change to the hills for a couple of years, after intervals of four or five years, would be equally conducive to the health of a steady man of good constitution, as a longer residence in the hills and shorter service in the plains, if suit-

References to Subjects and Queries.	Replies.
IV. Health of the Troops—*cont.*	able indoor employment and amusement were provided during the hot weather and rains on the plains. Change of station on the plains about every two years would be beneficial. 15, 16. No experience of the accommodation at hill stations. The present hill stations range from 6 to 8,000 feet above the sea. 17. There is no higher ground near the station. 18. The most healthy ground for stations is a surface formed from disintegrated limestone mixed with vegetable mould, and a subsoil of sand mixed with light clay, such as is found in many parts of the north-west provinces. 19. Soldiers proceeding to India should not be under 22 years of age. The best period in which to arrive in India is from November to January. Strict attention should be paid to clothing on arrival; recruits should be prevented from unnecessarily exposing themselves in the sun, and they should be kept out of bazaars. 20. Recruits should be sent direct from home to India, and sent up at once to the north-west provinces and the Punjab. 21. Troops proceed to the interior in well-covered bullock carts, one-third of the men marching by turns, or they are marched up, proceeding some 10 or 12 miles each day, to the next encamping ground, where tents are pitched and arrangements made for their comfort; or they proceed by water in large roomy flats towed by steamers. Every reasonable precaution is taken to prevent exposure by land, or overcrowding in the flats, and to provide for the comfort of the men. 22. As regards the length of service in India, a man of sound constitution, acclimated and of steady habits, might serve as long in India as in any other part of the world out of England, if due precaution against unnecessary exposure be observed. 23. In conducting medical boards, every member is free to express his opinion, which receives due weight. As a general rule there is little room for doubt as to the propriety of seconding the regimental surgeon's recommendation. No improvement can be suggested on this head, except that regimental medical officers should be authorized to apply for a board whenever they deem it necessary to bring a patient before one without reference to season. 24. The best season for invalids leaving India is from December to March.
Diseases.	1. There are health inspections every Saturday. 2. There is no scorbutic disease at the station. 3. The admissions into hospital from hepatic disease amount to 1 in 10·2 of the total admissions. Intemperate habits, exposure to the sun's rays, and malaria, are the chief causes of hepatic disease. It is generally preceded by derangement of the digestive organs, or by intermittent or remittent fever. The most likely measures to diminish the frequency of hepatic disease would be to provide indoor amusement and employment for the men, and so diminish the attraction of the canteen. Coffee and biscuit should be substituted for the morning dram, and the cleanliness of the men and of their quarters most strictly attended to. 4. There have been no cases of dracunculus. 5. Admissions into hospital from venereal diseases are 1 in 6·2 of the total admissions. No precaution for diminishing the frequency of this disease can be suggested, unless that when the men are in hospital from it, they should be subject to the loss of pay and of the time for service, a precaution of very doubtful benefit, as it might lead to long-continued concealment of the disease. Lock hospitals do not appear to be necessary in this country. 6. The troops suffer from epidemic diseases. The subjoined table is made up from very limited data, there being but a wing of Europeans (269 men) and two companies of natives at the station :—

Admissions to Total Admissions.

——	Quotidian Intermittent.	Tertian Intermittent.	Quartan Intermittent.	Remittent Fever.	Common Continued Fever.	Dysentery.	Cholera.	Rheumatism.
Europeans -	1 in 10	None.	None.	1 in 11·2	1 in 8	1 in 37·33	None.	1 in 9·33
Natives - -	1 in 5·13	1 in 20	1 in 120	1 in 6·9	1 in 10	1 in 17·2	1 in 69	1 in 6·5

	There have been no deaths from these diseases. 7. The type of disease is endemic, with rapid prostration of strength. These diseases prevail in the latter part of the rainy season and early part of the cold weather. The favouring atmospheric conditions are, a humid state of the atmosphere, the sun at the same time acting on the decaying vegetable matter exposed on the surface of the soil. There cannot be a doubt that the absence of sufficient attention to drainage around cantonments, and the difficulty if not impossibility of enforcing attention to cleanliness and ventilation in the native dwellings of the bazaars, which close in the station on two sides, and the foul holes full of stagnant water in the immediate neighbourhood, tend much to the prevalence of these diseases. From the preceding remarks it will be seen how much of the evil is attributable to the personal habits and conditions of the natives. Intemperate habits among the troops, and neglect of personal cleanliness, would also predispose to these diseases, as would exposure. Rheumatism is in the great majority of cases connected with a syphilitic taint. 8. The duties and occupations of the European soldier in barracks are not of a nature likely to increase the prevalence of epidemic disease. 9. Small doses of quinine have not been tried as a prophylactic at this station. 10. For the mitigation of epidemic disease I would recommend thorough attention to ventilation and cleanliness in barracks, as well as to personal cleanliness, also attention to the drainage and cleanliness of the station generally. The conservancy establishment should be raised to an efficient strength, and placed under a steady European, who should be held responsible for the cleanliness of the barracks and station. No native bazaar, not under military control, should be allowed within a mile of the station.

References to Subjects and Queries.	Replies.
V. Intemperance.	1. The soldiers at this station are usually temperate, and there are no confirmed drunkards.
	2. The proportion of admissions to hospital for diseases produced by intemperance are as follows:— Diseases directly produced - - - - 1 in 120; „ indirectly produced - - - - 1 „ 10. There are no total abstainers in the wing. 45·5 per cent. of the sickness, and 34·25 per cent. of the crime, occur among temperate men, and among drunkards the proportions are of sickness, 52·5 per cent.; and of crime, 65·74 per cent. Drunkenness *per se* is punished as an offence.
	3. Spirits are sold both at the canteen and at the bazaar. Canteen spirits are good; bazaar spirits are very bad. The average consumption of spirits per man per diem during three months ending March 31st, 1860, were—canteen spirits, 1·66 ounces; bazaar spirit, unknown. Spirit is no part of the ration at any time. Men are not known to take a dram before morning parade. Spirit is never given as a ration to convalescents.
	4. The consumption of spirits is injurious, except to old soldiers who have long indulged in the habit. It is conducive neither to discipline nor efficiency.
	5. It would be beneficial not to allow spirituous liquors as any part of the ration, and to abolish their sale in the bazaar, if such could be done. The sale of spirits might be allowed in the canteen under proper restriction.
	6. Malt liquor is far less injurious than spirits, and in many cases beneficial.
	7. Coffee, tea, lemonade, and other similar drinks are used at the station, and are highly beneficial.
	8, 9. It would be beneficial to substitute beer for spirits, except for those who have long indulged in excess in the use of spirits.
	10. I would recommend that the sale of good spirits be allowed at the canteen under proper restrictions, and to establish well conducted coffee and reading rooms at a distance from the canteen.
	11. There are no bazaar regulations on these points. Spirits are not allowed to be sold there, except with the sanction of the authorities. The canteen regulations are as follows:— 1. A non-commissioned officer will be daily appointed to superintend the canteen. 2. The canteen will be closed at tattoo. 3. No liquor is to be taken out of the canteen except by officers' and the sergeants' mess. 4. No person is to be permitted to remain in the canteen who appears to be under the influence of liquor. 5. No men confined to barracks, or convalescents, are to be allowed in the canteen. 6. No credit, under any pretence, to be given by the canteen man or his servant to any individual in barracks.
VI. Diet.	1. The ration per man per day for Queen's and European troops consist of— Bread - - - - - 1 lb.; Mutton or beef - - - 1 lb.; Rice - - - - - 4 oz.; Sugar - - - - - 2½ oz.; Tea - - - - - 5/7 oz.; Or, coffee - - - - - 1 3/7 oz.; Salt - - - - - 1 oz.; Vegetables - - - - 1 lb.; Firewood - - - - - 3 lbs. The meat ration is generally beef. It is changed for mutton twice a week. The tea ration consists of one-third green tea and two-thirds black tea. The vegetables are such as are procurable in the bazaar at the season. The rations are inspected every morning by the officer on duty, and by the quartermaster.
	2. Rations as above are provided. No fruit allowed as a ration. There are no stoppages for rations. The soldier takes three meals a day, viz.:— Breakfast - - - - - at 8 A.M.; Dinner - - - - - „ 1 P.M.; Tea - - - - - „ 6 P.M. The nature of each meal is settled by the majority of the members of each mess. The amount of vegetables in the ration is 1 part to 3½ parts.
	3. The present rations are sufficient for health. It is a military crime to dispose of rations.
	4. Cookhouses are attached to each barrack. Cooking utensils are chiefly made of copper, and tinned once every fortnight. They are always kept clean. Besides these copper boilers there are gridirons, and frying pans, with ladles and choppers, &c. The kitchens are clean, well ventilated, and sufficiently supplied with water. Whether the food is boiled or roasted is decided by the majority of the mess. The cooking is good. Tea, coffee, or other refreshment before a march is only provided by the men themselves.
	5. Soldiers' gardens could be advantageously established at the station, particularly during the cold weather, for then European vegetables and annuals can be raised. The management of the garden should be under an officer of the regiment, and a proportion of non-commissioned officers always present. The men might be allowed and encouraged to work during the greater part of the day in cold weather, and for an hour morning and evening during the rest of the year when off duty. They should be allowed to sell the proceeds on condition that they deposit the profits in the regimental savings bank.
VII. Dress, Accoutrements, and Duties.	1. The summer dress consists of cane helmet with cotton cover and a thick roll of cotton cloth around the outside of it over the temples. Loose white cotton tunic. White cotton trousers, socks, and shirt. Flannel under-shirt, ammunition boots. The winter dress consists of

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*cont.*	helmet as in summer during the day. Forage cap at night. Red cloth tunic, blue cloth trousers, woollen socks, white cotton shirt, flannel undershirt, ammunition boots, grey cloth great coat, only worn when necessary. The dress is suitable. The recent improvements in the hot weather clothing leave nothing to suggest in addition to the existing regulations. The men on guard are dressed as above and protected by sentry boxes.
Duties.	1. The men should be thoroughly drilled at home before being sent to India. 2. The usual routine of duties is as follows:—Reveillé at daybreak; second bugle half-an-hour afterwards; parade bugle in another half hour; guard mounting immediately before parade. Breakfast at 7.30 A.M. in hot weather, and 8 A.M. in cold weather. Dinner bugle 1 P.M. Tea 6 P.M. summer and 5.30 P.M. winter. Tattoo 9.30 P.M. in summer and 8.30 P.M. in winter. Drill parades twice a week from 1 to 1½ hours' duration. Bathing parades twice a week. The men do not suffer from parade or drill. There are no general orders respecting these. The best hours for drill and parade are one hour before sunrise in the hot weather, and in the cold weather an hour after sunrise, and an hour before sunset. When marching, the men should reach their ground in the hot weather before 8 A.M. The men have on an average four nights per week in bed. 3. The furthest European guard from barracks is 600 yards. The furthest native guard is about a mile. Guards last 24 hours, from 7 A.M. to 7 A.M. There are roll calls by day only for defaulters, three times daily. There is no bad effect from night guards on the health of the men now at the station. No additional precautions to those taken are requisite. During the rainy season and cold weather the sentry should always have his great coat within reach.
III. Instruction and Recreation.	1. There are five ball courts and two skittle grounds at the station. There are no schools. There is a library and reading room, but neither are lighted at night. There are no day-rooms, soldiers' gardens, workshops nor gymnasia. A theatre is being fitted up. The means of recreation are not sufficient. During the hot weather and rains the men are not allowed out of barracks between 8 A.M. and 5½ P.M. The restriction is beneficial to health. No restriction during the cold weather. 2. The establishment of reading rooms, workshops, theatres, and soldiers' gardens would greatly increase the existing means of recreation, and be very advantageous in every respect. 3. Savings banks have now long been introduced generally in European regiments. They are advantageous. 4. There is not sufficient shade to enable the men to take exercise without injury to health during the day.
IX. Military Prisons.	1. A new and commodious military prison, with every precaution for preventing injury to the health of the prisoners, has been constructed during the past year.
X. Field Service.	1. There are no regulations as to field service not included in the general Presidency regulations. 2. Medical officers are not consulted in general in the field, except in selecting the ground on which to pitch the hospital tents. 3. There are no sanitary regulations to which reference can be made at this station. Camping grounds are selected with as much care as circumstances allow of, particularly with reference to high and clean ground, and a supply of good water. Medical officers are not consulted, except in the choice of a site for the hospital tents. 4. There is no copy at the station of any regulations bearing on the subject of field hospitals.
XI. Statistics of Sickness and Mortality.	1. No returns.
XII. Hospitals.	1, 2. The hospital is situated about 250 yards N.W. of the barracks, about 180 yards S.W. of the bazaar, and about 250 yards from the nearest officers' and civilians' quarters. The upper story is open and exposed to the prevailing winds. The circulation of air round the lower story is much impeded by a high brick wall with earthen bastions at the corner, which completely surrounds the hospital. The site is objectionable; close to the bank of the Bhagirutty, which for six months in the year is a nearly dry sand-bed, exposed to the sun's rays. The hospital site is perhaps rather lower than that of the barracks. The drainage is very imperfect. The surrounding ground is uneven, but there are no marshes, nullahs, or water pits in the immediate vicinity. The bank of the river in the dry season is perhaps the greatest nuisance, as it is almost impossible to prevent natives resorting thither after dark. 3. Water is derived from two wells within the hospital enclosure, but the water from them, as elsewhere, requires to be filtered for use. Water for the purpose of ablution is obtained from the river. 4. The only means of drainage consists of one small drain for carrying off refuse water, &c., which communicates with a cesspool immediately outside the wall of the enclosure, about 30 yards from the hospital building. 5. The floors are raised two feet above the ground. There is no perflation of air underneath the floors. The roof water is all carried off by the surface drains. It does not sink into the subsoil. There are three principal surface drains made of brick and terraced over, extending the whole length of the hospital enclosure, parallel with the hospital. Into these all the lesser surface drains open. At one extremity they communicate with the open drains of the station, and at the other with the river. There is not sufficient fall to carry the rain-water rapidly off. The hospital is built of brick and mortar, walls 2 feet 6 inches thick; roof flat, terraced, 1 foot thick. The hospital is generally cool. There are enclosed verandahs on both sides, 15 feet 9 inches thick. There are no open verandahs. Sufficient shelter from the sun's rays is not afforded. The verandahs are not used for accommodation of sick or others.

References to Subjects and Queries.	Replies.

The hospital is two floors in height. Date of construction unknown. Seven wards; 156 beds.
The following table gives the accommodation :—

Wards.	Regulation Number of Sick per Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area per Bed.	Height of Bed above the Floor.	Doors or Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.

XII. Hospitals—*cont.*

There are no windows on the lower story. There are Venetian doors. The upper story is provided with glazed doors as well as Venetian doors. The glazed doors are in two leaves, which fold back from the centre inwards. The arrangement is conducive to ventilation and coolness. The Venetian doors open outwards in their upper two-thirds. The lower third is fixed.

6, 7. Ventilation is provided for by openings above each door, 3 feet high and 2 feet wide. Punkahs are pulled night and day during the hot weather in each ward. The upper story wards are at all times free from odour and closeness. The ventilating openings are about 2 feet above the doors, and are fitted with jalousies. No means of cooling the air except punkahs.

8. No means of warming required.
The walls and ceilings of wards are cleansed and limewashed twice a year.

9. The two principal privies are placed 36 yards behind the hospital, to the north of it, and there is a covered archway leading to each. The privies are supplied with copper pans, having metal covers. The pans are 2 feet deep. The urinals are cylinders of plate iron, 3 feet deep and 18 inches in circumference. There is a separate privy for the natives, not much used. The drainage is very imperfect. There is a cesspool attached to the privy for natives, but not to either of the others. The pans being kept clean they are not offensive.

10. The lavatories are provided with baked earthen basins, which appear to be sufficient.

11. The bathing house, provided with hot and cold baths for the sick, is out of repair. The men are now provided with wooden tubs, 3 feet in diameter and 2 feet deep. The arrangement is a very inconvenient one for the sick.

12. The hospital linen is washed by washermen, at a distance from the hospital.

13. The hospital storage is sufficient and dry.

14. The bed cots are wooden frames with laced iron bottoms. The bedding consists of a mattress, large and small pillows, stuffed with country hemp, two sheets, one country blanket, and one ditto lined with chintz.

15. There are two hospital kitchens, placed about 40 yards behind and north of the hospital. The fire places are the same as those used by the natives for cooking. The cooking utensils are of copper, tinned once every fortnight. The arrangements appear to be sufficient, and the diets can be varied as may be necessary.

16. Diet tables and rolls are the same as in other European hospitals.

17. As regards attendance on the sick, one hospital serjeant is allowed, and orderlies, chosen from the men in barracks, are obtained when necessary, on application of the medical officer. There are no regular nurses or orderlies. Trained orderlies would be greatly preferable to the present arrangement.

18. With reference to the general sanitary state of the hospital, it has not been necessary to place any sick on the ground floor of the hospital since the arrival of the troops now here. The state of the upper floor appears to be satisfactory. No epidemic disease, hospital gangrene, or pyæmia have appeared among the sick.

19. As to general defects, the drainage of the hospital compound and surrounding ground is very defective. The bath room is of no use in its present state, but if repaired might be made serviceable in treatment.

20. Patients are allowed to walk in the compound and on the flat roof of the hospital, morning and evening. There is no shade from the sun's rays, no walks or seats set apart for the use of convalescents.

21. A ward is set apart for soldiers' wives and children, who are on a similar footing as regards medicines and comforts as the soldier; but one anna a day only is deducted for stoppages. The arrangements are satisfactory.

22. There are no local hospital regulations.

23. Repairs in the hospital buildings are executed on the requisition of the medical officer countersigned by the commanding officer of the station. Hospital diets and all changes in them are arranged by the medical officer only. Medical comforts are supplied to any extent required, the only check being that the approval and counter signature of the Deputy Inspector General are required every month.

24. There are no convalescent wards; the broad enclosed verandahs render such wards unnecessary when the number of troops is so limited.

XIII. Burial of the Dead.

1. The European burial ground is about a third of a mile from the barrack square, in an E.S.E. direction; the prevailing winds being S.E. and N.W. There is a separate burial ground for officers and non-military residents.

2. The burial ground is 600 feet long by 421½ feet broad. Soil and subsoil as already described. Drainage none. The ground is a perfect swamp in the rains. It is kept as carefully as this circumstance admits of. It is surrounded by a wall 4 feet high.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead —*cont.*	3. There is no limit as to size of grave spaces. The depth is 5 feet, and graves are not reopened. There is no limitation as to times of interment after death, either at ordinary times or during epidemics. The bodies of Hindoos are burnt and thrown into the river. The bodies of Mohammedans are buried in their own burial ground, at a distance and beyond the limits of military authority. 4. The European burial ground is offensive occasionally from decaying vegetable matter rather than from other causes. Attention to drainage and preventing the growth of long grass would prevent all nuisance. Burial generally takes place 12 hours after death. In all cases the time is left to the military surgeon. 5. The dead of the camp followers are disposed of in the same way as the dead of native troops. 6. The river is frequently most offensive from the remains of half burnt or unburnt bodies floating down. The birds of prey prevent the nuisance being of long duration. 7. Complete incremation should be enforced before a body is thrown into the river. It would be a blessing to the country if throwing bodies into the river could be entirely prohibited.

Thos. Ross, Lieut.-Col., Commanding the Station.
Fred. P. Layard, Captain, Executive Engineer, Bengal District.
J. A. Guise, Surgeon Major, Bengal Medical Establishment.

10th June 1860.

DINAPORE.

Accommodation
- Queen's Troops
  - Artillery — 1 company with battery, and 1 reserve company; but not completed.
  - Infantry — Old Barracks—6 companies. New Barracks—A full regiment.
- Native Troops
  - Cavalry — Lines for 1 Cavalry regiment to be erected.
  - Infantry — Ditto. ditto.—1 regiment.

I. Topography.	1. The surrounding country is a dead level, little above high flood mark. It is flat, and much covered with water in rains. It is dry in the cold weather, and during the hot the soil cracks. The Ganges runs along the north face of the cantonment. A nullah passes along the south side on the western portion, and afterwards passes through the centre towards the Ganges; during the rains the nullah is flooded. There is much wet land, more or less flooded, to the south and west: on the south side of the cantonment is a filthy hollow, and behind it a deep and offensive hole. 2. The elevation of the above the level of the sea is 212 feet, and above that of the adjacent country a few feet only. The Ganges is the nearest river. A nullah runs through the station, and there is a swamp near the magazine, on the south side of the cantonment. I do not consider there is any higher or healthier ground adjoining the station. 3. The nearest table-land I believe to be at Burhee, on the Grand Trunk road, distant about 120 miles. The elevation of Burhee is about 1,500 feet above the level of the sea, and about 1,290 feet above the station. 4. With regard to the nearest water from the station, the Ganges forms the boundary on the north; the nullah runs through, and there is a marsh within the boundaries on the south side. N.B.—Both nullah and marsh dry up in the cold weather. The vicinity of the station is liable to overflow. In wet seasons the station may be said to be under water all but the strip on the river bank. In ordinary years the west parade ground is half flooded after every rise of the river. There is much broken ground along the banks of the nullah, where earth has been dug for bricks and other purposes; but the worst is the hole near the magazine, and the hollow in Moorgeeah chuck, behind. They undoubtedly tend to increase fever and dysentery in the drying up season, September and October. 5. The station is tolerably open, and nearly a dead level. There are not many walls of any height. The officers' bungalows on the river's bank are rather crowded, and the trees scarcely trimmed enough. The bungalows to the west of Racket Court are still more crowded. The worst are the bazaars which crowd upon the east, south, and south-west of the station, and in which there is no proper ventilation. The temperature of the station is not raised by being exposed to reflected sun heat; the nights are fairly cool on the whole. The prevailing winds are the east before and during the rains (April to September), and the west for the rest of the year. The setting in of the west wind is generally attended with increase of sickness, this being the time of desiccation; and in November and December bronchitis, fever or dysentery are produced from the cold, which is sharp, especially at nights. 6. The surrounding country is highly cultivated. There are no works of irrigation, properly so called; but every hollow which holds water is used as a tank from which to water the neighbouring fields. I am not aware that artificial irrigation, as practised here, has been

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	found to have any effect on the health of the station. Rice cultivation is not prohibited. The ground being for great part under water, it is probably better that rice (the only suitable crop) should be cultivated. Indigo is not cultivated near the station. Hemp is prepared within a mile or so, but in small quantities, and not so as to cause a nuisance in the cantonment, or to be injurious to health. 7. The bazaar in 1807 was estimated to contain 16,000 inhabitants, and now probably numbers many more. The city of Patna commences at Bauhipore, 7 miles distant, and runs for 10 miles to the east. 8. The geological structure of the district is alluvial, light, sandy soil, and low down in the river bed a few patches of kunkur exist, but in very small quantities. I believe that the station was new ground when selected. 9. Water is found during the dry season at 30 feet below the surface, and at the depth of 6 feet during the rainy season. 10. When the station is not flooded from the Ganges, the rain-fall, if light, runs off at once, if heavy, it takes some hours to do so; but is eventually chiefly run off by the nullah into the Ganges. There is no drainage from higher ground passing into the subsoil of the station. 11. The water supply is obtained from wells, and also from the Ganges. There are no tanks. The well water is little liable to pollution from leaves; but the wells of the barracks were some years ago poisoned by infiltration from privies, which were too close. 12. Any amount of water can be supplied for the use of the station. It is clear and sparkling, without smell. That of the river is tasteless; but some of the wells are a little brackish. Tested by Dr. Dunbar, Her Majesty's 5th E. I. Regiment, the water of the wells shows sulphate of lime, oxalate of lime, carbonate of lime, and some chlorides, and in one well with a slight excess of vegetable matter and a little ammonia. The water is generally raised in leathern or iron buckets, and distributed by bheesties in leathern bags. The river-water after filtration is the best, especially during the dry season. 13. The overcrowding, bad drainage, and filth of the bazaars must add greatly to the unhealthiness of the station. Some of the streets were last year impassable dunghills until drained and cleared by order of the Brigadier; and all the south of the station, the elephant sheds, and Moorgeeah chuck, are in a state disgraceful to any cantonment. The meat market also was in a very bad state during the rains. 14. I am not aware what are the regulations in force respecting the selection of a new station; they appear to vary. There ought to be a special committee, consisting of two or three senior medical men, two or three commanding officers of regiments, the chief civil authority, and the executive engineer. The ground should be examined, the population, especially children, looked to, and, if possible, a trial made on a small scale, by putting a detachment there, before permanently selecting a new station.
II. CLIMATE.	1. The only meteorological instruments at this station are one or two thermometers or rain guages with the European troops. 2. No data. 3. The climate is generally a medium one, between the damp of Bengal and the drought of the north-west. It is tolerably dry in the cold weather, yet not so much as to wither up the grass. It is damp, of course, in the rains, but neither is the heat (April, May, and June), nor cold (in November, December, and January), so great as in the north-west. It is tolerably free from dust, and moderately variable only. There is fog occasionally in November and December, generally going off in the forenoon. Bronchitis and bowel complaints are produced by the cold nights in cold weather, and the same with dysentery, and perhaps cholera, from sudden chills, from storms, during the rains. Warm clothing is required during the cold weather, and flannel should be worn at all seasons. The diet should be nutritious; but the animal food should be reduced during the hot weather and rains. Drills and exercises may be carried on all day, or at any time in December, January, and February. For the rest of the year, they should be diminished, and in the hottest part not more than one hour in the mornings should be devoted to them. The men should not be unnecessarily exposed to the sun. During the cloudy weather of the rains the men may be out more if the opportunity is watched; but in September and October great care is necessary. In average years the most healthy months are December, January, February, and March. The most unhealthy are June, August, September, and October. The prevailing diseases during the latter are heat apoplexy, fevers, dysentery, and bowel complaints, and hepatic diseases. 4. I cannot say there is any district near the station the climate of which is more conducive to health than that of the station. Arrah did not prove healthy lately when occupied by Europeans. Burhee is 120 miles distant, and therefore can scarcely be called near. 5. The following are the stations at which I have served, with the comparative salubrity of each :— 1. Hazareebaugh is very healthy, and perhaps best of all suited for European troops. 2. Dinapore is sufficiently healthy for officers. The men used to suffer fearfully from dysentery, and a good deal of cholera, but less latterly. 3. Agra is in general years favourable, but is subject to frequent and severe outbreaks of cholera. 4. Bareilly is a very pleasant and favourable station, yet with a considerable tendency to fever. 5. Barrackpore; I served with natives. It is not considered favourable to Europeans. 6. Kyooh-Phyoo. I was there for three months. The natives suffered a good deal; but not an officer was on the list the whole time. 7. Rangoon. I served there during the second war. It is not nearly so unhealthy as was expected, the troops averaging only about 10 per cent. on the list after they were housed. Fever and dysentery were the prevailing diseases. 8. Delhi. The old cantonment is very unhealthy from fever and dysentery. The city is in ordinary years favourable, cholera being rare. 9. Umballa is a very favourable station.
III. SANITARY CONDITION OF STATION.	1, 2, 3. Application for a map of the station must be made to the Surveyor-General. Plans of the station and barracks are transmitted.

4. Table of Barrack Accommodation.

The date of the construction of the permanent barracks is unknown; that of the temporary barracks is 1858–9.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Stations—*cont.*	5. There are doors and doorways in the barrack rooms on opposite sides, and facing each other; they are double flapped, and open on hinges. There are no windows. In the permanent barrack there are pillars and verandah on the south side, 10 feet wide, and in the temporary barracks pillars and verandah on the north-east and south sides, 10 feet wide. These are never occupied as sleeping quarters for the soldiers. In the permanent barracks there are jalousies and jhilmils, but in the temporary barracks there are none. The doors are all battened. 6. The bedsteads used in the barracks are wooden framed cots with rattan bottoms, and some few are wholly of iron. 7. The tents used are double poled, with double fly and single kanats covered with three fold cloth, 21 by 15. There are 16 men to each tent, and the space allotted to each man nearly 138 cubic or 20 superficial feet. 8. The means of ventilation in the barracks and guard-rooms are by doors and skylights (which latter however do not open), and in the tents by doors, by air entering beneath the kanats, or by tricing up the latter. These means are sufficient for ventilation during the day, when many of the doors are open, but not so during the night with closed doors. Tatties, or porous screens, upon which water is thrown, are allowed in the barracks for cooling the air, which passing through them absorbs the moisture and is cooled. Punkahs also are allowed, which act by moving the air over the men and thus causing it to absorb the perspiration and cool the body. The tatties I consider are apt to cause chills and bring on rheumatism or ague. 9. The materials used in the construction of the permanent barracks are brick and lime mortar masonry, with flat terrace roof, and in the temporary barracks brick and lime mortar masonry for foundation plinth. 10. The permanent barracks are terraced 1½ feet above the ground and solid beneath. The temporary barrack floors are tiled, raised 2 feet above the ground but are solid beneath. 11. The materials are generally suitable. The flooring however of the temporary barracks is bad, being constructed of half-burnt brick; it should have been of chunar stone. The chief permanent barrack is bad, for it runs east and west, which is the prevailing direction of the wind and therefore it is badly ventilated. The cross has always been more healthy than the others. The barracks and cantonments are kept in repair by the Executive Engineer; repairs are quickly executed. The walls and ceilings are cleansed and limewashed annually by regulation, but it can be done under the authority of the Commanding Officer when required as a sanitary precaution. Hospitals are whitewashed quarterly to a height of 6 feet, and twice, completely, in the year. 12. The water for the men's wash-houses is supplied by bheesties from the wells; they are drained into the nullah on the south side by masonry drains. Two double wash-houses and one plunge bath are attached to each wing of the barracks. In the temporary barracks

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	there are no plunge baths, but there is one wash-house to each barrack, supplied by bheesties with water from the river. They are drained into cesspool wells. 13. The cookhouses of the permanent barracks are supplied by bheesties with water from the wells, and are drained into the nullah on the south side by masonry drains. In the temporary barracks water for the cookhouses is supplied from the river by bheesties; they are drained into cesspools. Linen is washed in India by dhobies or native washermen, who take it to the river side, wash, dry, and return it. 14. There are no urinals at present to the permanent barracks, but the building is drained into the nullah, the filth being removed daily in carts and thrown into the river. The privies of the temporary barracks are drained into deep pools; the filth is removed daily in carts and thrown into the river. 15. In the permanent barracks the buildings are ventilated by means of tin ventilators in the roof, and by wooden barred windows to the south, with some open brickwork in the walls. The temporary barracks are ventilated by ventilators along the ridge of the roof, and by wooden barred windows. The barracks are lighted at night by oil lamps. 16. The drainage of the permanent barracks is effected by open saucer-shaped drains, along the north and south sides, 3 feet wide, turning off south to the nullah, distant 160 yards. The ground is sloped off round each of the temporary barracks towards an earthen drain to the south, whence it crosses the road by a brick culvert east of the public gardens, and thence to a nullah distant 780 yards from married barracks. The drainage is sufficient. The buildings all become more or less damp in the wet season, the temporary barracks more so than the permanent. The worst, if not the only foul ditch, is behind to the west of the garden range leading to the nullah. This is often very offensive. I have heard that a new pucca drain has been sanctioned. 17. The surface cleansing within the cantonment is generally fair. The sweepings were, if not still, thrown on a bank to the south side of the nullah, and part to the south-west of the magazine, performed daily by filth carts. 18. The parade grounds are covered with grass, which is eaten off by cattle. There is a good deal of vegetation in some of the gardens, and it is excessive in the neighbourhood of the orderly bazaar. Trees and bamboo clumps in some parts are too thick, and not trimmed up enough. The walls are generally low; one, however, round the permanent hospital, has been recommended to be lowered. There are few, if any, hedges. 19. The drainage of the bazaar is very deficient, there being no regular system; and the drains are in many places choked up, in others forming deep holes of festering mud. The ventilation is very bad. The water-supply from wells and rivers is sufficient. Cleanliness is only external; there are no latrines, and the population is as thick as it can be. The bazaar inhabitants are compelled to keep the space in front of their houses swept every morning before breakfast, and the sweepings are afterwards carted to a distance. The bazaar serjeant goes round daily to see that this is done, and reports by memorandum made on the spot any person near or on whose premises he finds nuisances, such as accumulations of filth, cesspools, stagnant water, &c. These parties are then punished by fine. Until lately there was but one filth cart; there are now three, with a sweeper and driver to each. These are paid for by the inhabitants, upon whom a tax is levied to cover this and a night watch. No Government conservancy establishment is now allowed; a gang of convicts formerly was. What is most required is a conservancy police, with the establishment of public necessaries. The native houses are crowded together. Cesspits, I believe, do not exist; but there are many holes caused by excavations of mud to make walls. These are gradually filled up with straw, sweepings, &c., which, of course, ferment when wet with rain. I have heard that dead bodies are sometimes buried in some of the huts near Dugah. I am not aware that any nuisance is experienced in barracks from wind blowing over the native houses. 20. A slaughter-house was formerly situated in the heart of the bazaar, but is now in the open fields to the south-east of the cantonments, and beyond the boundary pillars. This, however, would change if another contractor were appointed, as it is private property. There should be a Government slaughter-house. The offal is sold to or removed by people of dome caste (very low), who use it. At present there is no nuisance from the slaughtering place, it being well removed, but it should not be allowed to be re-established within the cantonment. There is a nuisance from the cattle being kept on the premises of the contractor in the bazaar. Sheep thus kept are particularly offensive; but even large cattle, in the number and manner they are kept, are objectionable. 21. There are no regulations for stabling the bazaar horses. They are put up within and without the cantonments, according to the owners' pleasure. Much of their dung is made into cakes, dried, and burnt, the refuse being carried off by filth carts. 22. The artillery stables consist of three sheds on wooden posts, with tiled roofs, each shed containing two rows of horses. The sheds are situated south-west of barracks, distant about 150 yards, and about the same distance to the south of the hospital. There are no dung-heaps, the whole of the sweepings of the stable being used for the riding school. There are no picketing grounds. 23. There are sufficient quarters for the married men; none occupy barrack rooms with the single men.
Officers' Quarters.	1. The drainage, &c., and the ventilation are the same as the barracks, only quarters have glass doors. Officers also live in bungalows by the river's bank, and others on the south side of the station. The accommodation being scanty, interlopers should be turned out, at least to a moderate extent.
IV. HEALTH OF THE TROOPS.	1. The station and district are generally healthy, especially to natives. 2. The prevailing diseases are fevers, including small-pox, cholera, and bowel complaints, also a peculiar kind of palsy affecting the lower limbs: at first causing a peculiar strut, afterwards a drag of the foot, the toe being turned inwards and drawn along the ground. There is some tremor with this, but not much; the upper extremities are free. Spleen disease is not common. 3. The unhealthiness of the native population is caused by too much or too little rain, bad drainage, and the holes near all the native houses. Some of the native towns, Arrah and Gyah for example, are disgracefully filthy. 4. The last station which the 4th company 5th Battalion Artillery occupied was Thyat Myo, Burmah, where they remained from August 1855 till May 1857. Their health was pretty

IV. Health of the Troops —*cont.*	good; but they suffered from fevers, syphilis, diarrhœa, dysentery, and a few hepatic cases. They arrived at this station June 17, 1857, in good health, and have since suffered from fever, dysentery, and syphilitic affections. Her Majesty's 5th E.I. Regiment left Berhampore on the 20th November 1859, after a residence of 12 months. Their health there was good, the men suffering chiefly from diarrhœa, dysentery, and fever; they were very free from syphilis. Their state of health on arrival was generally good; the prevailing diseases since being syphilis, gonorrhœa, hepatitis, dysentery, and diarrhœa. Her Majesty's 73rd were at Lucknow from the 19th July to 1st November 1859. Their health on leaving was good, but the regiment had suffered from fever, diarrhœa, dysentery, and syphilis. They arrived on the 15th November 1859 in good health, 39 sick; they have since suffered from fevers, diarrhœa, dysentery, and venereal affections. In the permanent barracks, the south side is less healthy than the east, probably because the latter is best ventilated, owing to the prevailing direction of the wind. The temporary barracks became very unhealthy at the beginning of the cold weather, partly from the constitution of the year, partly, perhaps, from defect of light in them, and from the exhalation from a mud bank in the river. The Mynpooree levy suffered greatly; but they occupied some miserable huts, the remains of a bazaar. 5. The troops at the station are not camped out; it would however be useful. The 19th were recommended to be sent into camp, and marched up the Grand Trunk road to Benares with much benefit. 6. I have never been in charge of troops in a hill station. 7. My experience does not enable me to speak as to the men, but officers assuredly, if their cases have been properly selected and managed, are less liable to fever and other diseases on returning from the hills to the plains, owing to improvement in the general health and tone of the system. 8. As far as my experience enables me to speak, I approve of hill stations for troops; but there is too often a want of room for exercise, and sometimes difficulty in feeding the men properly. I believe this has been greatly overcome now. Hazareebaugh I consider a climate almost equal to the hills for health, having abundant food, room for exercise, &c. Of course it is hotter than the hills, but it is considerably cooler than ordinary plain stations. 9. Hill diarrhœa attacks in some stations men, officers, ladies, and children. It is more prevalent at the sanitaria in the neighbourhood of Simla; but not met with, I believe, at Darjeeling. 10. Clothing, diet, shelter, and proper exercise must be attended to, and, of course, are useful to preserve the health of the troops; but as many officers, ladies, and children suffer who are well off in all the above respects, it is evident that all these precautions will not completely guard the soldiers. 11. The hot and cold seasons are the best for residence in hill stations; but the rainy season must also be spent there, not as being good, but as better than the plains. Patients often gain nothing until the dry weather sets in. One year is generally sufficient for a residence in a hill station in order to produce a beneficial effect on the health of troops. 12. I know of no period of residence in a hill station which would be likely to inflict injury on troops returning to the plains. Many officers retain the most perfect health in the hills for many years; a few, generally men much exposed, such as medical officers, break down and are compelled to go home on sick leave. 13. Troops when about to descend to the plains should only be sent down at the beginning of the cold weather, and the rations might perhaps be somewhat reduced on coming to the plains, yet officers come down at all seasons, make no change in their manner of living, and keep their health. 14. With respect to troops serving in India being located in hill stations, with short periods of service on the plains, this depends entirely on the locality. There are some stations in the plains in which the men would remain nearly as healthy as in the hills; there are others which never can be anything but extremely injurious. In these latter, the shorter the time in the plain, and the longer in the hills, the better. In the healthy localities an occasional short tour in the hills would be sufficient. Change is very beneficial from an unhealthy to a healthy station. I have seen the reverse very injurious. 15. The only sanitarium with which I am acquainted is Jullah Pahai (Darjeeling); there the barrack and hospital accommodation is very defective. The rooms are very dark, not sufficiently ventilated, independently of doors and windows; the wash-houses are cold, no hot water-supply; the cook-rooms small and dark, and the privies and drains defective and ill arranged. 16. I have not had sufficient experience to show what ranges of elevation above the sea form the best sites for hill stations. 17. I have before pointed out Burhee as a station which could be very advantageously occupied. It is 120 miles distant, and accessible by a decent road in the dry weather, which is much cut up in the rains, its elevation about 1,500 feet. The climate is generally like that of Upper India, but modified by locality and elevation, the nights being cooler and the days not so trying as in the north-west, while there is little of the great damp and treacherous sun of Bengal. 18. A sandy soil and subsoil is generally, *cæteris paribus*, the most healthy. 19. If soldiers proceeding to India are not to be exposed or put on duty at once, they may be sent out from 16 to 20, but if required for service or exposure, from 20 to 25, at least. The constitution of the lads breaks down. The best months for troops to land in India are November and December undoubtedly. Never having been stationed in Calcutta, I cannot say how troops are disposed of on first landing. Recruits should land at the commencement of the cold weather, should not be allowed to remain a day in Calcutta, but be at once despatched to a healthy locality under charge of officers—regimental and medical—well acquainted with the country. 20. No experience to enable me to judge whether troops should be sent to intermediate stations before being landed in India. For the soldier landing in India, if not too young, a residence for a few years in a climate like Burhee or Hazareebaugh would be sufficient, but if young, with unformed constitutions, residence in a hill climate would be very advantageous. 21. The mode of transport to the interior should be conducted by officers, who have had the charge of men "en route." I may only say there is the route by steamers on the Ganges, and by land on the Grand Trunk Road; either making the ordinary marches of 12 miles daily, or being conveyed by carts, with relays of bullocks, 30 or 35 miles daily.

DINAPORE, BENGAL.

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops —*cont.*	22. The number of years a British soldier should serve in India should not be more than 10, without a break, but by sending him occasionally to a hill station, this might be extended. 23. The manner of conducting medical boards is not such, as altogether to avoid conflict of opinion as regards invaliding. Men passed by the station committees are sometimes sent back by the presidency ones; yet I think there should be a subsequent examination of invalids before embarking. I have known them to be so much improved by the voyage down, that further change was unnecessary. 24. Troops should be sent home from India, if viâ the Cape, from 1st February to 15th March; if by overland route, from 1st April to 15th May.
Diseases.	1. There are regular inspection parades held weekly at this station, for the discovery of incipient diseases. 2. There has been no case of scorbutus at this station at present. H.M.'s 19th, however, last cold weather, were in very indifferent health, and there was in some of the men a tendency to scorbutus. It is, perhaps, to be attributed partly to prevailing fevers during October and November, and partly to darkness of the barracks. For H.M.'s 19th, lime juice was served out twice a week, and they were sent under canvass. I have recommended more glass in the doors of the temporary barracks and hospital. 3. The total number of cases of hepatic disease treated during 1858–9 was 210, with 21 deaths, giving a ratio of 6·5 per cent. on the general admissions, and of 24·1 per cent. upon deaths, abscess having been very common. The disease, in a good measure, was owing to the exposure of the troops in the district, though there has always been a tendency to abscess here in severe dysentery cases, often not discovered till after death; it is not the consequence of any other disease. The very full diet of the men during the hot season is probably partly a cause of frequent hepatic disease, fatty liver, or a tendency to it, being common. Reducing the amount of this, and also its stimulating nature, would be useful. 4. Dracunculus is not found at Dinapore. 5. Venereal complaints have increased much of late years. The proportion at present among the European troops is 62 in 116, or about 53 per cent. It would be advantageous to the health of the army to establish a lock hospital. Is it possible to increase the facilities for marriage? this would be greatly preferable. Among the Native troops, syphilitic diseases are at present only 8 in 56, or at the rate of 14 per cent., and this is higher than formerly used to be the case; the Sikhs being much worse in this respect than Hindostanees. 6. The diseases from which the troops at this station suffer are as follows:— *Fever.*—Remittent fever prevails more or less towards the end of the rains, and beginning of the cold weather. At other seasons, quotidian and tertian are the common forms. *Dysentery* is prevalent and severe. *Cholera* presents itself at this station almost every year in variable severity. *Small-pox.*—There are occasionally a few cases. It occurs generally in March, April, and May, and ceases when the rains begin. *Rheumatism* is not so prevalent here as at many stations. Taking the medical year 1858–59 as a sample, the proportion which admissions and deaths from these diseases bear to the total admissions and deaths is as follows:— Total admissions - - - - - - 3,186 Total deaths - - - - - - 87

Admissions from		Per-centage.	Deaths.	Per-centage.
Fevers - - - -	622	19·5	7	8·0
Dysentery - - - -	420	12·1	36	41·4
Cholera - - - -	24	0·75	9	10·3
Small-pox - - - -	3	0·09	2	2·3
Rheumatism - - - -	100	3·1	0	0·0

	7. With regard to the nosological character of the more frequent diseases, abscess of the liver used frequently to be found in dysenteric cases, and often, though not suspected before death, very extensive ulceration of the colon. I think these characters are less marked now than 20 years ago. In April, May, and June, or during the rains, small-pox and cholera are prevalent; cholera is sporadic at other times. Fever is prevalent chiefly at the end of the rains and beginning of the cold weather. The climatic and atmospheric conditions, which precede or accompany small-pox are variable; the drying up of the country with hot days and cold nights accompany fever. The west end of the south barrack is said to be most liable to cholera at the season when this prevails, it being to leeward, and, consequently, by far the worst ventilated. In the bazaars there is neither drainage, water-supply, as such, or ventilation, and they are greatly crowded. The predisposing causes to these diseases among the troops are probably sleeping with open doors, standing before a tatty, or in a draught, when greatly overheated, and perhaps too full a dietary for the season. Among Natives the predisposing causes are overcrowding, bad drainage, and want of ventilation. 8. Epidemic disease at this station is little, if at all, influenced by the nature of the soldier's duties, occupations, or habits. 9. Small doses of quinine have not been tried at this station as a prophylactic against malarial diseases. 10. To prevent or mitigate epidemic disease at the station, clearing away the bazaars, draining them properly, filling up the holes, and using all means to prevent the flooding of the station, would all be of great service in effecting this object.
V. INTEMPERANCE.	1. The soldiers at the station are temperate. The per-centage of confirmed drunkards in the 4/5 Artillery is 2½ per cent.; in H.M.'s 5th E. I. regiment, 2 per cent.; and in H.M.'s 73rd regiment, about 1 per cent. 2. The proportion of admissions into hospital from diseases caused by intemperance, are,—

	4/5 Artillery.	H.M.'s 5th E. I. Regiment.	H.M. 73rd Regiment.
Directly -	4	9	6
Indirectly -	0	7	1

There are no means of ascertaining the effect of total abstinence, temperance, and drunkenness, on the amount of sickness, mortality, and crime at the station. It depends on the character of the man, whether drunkenness is ever punished as an offence.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	3. Distilled spirits are sold in the canteen, but not in the bazaar. The rum supplied to Her Majesty's 73rd and Her Majesty's 5th E. I. regiment is good in quality. The former consume about 1 dram each man per diem, and the latter about $1\frac{1}{3}$ dram. Spirit is no part of the soldier's ration at the station, on the march, or in the field, but is supplied on payment. The allowance to Her Majesty's 73rd is 2 drams; but none is served out till 1.30 p.m. To the 5th E. I. regiment the allowance is 2 drams; none, however, is served out till the evening. Spirit is not given as a ration to convalescents. Ginger beer, if ill made, is certainly injurious, and its sale is often stopped when cholera threatens. 4. The consumption of spirits is probably beneficial in old soldiers, but not to the young ones, or those unaccustomed to it. With regard to its effect on efficiency and discipline, as it is at present regulated, it has not much influence either way. 5. It would be beneficial to abolish spirits as a ration, and to restrict the sale in canteens. They should not be allowed in any other place. 6. Malt liquor is much preferable to spirits. 7. Tea, coffee, ginger beer, and ginger tea are chiefly used by the men at the station. They have little if any influence on health, efficiency, or discipline. 8. It would be better to suppress the spirit ration, and substitute beer, tea, or coffee. 9. It would be beneficial to prohibit the sale of spirituous liquors in the canteen, and to permit only beer, coffee, tea, lemonade, &c., to be sold to the troops. 10. Coffee-rooms ought to be established in barracks, where the men could be supplied with coffee, tea, lemonade, &c., also with newspapers and periodicals. 11. No spirits whatever are permitted to be sold in the bazaar. The shopkeepers can sell 10 bottles on a wholesale, or 1 bottle on a retail licence, but none under any circumstances to soldiers, non-commissioned officers, or camp followers, except in last case to servants on account of their masters. The rules for Her Majesty's 5th E. I. regiment are those laid down in the Military Code, sec. x., p. 47, with this addition, that each company furnishes an orderly, with an abstract of the men's names, who remains whilst the liquor is served out, and checks over issue to any. The canteen is open from 12 to 1 for the issue of beer only, and from tea to tattoo for spirits. The canteens of Her Majesty's 75th regiment are open in the hot season, from 1st April to 1st November, from gun-fire until 10 a.m., and from 5 p.m. to watch setting, and during the cold season, or from 1st November to 1st April, from gun-fire till 12 o'clock. Whenever practicable, and in accordance with the wishes of the men, the allowance of malt liquor may be issued for consumption with the dinner. No country-made spirits except that furnished by the commissariat is to be allowed in the canteens. No person who may appear intoxicated, or who is under punishment, is allowed to enter the canteen. An orderly serjeant is in constant attendance at the canteen to preserve order and report irregularities. No spirituous liquor, &c., is sold or issued to any native whatsoever, nor can any article be taken from the canteen by a soldier, except by an order signed by the Commanding Officer. No spirits are issued on any occasion before the usual dinner hour, nor is any man allowed more than two drams per man, and these are never issued at the same time.
VI. Diet.	1. The ration for Queen's British troops and European troops in the Indian army is the same, and consists of bread 1 lb., meat 1 lb. (mutton twice a week, beef five times), 4 oz. rice, $2\frac{1}{2}$ oz. sugar, $\frac{3}{7}$ oz. tea, $1\frac{3}{4}$ oz. coffee, 1 oz. salt, 1 lb. vegetables, and 3 lbs. firewood. There is no periodical change except as vegetables come in or go out of season. The ration is regularly inspected by the officer of the day and the quartermaster. If objected to it is then submitted to the surgeon. 2. A complete ration, including vegetables, is provided for the troops, the stoppage for which is 3 annas 4 pie. Her Majesty's 73rd have three meals a day, viz., breakfast at 7.30, consisting of tea or coffee, and butter, or milk, &c., provided by the soldier; dinner at 1 o'clock, consisting of soup, meat, vegetables, and bread; tea at 5.30, composed of tea and bread. The nature of the meals is the same in Her Majesty's 5th E. I. regiment, and the hours of meals are respectively 8 a.m., 1 p.m., and 4.30 p.m. The proportion of vegetables in a ration is 1 lb. 3. I consider the vegetables supplied to Her Majesty's 73rd inferior, and attribute this to the allowance for them being too small (one pice daily). Those supplied to Her Majesty's 5th E. I. regiment are considered fair in quality. At times, from the season, there is a difficulty in getting a good supply. A cup of tea or coffee should form part of the ration to be supplied on rising in the morning. The supply of tea, if husbanded, is large enough to allow of this, but the coffee would require to be increased. Some men would prefer ginger tea. There is no arrangement for preventing the men of Her Majesty's 73rd regiment disposing of their rations; but in Her Majesty's 5th E. I. regiment the mess orderly (one of the men) remains in the cook-room until all the meat is in process of cooking. 4. The means and apparatus available for cooking are large pots, spits, frying pans, &c. native fashion. A very few and simple means are all that are required. The kitchens cannot be kept clean from the nature of their construction, but are blackened with smoke. They are well supplied with water by bheesties. The food is boiled or roasted as the men please. The cooking is sufficiently varied. Tea and coffee are properly prepared. The men of Her Majesty's 73rd regiment have not been supplied with refreshment before a march, as when moving about the country was in a disturbed state. On the only short march which Her Majesty's 5th E. I. regiment has made, they had refreshment by saving from the rations. 5. The supply of vegetables is good at the station. The soldiers will not work in a garden unless it be close to the barracks, and where they can go out in undress.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress in the cold weather consists of tunic, cloth trowsers, boots, and helmet with cover, in the summer khakee tunic and trowsers. The accoutrements are shoulder pouch, belt and pouch over left shoulder, with 40-rounds, waist belt with pouch and 20-rounds, and bayonet attached. A cap-pouch is attached to the cross belt. Upon the whole, the present dress is suitable to the climate, and for the soldiers' day and night duties at different seasons; but the coverings to the wicker helmets are too thin; a regular turban on a wicker frame would be a much greater protection against sunstroke. The guard dress is the ordinary dress with black trousers at night, and a great coat when it is cold or wet. There is a guard room and sentry boxes.
Duties.	1. It would be advantageous to have the men thoroughly drilled at home, before proceeding

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*cont.*	to India, but if possible they must be protected from syphilis, from which they are apt to suffer in large camps. 2. The routine of the duties of Her Majesty's 73rd, is morning parade and drill for one hour at daybreak, and in Her Majesty's 5th E. I. regiment, morning parade one hour five times a week, evening do. twice a week for half an hour—four times for one hour. The men do not suffer from ordinary guards. The best hours for drill, parades, and marches in hot weather, is the early morning, and to 9 or 10 in the cold season. With regard to the average number of nights the men are in bed, those of Her Majesty's 73rd are out once in eight days. The men do not suffer from night guards. The men of Her Majesty's 5th E. I. regiment have always three nights in bed, and sometimes four. 3. One guard of the 73rd regiment is mounted at the magazine half a mile distant from the barracks. The others are mounted in the square. The magazine guard of the 5th E. I. regiment is mounted at a mile and a half distant, the others are mounted in the lines. Guards last 24 hours. There are roll calls at breakfast, dinner, supper, and tattoo and afternoon parade in the 73rd regiment, and in the 5th E. I. regiment at breakfast, dinner, and supper, but if no afternoon parade there is roll call at 5 p.m.
VIII. Instruction and Recreation.	1. The means of instruction and recreation are as follow:—There is a fives court and two skittle grounds for the permanent, and two for the temporary barracks. Also a school with serjeant acting as schoolmaster for the 73rd regiment, and a library and reading-room, both well lighted. The 5th have a school and normal master, also a library which is not lighted at night, but they have no reading-room. The day-room and soldiers' club of Her Majesty's 73rd regiment, are the library and reading room; the 5th have none. There is a soldiers' garden but it is not used by them. There are no workshops for the 73rd regiment; but the 5th have workshops for tailors, shoemakers, and armourer serjeants. There is a station theatre which is hired, it being private property. There are no gymnasia. The means are not at all sufficient to keep the men occupied during the wet season and heat of the day. The men of the 73rd regiment are not allowed out of the barracks from 8 a.m. to 5. 30 p.m. in hot weather. The 5th are kept to barracks from 8 a.m. to 5 p.m. during the hot weather. The confinement is beneficial to health. 2. To improve the existing means of recreation and employment, a large covered space like a railway station, to contain workshops, skittle grounds, ball alleys, quoit grounds, &c., &c. should be erected. A farmyard might be part of the station with advantage, both for the supply of milk, &c. and the amusement of the men. 3. The institution of soldiers' savings banks would be advantageous. 4. There is no shade but that obtained from verandahs, which may be used to enable the men to take exercise during the day.
IX. Military Prisons.	1. The cells of the temporary barracks are the only ones fit for use; they are well ventilated and lighted. Those of the main guard although large enough are ill ventilated and lighted, and the station cells although better ventilated and lighted are greatly too small.
X. Field Service.	1. There are no local regulations for field medical service, not included in the General Presidency Regulations. 2. As regards the conduct of the line of march, the powers of the medical officer depend partly on the commanding officer and partly on the tact of such medical officer; some are ready to take advice, but others despise it, especially if it come from a young man. 3. When not on service in India the camping grounds are marked out, the water-supply arranged for, and nothing remains to be done. On service there are many points to be considered at the same time with medical ones, and it would be an extreme case which would call for the remonstrance of a medical officer. I say remonstrance, because however bad the locality might be, he has no power to cause the camp to move. 4. The hospital tents are carried on elephants; the stores on camels in large trunks carefully arranged, so that everything is at hand; two trunks with a small board between them make a good operating table. The sick and wounded are carried in doolies, which is the best conveyance in the world for a wounded man; the slighter cases on carts or camels. The hospital supplies are furnished by the commissariat on indent as required. A medical depôt is formed generally near the seat of war. I am not aware of any regulations on the subject other than those published in the Medical Code.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1, 2. Plans of the hospital are transmitted. The permanent hospital is situated on the river bank about one-third of a mile from nearest barracks, to the west and N.N.W., and far removed from the stables. The barracks and some private bungalows and the barrack master's yard lie between it and the bazaar. The site is not well ventilated. There are cook-houses and privies to the north, a high wall to the south and west, and the same with trees to the east. The site is as healthy a one as can be obtained, the drainage is fair, and the river bank is not injurious. There are no holes or pits. The temporary hospital is at one end of the barrack ranges. The artillery stables are about one-eighth of a mile to S.S.E.; the building is on the river bank. There is an old bazaar, now being pulled down, to the westward, but there are no houses near. The site is open and well ventilated, but to some extent interfered with by the cookhouses and privies, which are not judiciously placed. It is situated in a very fair locality, with good drainage, and without pits or holes near. More sand is in the river bed this year than usual, but this may be carried away next rains. 3. The water-supply of both hospitals is obtained from wells and the river, and is abundant. 4. The refuse water and impurities from the permanent hospital are carried away by pucca drains into the river close by; that from the temporary hospital is drained into cesspools by the out-offices. 5. The height of the wards of the permanent hospital is 1½ feet above the ground; there is no perflation of air beneath. Those of the temporary hospital are 2 feet above the ground; there is no perflation of air beneath. The hospitals are both drained into the river, but much of the roof water of the latter building still sinks into the soil. The ground round the hospitals is sloped, and small drains, or rather slopes, in the hollows carry off the rainfall very fairly. The permanent hospital is built of brick and lime mortar masonry; the walls and roof are simple, but sufficiently thick; it has verandahs, which afford sufficient shelter

References to Subjects and Queries.	Replies.

XII. Hospitals—*cont.*

from the sun's rays. The construction of the temporary barracks is the same as that of the permanent barracks, the walls are single, and the roof of tiles and thatch. There is a verandah on the north side 10 feet wide, which affords sufficient shelter from the sun's rays. The verandahs are used for the accommodation of the sick in case of the centre ward being full, but not otherwise. The hospitals consist of ground floors only.

TABLE of Hospital Accommodation.

Date of construction of the permanent male hospital, 1821; permanent female hospital, 1851; temporary male and female hospital, in 1859.

Wards or Hospital Huts, Number.	Regulation Number of Sick in each Hut.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patients' Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Ft.	Ft.	Ft.	Ft.			Ft.		Ft.	Ft.

Ditto Female ditto	32	151	20	17	51,680	—	—	2	28	9	4½
In the following lines are given the correct cubic and other contents of the temporary Male and Female Hospitals as occupied by the Sick. The measurements above include the whole length of the Hospital Buildings.											
	128	330	20	17	132,600	1,036	61				
	—	96	20	17	34,340	1,079	63				

The permanent hospital stands E. and W., and this being the prevailing direction of the wind, it is not properly blown through. The temporary hospital is better, being nearly across the direction of the prevailing winds. All the windows are doors, and open to the ground, and they are well suited for ventilation. Closing them is a great means of coolness during the very hot weather.

6. The permanent hospitals are ventilated by doors and skylights, and the means are sufficient except when all the doors are closed in the cold weather. In the temporary hospital ventilation is effected by doors, openings in the walls, and by roof openings. I believe that even at night this hospital is free of odour. In the permanent hospital the doors are double, glass in the interior, and venetians externally, which can be set open by a centre bar, so as to admit air and light, or else closed. The temporary hospital doors are wooden, with a few panes of glass over the top.
7. Tatties as described for the barracks are used for cooling the wards.
8. There are no means of warming them. The walls and ceilings of the wards are cleansed and limewashed twice a year, and every other three months to a height of 6 feet, but it can be done under the authority of the commanding officer when required as a sanitary measure.
9. The privies of the permanent hospital are on the north, by the river side. The privy of the male ward of the temporary hospital is on the north and that of the female ward on the south-west side. They are not placed over cesspits, but are drained out to the river bank. The water is supplied by hand. They are offensive, in spite of the use of lime and charcoal, the ventilation being insufficient; this has been represented, and will be improved. (It has since been done.)
10. The lavatory arrangements for the sick are sufficient.
11. There are shower and slipper baths for the use of the sick, and earthen dishes for the feet; also a lavatory with basins for men able to use it. The footwash and bath water is kept in reservoirs supplied by bheesties, and turned on with a cock. The means are sufficient for the purposes.
12. The linen is washed and dried by dhobies on the river bank. The means for this purpose are sufficient.
13. The storage is ample. It is dry in the dry season, but damp, as all places are at the station, during the rains.
14. The bedsteads used in the hospitals are of iron, or wooden frames with iron straps. The bedding consists of one mattress, one large and two small pillows, all of country hemp, two sheets, one or two country blankets, one covered with dimity, bolster slip, and two pillow cases, and a small bedside carpet. The mattress and pillows should be of hair, and it would be an improvement to have English blankets.
15. The kitchen of the permanent hospital is a building to the north, with doors and windows to the south, and a blank wall to the north. There are small fireplaces on the ground, and these with pots, pans, fry pans, and spits enable an Indian cook to prepare anything. The kitchen of the temporary hospital is a building to the east of part of the hospital on the same plan as above.
16. The diet table, &c., are according to regulations of the medical code.
17. In reference to the sick, hospital serjeants merely watch over the discipline of the hospital; there are no nurses. 20 ward coolies and one superintendent are allowed for a regiment to attend on the sick, and these are generally very kind and attentive. There are also sweepers for removing filth and water carriers; besides this in severe cases a comrade or two are told off as orderlies. This attendance is enough in ordinary cases, but there is sometimes a difficulty when the men understand no Hindostanee, although coolies of any standing pick up a good deal of English.
18. The sanitary condition of both hospitals is generally good; there has not, in my time at least, been any hospital gangrene or pyæmia, and although cholera and fever have appeared at times, they have not done so more than in the station generally.
19. I have already stated that the ventilation of the permanent hospital is not all that coul be wished; there are too many buildings and heavy passages about it. The temporary hospital is much too dark, and there are not enough means for shutting out the wind in the

DINAPORE.
BENGAL.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	cold weather. The first defect is in progress of remedy and the second has been partly cured by screens. 20. In the permanent hospital the roof forms a nice airy walk for convalescents, and there is a covered seat by the river side. In the temporary barracks there is a large space fenced in and a river frontage, but in neither are there any walks or shade. Convalescents are often sent out on elephants morning and evening to take the air, and the weaker men in doolies. 21. Female wards are provided for soldiers' sick wives and children, separate from but near the male wards. They are provided with female attendants. The present arrangements are satisfactory. 22. There are no special local hospital regulations. 23. The medical officer is expected to see that the establishments properly perform their duty, that drains are cleaned, water supplied, and the regular hospital routine carried out. In small repairs up to 50 rupees a requisition on the Executive Engineer will obtain what is required for the building; more extensive changes must be reported on by a committee, when, if within 100 rupees and urgently required, they can be ordered by the officer commanding the station; if beyond the latter sum, they must go up for sanction to the higher authorities. As to diet and medical comforts, he can by means of the separate statement make any change or alteration deemed necessary. A medical officer's power is the same in any locality, in so far as what is required is obtainable. 24. There are no convalescent wards or hospital. Men discharged, and not in full strength, are often ordered to appear at hospital night and morning, for a certain time; this excuses them from drills, &c., and gives them a walk. Convalescent wards are not, I think, required.
XIII. BURIAL OF THE DEAD.	1. The British burial ground is immediately on the south side of the nullah, quite out of the line of the prevailing winds. 2. The area of the ground is 4a. 3r. 7p.; the soil is light, and decomposition appears to go on rapidly. Too much grass is allowed in the wet season, at which time the subsoil becomes infiltrated with water. 3. The graves are eight feet long and three feet broad, with an interval of one and a half feet between each; they are five feet in depth. Graves are, as a rule, never reopened; but in one case, some time since, a little boy was buried on his father's coffin. There are no regulations as to interment at ordinary times, or during epidemics. The Hindoos burn their dead on the river bank, and if this be completely done, nothing remains but a few charred bones; but the odour of combustion is disagreeable, and although the burning ghat is out of the station, it should be removed further off. There is now no Mahommedan burial ground within the station; such are apt to be very offensive. The graves being shallow, they fall in at once, and an offensive effluvium comes forth. One, a mile out of the cantonment to the east, has been closed lately. 4. The graveyard is never offensive. Rapid decomposition calls for rapid burial. As a rule, a corpse is only kept long enough for the coffin to be made, and is buried within 24 hours at furthest. 5. The dead of camp followers or bazaar people, if Hindoos, are burned; if Mahommedans, buried. 6. The Mahommedan burial grounds should be placed under surveillance, as they are apt to be very offensive. The burning ghat of the Hindoos also should be watched, as the poorer people sometimes only singe the body, and throw it into the river. 7. Graves ought to be marked with a number, so as to be capable of identification; a tile, stamped with a number, set in the ground, would be sufficient. Improvements with regard to burial of Hindoos and Mahommedans have already been adverted to. The present division marks of the burial grounds are indistinct, and it is suggested that a pucca walk, which runs through part of the ground, might be slightly moved and completed, so as to make a permanent boundary.

I. TOPOGRAPHY.	1. The country round the station is open undulating table land. The station itself is dry and the soil porous, not retaining moisture. There are five or six small hills in the vicinity, that is, at a distance of from two to four miles, which appear volcanic. The jungle from N.E. to S. approaches to within four or five miles of cantonments, and is chiefly bushy, with here and there larger trees. There is not much water, except what is artificially collected in tanks by damming up ravines for the purpose of rice irrigation. 2. According to recent surveys the elevation above the sea is about 1,900 feet. A late barometrical observation of the revenue surveyor gives the height at about 1,800 feet. Being elevated table land the station may be said not to be above the level of the adjacent country. There is a gradual ascent up to the station on the N. side of 200 feet, approaching it from Burhee. Burhee itself, on the Grand Trunk road, is about 700 feet lower level. It is 23 miles distant from Hazareebagh.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	3. There are no large rivers, lakes, or canals in the neighbourhood. There is a nullah to the N., about a mile from the cantonment boundary, and separated from the cantonment by a ridge. There is also another nullah to the E. and S.E., by means of which chiefly the cantonment is drained. A committee examined and reported favourably on a site for a cantonment about 2½ miles to the E. of the present station, and from 25 to 30 feet high in level. This was not in consequence of any unhealthiness in the present site, but because it was contemplated to make Hazareebagh a larger station, and the present cantonment was not calculated to accommodate more troops than one regiment. The site chosen would have given more room, was open, and presented natural qualities of drainage, but had the disadvantage of approaching nearer the jungle. There is another good site to the N., about two miles or less from the present cantonment. 3. With the exception of the little detached hills from 300 to 600 feet high already spoken of, there are no considerable mountains or higher table lands in the vicinity. 4. Rice marshes approach the cantonment boundary to the N. and W. The nearest river of any magnitude is the Damoodah, about 30 miles to the S. There are no lakes or canals. The two nullahs have already been mentioned. The vicinity is not liable to the overflow of water, with the exception of the rice lands already spoken of, which are artificially prepared for the retention of water. The surrounding country is intersected with ravines, and here and there artificial tanks, but they do not appear to affect the health of the troops injuriously. 5. The station generally is open and freely exposed to winds. The aloe grows very luxuriantly, and forms the chief hedges of the station. Some of these hedges, which appeared to obstruct the ventilation, have been already removed, and lately it has been proposed as a sanitary measure to level another long aloe hedge which approaches the barracks to the N. side. Also to keep down the height of all hedges to 3 feet above the road level, and to clear away where practicable the lower branches of all trees (not fruit trees) in cantonment to a height of 18 feet from the ground. There is no higher ground, nor house, nor walls likely to interfere with free ventilation. From the barracks being pretty close together it is to be expected that the reflection from the white walls, and radiation of heat at night, must add somewhat to the temperature, but there are no surrounding hills, nor rocks, nor buildings, other than regimental buildings, calculated to produce this effect. The station is not exposed to cold and variable winds, but any long-continued drought is usually followed by storms of rain or hail, particularly in the latter end of March and in April, at once reducing the temperature by many degrees. No prejudicial effect has been observed in consequence on the health of the troops. 6. As already mentioned, there is cultivation of rice to the N. and W. of cantonments, and other patches here and there, where the ground is favourable, but there is not much other cultivation. There are no works of irrigation, except the damming of nullahs and ravines in a few places in the outskirts of cantonments, which have been mentioned above. The artificial irrigation of the rice lands must, it is presumed, to a certain extent affect the sanitary condition of the station, but as Hazareebagh has only been recently occupied by European troops, there are not sufficient data before the committee to enable them to form an opinion on the point. Rice cultivation is not prohibited, except, of course, within the cantonment boundary. It was proposed at one time to forbid the cultivation within half a mile of cantonments, but the proposition was negatived, chiefly, the committee believe, on account of the great expense the measure would entail. In 1858, when the European cavalry depôt was stationed at Hazareebagh, the rice cultivation came close up to the barracks on the E. side, but on the recommendation of the medical officer all that land was taken into cantonments on the fixing of the boundaries the following year. Since then it has been thrown out of cultivation and drained. There is no cultivation of indigo, hemp, or flax near the station. 7. There is no large city or town, except the town of Hazareebagh itself, containing a population, according to native estimate, of from 5,000 to 6,000. The cantonment boundary passes through the town. 8. The surface soil on the rice lands contains clay loam, but in other places, which may be regarded as the natural soil, it is sandy and gravelly. The gravel is quartzose and granitic. Deeper down, about 3 or 4 feet from the surface, you come to tenacious clays, and beneath these, at a depth of from 20 to 25 feet, is found loose black earth in which the water of wells is struck. As far as the committee are aware, the site of the present cantonment has never been occupied by population. Hazareebagh was a station for European troops up to the year 1843, when it was abandoned for military and political (not sanitary) reasons, and it has been reoccupied since the hot weather of 1858 only. 9. During the dry season, water is found at the depth of from 25 to 30 feet. During the rainy season, the wells fill up to within 10 or 12 feet of the surface. 10. The rainfall flows away very readily, as is proved by the fact that after a long continuous rain, a few hours of sunshine suffice to remove all traces, except the dampness of the surface. The natural fall of the ground prevents the rain from sinking deep down, and what does not at once flow away on the surface, drains off through the porous surface soil, and between this and the clay subsoil. During the rainy season, the water of two springs oozes out at the lower end of two of the barracks, considerably below the plinth. Nowhere does the water lie on the surface until evaporated, except where artificial means are employed to retain it. There is no adjacent higher ground, the drainage of which passes into the subsoil of the station. The drainage is all carried off by the nullahs. 11. The water supply is derived from wells and tanks. It is stored in open tanks; there is only one used in the station for drinking water. The area is about 300,000 superficial feet. There are two outside the cantonments, one near the jail, with an area of about 160,000 superficial feet, and one on the Burhee road, about 15,000 superficial feet. The tanks get full in the rains, and the supply gradually diminishes until the end of the hot season, when some of the tanks become almost, if not altogether, dry. Two of these tanks, one in the limits of cantonments, and the other a bunded ravine, never become dry. Another large artificial tank, about half a mile from cantonment, on the Burhee road, always contains an ample supply. The nature of the plants and animals they contain is not known. They are tolerably free from weeds and vegetation. All contain small fish. One of the tanks in cantonment appears to be used both for drinking and bathing, but most of the water for

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	drinking purposes is taken from wells. The water is not liable to pollution to any extent. Surface impurities must, of course, pass into the tanks, but no drainage known to be foul is allowed to do so. There is a very offensive tank in the station bazaar (not in cantonments), which must be injurious to the townspeople living in its neighbourhood. There is also a pucka tank near the cantonment post office, which becomes offensive in the hot weather. It ought to be cleaned out thoroughly every year at that season. 12. The supply of water is abundant, but in some of the wells it has a slightly saline taste. There are, however, several good wells in the station, from which persons, particular about the quality of their drinking water, obtain their supply. In these wells it is clear, and free from all colour and unpleasant smell. All water at Hazareebagh used for drinking purposes should be filtered when practicable. The available means for making chemical analyses are very imperfect. Three samples of water have been tested, two of them being well water procured from the two best wells, and one tank water from the only large tank in cantonments, the one already mentioned as supplying water both for drinking and bathing purposes. Both samples of well water were clear and agreeable to the taste, giving no deposit after 24 hours standing, and slightly acid to test paper. The alkaline bases they contained were lime and potash. One contained a slight trace of magnesia, and the other a slight trace of iron. There were no means of testing for soda. Acid bases were silicic, phosphoric, hydrochloric a trace, and carbonic, also free carbonic acid. Very slight trace of organic matter. Degree of hardness by Professor Clarke's soap test, 4·5. Both these samples were wholesome. Sample No. 3.—Tank water, of a pale brown colour depositing copiously on standing. Alkaline to test paper. Organic matter in considerable quantity. No means of ascertaining its microscopic characters. I consider it unwholesome without very careful filtering. Amount both of well and tank water abundant except in very dry seasons. The usual means of drawing water is by bullocks and chursas, but more frequently by a long pole used as a lever and an iron bucket. The committee do not consider any change called for except the filtering already recommended. 13. The previous queries appear to include every topographical point bearing on the health of the station. A small tank to the north-west of No. 4 barrack, very conveniently situated for supply water in case of fire, should be kept at as low a level in the rainy season as the drainage will admit of. This will be provided for at once. 14. New stations are selected by a committee of the chief civil officers of the district or division. Two military and two medical officers, one subordinate civil officer, and the executive engineer of the division in attendance. Any member of the above committee differing on any point or points can specially record his own opinion. The sites chosen are generally the most elevated and open spots in the locality, inquiry having been made respecting the health of the population round about. The position is generally settled by the Supreme Government. The committee settle the site.
II. Climate.	1. The means and instruments available at the station for conducting meteorological observations are very imperfect. In the regimental hospital there is but one thermometer, and no other instruments whatever for registering meteorological observations. The annexed table is prepared from observations kept by the civil assistant surgeon, but his instruments also are imperfect, and as the observations extend over only two years they cannot be considered of any great statistical value. 2. The following is a table of observations:—

Years of Observation.

From 1st April 1858 to 31st March 1860.

II. Climate—*cont.*	3. As I have been at Hazareebagh only since July 1858, any opinion of mine derived from personal observation cannot be so valuable as that of an older resident. It appears to me that the climate occupies a medium position between those of Bengal and those of the Upper Provinces. It is markedly drier than Bengal Proper, while the quantity of grass in the place, which at no time gets thoroughly burnt up, proves that it is damper than Upper India. This abundance of grass keeps the air free from dust and other impurities. Last year I was forcibly struck with this coming from the Upper Provinces after three months absence. The climate of Hazareebagh is sensibly cooler than either that of Bengal or Upper India, more so than can be accounted for by the difference of elevation. Taking the height at 1,800 feet and calculating by the usual rough rate of one degree of temperature to 300 feet, this would only give it 6 degrees cooler, which is hardly sufficient. I should estimate Hazareebagh at 8 or 10 degrees cooler than most Indian stations. The climate is certainly more variable in temperature. I consider the climate excellently adapted for European troops, especially for recruits fresh from England to get acclimatized in a moderately tropical climate like Hazareebagh before being exposed to the fierce heats of other stations. As regards precautions, open airy barracks with good ventilation and plenty of light are of course to be recommended. There is not the same necessity for thick thatch under the tiles of the roof. The rains being heavy and the climate somewhat variable during eight months of the year, very light clothing is not advisable. In the rainy season a flannel or woollen belt round the abdomen would be a useful precaution against the dysentery and diarrhœa which prevail in these months. Although the air is cool, the sun is nevertheless markedly a tropical sun, and care should be taken not to have drills and parades too late in the morning or too early in the afternoon. Helmets and cap covers should be worn at morning and evening parades from the 15th March to the 15th October. The most unhealthy months here, as at other stations, are those at the end of the rains and before the cold weather has fairly set in. These are September, October, and November. Last year, which may be considered somewhat exceptional, the sickness continued into December. December to April inclusive are the most healthy months. Cholera is said to prevail sometimes in the latter end of April and in May. In the rains, fevers of the typhoid type, remittent and intermittent fevers, and bowel affections are the most common diseases. As the cold weather advances the continued and remittent type becomes rarer, most of the cases assuming the intermittent character. The jungles are not safe until the beginning of December. In September, October, and the early part of November they are very fatal and deadly. 4. I know of no district near the station so healthy as this is. The hill of Parisnath, about 50 or 60 miles distant, is much higher, and of course much cooler, and is supposed will prove very salubrious, but it has yet to be tried. Steps are now being taken to adapt it for a sanitarium for troops. The table land at the top is, I believe, somewhat confined for barracks, but everything else is in its favour. The height is between 4,000 and 5,000 feet, and there is a good supply of water, and, of course, good drainage. 5. I have served at the following stations, enumerated in the order of their salubrity. Rawul Pindi, very healthy. Hazareebaugh ,, Simla ,, Jhelum ,, Bareilly, healthy. Benares, hot, but healthy. Loodiana, not healthy. Delhi (old cantonments), very unhealthy. Banda, very unhealthy.
III. Sanitary Condition of Station.	1, 2, and 3. Plans attached. 4. The following table gives the accommodation:— Date of construction of barracks at Hazareebagh, 1858–59. Total number of barracks, 15. Total regulation number of non-commissioned officers and men, one regiment of British infantry.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms, or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.

Prison Cells - - -	20	8	6	18	17,240	864	48	1½	Pigeon holes, 6 to each cell.		

5. There are no windows in the Hazareebagh temporary barracks. The doors are planks secured by battens with glazed fanlights 4½ × 1 over them, as per standard plan. There is a verandah 10 feet wide on both sides, as per standard plan. The verandahs are never used as sleeping quarters. There are no jhilmils.
6. In tents, on the march, no bedsteads are allowed, only straw. In barracks the bedsteads are iron-hooped cots. These possess the great advantage of being cool, and do not harbour

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	vermin. Those in use at present are not high enough to admit the soldier's chest to be put under them. It would be an advantage if this could be done, as it would give more room in the barrack when the chest is not in use. The ends of the hoops should in all cases be continued round and screwed into the wood underneath. When they are fastened at the side the least projection tears the bedding and the clothes of the men. Without a mattress these iron hoops are at present too far apart. They might either be brought closer or a bamboo matting be allowed as a cover before putting on the bedding. The men get as bedding, each 1 cotton setringee, 2 cotton upper sheets, 1 quilt of double chintz containing 8 lbs. of carded cotton, 1 good country blanket. After the first issue they get annually 1 quilt and 1 sheet; 1 blanket every second year, 1 setringee every third year. On issue of new bedding the old articles are kept till worn out. 7. The regulation tent for European soldiers is double poled, with single standing kanâts (or sides), two flies and four doorways. It is intended for 16 men in health, and 8 when for hospital use. The dimensions are as follows: length, 20 feet; breadth, 16 feet; height of the kanâts, 5 feet; height of poles, 11 feet; distance between poles, 6 feet; superficial area for each man, 20 square feet; cubic space for each, about 140 cubic feet. 8. The barracks are all provided with ridge ventilators, running their whole length, according to standard plans for temporary barracks. They have in addition fanlights over each door, which are made to turn on pivots so as to open and shut at pleasure. The guard rooms have the same. The means of ventilation are quite sufficient, because in most seasons one or more doors can be kept open. It would be advantageous to have outside jhilmil doors, and half-glass doors in place of the present wood ones. Punkahs are pulled from April to September, but it has never been considered necessary in the comparatively temperate climate of Hazareebagh, to employ the other usual means of tatties and thermantidotes. 9. Barracks are constructed as per standard plan; foundation and plinth of burnt bricks in mortar; superstructure to a height of 10 feet burnt bricks; in round arching ditto; remaining portion of superstructure, sun-dried bricks in mud; roof of tiles, over 3 in. of thatch. The tent kanâts or walls and fly tops are double, and of four folds of cloth, strengthened with coarse tape where the rope bears. There are no huts at the station. 10. The floors are of bricks laid flat and on edge, also of stone and terraced. The flooring of barracks is 2 feet above the ground, and of hospitals 4 feet. No passage for air passing underneath is provided nor deemed necessary in this station. 11. The committee consider that the materials and construction of barracks are suitable for the climate. With regard to tents, the committee are of opinion that it would be an improvement to keep the flies entirely separate; at present the outer and inner flies are sewed together in their entire length, where they meet the kanâts or standing walls. This plan saves ropes, but the tents are more likely to leak, and there is little or no ventilation between the flies. By keeping the flies separate, and bringing the outer ones a few inches beyond the standing walls, the tents will always be water-tight, and a free circulation of air always admitted between the flies. By keeping them separate, however, extra ropes are necessary for the outer fly; sewed together, as at present, the same ropes answer for both flies. The barracks and cantonments are kept in repair by the barrack master and executive engineer. Repairs are always executed promptly. The commanding officer is responsible for the general state of the cantonments; and the senior medical officer is *ex officio* sanitary officer. Walls and ceilings of barracks are cleansed and limewashed annually; generally in April and May; oftener, if necessary, on medical officer's requisition. 12. There are 10 double lavatories, and 1 single; each lavatory is provided with cisterns to hold water. Pipes and taps communicate with these cisterns, and over each basin is a tap. The dirty water passes off by a plug at the bottom into a permanent covered drain, which is carried off by a main drain to a distance of three quarters of a mile from the barracks, where it falls into the main drainage of the station, which has a good fall, and is rapid. 13. Cookhouses are of the standard plan, and the water supplied by water carriers. The refuse water is carted away to about $1\frac{1}{2}$ miles from the barracks into a rivulet, whose fall is rapid. There are no particular arrangements for washing; the clothes are washed instanter, and are dried in the country in less than half an hour. 14. Privies and urinals are of the standard plan. Each privy seat is provided with a bucket of iron, and each urinal with urinary pan and iron bucket. All filth and urine is carted to a distance of 2 miles from the barracks, where is a rapid rivulet. 15. All privies are built on the standard plan. They have ridge ventilators, and have 4 doors and 6 windows. They are lighted by one lantern suspended from the roof. 16. All filth from privies and urinals is caught in buckets, pans, &c., and carted away 2 miles off; so with the refuse from cookrooms; the remainder, such as washhouse water, is caught in a covered drain. There are in all 1,825 square feet of washhouse drain communicating with 15,610 square feet of main drain. The country here being naturally undulating, surface drainage vanishes rapidly. All drainage from lavatories, baths, &c., passes off rapidly by the covered drains as noted above. No part of the barrack is damp. No cesspits exist at the station, nor are there any foul ditches. 17. Every day a cart perambulates cantonments, attended by 2 sweepers. All refuse, dead leaves, bones, ashes, &c., are carried away to a distance of some 2 miles. 18. Vegetation springs up very rapidly in the rains, but is kept down as much as possible by the barrack master's department. There are no old walls, but the aloe hedges already mentioned are inclined to grow too luxuriantly. Measures are being taken to keep these within proper limits; and some, which, from proximity to the barracks, are considered objectionable, are to be removed entirely. 19. The water supply for the bazaar is sufficient, and the streets are kept clean. There is not more crowding than is observed in all native bazaars, but latrines are very much required. The bazaar is open, and well ventilated. The natural fall of the ground ensures a complete drainage with very little care. The occupants of the houses in the bazaar are responsible for keeping the roads in front of their dwellings clean and regularly swept. The bazaar chaprusies are employed as a part of their duty to see that the regulation is enforced. No accumulations of filth are permitted. There are no dungheaps or cesspools near or at the station; but the first half mile out on the Burhee road, and other roads leading out of the town, are in an offensive state, from being resorted to by the natives in the absence of

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Troops—*cont.*	latrines. It is contemplated to establish latrines at once on the principles of those at Agra and other large stations. No nuisance is experienced in the barracks from wind blowing over the native dwellings. 20. There is one slaughter house for the use of the soldiers conveniently situated in an isolated spot about half a mile from the barracks to the south. At no time has any nuisance been experienced from it, and it is kept clean, all the offal being carted away. It is at some distance from every other building; and the wind at Hazareebagh very rarely blows from that quarter. 21. Very few horses are kept at the bazaar; and, as no nuisance whatever is experienced from them, no special rules seem to be required. The manure is either carted away with the other filth or is taken specially as manure by the owners of gardens. 22. No troops of cavalry or artillery are at present located at Hazareebagh. 23. The accommodation for the married men being ample, no women are obliged to occupy barrack rooms with the men.
Officers' Quarters.	1. What has already been said in regard to the drainage of the station applies equally to the officers' quarters. The officers occupy several detached houses, and one long barrack partitioned off into rooms is especially given up to the unmarried officers. These rooms would be hot in any other station, but are well suited to the climate of Hazareebagh. They are well raised and ventilated. For temporary quarters they are very good, but more servants outhouses are required.
IV. Health of the Troops.	1. I should say that the inhabitants of the station and the population of the district enjoy at least an average share of health. The latter are for the most part a poor puny race, owing perhaps to their poverty and insufficient unstimulating food. Rice is the only grain consumed. 2. The most prevalent disease is unquestionably fever, particularly of the intermittent type. Bowel complaints are not uncommon. Spleen disease is always found where fever extensively prevails, but I do not consider it a marked peculiarity of this district. Of epidemics, cholera and small pox are the most common and the most fatal. There are every year a few cases of the former at the setting in of the hot weather. 3. The general healthiness of the native population is probably attributable to their very simple habits of life, and to their being but little addicted to the use of ardent spirits. What unhealthiness there is may be put down to the jungle, malaria, and rice cultivation. 4. The regiment is now being raised at the station, and is for the most part composed of recruits fresh from England, who have, however, for one or two months previously, remained at the Barrackpore recruit depôt. They have for the most part arrived at Hazareebagh in good health, but more than one party have suffered on the road up from cholera. About 80 out of the 520 of which the regiment consists are volunteers and drafts from other regiments. The most prevalent diseases have been fevers, remittent and intermittent, venereal diseases and bowel complaints. No. 1 company was markedly more unhealthy than the others, as appears from careful statistics of admission from fevers and other malarious diseases kept for July, September, October, and November of last year. The next barrack to No. 1, occupied by No. 3 company (though marked No. 2 on the executive engineer's list), ranked next in point of unhealthiness. This comparative insalubrity was attributed to the proximity of a large rank aloe hedge which shut out ventilation to the north, and also to the jungly state of a private compound which approached that barrack, being divided from it only by the aloe hedge above mentioned. The hedge is to be removed and a low wall substituted for it, and care will be taken this year that the compound is kept clean and free from jungle. 5. The state of the troops has not been such as to require that they should have been camped out either in 1858 or 1859. They have been very healthy years on the whole. 6. I have never been in charge of troops at a hill station, but have had some general experience of hill climates. For healthy men visiting the hills the effect is almost always favourable. For invalids more caution is to be observed as the hills are quite unsuited to many diseases, especially to bowel complaints, hepatic and other visceral affections, with organic lesions. Contrary to generally received opinions, I consider a hill climate favourable to most lung diseases, especially in incipient phthisis. 7. I cannot say whether troops returning to the plains from hill stations are more or less liable to attacks of febrile and other diseases. 8. Although I have not had charge of troops at hill stations, I have been on several occasions on leave at Landour and Mussourie, and held medical charge at Simla for an entire year. My general opinion is that well-selected hill stations are very favourable for European troops. Some of our hill stations, as Subathoo and Kussowlie appear to have been ill chosen, although I understand the latter is recovering its reputation as a sanitarium. 9. Not having had extensive experience I can only give a general impression, taken up in the course of several visits to the hills, that persons coming from the heat of the plains to the cooler climate of the hills, suffer frequently from bowel complaints. The free action of the skin being suddenly checked may probably be regarded as the exciting cause. This is well known in the case of persons visiting Simla, and before they get acclimatized to the station. 10. I consider that warm clothing and shelter are the most essential points to be attended to at hill stations. As a general rule all people coming from the plains are apt to under clothe themselves. If soldiers have a sufficient stock of clothing to allow them to change their wet clothes after exposure to rain, I consider that it would be of great advantage to teach them to disregard the weather. At present it is too much the fashion to coop the men up on rainy days in their gloomy hill barracks where it is too dark to read or employ themselves profitably. 11. In the hot weather and rains the most good is doubtless obtained indirectly by escaping the same unhealthy and exhausting seasons in the plains, but to derive the full benefit of a hill climate, troops and especially invalid troops should in my opinion remain over the winter months, leaving, according to the distance they have to travel, some time in February. I should think two hot seasons and one winter the very shortest time to enable troops to obtain the full benefit of a residence in the hills. 12. I should say there is no fear whatever of injury to health from any length of residence at the hills.

IV. Health of the Troops —*cont.*	13. I am not aware of any special precautions required on returning to the plains, except such as would naturally suggest themselves for protecting men from the fiercer heat of the plains after they have been accustomed to expose themselves without risk in the cooler climate of the hills. 14. Considering the matter only in a sanitary point of view, and supposing the hill stations to be judiciously chosen, most good would in my opinion be derived from making the hills the normal residence of the European troops, giving the corps short periods of service in the plains. Troops undergo a certain amount of tropical acclimatization even in the hills. The sun is always a tropical sun, and the climate partakes of the same character, cool as the air may be. I should therefore consider that troops visiting the plains after a lengthened hill residence are not to be placed in the same category as unacclimatized troops, fresh from England. I reason, however, only from general impressions, and have no statistical data to guide my opinion. If from any particular cause a regiment is unhealthy at a station it is no doubt an advantage to remove it, but very possibly the regiment succeeding it may not suffer in the same degree. As a general rule I am of opinion that troops are moved too frequently, considering the question in its sanitary aspect. There are climatic peculiarities in each province, and troops have always to undergo a certain degree of local acclimatization in each. I believe it will be found that the health of troops is better the second year than the first, and the third year than the second. I put aside of course the cases of those unhealthy stations where the exciting causes of sickness being in constant operation, the general tone of health of the regiment is day by day gradually lowered. 15. I have not experience to enable me to give a decided opinion whether the barrack and hospital accommodation in hill stations is sufficient. 16. I have no experience to show at what elevation the most suitable sites may be obtained. 17. The only higher ground near the station, and which I only know by general report, is the hill of Parisnath, about 60 miles distant, and I believe about from 4,000 to 5,000 feet high. I have no personal knowledge of its capabilities as a hill station. 18. All sandy and porous soils which do not retain water, and those which are rocky though often hotter, are I conceive as a general rule more healthy for stations, *cæteris paribus*, than the richer vegetable loams and clays. 19. I consider from 20 to 25 the best age for soldiers proceeding to India, and from the 15th October to the end of December or January, the best period for them to land. I do not know how troops are disposed of on first landing. Next to choosing the proper season for landing the troops, the best means of preserving their health would in my opinion be to forward them as quickly as possible to their respective regiments. Detention in the river or in the neighbourhood of Calcutta must for many obvious reasons be most prejudicial. 20. I do not believe that any advantage is gained by sending the troops to some intermediate station in the hope of gradually acclimatizing them to the tropical peculiarities of India. A regiment which came lately from the Cape to India suffered, I believe, more than many others coming direct from England. I should certainly consider it an advantage if all fresh troops were sent in the first years of their service to hill districts, or to those stations which experience proves to be specially adapted to young soldiers fresh from England. Hazareebagh is eminently one of these stations. 21. The three modes of transport now employed from the port to the interior are, 1st, (if by water,) river steamers as far as Allahabad; (if by land) either daily marching or Government bullock train. By daily marching the progress made is from 10 to 14 miles in the 24 hours with one halt in the week. By Government bullock train it is about double that distance. The best precaution of all is moving troops at the proper season of the year, that is to say, in the cold weather, and, if by water, guarding against the undue crowding of the steamers. In time of war or other emergency this may not always be practicable, but in peaceful times no consideration should induce the authorities to overcrowd the boats. Probably nothing is healthier than daily marching in the months of November, December, January, and February, and (if in the upper provinces) March. After that month and more particularly in Lower Bengal, cholera is very apt to make its appearance. The advantages of the bullock train are, 1st, its rapidity as compared with marching. 2nd, that tents are not required for the accommodation of troops on the road, as temporary stations have been formed along the trunk line at proper intervals. The arrangements of the Government bullock trains for the transport of troops, first organized in the times of the mutiny, appear very good. It is to be expected, however, that a few years will see all these methods superseded in most cases by the rail. Already 120 miles of rail, from Calcutta to Raneegunge, and again from Allahabad to Cawnpore, are habitually employed for the purpose of transporting troops. 22. Due regard being had to economical and sanitary considerations, I am of opinion that from 15 to 18 years should be the limit of a soldier's service in India. 23. I am not sufficiently acquainted with the working of medical boards to say whether the manner of conducting business is such as to avoid conflict of opinion as regards invaliding. 24. The time of year desirable for invalids to leave India is towards the end of the cold weather, as this enables them to march to the port of embarkation in the healthy season.
Diseases.	1. There are regular inspection parades every Saturday forenoon, chiefly with a view to discover venereal disease in its early stages. 2. There has been no scorbutic disease at this station since I have been here. If it ever occurred, which I do not think likely, it might safely be attributed to some error in diet, and ought readily to be checked by the free use of lime juice and green vegetables. 3. In 15 months, out of an average strength of 338 men, there have been only 9 men admitted on account of hepatic disease, and of these all but two were chronic cases contracted elsewhere, and occurring in men drafted from other corps. Acute hepatitis and hepatic abscess are very uncommon at Hazareebagh. 4. There have been no admissions on account of filaria dracunculus, but the disease is known in the district, though it does not prevail even among the natives to any great extent. 5. At most seasons of the year at least one-fourth of the men in hospital are there either on account of gonorrhœa or syphilis, primary or secondary, and many of those returned as rheumatism probably owe their rheumatic pains to some syphilitic taint. In the months when fever is prevalent, of course the proportion is not maintained. In 15 months 291 venereal cases are recorded, out of 1,416 total of all other diseases, or 20·55 per cent. Next to

IV. Health of the Troops —*cont.*	drunkenness, I consider syphilis to be the great curse of the army, and the question is certainly a difficult one to handle. Most of the methods employed in various regiments in this country resolve themselves into the maintaining of regimental brothels, that is to say, certain prostitutes are permitted to exercise their calling in the regimental bazaars, and are regularly examined, reported on, and removed when diseased. This is exactly the French system in Paris and other French towns, and of its efficacy there can be no doubt. Were it not impossible to recognize such a system on moral considerations, there would be comparatively little difficulty in keeping the regimental bazaars untainted. Stringent bazaar regulations, and a regular examination of the prostitutes, would ensure this result. The English Government, however, have always wisely refused to extend this practice to London and other English towns, and surely it is equally immoral, however customary and expedient, to resort to such a system in a regiment. I would refuse as a medical officer to lend my sanction to the practice by examining the regimental prostitutes, while I fully acknowledge its sanitary expediency. I confess at the same time I know of no other remedy for this frightful evil. I do not consider that there would be much advantage gained by establishing lock hospitals for the women. They are generally most unwilling to come to the doctor when diseased, and would certainly not resort to the lock hospital except under compulsion.

6. The troops at the station suffer from diseases of the epidemic and endemic class, especially in the months of September, October, and early part of November, such as fever, dysentery, and diarrhœa.

Fevers are continued (assuming the typhoid type towards the end of the rains). Remittent and intermittent (the last the most common of all).

Dysentery and *diarrhœa* are also prevalent at those seasons; the former, known as hæmorrhagic dysentery, being the most fatal.

Cholera did not occur here last year as an epidemic. Five cases are recorded in the hospital returns since 1st December 1858, but these occurred amongst the draft which came from Barrackpore depôt, and the disease was in all cases contracted on the road.

Small-pox.—No case has been recorded since the regiment was formed in November 1858.

Rheumatism is somewhat prevalent; 60 cases are recorded, but many of these might, perhaps, be regarded as partly syphilitic in their true character, rather than idiopathic rheumatism.

The average strength of the regiment for 15 months has been 338. Total of all diseases, 1,416; of these, 433 have been fevers; continued fevers, 54; remittent fevers, 23; and intermittent fevers, 356; Dysentery, 61; diarrhœa, 119; cholera, 5; small-pox, none; rheumatism, 60; other diseases, 738; or, per cent.,—

Total	13

7. The remittent and continued fevers have generally cerebral complication, and after the first few days assume a typhoid character, requiring stimulants to be freely administered. The bad dysentery cases, particularly those known as hæmorrhagic, are attended with little tenesmus, but there is great ulceration, thickening and disorganization of the mucous coat of the large intestine, terminating in extensive sloughing. Many of the cases, entered as diarrhœa, and apparently not dysenteric at first, assume the dysenteric form very rapidly. The seasons when these diseases are most prevalent are the months of September, October, and the early part of November. The sun is powerful at that season, the atmosphere humid, and the vegetation rank. The air is impregnated with malaria from decaying vegetation. No portions of the bazaar or native dwellings have been observed to be more affected than others, and I am not aware of any habits or conditions among the troops or natives, which appear to predispose to disease.

8. Every care being taken not to expose the men to the sun at morning parades and drills, and dry ground being chosen for these duties in the rainy season, the prevalence of epidemic diseases cannot be said to be at all increased by any duties or occupation of the soldier. It is rather the want of all occupation which predisposes men to their attack. Listlessness and vacuity of mind react injuriously on the bodily health.

9. Quinine has never been tried among the troops, for the simple reason that the surgeons indents are kept rigidly down to the bare requirements of those actually sick; but from partial experiments made by myself, and from what I have heard mentioned by others, I have not the slightest doubt that a grain of quinine, daily administered as a prophylactic, just before and during the unhealthy season, would diminish the prevalence of fevers and malarial dysentery 50 per cent. or more, but the consumption of quinine, and the expense, already great, would be enormous.

IV. Health of the Troops: *Diseases—cont.*	10. In the unhealthy months, and particularly when dysentery and other bowel complaints are prevalent, I consider that an abdominal belt of flannel, or similar material, ought to form part of the soldier's kit, and be worn as a matter of duty. When exposed to the sun on field service, something corresponding to the native cummerbund might advantageously be served out. It is a mistake to suppose that the head is the only part of the body which suffers from exposure to the sun's rays. All healthy out-door games should be encouraged whenever the weather admits, and everything which affords healthy occupation for the mind. Reading-rooms, and all indoor games which do not lead to gambling, are wonderfully conducive to health.
V. INTEMPERANCE.	1. The soldiers at the station, as a body, are very temperate. There may be many men who habitually take more spirits than can possibly be good for them, but I know of no single man who could be called a confirmed drunkard. 2. No returns have been kept of the proportions of admissions into hospital, directly caused by intemperance. Only eight admissions from drunkenness and delirium tremens are recorded. Of those *indirectly* caused by intemperance, I doubt if it would be possible to give even an approximation by the most careful return. For instance, a soldier, while the worse for liquor, may lie out in the wet, and return to barracks sufficiently sober to escape notice. While exposed, he may have taken in the poison of a malarious fever, or of acute dysentery, or of many other diseases, and yet it would be impossible for the hospital records to give this admission as "indirectly" caused by intemperance. I believe myself that it would be under the mark to say, that one-third of the diseases of, and one-half of the crimes committed by, soldiers may be put down to the effects of drink, directly or indirectly; but I have no statistical data to give which would be satisfactory. Drunkenness is punished as an offence. 3. Spirits are sold at the canteen, but the sale is prohibited in the bazaars. The canteen rum is 24 per cent. under proof. The amount which each man is allowed to take is 2 drams, or $\frac{1}{20}$th part of a gallon. The amount actually consumed in 1859 was 2,020 gallons. The average monthly strength being 323, this gives the annual consumption per man very nearly 6·25 gallons. The canteen returns show spirit drinking to be decreasing. The first two months of the present year give a little over the rate of 3½ gallons per man per annum. Some of the improvement may doubtless be put down to the men being under stoppages, and unable, therefore, to afford much liquor; but a good deal, it may be hoped, is real improvement. Spirits can never be said strictly to form part of the daily ration of the soldier; he is allowed to draw a certain amount, paying for the same. At the station and on the march he is allowed to take either beer or rum: a quart of the former or 2 drams of the latter; or he may take one part of beer and 1 dram of rum. In the field, from the impossibility of transporting beer, only rum is issued. No rum is issued in the field till afternoon, and, in quarters, not till after evening parade. Beer, however, is allowed even in quarters in the middle of the day. It would certainly be injurious to allow it to be issued in the early morning. No man on the convalescent list is allowed to enter the canteen except by special permission, and that is given by the surgeon very rarely. No other drinks are sold at the canteen or bazaar which are injurious to health. 4. In my opinion, the consumption of spirits is decidedly injurious to health, and is certainly not conducive to the efficiency and internal discipline of the corps. 5. I consider that it would be in every way beneficial to abolish altogether the sale of spirits in the canteen and bazaars. Most medical men of the present day have, I believe, come to the conclusion that the habitual use of ardent spirits even in moderation is injurious, and certainly the long-cherished idea that the British soldier required daily drams to maintain him in health and efficiency is now thoroughly exploded. I feel fully convinced that the man who drinks nothing stronger than tea or coffee will do more work, *cæteris paribus*, than the dram drinker, even though the latter be what is called in the regiment a sober man. The argument that the soldier will get drink somehow, and that therefore it is better to provide him with a certain amount of good spirits from the canteen rather than force him to seek worse elsewhere, I conceive to be entirely erroneous. Stringent regulations could in most stations make it impossible for the soldier to obtain liquor in the bazaar; and, even were it otherwise, I believe that the serving out of spirits from the canteen, far from checking the desire, creates an artificial thirst, and a further craving, which the soldier seeks to gratify elsewhere. At first, doubtless, the large quantity which each man is allowed to take from the canteen suffices to satisfy him, but gradually his stomach requires a further daily stimulus, and he will use all his energies to procure it. I have no hesitation in recording my opinion, that the selling of rum in the canteen is an unmitigated curse to a regiment, destructive alike to health and discipline, and that to this more than to anything else we owe the great number of drunkards which disgrace our army. 6. I do not consider that even malt liquor is necessary to health in this country, but am not prepared to say it is injurious, if taken in moderation. It is, at all events, much less injurious than strong brandied wines and spirits. 7. I think coffee, tea, lemonade, and similar drinks are more used at this than at other stations; and I believe it will be a happy day for the army when nothing stronger is issued to the troops. 8. It would certainly be beneficial in every way to suppress altogether the spirit ration. 9. It would be beneficial in every way to prohibit the sale of spirituous liquors in the canteens. 10. I have no recommendation to make, except the entire abolition of the custom of issuing spirits at all from the canteens, and giving, perhaps, some trifling compensation for taking away the indulgence. 11. The canteen regulations are as follows:— 1. The canteen will be open daily from 12 to 1 o'clock for the issue of malt liquor, and from 6.30 to tattoo for the issue of rum. 2. No malt liquor to be issued before 12 o'clock. 3. The quantity of malt liquor and rum sanctioned per man is 1 pint of ale or porter and 1 dram of rum daily; or 2 drams of rum, without ale or porter. 4. One pegging serjeant or corporal from each company will attend at the canteen during the issue of all liquor, for the purpose of seeing that no man has more than his proper allowance. 7. No liquors to be taken from the canteen without a written order from the commanding officer; and no strangers are on any consideration to be allowed to enter the canteen.

V. Intemperance—*cont.*	11. No liquor to be sold on credit. N.B.—The other canteen regulations relate to the keeping of order, instructions to the non-commissioned officers how to act in case of disturbance, &c., but do not bear directly on the question under consideration. There are no liquor shops established in the bazaar, and no bazaar regulations beyond their prohibition altogether in cantonments.
VI. Diet.	1. It is not positively known what is the ration for Queen's British troops, but it is presumed to be identical with that of the other European troops in India. For European troops in the Indian army the ration is composed of beef, mutton, rice, coffee, tea, bread, sugar, and vegetables according to the season, in the following quantities:—Meat, 1 lb., vegetables, 1 lb., rice, 4 oz., coffee, $\frac{5}{14}$ oz., tea, $\frac{5}{7}$ oz., bread, 1 lb., sugar, $2\frac{1}{2}$ oz., and no periodical change is made. Before issue the rations are inspected by the mess orderlies of companies, who make known any objection they have to them. They are then inspected by the quartermaster and orderly officer of the day, and if they are considered of bad quality, the contractor has the option of changing them. Should he decline to do so, a committee is called, composed of the captain on duty, orderly officer, and medical officer, and if deemed unwholesome, it is buried or destroyed; if only of inferior quality and not positively unwholesome, the contractor is directed to supply fresh. 2. The ration includes only vegetables, no fruit, for which the stoppage is 3 annas and 4 pice per diem. The soldier takes three meals daily, viz., Breakfast at 8 a.m. in the hot weather. Dinner at 1 p.m. „ Tea at 4 p.m. „ In the cold weather each meal an hour later. About 27·5 per cent. of the ration is vegetables. Rice is not considered a vegetable. 3. In my opinion there ought to be two scales of diet, one for the hot, and one for the cold weather. The hot weather scale should provide less meat and more vegetables, and farinaceous food. In the cold weather the soldier, when not on duty, is generally out of barracks either walking about or engaged in games which call for a considerable amount of physical exertion. In the hot weather he is not even permitted to leave his barrack in the heat of the day, and too often he spends a listless lazy life, half asleep perhaps the greater part of the time. It stands to reason that the diet should be changed to suit his altered circumstances. I think, too, that the soldier's diet is too unvarying. Dall, soojee, oatmeal porridge, and many other articles might be employed both with economy and advantage. 4. The means of cooking are by the ordinary choolas or cooking places. Copper frying pans and the usual cooking utensils are supplied on indent by the Commissariat department. The kitchens are kept clean, are light and well ventilated, and amply supplied with water. The food is prepared in every variety of way. The cooking is very fairly done, and as much varied as the stereotyped nature of the raw articles admit of. There are seldom complaints on this score. The tea and coffee are properly prepared. The regiment in this station has not yet made regular marches; but the usual method would be adopted of providing tea or coffee at the half-way halting ground. 5. At present, this being a young regiment, and the men much employed in their drill and duties, they would have but little time to work in their gardens; but ultimately there cannot be a doubt that the establishment of gardens for the cultivation of vegetables by the soldiers would be in every way advantageous. The committee consider that it would be advisable, after selecting a proper piece of ground sufficiently near to the barracks, that the whole should be laid out on one general plan, and while it should be understood that vegetables and useful wholesome fruits should be the chief produce looked for, the cultivation of flowers and ornamental shrubs would also be encouraged. At least as much benefit might be anticipated from affording the soldier a healthy, pleasing occupation, as from the value of the garden produce. After the ground had been thus laid out on a general plan, portions should be subdivided off for the different companies. Small prizes might be given once a year for the best flowers, fruit, and vegetables; but even without this inducement a wholesome rivalry would doubtless spring up between the different companies, who would vie with each other in perfecting their several plots. Seed should be supplied by Government, and the vegetables purchased at a fair rate by the Commissariat, if there were at any time a surplus available. It should also be a standing regulation of the army that a corps succeeding another at a station should be bound to purchase the soldiers' garden at a fair valuation.
VII. Dress, Accoutrements, and Duties.	1. The component parts of a soldier's dress are according to regulation. Dress during cold weather months, from the middle of October to the middle of March, consists of a cloth tunic or shell jacket, cloth pantaloons, ammunition boots, forage cap, and great coats on guard at night when required. Dress during hot weather months, khakee (drill dyed of a drab colour), tunic and trousers, wicker helmet, with khakee cover and turban. Under clothing: flannel shirts, white or blue cotton shirts and cotton socks. Accoutrements: pouch belt and pouch, with 40 rounds of ammunition, expense pouch, waist belt, bayonet and scabbard. I consider the dress suitable. Either the hot or cold season dress, or a mixture of the two, as may be required, appears well adapted for all the stations and climates I have known in India. The helmet might, perhaps, be improved upon and rendered more sightly and convenient. Men on guard wear the dress of the season, and their great coats, if considered necessary. The guard-house affords ample protection from the sun and wet.
Duties.	1. As a general rule, I should think that drill and exercise, so far from being prejudicial to health, were conducive to it. 2. Guard comes round about once in five days; the hours of drill are an hour about sunrise, an hour in barracks, about 10 a.m., for those men who require it, and an hour about sunset for all. The men do not appear to suffer in health from this. The early morning is generally the best time for drills, parades, and marches, but circumstances may, of course, render other hours preferable. I am not aware of any general orders which prohibit a commanding officer from using his own discretion in these matters. The men have four nights out of five in bed.

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*cont.*	3. The barracks are from 50 to 200 yards distant from the ground where guards are mounted. All guards are relieved daily; they go on for 24 hours. The roll is called at daybreak, at breakfast hour, at dinner hour, at tea, also at tattoo in the evening. On days when there are no parades, roll is called at the hours of morning and evening parade. I am not aware that the night guards have, in any instance, been considered prejudicial to health. The only precautions observed are the adoption of woollen clothing, and the men taking their great coats with them when the weather requires it.
VIII. Instruction and Recreation.	1. There is a ball court, but little used by the men. One skittle ground and a second is in course of erection. There is a regimental school, with two soldier assistants. The services of a trained schoolmaster have not yet been secured. There is a Government library, which is not lighted at night. The soldiers have a temperance reading room, with upwards of 200 members, which is well lighted at night. This room is the only institution of the kind which can be considered a club or day room. There are as yet no gardens. There are armourers', shoemakers', and tailors' shops. A small theatre has been established in one of the barracks. Quoits, cricket, and other out-door games are a good deal played by the men when the weather is cool enough to admit of their being out of barracks, but there is no gymnasium. It would be advisable, if practicable, to afford further means of amusement and occupation, as the long days of the Indian hot weather hang heavily on the soldiers' hands. During the hot months the men are not allowed to leave the barracks after the sun becomes hot, except for the purpose of visiting the reading room, and the result is beneficial to health. 2. As the regiment has only lately been raised, and consists principally of recruits, who have to be instructed in all their drills and duties, there has been no time as yet to devote to soldiers' gardens, but I hope soon to establish them. 3. The savings of the soldiers are at present lodged in the Government savings bank, but it has been decided that regimental savings banks shall be instituted from the 1st May next. 4. During the greater part of the day the men, if they please, can take exercise in the verandah of the barracks without injury to their health.
IX. Military Prisons.	1. The cells of the military prison are 20 in number, and each contains 1,365 cubic feet of air, being 10 feet long by 7 feet broad, and 19½ feet average height. They are inefficiently ventilated and are very dark, having only 4 small holes above the wooden door, to admit air and light. Being of tiled and thatched roof, there is some irregular ventilation between the top of the walls and the grass. They would not be habitable in their present state in the hot weather in a station of the plains of India, but I have not observed any bad effects on the prisoners at Hazareebagh. The longest term of solitary confinement permitted at one time is 14 days; but it is rarely awarded as a punishment for more than 168 hours. The state of the cells as regards light and ventilation has some time since been brought before the notice of the proper authorities, and immediate alterations are to be made.
X. Field Service.	1. There are no local regulations for field medical service which are not included in the general presidency regulations. 2. The recommendations of the medical officer would always be attended to in the course of ordinary marches, as well as on field service, where strong military reasons did not prevent his suggestions being adopted. In the event of an epidemic such as cholera breaking out he would practically have plenary powers to carry out any changes he might consider advisable. No commanding officer would be willing to accept the responsibility under these circumstances of refusing to attend to his suggestions, though necessarily possessing the full power to do so. 3. In the course of the ordinary relief of regiments, the camping grounds are certain fixed spots, marked out by boundary pillars, which have been carefully selected and set aside for this purpose, and are presumed to be the best available in the neighbourhood. The first points looked to in the selection are abundant water supply and natural facilities for drainage. Wells are sunk when the water supply afforded by the wells of the place is insufficient. Should a regiment be marching through a new country not so marked out, it would be the duty of the quartermaster to select good camping ground. There is generally ample room for making a good choice, and any interference of the medical officer would, for the most part, beuncalled for. Doubtless here, as elsewhere, his suggestions, if he thought it necessary to make any, would be attended to. In a standing camp more especially his advice would probably be taken, or even asked for. The present system works so well, and the medical and military authorities, as far as I am aware, so seldom clash in these matters, that I consider no alteration called for. 4. I am unable to give the details as to the arrangements for field hospitals, ambulances, transport of sick, &c.
XI. Statistics of Sickness and Mortality.	1. These could only be obtained at the office of the Presidency Inspector-General.
XII. Hospitals.	1. Plan annexed. 2. There are two hospitals, one for the men and one for the women of the regiment. These are in one line, and separated by about 50 or 60 paces from each other. The nearest barrack is distant about 350 yards. There are no stables in the station. The north boundary of the hospital compound runs along the bazaar and native houses, a thick aloe hedge separating them. The hospital is 100 yards distant from the hedge, the apothecaries' quarters being built on the centre of the intervening space. I think the site excellently chosen, as it is open and freely ventilated, no buildings whatever obstructing it on any side. I consider the site very healthy, and unexceptionable in every way. 3. One of the best wells in the station is across the public road to the east, and it is most conveniently situated for the requirements of the hospital. There are two other wells in the compound, one Government well recently built, containing very good water. 4. All the sewage and impurities from the privies and cook-room are removed by carts to a distance, as in the case of the barracks. The rain water drains off by the ditch in front and outside the hospital wall to the east. 5. The hospitals are similar to the temporary barracks. The plinth is 4 instead of 2 feet as in the barracks above the level of the ground. There are no air passages under the floors. The country about being hilly, very little water sinks into the subsoil. It passes off rapidly

References to Subjects and Queries.	Replies.

XII. Hospitals—*cont.*

into the main drainage to the east. A layer of concrete 10 feet wide, with a slope of 6 inches to 10 feet is spread around the hospital, outside which a small gutter is made. Rainfall disappears rapidly. The foundation and plinth are of stone in mortar. The superstructure of burnt bricks in mortar, and in places in mud. Above 10 feet sun-dried bricks in mud. The floor of bricks laid flat in mortar. Roof of tiles over 3 inches of thatch. The roofs and walls are single exactly similar to the barracks. There are verandahs on both sides 10 feet wide. Open verandahs on the east side. Closed verandahs on the west side. They afford sufficient shelter from the sun's rays.

The verandahs have never yet been used for the accommodation of sick or convalescents. The hospital is meant to accommodate 96 patients, namely 16 in each of the 6 wards, and that number has never yet been approached.

The hospitals are single storied; plinth perfectly level from end to end.

Date of coustruction, 1858–1859.

Total number of male wards, 6. Female wards, 5.

Total regulation number of men's beds, 96. Women's beds, 80.

Wards or Hospital Huts, No.	Regulation Number of Sick in each Ward or Hut.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed's above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Ft.	Ft.	Ft.	Ft.			Ft.	Fanlights per ward.		
Single Men's Hospital similar to temporary Barracks, standard plan ; 6 wards.	16	48	20	18	17,280	1,080	60	1½	8	1 foot.	4½ feet.
Women's Hospital, do. ; 5 wards.	16	48	20	18	17,280	1,080	60	1½	8	1	4½

Both men's and women's hospitals are placed broadside east and west so as to receive the full benefit of the prevailing winds. There are no windows except the fanlights above the wooden doors. I consider that it would be conducive to health and comfort if the present wooden doors were removed and glass doors with separate outside jhilmils or Venetian doors substituted for them.

6. The hospitals have the long roof ventilation mentioned in a former part of this report, and the fanlights above the doors, but for the greater part of the year the climate admits of one or more of the doors in each ward being kept open. At the same time I think the outside Venetian doors and glass half doors would be an improvement. There are no jalousies or jhilmils.

7. The ordinary means of cooling by tatties and thermantidotes have not been considered necessary in this station, where the heat is at no time very oppressive. Punkahs are, however, available whenever the medical officer considers them called for.

8. There are six open fire-places in the west closed verandah placed at regular distances. The walls and ceilings of the hospital are regularly whitewashed once a year, but this can be done at any time on the requisition of the medical officer.

9. The privies and urinaries of the hospital are exactly on the same plan as those of the barracks, and all the arrangements connected with their conservancy are the same. They drain into a masonry well, which is emptied out and the urine and ordure removed to a distance. They are sprinkled with lime and charcoal every day, and are not offensive.

10. The lavatory arrangements are sufficient and are similar in every way to those of the barracks.

11. There are no baths for the sick. They wash in the basins of the lavatory, and can always afterwards if they please get a mussah (or skin) full of water thrown over them by the water carrier, this being the usual method of bathing employed in India. It would not answer when so many patients are in hospital with venereal complaint to have a plunge bath to which all might indiscriminately resort. The present system is more convenient and appears sufficient for all purposes of cleanliness.

12. It is not the custom of the washermen of India to wash inside the houses as in England. The hospital head washerman takes over the foul linen from the steward, and carries it away to some tank or nullah a mile or more perhaps from the hospital. After it is washed it is spread out in the sun to bleach and dry, and is brought back to be ironed or made up in the washerman's own house. This system appears to answer best for India, and is almost universally adopted. The number of dhobies or washermen allowed for the hospital of a full corps is one head washerman and four ordinary do.

13. An outbuilding was formerly used as a store room, but was not found sufficiently dry in the rainy season, and the hospital clothing, bedding, &c., have since been removed to an unoccupied end room in the women's hospital where there is ample space and every protection against damp.

14. The cots are the same as those employed in the barracks and already described. The same remarks apply to hospital cots as to the others, and the same improvements are suggested for them. Unlike those in barracks the hospital cots are supplied with mattresses, but these are seldom sufficiently thick to prevent the patients feeling the iron hooping underneath. A bamboo matting might be advantageously employed. In long bedridden cases it is my custom to serve out two mattresses to the patient as there are almost always spare ones in store. Besides the mattress each patient has one large and two small pillows stuffed with country hemp, two sheets, and one or two blankets if necessary. For uniformity, a chintz covering is stitched over one side of the blanket.

15. Here, as in the case of the wash-houses, the tidiness and appliances of a well-regulated English kitchen are not to be looked for. If supplied, the native cooks would probably not use them, and practically it is better to give them their own simple chulas or cooking places, and the ordinary cooking utensils. Any deficiencies in the cooking department are not owing to a lack of these appliances, but to the want of skill in the cooks themselves. For the small pay allowed to hospital cooks in the commissariat department it is impossible to secure the services of any with even moderate pretensions to the name. If they

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	can roast and boil tolerably well, and prepare simple puddings, they are considered to be perfectly qualified for the situation. No delicacy of any kind likely to tempt the capricious appetite of a sick man could be prepared by these miserable pretenders. 16. A complete set of hospital forms are forwarded with this report, but they are too long to be attached to the margin. 17. There is a hospital serjeant and sick orderly always attached to the hospital. The duty of the former is to assist in the steward's department, to see that all standing rules of the hospital are carried out, and to report all breaches of the same to the surgeon; to write out the daily report of sick, and generally to look after the hospital in subordination to the apothecary. He is not, however, in any sense a nurse or attendant on the sick. The sick orderly's duty is to go to each company every morning and evening, to collect the company sick reports, and bring up the men who require to be seen by the surgeon, both sick and convalescent; to march back those who are prescribed for without being admitted, and to take charge of the discharged men in the evening. The usual attendants on the sick in hospital are the ward coolies. In serious cases, when the comfort of better attendance seems to be required by the patient, it is usual, on the application of the medical officer to the captain of the company, for a comrade to be told off for this duty. In the serious illness of a woman the husband would be permitted to attend her. In ordinary cases there is an ayah and matranee for this purpose. The system of employing European nurses professionally trained might, I think, be most advantageously introduced into the hospitals in this country. 18. No epidemic has yet appeared in this hospital, nor any diseases which could in any way be attributable either to faulty position or other defective sanitary condition of the hospital. Both the men's hospital and that for women and children are excellently adapted for their purpose. 19. As a minor point I have already mentioned that more light might advantageously be admitted by substituting half glass doors for the wooden ones at present in use, and by having outside jhilmil doors; but, on the whole, nothing could be better than these hospitals. 20. There are no shaded walks for convalescents taking exercise, but there is a small garden attached to the hospital, and a good sized compound, in which the patients whose cases admit of it can take walking exercise morning and evening. When the weather is moderately cool they can sit outside in a covered verandah, which faces eastward, and which extends the entire length of the building. This also makes an uninterrupted promenade, and benches and easy chairs are placed for the convenience of the sick in different parts of the verandah. Elephants are usually available on the requisition of the medical officer for such men as he may consider likely to benefit by this mode of taking the air. 21. The sick wives and children of soldiers are treated in a separate hospital, as already mentioned, to which is attached a female establishment, consisting of an ayah and matranee. I consider the present arrangements very good and satisfactory. The women are very kind and attentive to each other in sickness. 22. A copy of the standing hospital regulations, which are affixed to the walls of each ward, is here enclosed. 23. In all matters appertaining to the sanitary condition of the hospital, to repairs, diet, and medical comforts, the medical officer may be said to have almost plenary powers. His suggestions, unless utterly unreasonable, would always be attended to. 24. There are no wards especially set apart for convalescents, and I do not think that much, if any, advantage would be gained by doing so. The convalescents are entered in the returns as "discharged from hospital." They go back to their barracks, do not attend drills or parades, and have to come up every morning under charge of the sick orderly to be inspected by the surgeon. They are not permitted to enter the canteen at all, nor to leave their barracks in the middle of the day, even in the cold weather, while encouraged to take morning and evening walking exercise.
XIII. BURIAL OF THE DEAD.	1. The burial ground used by British troops is about half a mile from the hospital, and between 500 and 600 yards from the nearest barrack. It is in a south-easterly direction from the station, the prevailing winds being W. and N.W. 2. The area is 1·06 acres, being 160 feet by 288. The subsoil is gravelly and porous, resting on clay, and the drainage is good. The ground is carefully kept. 3. There are no regulations about space, but practically the graves are at intervals of about two yards. The depth is generally six feet. None of the graves have yet been re-opened, only one body being interred in each grave. There is no compulsory regulation as to the time after death at which interment should take place, but if a death occurs before 11 A.M. in the hot weather the burial is usually the same evening; if after that hour the following morning. The only delay is on account of preparing the grave and providing a coffin. There are no native troops, or burial grounds for them, at the station. 4. The graveyard is never offensive in the slightest degree, and no particular precautions require to be adopted. On the death of a soldier the corpse is removed to a small detached building known as the deadhouse. As soon as a coffin can be prepared and the grave dug, burial takes place; if in the evening, half an hour before sunset, or in the morning at sunrise. 5. In regard to the dead of camp followers, or bazaar people, if Hindoos, they are burnt at a considerable distance from the station; if Mussulmen, they are buried in the Mussulman burial-ground, which is a good way out of the town. 6. I believe no injury to health accrues from the present practice. 7. I do not consider any alterations are called for.

I. Topography.	1. The country surrounding the station has an arid aspect, with very few trees, except a tope here and there. It is flat and somewhat sandy and dry. There is no jungle whatever in the vicinity of the station, but on its eastern boundary there are many rows of trees and a large river, and a canal on the northern boundary.
	2. The elevation of the station above the level of the sea is not known, and it is raised very little above the adjacent country, but there is a slight incline towards the river Ganges, above which its elevation is 60 or 70 feet, while it is raised above the canal on the north 15 feet. The country surrounding the station is a continuous flat. The infantry echellon barracks appear to be on rather low ground; however, everything is as yet unfinished, and the drainage imperfect.
	3. There is no tableland or mountain nearer than the Himalayas.
	4. The nearest waters are the river Ganges, which bounds the station on the east, the canal on the north, and the nullah on the south. The vicinity is not liable to overflow of water. There are many ravines near the station, but as no filth is allowed to be deposited there, they do not produce any appreciable effect on the health of the troops.
	5. The station is open and freely exposed to winds, the echellon barracks particularly so. Many of the officers' quarters have gardens and trees, but nothing objectionable further than the compound walls being in some instances very high, and in some degree interfering with free ventilation. The temperature of the station is not raised to an extent worthy of notice by the buildings being exposed to reflected sun heat. Westerly winds generally prevail in the spring and hot months, and are considered healthy, though accompanied with much dust.
	6. The surrounding country is cultivated in parts, but not in the immediate vicinity of cantonments; neither are there any works of irrigation anywhere near. Neither rice, indigo, hemp, nor flax are grown anywhere about the station.
	7. There is a large native town to the north of the station, about a quarter of a mile from the canal boundary.
	8. The soil of the station is marly, containing a good deal of sand, yet sufficiently stiff to prevent the rapid percolation of water. It extends to a very considerable depth, and is alluvial; while beds of kunkur (silica and lime) are found at a depth of 10 or 12 feet. There are no remains of former habitations.
	9. To keep wells from drying up during the hot season they require to be about 70 feet deep.
	10. The rainfall in the surrounding district is chiefly carried off by nullahs, which terminate in the Ganges. Some water remains many days on the surface, and is disposed of by percolation and evaporation. There is no drainage passing into the subsoil of the station from any adjacent higher ground.
	11. The water supply of the station is derived from wells. There is a tank about 80 yards square, situated within the cantonment. I have never observed this tank to be dry, even in the hottest season. It is not used for any purpose that I can discover, and it is not liable to pollution from leaves or other matter falling into it. I have not been able to trace malaria as having arisen from it.
	12. The supply of water available for the station is abundant, and there is no peculiarity of flavour or odour about it. I have not made any chemical analysis of the water, but judging from the soap test, I should say it contained very little earthy impurity. It is neither hard nor does it possess the quality of softness to any extent, and I consider it good, and the supply abundant. It is raised from wells in leather buckets and prepared skins, conveyed by the native water-carriers to the barracks, &c., and kept in earthenware vessels for use.
	13. There are no more topographical points bearing on the health of the station not included in the foregoing queries.
	14. New stations are selected by committees appointed by the Government, consisting of experienced military officers, an engineer, and one or two experienced medical officers if practicable, as members, with the view of examining the topography and climate, ascertaining the prevailing diseases, and the general healthy condition of the neighbouring population.
II. Climate.	1, 2. There are no means or instruments available at this station for conducting and registering meteorological observations, and the records of these for past years, if any existed, were all lost during the year of mutiny.
	3. There are great fluctuations of temperature, humidity, and pressure at this station. There are no records of the density or otherwise of the atmosphere, or any means of ascertaining the electric tension of the air, or electric force of the different winds, or the presence or not of ozone. No bad effects can be attributed to irrigation. The air is impregnated with dust from April till the end of June. The temperature ranges extremely high during the hot winds, and some mortality usually occurs from heat apoplexy, sun-stroke, &c. The precautions necessary are to avoid exposure, excesses, &c., and that the drills should be restricted to the time between daybreak and sunrise and after sunset in summer. The clothing is varied according to the seasons, and well adapted to them. Evening drills might be advantageously dispensed with during the hot season, and all drills for infantry when the ground is wet, &c., during the rains. The most unhealthy months are from April to September, and the most prevalent diseases are fevers, cholera, dysentery, and rheumatism.
	4. There is no district near this station the climate of which is more conducive to health than that of Cawnpore.
	5. The following are the stations at which I have served, viz.:—Meerut, Sukkur, Umballa, Saugor, Sealkote, Jullundur, and Lucknow. Sukkur proved highly injurious to the troops, and great mortality arose from fevers of the remittent and intermittent types, and organic

CAWNPORE. BENGAL.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	affections arising from these. The station was situated on a limestone formation, elevated above the surrounding country, and perfectly bare of trees and vegetation. Some time in August the surrounding country, which had been inundated for two months by the overflowing of the Indus, became rapidly drained of the surface water by the falling of the river, leaving the soil impregnated with decomposed organic matter exposed to an intensely hot sun. Sickness and mortality soon commenced, and raged with great violence, particularly in H.M.'s 78th regiment, during the autumn of 1844. The station of Saugor is not a salubrious one. The geological nature of the soil, which is volcanic and ferruginous, occasions at certain seasons severe paludal fevers.
III. SANITARY CONDITION OF STATION.	1, 2, 3. Plans of the station and ground plan of the barracks, &c., are transmitted. 4. Table of barrack accommodation. Date of construction unknown, all records having been destroyed. Total number of rooms or huts { Echellon barracks - - - 10 ranges. Several bungalows at the Cawnpore intrenched position are occupied by troops. Plans are transmitted herewith. Having originally been private residences, they are irregular in form and height, and cannot be brought under the classification of barracks. The allowance of air per man as at present occupied far exceeds the amount allowed per regulations.

5. The doors of the barracks are on opposite sides, and open inwards; and there are also inner and outer verandahs on both sides. The outer verandahs are not occupied, and the inner ones are supposed not to be; but of late years they have invariably been occupied, consequent on the influx of Europeans into the country. There are no jalousies or jhilmils.
6. The bedsteads used in the barracks are constructed of wood with twine bottoms, to which is added a tow mattress. I think iron bedsteads, with elastic iron bottoms, the best, and mattresses stuffed with cocoa-nut fibre.
7. The tents used in camps are of Government pattern and regulation area.
8. The ventilation is effected in barracks by doors and windows, and over-lights near the top of the walls, moveable on horizontal axes; and these means are quite sufficient for the purpose. The barracks are cooled during the hot winds by means of tatties, which are placed opposite the door openings in the western verandahs; these are supplied with water, and kept thoroughly wet during the whole of the day by an establishment provided by Government for the purpose. The apparatus is constructed of layers of the root of kuskus grass, fixed on a framework of split bamboo made to fit the doorways, and costs about 2½ or 3 rupees. The effect is a reduction of temperature to the extent of about 10 degrees or more.
9. The barracks, &c., are constructed of bricks and mortar plastered and whitewashed.
10. The floors are of stone flagging laid on rammed earth and broken bricks. They are raised on an average three feet above the ground; but there is no passage for air beneath them.
11. Can suggest no improvements in the materials and construction of the barracks, &c., which are kept in repair and their sanitary condition attended to by the brigadier, engineer barrack-master, and sanitary officer. The walls and ceilings are cleansed and limewashed annually, or at the request of the regimental surgeon.
12. Baths have not yet been constructed in the echellon barracks, but plans of the attached wash-houses are transmitted; and two plunge baths will be constructed in due course. Plans of the baths, male and female, attached to the foot artillery barracks are forwarded; baths and wash-houses are constructed near the barrack wells, from which water is brought by pipes, and similarly carried off to the nearest drain.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	13. The barrack cook-houses are rectangular buildings, in two parallel wards, about 30 × 12 each. Water is supplied by hand labour; and when used is thrown into sinks communicating, by open drains, with small cesspools immediately outside, and which are cleaned out daily. Europeans do not cook their own victuals nor wash their own linen in India.
	14. A sketch of the privies and urinals is forwarded; the urine passes by covered drains into cesspools, which are cleansed out every day; the ordure is removed by hand labour to the same receptacles, and conveyed daily to a distance from the station.
	15. The barracks are lighted at night by oil lamps.
	16. The barracks are drained by surface drainage; but the drainage of the echellon barracks cannot be perfectly carried out as long as the buildings are in progress. There are no sewers, and the drains are merely for carrying off the rainfall, all dirt, &c., being removed in carts daily. The drains when finished will be sufficient for the surface drainage; but they are not intended for draining cook-houses, privies, &c. The echellon barracks, being in an unfinished state, have been damp during the past rainy season, caused by leakage through the roof. The fluid refuse is all carried into cesspits, and removed to a distance from the station. These cesspits are near the outbuildings, viz., the cook-house and bath-house, &c.; they are chunamed, and do not admit of percolation. There are no foul ditches near the station, with the exception of one from the town of Cawnpore, near the cantonment boundary, and which is occasionally offensive when the water supply from the canal is deficient.
	17. The general surface cleansing of the cantonment and its vicinity is good. Persons are employed to remove all filth, &c., which may be found. The sweeping contractor removes the manure, &c., outside the cantonment boundaries.
	18. A little grass springs up on the surface of the cantonment during the wet season only. There are at present ruined bungalows and sepoy lines which interfere with the ventilation of the station, bazaar, &c., but they are in progress of removal.
	19. The drains in the bazaar are in good order generally; and its ventilation and water supply sufficient; the latrines also are kept clean. The regimental and artillery bazaars are crowded and in many parts ruinous. If these were levelled, and sites granted to the residents (except those actually attached to and required for the 54th regiment and artillery), it would add much to the sanitary improvement of this part of the cantonments, and promote ventilation and cleanliness. The regulations for preserving due cleanliness are good and improving. Every shopkeeper is required to keep the space in front of his premises clean; the litter accumulating there being regularly taken away every morning by the contractor for bazaar sweepings. The bazaar serjeant daily visits one or other of the bazaars, to see if they are kept clean; and any infringement of the regulations subjects either the shopkeeper or contractor to a fine for neglect, on their being reported by the serjeant. The generality of native houses in and near the station are built of mud and plastered over; a few only are built of bricks, with low-tiled roofs. No dungpits or cesspools are allowed; and if such be found they are filled up, and the owners are punished by fines. No nuisance is experienced in barracks from wind blowing over the native houses.
	20. The slaughter-house is in the commissariat yard, within the cantonment boundary, but a long distance from the barracks. The offal is carried away into the country; and no nuisance is experienced in barracks.
	21. There exists no particular arrangement for the picketing of horses and other cattle, which are generally kept near their owners' residence. One Arab merchant has been permitted to build a range of stables near the sudder bazaar; but this is the only one of the kind. Manure is regularly removed.
	22. There are no stables. Dung heaps are not allowed to remain any time; but the manure is sold, and conveyed some distance into the country. The picketing ground of the artillery is close to the barracks on the west side, which is objectionable; that for the cavalry is at least half a mile from the barracks occupied by the men, and at a greater distance from the building used as a hospital. The building occupied by the artillery sick is a quarter of a mile from their picketing ground, and is well situated as regards the prevailing winds.
	23. The few women now with Her Majesty's 54th regiment are well accommodated out of the barracks. In the artillery the women occupy part of the building temporarily used as a hospital. In the cavalry there are very few women; and these occupy the same barracks with the men, but have quarters at the extreme end of the building and are quite separate.
Officers' Quarters.	1. The officers' quarters at this station are healthy; but I think the height of many of the compound walls might be lowered with advantage.
IV. Health of the Troops.	1. From the appearance of the native population I do not think they suffer from the effects of malaria, and there is but little spleen disease amongst them.
	2. Cholera and small-pox occasionally prevail among the natives, aggravated by the crowded state of their dwellings, want of ventilation, &c.
	3. The inhabitants of Cawnpore are generally healthy, which may be attributed to a running stream of water, which flows from the canal through the town, and empties itself in the Ganges, by which means all filth and impurities are carried off.
	4. Her Majesty's 54th regiment, right wing, was stationed at Sultanpore from January to November 1859, during which time fevers were prevalent; but the general state of health was good. The left wing was at Fyzabad from February till October 1859; fevers were there prevalent, but general state of health good. The regiment was, on its arrival here in January 1860, healthy; since then fevers and venereal diseases have been prevalent. Her Majesty's 1st light cavalry arrived here from Allahabad in June 1859. Cholera, fevers, and bowel complaints prevailed during that year; but the regiment has continued healthy during 1860. No portion of the men's accommodation at this station is more unhealthy than the rest.
	5. The troops at this station are not camped out during any part of the year.
	6 to 13. No experience in hill stations; but I should think there is no period of residence in

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	them beyond which injury is likely to be inflicted on the health of troops on their return to service in the plains. 14. Troops serving in India should be located in hill stations, with short periods of service in the plains. However short, periods of change to the hills are decidedly beneficial to troops serving in the plains. Instead of sending troops to hill stations, a certain number of men should be selected from all the corps serving in India, so as to give every regiment a chance. Regiments contain many men who would be injured instead of benefited by a residence in the hills. Men of cavalry corps also would in this way derive the advantage of hill climate, which at present they are debarred from. For troops stationed in the plains, a change of station every three years is sufficient. 15, 16. No experience to enable me to reply to these queries. 17. There is no higher ground near this station which could be advantageously occupied as a hill station. 18. I have found volcanic, ferruginous, and limestone soils extremely insalubrious. 19. The best age for troops to be sent to India is from 21 to 25 years, and no soldier should be sent there until he has attained his full growth, and he should land there in November. I think troops preserve their health best when on the ordinary line of march, and would therefore move them up country in this way during the months of December, January, and February. Flannel belts should be provided for the men; and all recruits should be thoroughly drilled at home. 20. As far as I know, troops coming direct from the home depôts do not suffer more on their arrival in India than those sent from intermediate stations, such as the Cape, Mauritius, or New South Wales. I am not aware that a residence in hill stations would in any way accustom troops to the climate of the plains. Young soldiers suffer only from more acute forms of disease than those who have served in the country for two or three years or more. If troops newly arrived could be occupied and amused, &c., in barracks, and entirely prevented from exposing themselves to the habits generally of the soldier in India, and from indulging in spirituous drinks, sickness and mortality during the early years of service would be little as compared with those long resident in the country. 21. Troops are sent to the interior by steam-boats as far as Allahabad, or by bullock waggons; but I consider marching them up country preferable. 22. The British soldier should not serve in India more than from three to five years. I think a prolonged residence produces a morbid physical and intellectual change, and chronic disorders, necessitating the invaliding of a great number. If corps have a short service, viz., three years in India, their strength would be sustained for a much longer period, and their efficiency in other parts of the world not impaired. 23. The Presidency Board occasionally rejects men sent down as invalids by the Stationary Boards. 24. Invalids should leave India for home in February or March.
Diseases.	1. There are weekly inspections held at this station for the discovery of incipient diseases. 2. There have been no cases of scorbutus or scorbutic disease among the troops here. 3. There have been no cases of hepatic disease amongst the men of H.M.'s 1st European cavalry; but in H.M.'s 54th regiment the proportion of admissions for the last six months is as 35 to 1,009. The disease is attributable to intemperate eating and drinking, and is considered consequent on digestive derangements. No practical prophylactic measures can be suggested. 4. No case of dracunculus has occurred at this station. 5. Latterly, the proportion which venereal disease has borne to the total sick in hospital has been from one-third to one-half. Soldiers frequently visit other bazaars instead of confining themselves to their own regimental prostitutes, and in this way contract the disease. Lock hospitals would, I consider, be of little, if any, advantage. 6. The following are the diseases from which the troops at this station suffer, viz., intermittent and remittent fevers, dysentery, cholera, small-pox, and rheumatism. The following table shows the proportion which admissions and deaths from the above diseases bore to the total admissions and deaths in the year from April 1, 1859, to March 31, 1860.

In H.M.'s 1st European Cavalry.

Admissions from these Diseases.	Total Admissions.	Deaths from these Diseases.	Total Deaths.
	1,560	48	59

In H.M.'s 54th Regiment it is stated, viz.:—

1 to	13	18 to	42

7. The nosological character of the more frequent zymotic diseases is miasmatic. They occur more frequently during the hot and rainy seasons, from April to September. No particular state of the atmosphere has here been observed to precede or accompany these diseases. I cannot say what particular habits and conditions of the troops and native population predispose to these diseases.
8. The prevalence of epidemic disease is influenced to a considerable degree by the soldiers' duties, habits, &c., but the precise extent cannot be specified.
9. Small doses of quinine have not been given as a prophylactic against malarial disease at this station.
10. I would suggest, towards the prevention and mitigation of epidemic disease at this station, more varied means of occupation and amusement.

References to Subjects and Queries.	Replies.
V. Intemperance.	1. The troops at this station are fairly temperate, and there are not many confirmed drunkards among them. 2. I am unable to give any information as to the proportion which admissions from diseases caused directly or indirectly by intemperance bear to the total admissions, and the medical officer of H.M.'s 54th regiment is likewise ignorant on this head. H.M.'s 1st European cavalry is a young regiment, and very few of the men have been 12 months in the service. Drunkenness is always punished as an offence. 3. Distilled spirits are sold in the canteens and bazaars. The bazaar liquor shops are under Government supervision, to prevent liquor being taken away and sold to European soldiers. Bazaar spirit is of various proof, and commissariat rum of the ordinary quality. The amount consumed per man per day is one-fortieth of a gallon at present, and whenever a full supply of malt liquor can be got the men have it. The soldiers at this station do not have spirit issued to them as part of the ration, either here, on the march, or in the field. It is always optional for a soldier to draw spirit up to his regulated allowance or not to have any. The practice of allowing a dram to be issued before morning parade has never been tried in H.M.'s 54th or the 1st Bengal cavalry. Colonel Herbert, C.B., of H.M.'s 54th regiment, has had experience of this practice in his late corps (H.M.'s 75th regiment), and found it answer very badly. Spirit is never given as a ration to convalescents. No drinks other than intoxicating drinks and injurious to health are sold at the canteens or bazaars. 4. The consumption of spirit by troops is neither conducive to their health nor to their efficiency and internal discipline. 5. If the sale of spirits could be abolished in both canteens and bazaars it would be highly beneficial to the health of the troops. 6. The use of malt liquor in preference to spirit ought to meet with every encouragement. 7. Neither coffee, tea, lemonade, nor ginger beer, &c., are used to any extent at this station. 8. Beer, tea, and coffee are far preferable to spirits, but if the sale of the latter were abolished in the canteen the men would be driven to the bazaar liquor shops, at least they would employ natives to procure liquor for them, and which they nearly always succeed in doing, notwithstanding the Government supervision. 9. It would be decidedly beneficial to the health of the troops to prohibit the sale of spirituous liquors in the canteens, provided there was a severe penalty inflicted on natives selling spirits to soldiers, otherwise it would be injurious. 10. No reply to this query. 11. The hours of issue at the canteens are ¼ to 1 o'clock, when 1 pint per man of malt liquor is sent to each troop or company for dinner, between 2 and 4 p.m. 1 pint is issued, and from ¼ past 6 to ½ past 8 p.m. 1 dram of rum per man. The serjeant on duty at the canteen sees that these quantities are not exceeded, that no spirit is carried away, and that the canteen is regularly conducted, and shut at the proper hour. The bazaar liquor contractors are bound down in heavy penalties not to sell to the European soldiers or any one connected with them. Natives can obtain liquor, but cannot take any away without the magistrate's pass. Each liquor shop is furnished with a ticket in English, informing soldiers that the shopkeepers are not allowed to sell to them under any pretence whatever. There is only one shop in cantonments, but there are liquor shops in the sudder bazaar in the city not far from the cantonment boundary.
VI. Diet.	1. The ration for Queen's British troops and European troops in the Indian army is the same, and is composed as follows, viz.:—1 lb. bread, 1 lb. meat, 4 oz. rice, 2½ oz. sugar, ⅜ oz. tea, or 1⅜ oz. of coffee, 1 oz. salt, and 1 lb. vegetables. The only variety in this is the issue of mutton twice a week instead of beef, and in the vegetables. A responsible inspection of the ration is daily made by the subaltern officer of the day, quarter-master, and occasionally by the commanding officer, and a medical officer. 2. A complete ration is provided for the troops, and for which there is no stoppage. The men have three meals a day, viz.:—Breakfast at 7 a.m., consisting of tea and bread, and a portion of meat; dinner at 1 p.m., soup, meat, vegetables, and bread; and supper at 5 p.m., tea and bread. About one-third of the ration is composed of vegetables. 3. The ration is good, as at present provided for the men, and I cannot suggest any improvement in it. It is served out in messes, and could not be disposed of. 4. The cooking is fairly performed, and boilers, frying-pans, &c., are used. The cookhouses are kept clean, and sufficiently supplied with water. The cooking of the food is varied as the different messes may prefer, generally stewed with vegetable. It is well performed, as is also the making of tea and coffee. The men usually have coffee and a piece of bread before a march. 5. The establishment of gardens for the cultivation of vegetables would be very advantageous if so conducted that the whole work was performed by the soldiers themselves, with the exception of drawing the water for irrigation. If other native labourers were allowed, their chief value as a healthful employment and recreation for the European soldier would be destroyed.
VII. Dress, Accoutrements, and Duties.	1. The regulation dress according to the season is worn at this station; dyed cotton for summer, a cloth tunic for winter, and wicker helmets through the year. The accoutrements do not vary, and a forage cap is worn during the cold weather in the evenings, and always for night duties. I consider the present dress as suitable to the climate and for the soldiers' duties by day and night and at different seasons. Flannel belts, however, would be a great advantage to the troops, and should always be worn. Great coats are used on guard in cold and wet weather, and the sentries are protected from the sun and rain by sentry boxes, verandahs, &c.
Duties.	1. It is advisable that men be thoroughly drilled at home before being sent to India. 2. In the hot season a soldier's duties are light. He is on duty once a week, and on inlying picket once every 14 days. He has a morning parade at 5 o'clock, and generally a drill, varying from 20 minutes to an hour's duration. The evening parade at 6 p.m. is seldom more than a roll-call and inspection, except for awkward men, who have half an hour's drill. Cavalry regiments are subjected to severe drill in the riding school: they should be thoroughly

CAWNPORE. BENGAL.

References to Subjects' and Queries.	Replies.
VII. Dress, Acoutrements, and Duties—*cont.*	drilled at home. The best hours for drills, parades, and marches depend on the season. The average number of nights which the men have in bed during the week is 7 (i.e., on guard not quite once). At the intrenchment the duty comes round a little more frequently, the men having six nights in bed. 3. Guards are mounted in the immediate vicinity of the barracks. They last 24 hours, but a portion of the men on the larger guards are sent to their barracks during the day, mounting again at sunset. The roll-calls are as follows: for breakfast at 7 a.m., one at 11 a.m., 1 p.m., 5 p.m., 6 p.m., and tattoo at 9 p.m. Additional precautions for night guards are not thought necessary.
VIII. Instruction and Recreation.	1. The following are the means of recreation and instruction provided for troops at this station, viz., a ball-court, skittle-grounds, regimental schools, libraries, reading rooms, workshops for tailors, shoemakers, and armourers. Cricket is a favourite amusement, and the theatre is occasionally used, but its distance from the barracks is inconvenient. Putting shot and quoits are practised, but there is no regular gymnasium. Men fond of reading may be amused during the daytime; but ball-courts, skittle-grounds, &c., are not the kind of occupations for soldiers during the heat of the day, and as they are at present constructed, The men are not allowed to expose themselves from 7 a.m. till 5½ p.m.; at least there is an order to that effect, but it is often disobeyed. 2. I would have skittle-grounds in a properly constructed building, with doors, and have tatties supplied during the hot winds, also gymnasia, shooting galleries, and swimming baths on a similar plan, so that those who cannot read or amuse themselves in the libraries, schools, or workshops might find other occupation. 3. The regimental savings' bank of H.M.'s 54th regiment is in full operation, about one-third of the men being depositors, some to a large amount. It has the best result. 4. There are no means whatever, except the barrack verandahs, to enable the men to take exercise during the heat of the day without injury to health.
XI. Military Prisons.	1. The military prison is not sufficiently raised, the roof is far too low, and the temperature, in consequence, extremely high. Ventilation is now perfect enough, as the high mud wall which formerly surrounded the building has been removed. Most prisoners fall sick after a short sojourn there in the hot months, owing to the heat, glare, and hot winds and dust blowing through them.
X. Field Service.	1. There are no local regulations for field medical service not included in the General Presidency Regulations. 2. Medical officers can only make suggestions as to the line of march, camping, &c., which may or may not be attended to. They have no powers. 3. Camping grounds are selected by the quartermaster-general of the force, with reference to good ground, water supply, &c. There is nothing to complain of in respect to ventilation in camp. Excavations are made in certain positions to be used as privies, and are afterwards filled up with earth. The general surface cleansing is performed by the quartermaster's establishment of corps. The principal medical officer may recommend any sanitary arrangement he deems requisite. 4. Information respecting the arrangements adopted in the presidency for field hospitals, ambulances, hospital supplies, &c., can be more conveniently afforded from the office of the principal inspector-general.
XI. Statistics of Sickness and Mortality.	No information is afforded under this head.
XII. Hospitals.	1. The only hospital here is the artillery one, occupied by Her Majesty's 54th regiment, a plan of which is transmitted. 2. It is well away from the native buildings or bazaar. The site is a good one, being open, and nothing to interfere with the free ventilation. 3. The water supply is abundant and good. 4. Surface drainage removes the refuse water from the hospital, and all impurities, &c., are conveyed to a distance in the country every day. 5. The floors are of stone, and raised 3½ or 4 feet above the ground, but no current of air passes beneath it. The roof covering consists of six inches of thatch overlaid with tiles. The drainage arrangements which are merely surface, seem sufficient for carrying away the roof and rain fall rapidly. There are verandahs on both the inner and outer sides of the hospital, *vide* plan. The inner ones are made use of when necessary for the accommodation of sick, &c. The hospital consists of one flat.

Table of Hospital Accommodation.

Total number of wards - - - - - - - - 3
Total regulation number of beds - - - - - - 72

Wards or Hospital Huts.	Regulation No. of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
No. 3	24	ft. 87	ft. 24	ft. 27	ft. 56,376	2,349	87	ft. in. 1 6	12	ft. 8	ft. 5 per ward.

If the inner verandahs be occupied the number of beds is doubled, or the hospital becomes suited for 144 beds. In the above calculation the cubic contents of the air in either verandah has not been taken into consideration. The hospital is so placed as to receive the full benefit of the prevailing winds.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	6. The ventilation of the hospital is effected by doors, and pipes carried through the thatch. These means are found sufficient. There are no jalousies or jhilmils. 7, 8. The means used for cooling the air admitted into the wards are the same as those used in the barracks. There is no apparatus for warming it. The walls and ceilings of the wards are cleaned and limewashed every six months, or whenever the medical officer may deem it necessary. 9. The privies, urinals, &c. are about 40 yards to the rear flank of both ends of the hospital, and are square rooms 40 feet by 20, and are 10 feet high. Round one side there are a number of small walls, 1½ feet high, and distant about a foot from each other, immediately in front of which is a shallow drain for the receipt of ordure, &c. They are not over cess-pits, and are offensive, as they are not properly drained, but are about to be improved. 10, 11. There is a small plunge bath, with a narrow edging, on which are vessels for washing, &c. These means are neither sufficient nor convenient. 12. The linen is washed and dried by the native washermen at a distance from the station. 13. The storage is sufficient and dry. 14. Some of the bedsteads used in hospital are of iron and some of wood, with twine or tape bottoms. Iron cots are the regulation ones, with elastic iron bottoms, and are well adapted for the purpose. The mattress is of red cloth, stuffed with tow, but cocoa-nut fibre would be best. 15. The hospital kitchen is a square building, about 40 feet by 20 feet, with apparatus. The cooking is tolerably well performed. 16. Copies of the diet tables, diet rolls, &c. can be best supplied from the office of the principal inspector-general. 17. There are a hospital serjeant and orderlies, at the discretion of the medical officer, for attendance on the sick, also ward coolies, and these are sufficient for the purpose. 18. The sanitary condition of the hospital is tolerably good. No epidemic has appeared in it. 19. The construction of the hospital privies might be improved, which, I believe, is about to take place. 20. Convalescents can walk about the hospital compound, and elephants and spring bullock carts are also provided for them, but there are no shady walks. 21. The soldiers' sick wives and children are at present accommodated in their barracks, but a hospital will soon be appointed for them, which will be a great advantage. 22. There are no special local hospital regulations not included in the General Presidency Medical Regulations. 23. The medical officer has an absolute power as regards change of diet, &c., but with respect to the sanitary state, repairs, &c., he must make a requisition on the proper department, and which is usually attended to if practicable. 24. There is no convalescent ward, or hospital for convalescents, provided at this station. I think accommodation of this sort would be highly advantageous.
XIII. Burial of the Dead.	1, 2. The graveyard for British troops is within the cantonment, and about half a mile from the echellon barracks. It lies in a westerly direction, and the prevailing wind is westerly. Its area is about seven acres, with a surface and subsoil of marl. There is a shallow ditch outside the mud wall of the graveyard. As the graves are not re-opened, I am unable to say whether decomposition is rapid or not. There is no care bestowed on the ground, further than having a chowkeydar to keep out trespassers and animals, no funds being available. 3. Graves, which are never re-opened, are about 6 feet in depth, and have an interval between them of about 3 feet. The time of interment after death varies from 10 to 24 house, according to the time of year. The hot season, rather than the prevalence of epidemics, regulates the time of interment. The majority of natives, being Hindoo, have no graveyard, but the dead bodies are burnt. Mohammedans are buried, but not within the cantonment. 4. The graveyard is never offensive. British troops are buried at sunrise and sunset, but there is nothing peculiar in their mode of burying. 5, 6, 7. The dead of camp followers and bazaar people are either burnt, buried, or thrown into the Ganges. No injury accrues to the public health from the present practice, nor is any improvement to be suggested.

(Signed) M. K. Atherley, Brigadier,
Commanding Cawnpore.
David Simond, Captain, Bengal Engineers,
Ex. Engineer, Cawnpore Division, N.W.
John Campbell, M.D., Surgeon,
1st Bengal Light Cavalry.

I. Topography.	1. The station of Chunar is situated on the right bank of the Ganges. The aspect of the country is open on the river side, but on the land side it is undulating, hilly, sandy, and dry, except in the rainy season, when it is swampy, and more or less under water,

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	from the overflow of the Ganges. There is not much wood, and no jungle in the vicinity; water, however, is abundant. 2. The elevation of the station above the sea is taken at 250 feet. It is rather below the elevation of the general level of the adjacent country. The river Ganges is immediately on the right or north side, and the Jurghoo Nuddee is within a quarter of a mile to the south. There is higher ground than that on which the station is situated by 20 or 30 feet; but there is no reason to infer that it is healthier. The cantonment formerly occupied ground on the south of the Jurghoo, and to the west of the fort, but for military purposes it was removed to its present site. 3. The nearest table land is about 1½ miles distant from the station, and is about 200 feet above its level. 4. With regard to the nearest water, the station and town of Chunar, which are closely approximated, occupy a delta not exceeding half a mile in the greatest width between the Ganges and the Jurghoo Nuddee. The Ganges overflows its banks annually in the rainy season, and generally in the month of August. The overflow does not last above a fortnight. There is some broken ground and many ravines, caused by the water-courses from the hill streams; but I have not found that they affect the health, as the water drains rapidly into the Jurghoo. 5. The fort in which the troops are mostly located, from its great elevation is freely exposed to winds. The rest of the station is open only to winds from the river side; the fort and the buildings in the town interfere with free ventilation on the other sides. The temperature of the station is raised in very hot weather, by the buildings being exposed to reflected sun heat. The station is very little exposed to cold or variable winds, or to land winds except in the fort; it is, however, exposed to the river breeze, which is pleasant and generally healthy; but sometimes induces colds and fevers at the termination of the rainy season. 6. The surrounding country is generally highly cultivated, except where the sandstone hills of the Vindyan range approach closely the south of the station. Near their base the soil is of a kunkury nature and unproductive. There are no works of irrigation in the vicinity. Irrigation from wells is carried on to a small extent,—it has no effect on the health of the station. The soil near the river bank is overflowed by the Ganges in high rains, and at all times is tolerably moist. No rice is grown within several miles of Chunar, as the nature of the country is not suited to its production. Indigo is cultivated to a small extent, but not in the immediate vicinity of the station; no hemp or flax is prepared. No nuisance or injury to health results from the partial cultivation of indigo. 7. The town or city of Chunar with a population of 14,000 is in immediate proximity with the station. 8. The sandstone hills of the Vindyan range approach the Ganges at Chunar, and a detached offshoot from them forms the site of the fort of Chunar, which overhangs the river. The sandstone is of the nature called "new red." Near the base of the hills the ground is undulating, and contains much limestone kunkur. The subsoil is mostly Gangetic deposit, composed of different kinds of clay and sand. The station has been built on the verge of a suburb of the city; part of it was formerly occupied, but the greater part has been built on new ground. 9. Water is found at a depth of between 40 and 45 feet in the dry season, and of between 25 and 30 feet in the wet. 10. The rain-fall drains readily from the surface. There are no surface springs or subsoil drainage, and generally very little water anywhere, except in a high flood of the Ganges, when a great part of the station and of the suburbs of the town is under water. There is no adjacent higher ground from which the drainage could pass into the station. 11. The water-supply of the station is derived from the Ganges and from wells. There is no tank in the station nor within half a mile of it. Care is taken to prevent leaves or other matter falling into the wells. There is no nuisance experienced from the wells. 12. The water-supply available for the station is inexhaustible. If allowed to settle before it is drank, it becomes clear, sweet, and inodorous. Its chemical composition has not been ascertained, but it is probably similar to that at the neighbouring river stations. It is soft, and examined by the microscope nothing is seen but dust, consisting of minute fragments of vegetable matter, and a few feathers of insects. The quality of the water is good and wholesome. The water is filled from the Ganges into puckals and mussaks, and conveyed by bullocks and bheesties to the barracks. From the wells it is raised in ghurras by hand pulleys, and filled into mussaks; no better water is procurable. 13. The row of huts westward of the thatched barracks, as well as most of those on the river front of the barrack square, should be levelled, as they materially interfere with the ventilation. The road between the barrack square and the church is narrow, and shut in on the south by huts, which should be thrown back and the road widened to admit of a free current of air into the square. 14. New stations are selected by a mixed committee of military, medical, and civil officers. The Engineer Officer attached to the division, if not a member of the committee, is directed to be in attendance. The committee are furnished by the Quarter-master-General's office with a printed copy of Dr. Dempster's rules for the selection of sites for cantonments. I cannot suggest any improvement in the manner of selection.
II. CLIMATE.	1. An ordinary thermometer and a common tin rain-gauge made by a native workman are the only meteorological instruments at this station.

2. TABLE of Meteorological Observations from 1st January 1850 to 31st December 1859.

Months.	Barometer. Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Sun Temperature.	Rain, inches.	Winds.		Days of Sunshine.	Remarks.
								Direction.	Force.		
January -	—	65	22	76	54	84	·5	S.W.	Moderate	27	A few fleecy clouds, heavy dew, winds cold, no storms.
February -	—	69·5	25	82	57	90	1·5	S.W.	Calm	25	Dark clouds for a few days about the middle of the month, dew not so heavy as in January, wind rather cold.
March -	—	78	30	93	63	100	·75	S.W.	Calm	28	A few light fleecy clouds, very little dew, wind pleasant.
April -	—	86	24	98	74	106	·5	S W.	Moderate	27	A few light fleecy clouds, no dew, wind warm at mid-day, no storms.
May -	—	91	22	102	80	113	·5	S.W.	High Winds.	26	A few light fleecy clouds, wind hot, no dew.
June -	—	92	22	103	81	120	10	N.W.	High, with occasional storms.	15	Clear the first half, cloudy with storms and lightning, wind hot to 15th, no dew, rain, and occasional storms.
July -	—	87·5	17·5	96	79	110	14	N.W.	Do.	6	Dark heavy clouds, wind cool, no dew, occasional storms.
August -	—	86	16	94	78	107	12	N.W.	High, with occasional gales.	8	Dark heavy clouds, no dew, wind cool, occasional gales, but no storms.
September	—	85	16	93	77	100	6	N.E.	Moderate	13	Dark clouds from 1st to 15th, no dew, wind cool and pleasant.
October -	—	81·5	19	91	72	95	2·5	N.E.	Moderate	22	A few light clouds, dew falls about the 15th, wind cool.
November	—	73·5	23	85	62	90	·5	N.E.	Moderate	27	A few light clouds, heavy dew, wind cold from 15th to 30th, no storms.
December	—	65	24	77	53	85	1·25	S.W.	Calm	26	Occasional dark clouds about the end of the month, heavy dew, wind cold, no storms.

References to Subjects and Queries.	REPLIES.
II. Climate—*cont.*	3. The general character of the climate is hot and healthy; very hot and dry during the season of the hot winds; hot and moist in the rainy season; pleasantly cold in the cold season; the variability of temperature not excessive at any period; very little subjected to fogs, and generally free from dust and other admixtures affecting the atmosphere. Acclimated soldiers of temperate habits preserve their health in Chunar. Good diet, shelter, and clothing, varied according to the season, are required. There are no drills or exercises, the only duty devolving on the soldiers being guard mounting. The day sentries are necessarily protected as much as possible against the sun's rays. The night sentries in the cold weather are provided with great coats. Generally the months of October, November, and half of December are the most unhealthy from the prevalence of intermittent fever. In some years the hot weather sets in with an accession of fever and cholera, but generally the season of the hot winds is the healthiest part of the year.
	4. There is very little, if any, difference in the climate of Chunar and in that of the neighbouring district. The fort of Chunar, from its elevation and favourable position, is perhaps healthier than any place in the vicinity. The station though less favourably situated, is generally healthy, and with reference to the fort one more convenient could not be selected.
	5. The stations at which I have served are as follow: Fort William, Barrackpore, Purtaleghur, Bancoorah, Dinapore, Kyouk-Phyoo, Nursingpore, Benares, Allahabad, Burripore, Merut, Ferozepore, Kurtarpore, and Chunar. I served principally with native troops, having occasional charge of a civil station and European artillery. I found Purtaleghur and Kurtarpore the healthiest; next to them Merut and Ferozepore. Kyouk-Phyoo alone I considered injurious to health. The health of the troops at the other stations was generally good.
III. SANITARY CONDITION OF STATION.	1, 2, 3. No map of the station exists; plans of the station and barracks, &c. are forwarded.
	4. TABLE of Barrack Accommodation.
	Date of construction of barracks at Chunar is unknown. No. 1 was first occupied as a barrack in 1840–1; No. 2 was converted into a temporary barrack in 1857; No. 3

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	was built for the subordinate officers of the arsenal and magazine, and afterwards made over as a barrack; No. 4 was constructed probably in 1814, when the hospital was purchased.

Total number of rooms or huts, 25.

Total regulation number of non-commissioned officers and men, 268.

5. The windows of the barracks are on opposite sides and open inwards. The house barrack has a 10 ft. verandah east and west. The gun shed barrack has a 13 ft. verandah to the west; the veteran barrack, a verandah 11 ft. wide all round; and the thatched barrack, a 9 ft. verandah all round. The verandahs are commonly occupied as sleeping quarters by the soldiers in the hot season. There are properly constructed jhilmils.

6. The cots are made of wood and string. The bedding consists of a thick cotton quilt, a blanket, sheet, and sitringee. I think the cane-bottomed cots, such as are in use in the hospital here, preferable to the stringed cots, being stronger, more easily kept free from insects, and better for sitting on.

7. Tents are made of layers of country cloth, strengthened with tape and bamboos. They have double flies, two poles 10 ft. high, and 6 ft. kanats, with four openings for doorways, 4 ft. wide. The dimensions are 21 × 16, which gives 168 ft. of cubic space per man, and 21 ft. superficial area. They are made to hold 16 men. Any amount of air can be obtained by bracing the kanats to the fly ropes, which is commonly done in the hot weather.

8. In barracks and guard rooms the ventilation is effected by means of doors, windows, and openings in the roof, and in the tents by openings in the kanats and the open space between the flies. Larger roof openings are required to keep the air pure at all seasons, should the barracks be fully occupied. The means used for cooling the air in barrack rooms are punkahs in the hot weather and rains, and kus-kus tatties in the season of the hot winds. The punkahs are fixtures; the tatties require to be renewed every year; their cost is about 3 rupees each.

9. The barracks here are constructed of stone and mortar. The tents are made of country cloth (dosub), tape, and bamboos, as before mentioned.

10. The floors are terraced, except in the gun-shed barracks, the floor of which is paved. In the house barrack the floor is 3 ft. 3 in. above the ground; in the gun-shed barrack, 1 ft. 6 in.; in the veteran barrack, 1 ft. 6 in.; and in the thatched barrack it is 1 ft. 5 in. above the ground. There is no passage for air beneath.

11. The materials are good, but the construction of the three barracks in the fort is faulty, as may be seen by reference to the ground plans. Barracks, whether of a single or double story, should be built on the plan of the thatched barrack, and in a position freely open to the wind (which, however, that barrack is not). The barracks are kept in repair by the Barrack Master of Benares and the executive Engineer of the division, who have subordinates on duty at the station. Generally, repairs are promptly attended to. The senior Medical Officer is ex-officio the sanitary officer;

III. Sanitary Condition of Stations—*cont.*	but he is only responsible for bringing sanitary matters to the notice of the superior authorities; he has no executive power. The walls and ceilings of the barracks are cleansed and lime-washed once a year. 12. There is a washing place for each barrack, except the veteran barrack. The water is procured by the same means as the drinking water, and runs out through the wall into the drains. There are no baths, but the soldiers have the advantage of bathing in the Ganges, which runs round the northern side of the fort. 13. The cook-houses are provided with the common clay fire-places used by the native cooks. The water is supplied by the bheesties. The refuse water drains off through an outlet in the wall. The washing and drying are done by the dhobies. The station being so near the river, there is every convenience for the purpose. 14. The privies are provided with a range of open seats, and a guttering for the urine. In the fort, the contents are carried off by hand by the mehteers, and in the lower lines are drained into a cesspool. 15. The means used to ventilate these buildings are windows, doors, and roof openings; The barracks are lighted by lamps at night. 16. There is no sewerage. The drains are open from 9 to 18 inches wide, and the same in depth: where the ground admits they are close to the verandahs. In the fort, owing to the inequality of the ground, they are from 8 to 18 feet distant. The fort standing so high above the Ganges, the natural drainage is good. The drainage of all the buildings is sufficient. There is no part of any building used as a barrack or hospital which is damp. There are two cesspools in the lower lines, into which the contents of the thatched barrack and hospital privies are drained. The cesspools are to the north of the barrack and hospital. The barrack cesspool is 4 ft. deep and 4 ft. wide, and 200 yards distant from the nearest well; that for the hospital is 3 ft. wide and 3 ft. deep, and 80 yards from the nearest well, but not in a line with it. The barrack cesspool is 68 yards distant from the thatched barrack; the other is 30 yards from the hospital on the outer side of the wall. The contents are taken away in casks night and morning. There are no foul ditches at this station or near it. 17. The surface of the cantonment, which is small, and contains no native bazaar, is generally clean. The banks of the Ganges and Jurghoo, in the vicinity of the city, are frequented by natives, and are dirty. There is a small establishment of mehteers employed to remove the filth from the city. At present the surface cleansing is not effectual; but more efficient arrangements are about to be made by the civil authorities. 18. The surface of the cantonment is kept free from all vegetation. There are some unroofed huts on the road between the lower barracks and the church, which I have reported as interfering with the ventilation, and have recommended their being demolished. 19. There is no bazaar within the cantonments. The bazaar in the city is entirely under the management of the civil authorities, and is kept clean, and in good order. The natives are compelled to keep the road in front of their houses clean, and are forbid to commit any nuisance in the vicinity. Mehteers are employed to sweep the streets, and carry off any filth. The bazaar always appears clean. I have no suggestions to offer. Many of the native houses are in a ruinous condition, and some of them I have recommended to be pulled down to improve the ventilation. There are some cesspits and privies, the contents of which are carried to a distance by the mehteers. When there is an overflow of the Ganges and Jhurgoo, the natives are driven to commit nuisances near their huts. The only remedy I can propose is to knock down the greater part of the huts between the church and lower barracks, and forbid their being rebuilt. 20. The slaughter-house compound is a quarter of a mile from the station. The place is under the superintendence of the commissariat serjeant, and kept in very good order. The offal is disposed of on the banks of the Jhurgoo, and is immediately devoured by birds and pariah dogs. The condition of the slaughter-house and arrangements are satisfactory. 21. There are no horses in the station, except those kept by officers and civilians in their own stables. 22. There are no artillery or cavalry stables, nor any picketing grounds at this station. 23. There are separate quarters for 13 married men in the veteran barrack, and for two in the thatched barrack. The accommodation is insufficient. Many married men occupy barrack rooms, and some few have permission to live in houses in the barrack square, for which they pay rent.
Officers' Quarters.	1. There are no quarters for officers at this station.
IV. Health of the Troops.	1. The district adjoining the station and the native population are generally healthy. 2. Among the native population intermittent fevers, small-pox, and cholera prevail in the hot weather, and diarrhœa and intermittent fever on the breaking up of the rains. Enlargement of the spleen is common. 3. The general healthiness of the native population may be attributed to the goodness of the water, the general equality of temperature, and the protection afforded by the neighbouring hills from variable winds. 4. The troops at this station are composed of men from every station in this Presidency where European troops of H. M. Indian army, artillery, infantry, and cavalry, are stationed. Wounded men and men broken down by disease, and considered unfit for field service, are invalided into this battalion. The invaliding committee are assembled on the 1st September, and the men mostly arrive here in December and January. The diseases to which new comers are mostly liable are bilious attacks, with more or less fever. The accommodation of the men in the veteran barrack and gunshed barrack is more unhealthy than the rest, from the bad style of building, low roof, and imperfect ventilation. 5. The troops at this station have never been encamped, they were sent here as fit for garrison duty only. 6 to 10. No experience of hill stations; but approve of them for troops. The disease most to be dreaded in the hills is diarrhœa. Flannel should always be worn, and a flannel belt round the belly by those who are disposed to bowel affections. The diet should be good, and free exercise in the open air taken at all times.

IV. Health of the Troops —*cont.*	11, 12. The season of the hot winds from April to June, and that from the commencement of the rains in September to December are the best adapted for residence in hill stations. In November the climate is very fine. The shortest period for troops to benefit by such residence is six months. In general I should say that a prolonged residence is conducive to health. Most persons on their return to the plains are subjected to a bilious attack, caused by the change of climate and temperature. 13. Troops if possible should not be allowed to leave the hills before November, and on approaching the plains they should be forbidden to expose themselves unnecessarily to the sun. 14. In order to preserve the health of troops serving in India, I think it would be better, if possible, to keep them on the hills for eight months of the year, and allow them to pass the other four months on the plains. Some stations in the plains being more healthy than others, it follows that a frequent change of stations in the plains may not always be beneficial, except to convalescents, whose health is generally improved by change of air and scene. I think it would conduce, however, to the health of the troops if they were encamped for two months in the cold weather and marched about the district. 15, 16. No experience of hill stations. 17. Not aware of any higher ground near the station which could be advantageously occupied as a hill station. 18. I think the dry gravelly soil the most healthy for stations; but any surface or soil will generally be healthy if the natural drainage is good. 19. Soldiers should not proceed to India under 20 years of age. The best period to land there is in the cold weather months of November, December, and January. I cannot speak positively as to the mode in which troops are disposed of on first landing, as I have not been on duty at the Presidency since 1841, but to preserve their health, they should be sent up the country as quickly as possible. Hazareebaugh I think would make a good depôt for troops newly arrived. 20. Troops for India should be sent direct from the home depôts. Every atom of their strength and energy is required to enable them to stand the debilitating climate of India. They should be sent to a hill district if possible, but certainly as far as Hazareebaugh. 21. Troops are at present sent by railroad to Raneegunge, and from thence by bullock train to Allahabad, where the railroad is again available; they are also sent up in steamers. Troops coming up by land generally arrive in good health. Great care should be taken not to overcrowd the steamers, and when it is possible the men should be allowed to go on shore of an evening for exercise. 22. The number of years a British soldier should serve in India depends on his constitution and habits. A man moderate in his habits may serve for 15 years if he has the benefit of a change to the hills once in four or five years. 23. With regard to the powers of Medical Officers in reference to invaliding, the medical committee at the Presidency have the power of nullifying the award of the station committees, and not unfrequently exercise it by remanding a man to his duty. I doubt whether the Presidency committee should have this power, as the man thus sent back almost invariably becomes a hospital skulker and an incumbrance on his regiment. 24. Invalids should leave India for home in the months of January and February.
Diseases	1. There are no regular inspection parades for the discovery of incipient diseases at this station, nor has such been the custom in the invalid battalion; every man observed to be ill is immediately sent to hospital by the non-commissioned officer on duty at the barracks. 2. There has been no scorbutus amongst the troops at this station. 3. The average proportion of hepatic disease of the last five years is as 1 to 31. The causes are intemperance and exposure to the sun, the disease occurring in men who had previously suffered from it, and had been invalided in consequence. The most effectual prophylactic measure is to discountenance, as much as possible, the use of spirituous liquors. 4. I have not had a single case of dracunculus in hospital. 5. The proportion which venereal diseases bear to the total sick in hospital from all other diseases, taken from the returns of the last five years, is as 1 to 31. The soldiers at this station are singularly free from venereal disease, owing probably to the greater number of married men in the battalion with families and female servants in attendance on them. I think that a small inexpensive establishment, consisting of an experienced native doctor and two or three women, dhyes, should be attached to every bazaar where European troops are stationed, and a house taken in the bazaar, and proper medicine supplied, the whole being under the superintendence of the sanitary officer and cantonment magistrate. The prostitutes, who are a distinct class in India, and do not disguise their vocation, should be registered and numbered. An establishment of this kind would be more suitable to the native ideas and feelings than a regular lock hospital, and I think would prove more effectual in reducing the amount of disease. 6. The troops occasionally suffer from epidemic and endemic diseases of the following class:— *Fevers.*—Intermittent fever in all its forms, but mostly from quotidian and tertian. *Dysentery.*—There has been no case of this disease. *Cholera.*—Occasionally there is a visitation of cholera. *Small-pox.*—There has been no case of this disease. *Rheumatism.*—There have been only a few cases among the older men. The proportion which admissions and deaths from these diseases bear to the total admissions and deaths, are taken from an average of the returns for the last 10 years.

Diseases.	To Admissions.	To Deaths.
Fevers	1 in 4·67	1 in 15·45
Dysentery	1 in 53·05	1 in 15·45
Cholera	1 in 47·91	1 in 4·41
Small-pox	None.	None.
Rheumatism	1 in 25·61	None.

. Health of the Troops —*Diseases—cont.*	7. The most frequent zymotic diseases are intermittent fevers and cholera. Intermittent fevers, in addition to the usual symptoms, are often attended with much gastric irritability, which continues sometimes for two or three days, with very little remission. Cholera is seen in all its varieties, but with no symptoms to distinguish it from the cholera of other places, the pulseless and spasmodic form being the most frequent and the most fatal. The fevers, with ague and gastric irritability, are prevalent at the setting in of the cold season. Cholera more frequently prevails in the hot weather. In the months of October, November, and the early part of December, when the sun is still very hot, and the nights and mornings are raw and chilly, fevers prevail. Cholera is more to be dreaded when the heat is excessive, the atmosphere heavy and oppressive, with little or no winds, and those from the south and south-east. The same attention is paid to the sanitary arrangements of the town and station at all seasons. When cholera appears the greatest anxiety is shown by the authorities to remove every possible cause for its further progress. Intemperance, which leads to undue exposure, and the debility caused by the state of collapse which follows the indulgence, predispose the troops to these diseases. Among the natives want of sufficient good food and clothing are the most frequent predisposing causes. 8. The prevalence of epidemic disease is also influenced by exposure to the raw chilly air which prevails at night, at the setting in of the cold weather, when on sentry duty; and by undue exposure to the sun and night air when under the influence of liquor. 9. Quinine has not been tried at this station as a prophylactic against malarial disease. I am averse to giving it until the state of the liver and *primæ viæ* have been attended to. It is given to convalescents to prevent a return of fever, but I find that chyretta answers nearly as well. 10. Epidemic diseases are not of common occurrence at this station; and, cholera excepted, the visitations are not remarkable for their severity, and cause no apprehension. They prevail at particular seasons, and are caused by the natural vicissitudes of the climate and atmosphere. Sober, well-conducted men, are less frequently attacked than men of irregular habits. Except guard duty, the soldiers have no military duty, and the means of amusement are very scanty. The want of employment leads to intemperance and consequent disease. More work and more amusement are the best prophylactic means for the prevention and mitigation of disease.
V. Intemperance.	1. The greater portion of the soldiers at the station are usually temperate. The number of confirmed drunkards is about 1 man in 20. 2. The proportion of admissions into hospital from diseases directly caused by intemperance, as given from the returns of the last 10 years is 1 in 2·91, and the admissions indirectly are 1 in 7·54. The following table, showing the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station, is prepared from the returns of the last six years, no earlier records of crime being extant.

Classes.	Total Strength.	Admissions.	Deaths.	Ratio of Admissions to strength per Cent.	Ratio of Deaths to Strength per Cent.	Ratio of Deaths to Admissions per Cent.	Ratio of Crime to Strength per Cent.
Total abstinence -	12	3	—	25	—	—	—
Temperance - -	576	1,237	51	213·02	8·84	4·12	42·01
Drunkenness - -	387	676	55	174·67	14·21	8·13	426·87

Note.—Although the greater number of the men are usually temperate, yet with very few exceptions, they all drink occasionally, and the admissions into hospital from drunkenness and its effects are consequently numerous. Notwithstanding the high per-centage of crime from drunkenness, there were only three crimes of magnitude sufficient to call for courts-martial. Drunkenness is always punished as a crime.

3. Distilled spirits are sold both at the canteens and bazaar. The commissiarat rum sold in the canteen is 24 per cent. below proof. The amount consumed is about two drams for each man per diem. It is impossible to state the amount sold in the bazaar. Spirit does not form any part o a soldier's ration at the station, on march, or in the field. It is never given as a ration to convalescents. No other than intoxicating drinks are sold either at the canteen or bazaar.
4. The consumption of spirits generally is injurious, except to some few, who from long habit are accustomed to it. In my opinion, it is most destructive to the troops, both as regards their efficiency and internal discipline.
5. Spirit forms no part of the soldier's ration. The sale of spirit in the canteen is restricted to two drams per man per day. It is prohibited to be sold in the bazaar to Europeans, except by permission. It is sold clandestinely.
6. The influence of malt liquor is favourable to health. Wine is never given except in hospital. The continued use of spirit is destructive to health.
7. Coffee and tea are commonly used, ginger beer and lime sherbet are occasionally used. I think their use decidedly beneficial.
8. As before stated, spirit forms no part of the soldier's ration. Beer is procurable at the canteen. Tea and coffee are served out in the daily ration. It is optional with the soldier to purchase spirit or beer.
9. It would generally be beneficial to prohibit the sale of spirituous liquors in the canteens, but there are some old soldiers who prefer spirit to beer and other drinks, and from long habit could not dispense with their daily drams, and who, if they could not get it at the canteen, would get a worse liquor elsewhere.
10. As drunkenness is the common cause of disease and crime among troops in India, I recommend that troops should be discouraged by every possible means from acquiring a taste for spirit; that its use should be absolutely interdicted on the passage out, and that malt liquor should be supplied in its place.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	11. There is no regular canteen at the station. Twice a day, at regulated hours, it is opened for the sale of rum and beer. There is no military bazaar. The sale of spirits in the bazaar of the town is interdicted to soldiers, except they have written authority to purchase; and any dealer transgressing the rule, is subjected, if detected, to a heavy fine.
VI. DIET.	1. There is no difference in the composition of the rations served out to European troops of whatever denomination. The daily rations consist of 1 lb. of bread, 1 lb. vegetables, 1 lb. meat, 3 lbs. of firewood, 4 oz. of rice, 1 oz. of salt, $2\frac{1}{2}$ oz. of sugar, $\frac{5}{7}$ oz. of tea, or double the amount of coffee. Coffee is served out twice a week commonly, oftener, if the men like it. In the cold weather beef is mostly issued; in the hot weather, mutton. The inspection of the constituents of the ration is made by the adjutant and quartermaster serjeant. 2. There is a complete ration provided for the troops, including vegetables, but no fruit. There is no stoppage for rations. If absent on leave, and not provided with rations, the soldier is allowed as compensation, three annas and four pie per diem. The soldiers make three meals a day, one at 8 a.m., one at 1 p.m., and one at 7 p.m. Their meals are composed of their rations, with such additions as they choose to make. The proportion of vegetables which enter in the composition of the ration is 1 lb. 3. It is reasonable to suppose that any improvement in the ration would be conducive to the health of the troops of both services. No instance is on record of any part of the ration being sold. The rations are made over on the spot to the cooks, who manage the men's messing. 4. The cooks are paid by each mess. The apparatus for cooking is of the kind in use India; boilers, gridirons, frying-pans, &c. are provided by Government. The kitchens are clean, but deficient in light and ventilation. The water-supply is sufficient. The food is sometimes boiled or roasted; more frequently stewed; occasionally grilled. The cooking is properly done, and to the men's liking; and the same may be said of the tea and coffee. The battalion does not march. 5. Owing to the annual overflow of the Ganges, it would be difficult to find ground suitable for the establishment of gardens for the soldiers within a convenient distance, and the expense of providing water would be greater than the men would like to incur. From their age and general state of health I do not think they would care for a garden, except Government took upon itself the expense of managing it.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. A soldier's dress consists of head-dress, wicker helmet with cloth cover, and turban; dress, easy fitting khakee tunic, free and open in the neck, pantaloons of the same material and colour. As regards accoutrements—the Artillery wear only sword and waist belt—the Infantry carry the regulation musket, with cross-belt and pouch. In the cold weather cloth clothing is substituted for the khakee. The men provide their own under clothing. Great coats are allowed for the night sentries. I think the present dress is suitable for the climate and for the soldiers' duties. I think every soldier should be provided with two flannel shirts for cold weather wear, and two broad flannel abdominal belts to wear in the rainy season, and at any time when the bowels are relaxed. The guard dress is khakee or cloth according to the season. Sentries are protected from sun and wet by sentry boxes and covered sheds. In the cold weather they are provided with great coats.
Duties.	1. It would be advisable that recruits, especially those for the cavalry, should be thoroughly drilled at home before being sent out to India. 2. There is no drill in the invalid battalion. There are four inspection parades in the week at sunrise, when the men are told off for duty. I think the men would enjoy better health if they had more duty to perform. The best time for parade is from daybreak to $1\frac{1}{2}$ hours after sunrise, for marches from 2 a.m. to 8 a.m. These remarks apply to Central India and Bengal. There are no general orders on the subject that I am aware of. The average number of nights the men have in bed during the week is $3\frac{1}{2}$. 3. Guards are mounted within 100 yards of the barracks. Guards are relieved daily, sentries every two hours. There is a roll-call nightly. The effects of night guards is rather beneficial in the hot weather, and not prejudicial at other times except when epidemic fever prevails, and the sentry neglects the precaution of wearing a great coat.
VII. INSTRUCTION AND RECREATION.	1. The following are the means of instruction and recreation at the station. There is no ball court, nor any skittle ground, but one is being constructed. There are two schools, one for boys, and one for girls, with efficient teachers. There is also a library and a reading room, but they are not open at night. There are neither day rooms, soldiers' clubs, soldiers' gardens, workshops, theatre, nor gymnasia. The present means are insufficient to keep the men occupied during the wet season and heat of the day. There are no restrictions as to exposure to sun and rain out of barracks when off duty. The men go about at all times, and except when under the influence of liquor, they do not appear to suffer from exposure. 2. To improve the existing means of recreation, a soldiers' club-room, with wide verandahs, which could also be used as a theatre, should be erected, also another skittle ground for the lower barracks, and a ball court. A gymnasium should also be constructed principally for children. 3. Soldiers' savings banks already exist, and have been found advantageous. 4. There is not sufficient shade from trees and other means to enable the men to take exercise without injury to health during the day. There were some beautiful trees in the fort, but they were cut down in the mutiny by order of the engineer officer. The verandahs do not afford sufficient protection.
IX. MILITARY PRISONS.	1. The cells are constructed of stone and badly ventilated; they are not fit for occupation in the hot weather, and are not used. I have recommended that the cells should be enlarged and otherwise altered, so as to admit of their being habitable at all seasons.
X. FIELD SERVICE.	1. There are no local regulations for field medical service, not included in the General Presidency Regulations. The invalid battalion is exempt from field service.

References to Subjects and Queries.	Replies.
X. Field Service—*cont.*	2. The arrangements as to the conduct of the line of march of troop, bivouacking, camping, billeting, &c. are directed by the Quartermaster-General's department, with the senior of which, Medical Officers communicate on all matters affecting the health and comfort of the troops. 3. As far as my experience enables me to judge, the regulations as to the selection of camping grounds, &c. are good and generally well observed. The senior medical officer in camp has the general superintendence of all sanitary arrangements, and his recommendations if beneficial and practicable are invariably attended to. In a large camp I think it would be advisable that a sanitary Medical Officer should be specially appointed; and, having no other duty to perform, should be held responsible for the due observance of all sanitary regulations. 4. The regulations and arrangements for field hospitals are fully described in the Bengal Regulations, chapter xxv., at page 153.
XI. Statistics of Sickness and Mortality.	No information under this head. Chunar is not a civil station, but latterly a civilian has been stationed there.
XII. Hospitals.	1, 2. The hospital is situated at the east end of the station on the corner of the road leading from the barrack square to the fort. It is to the west of the thatched barrack, from which it is distant 300 yards, and about the same distance from the nearest officer's stables. It is a quarter of a mile from the bazaar of the town of Chunar; on the opposite side of the road to the south, there is a row of native huts, and behind it the village of Mohana. The site is partially open and freely ventilated only on the north and west. The row of subordinate Medical Officers' quarters and the women's hospital interfere with the ventilation to the east, and the huts before described to the south. The site is generally healthy as to elevation, drainage, and absence of malaria. The ground is high and the elevation six feet. 3. The water-supply is abundant. 4. The refuse water and other impurities are carried off in a large drain, which commences at the north-east angle of the hospital, and runs parallel with the women's hospital. The outlet for the sewerage is 30 yards from the hospital. 5. The wards are all of the same height, viz., six feet above the ground. There is no free perflation under the floors; the floors are terraced and would not admit air. The greater part of the roof water is conveyed away in the drain before mentioned: towards the south-west corner it sinks into the subsoil. The ground on which the hospital stands being high the natural drainage is good; very little water remains on the surface at any time. The guttering is mostly confined to the south-west corner. I did not consider the drainage sufficient; I have communicated with the executive Engineer on the subject. The hospital is built of stone and mortar, the roofs and walls are single, the latter, however, are sufficiently thick to keep the hospital cool. Stone roofs, however thick, are always warmer than thatched ones, as they retain the heat. The hospital has outer verandahs, 10 feet wide, on the east and west sides, and an inner verandah, 12 feet wide, on the east, south, and west sides. These afford sufficient shelter on those sides; but a verandah over the entrance to the north is required. The inner verandahs have been used for the accommodation of the sick, but not for the last 20 years; they are now occasionally used by convalescents. The building is a one-storied building.

Table of Hospital Accommodation.

Date of construction is unknown; it was purchased in 1814.

Total number of wards, 4.
Total regulation number of beds, 46.

Hospital Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patients' Beds above the Floor.	Windows.		
		Length.	Breadth	Height.	Cubic Contents.				Number.	Height.	Width.
		Ft. In.	Ft. In.	Ft. In.	Feet.			Ft. In.			
Two Middle Wards	16	61 9	17 9	17 4	18,994	1,187	68½	1 6			
	6	26 4	19 10	15 0	7,851	1,308	87⅙	1 6		None.	
Two Side Wards -	12 each	118 8	15 8	7 0	31,588	1,316	77	1 6			

The hospital is not so placed as to receive entirely the full benefit of the prevailing winds. There are no windows.

6. The ventilation of the wards is effected by openings in the roof, which admit of a draught from the numerous doors, all of which are kept open at night, and some in the day. Occasionally, in the very hot weather, there is a feeling of closeness common to all stone roofed buildings. The lower thirds of the jalousies are fixed; the upper thirds open externally.
7. The wards are cooled by punkahs and kus-kus tatties, the construction of which is well known.
8. There are no artificial means of warming the wards. The walls and ceilings are whitewashed once a year, but oftener if required by the Medical Officer.
9. The privy is 50 feet from the hospital, and connected with it by a covered passage. It is 20 ft. long by 10 ft. wide, and has 10 stone seats on each side, with guttering for the urine, leading to the drain, which runs into the cesspit on the outside of the hospital compound wall. The privies are properly drained and supplied with water and

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	lime. They are not placed over a cesspit, and are not more offensive than such places are in this country. 10. The men commonly wash in the western verandah, and in the bathing room parted off from it. The hospital end of the covered passage to the privy is also available as a lavatory. The arrangements are sufficient. 11. There is a convenient bathing room at the south-west corner, with the doors opening into the inner and outer verandah, sufficient for the purpose of bathing the sick. 12. There is an establishment of dhobies (washermen) for washing and drying the hospital linen. The work is done at the river side, and the means are sufficient. 13. The storage is sufficient and dry. 14. The hospital cots are cane-bottomed, most of them 6 ft. 4 in. long and 2 ft. 9 in. wide, with a head rail. The mattress is stuffed with tow 2 in. thick, and made to fit the cot. One bolster and two pillows are allowed; and one thick country blanket, 7 by 5, one thick blanket covered with chintz, one sheet and two pillow-cases. Each man has a small carpet (setringee) for the bed side. In addition, I think every man should have a country quilt (ruzaee) for use in the cold weather. 15. The kitchen has been placed opposite the north-east corner of the hospital, at a distance of 28 yards. It is fitted with Hindostanee and English cooking apparatus to a sufficient extent. The cooking is properly done, and varied according to order. 16. Copies of the diet table, diet rolls, &c., in use in European hospitals are given in chap. xiii., pages 93 to 101, of the Bengal Medical Regulations. In the appendix of the same work the forms are laid down for all periodical returns, and from these the statistics of mortality, sickness, &c. are prepared. No other records than the copies of those returns are maintained. 17. One hospital serjeant performs the duty of overlooking the sick; there is no nurse or orderlies. There is a native establishment, consisting of one mate and six ward coolies, for attending upon the sick in the men's hospital, and an ayah and mehtranee in the women's. In every serious case requisition is made for a waiting man from the battalion, who is relieved daily. I do not think the attendance sufficient; the work falls very hard on the hospital serjeant. I think there should be two orderlies and a nurse for the women's ward. 18. The hospital is spacious and healthy, with ample accommodation for double the number of sick than are usually under treatment. I have never known or heard of any epidemic or particular disease appearing in the wards of this hospital. 19. I think a small verandah is required for the northern entrance to the hospital. I disapprove of the position of the privy and kitchen, which I think should be reversed. The row of subordinate officers' quarters interferes with the ventilation; but it would be difficult to find another site for them. If the strength of the battalion was much increased, it would be necessary to enforce attention to these points. I have called the attention of the executive Engineer to the necessity of giving a verandah on the north side of the hospital. 20. Convalescents in hospital are allowed to take the air on the river side; out of hospital they can walk on the ramparts of the fort, where the air of the morning is generally fine and clear. There is no place set apart for their use, and none I think required. 21. There is a hospital in the same compound as the men's for women and children, consisting of two wards and a verandah 10 feet wide all round. The building is thatched, and generally cool, and is well adapted for the purpose. I think the present arrangements are satisfactory, the only improvement I can suggest being the employment of a nurse in addition to the ayah and mehtranee. 22. There are no special local hospital regulations not included in the general Presidency Medical Regulations. 23. The Medical Officers' requisitions for repairs, for buildings, &c. are always attended to. On all matters relating to the comforts and diet of the sick, he exercises his own discretion, subject of course to a call for explanation from the superintending surgeon. 24. There are no wards for convalescents. The hospital affording ample accommodation for them. On being discharged from hospital it is usual to give the convalescent a few days' leave that he may gather strength before he is put upon duty. There would be no advantage in having a separate barrack for convalescents.
XIII. BURIAL OF THE DEAD.	1. The burial ground for British troops is in the N.E. corner of the station, about a mile from the fort, and 400 yards from the thatched barracks; and the prevailing winds being from the west, the position of the burial ground in reference to the station is favourable. 2. Its area is 85,984 square feet; the soil and subsoil are much alike, but there is a little more sand in the latter, both are of a light rich and slightly sandy mould. There is no artificial drainage; the water however does not lodge on the surface, but drains naturally into the adjoining Nuddee. It is not known whether decomposition takes place rapidly, as no old graves have been opened. The ground is kept clean. 3. No particular regulations as to grave space have hitherto been observed. The graves are mostly placed on a line, and are about 2 feet apart. The usual depth is from 5 to 6 feet; sometimes to admit of a corpse belonging to the same family, but not often, a grave has been reopened; but not more than two have ever been buried in the same grave. Interment is compulsory at ordinary times, in the cold weather on the following day, and in the hot weather within six hours, or as soon as the arrangements can be made. During epidemics interments take place as soon as possible. There are no native troops at the station. 4. I have never heard that the grave yard is offensive. When a British soldier dies in hospital, a death report is sent to the chaplain or priest, and to the Fort Adjutant, signed by the Medical Officer, who also names the time for the burial. 5. The dead of camp followers or bazaar people are generally burnt on the opposite bank of the Ganges. A few bodies are committed to the river. 6. No injury to the public health accrues from the present practice.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead—*cont.*	7. As regards the burial of the dead, the only improvement I can suggest is that some wheeled carriage might be allowed for the conveyance of the coffin from the dead house to the burial ground. Decomposition takes place so rapidly at times, that the men cannot shoulder the coffin without a feeling of annoyance.

(Signed) George Blake, Lieutenant-Colonel,
Commanding at Chunar.
H. M. Tweddell, Garrison Surgeon.
J. Hovenden, Major, Executive Engineer.

Date, 1st July 1860.

APPENDIX.

Note by the Garrison Surgeon.

The station of Chunar is occupied entirely by the European Invalid Battalion, consisting of two companies of artillery, and two companies of infantry. The average strength for the last 10 years is 180. The number of the women and children present with the battalion is 153. Unattached to it, but drawing pension and pay, are 34 widows and 26 children. There are besides a great number of pensioners with and without families, and widows * and children receiving no support from Government, who reside in the station and occupy the small houses in the vicinity of the barrack square. In 1846 Lord Hardinge proposed to remove the Invalid Battalion to Almorah; a measure strongly advocated by the late Sir Henry Lawrence, who was desirous that the women and children should have the benefit of a hill climate. This arrangement was frustrated at the time by the influence of the house proprietors at Chunar, but was not abandoned, and if Lord Hardinge had remained longer in India it would certainly have been carried into effect.

The present appears to be a proper time for reviving the subject. Two of the barracks in the fort have lately been condemned by a committee called for by the executive Engineer. It has been recommended that others be constructed in their places. There is only one barrack in the lower lines. For military purposes it is advisable that there should be barrack room in the fort for the entire battalion. During the late mutiny it was necessary to keep all the troops in the fort, and the want of proper barrack room was severely felt. The intercourse between the fort and the lower lines could not be maintained in disturbed times, except the strength of the garrison was greatly increased. But as the fort occupies a hill about 180 feet high, and it is difficult of access, having only one gateway, with a very steep ascent, the construction of barracks for the whole battalion, and women and children, would involve a large outlay. I think it advisable in every way to take up Lord Hardinge's plan, and remove the battalion to Almorah or some other hill station, where it would form the nucleus of an European colony. On their departure the fort might be held by a small detachment from Benares, for which the present accommodation would be ample; and as I consider the fort to be the healthiest part of the station, I would recommend it as a sanitarium for convalescents from Benares and Ghazeepore, who might require change of air for a few weeks in the cold and rainy season.

(Signed) H. M. Tweddell,
Senior Surgeon,
Garrison Surgeon.

* There are about 100 widows, most of whom are in destitute circumstances.

I fully concur with the Garrison Surgeon in this opinion.
(Signed) J. Hovenden, Major, Executive Engineer,
Benares Division.

I also concur with the Garrison Surgeon in his remarks above stated.
(Signed) George Blake, Lieutenant-Colonel,
Commanding at Chunar.

I. Topography.	1. The country surrounding the station is flat and intersected with nullahs (which form a natural means of drainage), and it is for the most part under cultivation. In some parts the country is rather sandy and dry, with the exception of a large portion of ground extending from the fort towards Papahmhow. This tract is under water in July, and remains so till after the fall of the river, in October or November, when a large portion of swampy ground is left immediately adjoining the station, productive of unhealthy exhalations. The ground on which the cantonment is built is comparatively high. There is a great deal of wood in the vicinity, principally mangoe topes; for instance, Alopee Bagh, also a large tope west of Papahmhow Ghât, which has been used with success as a camping ground in cases where troops have been driven from barracks by cholera. There is little or no jungle, and no water, with the exception of the rivers Ganges and Jumna, which wash the station. 2. The station is about 368 feet above the sea and about 40 feet above the surrounding country, in some parts less, and about 60 feet above the low-water levels of the rivers. One third of the station is actually below the level of the river. This part is protected from inundation by two very large earth embankments or bunds. There is some higher ground adjoining the station in the direction of Kutchpoorwa, higher than a portion of the present cantonment, as the level decreases towards the apex of the "Doab," where the fort is situated. This situation appears to have great advantages in a military point of view, but before going into the question, it would be well to mention some of the disadvantages of the present cantonment situation. There are two separate cantonments. It would appear that as occasion required, in 1858, different lines of temporary barracks were built in the most eligible spot for each individual set of barracks, but without any view to

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	their being brought into one cantonment afterwards. Large civil bazaars separate these barracks. One set of lines (the Kuttra hospitals) is immediately adjoining a large civil bazaar. The evils of this are manifest, as no exertions on the part of the authorities, however persevering, can keep these lines as free from filth and injurious smells as they would be in a cleanly situation. Again, the advantages which the vicinity of these bazaars offer to breaches of discipline are great, more especially the difficulty of detecting the shops where liquor is sold to the soldier. The ground mentioned in the neighbourhood of Kutchpoorwa is free from these disadvantages, being open, and suitable as a site for new cantonments. 3. Due south from this, running east and west, are the Kymore Hills, upwards of 2,000 feet in height. From Mirzapore, on the Ganges, a branch or spur of this range, in some places 1,000 feet high, is within 15 miles. 4. The Jumna and Ganges wash the station. A large portion of the station on the river side of the "Bund," extending from the Fort to Papahmhow, is under water during the rainy season of every year—from the commencement of July to the end of October. There is much broken ground on that part subtending the river Ganges, exercising a deleterious influence on the health of those troops stationed in the vicinity of those ravines or broken ground. 5. The station is not so much encumbered with trees as to be unhealthy. The lower branches are lopped off to a height of 12 feet from the ground, to admit of ventilation. The station is open, and freely exposed to winds. The temperature is raised by reflected sun heat from the dry, light coloured, and denuded surface of the ground. Hot westerly winds prevail during April, May, and part of June, favourable to health generally. During the cholera of 1859 the disease, which broke out after a continuance of easterly winds, invariably subsided when the wind veered round to the west, and increased as surely when the wind returned to the east. 6. The surrounding country is under cultivation for grain and indigo. Irrigation is carried on by wells, but to so small an extent as not to be considered injurious to health. The cultivation of rice is prohibited within one mile of the cantonment or civil station boundaries. The land in the neighbourhood is not suited to the growth of rice. Indigo is cultivated at Papahmhow, close to Wellington Barracks. During its preparation, most nauseous effluvia are given off. It is a nuisance, but has not been observed to be injurious to health. 7. Allahabad, with a population of 73,000 inhabitants, is about 2½ miles from the Clydesdale and Mansfield Barracks, and 3½ miles from Chatham and Wellington Barracks. 8. The general geological structure of the soil is kunkur or clay, charged with calcareous nodules, on a substratum of fine sand. The ground adjacent to the river consists of fine sand, with a clay substratum. The ground occupied by troops has not been occupied by native population previous to its being made the site of cantonments. 9. Water is found during the dry season at a depth of 60 feet, and during the wet season at a depth of about 45 feet. 10. The station generally has a natural drainage by a fall towards the rivers Jumna and Ganges, which almost encircle it. The extensive plain within the "Bund," between the station and the fort, is flooded in the rainy season owing to its flatness, the water either sinking into the subsoil or disappearing from the surface by evaporation. The station is not affected by drainage from any higher ground adjacent. 11. The water-supply is derived entirely from wells; it is not stored in tanks. There are two tanks of limited extent about half way between the station and the fort. They are dry during the whole of the hot season, and are only full during the height of the rainy season in July and August. The drinking or well water is quite free from animalcules or infusoria when examined under the microscope. Bathing in the tanks is prohibited. The wells in general are protected from pollution from leaves or other matters falling into them. No nuisance or malaria arises from the tanks without or within the station. 12. If the wells be secured, of a proper depth, and clean, they afford an abundant supply of water, colourless, of good taste, and devoid of smell. The water contains carbonate of lime, and is hard in quality. It is improved by filtration. It is raised and distributed by bullocks and water carriers. The best means seem to be adopted for the purpose of ensuring an abundant supply of the best water. 13. No other points require consideration beyond those on which information is sought. The station may be said to be in a transition state at present. The barracks being, with the exception of those in the fort, of a temporary character, and not likely to be available for any lengthened period. 14. Stations are selected by a mixed military and medical committee, appointed by the Commander-in-Chief. Hill stations are selected partially on the report of observations made by a medical officer commissioned to reside there, and to consider accurately the fitness of the place as a residence for troops. This proceeding has hitherto worked satisfactorily.
II. CLIMATE.	1. 2. No records. They were destroyed, as well as the meteorological instruments, at the time of the mutiny. 3. The seasons may be divided into three periods. The dry embracing March, April, May, and June; the wet season, from July to November; the cold season, from October to March. These periods are steady. Being within the influence of the S.W. monsoon, the season of rains is regular, not depending on tree planting or canal irrigation. In the dry season the air is frequently heavily laden with dust, and dust storms, at times violent, occur. This condition is not supposed to exercise an unhealthy influence. The climate requires generous and varied diet; clothing adapted to the several change of seasons and periods of the day and night; a large amount of cubic space to each man. Houses well raised above the surface of the ground, with good ventilation and well fitting doors; thick walls and roofs capable of resisting heat. The barracks at present occupied here do not fulfil these conditions, but the clothing seems well suited to the climate. The climate absolutely demands that the duties should be as light during the hot and rainy seasons as the service may admit of. As regards the relative healthiness of the different months, it may be stated that in April, May, and June fever, dysentery, sun-stroke, and

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	cholera appear. During the rains dysentery and cholera, and in the cold season fevers chiefly of the intermittent type. November, December, January, February, and March are, as a rule, the most healthy months. 4. A spot might be selected within 50 miles of the station, on the table-land of India, in the Rewah district, at an elevation of 1,500 or 2,000 feet above the level of the sea. An inquiry is invited on this important head, as convalescence is very protracted after severe illness at this station.
III. Sanitary Condition of Station.	1. 2. 3. Plans. 4. The following is the barrack accommodation :— Date of construction, 1858–59. Total regulation number of non-commissioned officers and men, 4,280. Total number of rooms or huts, 46.

5. There are no windows to the barracks. There are folding doors opening inwards, and for the most part badly fitting. The doors are the same on both sides, and opposite each other. They have no jalousies. All the barracks have verandahs, 15 feet in width on both sides. These verandahs are not used as sleeping quarters except on emergencies.
6. The cots are of wood, with cordage bottoms. They harbour vermin and are easily broken. Iron cots with sacking bottoms are infinitely better. The bedding consists of 1 cotton setringee or carpet, 1 quilt, 1 country blanket, 2 sheets.
7. The tent used by European privates is 20 feet long and 16 feet wide, 10½ feet high inside and 12 feet outside. It is double poled with double flies, the outer fly having 3, the inner 2 cloths. The walls are 5½ feet high, composed of 3 cloths. There are four doors, one on each side. Each tent holds 16 men. To each man is allowed 20 superficial and 140 cubic feet. The tent, "Staff Serjeants," holds one man; it is 12 feet square, 12 feet high; single poled with double flies, of 3 cloths each; wall of 4 cloths, with 2 doors. The superficial area is 144 feet, and the cubic space 960 feet per man. Tent, "Sepoy," is 32 feet long, 16 feet wide, and 8½ feet high. It consists of a single fly, with a wall or fringe 1 foot deep, and is intended for half a company of sepoys. Cubic contents, 2,176 feet.
8. The barrack ventilation is imperfect; by doors, and in some instances in addition by small semilunar windows over the doors, and by roof ventilation. In cells by small gratings. In no instance, except at the Mansfield barracks is there thorough ventilation in the cells. Generally the ventilation is insufficient, especially as the doors, which are almost the only means of ventilation, have to be closed during high winds, dust storms, and rain with wind.
   The air is cooled by tatties applied to the doors on the windward side in the hot months, and by punkahs.
9. As to materials, the barrack walls are constructed partly of burnt, partly of sun-dried bricks. Roofs in some instances of thatch, in others of thatch and tiles. Tents are of the cloth of the country, and of excellent materials.
10. The floors are of flags, not raised sufficiently, and there is no provision for a current of air below them.
11. The barracks at this station are all of a temporary character. The walls of sun dried bricks, the roofs of grass in bamboo frames. The materials are suited to the class of buildings, but would not be suited for permanent buildings, as they fall rapidly into decay, the walls become sapped by white ants, and the materials of the roof are speedily consumed. Constant repair may maintain them for some years in a habitable state, but they eventually become unsafe. The Executive Engineer considers the construction deficient. The system

ALLAHABAD.
BENGAL.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	of continuous roof ventilators is objectionable, as liable to damage by storms, and admitting hot winds, dust, and rain. Ventilation by opposite windows would be better. The barracks are handed over to the Barrack Master, by whom all small repairs are executed. When out of repair the barracks are vacated, and placed under the Executive Engineer till rendered habitable. The Sanitary Officer reports to the station authorities all matters coming under his own or brought to his knowledge by the Medical Officers. The Deputy Quartermaster-General, Executive Engineer, Barrack Master, and Cantonment Magistrate carry out all sanitary measures. Cleansing and lime-washing of walls and ceilings is done once in twelve months in permanent barracks, in accordance with the regulations. In temporary barracks lime-washing is required more frequently. 12. The lavatories are separate from the barracks. They are supplied with cast-iron basins, lined with porcelain, and in each lavatory is a masonry foot bath 7 feet by 1½ feet by 1½ feet. The basins stand on wooden platforms, and a masonry trough is carried below them, into which the water flows, and runs into shallow wells or cesspools. Water is supplied to the basins from the wells by bheesties. 13. Cooking is carried on in portable coppers placed over open fireplaces. Water is supplied by bheesties; the refuse water runs into small cesspools outside the buildings, whence it is removed daily by the Conservancy Establishment. Washing is done by native washermen. It is satisfactory, but the process is very destructive to the linen. 14. The privies are cleansed at regular intervals by the Conservancy Establishment. They are not drained or sewered. The flooring of the privy has a sharp slope to the rear to convey the contents into a stone trough outside the building, which is cleansed by hand labour. 15. The privy buildings are ventilated at the ridge. The barracks are lighted at night by lanterns with oil burners, and in the opinion of the committee, imperfectly. 16. There are no drains or sewers. Each barrack has a small channel about a foot deep at a distance of 10 feet from the walls, the intermediate space being made to slope from the barrack. These channels communicate with one another, and are carried out into ravines or low ground so as to allow the water to run off freely. There are no cesspools properly so called, but attached to each wash-house is a shallow well into which the water runs and is absorbed. In the wash-house of the Kuttra hospitals a shallow tank has been built in place of the cesspool. It is emptied morning and evening, and is found to answer well. The surface water runs off freely from the barracks. The drainage is much facilitated by the ravines. The buildings are in some instances slightly raised above the ground by a plinth. In some instances their floor is below the level of the surface, in which cases the building is damp. The Executive Engineer is of opinion that the barracks generally are not sufficiently raised. Some of them are on high plinths, while others are built below the surface of the ground, and are damp in the rains. The injurious effect in health to men dwelling in buildings like these latter is obvious. As regards the efficiency, or otherwise, of the drainage, the surplus water partially evaporates, partially sinks into the subsoil, while the greater portion runs off by natural drainage. There is one cesspool at the end of each lavatory 6 feet in depth and 6 feet in diameter. These cesspools are at various distances from the wells, but in no instance so near as to affect the purity of the water in them. These cesspools are from 10 to 30 paces from the nearest men's quarter. They are cleaned out once daily by the regimental Conservancy Establishment. There are no foul ditches near to barracks. The contents of the privies are carted away and deposited at long distances from the barracks. 17. Surface cleansing is carried on by a general Conservancy Establishment under the Barrack Master. It is done as effectively as possible in a cantonment where civil bazaars intervene between the different lines, and where enormous excavations exist (originally made by the Public Works Department for the erection of barracks), the cost of filling up which would be very heavy, and perhaps not justifiable, as the barracks are all temporary. 18. The surface of the cantonment itself is kept free of injurious vegetation. There are no old walls or thick hedges interfering with ventilation. 19. There are no military bazaars, except those of the several regiments, in which cleanliness, order, and regularity prevail. There are regular patrols of police for preserving order and cleanliness in the Sudder Bazaar and cantonments. Any person found committing a nuisance is severely punished by the Cantonment Magistrate. The cantonment police is found efficient. The native houses near the station are generally clean and free from dung heaps and filth. There is no nuisance experienced from wind blowing over the native dwellings. 20. The slaughter-houses are situated close on the north-west limit of the cantonments, and at a point equidistant from the barracks, the fort, and Kutchpoorwa station. They are inspected by the Deputy Commissary-General periodically, and frequently by the Assistant Commissary-General. The premises are kept scrupulously clean. Dung is sold for fuel and offal for manure. The blood is offensive. It is received into open headed casks, and emptied into covered cesspools with stink traps. The slaughter-house is as free from taint as the enclosure of any residence at the station. 21. A few ponies are attached to each regimental bazaar, and are picketed at some distance from it. The manure is removed by the soil carts of the respective barracks. 22. The horse lines are about 65 yards from the barracks and 300 yards from the hospital. There are no regular dung heaps. The manure is thrown out about 130 yards from barracks and carted away from time to time. The horses are separated by small mud divisions, renewed by the brickmakers every two or three days. 23. The quarters for married people are sufficient. No married couples inhabit the same quarters with single men.
Officers' Quarters.	1. Officers for the most part occupy bungalows in the vicinity of their regiments. They are nearly all new and built on good sanitary principles. Long experience has proved that bungalows on the present plan are admirably adapted for the climate.

References to Subjects and Queries.	Replies.
IV. Health of the Troops.	1, 2. The native population is on the whole healthy. The more common diseases among them are fevers of the intermittent and remittent types, cholera, dysentery, and a peculiar paralytic affection of the loins produced by eating a description of pulse (*Lathyrus sativus*) grown chiefly in the district of Barrah. 3. The comparative healthiness of the native population arises from their having full occupation and an abundant supply of food and water. 4. The sanitary condition of the troops at the station is uniform. Troops stationed at the fort at the season when the river recedes from its banks are specially liable to intermittent fevers. 5. It has not been the practice at this station to camp out the troops except during epidemics of cholera, when this proceeding has been found most efficacious in checking the disease. 6, 7, 8. Occasional residence on the hills is strongly recommended. It would exercise on the health of the troops, as well as tend to dispel *ennui*. Their *morale* too would be improved, as the regimental authorities could exercise effectual contro as regards indulgence in drink, and venereal disease would be less frequent. This disease and drink are fertile sources of admissions to hospital. 9. Diarrhœa prevails at hill stations, but the liability to this disease is neither so probable nor so general as to make it a ground for denying the men those other benefits certain to be reaped in a hill climate. 10. Barracks well placed, and sufficiently raised from the damp surface, and the adoption of flannel to guard the chest and abdomen, would contribute greatly to give immunity from bowel complaints in hill stations. 11. In going to hill sanitaria weakly men should leave the plains before the setting in of the hot season. They should arrive at the hill sanitarium not later than the 1st April, so as to have from 2 to 2½ months' residence, before the setting in of the periodical rains. They should remain until the 1st of January, except those suffering from chronic rheumatism, and they should return, remain throughout the snowy season, the alterative period of the hill climate. The above are the shortest periods in which benefit would accrue to the sick. 12. It is improbable that any amount of hill residence should give additional predisposition to the diseases of the plains. 13. No precautions are necessary in transferring troops from the hills to the plains, if it is done at the proper period of the year. 14. Men should have the benefit of occasional residence in the hills, but there is no necessity for keeping them there permanently. The standard of health among the troops in the upper provinces is, as a rule, not inferior to that of troops on the hills. Frequent change of station is not necessary, as affecting the health and spirits of the troops under ordinary circumstances. If their *morale* has suffered from special trials, severe epidemics, or harassing duties, a change of quarters might be desirable. The men themselves prefer a continued residence for three or four years. This is shown by the contented condition of the British cavalry regiments at Bangalore, in the Madras presidency. 15. 16. The average height of the hill stations above the level of the sea is about 6,000 feet. The most satisfactory results are obtained at this elevation. 17. The table-land of India, already mentioned, in the direction of the Rewah hills, might afford a site for a sanitarium. Its height is from 1,000 to 1,400 feet above the sea level; it is accessible by roads easily improved, and is about 45 miles distant from Allahabad. This has special reference to Allahabad, where convalescence is very slow, and would be much accelerated at the above elevation. 18. As regards the comparative healthiness of particular soils for stations, the Kunkur soil, being dry, is preferable to the deep black cotton ground in the plains and valleys of Bundlecund. 19. Twenty is the best age for soldiers proceeding to India. The best period of the year for troops arriving in India is from November to January. On arrival at Calcutta the troops generally proceed to Fort William, Dum Dum, or Barrackpore, and proceed to the upper country by steamers; by the trunk road by marching or by bullock train. Their clothing is at once adapted to the season, and they are not subjected to drills or marches prejudicial to health. The precautions requisite are avoidance of drink and of exposure to the sun, moderate drill and attention to clothing, well constructed barracks, lavatories, cells, guard rooms, and sources of amusement suited to the climate. 20. Troops should be kept at home until fully drilled and of proper age, and should then be sent to India direct. It would be highly advantageous to the troops to proceed to the hills on landing, but as the exigencies of the service will not admit of this, the relief should be so arranged in time of peace as to give each regiment its tour of residence in a hill climate as early as possible, and afterwards in succession. 21. Troops reach the interior, 1, by bullock train, admirably conducted; 2, by regular marches; 3, by steam. In the last case great care should be taken to avoid overcrowding, especially in the case of transport of sick or invalids. 22. Twelve years in the best period for service of the British soldier in India. 23. There is an excellent consent among the Medical Officers composing medical boards. 24. The best period of the year for invalids to leave India for home is January and February. Thus troops arrive at a genial season in England, and travel in a cool season to the port of embarkation in India.
Diseases.	1. Regular health inspections take place weekly; during epidemics daily. 2. The only cases of scorbutus have been in a few recruits arriving after a long sea voyage. 3. The proportion of cases of hepatic disease in this circle in 1858–59 was 1 in 20 strength 1 in 37 treated; 1 in 22 proved fatal. The disease is attributable to climate and intemperance. It occasionally supervenes in fever, and is generally found complicated with disease of the large intestines. Its frequency might be diminished by abolishing the use of spirits, added to the strictest attention to cleanliness, clothing, nature of duties, quality of food, efficient housing, and healthy recreation. 4. At this station dracunculus is almost unknown. 5. The proportion of sick from venereal diseases to the constantly sick is as 1 to 11. By lock

References to Subjects and Queries.	Replies.
IV. Health of the Troops—Diseases—*cont.*	hospitals, the registration of women, and stringent police regulations in connexion with those women, much good in the way of prevention might be done. 6. The troops at this station suffer from endemic, remittent, intermittent, and common continued fevers and dysentery, epidemic cholera and small-pox, and endemic rheumatism. The following are the proportions which the admissions and deaths from each disease bear to the total admissions and deaths, which are obtained from data since the mutiny, no other being available:— Fevers - - 50 per cent. - - less than 1 per cent. Dysentery - - 5½ „ - - - 11 „ Small-pox - - 1½ „ - - - 2 in 13 Rheumatism - - 5 „ 7. The nosological characters of these diseases are *Dysentery*, acute and chronic; *Diarrhœa*, acute and chronic; *Fevers*, intermittent, remittent, and continued; *Hepatitis*, acute and chronic; *Cholera*, sporadic and epidemic. Cholera, dysentery, and sun-stroke are most common during the hot season. Cholera and dysentery in the rains. Fevers, during the cold season; generally mild, continued, or intermittent. Remittent and epidemic fever during the hot and rainy seasons. It has been particularly noticed that the advent of an east wind, while cholera prevailed, has materially increased the spread of this disease. The sanitary condition of the native dwellings where these diseases prevail, taking into consideration the character of native dwellings and the habits of the people, may be considered unobjectionable. Exposure to the sun, and living in crowded dwellings are predisposing causes of disease among the native population. Living in a tropical climate, where the sun's heat is fierce, naturally predisposes to disease among European troops, to whose health and constitution such a condition of climate is antagonistic. 8. Exposure, although as little subjected to it as the service admits of, night duties, want of occupation, want of suitable recreations, produce a certain amount of *ennui* and weariness, which must indirectly contribute to the production of disease. Troops are observed to be more healthy when on the march or engaged in active operations than when in cantonments. 9. Quinine has been tried as a prophylactic in a very limited degree. 10. With regard to the prevention or mitigation of epidemic disease, the following measures are recommended:—Keeping troops in motion. Removing them from the locality where the outbreak occurs. Cutting off communication from the hospital and camp as far as practicable. Special hospitals for the then existing epidemic. Frequent inspections for the detection of incipient diseases, and giving encouragement to the men to report themselves sick at an early period.
V. Intemperance.	1. The soldiers at the station are temperate. There are very few confirmed drunkards; about 1 per cent. 2. Of 5,021 admissions in the circle during 1859, there occurred 36 cases of delirium tremens, 5 of which were fatal, and 25 cases of ebrietas. On account of loss of records during the mutiny, there are no means of arriving, with any degree of accuracy, as to the amount of disease indirectly produced by intemperance. There is little doubt that many diseases, especially those affecting the liver, are indirectly produced by drink; still, from reports from the several commanding officers at this station of the very few confirmed drunkards in their regiments, as well as from their testimony as to the generally temperate condition of the men, the Committee hesitate in stating that much sickness and mortality indirectly proceed from intemperance. Drunkenness *per se* is punished as an offence. 3. Spirits are sold at the canteens, but not at the bazaars. The probable daily amount consumed per man is less than one dram a day. The quality is good, and 24 per cent. under London proof. No spirits are included in the rations, neither for healthy men nor for convalescents. There are no intoxicating drinks sold in the bazaars. 4. The consumption of spirits is considered to be injurious to health. The quantity issued from the regimental canteens is not considered to affect the efficiency and internal discipline of the troops, but that obtainable by the men from other sources decidedly so. 5. 6. In exceptional cases spirits might be administered with advantage under medical superintendence, if practicable. But the entire substitution of malt liquor in canteens for spirits cannot be otherwise than beneficial to the health of the troops. While the use of spirits is to be condemned, the moderate use of sound malt liquor and pure wines is highly advantageous. 7. Coffee, tea, lemonade, &c. are much used. They are a comfort to the men, but not to the exclusion of sound malt liquor or good wine. 8. It would be beneficial to suppress spirits, and to substitute light drinks and malt liquor. 9, 10. The sale of spirits should be prohibited in canteens, and only those drinks mentioned permitted to be sold. The drinks sold should be the best of their kind, under such conditions as would ensure frequent inspection by the bazaar master or other competent authority. 11. (Canteen regulations of 48th, 70th, and 75th regiments transmitted) abstract as follows: 48th Regiment.—Only rum and malt liquor from commissariat to be sold. Each man allowed one quart of beer and two drams of rum per diem. Beer 3 annas per quart, rum 1 anna per dram. No rum to be served before evening. Canteen open from 12 to ¼ to 1 to issue beer for men's dinners, and from 6 p.m. to tattoo first post, when men may drink their liquor on the premises. One dram of rum only to be served out at a time. Liquor cannot be taken from canteen and men not to drink each other's liquor, but only their own quantity. A native to attend at the canteen with coffee, bread, butter, cheese, lime juice, &c. for the use of the men who want them. Prices to be hung up. (Other regulations as to general management, guards, checking issues, &c.) All stated to be strictly carried out. 70th Regiment.—Canteen to be cleared at the quarter bugle before tattoo. No men on duty, defaulters, convalescents, or men with appearance of drink to be admitted, nor men of other corps without a pass from commanding officer. No liquor to be taken out of canteen without a pass, or unless for serjeants' mess. Canteen to be open from 1 till 2 p.m. A quart of beer or porter may be issued to each man, but no spirits till after evening parade. Daily issues per man not to exceed one quart malt liquor and one dram rum; or two drams rum

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	and no malt liquor. Each soldier provided with tickets to check issues. Soldiers not to drink together in canteens, or lend their tin pots, or give each other liquor. 75th Regiment.—These regulations refer mainly to the receipt and care of rum at the canteen. There are no times for opening or closing the canteen; there are no regulations as to the amount per man to be issued, only the number of drams each company has been supplied with is to be returned, and no liquor is to be taken out of the canteen.
VI. Diet.	1. The ration consists of 1 lb. bread, 1 lb. beef or mutton, the latter twice a week, $\frac{5}{7}$ oz. tea, or $1\frac{3}{7}$ oz. coffee, 2 oz. 8 drs. of sugar, 4 oz. rice, 1 oz. salt, 3 lbs. firewood, 1 lb. potatoes, or such vegetables as may be in season. The rations do not vary except in regard to vegetables. The present proportions are $\frac{7}{8}$ lb. of potatoes and $\frac{1}{8}$ lb. of onions for soup. The ration is inspected by the Quartermaster, Subaltern of the day, Captain of the week, and by a Commissariat subordinate. 2. A complete ration without stoppages is supplied. The men have three meals daily, breakfast at 7 a.m. in summer and 8 in winter; dinner at 1 p.m.; tea at $5\frac{1}{2}$ p.m. in summer and 5 in winter. 3. As regards quality, the food products of the country are rendered properly available, and the soldiers generally seem to be content with the present system of rationing. A non-commissioned officer of each company is responsible for drawing the rations, seeing them cooked, and that no part is disposed of otherwise than is intended. 4. For cooking each company has a cookhouse and utensils, one head cook and seven coolies, the latter are paid by the company at the rate of 10 annas per man per month. The kitchens are clean, well ventilated, and sufficiently supplied with water, but the water falls off before the rainy months. The food is boiled, roasted, stewed, or curried, as desired by the men. It is sufficiently varied and properly done. Tea and coffee are also properly prepared. Coffee is provided for the men on march at a small charge. Rations are issued immediately on the arrival of the men in camp. 5. Soldiers' gardens for the cultivation of vegetables, &c. might be advantageously established in the vicinity of the barracks.
VII. Dress, Accoutrements, and Duties.	1. In the hot and rainy season the clothing consists of cotton or khakee coat and trousers, wicker helmet with wadded khakee cover, woollen socks, ammunition boots and cholera belts, with the usual accoutrements. In winter a serge tunic and check cloth trousers and forage cap. Great coat of stout warm woollen cloth. The clothing has been subject of much consideration, and is admirably adapted according to the seasons and men's duties. There is little room for improvement, except in quality of material. Trousers of a less coarse texture for the cold season, and drawers, would be much more comfortable. The present trousers are of a spongy, bad, heavy texture, and gall the men on march. In most regiments the men on guard have a second suit of clothing for change in wet weather.
Duties.	1. Young soldiers should be thoroughly drilled at home before being sent out to India. 2. There is a little drill in the hot season at early hours or at sunset. Guards are relieved every 24 hours. In winter there is sufficient drill to give the men wholesome exercise. They do not suffer in health from drills. The best hours for drill and parades are from 5 to $6\frac{1}{2}$ a.m. in summer, and after sunrise in winter. After sunset in the hot season. There are orders to this effect, which are strictly obeyed. The men have consecutively eight or nine nights in bed between each turn of guards. 3. There are few guards mounted more than one mile from barracks. The roll calls are as follow:—In the 48th regiment six roll calls daily; in the 70th, at all meals and at tattoo; 75th, the same. The effect of night guards is without doubt injurious to health. As precautions, the men should be suitably clothed according to the season, and have a change of clothes on returning wet from sentry duty.
VIII. Instruction and Recreation.	1. There are skittle grounds, but no ball courts at the station. Covered ways should be used to the skittle grounds. There are schools, and good schoolmasters. In some corps there are good libraries, with reading rooms well lighted; but generally the lighting is defective. There are no day rooms, soldiers' clubs, workshops, nor soldiers' gardens. All commanding officers here concur in recommending workshops for the men. There is no theatre nor gymnasium. The means of recreation provided are not sufficient for the men in hot or wet weather. There is a stringent order against European soldiers leaving barrack rooms from 8 a.m. to 5 p.m. during the hot and rainy season. It is most beneficial to health. 2. The means of recreation alluded to above would be sufficient. 3. Savings banks have existed in all European regiments since 1833, and are found to be highly advantageous. 4. The men take exercise in the verandahs. The station is well planted with fine forest trees, but not in the immediate vicinity of the barracks.
IX. Military Prisons.	1. The cells at this station are generally defective. They are small, ill ventilated, not well situated, and not provided with lavatories or latrines. Their condition has recently been under consideration with reference to building new cells.
X. Field Service.	1. The Bengal Medical Code, and the report of Superintending Surgeon Renny and Field Surgeon M'Rae are considered guides for field medical service. 2. Due weight is given to suggestions from medical officers as regards sanitary arrangements for the march, bivouacking, camping, &c. 3. The sanitary regulations for camping are as follows:—"Along the grand lines of road, ground for camping is marked out by posts. Strict regulations for the cleanliness of these spots are in force. Wells are provided at these places. Operations for protecting health in camp are carried out under the Medical Officer and Quartermaster, and their suggestions are attended to by Commanding Officers. 4. The regulations referred to above contain the arrangements for field hospitals, ambulances, &c.
XI. Statistics of Sickness and Mortality.	No information.

ALLAHABAD.
BENGAL.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1. The hospital plan is precisely the same as the barrack plan. 2. The hospitals are situated within 200 or 300 yards of their respective lines, and are in no case under the influence of proximity to stables or bazaars. The buildings are open and freely ventilated, and the ventilation is not obstructed by high buildings, trees, &c. They occupy the best sites within the lines. There is some broken ground in the vicinity of the Chatham lines, but no noxious effluvia. 3. The water is good and wholesome. It is filtered through sand and charcoal. The wells require to be cleansed and deepened occasionally. 4. The hospital drainage is very imperfect and inadequate to carry off the water during the rains. The surface drains carry off much of the surface water into the ravines. Other impurities are removed by hand or by conservancy carts. 5. The floors are in most instances on a level with the ground, and there is a total want of free perflation of air beneath them. It would be highly desirable that the buildings should be elevated several feet above the ground, as much malaria must necessarily arise during the rains. Most of the roof water sinks into the subsoil, owing to the flatness of the ground and the imperfect nature of the drainage. The means of surface drainage consist of shallow narrow guttering too small to accomplish the objects intended, and insufficient to carry away the rain-fall rapidly. The buildings are constructed, partly of baked partly of sun-burnt bricks; surrounded on all sides by verandahs 15 feet wide; roofs in some instances of thatch, in others of tile and thatch; in both cases insufficiently thick to keep the buildings cool. The walls are sufficiently thick. The verandahs are very seldom used for sick except on a great emergency. The buildings are on one floor only. The following is the accommodation:—

Hospitals.	Wards.	Regulation Number of Sick Persons.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area per Bed.	Height of Patients' Beds above the Floor.	Windows.

Total accommodation, 780 sick. Date of construction of hospitals, 1858–59. Wards, 8. The aspect of the hospitals is east and west, so as to have the advantage of the west winds during the months of March, April, May, and part of June.

In most instances there are no windows except small semilunar orifices over the doors, sometimes glazed, in other cases open. The plan of ventilation is on the whole very defective.

6. The ventilation is by means of doors, and of an interval between the main roof and a second shallow roof superimposed, through which interval hot air is given exit to. Under circumstances which require the doors to be closed (as during high winds), this mode of ventilation is by no means successful. There are no jalousies, or jhilmils to the doors.
7. During the hot winds, from 15th April to 15th June, the ordinary tatties are used for cooling the air. Fresh grass is used every year, as the old tatties become offensive. They are put into each opening on the windward side. Tatties for a hospital or temporary barrack would cost 200 rupees.
8. Warming is seldom necessary, but were it so there are no means of affording it.

The hospital walls and ceilings are cleansed as often as the Medical Officer considers it necessary.

9. The privies are situated about 25 yards from the hospitals. Access to them is gained by covered ways. The soil is removed daily or oftener, and lime plentifully supplied with a view to counteracting noxious effluvia. Urinals are attached to these buildings. The urine is received into cesspools, which are daily emptied. The drainage is not perfect, although it cannot be said they are offensive. There are no cesspits for the privies.
10. There are lavatories, but at too great a distance from the hospital. The arrangements are the same as those for the barracks.
11. There are no baths.
12. Linen is washed by washermen, and is well done.
13. Most of the hospital stores are of sun-dried bricks, small and fragile, but tolerably dry.
14. The beds generally in use are wood, with mat bottoms. They are fragile, harbour vermin, and are constantly requiring repairs. Iron cots with sacking of canvass are in use at Cawnpore, and are found to answer well.
15. The hospital kitchens are those generally in use, where native cooks are employed. Although the cooking is satisfactorily done, it would be an improvement to introduce proper cooking stoves. Roasting and grinding of coffee are imperfectly done, on account of want of suitable apparatus.
17. The attendance on sick is ample. In a regiment 1,000 strong it consists of 1 apothecary 1 steward, 1 assistant apothecary, 3 hospital apprentices, 1 head compounder, 1 assistant ditto, 1 head dresser, 1 assistant ditto, 2 shop coolies, 1 native writer, 2 stewards' servants, 7 bheesties, 9 sweepers, 1 sirdar, and 20 ordinary ward coolies, 1 ayah, 1 methranee, 1 head and 4 ordinary cooks, 1 head and 4 ordinary washermen, 1 clothier, 2 tailors, 1 barber. These are permanent, but can be increased on emergency.

Six European nurses have been allowed for Allahabad General Hospital since 1858, and have been found to add much to the comfort of the sick in that hospital. European nurses are not employed in any regimental hospital. European orderlies to attend to special cases are always available on application to the regimental authorities.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	18. The sanitary condition of the hospitals may be considered as good. Hospital gangrene or pyœmia has not occurred. Cholera, when epidemic, has occurred among the sick in several hospitals, but not in undue proportion. 19. The hospitals at Allahabad, being generally merely temporary barracks occupied as hospitals, are deficient in many requirements for regular hospitals. It would be useless to suggest improvements under existing circumstances. 20. Convalescents take exercise daily on elephants. A great want is felt in the hospital precincts not being defined, and being totally devoid of trees, shrubs, walks, or seats. 21. There is no separate hospital accommodation for the sick of soldiers' families. Wards in the hospitals are, however, set apart for them. In the general hospital there is a female ward, attended by European nurses, where sick women and children have every comfort. An ayah and methranee are allowed to each regimental hospital, for attendance on women and children. 23. As regards the powers of Medical Officers in their hospitals, all suggestions and representations made by them through their Commanding Officers meet with due attention as far as the exigencies of the service admit, from the Barrack Master and Executive Engineer. Change of diet and the issue of medical comforts, are strictly within the jurisdiction of the Medical Officer, at stations, in camp, and on the march. Extra diets and medical comforts are readily sanctioned by the Deputy Inspector-General on requisition, accompanied by an explanation as to the necessity. 24. There are no convalescent wards. The practice at the station is, that men on becoming convalescent are discharged from hospital, but attend daily for inspection by the Medical Officer; while they attend morning parade, they are exempt from all duty, until returned fit for duty.
XIII. Burial of the Dead.	1. There are two cemeteries for interment of troops, one north, the other west of cantonments. 2. The soil is Kunkur or calcareous clay, on a substratum of sand. Decomposition takes place readily. Grounds carefully kept. 3. The following rules for interments are in force at present. Graves to be 7 feet long, 2½ feet wide, and 5 feet deep. Two feet between the graves. No grave to be reopened for fresh interments, nor for other purposes, without permission of the Medical Officer. The time of burial is sunrise or sunset, as fixed by the Medical Officer. Burial takes place 12 to 18 hours after death. 4. The grave yards are never offensive. 5, 6. The dead of camp followers and bazaar people are burnt, or cast into the Ganges. No injury accrues from these practices. 7. The present rules and practices answer satisfactorily.

(Signed) Jno. Fordyce, Brigadier.
J. B. Dickson, Deputy Inspector-General of Hospitals.
Augustus Shelton, M.B., Surgeon, 48th Regt. (Secretary).
J. Fullarton Beatson, M.D., Surgeon, Bengal Army.
F. W. Peile, Captain, Engineers.

I. Topography.	1 to 14. There are five principal military stations in Oude:—Lucknow, Roy Bareilly, Fyzabad, Gondah, and Seetapore. Lucknow, which is the largest, is situated in lat. 26° north, long. 81° east; Roy Bareilly is 49 miles to the south-east; Fyzabad 82 miles nearly due east; Gondah about 70 miles to the north-east; and Seetapore 53 miles a very little to the west of north. Around all the country is flat and cultivated. Irrigation is carried on chiefly by wells, but surface water, which collects in the rains, is also used for the purpose. The elevation of Lucknow above the level of the sea is 360 feet, Roy Bareilly and Fyzabad are, I imagine, very nearly the same height; Gondah and Seetapore are probably a few feet higher. They are all situated on the highest ground in their immediate vicinity. As a sanitary position I prefer the old Lucknow cantonment to that of the new one; the former was at Marion to the north of the city, the latter is at Dellkoosha to the south. On military grounds, and because it was thought that the present position would not prove unhealthy, the site was chosen by a committee appointed to decide on one in the beginning

I. Topography—*cont.*	of 1859. The stations are all open and freely exposed to the winds, and at none, I believe, is the temperature raised by reflected sun heat. There are no important works of irrigation near any of the stations. The distance of Lucknow from the nearest hills is 100 miles; Roy Bareilly is between 40 and 50 miles farther off; that of Fyzabad may be about 70 miles off; Gondah 50 miles; and Seetapore 70 miles. The exact height of the Hymalayan range immediately to the north of Oude I do not know. Irrigation is not observed to have a marked effect upon the health of any of the above stations. Rice cultivation is not prohibited, but it is an article not very extensively grown in the province; and I believe there is no indigo grown near any of the stations referred to. There is not, I believe, any adjacent higher ground from which the drainage must necessarily pass into the subsoil of the station. At all there are some open tanks or ponds. The cantonment site at Lucknow was selected by a committee composed of the brigadier commanding, the civil commissioner, the chief engineer, the superintending surgeon, the assistant quartermaster-general, and the executive engineer, aided by a sub-committee of medical officers. Other cantonments were, I suppose, chosen by committees somewhat similarly constituted. The Lucknow committee considered the nature of the soil and subsoil, quality of the water, elevation, facilities for drainage, surface of the surrounding country, &c., and the health of the native population in the immediate neighbourhood was minutely inquired into. Lucknow is two miles from the cantonment; though smaller than formerly, it is still a large city, and is supposed to contain between 400,000 and 500,000 inhabitants. Roy Bareilly is a mile from the cantonment; Fyzabad about two; Gondah and Seetapore are each about a mile and a half. Fyzabad is a town of some pretensions, the other three are small. Lucknow stands on the small river Goomtee, which is from 40 to 50 yards wide in the dry season, but increases very considerably in the rains, sometimes overflowing its banks. The overflow seldom lasts long. The cantonments are situated to the south-east of the city, about two miles from the river, the ground upon which they stand being about 40 feet above the level of the latter. To the south-west, within about a mile and a-half, there is a jheel of three-quarters of a mile in length, which enlarges considerably in the rainy season. It is fortunately out of the line of the prevailing winds. On the north they are bounded by a canal, which, except during the rains, contains but little water, and at that time it may almost be termed a running stream. A belt of trees stands between them and the native city. The soil is more or less sandy. Water is found about 35 feet from the surface, and in most of the wells it is good; in a few it is brackish. There are no jungles in the vicinity. The ground to the south-east of the Dragoon barracks is broken and full of ravines. As yet there has not been time to judge if this will have an injurious effect upon the health of the men. I may mention that the surgeon of the corps believes it to be a source of fever. The facilities for drainage are great, through ravines leading to the river in one direction, and the canal in the other. Roy Bareilly stands on the left bank of the Salree, a small stream which is nearly dry in summer, though navigable for small craft in the rains. Its banks are very much broken up by ravines in the neighbourhood. The soil is marly. Water generally good, at some spots containing nitre and common salt, and is found about 30 feet from the surface. Fyzabad is on the right bank of the Gograh, which during the rains is from two to three miles wide, and at other times from 600 to 800 yards. It is only when an inundation takes place that it is so wide as the first mentioned. The station is bounded on the north by the river, and on the west by a creek, which joins the river at both ends. This is filled with water in the rains, forming the land between it and the river into an island. A couple of months after the rains cease the greater part of the water dries up, leaving only a little remaining in about half a mile of it towards the northern end. The creek is altogether between three and four miles in length. There is, moreover, a tract of marshy ground in the west, which in the dry season is partially cultivated, and in the rains it is generally under water. The average height of the station is about 18 feet above high-water mark, and 30 feet above that of low water; it is tolerably well drained by two nullahs, which run on either side of the European barracks. There is reason to fear, however, that these nullahs serve as leaders to malaria from the marshy land in the neighbourhood. The station is a good deal wooded, but to the westward it is open to the evil influences of low ground by the river side. It has been proposed to plant a belt of trees along that boundary. The soil is alluvial; it consists at some parts of the surface of sandy clay, at others altogether of sand, and towards the west there is some limestone. Sand extends to the depth of upwards of 15 feet, below which it is clayey. Water is plentiful everywhere, and good, containing a small quantity of calcareous matter, and is found at a depth of about 20 feet. Gondah is to the north of the Gograh, about 30 miles to the north-west of Fyzabad, and 90 to the south-east of Seetapore. The surrounding country is flat, from 20 to 25 feet below the level of the cantonment, which stands on an elevated piece of ground. The plateau on which the troops are placed is separated from the country by a declivity of the height mentioned on all sides except the north, where it is continuous with a plain of about the same level. Half a mile to the south is a small stream, the Selivee Nuddee, which runs from the westward in an easterly direction, and empties itself into the Gograh near Fyzabad. The drainage of the station is excellent; all the surface water is carried off. A large drain cut in front of the European barracks leads to a nullah which communicates with the Nuddee. The banks of the stream are inundated during the rains, and the ground between it and the cantonment then and in the cold season is almost a swamp; that between the European barracks and the town is broken up by ravines, which contain more or less water in the rains, but are dry in the hot season. About two miles to the north there is a strip of jungle; small jheels and groves also exist in and about the station. The soil is sandy to the depth of about 20 feet, and then comes a bed of kunker. Water is abundant and good at about 20 feet from the surface. Seetapore stands on a plateau sloping on the west, south-west, and north-west sides towards the river Surain, about two miles distant. The height of the cantonment in the dry season is about 44 feet above the level of the river. There are several small jheels and groves about the station and in its neighbourhood, and the river banks are intersected by ravines, which give facilities for drainage. The soil is clayey, with a sandy subsoil, below which, at a depth of 24 or 25 feet from the surface, good water is found in abundance.

Dec. 1858	62	67	57	Rain.	Westerly.		Cool weather.
„ 1859	58½	65	52	Slight rain.	N.Wly.		Ditto.

3 to 5. The climate of the provinces, as in most other parts of India, is divisible into the cold, hot, and rainy seasons. The cold weather sets in at the beginning of October, and is at its height in December, when the night temperature is low enough to freeze water. Ice is also made in January, and sometimes even so late as towards the end of February. The cold season ends in March. Heavy dew often falls in the winter months, and there are not unfrequently showers of rain. The hot weather sets in towards the end of April, and hot winds blow throughout May and June till the rains commence, which they commonly do at the end of the last-named month. During this season dust storms are frequent, and often very violent, and while it lasts the air in the day is more or less charged with fine dust. As a rule it subsides at night, to be raised again by wind in the day. The sun and wind increase in power up to the time the rains begin to fall; the wind is chiefly westerly at this period, at all events in the day; in the early part of the night it not unfrequently becomes easterly. The rains, as stated, commonly set in towards the end of June, preceded by storms, accompanied by lightning—slight at first, but heavy in July and August, and occasionally there is a cessation for a longish period. On such occasions the vegetation produced by the first falls dies away for want of water, and the sun's rays and future falls of rain, acting on the decaying vegetable matter, must no doubt produce malaria, which cannot but act injuriously on people who may happen to be massed in the neighbourhood. Irrigation, which is carried on throughout the province by wells, does not seem to influence the climate of stations. The climate of Oude is beyond doubt superior to that to the south of the Ganges, though not, perhaps, so dry. The temperature at most of the stations is lower; I judge it to be so from its influence on the health of the troops. The kind of diet, shelter, and clothing required are the same as in other parts of the Upper Provinces. The climate calls for no special precaution as to drills, duties, and exercises beyond what are elsewhere considered necessary. During 1859 and 1860 the stations have stood thus in point of salubrity, as shown by the returns of European troops occupying them:—1st, Roy Bareilly; 2nd, Gondah; 3rd, Seetapore; 4th, Lucknow; 5th, Fyzabad. Fyzabad and Gondah appear from native report to be more subject to epidemics than the others. The temperature trans-Gograh is considerably lower than on the Lucknow side of the river, and the atmosphere is said to be more humid; natives of that district are subject to goitre. At all the stations the most healthy months are those of the cold and hot seasons, and the most unhealthy those at the breaking up of the rains. This is especially the case at Fyzabad. Fevers prevail in the hot, rainy, and early parts of the cold season. In June the greatest number of cases occur; in January the least. Bowel affections there also occur and prevail chiefly during the hot and rainy seasons. The greatest number of cases occur in August; the least in January. Liver affections are common in August and September; fewest cases occur in January, February, and March. Cholera is very variable with regard to its period of prevalence. Sporadic cases take place all the year round, but occasionally it takes on an epidemic character. At the end of the rain in 1859 there was a slight epidemic, and again in the early part of the hot weather of 1860. Catarrhal affections are common in the cold season. Heat apoplexy occurs in May and June; in May, June, and July 1858 it was alarmingly common; in May alone upwards of 500 cases occurred in the Lucknow field force. I never heard before of its being so frequent.

III. Sanitary Condition of Station. I.A.

1 to 3. A general map or tracing of each station with the surrounding country has already been forwarded with each separate report, and as the Engineer Department have complained of

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	the difficulty of preparing duplicates on account of the pressure of work, the preparation of them has not been urged. The same may be said with regard to the barracks, &c. The dimensions of those at Lucknow are entered in the subjoined form; those at other stations are much the same. The infantry barracks are constructed for half a company, or 48 men; those for the artillery and cavalry for a troop or company. In all the barracks in Oude the cubic space per man is from 1,500 to 1,700 feet. Each barrack has a mess-room across the centre.

4. Table of Barrack Accommodation:

Date of construction, commenced in February 1859.

Total number of rooms or huts { 20 barracks for infantry, 9 for cavalry, when all are completed.

Barrack Rooms or Huts.	Regulation No. of Men in each Room or Hut.	Dimensions of Rooms or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
					Ft.			Ft. in.		Ft. in.	Ft. in.
Infantry Barracks, each contain—											
Two Wards -	24 each.	72·6	22	23	36,685	1528·5	66·5	1 8	Doors in each, 12	7 6	4 1
									12 windows.	2 6	4 6
A Mess Room -	48	44	22	23	22,244	463·5	20·2	—	6 windows.	2 6	4 1
Cavalry Barracks, each contain—											
Four Wards -	18 each.	52	22	23	26,312	1644·5	72·5	1 8	8 windows.	2 0	4 1
A Mess Room -	72	46	30	23	31,740	440	19	—	6 doors	7 6	4 1
Four end or Serjeants' Wards, one at the corner of each Infantry and Cavalry Barrack - -	1	18	12	14	2,464	2,464	176	1 8	3 doors	7 6	4 1
Guard Rooms -	—	60·5	18	23	25,647	—	—	—	12 windows.	2 6	4 6
									14 doors	7 6	4 1
									In each Cell.		
Prison Cells - -	1	10	10	18	1,800	1,800	100	1 8	2 windows.	2 6	4 6
									2 windows.	4 6	4 6
									2 doors	7 6	4 6

At some stations the cubic contents of each prison cell amount, I believe, to 2,000 feet.

5. In nearly all the barracks there are windows on both sides. In a few of the married barracks they are only on one side; they open on swivels by ropes; there is a verandah surrounding the barracks 10 feet in width; these verandahs are not used as sleeping quarters in any barrack in Oude. There are no jalousies or jhilmils in the barracks at Lucknow, nor, I believe, at other stations.

6. The bedsteads are of wood, with tape bottoms; the bedding consists of two sheets, a quilt, setringee, and a blanket. Iron bedsteads would be an improvement; those of wood are much infested with bugs.

7. Tents are constructed of cotton cloth, with a pole or poles generally of bamboo. The dimensions of a private's tent for 16 men are as follows:—height, 10 feet; ditto of walls, 5 feet; length, 20 feet; width, 17 feet; which gives 21 superficial and 159 cubic feet per man.

8. The barracks are ventilated by doors and windows, and by ventilators in the top of the pent in the roof; the guard-rooms are also ventilated by the same means; tents chiefly by four doors. This method is quite sufficient. Kuskus tatties, and punkahs have been hitherto the only available means for cooling the air in barrack-rooms at Oude. Thermantidotes have not yet been established.

9 and 10. The barracks are constructed principally of burnt bricks, laid in mud cement, with tiled roofs. The tents are of cotton cloth, wooden or bamboo poles, generally the latter, with cotton ropes. The floors are formed of large square bricks or tiles; they are 3 feet above the level, and there is no ventilation beneath them.

11. Barracks constructed as above are believed to be well suited to the climate. The same remark applies to tents. The Engineer Department attends to whatever repairs are requisite; but hitherto attention has been principally devoted to constructing and completing barracks in Oude. The senior medical officer at the station is the sanitary officer. Whitewashing of barracks (internally), hospital cells, privies, and guard-rooms is done annually; hospitals more frequently, when specially required.

12 and 13. The lavatories and cook-houses at Lucknow are constructed in the following manner, and those at other stations in a similar way:—In the lavatories there is a long shelf of masonry used for washing basins, which is open; also a set of small rooms where ablution can be performed in privacy. At each end of the basin-shelf there is a cistern, into which water is brought by pipes from a higher cistern at the nearest well. The water can be partly got rid of by an outlet at the top, and wholly through one at the bottom of the cistern, into an outside drain. A small canal runs along the whole length of the bath-room to supply water to the bathers, who can draw it in earthen gurrahs or leathern buckets, and throw it over themselves. Iron bars across the canal prevent the bathers from lying at full length in it, and thus soiling the whole supply of water. The supply and discharge of the water is

References to Subjects and Queries.	Replies.
III. Sanitary Condition of the Station—*cont.*	arranged similarly to that of the cisterns. The cook-houses are large rooms, in which the native construction of fireplace has been generally adopted. Cooking vessels, which are supplied by the Commissariat Department, are tinned twice a month; they consist of copper pots and pans; there are likewise frying-pans and gridirons. With respect to washing linen, it is done at the nearest stream by washermen, who cleanse it, and then dry it in the sun by hanging it on ropes supported by poles. The convenience for this purpose is quite sufficient. 14 and 15. Privies in Oude are constructed on the same principle as at other stations; the drainage is arranged for by a narrow drain running the length of the building, sloping uniformly from one end to the other; at the higher end is a water cistern; at the lower a cesspool. The water from the higher cistern scours the drain into the lower cistern or cesspool. At the back of each privy there is an opening through which the sweepers remove all solid matter; the ordure is carried off to a distance in night-carts. The ventilation of privies is through ventilating tiles at the ridge, doors, and openings near the top of the walls. There are no special arrangements for lighting; it is done by lanterns, with candles or oil-burners. The openings in the walls are trellised with bricks. 16. There is no sewering as yet constructed; the only drainage that has been provided being for rain or surface water, which is carried off into natural watercourses. There is no doubt the drainage will be sufficient when the building operations now in progress are completed. Facilities for drainage are great. The small end rooms in barracks and hospitals are said to be slightly damp; the same may be said of those in hospitals; those at Roy Bareilly, occupied by the Royal Artillery, are the only ones that are in any way affected; at other stations it is not so. The rain water is carried away by shallow surface drains, which are sufficient; the small quantity thrown out from barracks evaporates or sinks into the soil. Urine is received into tubs or reservoirs from which it is removed and carried to a distance in conservancy carts. The reservoirs (cesspits) are close to barracks and hospitals; they are emptied twice a-day by sweepers. Tubs are in most general use. The reservoirs are attached to privies, and are small. Wells for ablutionary purposes have been dug, or are about to be dug, at no great distance from them. It is proposed to have a pucka reservoir to each wash-house, into which all the water used shall run; when full, to be emptied by earthen or leathern vessels; the water being either sprinkled over the surface in the neighbourhood or conveyed to soldiers' gardens when near. There are no foul ditches which may be really termed as such, near any of the stations. 17. The surface cleansing is generally good; it is performed by regimental sweepers, under the orders of quartermasters. The refuse is removed to a distance beyond the cantonment by carts, sometimes once and at others twice a day. 18. The surface of the cantonment at Lucknow is kept perfectly free from vegetation, and I believe it is so at other stations. At some stations there are some old walls, but they will not exist when the present arrangements are completed. 19. The bazaars are only being formed; that at Lucknow is well laid out, with fine broad open streets; when completed it will be capable of perfect drainage. Cleanliness is attended to by sweepers. Latrines are provided for inhabitants and camp followers; sweepers clean the bazaars morning and evening. Native houses in the immediate neighbourhood of stations are kept tolerably clean. There are one or two pits in each village, from which the materials for building purposes have been dug out. There is no nuisance experienced in barracks from winds blowing over the native dwellings. 20. Animals are slaughtered for the use of the soldiers at Gondah, Roy Bareilly, and Fyzabad, half a mile; at Seetapore, one mile; at Lucknow, two miles. Offal is chiefly eaten by vultures; at Fyzabad it is partly thrown into the river. No nuisance is experienced. 21. Bazaar horses, and those of camp followers, are kept in the station, picketed either in the bazaar or in the neighbourhood of grass-cutters' huts. Troop stables are on raised grounds sloping, so as to ensure water running off. Manure is carried away, but is partly used in riding schools; at some stations in burning bricks; at others, removed to a distance and deposited on the ground. 22. At most of the stations the horses stand in the open air. At Gondah the stables consist of a tiled roof on framework supported on pillars; there are no walls; at the ridge, the roof is double for the purposes of ventilation. At some stations the stables or horse lines are in front of men's barracks at about 100 yards distance; at others, they are between the barracks and the officers' lines. No dung-heaps are allowed to form; manure is carted away to a distance; the picketing grounds are well removed from hospitals. 23. Separate quarters are provided for married men, each one being allowed two rooms, measuring, one 18 ft. by 12 ft., the other 12 ft. by 12 ft.
Officers' Quarters.	1. Officers do not live in Government quarters, but in private bungalows. When all arrangements for drainage are completed, the sanitary state will be good. There is no improvement to be mentioned upon that which is being already carried out.
IV. Health of the Troops.	1. The stations in Oude are generally healthy; Roy Bareilly and Gondah are particularly so, likewise Seetapore. Lucknow and Fyzabad are above the average of stations of the north-west provinces. The native population in the country are healthy. 2. Fevers of different types are prevalent among the native population; bowel complaints and liver affections are also frequent. Spleen exists, and is most common, I believe, about Fyzabad. Cholera epidemics also prevail at times to some extent. 3. The climate, together with good feeding, probably renders the people of Oude more healthy than those of other districts. 4. A large proportion of the troops in Oude came to India from home in 1857, and were in camp or in tents in 1858–9, and have been gradually getting into barracks at the different stations since. The health of all has improved during the past year. They have suffered from fever, liver and bowel complaints, cholera (though not to a great extent), and ophthalmia; venereal has also been common, generally one-fourth to one-third of all the European sick. At some stations some barracks are considered not quite so healthy as others, but I believe there is nothing very marked about any. 5. Troops are not camped out, excepting for a short time, when barracks are being white-washed or repaired. 6. I have never held charge of European troops at hill stations, though for a number of years I was attached to the stations of Simla and Nitogle. 7. Have not had the opportunity of judging on a large scale. From the experience I have

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	had, however, I should say that troops are not more liable to febrile attacks on returning to the plains. 8. I approve of hill stations for troops. 9. Diarrhœa is a disease which is very likely to attack troops upon going to the hills. On the other hand, I have seen persons suffering from that disease on arrival get rid of it in the hills. 10. No fault is to be found as regards diet, shelter, and duty at hill stations. Men, I believe, often injure themselves by insufficient clothing, and by taking violent exercise in valleys, shooting and butterfly catching, exposed to the hot rays of the sun. 11. By far the best season for residing in hill stations is the cold one. In order to enable our troops to receive the benefits of such residence it is necessary to stay from 20 to 22 months, or it may be two years, in which the whole of one cold season and about half of a second should be included. 12. I should say that no injury would accrue to any one who stayed beyond this term upon his returning to the plains for service. 13. Proper attention to clothing and avoiding the direct rays of the sun are the special precautions for protecting the health of the troops on leaving hill stations for the plains. The slanting rays of a forenoon sun are, I think, especially hurtful. 14. I would recommend giving the troops a short service in the plains and locating them in the hills. Frequent change is beneficial. 15. No experience. 16. From 6,000 to 8,000 feet or higher above the level of the sea would be the most suitable site for hill stations. 17. There is said to be a good site about 80 miles to the north of Seetapore viâ Luckimpore; but, so far as regards myself, I have no correct information regarding it. 18. A dry sandy surface with sandy subsoil has always been found to be the most healthy soil for stations. 19. The best age for soldiers to proceed to India would be at the age of about 20 years, when the constitution is pretty well formed; and they should land at the commencement of the cold season. In order to preserve the health of recruits upon first landing in India, I would not allow them to remain a single day at a presidency town if it could be avoided. I would send them to their regiment with the least possible delay. Care should be taken that they are clothed for the season, a head-dress being furnished fit to give thorough protection. Every precaution should be taken to keep liquor from them, and they should be warned against the immoderate use of fruit. 20. I would send troops direct from the home depôts, and on landing, to the northern parts of the country, afterwards to the hills, and latterly to Bengal. 21. Troops are sent by boats and river steamers, also by bullock train, marching is, I believe, the most healthy mode of sending them. 22. A British soldier should serve from 10 to 15 years in India. 23. Medical boards frequently are not unanimous in opinion; the majority decide as to the disposal of cases before them. I have no suggestions to offer. 24. The best time for invalids to leave India for home is February or the early part of March.
Diseases.	1. There are, I believe, regular inspection parades for the purpose of discovering any incipient disease in all European charges. The times for them vary in different corps. 2. There has not been, so far as I can remember, any case of scorbutic disease among the troops in Oude. The supply of vegetables is abundant, which may account for its absence. 3. The proportion of cases of hepatic disease varies greatly, according to the nature of the season, the amount of exposure the men are subjected to, &c. In Lucknow itself it was 4 per cent. in 1858; in 1859 it increased; and it was larger in 1860. Good shelter, wholesome food, healthy exercise and amusement, steady habits, and avoiding over-exposure to the sun would tend to diminish its frequency. 4. There has not, to my knowledge, been a case of dracunculus amongst the European troops in Oude for the last three years. 5. The proportion of venereal cases has been from one-quarter to one-third of the total sick. Women should all be under surveillance, and lock hospitals should be established; one has been established in Lucknow in connexion with the King's hospital there; it has generally from 40 to 60 inmates. Diseased women from regimental bazaars are taken into it for treatment. The city itself contains upwards of 1,200 registered prostitutes; and when the hospital becomes in perfect working order there is no doubt it will be more generally resorted to than at present. 6. The troops at the station suffer both from diseases of the epidemic and endemic class. Fevers of the intermittent, remittent, and continued forms are common at all the stations. The largest number of admissions from the disease takes place in the months of May, June, and July; the smallest in December, January, and February. Dysenteric cases are common, the largest number occurring in August, September, and October. Cholera has not been severe at any station in Oude during the past three years, nor has small-pox. The cases of this disease have, however, been more numerous than might have been expected. Rheumatism has been of pretty frequent occurrence. The following statement shows the total admissions and deaths, in the Lucknow field force, in the year 1858–9, and the proportion of admissions and deaths, from the above diseases to the whole :—

Total treated	23,478	Deaths	976
„ Fevers	9,491	„	211
„ Dysentery	2,105	„	323
„ Cholera	21	„	10
„ Small-pox	109	„	27
„ Rheumatism	534	„	1

	7. The nosological character of the more frequent zymotic diseases may be briefly explained. Fever of various types, acute dysentery, diarrhœa, and cholera. These diseases are most prevalent in hot weather and rains, especially at the breaking up of the rains. At the time of their appearance the climate reaches a very high temperature, especially when combined with moisture in the air. As regards predisposing personal habits. Troops, from want of

References to Subjects and Queries.	Replies.
IV. Health of the Troops —Diseases—*cont.*	employment, are apt to go out of doors when they ought not to do so, and often give themselves up to dissipation and debauchery. 8. Over-work increases epidemic disease, and renders troops more liable to suffer from it. Strict discipline is conducive to health in barracks, on the march, and in the field. 9. Small doses of quinine have been used but little. In 6/14 Royal Artillery at Roy Bareilly it has been used with a satisfactory result. 10. In order to mitigate or prevent the ravages of epidemic disease at the station, I recommend the reduction of duties, as far as possibly can be done consistently with discipline, in the hot weather and rains; put restrictions on exposure; let the men use malt liquor freely instead of spirits; build good workshops, and provide the means of giving out-door amusements; encourage games, and attach a well-supplied reading-room to each corps.
V. Intemperance.	1. I have no reason to suppose that intemperance prevails to a marked extent in any corps or detachment in Oude. 2. Drunkenness *per se* is punished in all corps to the best of my knowledge. 3. Distilled spirits are sold in the canteen, not at the bazaar, each man having his allowance only. The quality is good. Spirits is everywhere considered a portion of the soldier's ration, if the soldier wishes it and is able to pay for it. Under ordinary circumstances it is never given in the morning; one or two drams in the day. Spirit is never given as a ration to convalescents, unless specially ordered by a medical officer; it is of good quality. At some stations ginger-beer is sold; nothing else injurious I believe. 4. As a rule, I believe the consumption of spirits is not conducive to health. 5. For the mass I believe it would be beneficial to abolish the use of spirituous liquors. In exceptional cases they are, no doubt, beneficial, and could ill be done without. 6. Malt liquor and wines are beyond doubt to be preferred to spirits. 7. Coffee and ginger-beer are used; not lemonade or soda-water. 8. I am quite satisfied it would be beneficial to suppress altogether the spirit ration, substituting beer, tea or coffee, &c. 9. It would be beneficial to prohibit the sale of spirits in the canteens, substituting beer, tea, coffee, lemonade, &c. 10. I recommend to arrange for the sale of beer, porter, tea, coffee, lemonade, &c., at a low rate, so that they may come within the soldier's means.
VI. Diet.	1. The composition of the ration is as follows:—Meat, 1 lb.; bread, 1 lb.; vegetables, 1 lb.; rice, 4 ozs.; salt, 1 oz.; sugar, 2½ ozs.; tea, $\frac{5}{7}$ oz., or double the quantity of coffee on alternate days. Rations are generally inspected by an orderly officer and quartermaster. 2. The troops receive three meals per day; first at 8 A.M., second at 1 P.M., and third at 5½ P.M., the first and last altered according to season. One lb. of vegetables enter into the constitution of the ration. The kinds of vegetables vary according to the season—potatoes, onions, cabbages, turnips, sweet potatoes, &c. &c. are used. 3. The present ration is excellent, more than enough, if no waste takes place; and yet some men pay for extra meat. Orderlies in some corps see to the safety of the rations, but men are more disposed to buy than to sell them. 4. The cooking apparatus consists of copper vessels, which are kept tinned, gridirons, frying pans, spits, kettles, &c. The kitchens are clean, light, and well ventilated, and sufficiently supplied with water. The meat is boiled, roasted, broiled, and fried. The cooking is properly done, and sufficiently varied. Tea and coffee are commonly well prepared. The men generally have refreshments before marching; coffee is the common beverage then. 5. Gardens could no doubt be advantageously established for the cultivation of vegetables; some are already in existence.
VII. Dress, Accoutrements, and Duties.	1. Cotton clothing is worn by troops here in the hot and rainy seasons; that now in use is well suited to the climate, as is also the present wicker helmet. Woollen clothing is used for cold weather.
Duties.	1. Men should be drilled at home, most certainly. 2. The usual routine of a soldier's duty consists in drills and guards; the former twice or thrice a day, according to the season. The men do not suffer in health from drill, if at proper hours. The length of time is from 1 hour to 1½. The best times for drills, parades, and marches is at sunrise and half an hour before sunset. I am not aware of any general order on the subject. The average number of nights the men have in bed during the week varies at different stations. Six, eight, or ten nights. 3. Guards are mounted close to barracks; no guard lasts longer than 24 hours. There are roll calls several times in 24 hours; I do not know how many. Night guards are prejudicial to health. Woollen clothing should be worn by the night guards, except at the hottest season. It may vary in thickness according to the time of year, but the texture should be of the kind stated.
VIII. Instruction and Recreation.	1. The means of instruction and recreation now being established consist of ball courts, skittle-grounds; schools, with good schoolmasters, library and reading-room, sufficiently lighted at night, day-room, or soldiers' clubs, soldiers' gardens, theatre, and gymnasia, all of which, except workshops, are in course of completion at Oude. When fairly established, they no doubt will keep the men occupied during the wet season and the heat of the day. In the hot months there are restrictions as to exposure to sun and rain out of barracks when off duty; at other times there are none, except as regards head-dress. The result is, I believe, favourable. 2. I suggest that workshops should be built. The means of recreation, when all arrangements are completed, will be ample. 3. I have no doubt the institution of soldiers' savings' banks would prove most advantageous. 4. There are clumps of trees at all the stations, or in the immediate neighbourhood, which give a good deal of shade, except perhaps at Gondah; but men in the hot months cannot go out in the day, even under the shelter of trees, without injury to health.
IX. Military Prisons.	1. Wherever military prisons have been completed, they are good, commodious, and well ventilated.

References to Subjects and Queries.	Replies.
X. Field Service.	1. I know of no local regulations for field medical service which are not included in the General Presidency Regulations. 2. Excepting occasionally regarding camping grounds, medical officers are not called upon for an opinion, so far as my experience goes. 3. As a rule medical officers are not consulted in the selection of ground for camps; the selection is generally made by the quartermaster or quartermaster-general, when one is present. Objections or suggestions offered, however, by them to the ground chosen are commonly attended to. In standing camps drains are always cut; all nuisances are removed; no accumulations of filth are allowed to take place. Latrines are arranged for. Tents might, perhaps, be improved by having some means of ventilation at the ridge. Water supply is generally ample, brought by bheesties from wells. 4. Field hospitals are arranged for in accordance with the rules laid down in the Medical Regulations. Ambulance carts were allowed in the late campaign for the conveyance of sick, but were not generally approved of by medical officers; all were desirous of substituting the four for the two-wheeled conveyances; dhoolies were generally preferred. Hospital supplies are carried on camels and in country carts, sometimes on elephants.
XI. Statistics of Sickness and Mortality.	No reply.
XII. Hospitals.	1 and 2. Plans have been submitted. All the hospitals are in the rear or flank of the barracks, distant from them from 150 yards to half a mile. They have been kept well clear of stables; and of the bazaar and houses belonging to the civil population. The sites of all are open and well ventilated. The dragoon hospital at Lucknow is not far from broken ground; the drainage will be good at all when completed; as yet it has not been properly arranged for. The ground on which the dragoon hospital stands is the best that was available, avoiding the windward of the stables. The river is some distance off; its banks are slightly marshy for a short time in the rains. The broken ground can be kept clean. The sites of all hospitals in the province are well elevated. 3. The supply of water at all the hospitals is abundant and wholesome. 4. All the drainage is surface drainage; there is no sewage. 5. The only wards that exist are raised three feet; there is no perflation of air beneath the floors. Water is carried away by surface drainage; part sinks into the subsoil and part evaporates. The surface drainage carries off the water, but at some parts, where the ground round the hospital is level, it does so slowly. The materials consist of burnt bricks laid in mud cement or lime cement; lime is used in the plinth. The walls are single, two feet thick; the roofs are tiled, and too thin, I think. There is a verandah on each side of all hospitals; the verandahs of the hospital 23 R. N. F. are 12 ft. wide, of all others only 10 feet. A 10-feet verandah is scarcely sufficient. No sick or convalescents are accommodated in the verandahs except in female hospitals, where they are double. All hospitals have only one flat. The dimensions of the wards in all hospitals are not the same. The wards of the 23rd R. N. Fusiliers' hospital are 24 feet in width; in all others at Lucknow, and most of those at out-stations, they are only 22 feet. The particulars of the 23rd hospital are entered in the following table:— Date of construction.—All hospitals in Oude were commenced in 1859. Total number of wards.—The number of wards varies from 2 to 10, according as the hospital is for a battery of artillery, a cavalry or an infantry corps. Total regulation number of beds.—Sixteen in each ward.

Wards or Hospital Huts. No.	Regulation Number of Sick in each Ward or Hut.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Doors in each Ward.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
										Feet.	Feet.
Two Wings, Five Wards in each	16	50	24	24	43,800	2737·5	75	1·8	8	7½	4½
Four End Rooms, One at each Corner -	1	20	14	17	4,760	4,760	250	1·8	3	7½	4½

All hospitals in Oude are placed so as to receive the benefit of the prevailing winds. Windows are up near the top of the wall, and open, as in barracks, on centre pivots, and are moved by ropes. The arrangement is very conducive to ventilation and coolness. Wooden shades are necessary to the latter.

6. The wards are ventilated by doors and windows, and a double roof, or ventilating tiles at the ridge. Ground ventilation by holes in the doors. There are no jalousies or jhilmils.
7. The air is cooled by watered kuskus tatties. Thermantidotes have not been brought into general use in Oude yet.
8. There are no means of warming necessary. The ceilings and walls are cleansed and lime-washed once a year regularly; oftener under special circumstances.
9. The privy arrangements are similar to those for barracks. In the whole of the hospitals, except the 23rd R. N. F., the privies are, I think, too close to the main building. The supply of water has not yet been very large. If sufficient water is used, they will be well drained, by which I mean largely used. They are not over cesspits. If sweepers are not allowed to neglect them, they are not offensive.
10. With respect to the lavatory arrangements, there is a small room to each ward of the hospital; in some rooms no arrangements are made; the patients wash in tubs, or earthen vessels placed there without arrangement; in others there is a shelf of masonry, on which washing vessels are placed; and in a few, one or two baths of masonry have been constructed.
11. In a few hospitals there are, as stated, one or two pucka baths; in the washhouses, earthen gurrahs, wooden tubs, and one or two hip-baths. In each hospital there are one or two iron or wooden tubs for warm baths. The means are not more than sufficient, perhaps barely so.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	12. The linen is washed by washermen at the nearest stream, and dried on ropes supported by poles; quite sufficient. 13. The storage is dry and quite sufficient. 14. The cots are of wood, tape bottoms; the tape an inch and a half and two inches in width; a quilt and one or two blankets, one large and two small pillows, a pair of sheets and pillow-cases. The supply is ample, as also the personal linen. Iron cots would be an improvement on the present wooden ones. A mattress also should have been named. 15. The kitchens or cook-rooms are much the same as those in barracks, generally about 40 yards from the hospital; cooking utensils are much the same; the cooking is good, and sufficiently varied. 16. The tables of dietary and other returns are laid down in the Medical Regulations. 17. Establishments for attending the sick in this country are native. There is one hospital serjeant. For cases requiring special care the services of comrades from the barracks are obtained; they are excused from all other duties. With their help in such cases, the attendance is sufficient. 18. The state of the hospitals in Oude is good. The hospital of the 2nd dragoon guards at Lucknow, with broken ground near it, is not so well placed as others. The position, however, I do not consider bad, and the broken ground in the neighbourhood can be improved. 19. Larger and better bathing houses would be an improvement. 20. No gardens or walks have been made in the neighbourhood of hospitals in Oude at present. Patients take exercise in the verandahs, or just outside the building; they go out also on elephants for air. 21. Female hospitals are provided, with two female servants attached. The arrangements are quite satisfactory. 22. There are no special local hospital regulations, as far as I know, at any of the stations. 23. Recommendations of medical officers are, as a rule, attended to. Hitherto, from heavy press of work, there has been not unfrequently some difficulty in carrying out repairs and alterations at once. All works in Oude are new, and the pressure has as yet been great. Medical officers have quite a sufficiency of changes of diet at their command. The supply of medical comforts has always been most liberal, both in camp and in quarters, and on the march. 24. There is no hospital for convalescents at any station in Oude. Medical officers arrange their wards in the regimental hospital as is thought best. For a few cases it might be advantageous to place them in a convalescent hospital until fit for duty. With a commodious well-regulated regimental hospital, however, such an arrangement would hardly be necessary.
XIII. Burial of the Dead.	1. Burial grounds at the various stations are from a quarter to one mile from the cantonments. They are out of the line of prevailing winds. 2. The area contains from 1½ to 2 acres or more, avoiding a rigid station; that at Roy Bareilly is 1½ acres; the Lucknow one is considerably larger. The soil and subsoil vary at different stations. The best spots have been chosen at each, and they are carefully kept. 3. The regulations as to burial are as follows:—The grave space allowed, 6 to 7½ ft. by from 2 to 3 ft.; from 2 to 3 feet between each grave. The depth of grave is from 6 to 8 ft. Never as yet have any of them been reopened. There is no compulsory time after death for the interment, but it commonly takes place within 24 hours, often in 12; during epidemics within 12 hours. The dead of native troops are disposed of according to caste. Mahomedans bury outside the cantonments, also a few Hindoos; others burn their dead, or throw them into the nearest stream. I have no information with regard to the rules followed where the dead are disposed of by burial. 4. No graveyards in Oude up to the present time have proved offensive. As regards the regulation of burials of British soldiers, a death report is sent by the surgeon to the adjutant of the corps, and also to the chaplain. A grave is at once dug, and the body is conveyed to it in a dhooly, after having been placed in a coffin, which is followed by a funeral party told off for the purpose. Funerals take place in the morning or evening. 5. The dead of camp followers and bazaar people are disposed of in the following manner:—Mussulmen are buried; Hindoos either burn their dead or throw them into the stream. 6, 7. No injury accrues to the public health from the present practice, but I believe that the best plan would be to burn all bodies at some distance from the cantonment.

A separate copy of this report for each station in Oude has been filled up by the commanding officer, the engineer, and medical officer of the station. I have filled up the whole of this myself, and therefore I alone sign it.

(Signed) J. Campbell Brown,
Deputy Inspector-General of Hospitals.

1st January 1861.

DELHI.

Accommodation:
- Queen's Troops: Artillery - 127; Infantry - 832
- Native Troops: Artillery - 26; Cavalry - 505; Infantry - 877

References to Subjects and Queries.	Replies.
I. Topography.	1. The country surrounding the station is uncultivated, the ground being very rocky and much cut up with ravines. It is in general flat and dry, a low ridge running from N.W. to S.E. about a mile or more from the station. The general aspect on this side is dry and sandy, but on the other side of the ridge there is much swampy ground; there is also some little jungle and a good deal of wood.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	2. The elevation of the station above the sea is 800 feet. It is about the same level as the surrounding country. The nearest water is the river Jumna, which flows beneath the walls, and the Western Jumna canal, running through the city. The nearest actual marsh is the Nuzufgurh jheel, 15 miles off, but during the rains there are many smaller jheels much nearer, but none, however, on this side of the ridge. There is no higher or healthier ground adjoining the station. 3. The nearest mountains to the station are the Himalayas, the foot of which is 100 miles off; the nearest hills are the Dadpoottras, which die out at Delhi itself; and the nearest table-land is that of Central India, distant 100 miles. 4. The vicinity of the station is not liable to overflow of water, but there is a portion of ground under the palace walls, a mile or so wide, which is generally overflowed by the Jumna for a few days in each rainy season. The ruins of old Delhi are about a mile from the city. The ground all about there is being much broken, but without prejudice to the health of the inhabitants. 5. The station is not well ventilated, and, being inside the walls of the city, the temperature is raised by exposure to reflected sun heat. The usual hot winds blow every year, but they do not affect the health prejudicially. 6. The country surrounding the station is uncultivated for a space of two miles, and the surrounding country beyond that distance is irrigated by the Western Jumna canal, which runs through the city, and also by the Eastern Jumna canal. I have not observed that artificial irrigation has any effect on the health of the station. The cultivation of rice is prohibited within a distance of three miles, and there are no indigo works near. 7, 8. Part of the present station was the former cantonment for the troops after the first taking of Delhi in 1803. A large portion of the city has since been levelled to form an extended cantonment. 9. With regard to the depth below the surface at which water is usually found, it depends upon the height of the ground above the level of the water in the river; but the average depth is, say, 30 feet. 10. The rain-fall and water from surface springs in this district flow readily off, either sinking into the sandy soil, or else running off along the surface; there is also the drainage of the ridge, which, however, does not affect the subsoil of the station. 11. The greater part of the water supply is derived from the river, and the rest from wells; and, with but few exceptions, the well water is brackish. There is no store of water, there being only one large tank at Delhi, the Ellenborough tank, which is dry about 11½ months out of 12, and contains neither plants nor animals. Some of the wells are shaded with trees, but they are in such constant use, that any impurity is detected, and measures taken to remove the cause. There is no nuisance or malaria proceeding from any tank affecting the present station. 12. The water supply is not good, the well water having a slight quantity of soda in solution, and being mostly brackish. The purer wells have carbonate of soda in small quantities. I cannot say that the water is very injurious to health. The wells are worked in the usual manner, by "motes" and "dolchees." A reservoir for the water, to be drawn from the main stream of the Jumna, at its second rise in August, would afford purer water. 13. The retreat of the Jumna in September leaves considerable pools of water to the south-east of the city, and when the wind blows in that direction before these are dry, it causes a heavy vapour, which however, in the absence of vegetable deposit, is not unwholesome, and only of rare occurrence. 14. No reply to this query.
II. CLIMATE.	1. The means and instruments available at the station for conducting and registering meteorological observations are a rain gauge and a common thermometer. 2. No meteorological table can be prepared, as all records were lost during the rebellion.

MEAN TEMPERATURE within the City Walls, from observations extending over a period of Three Years.

Months.	Mean Temperature.	Remarks as to Cloud, Dew, Wind, Storms, &c.
January	56	The rains commence usually at the end of June, and last, with many intermissions, until the end of September, and sometimes later. The quantity varies much, and in some seasons is as low as 10 inches. From November to April (the cold season), the prevailing wind is from the west, but in the rains from the south-east. Hot winds and dust storms prevail during the months of April, May, and June, the hot wind sometimes blowing day and night, and generally from the west.
February	61	
March	72	
April	83	
May	91	
June	92	
July	86	
August	83	
September	83	
October	77	
November	65	
December	58	

3. The climate is unusually dry, the prevailing wind being from the west, and blowing over a sandy and rocky soil; the presence of the river tends but little to modify this throughout the year; but the trees in the city tend to the purification of the air, by the absorption of carbonic acid. The canal irrigation does not act prejudicially upon the salubrity of the city. The sand wafted by the air, during the months of April, May, and June, is injurious chiefly to the eyes. Taking into account the facility for dissipation which a large city offers to British troops occupying it, the city of Delhi seems to possess a climate favourable to the constitution of Europeans, and unusually favourable to that of native troops. The most unhealthy part of the year is September and October for the natives, and, to a certain extent, for Europeans, the prevailing disease being a low fever.
4. There is no district in the neighbourhood of Delhi healthier than the city site.
5. No reply to this query.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station.	1, 2, 3, 4. None of the questions regarding this station can be answered, as nothing has been decided on or sanctioned; and many of the questions are such as could only be answered after barracks, &c., had been built, and had stood the test of several years; whereas, at present, there are no barracks at Delhi. 5 to 8. The temporary barrack rooms are kept cool by "punkahs," or large fans, suspended from the ceiling, and pulled by coolies, two of whom will keep a punkah in motion the whole night. Each coolie gets 4 rupees, or 8*s.*, a month. In April and May kuskus tatties, which are frameworks of bamboo, with the kuskus (a fibrous root) spread equally over them, are also used; these are fixed in the doorways, and kept constantly wet by coolies, who receive the same pay as those for pulling the punkahs; and the hot westerly wind blowing through them, effectually cools the room. The cost of a punkah is about 10 rupees, and a tattie 4 rupees. 9 to 12. No replies to these queries. 13. With regard to the convenience for washing and drying linen, each person keeps his own washerman; and a certain number are attached to each regiment. 14 to 16. There are no foul ditches near the station. 17. The surface cleansing of the cantonment is done by the conservancy establishment daily, the refuse and manure being carried down to the river. 18. The surface of the cantonment is kept entirely free from vegetation, and clearances, as recommended, are being carried on. 19. A sudder bazaar is being established. As the station adjoins the native city of Delhi, no dung-heaps or cesspits are permitted; nor is any nuisance experienced from wind blowing over native dwellings. 20. Animals are slaughtered outside the city, some miles from the men's quarters, and no nuisance is experienced from the offal. 21. Officers' horses are kept in stables in their own compounds, and the manure conveyed to a distance. 22. There are no stables or barracks. The artillery horses are picketed three-quarters of a mile from the temporary hospital, the men being located in a mosque on a higher elevation than the horses' picketing ground. 23. There being no barracks, married men reside in separate quarters.
Officers' Quarters.	1. There are no regular officers' quarters.
IV. Health of the Troops.	1, 2. The station is generally healthy, and so also is the native population; the most prevalent diseases among the natives are fever, spleen, ulcers, and smallpox. 3. The health of the neighbouring native population may, I think, at the present time, be attributed to the small quantity of rain which has fallen in this district for the last two years. When the country is much inundated by heavy rain, the people are said to suffer much upon its drying up. The people in the surrounding districts are said in some places to be dying of starvation, in consequence of the scarcity and dearness of food, caused by the want of rain. Ulcers, which are very prevalent in this district, are supposed to be caused by the water, which contains many different salts. Some of the water has been sent to the chemical examiner to Government for analysis. 4. Her Majesty's 88th Regiment were marching about the country at Cawnpore, Calpee, and Oude before arriving at Delhi, which station they reached in March 1859; the diseases they chiefly suffered from before arriving at Delhi were fever and dysentery, and since, from fever, venereal diseases, and ulcers peculiar to Delhi. The Artillery is composed of men who have come from different stations; some few have been at Delhi during and since the siege. 50 were volunteers from the 88th Regiment, and about 50 were men who arrived from Meerut, in December 1858; they have suffered since arrival at Delhi, from fever, hepatitis, venereal disease, and ulcers. No portion of the men's accommodation at this station is more unhealthy than the rest. 5. The troops at this station are never camped out. 6, 7, 8. I have never been in charge of troops at a hill station, but judging from the benefit I have myself received from a residence in the hills on sick leave, and also from men and officers whom I have often seen, who have also been restored to health by visiting the hills, I approve of the selection of such stations for troops. 9, 10. Troops proceeding to hill stations are sometimes liable to attacks of diarrhœa, and I do not know of any precautions which could be taken to enable them to obtain greater benefit from a residence there. 11. The months of March, April, May, September, October, and November, are the best adapted for residence at hill stations. I do not know what is the shortest period of residence which would enable troops to obtain the full benefit of such residence, it would depend upon the nature of the disease that each individual might happen to suffer from. 12. I do not know that the health of the troops is liable to injury on returning to service in the plains, but to the generality of people a residence in the hills for a long period is beneficial. 13. No special precautions are required to protect the health of the troops on leaving hill stations for the plains. 14. As a general rule, it is certainly preferable, and most conducive to the health of troops serving in India, to locate them on hill stations, with short periods of service in the plains; and frequent change of station in the plains is also beneficial to the health and spirits of troops and convalescents. 15. There is not sufficient accommodation for convalescents at any of the hill stations, owing to the large increase of European troops in Bengal within the last three years. 16. No experience. 17. There is no higher ground near, which could be advantageously occupied as a hill station. 18. I have not found any particular class of surface and subsoil more healthy or unhealthy for stations than others. 19. The best age for soldiers proceeding to India is about 20 years, and the best period for landing there is the month of November. Troops for Bengal and the north-west land at Calcutta, and go into barracks either in Fort William or Barrackpore, and are rapidly sent up country by bullock train to join their regiments. Troops for the Punjab and at Kurrachee, where there is a depôt and excellent barracks for recruits, who, for the preservation

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops —*cont.*	of their health, should, on first landing, avoid exposure to the sun, and excess in eating and drinking, and also too long and frequent parades; and should also wear hats and clothing suited to the climate and season of the year. 20. Troops should be sent direct from the home depôts to India, and on landing should join their regiments at once, wherever the regiment may be. Regiments on first arrival would be much benefited by going to the hills for a year. 21. Troops proceed from Calcutta by rail and bullock train to Cawnpore. From Kurrachee they proceed by river steamer to Mooltan. No additional precautions are necessary for preserving their health on the route. 22. British soldiers should serve in India 10 years, after which they should have the option of returning home. 23. I believe the business of medical boards is generally conducted so as to avoid conflict of opinion as regards invaliding, but I think there should not be more than two medical officers at most from the same regiment on the same committee. 24. The month of January is the best time of the year for invalids to leave India for home.
Diseases.	1. Inspection parades for the discovery of incipient diseases are held weekly in the 88th regiment, but not in the artillery. 2. Scorbutic disease does not occur at this station. 3. The proportion of cases of hepatic disease usually under treatment, is 3 cases per month out of 850 men of H.M.'s 88th Regiment, and $1\frac{1}{6}$ cases per month of the Bengal Artillery of 130 strength; in the year 1859–60 there were 5 fatal cases in the artillery; this disease is caused chiefly by climate, by excess in eating and drinking, and by exposure to the sun and night air. The prophylatic measures are avoidance of excess and exposure, and exercise for the body and mind. 4. No cases of dracunculus have occurred among the European troops, and very few among the natives. 5. The proportion of constantly sick from venereal disease to the total sick in hospital is about one third; the establishment of lock hospitals would be advantageous, and the women of the bazaar might be registered and inspected. 6. The troops at this station suffer from diseases of the endemic class, such as intermittent, remittent, and continued fevers, acute and chronic dysentery, and occasionally hæmorrhagic; cholera has not appeared lately, but in 1857 this disease prevailed during the siege outside and within the city walls. There have been a few cases of small-pox amongst the Europeans and native troops during the present hot season, and rheumatism also occurs. The proportion which admissions and deaths from these diseases bear to the total admissions and deaths is as follows:—in fever cases, admissions one-third, and deaths one-seventh; dysentery, admissions $\frac{1}{38}$th, deaths one-third; cholera, admissions 2 only during the year, deaths, one; small-pox, admissions 3 in the year, deaths 1; rheumatism, admissions $\frac{1}{20}$th, and no deaths. 7. The cases of fever have a tendency to be accompanied by head and low typhoid symptoms, and the dysentery by hæmorrhagic, and hepatic disease to terminate in abscess. Ulcers are of a peculiar character and very difficult to cure, disfiguring the face dreadfully and giving the nose occasionally a cauliflower appearence. Such diseases are most prevalent during the months of May, June, July, September, October, and November; and the climatic and atmospheric conditions which precede or accompany their appearance are, great heat in the three former months, and considerable alteration of temperature, and malaria in September and October. The buildings in the city are very much crowded in some places, and the streets are generally narrow and badly ventilated. The conditions which appear to predispose to these diseases are, exposure and night duty amongst the troops, and poverty among the natives, such as bad houses or huts, and insufficient food and clothing. 8. Troops stationed either in barracks or standing camp are much more liable to epidemic diseases than when marching or actively employed in the field, this is not caused so much by the habits of the soldier as by the monotony of his life, and the impure air consequent upon a large number of men being crowded together. Officers are not much affected by epidemics. 9. Small doses of quinine have not been tried at this station as a prophylactic against malarial disease, except in one case, that of a serjeant of artillery who was subject to fever, and in his case the exhibition of quinine was attended with decided benefit. 10. For the prevention or mitigation of epidemic disease at this station strict attention should be paid to the sanitary condition of the station and barracks, and to the isolation of affected patients.
V. INTEMPERANCE.	1. The soldiers at this station are inclined to be temperate, about four men per company in the 88th Regiment being confirmed drunkards, and in the Artillery several men drink to excess. 2. The proportion of admissions into hospital from diseases caused directly and indirectly from intemperance is unknown, and I have no data to go by to prepare a table showing the effects of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station. Drunkenness *per se* is punished as an offence. 3. Distilled spirits are sold at the canteens, but every precaution is taken to prevent their being sold in the bazaars. The spirit used is rum, mixed with about one-fourth of water, and about three-fourths of the soldiers take one dram, and one-fourth two drams per day. Spirit forms no part of the ration, either of soldiers or convalescents, nor is rum issued from the canteen before 12 o'clock at noon. No drinks injurious to health, other than intoxicating drinks, are sold at the canteen or bazaar. 4. The consumption of spirits by troops and convalescents is injurious to health, but as men *will* drink the issue of a small quantity is conducive to contentment, and content leads to good conduct, and good conduct to good discipline. 5. Spirituous liquors are not issued as a ration, but I think it would not be advisable to abolish the sale of it at the canteen. 6. A moderate quantity of malt liquor or good wine is wholesome and good for the health. Spirituous liquors are injurious. 7, 8. Coffee, tea, lemonade, &c. are much used at the station, and their influence on health, efficiency, &c., as compared with spirits and malt liquors, is good, but it would not be beneficial to suppress the spirit ration altogether.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	9. I do not think it would be beneficial to prohibit the sale of spirituous liquors in the canteens, as, if they could not be procured there, the country liquor would be more sought after. 10. I have no recommendations to make on these points. 11. No reply to this query.
VI. Diet.	1. The composition of the ration for Queen's British troops, and European troops in the Indian army, is as follows:—1 lb. of bread, 1 lb. of meat, 4 oz. of rice, $2\frac{1}{2}$ oz. of sugar, $\frac{5}{7}$ oz. of tea, 1 oz. of salt, 1 lb. of vegetables, and 3 lbs. of firewood; beef being issued five times a week and mutton twice. Potatoes are issued whenever they can be procured, but during the months of June and July onions and pumpkins are given to the troops, as potatoes cannot be got. There is a responsible inspection of the constituents of the ration made by the quartermasters and orderly officers of the regiment daily, and by the commanding officers frequently. 2. A complete ration is provided for the troops without any deduction from their pay. A soldier generally has his breakfast of bread and tea at 8 o'clock a.m., dinner of bread and meat at 1 o'clock p.m., and his evening meal of bread and tea at 6 o'clock p.m. This is from the Government ration, but, in addition, soldiers generally have a little meat or a couple of eggs for breakfast purchased by themselves. The proportion of vegetables in the constitution of the ration is one-third. 3. If it were possible to issue potatoes throughout the year it would be an improvement. The men cannot dispose of their rations. 4. There is a cook-house for each company of a regiment, and each company is provided with cooking pots by Government, and the food cooked by natives. The kitchens at Delhi are only temporary. The food is sometimes boiled and sometimes roasted, and the cooking is properly done, and tea and coffee are properly prepared. The men have no refreshment before a march; it is customary to have coffee in the middle of a march. The cooks are sent on over night, and select a convenient spot about half way. On a regiment arriving at the coffee place, the arms are piled, the men fall out, and the regiment generally halts for half an hour. 5. Soldiers' gardens could not be advantageously established at present, but arrangements will be made for them in the new barracks when built.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress and accoutrements at this station are, in summer, khakee clothing, a helmet of wicker-work, a pouch belt, and bayonet belt; in winter, a red tunic and cloth trousers. I would much prefer white clothing to the present khakee, except for service, and I would suggest, as improvements in the dress, a suit of flannel for the rainy season, and a waterproof cape, to be worn when exposed to the rain. The present guard dress is the uniform of the season, cloth in winter, and great coats when cold enough at night; in summer or the hot months, light clothing. Europeans are never exposed to the sun on guard in the day-time.
Duties.	1. The men being thoroughly drilled at home would not obviate the necessity of keeping up the drill in this country, and occupation of any kind is beneficial to their health. 2. The men do not suffer from drill. They parade for exercise every morning in the cold weather, and are out about an hour and a half. Their duties consist of the ordinary regimental guards. The first hours of daylight in the morning, and the last in the evening, are the best for drill. There are no general orders respecting these; it depends on the season of the year. The average number of nights the men have in bed during the week is five. 3. There are no regular barracks, but guards are mounted as near their temporary quarters as possible. There are roll-calls by day and night. The men do not suffer in health from night guards, nor are any additional precautions requisite.
VIII. Instruction and Recreation.	1. The means of instruction and recreation at this station are skittle grounds, schools, and a library and reading room, which are sufficient to keep the men occupied during the wet season and heat of the day. In the hot season, soldiers off duty are confined to barracks during the heat of the day, which is of great advantage to their health. 2. At present, I can suggest no improvements with reference to the means of recreation and employment for the men. 3. Soldiers' savings banks are in existence, and are of great advantage to the men. 4. There is not sufficient shade from trees or other means to enable the men to take exercise during the day without injury to health.
IX. Military Prisons.	1. These buildings are all temporary.
X. Field Service. XI. Statistics of Sickness and Mortality.	No information under these heads.
XII. Hospitals.	1, 2. There are no regular hospitals built. 3. The water supply is abundant, but the Delhi water is impregnated with saline salts. 4. The drainage is good, and is discharged into the river outside the ramparts. 5, 6. There is no regular hospital. The roof water is chiefly carried off by the drains. The temporary hospital is built of bricks, stones, and mortar. The roofs and walls are high, and no ventilation between them; but they are sufficiently thick to keep the hospital as cool as other houses at Delhi. It is supplied with temporary verandahs on both sides, which have not been used for the accommodation of the sick or convalescents, but would be if necessary. The hospital consists of one flat only, and is too much surrounded by other buildings and walls to receive the full benefit of prevailing winds. The doors serve as windows as well as doors. There are also ventilators made in the walls at the side and joining the roof. In some of the buildings occupied as hospitals there are skylights. The wards are ventilated by the doors and openings in the walls and roof, and the construction of the jalousies or jhilmils is as usual. 7, 8. The air admitted into the wards is cooled by means of tatties or punkahs, and the wards are warmed by means of fireplaces with wood fires. The walls and ceilings of the wards are cleansed and limewashed every six months. 9. The privies are within a few yards of the hospitals, and built of masonry. They are kept clean by sweepers employed for the purpose, and also by charcoal and lime being supplied abundantly twice a day.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	10. There are washhouses for lavatory purposes attached to the hospitals. 11. The means of bathing provided for the sick are iron and wooden baths. 12. Dhobies paid by Government wash and dry the linen excellently. 13. The storage is dry and sufficient. 14. The cots in use in the hospital are made of wood and webbing, but I think iron would be better, on account of the bugs which harbour in the wood. 15. The cooking apparatus is of the most simple kind, consisting of copper stew pans tinned, a spit, and a frying pan. The diets are pretty well cooked, and the cooks make simple puddings with tolerable skill. 17. There is a hospital serjeant to each hospital, but no nurses. Orderlies are allowed in any dangerous case that may require great care, and ward coolies are allowed in proportion to the number of sick. These men are generally attentive, and in ordinary cases quite sufficient, but I think two or three good matrons attached to each European hospital would be desirable. 18. The sanitary condition of the temporary hospital is good. No epidemic, gangrene, or pyæmia have appeared. 19. No reply to this query. 20. Some of the convalescents go out morning and evening on elephants provided by the commissariat. Occasionally, men who are very weak are sent out in doolies, but as only two doolies are allowed to a regiment, but few can avail themselves of this mode of conveyance. There are no shaded walks and seats set apart for their use. 21. The 88th Regiment have lately had a building put in order as a hospital for the sick wives and children of the soldiers of the regiment; but the Artillery have none, and are attended at their own barracks. The present arrangements are all temporary, as other barracks and hospitals are proposed to be built inside the palace. 22. There are no local hospital regulations enforced at this station. 23. The sanitary state of the temporary hospital is under the care of the medical officer, who may change the diet and give any medical comforts, such as wine, beer, &c., as he may consider necessary; but the expenditure of wine should not, according to the regulations, exceed one measure and one-fifth per patient daily without explanation. Repairs are done by the barrack master, on the requisition of the medical officer. 24. There are no convalescent wards nor hospital for convalescents at this station, but such accommodation would be very advantageous.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is just outside the walls of the city, and about half a mile from the fort. It is on the north, and therefore well away from the prevailing wind. Its area is about six acres. The soil sandy, with a rocky subsoil. It is well kept and well drained, as it stands on a ridge or rocky knoll of ground. 3. There are no particular regulations about graveyards here. The graves are never reopened, and seldom more than one body interred in the same grave. In the hot weather and during epidemics, interment is compulsory within 24 hours after death. There are no regular burial grounds for natives. 4. No complaints have ever been made as to any nuisance emanating from the burial ground, and as it is a new one, and there have been so few interments, it is not likely to become offensive. 5. The dead of the camp followers or bazaar people are burnt, buried, or thrown into the Jumna, according to their creed or race, or according to the disease which causes death. 6, 7. No injury to the public health accrues from the present practice, nor can I suggest any improvements in the way of regulation or otherwise in the burial or disposal of the dead.

(Signed) W. G. Brown, Brigadier Commanding.
C. J. Campbell, Captain, Executive Engineer.
R. H. Oakley, Surgeon, Artillery.

Delhi, 15th June 1860.

References to Subjects and Queries.	Replies.
I. Topography.	1. Benares is situated on the left bank of the Ganges, in lat. 25° 17′, long. 83° 4′. The river here forms a fine sweep, and the city stands on the external side of the curve, which is the more elevated shore, the river being about 30 feet below the level of the houses. The military cantonments are at Secrole, three miles west of the city. The country surrounding the station is flat or gently undulating, and well cultivated, the elevations being few and trifling, and formed of "kunkur," which in localities appears on the surface. The small Burna river forms the westward boundary of the station, and divides the latter from the civil lines, which are situate north-west of cantonments. There are several tanks, jheels, and low-lying fields in the neighbourhood where water lodges after heavy rains. No jungle exists in the vicinity, but the country is very agreeably diversified with mango, tamarand, neem, and other large trees, affording shade to the villages, and forming avenues along the principal roads. 2. The elevation of the station above the sea is estimated at 270 feet, but it is on a level with the adjacent country, which probably nowhere has a greater elevation above the sea than 300 feet. There is no higher or healthier ground near the station. 3. The Hill Fort of Rhotasgurh is on the nearest higher ground. It is on the left bank of the "Soane" 104 miles south-east from Benares and 24 miles from the station of Deheree on

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	the Grand Trunk Road. The hill is about 1,000 feet above the plain, and the table land on the summit is five miles long and four miles broad; but the surface is either too dry and rocky, or marshy where the water is collected in hollows. The heat at night is reported to be greater at the top of the hill than on the plain below, and the locality is considered insalubrious, and unfit for a cantonment. 4. The small stream of the Burna, where it approaches nearest, is less than a mile from cantonments. It is about 30 yards broad, winds between the civil and military stations, and debouches into the Ganges a short distance below Benares. Its deep channel gives the great advantage of a perfect means of drainage, but with the inseparable inconvenience of ravines. It has been the practice to throw an embankment across its bed annually after the cessation of the rains, so as to retain a depth of about 15 feet of water at the Burna bridge, the surplus water being allowed to escape by a side cut. This measure directly mitigates the heat and malaria which would otherwise be occasioned by the dry surface and damp and decomposing subsoil of the bed of the stream. The large body of water thus retained, and its constant fluctuation under the action of the alternately prevailing winds, prevent any general putrefaction of the water. The level of the embanked stream is about 20 feet above the low-water level of the Ganges. Notwithstanding the general purity of this large reservoir of water, its banks in the vicinity of villages and of this station become from the habits of the natives liable to offensive contamination. The level of the cantonments being high, they are not subject to inundations, and heavy rain readily escapes along the natural lines of drainage. On the east side of the parade ground is a deep irregular excavation, from which bricks were dug for the brick-works closed two years since. During the rains it is filled with water, which dries up after several months, and while this process is going on malaria is probably generated. The excavation might be partially filled up, deepened, and converted into a tank. On the west side of the cantonments the ground has been cut up by the periodical rains into a tortuous ravine, which passes close to the hospitals and forms the main line of drainage into the Burna river. During the greater part of the year the bed of this ravine or nullah is dry and generally kept free from filth and weeds, and in the rains the water only lodges in a few irregular hollows, of which the edges might be levelled, or cuts made where necessary, to prevent the water from stagnating. 5. The station is open, but its external ventilation s somewhat impeded by the proximity of the large city of Benares and its suburbs, and by a row of huts forming a bazaar east of the mint. The internal ventilation is much obstructed by the large Sudder bazaar in the centre of the station, close to and directly to windward of the European barracks. The direction of the principal streets in this bazaar is north and south, so that the westerly wind, which is the prevailing one, is impeded. This overgrown bazaar was recommended to be entirely removed to another site by a committee on 2nd May 1860, of which the major-general of the division was president; but Government has declined to sanction the expense which would be incurred by the proposed sanitary measure. The buildings being on a level with the ground, the surface of which is of a light colour and generally dry except during the rains, a considerable degree of reflected heat is unavoidable. The station is not exposed to cold or variable winds. The prevailing winds are east and west, the latter being the more prevalent throughout the year; sudden vicissitudes are rare, and have not been observed to have any appreciable effect in the health of the station. 6. The entire surrounding country is well cultivated, there are no works of irrigation near the station, and the fields are irrigated, in the usual native mode, from wells. This is not observed to have any effect on the health of the station. Rice is not cultivated in the vicinity of the station, and very little in the district. No rules exist forbidding its cultivation beyond the limits of the station, but it is presumed that all objectionable cultivation would be prohibited by Government on due representation by a sanitary committee through the commanding officer. A good deal of hemp is cultivated in the surrounding country, but not within four miles of cantonments. No injury to health accrues. 7. The city of Benares and its suburbs (together containing a population of 186,000) lie between the Ganges and the military cantonments. The length of the city along the left bank of the river is three miles, and its average depth one mile. The suburbs contain extensive gardens, with high walls, and bazaars line the road leading from the city to the cantonments. 8. The soil may be said to consist of an upper surface of light coloured argillaceous earth, interspersed with and resting on kunkur (or calcareous conglomerate), which forms deep beds, and appears also on the surface in localities, forming the small elevations which occur throughout the district. Benares has been a military station for many years past, the present European barracks having been built on the site of the lines of the three Native regiments which occupied the station previous to the mutiny in 1857. 9. Water is usually found at an average depth of 45 feet below the surface during the dry, and 25 feet in the rainy season. 10. The heaviest falls of rain flow readily away by the natural lines of drainage except at a few places at the south side of the parade ground, where the rain lodges, and forms shallow pools of water, which dry up by evaporation. There are also three or four hollows, or old excavations, in the officers' compounds, which get filled with water during the rains and slowly dry up. These have been repeatedly reported on by sanitary committees, but there appears to be difficulty in compelling the proprietors of the compounds to go to the expense of filling up the excavations or hollows in question. There is no higher ground the drainage from which must necessarily pass into the subsoil of the station. 11. The water supply of the station is derived from numerous wells. There are tanks in the vicinity, but no water for drinking purposes is stored in them. They are full during the rainy season, but nearly dry in the cold weather. These tanks contain one or two species of algæ, with suspended infusoria, minute fragments of vegetable matter, and some small species of fish. Tank water is not used by Europeans either for drinking or bathing, but the natives use it for the latter purpose. The mouth of each well is surrounded by puckah masonry, which prevents leaves and other impurities falling into it. There are three tanks in the vicinity of the barracks, which receive the surface drainage, and although two of them are enclosed to prevent contamination as much as possible, yet they must all be regarded as nuisances, and give out malaria when undergoing the process of evaporation. The third and most objectionable tank is in the centre of the bazaar, and emits very offensive effluvia when its stagnant contents are nearly dried up. These tanks ought to be filled up, but

BENARES.

I. Topography—*cont.*	more especially the one in the bazaar. The expense which would be incurred is the only difficulty in effecting so desirable a measure. 12. The supply of water for all purposes is abundant. Wells at convenient distances and also in every officer's compound. The water is clear and fine, without taste or smell. It is soft and pure, and contains a very slight trace of lime, chlorides in large proportion, and a slight quantity of potash, combined with carbonic acid. Means for correct analysis are not at hand, but the quality of the water appears to be good, and has not any injurious effect on health. The supply is ample. The water is drawn from the wells by native water-carriers, with leathern buckets; no better supply is required. 13. The above queries being very complete, nothing else requires to be remarked. 14. By Government General Orders, dated Fort William, 16th November 1858, it was directed "that in order to ensure a sufficient knowledge of the locality, the commissioner of the division, or deputy commissioner of the district, shall in future be placed on all committees assembled for the purpose of selecting new sites for cantonments, forts, &c. Such committees to be composed of two military officers, two medical officers, one civil officer or military officer in civil employ, and the executive engineer will attend the committee and render assistance. Any member of the committee who may dissent from the selection of a site or sites agreed to by the majority will record his opinion to that effect, and the reasons for it." If the above orders be carefully attended to, and the two medical officers selected for the duty be men of experience, no improvements can be suggested.
II. CLIMATE.	1. Thermometers are supplied by Government to every hospital. Under charge of the civil surgeon of Benares was also a barometer and a rain gauge. The barometer having got deranged, was sent to Calcutta to be adjusted, and has not been returned. Several medical officers are also supplied with aneroid barometers. 2. Table of two years Meteorological Observations from January 1858 to December 1859.

December	29·884	67·1	9·7	68·2	58·5	63·11	58·12	92·3	·12	25	6			

The above table has been compiled from the copies of the meteorological registers kept by the civil surgeon at Benares.

3. The climate of Benares, like its geographical position, is intermediate between that of Bengal and the North-western Provinces. The cold is less intense, and the heat less scorching than that of the North-west Provinces, and it is much drier than Bengal. It is not subject to sudden change of temperature, but there are considerable diurnal alternations, especially at the commencement of the cold season. There is but little tree planting; no canal irrigation, or irrigation of any kind to influence the climate generally. The atmosphere is generally loaded with dust during the hot westerly winds, but the climate may be said on the whole to be salubrious. The diet during the hot season ought to consist of a smaller proportion of animal food than in the cold weather. The clothing used by the troops is always suitable to the season—woollen during the cold weather and drill or other light materials during the hot season. The most healthy months are from November to March, and the most unhealthy from August to October, when the diseases most prevalent are malarious fevers, dysentery, and hepatitis.

4. There is no district near Benares the climate of which is more conducive to health than that of this station.

5. The following is a list of the stations at which I have served:—Agra, Kurnaul (Sukkur, Hydrabad, and Kurrachee, in Scinde), Moulmein, Thyetmew in Upper Pegu, Ghazeepore, and Canton. The following is the order of their comparative salubrity:—Kurnaul, Kurrachee, Moulmein, Agra, Thyetmew, Ghazeepore, Canton, Hydrabad, and Sukkur. Kurnaul 24 years ago was a very healthy station, previous to the extension of canal irrigation for the cultivation of rice. Kurrachee enjoys a constant sea breeze, and with the exception of a fearful outbreak of cholera in 1846 is comparatively healthy; so is Moulmein, Agra, and Thyetmew. Ghazeepore has of late years been very unhealthy. Canton is comparatively cool, and were the troops properly sheltered from malaria, might prove much healthier than it did when the writer served there in 1858–59. The stations of Hydrabad and Sukkur in Upper Scinde are excessively hot and debilitating to Europeans, the long-continued heat being unmitigated by any rainy season.

III. SANITARY CONDITION OF STATION.

1, 2, 3. Map of the station, district, and surrounding country, and plan of the barracks are transmitted. The drains are all open ditches, except in the vicinity of the cook-houses, privies, and wash-houses, where they are constructed of brick laid in mortar, and plastered with lime plaster.

* This is a building belonging to the Rajah of Benares, and it is only temporarily occupied, and is not suitable for a barrack being divided into several small rooms, which afford sufficient accommodation for 200 men.

5. There are no windows, but double doors, which are on opposite sides. There are also verandahs all round the barracks, 10 feet wide, but these ought not to be occupied as sleeping quarters. There are jalousies and jhilmils in some of the barracks, but not in all.
6. The bedsteads used in barracks are generally formed of wooden frames and iron hoop bands; others having cord lacing. Iron cots with cross-bands of iron are by far the best. Each soldier's bedding consists of two cotton sheets, one cotton quilt of double chintz, and one double country blanket. I would suggest that good English blankets be supplied to the troops, as is done in the colonies.
7. The European private's tent is formed of three layers of cotton cloth, and is of the following dimensions:—18 feet broad, 22 feet long, average height 8 feet, the walls being 5½ feet, centre of tent 10 feet in height, and the cubic contents 3,168 feet. Each tent is intended to contain 16 men, affording nearly 200 cubic feet of space, and a superficial area of 25 feet per man. There are four doors to each tent.
8. The barracks and guard-rooms have roof ventilation, and an ample number of doors, which admit as much air as is required. The means in use here are sufficient to keep the air pure by night as well as by day. During the hot season punkahs and tatties are supplied. A punkah is a large fan hung from the roof, and kept swinging to agitate the air. During the hot westerly winds the barracks are provided with kus-kus tatties, which are light bamboo frames, to which are fastened the roots of a fragrant grass. They are placed in the doors and windows, and are kept constantly wetted by bheesties and coolies. The sudden evaporation of the water cools the hot air, which passes into the room moist and cool. Each tattie costs about four rupees. The pay of a bheestie is five rupees per mensem, and that of a coolie four rupees. One bheestie is allowed to every three tatties, and one coolie to every two. About 20 tatties are required for one barrack of 100 men.
9. The barracks are constructed of sun-dried bricks and mortar. The tents are made of three layers of cotton cloth. There are no huts at this station.
10. The floors are constructed of Chunam stone, laid in mortar. As a rule they are not raised, but in some barracks they are two feet above the ground. There is no perflation of air, however, beneath them.
11. The materials of which the barracks, tents, &c. are constructed are quite suitable to the climate, only thatched roofs to the barracks would be better and cooler than tiled ones. The barracks and cantonments are kept in repair by the executive engineer. The walls and ceilings of the barracks are cleansed and lime-washed annually, or when reported to be necessary by the medical officer.
12. A wash-house is built for every company, supplied with water from a neighbouring well, and drained by a branch drain. There is one plunge bath, which is used both by the infantry and artillery; another is required.
13. The food is cooked by native servants in brazen pots provided for the purpose, and which are kept properly tinned by the commissariat. Water is supplied by regimental bheesties or native water-carriers, and the refuse water is carried off by a branch drain. All linen is washed by native washermen.
14. The privies are not drained, but the contents are received into a cesspool, and removed in a filth-cart morning and evening.
15. The buildings are mostly ventilated at the roof, and are lighted by the doors during the day and by lanterns at night.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	16. There is no sewerage at all. The barracks are built irregularly and at various distances from each other. No building used as a barrack or hospital at this station can be said to be damp. The drainage is tolerably efficient. It is received into cesspools, and carried off by the conservancy establishment. These cesspools are 2½ feet in diameter, and 2 feet deep; they are close to the privies and wash-houses, 30 yards from the nearest well, but only a few yards from the barracks and hospitals. They are cleaned by sweepers twice a day or oftener if required. The filth is removed in a conservancy cart morning and evening. I am not aware that there are any foul ditches near the station. 17. Two conservancy carts, with an establishment of two domes and two sweepers, go round the station every morning, and collect all rubbish and filth from the roads, ditches, and compounds. This refuse is carted out of the station and thrown into some excavations made near the old government brick-kilns. The surface cleansing of the cantonments is efficiently performed. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c., interfering with the free ventilation of the station or bazaar, &c. 19. There is a conservancy establishment, consisting of sweepers and filth carts, for the purpose of removing all rubbish and filth from the bazaar, which is kept tolerably clean, though many of the huts in rear of the principal streets are much crowded. The bazaar is well drained, and there is one large latrine in the centre under the supervision of the police, for the accommodation of the women, children, and sick. The men go to another public necessary built near the baths. It is the bazaar-serjeant's duty to go round the bazaar every morning to see that the drains are kept clean and all refuse taken away in the filth carts. There seems nothing to be desired to improve the sanitary police. The native dwellings near the station are kept clean and in good order, cesspits and dungheaps being prohibited. No nuisance is complained of in barracks from wind blowing over the native dwellings. 20. The slaughter-houses are within the limits of the cantonment, at the north-east corner, and well out of the range of the prevailing winds. The conservancy carts visit these places morning and evening to carry away the offal, &c., and the butchers are enjoined, under penalties, to use lime and charcoal to keep the place free from all effluvia. No nuisance is experienced in the station from these slaughter-houses, so long as vigilance is exercised in keeping them free from all filthy accumulation; though the immediate vicinity is unpleasant, and a substantial building with paved flooring and modern improvements is doubtless wanted. The lieutenant-governor of the North-west Province has just sanctioned an advance from the Government Treasury for building on the plan of the slaughter-house at Meerut, and as soon as a suitable site can be fixed upon, it will be begun. 21. The horses of camp followers are not allowed to be picketed in the bazaar, but no arrangements are made to have them at any appointed spot. There is a "burdasht khanah" for travellers' and other cattle, and the manure is daily removed and sold, the profits arising from which serve to defray the expenses incurred in repairs to the buildings. 22. The artillery stables are open sheds with roof ventilation; they are about 100 yards east of the barracks, and one mile from the hospital. The litter is generally used to make the lunges. The cavalry horses are picketed in column of troops about 100 yards south of the nearest barrack, and about 400 yards south of the hospital, the prevailing winds being east and west. 23. There is sufficient accommodation in the married men's barracks for all the families.
Officers' Quarters.	1. Officers at this station live in detached bungalows, the drainage and ventilation of which are good. No improvements are to be suggested.
IV. HEALTH OF THE TROOPS.	1. The station, surrounding district, and adjoining native population are generally healthy. 2. The most prevalent diseases among the native population are malarious fevers, affections of the spleen and bowels; and epidemics of small-pox, caused by the practice of inoculation, are common in February and March. 3. I attribute the healthiness to the dryness of the climate, the absence of much marshy ground, the general condition of the population, who have a sufficiency of food and clothing and the efficient sanitary police regulations enforced by the magistrate in the city. 4. The 19th regiment came to Benares from Dinapore, where they had been stationed 15 months. They marched from Dinapore on the 20th February 1860, and arrived here on the 12th March. The health of the regiment had been very indifferent at the former station, where they had suffered from intermittent fevers and scurvy. During the march they improved very much, and since their arrival at Benares the prevalent diseases have been fevers and venereal affections. There is no portion of the men's present accommodation more unhealthy than the rest. 5. During the cold weather a detachment is generally encamped a few miles from Benares, at rifle practice, and with very beneficial effects to the health of the men. 6, 7, 8. I have never been in charge of troops at hill stations. 9. Hill diarrhœa is a disease peculiar to hill stations. 10. The diet and clothing of troops at hill stations are believed to be suitable to the climate, and the principal precaution required is that the troops should have sufficient barrack accommodation. 11. The hot and rainy months are those best adapted for a residence at hill stations, and in order to obtain the full benefit of such residence, troops should reside in the hills for at least one year. 12. There is no period of residence in hill stations beyond which injury is likely to be inflicted on the health of troops on their return to service in the plains. 13. The troops ought to leave the hills for the plains at a proper season; that is, at the commencement of the cold weather. 14. I have had no experience to enable me to reply to this query in full, but I consider frequent change of station in the plains decidedly beneficial to health. 15, 16. No replies to these queries. 17. There is no higher ground near this station which could be advantageously occupied as a hill station. 18. All authorities agree that the proper site for an Indian station is a perfectly clear open space, free from marsh, forest, or low jungle, perfectly isolated, at as great a distance as other than sanitary considerations will admit of from the native town and its own bazaars, and separated from all dense jungle and rice cultivation by a zone at least two miles in breadth.

IV. Health of the Troops —*cont.*	The situation should be sufficiently raised to allow of free surface drainage in every direction. See Dr. Norman Chevers on the means of preserving the health of European soldiers in India. 19. Soldiers should not be sent to India under 20 years of age, and recruits ought to be well-formed soldiers before they are sent out. In the hot season our hospitals are filled chiefly with young recruits. Troops ought to land in India in the cold season; that is, between the 1st of November and the end of February. It is very desirable that they should arrive early in the season, in order that they may be sent up country and arrive at their destinations before the setting in of the hot weather. Troops on first landing here are quartered in the barracks at Dum Dum, Barrackpore, and Chinsurah, where the accommodation is very good, and are treated there as is usual with recruits learning their duty; or they are sent off by bullock train or river steamer to join their respective regiments up country. In order to preserve the health of recruits on first landing in India, I would recommend that all unnecessary exposure to the sun be avoided, and due attention paid to the clothing and diet of the men. 20. Troops should be sent direct from the home depôts to India at a favourable season of the year. I would recommend that troops on first landing in India be sent at first to some of the healthiest stations in the plains. 21. Troops are sent from Calcutta up country by bullock train, in parties of about 100 men each. They travel during the night, and are accommodated during the day in roadside barracks, situated about 30 miles distant from each other. Others are sent by the river Ganges as far as Allahabad in troop boats towed by steamers. The only additional precaution I would suggest is that troops should not be despatched from their stations after the 15th March, when the hot season commences. 22. A British soldier should not serve longer in India than 10 years. 23. No fault can be found with the manner of conducting the business of invaliding boards. 24. Invalids proceeding home from India should leave from the 15th of December to the end of February.
Diseases.	1. There is a regular inspection parade for the discovery of incipient diseases at this station once a week. 2. There has been no case of scorbutus at this station. 3. The proportion of cases of hepatic disease usually under treatment at this station is seven per cent. of the sick. It is caused chiefly by the great diurnal alternations of temperature during the hot and rainy seasons, and is not generally consequent on other diseases. The best prophylactic measures are temperance, attention to clothing, and non-exposure to night air. 4. Cases of dracunculus are unknown in this district. 5. The proportion of cases of venereal diseases constantly under treatment to the total sick in hospital from all other diseases is 23 per cent. I would suggest that all prostitutes be turned out of the bazaars, and that there should be at every station a native hospital for the treatment of diseases of every description, and where diseased women would also be admitted. A lock hospital is open to the objection of its being necessary to adopt with it a system of supervision of bazaar women, thereby licensing prostitution, which it is doubtful if Government would sanction. 6. The principal diseases from which the troops at this station suffer are as follow, viz.:— *Fevers.*—Intermittent and remittent in the proportion of 31 per cent. to the total admissions; and the mortality is 13 per cent. to the total deaths. *Dysentery.*—Usually of an acute form in the proportion of 6 per cent. to total admissions; and mortality of 17 per cent. to total deaths. *Cholera.*—0·5 per cent. to total admissions; mortality 17 per cent. to total deaths. *Rheumatism.*—2·3 per cent. to total admissions; no deaths. 7. The more frequent zymotic diseases are fevers, chiefly of malarious origin, and syphilis in its various forms. The former are generally mild in character, and rarely assume the typhoid type. These diseases are most prevalent in the hot and rainy seasons, particularly towards the end of the rains in September. A high temperature, combined with moisture in the rainy season, and great dry heat, with still states of the atmosphere, are the climatic and atmospheric conditions accompanying the appearance of the above diseases. There is no one part of the station or city more unhealthy than another. The crowded and badly-ventilated dwellings occupied by the native population may predispose them to these diseases. 8. The soldier is not injuriously influenced as regards epidemic disease by the nature of his duties or occupations either in barracks or on the march. 9. Small doses have not been given as a prophylactic against malarial disease at this station. 10. I have no recommendations to offer on any of the preceding points.
V. Intemperance.	1. The soldiers at this station are on the whole temperate, and there are no confirmed drunkards among them. 2. In the 1st battalion 19th regiment it is reported that only seven men were admitted last year from the direct effects of intemperance, and the diseases of five were clearly traceable to its indirect effects. There are no total abstinence men, neither is there a temperance society in the 19th regiment, there are therefore no data from which to prepare a statistical table showing the effect of total abstinence, temperance, and drunkenness, on the amount of sickness and mortality, and crime at the station. Drunkenness is always punished as an offence. 3. Distilled spirits are allowed to be sold only in the canteens. Each man is allowed to purchase two drams of rum of good quality per diem. During the last year the average quantity consumed by each man has been about half a dram of rum and half a pint of malt liquor daily. Spirit does not now form part of the soldiers' daily ration, neither is it ever given as a ration to convalescents. No drinks other than intoxicating drinks are sold in the canteen or bazaar. 4. The consumption of spirit by troops and convalescents is certainly injurious to health, and it is generally admitted to be the great cause of sickness and crime in a regiment. 5 Spirits do not form part of the soldiers' ration at this station, and it would be beneficial to the health of troops to abolish its sale in canteens. Its sale is prohibited in the bazaars. 6. Malt liquor of good quality is now supplied at the canteens, and its use is unquestionably beneficial to the health of troops, as compared with that of spirits.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	7. Coffee, tea, lemonade, soda water, and similar drinks are much used at this station. They are sold at the canteen and at coffee shops in the Sudder bazaar, and their influence on health, efficiency, and discipline, as compared with spirits and malt liquor, is most decidedly beneficial. 8, 9. It would be beneficial to prohibit the sale of spirituous liquors in the canteens, and to permit only beer, coffee, tea, lemonade, &c. to be sold to the troops. 10. I have no recommendations to make on these points. 11. There are no printed bazaar regulations regarding the sale of spirits, but none is allowed to be sold in this cantonment to soldiers at all. Venders of British and foreign spirits are bound down by the restrictions of the Abkaree Act of 1856, No. xxi. For the canteen rules see Bengal Military Regulations, Section x., page 47.
VI. DIET.	1. The ration for Queen's British troops and European troops in the Indian army is the same, and is composed as follows; viz.;—bread 1 lb., meat 1 lb., vegetables 1 lb., rice 4 oz., sugar $2\frac{1}{2}$ oz., salt 1 oz., tea $\frac{5}{7}$ oz., or coffee $1\frac{3}{4}$ oz., and firewood 4 lbs. The vegetables are changed according to the season, and beef is supplied six times a week, and mutton once. The rations are daily inspected by the quartermaster and officer of the day. 2. A complete ration, including a due proportion of vegetables, is provided for the troops, the stoppage for which is three annas and four pie (equal to 5*d.*) daily. The soldier takes three meals a day; viz., at 8 a.m., 1 p.m., and 5 p.m. Breakfast consists of bread, a little meat, and tea. Dinner of meat, vegetables, and rice, cooked according to his desire; and supper of bread and tea. The men generally supplement their rations by the purchase of milk, butter, and such other articles as they may fancy. The proportion of vegetables which enters into the composition of the ration is upwards of two-thirds. 3. The salt might be reduced one half and other condiments allowed in its place, and during the hot months it might be a beneficial change to issue mutton twice instead of once a week, as at present. The rations for each mess are placed in charge of its messmen, and are not liable to be disposed of. 4. The rations are cooked by native servants in copper boilers, large and small, and in stew-pans. The cooking utensils are carefully tinned twice a month. The kitchens are generally clean, light, and well ventilated, and amply supplied with water by native water carriers. The food is cooked in the manner desired by the men, and is properly done and sufficiently varied. The troops have coffee before a march. 5. There is a soldiers' garden near the barracks; but the men do not take much interest in it.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldiers' dress at this station consists in the hot and rainy seasons of a khakee suit of light cloth, basket helmet covered with calico, and a light turban, with flannel and calico underclothing. In the cold season, of a serge coat, cloth pantaloons, forage cap, and flannel and calico underclothing. I consider this dress as quite suitable to the climate, and for the soldiers' duties both by day and night, and at different seasons. A great coat additional is allowed in the cold and rainy seasons, and the sentries are permitted to use verandahs or sheds for protection from sun and rain. I have no improvements to suggest.
Duties.	1. It is most desirable that men should be thoroughly drilled at home before being sent to India. 2. In the cold season the men are drilled morning and evening for an hour each time, and in the hot and rainy weather occasional parades of short duration take place, which tend to keep the troops in health. Drills, parades, and marches always take place in the cool of the morning and evening during the hot weather, and at any hour except between 10 a.m. and 3 p.m. in the cold season. The average number of nights the men at this station have in bed during the week is four. 3. Guards are mounted close to the barracks, and while most last 24 hours some are only of 12 hours' duration. There are four roll-calls during the day but none after tattoo. The night duties are light and not prejudicial to the health of the men.
VIII. INSTRUCTION AND RECREATION.	1. The following are the means of instruction and recreation at this station. There is one ball court, three skittle grounds, two schools with good schoolmasters, one library and reading room, sufficiently lighted at night, one day room, one soldiers' garden managed chiefly by the regimental quartermaster, two workshops, and a station theatre used by the men. There are no gymnasia. These means are scarcely sufficient to keep the men occupied in the wet season and during the heat of the day. The men are confined to barracks during the hot and rainy seasons from 8 a.m. to half past 5 p.m., and with the very best effect on their health. 2. In order to increase the efficiency of the existing means of recreation and employment, I would suggest the erection of more workships and also of gymnasia. 3. Soldiers' savings' banks have been established in every regiment by Government orders, and must be advantageous. 4. There is not sufficient shade from trees, sheds, verandahs, or other means to enable the men to take exercise without injury to health during the day.
X. MILITARY PRISONS.	1. The cells at this station are too small, and are badly ventilated; but the defects are being remedied in compliance with the recommendations of a board.
X. FIELD SERVICE.	1. There are no local regulations for field medical service not included in the General Presidency Regulations. 2. The practical working of the powers of the medical officers, as regards the conduct of the line of march of troops, camping, bivouacking, billeting, &c. depends very much on the personal characters of the commanding and medical officers. 3. Camping grounds for regiments marching in course of relief are marked out by boundary pillars. They are cleared by the quartermaster's establishment, and by private servants of the officers, and men about to encamp. The tents are well ventilated and the water supply ample. On field service the selection of the camping ground rests practically with the commanding officer, who is guided chiefly by military reasons. The medical officer, if the ground were unhealthy, ought to suggest removal; but of course a large discretion must be accorded to the commanding officer.

References to Subjects and Queries.	Replies.
X. Field Service—*cont.*	4. Arrangements as regards field hospitals, transport of sick, and hospital supplies, &c. consist in the appointment of a field surgeon with an efficient staff of medical officers and subordinates, a sufficiency of hospital tents, of doolies, ambulances and boats for the transport of the sick; elephants, camels, and carts for the conveyance of tents and hospital stores, and also of a medical storekeeper, with an ample supply of medicines and instruments. The only authoritative regulations bearing on this subject, are contained in the Bengal Medical Code of 1851, Chapter XXIV. For further information I beg to refer to the report on the medical arrangement of the army of the Punjab, during the campaign of 1848–49, by superintending-surgeon, C. Renny.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1. Plan of the hospitals is transmitted. 2. The hospitals are 936 yards from the nearest barracks, more than a mile from the stables, and at a considerable distance from, and to windward of the bazaar, and houses of the residents in cantonments. The site is open, freely exposed to the prevailing winds, and is generally healthy; but there is a nullah to the westward, which is usually dry, except during the rains; this, however, is not supposed to be a source of noxious effluvia. 3. The supply of water is abundant and wholesome. 4. Refuse water, &c., is removed by means of filth carts, sent round morning and evening. There is no sewerage. 5. The floor of the hospital is of solid masonry raised two feet above the ground; but there is no perflation of air beneath. The roof water sinks into the subsoil or flows off by the natural lines of drainage, and the rain fall is carried rapidly away by means of small open ditches. The hospitals are built of kiln-burnt bricks, and have recently been roofed with thatch, which renders the buildings much cooler than tiles. There are verandahs all round the hospitals eight feet wide, which afford sufficient shelter from the sun, but are never used for the accommodation of sick, convalescents, or others. The hospitals all consist of one floor.

Table of Hospital Accommodation.

Dates of construction—various. Nos. 5 and 6 have been recently constructed.

Total number of wards, 6.

Total regulation number of beds, 176.

* This is not now used as a hospital ward; but has been partitioned off into store-rooms, &c.

Note.—Although wards Nos. 1, 3, and 4 were intended to contain 40 men each, never more than 30 patients are now placed in any of them, which allows 1,500 cubic feet to each man.

The hospitals are placed so as to receive the full benefit of the prevailing winds. There are few windows, but numerous doors on both sides of each building, opposite to each other, and are well arranged for purposes of ventilation. All doors and windows open inwards.

6. The wards are ventilated by means of the doors, windows, and ridge, and these means are sufficient to keep the hospitals at all times free of odour and closeness. There are no jalousies or jhilmils.

7, 8. The air in the hospitals during the hot and dry seasons is cooled by means of tatties similar to those used in barracks; the air never requires warming. The walls and ceilings of the wards are cleansed and limewashed twice a year, or oftener if required, for sanitary purposes.

9. The privies and urinals are situated a few yards from the end of each hospital, and have a covered corridor leading to each. The filth is received into iron pans placed underneath, which are emptied morning and evening into the conservancy carts. They are well supplied with water, and are not offensive.

10. There are lavatories off each corridor leading from the end of the hospital wards to the privies. They are sufficient for the sick.

11. One of the small end rooms of the hospital is used for bathing the sick, but a proper bath-room is required.

12. The hospital linen is always washed by native washerwomen, of whom a proper establishment is kept up.

BENARES. BENGAL.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	13. The storage is sufficient and dry. 14. The cots used in hospital are wooden frames, with broad tape lacing for the bottoms, and are excellent of the kind. The bedding is inferior, the mattress being made of strong red cloth stuffed with tow. The sheets are of good cotton calico, but the blankets are coarse, country made, and lined on one side with coloured chintz. I would suggest the substitution of English blankets for country-made ones. 15. The kitchens (of which there are four) are situated at convenient distances from the hospital wards. The diets are cooked by native cooks, who are allowed an ample supply of cooking utensils made of copper, and tinned twice a month. These means are sufficient. 16. No reply to this query. 17. The following hospital establishment is sanctioned by Government for a regiment of European infantry :—

Apothecary	1 European.	Steward's servants	2 natives.
Assistant ditto	1 „	Bheesties (water-carriers)	7 „
Apprentices	2 „	Sweepers	9 „
Head compounder	1 native.	Ward coolies	21 „
Assistant ditto	1 „	Ayah or native nurse	1 „
Head dresser	1 „	Female sweeper	1 „
Assistant ditto	1 „	Cooks	5 „
Shop coolies	2 „	Washermen	5 „
Steward	1 European.	Clothier	1 „
Apprentice	1 „	Tailors	2 „
Native writer	1 native.	Barber	1 „

One hospital serjeant is allowed to every European regiment.

18. The sanitary condition of the hospitals is good, and no epidemic disease has appeared in the wards.
19. No deficiencies or sanitary defects have come under my notice.
20. The convalescents are permitted to take an airing morning and evening on elephants and in ambulances along the public roads, but there are no shaded walks or seats for their use.
21. There is a small female hospital set apart for the use of soldiers' sick wives and children, but a large one is required, with a separate ward for lying-in women.
22. There are no special local hospital regulations not included in the General Presidency Medical Regulations.
23. The recommendations of the medical officer with respect to the sanitary state of his hospital, repairs, changes of dict, &c. when approved of by the principal medical officer, are always complied with.
24. There is no hospital for convalescents in the station, nor is such accommodation thought necessary.

XIII. BURIAL OF THE DEAD.	1, 2. A new burial ground for British troops has been used since 1856, situated at the south-west corner of the cantonments, not quite out of the direction of the prevailing winds, and about three-quarters of a mile from the barracks. The very dry westerly wind which prevails must have the effect of destroying any offensive exhalation which may arise. Its area is about 22,000 square yards, length of the enclosure being 130 yards, by 58 yards broad. The soil is light and sandy, resting on and intermixed with the "kunkur." The drainage is good, having a slight slope to eastward, and decomposition takes place readily. The ground is carefully kept. 3. The space allowed for graves is 7 ft. by 2½ ft., and that between each grave is two feet. The depth of graves is six feet, and they are never re-opened, nor are more bodies than one interred in the same grave. Interment takes place at all times in from 12 to 24 hours after death. The native troops, being chiefly Hindoos, burn their dead at a distance from the station. Mahometan soldiers are buried in the Mahometan burial ground of the neighbouring city or village. 4. The graveyard is never offensive. The bodies of British soldiers at this station are usually carried to the burial-ground in doolies or litters borne by native bearers. By recent General Orders of the commander-in-chief, a hearse for the above purpose is directed to be supplied to every military station, which will be preferable to the present mode of burial. 5. The dead of camp followers and bazaar people are disposed of in the same manner as the native troops. 6, 7. No injury accrues to the public health from the present practices, nor are any improvements to be suggested.

(Signed) GEO. CAMPBELL, Major-General Commanding at Benares.
A. G. PRIESTLEY, Captain Executive Engineers.
ALEXANDER GIBBON, Deputy Inspector-General of Hospitals, Benares Circle.

Benares, 1st May 1861.

I. TOPOGRAPHY.	1. The surrounding country is a level plain, intersected by the river Jumna, which passes a mile and a half to the east. It is flat, dry, and sandy, and there are few trees and no jungle. 2. The station is situated on a level with the surrounding country, at an elevation of 800 feet above the level of the sea, and 50 feet above the river Jumna. There is no higher or healthier ground adjoining the station.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	3. The nearest mountain land is a rocky ridge at Futterpore Seckra, about 100 feet high; there is no high table-land near. 4. The nearest water is the river Jumna, which passes within 1½ miles to the east of the station. The Kara Nudder is 12 miles to the south, and there is some marshy ground near Futterpore Seckra, about 18 miles to the west. The vicinity of the station is not liable to overflow. There are ravines along the bank of the Jumna, extending to the officers' bungalows; their vicinity is considered objectionable from being hot and unhealthy. 5. The station is open, with few trees in the gardens, the walls of which are low and offer no obstruction to the free circulation of air, nor do they prevent external ventilation. The temperature of the station is hot, from the baked dry soil, in the hot season, and the ravines contribute to the heat. The station is not exposed to cold or variable winds. 6. The surrounding country is cultivated, except in the vicinity of the ravines. There are no works of irrigation near the station; a canal was commenced near Futterpore Seckra, but it has not been used; the irrigation from the wells is not injurious. No rice is cultivated in this part of the country, and but little indigo in the vicinity, and none within five miles of Agra. There is very little hemp or flax cultivated, and they produce no injury to the health of the station. 7. The city of Agra, with its suburbs, is about a mile to the north of the station; it contains a population of 152,000 inhabitants. 8. The surface and soil of the district is composed of alluvial deposit of alternate strata of clay, sand, and lime. There were formerly suburban houses, gardens, and cultivation on the site of the present station. 9. Water is found at a depth of 65 feet below the surface during the dry season, and at about 55 feet during the rainy season. 10. The rain that falls on the parade and in the vicinity of the barracks chiefly sinks into the soil; in consequence of the ground being level a small quantity runs into the Mota Konah tank, which drains into the ravines towards the river. There is no marshy ground from water lodging on the surface, nor does the water ooze out on the surface. No drainage from higher ground passes into the subsoil of the station. 11. The water supply of the station is derived principally from wells; occasionally the river water is brought for drinking and gardening. The Mota Konah tank, which is 80 yards square, is in the middle of the station; there are two small tanks, 30 yards and 20 yards square, to the north and west of the station; also a small tank, 30 yards square, to the south of the parade. The Mota Konah generally contains water during the whole year,—the others are dry in the hot season. There are no fish or rank vegetation in the tanks; the Mota Konah is reserved for culinary and drinking purposes, the remainder are for bathing. The wells are not liable to pollution from leaves; the tanks receive the drainage from the vicinity, but they are not used generally for drinking purposes. No nuisance or malaria proceeds from any tank within or without the station. 12. The amount of the available water supply is limited by the number of the wells. The well water is very salt, with a few exceptions. Water is occasionally brought from the river. It is considered heating during the rainy season. The water contains large quantities of the muriate and sulphate of soda and lime. Few wells are used for drinking purposes, as the ordinary well water is laxative and apt to disagree at first. The supply is sufficient. It is raised in leather bags by bullocks, and carried in skins, called nussocks, by bheesties, for the use of Christian and Mussulman; the drinking water for the Hindoos is carried in brass or earthen jars. 13. There is a fall of about 32 feet from the station to the river, which carries off the rainfall rapidly, and the subsoil is sandy, filled with bricks, which renders evaporation quick. These, together with the absence of marshy ground and rank unhealthy vegetation, have given to Agra the reputation of being, after the hills, the healthiest station in India; but of late years it has lost its character from attacks of epidemic cholera. 14. With regard to the amount and kind of inquiry instituted before the selection of new stations, there is no established practice. The senior medical authorities ought to be consulted in the selection of cantonments or barracks, but it would be better to have a special officer selected for this duty. No ground ought to be selected till the history of the place is known,—whether it has been previously inhabited; where the people of the country consider the "howah pane,"—air and water—bad, should be avoided; and the state of the locality *during the rainy season*, and that of the surrounding country, ought to be ascertained. The barracks should be constructed according to the state of the ground; the damper and hotter that is, the higher the beds should be placed.
II. Climate.	1, 2. A thermometer is supplied to each regimental surgeon, by whom, in peaceful times, a daily register of the temperature of the hospital is kept. There is no meteorological register kept in this office. The registers are transmitted to the office of the Director-General in Calcutta. 3. The climate from the end of October to the beginning of April is cool, clear, and healthy; it is very hot and dry, and not unhealthy, till the end of June, when exposure to the sun must be avoided; till the end of September it is hot and moist, during which time fevers are prevalent, though not generally dangerous. The country is destitute of trees, and there is no canal irrigation influencing the climate. The atmosphere is impregnated with dust during the hot season, the heat of which is very exhausting to the constitution. Much animal food is not required; exposure to the sun is to be avoided, and the temples protected from its influence. Flannel bands should be provided to protect the stomach and loins from sudden changes of temperature; and violent exertion is to be avoided in the rainy season. The floors of the sleeping-rooms should be at least 10 or 12 feet above the level of the ground. The best times for drill is the morning and evening. November to April are the most healthy months; August, September, and October are the most unhealthy, during which months fevers of a miasmatic type prevail, complicated with dysentery. *Coup de soleil* is frequent in May and June, and liver complaints are prevalent in the hot and rainy seasons.

AGRA. BENGAL.

References to Subjects and Queries.	REPLIES.
II. Climate—*cont.*	4. There is no district near the station the climate of which is more conducive to health. 5. The stations at which I have served are Agra, Muttra, Meerut, Kurnaul, Umballa, Loodiana, Ferozepore. The climate in all these is the same, the cold season lasting the longer the further north the station. With the exception of Kurnaul, I consider these to be healthy stations. Kurnaul became sickly after 1837 in consequence of the extension of the canal irrigation. Towards the end of the rainy season it is most unhealthy, and miasmatic fevers with dysentery prevail. During the hot season sunstroke is frequent in the southern stations. Mhow, Nunald, and Indur have similar climates, but the cold season is shorter, the hot winds less intense, and the rains cooler than in the before-mentioned stations. Miasmatic diseases are prevalent and dangerous during the rainy season. The sanitary depôt at Landour enjoys a cold invigorating climate, very conducive to recovery from tropical diseases, except during the rainy season, from June to September, when the damp is excessive. Mineral springs abound in the vicinity; sulphureted and chalybeate waters were used with great advantage, and it was proposed to build a detachment hospital for the use of the convalescents; this was interrupted by war, but it is very desirable that it should be carried into effect as soon as possible.
III. SANITARY CONDITION OF STATION.	4. Table of barrack accommodation :— The date of the construction is unknown, the records being destroyed. Total number of rooms or huts—76 quarters for serjeants and 23 wards for men. Total regulation number of non-commissioned officers and men, 1,776.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.

Prison Cells, 20	1	8	8	16	1,024	1,024	64	—	1 Door. 1 Wind.	7 3	2·5 2

5. There are no windows, but a door on each side of the room, with glazed fanlights over them. There is a verandah all round the barracks, 12 feet wide, not now occupied as sleeping quarters, but they have occasionally been so occupied when there was a want of barrack-room. No jalousies or jhilmils are allowed to the barracks.
6. The bedsteads used in barracks are of wood, 6½ feet by 3 feet, raised 1½ feet from the ground; the bottoms are made of cotton-tape, called newar, or of grass rope, called mangh. The bedsteads should be iron, as being more easily kept free from bugs.
7. The tents are made of cotton, with a double fly.
8. The barracks are furnished with iron ridge ventilators, with ventilating holes in the inner walls. The ventilation is sufficient to keep the air pure night and day, provided the verandahs are not occupied as sleeping rooms. The barracks are cooled by tatties and punkahs (tatties are screens made of the roots of an aromatic grass, on which water is constantly sprinkled). The hot west wind, of the temperature of 120° Fahr., passes through reduced to 80°. The punkah is a rectangular framework, 6 feet by 2 feet, covered with cloth, and having a cloth fringe. It is suspended to the tie-rods, or beams, made for the purpose, by cords of thin wire, pulled by coolies. They cost about 10 rupees each.
9, 10, 11. The barracks are constructed of burnt bricks and mortar, with thatched roofs. There are no huts, the tents are of cotton cloth. The floors are made of stone flags over brick on edge laid in lime cement. They are raised 3 feet, and filled in underneath with rammed earth; there is no passage of air beneath. The materials are good and the construction solid, and the ventilation and space is sufficient. The barracks are objectionable from not being raised sufficiently above the malaria which exists in all tropical climates during the rainy season. They should be two storied buildings, the upper story being at least 12 feet from the ground; and if the lower story were raised 3 feet, and made 14 or 16 feet high, it could be occupied as orderly, school, reading, store rooms, guard-room, and workshops. It might also be occupied by the married families, or even part of the corps, who would be in a sanitary view as well as now, whilst the main body would be in a healthier atmosphere. The expense would

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	not be greater than the present style of barrack with the outhouses. The barracks are kept in repair by the executive engineer and barrack-master, and the repairs are quickly executed. The sanitary officer and medical officer in charge of the corps is responsible for the general sanitary state of the cantonment. The walls of barracks are cleansed and whitewashed annually by the executive engineer, and when required by the sanitary officer in excess by the barrack-master. 12. The lavatories are built of solid masonry, with a tiled roof. The hand basins are supplied with water from a copper cistern filled from a tank attached to the well, about 20 yards off, by an underground pipe. The waste water is collected in cesspools and carted away. There are four baths for the men, which are supplied by wells attached to the bath-houses, and the water is carried away by surface drainage. The urinals are in rear of the wash-house, and all water passes through the urine trough. 13. The cook-houses are built of solid masonry, with a tiled roof, with a verandah to the front, and to the back. Chulahs or native fireplaces are built, there being a row of ventilators above to pass the smoke off. Water is supplied by water-carriers, and the refuse water is drained into covered cesspits and carted away. The linen is washed and dried by dhobies, or washermen. It is washed in the river Jumna, dried on ropes, and ironed at home. The supply of dhobies is ample. 14. The privies are built like the wash-houses of solid masonry, with metal buckets beneath each seat, removable from behind; the seats are divided off by stone slabs. The soil is removed by carts. 15. The cook-house, privies, &c. have ridge ventilators, all the buildings being tiled. The barracks are lighted at night by oil lamps suspended from the centre of the building. 16. There is no flow in the drains, except during the rainy season. The barracks are drained by surface drains of various sizes, up to 3 feet deep by 8 wide; the outlet drain runs between the artillery and infantry lines. The surface water lodges within the vicinity of the barracks, in consequence of the dead level of the ground, until it sinks into the sandy soil, rendering raised paths necessary between the barracks. This ought to be remedied by a general system of drainage. The water from the lavatories is collected in an open cesspool, from which it is spread over the ground; deep wells ought to be sunk for the reception of this water. There is no unusual dampness in any part of the buildings used as barracks or hospital. The fluid refuse sinks into the subsoil; part is carried away in carts from the cesspits, and a portion evaporates. The cesspits attached to the wash-house are 6 × 8 × 3 feet deep, and about 100 feet from the well. They have been condemned, and deep wells recommended in their place. Their distance from the barracks is 80 feet. The refuse water is removed in barrels every morning. The cesspits in the hospital are deep wells, and never cleaned; but they are tried to be kept sweet by lime, but in vain. New privies on a similar plan to those in the barracks are in progress of construction. There are no foul ditches. 17. The barracks are cleaned, &c., the roads swept, and the refuse near the cook-rooms carted off outside the cantonments daily. 18. The surface of the cantonment is bare and brown, except during the rainy season, when grass springs up, and is grazed down very closely. There are a few gardens round the bungalows of the officers, but the water is salt, and not suited for floriculture; though vegetables grow well, particularly the Cruciferi. There are no old walls, thick hedges, &c. interfering with the ventilation of the station. 19. The bazaar is open, clean, and well ventilated, and not crowded. The supply of water from wells is abundant, but rather saline. The bazaar is swept daily, and all filth is removed. No improvement is necessary in the sanitary police arrangements. The native houses are clean for native villages, but are all too low. The streets are narrow and irregular, with dunghills at the skirts of the village. The more respectable houses have cesspools, which are emptied by the public sweepers. The surrounding fields are visited morning and evening for natural purposes by the inhabitants generally. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. The slaughter-house is at the western extremity of the station; the offal is removed to a distance, and is devoured by dogs and scavenger birds. There is no inconvenience experienced at the station from the slaughtering places. 21. There are no arrangements for stabling and picketing bazaar horses. There are very few of them, and they are kept within the enclosed areas of the houses. The manure is formed into fire-cakes, called "kund," and the bedding is eaten by buffaloes. 22. The artillery stables are open sheds running east and west; they are formed into two rows, and closed with mat or grass screens to shelter the horses from cold and rain; they are between the artillery and infantry barracks. Light and ventilation come from the sides; the manure is removed in filth carts. The stables are 150 yards from the barracks of the artillery to the south, and 350 yards east of the infantry hospital. 23. The married families occupy a large separate barrack with plenty of room; none of them occupy the barrack-rooms with the men.
Officers' Quarters.	1. The officers live in separate bungalows, well ventilated, and with large open compounds; they are well drained and kept clean. All tropical buildings should be two storied; at least there should be a room upstairs to sleep in during the rainy season, and the lower floor should be four feet above the surface of the ground.
IV. Health of the Troops.	1. The station, district, and the adjoining native population are healthy. 2. The diseases most prevalent among the native population are sun-stroke in the hot season, fever and dysentery in the rainy season, with a few cases of spleen disease in the low ground in the vicinity of Futterpore Seckra. Small-pox prevails every cold season. There have been three severe attacks of epidemic cholera, viz., in 1843, 1856, and 1857; in 1851 it was severe in the district, though the European troops were little affected. 3. The healthiness of the native population depends on the dryness of the climate and the absence of marshy ground. 4. The troops now at Agra have come from the campaign against the mutineers; they have been at no station. There has been more sickness in the infantry than in the artillery lines, owing to the surface water lodging to a greater extent near the infantry barracks.

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops —*cont.*	5. Troops are occasionally moved into camp in October or November for change of air, with marked benefit, when there is excess of sickness lingering in the lines after the rains. The artillery go into camp in an open plain three miles west of the station during the cold season for annual practice. 6. I was in charge of the sanitary depôt at Landour from September 1842 to October 1844. The climate is highly invigorating and bracing, except during the rainy season, when it is damp and raw; it is highly beneficial in debility arising from fever, ague, and spleen, bowel and liver complaints, especially in young men. In extensive, as in chronic diseases, a residence during the cold season is necessary. Diseases of the head, heart, or kidneys should not be sent to the hills. In affections of the lungs and scrofula, the benefit of residence in hill stations is doubtful, and questionable in rheumatism and venereal cases. Much benefit would arise in these cases if the detachment hospital which was approved of was constructed at the sulphur springs, where bathing in the waters proved very beneficial in otherwise untractable cases. 7. The regiments that came from the hill stations to the siege of Delhi were more healthy during the campaign than the troops which came from plain stations and the Punjab; the men had more stamina to start with. Children on coming down from the hills in November generally have attacks of feverish cold, owing to the great variation in the temperature of night and day. Attention to clothing and avoiding exposure to the sun in the middle of the day, on returning to the plains, will avert the danger. 8. I decidedly approve of selecting hill stations for troops. 9. There are no particular diseases to which troops are liable to be attacked on going to hill stations. In some stations there is a tendency to looseness, and colds are prevalent in April. 10. Sick men approaching convalescence get a strong appetite on going to hill stations, and are apt to eat more than they can digest. They should be much in the open air, with the head protected from the sun by a broad-brimmed hat; they should always wear a flannel belt, avoid violent exercise immediately after eating and exposure to the sun. 11. The hot season is most agreeable, but the cold season is most invigorating; the rainy season is most disagreeable and sickly, but more healthy at this season than in the plains. From April to November inclusive is the shortest period necessary in hill stations for recovery from debility following an acute attack where there is no extensive organic disease in a young man. Chronic cases, and those where there is extensive organic disease, require a residence during the cold season, and occasionally during two cold seasons. The convalescents should not return to the plains until the middle of November. Regiments stationed in the hills might return to the plains at the end of October. 12. There is no period of residence beyond which injury is likely to be inflicted on the health of the troops on returning to service in the plains. 13. The special precautions necessary on leaving hill stations for the plains is to avoid exposure to the sun and excess in eating or drinking. 14. The men keep up their stamina best in the hills, and even if ordered down to the plains on service in the hot season, they stand work better than troops that had not left the plains. This was proved in 1857, when troops were brought down from the hill stations of Kussowlie, Soobathoo, and Dugshai to Delhi in May, and served with the troops from Meerut and the Punjab; the hill troops had less sickness and were best able for work. Frequent change of station in the plains is beneficial. 15. The barracks are imperfect at Landour. A small hospital is much required near the sulphureted mineral springs in its vicinity for debilitated cases, affections of the chest, rheumatic and venereal cases, particularly during the cold season. This was approved of by the medical board, but the construction postponed in consequence of war expenses; it should be carried into effect. 16. The Himalayan hill stations vary in elevation from 4,000 ft. at Soobathoo to 8,000 ft. at Landour. The lowest is beyond the influence of tropical climates, and is less cloudy than the higher elevations, but not so cold and bracing. There is no objection to any intermediate elevation for sites for hill stations. Plenty of level ground, with a good supply of water, and easy access to the plains, including the extent of the Terrai at the foot of the hills, should regulate the locality. 17. There is no higher ground near the station which could be advantageously occupied as a hill station. 18. The black soil of Central India is unhealthy for stations after the rains; it induces ague and dysentery. 19. Soldiers should be sent to India as soon as they have attained their full growth, and should land there in November. Troops on landing in Calcutta are sent into barracks at Fort William, Chinsurah, and Dumdum, where there are good barracks. Duties and drill depend on the officers commanding. Clothing according to the seasons is supplied at once. To preserve the health of recruits, they should avoid exposure to the sun, eat moderately, and drink temperately; never taste spirits till after sunset, and only eat animal food once a day. Coffee in the morning is better than spirits on a line of march or in cantonments. 20. Troops should be drilled at home, and then sent out to India direct. The danger of the earlier years of service arises from imprudent living, exposure, and want of experience in diminishing the inconveniences of the climate when marching or in cantonments. These form innumerable petty details, which can only be learnt by practice. 21. Troops are transported from the port to the interior in carts drawn by bullocks, which travel about 40 miles a day. Staging barracks are being erected along the line of road. 22. The number of years a British soldier should serve in India is 10. 23. With regard to the mode of conducting the business of medical boards in reference to invaliding, commanding officers sometimes bring forward men for being stupid and inefficient, without bodily ailment to cause unfitness. Men of this description should be brought before a special committee of military officers. 24. Invalids should leave India for home in January, or so as to arrive in England in May or June.

IV. Health of the Troops —*cont.*—*Diseases.*

1. There are regular inspection parades every Saturday morning for the discovery of incipient diseases at this station.
2. Scorbutus has not prevailed among the troops at Agra. There were formerly a few cases among the native prisoners in the gaol; but not of late years, since vegetables have formed a part of their regular food. The disease was in their cases attributed to want of variety in the food and a deficiency of fresh vegetables. There was only one case of scorbutus out of 4,605 admissions last year.
3. The proportion of cases of hepatic disease was 4·89 per cent. during the year. The disease arose from over-action in the liver, caused by heat, exposure to the sun, and abuse of alcoholic liquors. It is a frequent sequela of miasmatic fever, but often an original disease, accompanied by fever. It would be diminished by avoiding alcoholic liquors, exposure to the sun, and excess in diet. A flannel belt should be always worn.
4. Dracunculus does not originate in Agra; it is a local disease, entering the system when bathing in tanks and other localities.
5. The proportion of constantly sick from venereal disease is 15·45 per cent. during the year on the strength, or 8·77 per cent. on the admissions from other diseases. To diminish the disease, the prostitutes should be under the orders of the cantonment magistrates and the quartermaster of the regiment; and they should be examined weekly by a medical officer. A Lock hospital should also be established.
6. The troops at the station suffer from diseases of the epidemic and endemic class. Continued fevers and sun-stroke are prevalent during the hot season. Miasmatic fevers prevail during and after the rainy season, when dysentery is also most prevalent. There were severe attacks of cholera in 1843, 1856, and 1857, and there were slight attacks in 1845 and 1851. There have been 239 deaths from cholera during the last 20 years, which is equal to an annual mortality of 1·13 per cent. on the strength. In 1847 and 1858 there were 22 cases of small-pox each year, and in other years an occasional case at the end of the cold season. There are a few cases of rheumatism at all seasons.

Table of Sickness and Mortality among the European Troops at Agra, from the Year 1839 to 1858, from the Records in the Office of the Superintending Surgeon.

7. The more frequent diseases are, in the rainy season, miasmatic fevers and bowel complaints; in the hot season, continued fever and affections of the head and liver; in the cold season, affections of the lungs and diseases arising from imprudence. The seasons when such diseases are most prevalent are May and June, when the air is intensely hot and dry; they are also prevalent in the rainy season, in August and September, with its warm moisture. These diseases are the effect of the general climate, and are not aggravated by imperfect conservancy nor localized in the station. Drinking spirits and going in the sun lead to sun-stroke in the hot season; and sleeping close to the ground in the rainy season predisposes to miasmatic fever.
8. There were severe attacks of epidemic cholera in 1851, 1856, and 1857, but they were not connected with the soldiers' duties or influenced by the barracks. The endemic diseases are the ordinary tropical diseases, appearing at certain seasons, but less here than in general in India. There was considerable sickness after the exposure during the hot season on service in 1858.
9. Quinine is frequently exhibited in small doses during the rainy season, and apparently with the effect of keeping off malaria. It should be alternated with cheryetta or some other tonic, as continued use blunts the action of any medicine.
10. The prevention of the diseases which prevail during the rainy season in all tropical climates can only be accomplished by removing the men above the influence of the cause, *i.e.*, miasma. This, experience proves, does not extend above 12 feet from the surface of the ground. This could be accomplished by having two-storied barracks and hospitals,—the lower story could be economized by being occupied as store-rooms, orderly-rooms, school-rooms, guard-rooms, serjeants' mess-rooms, married quarters, and workshops. If the floor of the lower story were raised three feet, and the rooms made 14 or 16 feet high, it would be as healthy and cooler than the present style of barrack, while the upper story would be unquestionably much healthier, and the expense would not be greater than that of the present barracks, including all the outbuildings.

V. Intemperance.

1. The soldiers at the station are usually temperate; there are no confirmed drunkards.
2. There were four admissions last year into hospital from diseases directly caused by intemperance, but the number admitted indirectly from the same cause is uncertain, as the connexion is not always evident. There are no total abstinence men, and no data available to form a statistical table showing the effect of total abstinence, tempe-

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	rance, and drunkenness on the amount of sickness, mortality, and crime. The troops now at the station are sober, and there is but little crime. Drunkenness is always punished as an offence when discovered. 3. Distilled spirits are sold at the canteen, but forbidden in the bazaar. During the cold season one quart of beer and two drams of rum are issued to each man per diem, and in the hot season, from April to September, one quart of beer and one dram of rum. The average consumption during the year per man per diem is one quart of beer and one dram of rum. Spirit is no part of the ration at any time. It is supplied to the canteen by the commissariat, and retailed under regimental regulation. No spirit is issued till 6 p.m. One pint of beer is issued at noon for dinner; another pint and a dram are issued after sunset; no liquor can be obtained at any other time. The evil effects of spirit drinking were manifest during the last service in the field. The canteen is shut to convalescents, unless the medical officer should recommend them to have beer. No drinks other than intoxicating drinks are sold at the canteen. Every kind of spirit or intoxicating agent is prohibited in the bazaar. 4. The consumption of spirits in excess is injurious, and they are also injurious during exposure to the sun. In moderate quantities, especially in the shape of beer or porter, it is useful in promoting digestion. Spirit is the bane of the European soldier when taken in excess, and a frequent cause of crime and breach of discipline, but the hardest drinkers are not always the least courageous or intelligent soldiers. Being issued from the canteen, it is better than to procure it from the bazaar. 5. It would be better if the troops drank only beer or porter, but they will have spirits, and it is better they should have good spirit from the canteen, than bad from the bazaar or surrounding villages. When the men have money and inclination, they get spirits; but it might be prohibited to boys or lads under 18. 6. Malt liquor and wines promote digestion, and are less liable to be taken to an injurious extent. The stimulant action of the alcohol is combined with a bitter and aromatic principle, which acts as a tonic and modifies the reaction from spirits, thus preventing the reaction which inclines to stimulants. 7. Coffee and ginger beer are largely consumed at the station. Coffee in the early morning and on the line of march is of the greatest advantage. Tea is agreeable in the hot season and rains. Spirits are always injurious in the morning, and it is better not to taste them, or wine or beer, till the sun has set. 8. It would be beneficial to the health to abolish the spirit ration, and to substitute for it beer, tea, &c.; but I doubt its being practicable, particularly with old soldiers. If all kinds of alcoholic drinks were stopped, there would be danger of opium eating taking their place. In marching, during a campaign, they cannot be dispensed with. 9. The abolition of the sale of spirits would drive the men to the bazaar to get a worse and cheaper liquor. 10. The recommendations I have to make on these points are to encourage the men to drink beer, by having it good and cheap, and not to sanction the use of spirits till after sunset. 11. The following are the more important of the canteen regulations :— "The canteen is opened at 12 o'clock for the issue of one pint of beer per man, which is taken to the barrack-room for dinner. "It is opened again at 5 o'clock for the issue of one pint of beer and one dram; one hour to elapse between these two. "A corporal from each company attends while the canteen is open to mark up issues. "The canteen is closed at gun-fire. "Defaulters are not permitted to enter the canteen. "A coffee shop is established near the reading-room." All the orders are strictly obeyed.
VI. Diet.	1. The daily ration issued to British troops consists of,—bread, 1 lb.; meat, 1 lb.; rice, 4 oz.; sugar, $2\frac{1}{2}$ oz.; tea, $\frac{5}{7}$ oz., or coffee, $1\frac{3}{7}$ oz.; salt, 1 oz.; vegetables, 1 lb.; and firewood, 3 lbs. The vegetables vary according to the season—potatoes in spring; cauliflower and cabbage in the cold season; and pumpkins in the hot and rainy season. Beef is issued five days and mutton two days in the week. The ration is inspected every morning by the quartermaster, and occasionally by the commanding officer and surgeon. A regimental committee is held on provisions considered unsuitable, whose decision is final. 2. The ration is complete, and the supply of vegetables is sufficient. There is no stoppage. The number of meals per diem is three—breakfast at 8 a.m., consisting of tea, bread, eggs, and fish; dinner at 1 p.m., of soup, meat, vegetables, &c.; tea at 5 p.m., consisting of tea and bread. Milk, butter, fish, eggs, &c. are provided in addition to fruit when in season. The troops have at least 1 lb. of vegetables, either potatoes, onions, turnips, carrots, cabbage or cauliflower, and pumpkins. About 20 oz. of green vegetables are allowed in the ration. 3. The grass-fed mutton, which is served out twice a week, is very inferior; it would be beneficial if a superior quality were allowed. The practice of allowing the men to purchase and use extra articles is general, and works well. The rations are cooked by responsible individuals; the men do not see them till on the table; they are served out to mess orderlies. No attempt to dispose of the rations by the cooks or men has ever been suspected. 4. The cooking utensils in use per company are—2 copper boilers of 8 gallons each, 2 ditto of 7 gallons; 2 ditto of 2 gallons; 4 gridirons, 4 frying pans, 8 ladles, 4 choppers, and 4 buckets. The copper vessels are tinned and repaired by the commissariat department when required. The kitchens are clean, light, well ventilated, and sufficiently supplied with water. The food is varied in its preparation according to the taste and pleasure of the mess. The cooking is good, and the facility with which cooking-places are constructed on a line of march, and a varied dinner produced under difficulties, is worthy of notice. The men have tea or coffee sometimes before a march, and sometimes during a halt half way. Coffee is generally used. 5. The wells being deep, and the water salt, and the hot dry wind being very intense, gardening can only be conducted under difficulties, which are rarely encountered by

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	officers who can afford to pay well for the amusement. The proceeds of a garden would not pay the expenses of an establishment, without which soldiers' gardens could not be kept up. They would be advantageous if the men could be induced to work in them; but this very few of them will do, except for a novelty the first week or so.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress consists of a wicker helmet with kakee puggree, or kakee American drill trousers, and short frock in the hot season, short boots, black leather pouch and sword belt, flannel waistcoat, shirt, cholera belt, and socks. For winter—full dress green cloth tunic and cloth trousers, undress serge frock and tartan trousers. A tight-fitting cloth coat is not suited for service in India, a loose cotton dress answers better, with a cotton padded overcoat for cold weather and night work. The Kilmarnock cap is not suited to this climate. The broad leather belt across the breast for supporting the pouch is oppressive during a march, two narrower belts crossing at the back and coming over the shoulder, and straight to the waist belt, would be an improvement. The dress should be made to fit loosely, particularly about the neck. The guard dress is the same as that for parade. Sentries are protected from sun and rain.
Duties.	1. Whatever perfection a recruit might attain in drill at home, he would have to go through it again at the head-quarters of his regiment; this is necessary, but as a recruit is non-effective till drilled, this period should be spent in the healthiest climate, more particularly in the case of growing young lads, who fill out best in a cold climate. 2. During the hot season the following are the soldier's duties:—He rises at gun-fire, half an hour after which is parade; guard mounting takes place at the same time. Short drill every morning, and three times a week without arms; setting up drill for half an hour. Breakfast at 8, and dinner at 1 p.m. Evening parade is at 6 p.m.; there is no drill then except for defaulters, 1 hour. During the cold season parade takes place at 6.30 or 7 a.m., drill till 8 every day; breakfast at 8.30; dinner at 1 p.m.; evening parade, 5 p.m. Instruction drill three times a week till 6 p.m., and three times a week general drill. The drills are beneficial to health, as exposure to the sun is avoided. The above-mentioned hours are satisfactory. The hours for marching should be so arranged as to enable the men to reach the camp at 8 o'clock in the cold season, and at sunrise in the hot season. The men have between four and five nights in bed on an average. 3. The regimental guards mount on the parade ground, and are relieved every 24 hours. The garrison guards mount on the grand parade, one mile distant from the barracks, once a week. Rolls are called by day at rouse, breakfast, dinner, evening meal, and at morning and evening parade, and at tattoo, and only at night when necessary. There are no particular evil results from night guards. As a precaution, it is necessary to insist on the wearing of a woollen belt in cold and damp weather.
VIII. Instruction and Recreation.	1. The means of instruction and recreation are as follows:—There is a good double ball court, and a good double skittle alley for the infantry; single alley for the artillery. There is a good regimental schoolmaster and five assistants in the infantry, but no assistant in the artillery; and there is a good Government library and reading-room, indifferently lighted at night. A soldier's garden exists in the vicinity of the artillery barracks, in which the men walk; it is worked by natives, and supplies the messes with vegetables. There are no soldier's clubs or day-rooms nor any workshops. No building is available in the barracks for the purposes of a theatre, but the company have use of a public building in the cantonment. There is no gymnasium, as the spot should be protected from the sun. The above means are insufficient to keep the men occupied during the wet season and the heat of the day. The men are strictly forbidden to leave the barracks in the hot season between morning and evening parades. This rule is essentially necessary when the hot winds are blowing; the restriction is very irksome, and the period of restraint is gradually diminished as the mornings and evenings get cooler, but the avoiding of exposure to the sun is essential to health. 2. A large covered building near the barracks, as a gymnasium, would be available for many games, and would draw many men from their cots where they idle and sleep all day. A large swimming bath is very useful. Workshops might be introduced with great advantage, where the men might profitably occupy their spare time both mentally and bodily. 3. Soldiers' savings' banks already exist, and are advantageous for provident men; but there is no harm in the men spending their pay in innocent enjoyment. 4. There is not sufficient shade from trees, sheds, verandahs, or other means for the men to take exercise during the hot weather without injury to health. Trees in the vicinity of the barracks would be objectionable.
IX. Military Prisons.	1. The cells are a range of tiled rooms, with a verandah on each side, surrounded by a high wall. They are freely ventilated, and no sickness has been induced by residence in them attributable to the locality.
X. Field Service.	1. There are no local regulations for field medical service not included in the general presidency regulations. 2. The medical officers are not consulted regarding the sites of camps, which are selected by the quartermaster in advance. Further than general advice as to the hour of marching, and the avoidance of low damp camping grounds, their advice is not looked for. 3. The camp is pitched in clear high ground near a supply of good water. In the hot season under trees the shade is agreeable, but in the rainy season it is dangerous; the water is supplied in leather skins by water-carriers. Nuisances are prevented close to camp, but in a few days the vicinity becomes disagreeable. When a camp is expected to be stationary for days, trenches are dug, which are covered in every day. The medical officer has to attend to the sanitary state of the lines of his corps. 4. During service in the field 10 per cent., and during peace 5 per cent., of dhoolies are supplied for the conveyance of the sick. There is no more comfortable conveyance for a sick or wounded man than this; the motion is moderate, the rate of progress is about

References to Subjects and Queries.	REPLIES.
X. Field Service—*cont.*	3½ miles per hour, and the dhoolie forms the bed of the wounded man, without the necessity of moving. The great objection to the dhoolie lies in the number of men required to carry it, viz. 6. A two-wheeled spring cart, drawn by bullocks, is well adapted to this country. The medicines and stores are carried by camels in large camel trunks. Food and necessaries are supplied by the commissariat department. The regulations in reference to field hospital service are contained in the new Medical Code, published in 1851.
XI. STATISTICS OF SICKNESS AND MORTALITY.	No information under this head.
XII. HOSPITALS.	1, 2. The infantry hospital is 400 yards north of the barracks. The artillery hospital 14 yards west of them, 835 yards distant from the stables, and 150 yards east of the bazaar. The city of Agra is about 2 miles to the N.N.W. The site is open, with neither houses nor trees to interfere with ventilation. It is healthy, but the drainage is rather defective. There is no malaria from the river, which is two miles off, and there are no nullahs, ditches, or other nuisances near that are the cause of sickness. 3. The supply of water is ample from wells, though it is generally very salt. There are several sweet wells that are generally used for drinking purposes; they are near tanks. The river water, when filtered, is good, except during the rainy season, when it is said by the natives to be heating. 4. There is no surface drainage during the hot and cold season, the washing and bathing water spreads over the ground and sinks into the soil or evaporates. The stool pans are emptied into the well privies; this is being altered, and a privy and wash-house like those used in the barracks are being built. The main drain which runs after heavy rains, during the rainy season, passed in front of the hospital gates, but it is not offensive. 5. The hospital has only a single floor, which is raised 2½ feet, and is filled in with earth. The roof water sinks into the subsoil when not very heavy. After a heavy fall it runs off by the compound drains to join the main drain in front of the hospital gate. There is a saucer drain between the two blocks of buildings, which drains the whole compound, the earth being sloped down from the hospital to the drain. The surface water does not lodge in the compound. The walls of the hospital are built of brick and mortar, 2 feet thick, with a thatched roof, 9 inches thick; neither are double. There is free ventilation, and the roof and walls are sufficiently thick to keep the building as cool as practicable. The inner ward is surrounded by double verandahs, 12 feet and 10 feet wide, and they afford sufficient shelter from the sun's rays. The inner verandah is frequently occupied by the sick and convalescents. The hospital consists of a ground floor only. Table of hospital accommodation:— The date of construction is unknown, the records having been destroyed. Total number of wards - - - 3 Total regulation number of beds - - 120

Wards or Hospital Huts, No.	Regulation Number of Sick in each Ward or Hut.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patients' Beds above Floor.	Doors.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Feet.	Feet.	Feet.				Feet.			
European Infantry 2	40	123	24	29	85,408	2,135	73·7	1·5	20	8·25	4
Artillery 1 - -	40	110	20	24	52,800	1,320	55	1·5	20	9·	4

The hospital receives the full benefit of the prevailing winds. There are no windows, only doors, which, when open, allow of free ventilation.

6. Ventilation is effected by open ridge ventilators all along the roof. The doors are all opened in the morning, and kept open during the day in the cold season; they are closed by tatties during the hot season, through which the air passes freely. The thermantidotes also serve to renew the air in the wards, which at all times are free from odour or closeness. There are no jalousies or jhilmils.
7. The tatties used to cool the air of wards are bamboo framework, covered with the aromatic roots of a marshy grass. They are kept constantly wet, and the evaporation cools the dry wind in passing through in the hot season. The thermantidotes are machines on the principle of the blast furnace in England; they draw the air through the tatties and blow it into the ward, reducing the temperature from 120° Fahrenheit to under 80° Fahrenheit. Punkahs are used day and night to cool the patients; they are wooden frames covered with cloth with a deep fringe.
8. There is no apparatus for warming the wards. They are cleansed and whitewashed quarterly by regulation, or oftener if the sanitary officer recommends it.
9. The privies and urinals are of the same construction as those in the barracks, and are connected with the building by a covered way. The old privies were over cesspits, and were very offensive, but those now being constructed are as already described.
10. A wash-house like those in the barracks is in the course of construction, and will be sufficient for the wants of the sick.
11. There are bathing tubs for the use of the sick, which are sufficient for the purpose and convenient.
12. The hospital clothing is taken by the dhobies, or washermen, to the river and washed, and afterwards dried on ropes. The washing is well and efficiently done.
13. The storage is sufficient and dry.
14. The cots used in the hospital are wooden frames, 6 feet by 2 feet, raised 1½ feet from the ground, and covered with newar or rope. The mattresses are 3 inches thick, stuffed with hemp and covered with red cloth; the pillows are similarly constructed. The covers and sheets are cotton, with woollen blankets or wadded cotton resais.
15. The hospital kitchen is similar to that in the barracks, and is about 60 yards to the north of the sick wards. The cooking vessels are copper, tinned twice a month, and kept in good order; they are sufficient for the requirements. The diets vary according to the orders of the medical officer.

References to Subjects and Queries.	Replies.

XII. Hospitals—*cont.*

16. Copies of returns forwarded which are required for working the internal economy of the hospital.

17. Besides the regular subordinate hospital establishment of apothecary, steward, assistant apothecary, and hospital apprentices, and the native establishment of compounders, dressers, coolies, &c., there are no regular hospital nurses or orderlies. In special cases soldiers are allowed to act as orderlies, and particularly when restraint is required, or the patient is dangerously ill. The duties of the hospital serjeant are confined to the discipline of the patients. When the medical officer cannot speak the language of the natives, he is much at the mercy of his subordinates, and this should be avoided. Every medical officer should pass the colloquial examination before receiving charge of a corps in India.

18. The hospitals are kept clean and well ventilated, and as free from disease as ground-floor hospitals of this construction can be. No hospital gangrene or pyœmia have appeared in them.

19. All tropical hospitals should be two-storied buildings. Privies and wash-houses are in progress of being built, and the ground levelled and the drainage improved.

20. Convalescents are taken out morning and evening on elephants, and occasionally in the dhoolies for exercise. No trees or shaded walks are allowed near the hospital; the compound enclosed being a bare grass field, green in the rainy season, and brown during the hot season. There are seats in the verandahs, and arm chairs for the use of the patients.

21. There is a female hospital adjoining the general hospital, with female servants, for serious cases. Slight cases are treated in the barracks. The present arrangements for the attendance on the soldiers' sick wives and children are satisfactory.

22. There are no special local hospital regulations not included in the general Presidency Medical Regulations.

23. The sanitary state of the hospitals is entirely under the authority of the medical officer, under the supervision of the sanitary officer of the station. His requisitions regarding repairs are attended to, and if necessary enforced by the requisition of the deputy inspector general of hospitals. All changes of diet and medical comforts within the hospital are made by the medical officer. The supply of medical comforts is most liberally furnished, both in stations and on the line of march.

24. There are no convalescent wards. When free from disease, the men regain strength more rapidly under light duty in the barracks than lingering in hospital.

XIII. Burial of the Dead.

1. The burial ground for British troops is half a mile to the east of the European barracks. The prevailing winds are westerly.

2. Its area is about 100 yards square, on a light sandy soil, where water does not lodge. Decomposition takes place readily. The grounds are carefully kept.

3. The interval between the graves is about six feet, and the depth of the graves is five feet. They are not reopened. Only one body is buried in each grave. Interment is compulsory from 10 to 16 hours after death at ordinary times and during epidemics. The bodies of natives are removed immediately after death, and those of the Hindoos are burnt or thrown into the river. Those of the Mussulmen are buried.

4. The grave yard is never offensive. After death the bodies of British troops are removed to the dead house and examined by the surgeon; then put into a coffin, and taken to the burial place in the cool of the morning or evening.

5, 6, 7. The dead of the camp followers and bazaar people are burnt, if Hindoos, on the banks of the Jumna; and if Mussulmen, buried beyond the limits of the cantonments. No injury accrues to the public from the present practice. No improvements are suggested.

(Signed) John Murray, M.D.,
Deputy Inspector General of Hospitals,
Agra.

27th August 1860.

LANDOUR (CONVALESCENT DEPÔT).

Accommodation,—Queen's Troops - - - { The barracks and bungalows will accommodate something under 200 fighting men, and these are selected from all branches of the two services annually.

Native Troops.—Infantry.—A serjeant and 25 men take the guard.

References to Subjects and Queries.	Replies.
I. Topography.	1. The country surrounding this station is mountainous. There is less wood and jungle in the vicinity of Landour than at other hill stations. No prohibition exists for their removal for domestic purposes. The supply of water, excepting in very hot weather, has been tolerably good until the last few years. This year it has been very scanty, which is said to be due to the absence of trees in the neighbourhood of the springs. 2. The elevation of the station above the sea is from 6,500 to 7,000 feet, and about 4,000 feet above the adjacent country. There is plenty of higher ground adjoining the station; but as to its being healthier depends upon a variety of circumstances. Its nature is mountainous and its elevation varies from 7,000 to 10,000 feet or more. 3. No answer to this query. 4. The Ganges and Jumna run through the Dhoon at a distance of about 5 or 6 miles in a straight line from Landour. The vicinity is not liable to overflow of water. There are immense khuds between the various mountain peaks. 5. The station generally is open and freely exposed to the prevailing winds, uninterruptedly so in the direction of the plains. In the north-east and west it is surrounded by immense chains of mountains. The temperature of the station is not raised by exposure to reflected sun-heat. The station is exposed to winds from the plains, and more frequently, I believe, from the interior hills (the snowy range). The effect on health is beneficial. 6. The surrounding country is very slightly cultivated. There are works of irrigation at a distance of 7 or 8 miles in a direct line. 7. The town of Dehra is distant about 10 miles from the station. 8, 9. No answer to these questions. 10. There is adjacent higher ground, but the drainage does not pass into the station; it simply passes through it here and there. 11. The water supply of the station is derived from wells; it is not stored in tanks. 12. I cannot ascertain, with any degree of precision, the amount of the water supply available for the station; but it is not abundant, excepting in the rains. Its colour, taste, and smell are good. 13, 14. No replies to these queries.
II. Climate.	1. There are no instruments for conducting meteorological observations, excepting those in private hands, and a rain gauge at the office of the Trigonometrical Survey. 2. Table of meteorological observations for 10 years.

From January 1850 to December 1859.

Months.	Mean Dry Bulb.	Mean Wet Bulb.	Rain, Inches.
	°	°

3. The climate of Landour like that of all hill stations is very moist for some months of the year; but I am not aware of any peculiarity in the nature of the atmosphere, excepting that due to elevation. I have only resided here during one entire season, and am, therefore, unable, satisfactorily, which are the most healthy and unhealthy months. Diarrhœa of an obstinate character, dysentery, and chest affections of children have lately been prevalent.

4. There is plenty of higher ground near the station, but there is no proof of its greater salubrity.

5. I have served at most stations in this presidency since 1842, and at several in Madras. Some of the Punjab stations, such as Rawul Pindee, and Sealkote, are the healthiest perhaps, and Meerut and Umballa are also healthy if the troops are well looked after, for much depends on this. Among the positively injurious stations at which I have served, I may mention Calcutta, Chinsurah, Berhampore, Dinapore, and Allahabad fort. The hill stations vary so much that I cannot here give the information as I would wish.

Guard Rooms 1	2	10	15	12½	1,875	937	75	1½	1	3	2
Prison Cells 4	4	13	8	14	5,824	1,456	104	—	1	2½	2

5. The windows of the small rooms are on one side, and the doors on the other, and the windows of the large rooms are on opposite sides. The windows open in the inside, and the jalousies or venetianed shutters on the other. There are open verandahs 38 feet by 8½ feet, on both sides of the barracks. These are never occupied as sleeping quarters, but the men breakfast and dine in them. All the windows which are not protected from the weather by verandahs have jalousies or jhilmil shutters.
6. The bedsteads are wooden, with interlaced tape or Newar bottoms; a highly objectionable plan, as they harbour vermin and accumulate dust and dirt. Iron bedsteads are the best.
7. There are no tents in use here.
8. The barracks are ventilated by means of the doors and windows, placed opposite each other, and opening inwards. The ventilation is only sufficient for a part of the season, and the barracks cannot be said to be well ventilated, and are moreover overcrowded. There is no roof ventilation in some of the barracks. No means are required at this station for cooling the air of barrack rooms.
9. The barracks are constructed of stone, and lime plastered and whitewashed within and without. The roofs are thatched.
10. The floors are terraced, and generally raised about one foot above the level of the ground. Some of the rooms are approached by steps of stone.
11. The materials of which the barracks are constructed are all that could be desired. Better ventilation is wanted, but this can hardly be effected without rebuilding the whole. The barracks and cantonments are kept in repair by the Public Works Department, and I have experienced no delay in getting repairs executed. The medical officer is believed to be responsible for the sanitary state of the cantonment. The periodical repairs, whitewashing, &c., are executed annually, when the buildings are vacated by the troops re-joining their corps, and at any other time when the medical officer may deem it necessary.
12. To all the large barracks is attached a spacious washing house, furnished with brass basins fixed in a row, in a trough, but from the scanty supply of water during the dry season these are not used much, and the men wash in earthen vessels. The drainage is at each end, towards the slope of the hill.
13. Water is supplied to the cook-room by the barrack department. It is carried on mules from a distance of 1½ miles. The refuse water is drained off, as above. The washermen frequent a ghat or stream about a mile down below the barracks, where there is an abundant supply of pure running water at all times, and here they perform the washing and drying of the linen of the station.
14. The privies and urinals are properly drained. Their contents are removed twice daily by sweepers and carried away to a sufficient distance from cantonments.
15. Barracks are ventilated and lighted by doors, windows, and chimnies as formerly stated. At night they are lighted by lamps, but not sufficiently; this is to be looked to and improved.
16. The barracks being situated on the summit of a hill range, no artificial drainage is required, the natural drainage being sufficient to carry the whole of the surface water down the surrounding khuds or ravines into the numerous mountain torrents. For three months of the year during the periodical rains, every house is more or less damp; but this is obviated as much as possible by fires, &c. There are no foul ditches near the station.
17. An establishment of sweepers has this year been sanctioned for keeping the public roads and their vicinity and the neighbourhood of the barracks clean. This is in addition to the work performed with the same object by the barrack-master's department, and private householders, &c., are held responsible for their own domains and grounds.
18. The surface of the cantonment is kept as free as possible from vegetation by an establishment of men kept for the purpose. There are no old walls, thick hedges, &c., interfering with the ventilation of the station, bazaar, &c.

LANDOUR (CONVALESCENT DEPÔT). BENGAL.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station —*cont.*	19. A small establishment of sweepers is kept up from a fund produced by a light house tax, for police purposes. Native residents are besides held personally responsible for the cleanliness of the interior and neighbourhood of their dwellings. Native houses in cantonments are kept clean; but those in the neighbourhood are not remarkable for cleanliness, all the hill men of the district being filthy in their habits. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. The public slaughter-houses are a mile below the barracks, in the neighbourhood of the principal bazaar. The offal is removed and burnt or buried. There is no nuisance discernible. 21. There are few, if any, horses kept in the bazaar. Those of residents are scattered all over the station in the stables attached to private dwelling houses. The manure is frequently sought for for private gardens. 22. There are no artillery or cavalry horses at the station. 23. The married people occupy separate houses, or, in one or two instances, rooms in the barracks, but quite apart from the unmarried soldiers.
Officers' Quarters.	1. The officers at Landour live in bungalows, rented by them for the season. There are no separate officers' quarters at this station.
IV. HEALTH OF THE TROOPS.	1. The station is undoubtedly healthy, and is, therefore, used as a sanitarium for regiments on the plains by officers and their families, and by retired officers, invalids, &c. 2. Small-pox is occasionally met with in the neighbourhood. Bad fever or its effects (spleen) only in the valleys of the mountains, far from the station. Goitre is also a common affection among the hill people. 3. The healthiness of the neighbouring native population is attributable to the pure bracing climate. The natives, it is presumed, would be less liable to disease were it not for their inveterate filthy habits. They seldom wash or change their clothes. 4. The troops at present stationed here are entirely sick and weakly men, sent up for the recovery of their health at the commencement of the hot season (about the 1st of April) from Agra, Delhi, Meerut, &c. The chief diseases are fevers, liver and bowel complaints, and general debility. Very few of the men are under treatment here, except for their original maladies or accessions of them. I am not aware that any portion of the men's present accommodation is more unhealthy than the rest. 5. The troops at this station are never camped out. 6. I have been for several years with troops in the hills, viz., Kussowlie and Landour, and have visited Simla, Subathoo, and Murree (sanitaria). I think that cases properly selected do well generally at these hill stations. Fevers and diseases of the liver and bowels contracted on the plains usually recover, but rheumatism, bad syphilis, &c., get worse. 7. I have observed that diarrhœa, &c., contracted in the hills (I allude particularly to Kussowlie) never almost gets well until the patient is removed to the plains, and not then, unless the disease be taken in time. I do not think bad fever (intermittent) cases, with spleen affection, should have less than 12 or 18 months of a hill station. 8. I think the hill stations should, as a rule, be set aside for the reception of sick and weakly men, carefully selected at intervals from regiments on the plains, and not used as stations for whole regiments. I speak from experience of the fatal diarrhœa, so usually prevalent at Kussowlie, &c.; but this may have been from overcrowding in faulty barrack rooms. 9. There are no particular diseases by which troops are liable to be attacked on first going to hill stations; but in former years I have known scorbutic diarrhœa almost decimate a regiment at one station (Kussowlie). Landour is remarkably healthy, and free of that disease. 10. All the necessary precautions for preserving the health of the troops are generally enforced here, and at other stations in the hills which I have visited. To give the men fair play, they ought not to be overcrowded in barracks. 11. As a rule, from 15th March to 15th November is the best period adapted for a residence in the hills, as weakly men thus escape the hot season in the plains, but there are exceptional cases which require a cold season in the hills besides. Six or eight months is the shortest period of residence which would enable troops to obtain the full benefit to their health. 12. There is no period of residence in the hills beyond which injury is likely to be inflicted on the health of troops, except where they suffer from hill diarrhœa. 13. Ordinary precautions I have found to be sufficient, if properly enforced, for protecting the health of troops on leaving hill stations for the plains. 14. I incline to think that service in the plains, with short periods of service in the hills, is most conducive to the health of troops; but I would insist on numerous sanitaria in the hills, with the best possible barracks, &c. Troops should never be kept long in an unhealthy station, nor even in a healthy one which has suffered from a bad epidemic visitation, as they are sure to suffer in health and get reckless. On the other hand, frequent removal of troops entails great expense on the married people and on all the officers. 15. The hospitals I have visited at hill stations seemed ample in accommodation and well constructed. In some particulars the barracks, as already stated, are faulty, but chiefly from putting more men into them than they ought to hold. 16. I think an elevation of 7,000 feet on the whole would be the best for sanitaria. For regiments or large detachments of men presumed to be in health, perhaps this is too great an elevation—say, 4,500 to 6,000 feet for them. 17. Although there are higher ranges in close proximity to this station, they could not be advantageously occupied as hill stations. 18. With reference to the particular class of surface and subsoils most healthy for stations, I think limestone formations, with good natural drainage and moderately wooded, the best; but many circumstances must influence a definite answer to this question. 19. Troops should not be sent to India under 21 years of age; but from that to 25 is the best period. They should land here from 1st November to 1st February in the best season at Calcutta or Kurrachee, as many of them have to march 1,000 or 1,500 miles, and exposure in tents, even in March, does not suit any one, especially a recruit fresh from aboard ship. I do not know what is the rule now for the disposal of troops on first landing. They used to be sent at first (in Bengal) to Chinsurah, the worst and most objectionable station in the world, and then marched or sent up the Ganges in country boats. I would send recruits as soon as possible to the head-quarters of their regiments, give them no spirits, moderate

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	drill at proper hours in proper season, and attend particularly to their head-dress and clothing. 20. I think troops should be sent direct from the home depôts to India. A soldier is always better off, happier, and most carefully looked after with his own regiment. Perhaps selected cases ought to be sent to the hills on landing, but if a regiment is stationed at Meerut, and above it (I only allude to this Presidency), the recruits who land, say in October, ought to march up to join. No regiment should be stationed in Lower Bengal at first, in such stations as Calcutta, Berhampore, Ghazeepore, Dinapore, Benares, or Allahabad. 21. Detachments often proceed, 100 or 150 men at a time, by bullock train, each cart holding about six men, and travel by night about 24 miles on a stretch. Sometimes they march 600 or 1,000 miles from Calcutta to their regiments, and I think usually keep very healthy by either of these modes. Steamers with flats attached are occasionally resorted to. Country boats have been discontinued for many reasons. 22. As a rule, 10 years is quite long enough for a British soldier to serve in India, and every man ought to have a season or two in the hills out of that. 23. I have always seen medical boards fairly conducted, and therefore make no suggestions. 24. Invalids should undoubtedly leave India for home in the spring, so as to land in the finest weather, avoiding of course the bad season in south latitudes.
Diseases.	1. At the commencement of the season when the invalids arrive at this station, every man is daily examined; afterwards once or twice a week, or, if any disease prevails, oftener. 2. There has been no scorbutus or scorbutic disease among the troops at this station. 3. I find that about 12 per cent. of the cases sent for recovery this season are hepatic. The causes are the climate and exposure, with here and there dram drinking. I think hepatitis is usually, at least out of Lower Bengal, idiopathic. Plenty of healthy exercise, athletic games, &c. would diminish the frequency of liver disease. 4. No cases of dracunculus are ever seen here. 5. A good many cases of secondary syphilis and sypbilitic cachexia are very improperly sent here. As a rule, they do not derive any benefit from the climate; and nodes and rheumatic affections, complicated by syphilis and mercury, get worse. Primary venereal affections are extremely uncommon here. I always endeavour to make the soldier point out the woman who he believes diseased him, and examine her. Periodical inspections for venereal among the troops is an unnecessary and filthy duty. There should be a lock hospital at every station, and the medical attendant paid. 6. The troops at this station suffer from :— *Fevers.* Usually relapses of the intermittent, quotidian, or tertian contracted on the plains, and occasionally from common continued fever, from exposure. *Dysentery.* Seldom, except as a relapse. *Rheumatism* is common enough among the men, and occasionally happens as a fresh disease. There are no data to enable me to state what proportion admissions and deaths from the above diseases bear to the total admission and deaths. Cholera is not known here among the troops, and no case of small pox has occurred for several years. 7. Very few cases of disease of any description originate among the troops stationed here. All of the men are invalids from regiments on the plains sent here for their recovery. 8. No epidemics have prevailed here. 9. Small doses of quinine are never required at this station as a prophylactic against malarial disease. I give large doses to cases of intermittent fever in preference to small ones. 10. A dispensary for the treatment of natives would be a great advantage. All cases of contagious disease (*e.g.*, small pox) are instantly, on being discovered, sent down from the hill some miles from the station.
V. Intemperance.	1. The soldiers at this station are very temperate generally. Men of bad character are prohibited from being sent here. Very few men have the chance of drinking hard at this station. Liquor is difficult of obtaining from various causes, and the canteen and police regulations are good and strictly adhered to. Moreover, as every soldier at the depôt is looked upon as an "out-patient," none of them are allowed spirits or malt liquor even, without the express sanction of the medical officer in charge. 2. I am not aware of any fresh case of disease having been under treatment in hospital this year caused by intemperance; though doubtless many cases of outstanding hepatitis are due in some degree to that cause. There are only two or three total abstinents, and not above that number of inveterate drunkards. Drunkenness is always punished as an offence. 3. Distilled spirits are sold in the canteen to such soldiers as are allowed, by the surgeon, to procure them. They are not sold in the bazaar to the troops. The maximum allowance is two drams a day per man. The canteen is open for the sale of malt liquor only at the dinner hour, and for spirits only in the evening. No man attending hospital draws spirits on any pretence. No drinks other than intoxicating drinks, injurious to health, are sold at the canteen or bazaar. 4. I see no objection to the use of good spirits as part of the ration, and consider that, in moderation, they are conducive to the health of the troops. Of course I do not allow it to convalescents. In well-regulated canteens I see nothing deleterious to the discipline or efficiency of a corps in the consumption of good spirits by the men, and it is much better that the soldier, who in these and in all times past and present will have his liquor, should draw it openly from his canteen, with good rules and strict surveillance, than be driven to seek deleterious trash from natives or others. 5. I would not advocate, for the above reasons, the abolition of spirits to the soldier. Every regiment has a different code of laws on this subject. I would never issue spirits, however, before sunset. 6. I think the health, morality, and discipline of the troops have very much improved during the past few years that malt liquors have been so much encouraged. 7. Coffee, tea, lemonade, soda water, &c., although always procurable, are not much sought after, owing to the coolness of the climate. 8, 9. I do not advocate the entire suppression of spirit, but would discourage it as much as possible, substituting good malt liquor. There is excellent beer and porter brewed by

LANDOUR (CONVALESCENT DEPÔT). BENGAL.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	Messrs. Mackinnon & Co., close by, but the commissariat issue their own malt liquor which is occasionally bad. 10. No recommendations to make on these points. 11. The general regulations of the service for canteens are strictly adhered to. Spirits are always "drunk on the premises," the names of the men being checked by the orderly serjeant on duty. The issue of malt liquor is checked in a similar manner, but the men are permitted to carry away their allowance to the dinner tables. There are no particular bazaar regulations, merely a general order absolutely prohibiting the sale of liquor of any kind to soldiers, and there is every reason to believe that the order is strictly obeyed. No native liquor is manufactured in the station, and its clandestine introduction is strictly guarded against, and with considerable success.
VI. DIET.	1. The composition of the soldier's ration at this station is as follows:—bread 1 lb., beef or mutton 1 lb., vegetables, generally potatoes, 1 lb., tea, black and green, $\frac{5}{7}$ oz., or coffee $1\frac{3}{7}$ oz., sugar $2\frac{1}{2}$ oz., rice 4 oz., salt 1 oz., and firewood 3 lbs., throughout the year. Every article of the ration is daily inspected by an European officer with the quartermaster serjeant previous to issue, and occasionally by the commanding officer and surgeon. 2. A complete ration with vegetables (potatoes for at least nine months of the year) is provided for the troops. The soldiers have three meals daily, breakfast at 8.30 a.m., dinner at 1.30 p.m., and tea or supper at 5 p.m., varying slightly with the season. The stoppage is 3 annas and 4 pice daily. One lb. of vegetables enters into the composition of the ration, but the supply is uncertain, and not much varied. Excellent potatoes, however, are grown in abundance in the neighbourhood. 3. No improvement can be suggested in the ration, which is very good in quality (bread excepted occasionally) and sufficient in quantity. 4. The cook rooms are furnished with the usual apparatus for boiling, stewing, and grilling, and occasionally baking may be accomplished. The kitchens are clean, and pretty well ventilated, but the cook boys are filthy in their habits and persons. The cooking is properly done and sufficiently varied, and tea and coffee are properly prepared for the men. 5. The establishment of gardens for the cultivation of vegetables by soldiers would be advantageous, but the scarcity of water here is a great drawback. Moreover, the men are weakly, and not here long enough to take much interest in horticultural pursuits, although there are a few plots of vegetables, &c., about the barracks.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The dress which is the ordinary costume of the soldiers varies with the season. There are no arms or accoutrements of any kind. The dress, as enforced by the military and medical authorities, is suitable to the climate and the soldiers' duties by day. There are no night duties at this station. I think the introduction of the khakee or drab colored loose tunic for the hot weather leaves little to be desired. This with a felt or other light helmet properly constructed, and further protection to the head by folds of cloth round the helmet as a turban, is most suitable. I strongly advocate a flannel shirt at all times, as it is cool in summer, and with other clothing adapted for night duties in cold climates. Of course cleanliness would have to be looked to. I think the men's boots are generally as badly made as possible.
Duties.	1. It would, perhaps, be desirable to drill the men at home before sending them to India, but not at any intermediate station. 2. The men in tolerable health here are marched round the hills (about 2 miles) daily. There are no drills, only an occasional commanding officer's instruction parade. The best time for drill is before breakfast, except in the winter months. The men have 7 nights in bed during the week. 3. A guard without arms is mounted daily. There is also a guard of a corporal and 4 men whenever there is a prisoner, which is rare. There are no roll-calls.
VIII. INSTRUCTION AND RECREATION.	1. The following are the means of instruction and recreation at Landour: a first-rate ball court; 3 skittle grounds, and another one in course of construction, a schoolroom for children only, attended by a few soldiers daily, a good library well supplied, and also a theatre, but not much frequented. There are no reading rooms, day rooms, soldiers' gardens, workshops, or gymnasia. The climate is usually so good that the men are much and advantageously in the open air. No restriction on the men as to exposure to sun and rain is required in this climate. 2. A good and well looked after reading-room would be advantageous. 3. I do not think it would be of any use to institute soldiers' savings' banks away from the regiments. The regimental savings' banks are open to soldiers at the depôt. 4. The men are not allowed to stray far from the barracks during the hot season.
IX. MILITARY PRISONS.	The sanitary state of the military prison at this station is very good. It is well ventilated, and heated by a stove for winter use; but the cells are very seldom required.
X. FIELD SERVICE.	1, 2, I think there has been some improvement latterly in the working of the powers of medical Officers, and in a good regiment, with a reasonable commanding officer, I cannot conceive how a medical officer's powers can be merely nominal. But this is too wide a field for discussion, or even to touch on in this place or space. 3, 4. These questions do not apply to this station.
XI. STATISTICS OF SICKNESS AND MORTALITY.	No information under this head.
XII. HOSPITALS.	1. A rough sketch of the hospital is transmitted. 2. It is built on an elevated ridge open to every breeze, and it is about $\frac{3}{4}$ mile from the nearest, and $1\frac{1}{4}$ from the farthest barracks. It is 2 miles from the bazaar, and 500 to 700 feet above it. There are some private houses in the neighbourhood, but they in no way interfere with the hospital. The site is remarkably free and open, and in all respects healthy and unobjectionable. 3. The water supply suffices for culinary drinking and for ordinary ablutions, but as it is only to be had during the dry season from springs situated a considerable distance down the hill, general bathing is not obtainable. A tank might be constructed probably with advantage.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	4. The surface water flows right down the khuds or ravines, on either side of the buildings. No water can lodge. 5. The lowest wards are raised about 2 feet above the ground, and there is a free circulation of air beneath the floors. Water is conveyed from the roof by tubes aided by the slope, and it quickly drains away down the ravines. The surface drainage, &c., is sufficient at all times. The hospital is built of stone and lime, plastered and lime-washed within and without. The roof is terraced, and of composition, and pitch, and cloth (I believe). It is double and sufficiently thick to keep the place cool. A verandah 8½ feet wide runs along the north-east front of the hospital. There are none behind, but outhouses and small wards suffice to protect that from exposure to the weather. They are sufficient for the purposes required; moreover, the verandahs all have chicks or screens to shade from glare, dust, &c. The verandahs are never used for the accommodation of sick, convalescents, or others. The hospital consists of one flat.

Table of Hospital Accommodation.

Date of construction, 1846.

Total number of wards 4 (2 large and 2 small, with several small closets for select cases.

Total regulation number of beds 60 at a stretch, 50 with ease.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.*				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Feet.	Feet.	Feet.	Feet.			Feet.		Feet.	Feet.
No. 2 - -	16	23	18	17	14,962	935	53	1¾	4	4	3
„ 2 - -	44	67	18	17	42,525	966	55	1¾	16	4	3

The hospital is very well placed in respect to the prevailing winds. The glazed windows open on the inside, and the Venetian shutters or jhilmils on the outside.

6. The wards are ventilated by ventilators in the walls under the eaves, and this, together with the ventilation by doors, windows, and chimneys, is sufficient.
7. The air is cool enough at all times, without the aid of any apparatus. There are double jhilmils.
8. The wards are warmed by means of open fire-places, two in each ward. Wood is used for fuel solely. The walls and ceilings are cleansed and lime-washed once a year or oftener if the surgeon deems it necessary.
9. The privies are properly drained, and there is never any offensive odour; lime and charcoal are used to obviate this.
10. Brazen vessels filled from a trough placed above them are used for washing the sick; but at times the water supply is scanty, and the patients wash in smaller vessels.
11. The sick resort to this washhouse, or if forbidden they have the water brought to them, and this is sufficient. There are of course portable warm baths, &c.
12. The washing and drying of the linen are done down the hill at the ghat referred to in a former paragraph, and it is quite sufficient.
13. The storage is sufficient and dry.
14. Wooden bedsteads with tape bottoms, as in barracks, and a few rattan bottomed are in use in the hospital, also double inclined cots for particular cases. All cots should be of iron. The bedding is very good and supplied yearly on indent.
15. The hospital kitchen is well situated, contains every requisite, and the diets for the sick can be sufficiently varied.
16. Copies of diet tables, diet rolls, &c., are transmitted.
17. There is a hospital serjeant selected by chance, or rather by necessity, for the hospital, from the sick men on their arrival. This is a great grievance and has been repeatedly, but fruitlessly, represented. There ought to be a permanent hospital serjeant at an invalid depôt, as there are serjeant-majors and quartermaster serjeants *en permanence*. Orderlies can be obtained from barracks to wait on particular cases, and there is usually one standing orderly to help the serjeant. There are no nurses.
18. The hospital has been remarkably free of any disease or epidemic as far back as I can ascertain.
19. A separate building for female patients has been applied for, and will, I hope, be sanctioned. The hospital and its appurtenances are very good indeed.
20. Weakly men are carried out for air in sedan chairs (janpans). There is very little available ground for exercise from the position of the buildings, but such as there is has been appropriated for the purpose, and furnished with benches. There are good roads round the hills for all the men to walk about on.
21. Soldiers' sick wives and children are of course treated at the hospital, but are obliged to be taken into a spare ward.
22. As the men stationed here are considered out-patients, they are exempted from all parades and duties at the discretion of the surgeon, but otherwise there are no special hospital regulations.
23. The medical officer, with respect to the sanitary state of his hospital repairs, diet, medical comforts, &c., is very well off at this station, as every man at the depôt is supposed to be an out-patient, and no parade or duty can be held without his consent as regards time, duration, &c. Every wish or suggestion of the surgeon is attended to by the military authorities. The buildings are, of course, more under the barrack department, and are periodically looked to, but most suggestions emanating from the medical officer regarding them are quickly carried out.
24. A man discharged from hospital does nothing but attend as a convalescent until he is deemed recovered. There is no necessity for a convalescent ward.

LANDOUR (CONVALESCENT DEPÔT). BENGAL.

XIII BURIAL OF THE DEAD.	1, 2. The burial-ground for British troops is in the station, but in a suitable secluded situation on the north side of the hill, and below the barracks. The wind seldom blows towards the barracks. There is a separate cemetery for Roman Catholics still farther down. The area of the former ground is about 4 acres, with a soil and subsoil similar to that of the neighbourhood. The drainage is natural and sufficient towards the ravines below. The ground is very slovenly kept, as is the case in nearly every burial-ground I have seen in India. 3. The space allowed for graves is ample, with a proper interval between each. Graves are about 6 to 8 feet deep, and are never re-opened as far as I know. Interment, as a rule, takes place in about 24 hours after decease, but not of necessity so quick in this climate. 4. The above is both regulation and practice as regards the burial of British troops. The graveyard is never offensive. 5. The dead of camp followers and bazaar people are burned or buried according to caste. 6, 7. No injury is known to accrue to the public health from the present practice, nor can any improvements be suggested.

(Signed) F. H. CRAWFORD, Captain 98th Regiment, Commanding Landour.
L. C. STEWART, Staff Surgeon in medical charge, Landour.

1st November 1860.

N.B.—The answer to the questions under the head of topography, and as far as question five, "climate," have been given by Assistant Surgeon Jones, in medical charge of the neighbouring station of Mussoorie, where there are, however, no troops located. The book of questions was, it appears, transmitted to him in mistake, and after he had filled in the questions, so far as indicated, it was sent to me for completion. I am likewise responsible for the answer to question five, "climate."

L. C. STEWART, Staff Surgeon in medical charge, Landour.

Landour, 1st November 1860.

DARJEELING.

Accommodation { British Troops, Infantry, about 115 or 120 convalescents.
Native Troops, Infantry, 210 Scbundy sappers and miners.

References to Subjects and Queries.	Replies.
I. TOPOGRAPHY.	1. The country surrounding the station is mountainous and sandy. There is much forest and low jungle, but no water save that from springs. 2. The station is 7,000 feet above the level of the sea, and about 6,000 feet above the plains. The nearest river of any size is the Great Rungeet, 12 miles from the station by road, but about four miles in a direct line. There are many higher hills near the station, but much too high for military purposes. 3. The station is situated on the western side of a mountain, surrounded by much more elevated mountains at a considerable distance. 4. The nearest water is the river already mentioned. The vicinity of the station is not liable to overflow of water. There are numerous ravines and water-courses near the station. 5. The station itself is pretty well cleared of jungle and forest, and is open and freely exposed to the winds, though there is much forest at a short distance, which does not interfere with the free circulation of the air. The temperature is not raised by reflected sun heat. There is comparatively little wind; it chiefly blows from the south and south-east. Its effect is beneficial. 6. The surrounding country is considerably cultivated up to 7,000 feet, but there is much uncleared ground. There is no irrigation. Rice is only cultivated in the valleys many miles from the station, and cannot affect the health of the station. There is no indigo, flax, or hemp in the neighbourhood. 7. The native town is close to the station, and contains about 1,500 inhabitants. 8. As regards the local geology, the rocks are generally gneiss. The subsoil is clay covered by sandy soil and vegetable humus. The station occupies new ground. It was covered with forest before it was built on by the Indian Government. 9. Water is obtained entirely from springs. 10. The rain water, and water from springs, flows rapidly away. Half an hour after a heavy fall of rain the station is dry and clean. There is no higher ground, the drainage from which passes under the station. 11. Water for use is derived from springs. It is not stored in tanks. The springs at the beginning of the rains are polluted by surface drainage, which percolates through the decayed vegetable matter on the ground and is consequently unwholesome. 12. The springs in and near the station are numerous, many of them are permanent and afford an ample supply of water during the whole year. The water is exceedingly pure, and fit for photographic purposes without distillation. The most careful analysis has only discovered traces of iron and lime. Some of the springs contain a considerable quantity of the sesquioxide of iron. These are used medicinally. The chief is the Soontook spring, used by the Government for invalid soldiers. There is an ample supply. 13. The station should be kept clear of low jungle, or as the population increases there will be considerable sickness. 14. As regards the selection of stations, in the Medical Code, edition 1851, I can find no directions as to how or by whom stations are selected. For the selection of stations men of known ability should be appointed. The station of Suichul, which has not yet been occupied, although barracks for a regiment have been built, is about 1,000 feet above that of Darjeeling. The site was, I believe, chosen by the executive engineer. I heard of no inquiry being made as to its climate or sanitary condition. In selecting stations I would suggest a committee composed of the chief civil authority, the chief military authority, the deputy inspector-general of hospitals, and the medical officer in medical charge of the locality, to report on the site of any proposed new station.

II. Climate.	1. There is an observatory here containing a good set of instruments, in charge of the civil assistant-surgeon, with a writer to take the observations, which are registered four times in the 24 hours. 2. The three years I have taken in the following table give a fair average account of the climate, It is remarkable for its equability of temperature. The greatest variation in any 24 hours is only 12° F. The average temperature for the year is about 53° F. There is necessarily a good deal of mist and fog in the rainy season, but the quantity has considerably diminished since the hills have been cleared of jungle for the cultivation of tea, coffee, &c.

* The average rain fall in 7 years is 124 inches a year. † Calculated on Lambert's formula.

3. The climate, as stated above, is temperate and damp. Its influence on the convalescent depôt as regards cases of fever of the remittent and intermittent types caught on the plains, or in those of simple debility, is beneficial. In cases of such organic disease as that of the lungs, liver, or intestines, I mean serious organic disease of these viscera, the climate is not beneficial; neither is it beneficial in rheumatic cases.

The clothing worn should be chiefly woollen. The duties are light. Every convalescent should be provided with a complete suit of waterproof. I think May and June are the most unhealthy months at the station. The springs have generally become low, and are only supplied by the first showers of the lesser rains. The water percolating through the decayed vegetable matter of the previous nine months is rendered more or less deleterious, hence diarrhœa is somewhat prevalent in these months.

4. Already answered in a report I wrote to the Royal Commissioners some months ago.

6. I have served at Dum Dum, Muldah, and Minghyr. This is by far the most healthy station I have been at in India, indeed the healthiest spot I have ever lived in, either in Europe or India. Assistant-Surgeon Maclean says, "No where and at no time have I ever seen troops so healthy as were ours in the Crimea during the winter and spring of 1855-56." The only climate I have served in which I should consider really injurious to health is that of Bengal during one half of the year at least.

III. Sanitary Condition of Station.

1, 2, 3. Sketches.

4. The following table gives the barrack accommodation:—

Two barracks built in 1854; one barrack built in 1849.

Two large rooms to each barrack, and four non-commissioned officers' rooms at the ends.

Total accommodation, 112 non-commissioned officers and men.

Barrack Rooms.	Regulation Number of Men per Room.	Dimensions of Rooms. Length.	Breadth.	Height.	Cubic Contents.	Cubic Feet per Man.	Superficial Area per Man.	Height of Beds from Floor.	Windows. Number.	Height.	Width.

III. Sanitary Condition of Station—*cont.*	5. The barrack-room windows are on opposite sides, and open in the centre. There are verandahs 14 feet in width on both sides. Those on one side are glazed. There are no jalousies or jhilmils. The verandahs are never occupied as sleeping quarters. 6. The cots are the same as those used in barracks, cane-bottomed, about 2 feet high. The bedding stuffed with hemp. 7. No tents are used at Darjeeling. 8. Ventilation by doors, windows, and chimneys. No roof ventilation. The present ventilation is not quite sufficient. No means are used for cooling the air. 9. The barrack walls are built of thick solid brick and mortar. Floors are of wood, and roofs shingled. 10. The floor is raised about 2 feet above the level of the ground. There is not a very free passage of air beneath. 11. Barracks and cantonments are kept in repair by assistant executive engineer and barrack-master. Lime-washing is done once a year. 12. There are eight bath-rooms, each 8 feet square, to each barrack building. A good supply of water is obtained from a spring close at hand. The refuse water is carried off in open stone drains. 13. There is a cook-house to each barrack building, small, and very badly lighted. Good water from a spring close at hand. Refuse water carried off in open stone drains. 14. The privies are fitted up with seats, beneath which are placed portable vessels, their contents being taken away daily to a distance, and buried in deep pits. The privies are used as urinals by day, but at night the portable barrack utensil is used in the barracks. 15. These buildings are ventilated by small apertures in the walls. The doorways are open, having merely a wall of masonry a few feet in front of them as a screen. The privies are lighted up at night with oil lights secured in a glazed lantern. 16. The drains of the barracks are all constructed of stone, and are open. The greater portion of the refuse water and filth is washed away down these drains. The remainder is taken away daily to a distance, and thrown into cesspits. The drainage of the depôt is, in the opinion of the medical officer, defective. The upper married barrack at this depôt is damp, on account of its situation; and the others, viz., three single barracks and another married one, are also damp, their roofs being old, and leaky during the rainy season. The roof of the hospital is also in a bad state of repair. Part of the fluid refuse of the barracks sinks into the subsoil, and the remainder goes a short way down the hill in the open drains, except that from privies and urinals, which is taken away daily to a distance, and thrown into pits constructed for the purpose of receiving it. These pits are two or three hundred yards off from the nearest men's quarters and hospital. Sweepers collect the filth every morning, which is taken to a distance and thrown into the cesspits, a layer of earth and lime being placed over it. When the pit is filled up a new one is constructed. There are no foul ditches now near the depôt. 17. The surface cleansing is done by the conservancy establishment. As to the mere surface cleansing within the cantonment, it is performed satisfactorily enough. The refuse and manure, except what of these enters the subsoil, are removed daily outside the cantonment. 18. The surface of the cantonment is kept free of vegetation. There are no old walls, thick hedges, &c., interfering with the ventilation of the station. 19. As regards the sanitary condition of the bazaar, it is well drained, but the huts and native buildings generally are too near together to admit of free ventilation. The Government bazaar is good and well kept. The bazaars are swept by the prisoners. The native houses are built mostly of mats and bamboos, and are generally surrounded by all kinds of filth. The medical officer states that these are the most filthy villages he has ever entered, and so impure is the atmosphere in them that it is quite sickening to walk through any of them. The depôt is fortunately placed at too high an elevation in regard to these villages, and at too great a distance from them, to be injuriously affected by their sickening effluvia. 20. On my arrival at this depôt it was the custom to slaughter animals within the cantonment; since that time the practice has been put a stop to. 21, 22. There are no stables nor picketing grounds. 23. At present the accommodation for married non-commissioned officers and men is, as regards mere space, sufficient. None of the single barracks are occupied by married people.
Officers' Quarters.	1. The difference between the sanitary condition of officers' quarters and that of the non-commissioned officers and men is, that the former are better lighted and ventilated, and, as regards the individual, more spacious than the latter. Both the officers' quarters and those of the men are leaky. They require to be put in a state of proper repair.
IV. HEALTH OF THE TROOPS.	1. The station is healthy. 2. The most prevalent diseases among the native population are small-pox and fever, and some cases of spleen, but it is not a very frequent disease. Small-pox is the scourge of the hill population; Europeans are seldom attacked. Goitre is also a very common disease. 3. The people (Lepchas, Booteas, and Nepaulese) are generally healthy and strong. They live very much in the open air, are not crowded together in large villages, and all generally well clothed and fed. 4. The convalescents usually arrive here from the plains in April; and such as have been invalided, or have been pronounced fit to rejoin their regiments, leave this in December. These belong to different regiments, and suffer, the greater number, from fever, ague, and remittent; hepatic, pulmonary, and intestinal disease; syphilis, rheumatism, and ophthalmia. No portion of the station is more unhealthy than the rest. 5. The troops are not camped out here. 6. I am at present in medical charge of the Darjeeling sanitary depôt. My experience of its climate on the health of convalescents I have given to the Commissioners in the report already alluded to. 7. No information. 8. I approve strongly of hill stations for European troops, and am quite of the same way of thinking as Mr. Jeffreys is on this subject. 9. There are no diseases peculiar to Darjeeling, but I believe there are at some of the other hill stations.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	10. As regards precautions, all convalescents sent to the hills should, on their arrival there, be provided with good warm clothing; a blanket suit for each man would, I think, be as good as any. Suitable amusements should also be provided; and, as regards duties and exercises, these should be regulated with a strict regard to health and efficiency. Every man should also have given him a complete waterproof suit on his arrival here. 11. The period during which convalescents recover best on the hills is from the time when the rains cease until they recommence, and from about the 1st October to the middle or end of May. For healthy troops, if those in Bengal can ever be called so, the hills would at all seasons be suitable as a residence. The question as regards the duration of residence must be answered according as to whether the troops are in a tolerably good state of health, or very sickly, on their arrival in the hills. If they are in the former condition, a residence of six or twelve months might be sufficient. If in the latter, one of one or two years would in general be necessary. 12. I do not think that there is any period beyond which residence on the hills would be injurious. A transition climate would, I think, be best for men sent from the plains, say one at an elevation not under 4,000 feet, and not exceeding 6,000 feet above the level of the sea. 13. On leaving the hills men should be gradually moved down. On proceeding to the hills sickly troops should on no account be forced to march on foot up till a late hour in the day during the months of March and April under a blazing and destructive sun. The more weakly portion should be amply provided with proper conveyance. This year, the first sick from the plains arrived here on the 15th April, much worse for a journey so late in the year. Four of the party died on the march, and two immediately after its arrival here. 14. As regards the proper use of hill stations. It would most certainly be most conducive to health to locate the troops in hill stations, with short periods of service on the plains. It would not, in my opinion, be advantageous to locate them on the plains, with short periods of change to hill stations. Frequent change of station in the plains is beneficial. 15. The barrack and hospital accommodation at Darjeeling is not sufficient for health and comfort. I have spoken at some length on this in the report to your Commission mentioned above. 16. The best elevation for hill stations is from 5,000 to 7,000 feet. Certainly not above 7,000 feet or below 4,000. 17. There is no higher or healthier ground near this station. 18. I have not observed the influence of particular classes of soils on health. 19. With reference to the best age for troops coming to India, the younger they are, I believe, the better. The best time for arrival is the beginning of the cold weather. The precautions necessary on arrival are to prevent altogether, if possible, over-crowding, needless exposure to the sun, and to trying extremes of temperature; also drunkenness. The dress should be suited to the climate and duties, and not fashioned after any pattern got up to satisfy wrong-headed ideas about appearance, at the expense of health and efficiency. 20. I think that sending fresh arrivals to hill districts, and bringing them down again to the plains after some little time, gradually, would be advantageous. 21. No reply. 22. As regards the number of years soldiers should serve in India, I am an advocate for European regiments being sent to the hills, say every two years, and for their hill service being equal, at least, in amount to their plain service. If the soldier is to be kept altogether in the plains, of Bengal especially, five years' Indian service would, I think, be ample. Ten years' service would be all we could expect from men who have served five of these in the hills. 23. As regards medical boards, the recommendation of the regimental surgeon and of the District Invaliding Committee should, in the cases of non-commissioned officers and soldiers, be acted upon at once, and not left to be adopted or rejected by the general invaliding committee. The recommendations of invaliding committees held at convalescent depôts should, of themselves, be final. 24. Invalids should leave India so as to be at home by the commencement of the summer weather.
Diseases.	1. There are inspection parades for the discovery of disease once a week. 2. I have not seen a case that I could call distinctly scorbutic at this depôt. 3. No answer regarding hepatic disease. 4. No dracunculus among Europeans. 5. Venereal disease. No answer. 6. Ague and remittent fevers occur, but they are brought up from the plains. Dysentery is also imported. Cholera has never occurred as far as I know. Small-pox. Although this disease is rife in all the surrounding country, and two of my own native hill servants got it, of which one died within the last few months, on referring to the annual returns from 1848, the date on which the depôt became established, until the present time, I can find no admission to hospital from this disease. Rheumatism. There is a good deal, but then it is also brought up from the plains. The following are the admissions and deaths from these diseases:— Fever - - - - Admissions 31 - - Deaths None. Dysentery, acute - - „ 6 - - „ 1. „ chronic - „ 8 - - „ None. Rheumatism - - - „ 6 - - „ None. Although there were only six special admissions in men suffering from rheumatism, a great many cases suffering from other diseases under which they were admitted, were also suffering from rheumatism. There were only two more deaths last year at the depôt, viz., one from acute hepatitis, and one from acute bronchitis. 7. With reference to nosological character, the more frequent zymotic diseases at this depôt are ophthalmia, dysentery, diarrhœa, ague, rheumatism, syphilis of the secondary kind, tape-worm. These diseases are chiefly of a chronic nature, and, except the last, are very difficult to cure, chiefly from their long standing. The predisposing personal causes of epidemic disease among the native population are their exceedingly dirty habits. The Lepchas and Bootiahs seldom change their woollen clothes or wash themselves. 8. The monotony of a soldier's life in India, and the harassing nature of many of his objectless

References to Subjects and Queries.	Replies.
IV. Health of the Troops: —*Diseases—cont.*	duties; his aversion to bestir himself to exertion that might be beneficial, and his want of incentive to do so; the discomfort of an overcrowded and unhealthy barrack room, where secrecy being impossible neither the decencies of life nor the duties of religion can be observed as they should be; his notorious tendency to exceed in the use of strong drink, arising in a great degree from the misery of his condition; the general depression produced in him by these and other causes,—all tend to render the British soldier in this country, as in others, more than any one else liable to be seized upon and overpowered by epidemic and other morbid influences.—A.M. 10. To prevent the occurrence, as well as to mitigate the violence, of epidemic onsets, the best plan would be to promote the health of the troops by every means in our power. These means, although quite within our reach, have hitherto been sadly neglected, and so are they likely to remain until those in power have both the knowledge to appreciate, and the humanity to carry out, the invaluable but unvalued recommendations of military medical men.—A.M.
V. INTEMPERANCE.	1. The soldiers of this station are temperate.—A.M. 2. There are no admissions to hospital occasioned either directly or indirectly by intemperance.—A.M. 3. Distilled spirits are sold at the canteen. The quality is, I believe, what is called "good." Each man at this depôt not attending, or in hospital, is allowed to drink by purchasing it, two drams of rum 24 U.P., or instead of this quantity of rum one bottle of day (?) and one glass of rum 24 U.P. Spirit is not given as a ration to convalescents.—A.M. No drinks, other than intoxicating drinks, injurious to health, are sold at the bazaars that I know of.—A.M. 4. I have no hesitation whatever in saying that the consumption of spirits by troops is decidedly and highly injurious; and as far as I can judge, I should say that it is anything but conducive to the efficiency and good order of a corps.—A.M. 5. It would, without doubt, be beneficial to abolish altogether the use of spirituous liquors as part of the ration, as well as its sale in canteens. A sudden abolition might, however, be attended with some degree of danger as regards discipline, or even health, for the men might go and get worse liquor elsewhere than that sold in the canteens, but this is no reason why the abolition should not prove perfectly safe, if carried out gradually and wisely. One thing is certain, that by getting rid of this pernicious habit of drinking in the army, you get rid of much of that sickness and inefficiency, as well as of much of the mortality, crime, and misery in it, which at present owe their origin and aggravation to this habit. The soldier would not be such a drunkard, I am inclined to think, but for his condition. Better that condition, and then there will be some hope of making the British army a sober one.—A. M. 6. Wines, malt liquors, and spirits are all of them about equally injurious when taken in excess, but the use of malt liquor in a corps is not likely to be on the whole, I think, attended with such bad effects as ardent spirits would be.—A. M. 7. Tea, coffee, lemonade, &c., are, I think, not much used at this station. Instead of there being any comparison between the use of such drinks on health, and the use of spirits and malt liquors, there would, I think, would be a striking contrast, other things being equal, between the health and efficiency of the corps that drinks ardent spirits and malt liquor to excess and the one that is temperate.—A. M. 8. It would, in my opinion, be undoubtedly beneficial to abolish the spirit ration, no matter where a corps is serving, and to substitute in its stead good coffee and tea. 9. It would be beneficial to prohibit the sale of spirituous liquors in the canteens, and to permit only beer, coffee, tea, &c. to be sold to the troops. 10. I would recommend the establishment in every corps and depôt of "restaurants," where the men might go and sit down to have their tea and coffee or some other harmless drink, and their newspaper or magazine to read, and where the men of different companies and regiments would have an opportunity afforded them of mixing agreeably with each other, and in which there would be the pleasant prospect of an agreeable escape from the monotony and discomfort of the everlasting barrack-room.—A. M.
VI. DIET.	1, 2, 3. The following is the ration issued to a soldier attached to the Darjeeling convalescent depôt for one week. (Darjeeling, 14th June 1860.)

"The order concerning the supply of vegetables regulates that this part of a soldier's ration should be the best procurable at the different stations of the army during the different seasons of the year. But this is no reason why mixed vegetables should not be supplied at Darjeeling. Onions in considerable quantity are supplied at most of the stations in India to the European troops, and are highly recommended, particularly for those suffering from scurvy or similar complaints, and there should be a supply of them provided by the commissariat for daily issue to the men. The lb. of vegetables issued daily should be mixed if procurable."—J. BAILEY, Quartermaster Serjeant, Depôt.

"I may add that the salt meat will soon be all issued, so that the men will shortly have 1 lb. of fresh meat daily. I beg to add that mutton, in my opinion, should be issued to such men as those at convalescent depôts, the usual number of days each week (2). This

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	has been the case at this station till of late. You will perceive we only get it now once a week. This should be attended to by the commissariat officer. Hitherto it has always been served out to the men here three times per month."—J. Bailey, Quarter-master Serjeant, Depôt. " I agree with the Quarter-master Serjeant in what he says in this statement."—A. M. 4. There are cookhouses, but these are built on a very unintelligible plan, and are not what cookhouses should be, as they are not only very dark, but too small to provide against the men's food being badly or dirtily cooked. The kitchens are neither clean, well lighted, nor well ventilated. The water supply is good and ample.—A. M. Food is both boiled and roasted. Owing to the faulty construction of the kitchens, the cooking cannot be so good as it ought to be. I hear no complaints about the preparation of coffee or tea.—A. M. 5. There are two gardens attached to the depôt, but the men seem to take no interest in them.—A. M.
VII. Dress, Accoutrements, and Duties.	1. The men up here are provided with both woollen and karkee suits. I do not consider the dress as at all suitable for the plains. Mr. Jeffreys' remarks on this subject are, I think, very valuable, and I quite agree with him in thinking that the whole body should be enveloped in flannel, which is the best slow conductor fitted for a body dress I know of. The head-dress should be constructed with a reference to the properties of heat in the way that Mr. J. has suggested in his work on the British army in India. The guard dress in summer is the karkee coat and wicker helmet. I do not know whether or not a flannel shirt is worn. In the rainy season the men bring their great coats with them on guard. To protect them from the sun and rain there are sentry boxes, and what are called " shades." In winter the dress, especially when troops are on night duty, should be as warm as that worn in England at the same season.—A. M.
Duties.	1. Men should be thoroughly drilled before being sent to India. 2. As regards duties, the men here are, with only one or two exceptions, convalescents, and are all considered as " out patients."—A. M. During last winter the convalescents had only two nights in bed apiece. Now each man has about 15 or 20.—A. M. 3. There is but one guard, namely, the quarter-guard, which is within the precincts of the barracks. The guard is relieved every 24 hours.—K.R.M. There are roll calls by day about every three hours. The effect of night duty is certainly injurious, and no precautions in the way of shelter and clothing according to season should be neglected.—A.M.
VIII. Instruction and Recreation.	1. There are no ball courts. There are two skittle grounds in a very bad state of repair. One school with a soldier schoolmaster. There is a library and reading-room, both very good and well lighted at night. There is no day-room or soldiers' club. There are two gardens worked by natives. Some craftsmen, such as tailors, shoemakers, and tinsmiths, work at their trades in barracks. The carpenter is the only man who has a small workshop. There is no soldiers' theatre and no gymnasium. The means of instruction and recreation are not sufficient.—A.M. A reading-room has been established in connexion with the hospital, which answers well, and affords amusement and instruction to the patients. A reader is appointed, who reads aloud to those who wish it, as most of the men are unable to read themselves.—J.C. There is no danger up here from exposure to the sun. In the rains when the men have occasion to leave their barracks, they have been directed to put on their great coats. Each man should be provided with an umbrella besides his waterproof suit. 2. Numerous have been the means suggested both by my predecessor and myself, for improving the means of recreation and employment, without any satisfactory result.—A.M. 3. There is in every regiment a savings' bank. It is highly advantageous to the soldier. 4. As the rains here fall incessantly for five months out of the twelve (at least they did so last year), during which the men for want of outside amusements, are pent up in their barrack rooms all day and night, one might say, to the great injury of their health, there should not only be a sufficient number of different kinds of recreation provided, but these should be so got up as to allow of the men during the wet season being under cover.—A.M.
IX. Military Prisons.	1. The cells at this depôt are not now used as places of confinement, having been condemned as such by a committee assembled at my request.—A.M.
X. Field Service.	Questions not applicable to station.
XI. Statistics of Sickness and Mortality.	No replies obtainable.
XII. Hospitals.	1. Ground plan already sent. 2. The hospital is within a few yards of the barracks. The depôt bazaar is about half a mile down hill from the hospital and to the west of it. The station is about 1¼ miles distant from the depôt. The hospital is in a position far too exposed. The drainage, like that of the barrack generally, is not carried far enough down hill. There are no marshes, nullahs, &c., near the depôt.—A.M. 3. Water supply good and sufficient.—A.M. 4. A previous report on drainage referred to. 5. The ward floors are raised about two feet above the ground, there is no perflation below them. The drainage for conveying away the roof water is bad. The surface drainage and guttering is very much like that of the barracks, and insufficient for carrying away the rain fall rapidly. The walls are thick and solid, of brick and mortar. There are verandahs. The western verandah has been used for accommodating sick when the patients were compelled to leave their ward, the atmosphere of which, being surcharged with the noxious effluvium of an adjacent latrine, has been the cause of much mischief. This objectionable latrine, however, after five years writing about it, is now shut up, a new one having been built at the north-east corner of the hospital from which it is distant several yards in a direction from which the wind is seldom known to blow. The hospital is one story high.—A.M. Date of construction, 1852. Two wards, 17 men each at 1,100 cubic feet per man.

DARJEELING. BENGAL.

The following table gives the accommodation:—

Wards.	Regulation Number of Beds	Dimensions of Wards. Length.	Breadth.	Height.	Cubic Contents.	Cubic Feet per Bed.	Superficial Feet per Bed.	Height of Bed above Floor.	Windows. Number.	Height.	Width.
		Ft.	Ft.	Ft.	Ft.			Ft. in.		Ft.	Ft.
Hospital at Julla Puhar for sick of the Depôt, 150 strong, 2 wards -		53	24	15	19,080	1,100	75	1 9	4	6	4
		53	24	15	19,080	1,100	75	1 9	4	6	4

XII. Hospitals—*cont.*	The hospital, as already stated, is much too exposed. The windows open in the centre. They do well enough as ventilators, but being narrow, not numerous, and having by far too much wood in their construction, they do not admit a sufficiency of light.—A.M. 6. Ventilation is by doors, windows, and chimneys, but independently of these, there should be floor, wall, and roof ventilation. There are no jalousies or jhilmils.—A.M. 7. No means of cooling the air are required.—A.M. 8. Warming is provided for by fireplaces only. Lime washing is done once a year; too seldom. The walls and ceilings of both barracks and hospitals should be scraped also frequently.—A.M. 9. Like the other privies here, the hospital one, under the same roof as the hospital, is very badly drained; its supply of water is defective, and its state offensive.—A.M. 10. The floor of the lavatory, which is separated from the privy by a wall 8 or 9 feet high, is composed of lime and pounded brick. It is cold and smells offensively, owing to the proximity of the privy. There is no fireplace in it, nor in any of the other depôt lavatories. Several men have to wash in the same utensil, which at the barracks is made of wood, and to dry with the same towel several days running, only a very small number of towels being allowed. In fact, the inducements to remain dirty are, I think, especially in the case of sickly men, greater than those to be clean. Such a state of matters has not been left unrepresented.—A.M. 11. There are no means of bathing properly so called; these were applied for some time ago and will, it is hoped, be supplied soon. 12. The means of washing and drying hospital linen are sufficient, except during the rains.—A.M. 13. The storage is not sufficient.—A.M. 14. The bedsteads—there are no cots in use—are like those supplied to the barracks, and are far too narrow for sick men. The mattresses, blankets, and pillows, are of native manufacture of very inferior description. The former and latter are stuffed with coarse hemp, and being hard, lumpy, and furrowy, are not what even men in health should have. As to the blankets, besides being of an inferior description, they were,—last year's supply,—almost all of them worm-eaten, and had been previously in use in the plains.—A.M. 15. The kitchen is detached from the hospital. The cooks not having been numerous enough last year, nor good enough, I applied to have one more granted, and to have the wages of the head cook increased, as anything like a good cook it was impossible to get for the trifling wages offered, in a place like Darjeeling, where good cooks are scarce and highly paid. My applications were refused, and it was hinted that I should instruct the cooks myself. 16. The forms, diet rolls, &c., are the same as used in general hospitals on the plains.—A.M. 17. For attendance on the sick there is a hospital serjeant, but it is a pity that he is changed every two or three years, there should be a permanent one; there is also an European orderly and several coolies. The attendance is sufficient up here, but in the plains the majority of men not long in the country, not knowing the language of the natives, are at a great loss to make themselves understood; I would therefore recommend the appointment to each regiment of a certain sufficient number of soldier orderlies well paid, for their work is hard; this I would recommend most strongly, and also that the hospital serjeant, an important servant, should have better pay and higher rank than at present.—A.M. 18. The sanitary condition of the hospital is bad. No epidemic disease, gangrene, &c., has appeared in the wards. 19. Deficiencies were pointed out in the report of the committee which was appointed last year to examine and report upon the hospital; this report, which was forwarded to the Commander-in-Chief long since, has not as yet been followed by any satisfactory results.—A.M. 20. There is no provision for convalescents exercising. The verandahs are neither glazed nor have they wooden floors; they are, besides, quite exposed to the wind and the rain, which beat into them.—A.M. 21. Sick wives and children of soldiers are treated up here in their own quarters; this would be satisfactory enough if the married quarters were not so dark and damp as they are.—A.M. 22. No reply. 23. The powers of the medical officer, as regards the sanitary state of his hospital, as well as of the barrack buildings occupied by his regiment are, unfortunately, merely recommendatory or suggestive. Until officers of health, have, as regards the carrying out of their own suggestions, executive powers, and until Government admits that the office of a sanitary officer is not so totally worthless, as its refusal of remuneration to him would imply, there is, I believe, little hope of the army benefiting much from the application of sanitary principles, which, moreover, like their advocates, do not seem to be popular with, as they are certainly not understood by a large number of commanding and other officers.—A.M. 24. There are no convalescent wards or hospitals; they would certainly be an advantage.—A.M.
XIII. Burial of the Dead.	1. The burial ground is distant, say, half a mile from the depôt, and perhaps 100 feet higher. The position of the burial ground is to the south of the depôt. The prevailing winds are the south-westerly and south-easterly.

XIII. Burial of the Dead —*cont.*	2. No reply. 3. The bodies of natives are removed and buried at a considerable distance from the station, and as soon as possible after death. 4. The grave yard is not offensive.—J.C. 5. No reply. 6. I am not aware of any injury to the public health up here from the present practice of burial.—A.M. 7. No reply.

(Signed) K. R. Maitland, Major, 19th, Comm. Convalescent Depôt.

I. Topography.	1. The station consists of a small table land surrounded by hills on the north and west; to the east are deep valleys and glens covered with dense jungle. The surrounding country is mountainous, sandy, and swampy. There is plenty of wood, jungle, and water in the vicinity. 2. The elevation of the station above the sea is 4,118 feet, and to the bottom of the glen to the east is 3,000 feet. A deep mountain stream runs through the station. In the immediate vicinity of the station there is no higher and healthier ground, but in the interior of the hills more eligible sites for European stations can be found. 3. The whole country, more or less, is table land, but level spaces of any extent are rare. Small plateaus can be found at the height of 6,000 feet above the level of the sea. 4. A mountain torrent, with water in it all the year round, runs through the station. The vicinity is not liable to overflows. There are a number of ravines in proximity to the station, but they are not injurious to health. 5. The station is open, and freely exposed to every wind, and the temperature is not raised by the buildings being exposed to reflected sun heat. It is exposed to cold and variable winds, but we consider their effect beneficial to the health of Europeans and the natives of the hills. 6. The surrounding country is uncultivated. There are no works of irrigation; nor is the cultivation of rice or indigo carried on near the station. 7. There is a large village within one mile of the station, inhabited by independent tribes of Khasias. 8. The surface of the station is generally rocky, and where it is not so it is thickly covered with grass; the subsoil, for the most part, is composed of layers of sand, clay, and gravel, irregularly dispersed, and indurated by ferruginous cement. The ground upon which the station is built was formerly occupied by small Khasia villages. 9. No water is found below the surface. 10. The rain-fall and surface water generally flows readily away, but in some instances it lies on the surface until it evaporates. There is no higher ground adjacent, the drainage from which passes into the subsoil of the station. 11. The water supply is obtained from the mountain torrents. There are no tanks. The wells of the station are liable to pollution from leaves or other matter falling into them. There is a large pond in the station, formed by damming up a mountain stream, which, in the cold weather, from not being cleaned, emits unpleasant effluvia. 12. The water supply at the station is ample and of the best kind. It is not injurious to health. It is obtained from the mountain torrents, and no better water could be supplied. 13. The bareness of the station, and the severe storms that sweep over it, render the inhabitants of the plains who are resident here liable to diseases of the lungs and rheumatism. 14. New stations are generally selected by medical committees. The mode of inquiry suggested by Dr. Dempster is that generally adopted. We consider sufficient attention has not been paid to the healthiness of the road leading to different sanitaria; the whole attention of medical committees being generally directed to the sanitarium itself.
II. Climate.	1. The instruments available at the station for conducting and registering meteorological observations are a thermometer at the military hospital and a rain gauge. 2. The observations filled up in the following table embrace those taken by me during 12 months, from 1st March 1859 to the 29th February 1860. The temperature was noted five times each day, viz.:— At sunrise - - - in shade. „ 10 a.m. - - - „ „ 4 p.m. - - - „ „ 10 p.m. - - - „ „ 4 p.m. - - - in the sun's rays.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	3. The climate is healthy, but the moisture is excessive during six months of the year. The temperature is equable during the rainy and cold seasons, however it is very foggy. Trees will not grow to any extent from want of depth of soil. There is no irrigation of any kind; no impurity of the air from dust. The air is cold but invigorating. The troops here are very healthy, as also are the European residents. They require to be well sheltered and live in houses well raised from the ground; warm clothing is also necessary. As regards drill, duties and exercise the sun is rarely sufficiently powerful to prevent Sepoys drilling in the middle of the day. The most healthy months are January, February, March, April, July, August, September, November, and December, and the most unhealthy May, June, and October. During the latter months the changes from heat to cold render the men liable to fevers and bowel complaints. 4. Districts with, it is believed, considerably less moisture than the present station, although at a greater elevation, exist at a very short distance in the interior. Experiments to ascertain this fact are now being made at a place called Woormaipoonjee, 38 miles from here, on the road to Assam, at an elevation of 5,000 feet. Its drainage is good, being situated on the summit of a hill. Subsequent to this another locality in the same neighbourhood, near Shillong, has been strongly recommended for a military station, and has been visited by a committee, and reported favourably upon. The fall of rain at this latter place has been ascertained to be not one-fourth of that which falls at Chirrapoonjee during August and September. 5. In addition to the station concerning which this report has been written, I have only served at Cachai, where a detachment of the regiment of which I am now in medical charge was located. Cachai, which is situated on the plains, was, generally speaking, considered a healthy station; but the station of Chirraponjee is, in my opinion, more conducive to health and more suited for a European constitution.
III. Sanitary Condition of Station.	1, 2, 3. There is no map or plan of the station, and no engineer resident here to make one. There are no barracks for European troops at this station. 4, 5. No replies to these queries. 6. The natives sleep on bamboo mychauns. 7, 8. No replies to these queries. 9, 10, 11. The huts are built of stone cemented together with mud, and covered with a thatch of leaves. The buildings here require to be well raised. The sepoys huts are elevated from the ground from 2 to 4 feet. The materials and construction of their huts are suitable for the climate. The barracks and cantonments are kept in repair by the barrack department; and no delay usually takes place in carrying out orders if given at a proper time of the year. Dr. Dean, of the Silhet Light Infantry, is responsible for the general sanitary state of the cantonment. The walls and ceilings of barracks are cleansed and lime-washed twice every year. 12. There are no lavatories or washing places for the men; lavation is performed in the running streams. 13. There are no barrack cook-houses. 14, 15. No replies to these queries. 16. The natural drainage is so good at this station, and in the sepoys' lines, that all surface water and filth are readily carried off by the heavy rains which fall during nine months of the year. The whole of the buildings of the station are damp as the atmosphere is always charged with great moisture. The drainage is sufficient. There are no cess-pits, or foul ditches. 17. All moveable filth is carried away by the heavy rains. 18. The cows keep down the grass; there is no other surface vegetation in the cantonment. There are no old walls, thick hedges, &c., interfering with the ventilation. 19. The bazaar is on a healthy site on the bank of a mill stream; there is no crowding and an abundance of water. Each occupant keeps the ground opposite his house clean, under the inspection of the officers of the regiment. There are no native houses near enough to the station to cause annoyance. No nuisance is experienced from wind blowing over the native dwellings.

CHIRRAPOONJEE, KHASIA HILLS. BENGAL.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	20. There are no slaughter houses except those belonging to private persons. 21, 22. There are no bazaar horses, cavalry stables, or picketing grounds. 23. No reply to this query.
Officers' Quarters.	1. Officers reside at their own bungalows, which are healthy. No improvements to suggest.
IV. HEALTH OF THE TROOPS.	1. The station and district are both healthy and the adjoining native population decidedly so. 2. All bowel diseases are prevalent among the Khasia hill people. Small-pox and cholera are the chief epidemics, and commit great ravages among them. 3. The healthiness of the native population is to be attributed to the salubrity of the climate, owing to the elevation above swamps and consequent malaria: when visited by epidemics they are induced, and rendered severe, by the very filthy habits of the Khasias in their houses and persons; and by the bad food they consume. 4. The regiment (Sylhet Light Infantry Battalion) is a local one, and has always been stationed at Chirrapoonjee, with detachments at Cachai and Sylhet. Intermittent fever, diarrhœa, and dysentery, contracted generally by them during their periodical changes from one of these stations to the other are the principal diseases from which they suffer. All portions of the men's present accommodation are equally healthy. 5. Troops are never camped out. 6. I have been in charge of troops at no hill station but Chirrapoonjee; but hill stations are decidedly beneficial to the health of troops. 7. My experience of sepoys tells me, that when the men are not broken down from old age or excess, a residence in the hills improves their general health, and renders them less liable to contract febrile or other diseases. 8. I most decidedly approve of selecting hill stations for troops. 9. The diseases peculiar to hill stations, and to which troops are liable on going to them, are dysentery and diarrhœa. 10. In my opinion good diet, warm clothing, good shelter, plenty of duties and exercise are necessary to preserve the health of men in hill stations. 11. The seasons best adapted for residence at Chirrapoonjee are the spring and autumn; as during the heavy rains here care is necessary to prevent sickness. If in ordinary good health I think one year's residence on hill stations would be sufficient to obtain the full benefit of the climate. 12. There is no period of residence beyond which injury is likely to be inflicted on the health of the troops on returning to service in the plains. 13. No soldier should be permitted to leave the hills when labouring under sickness, or when weakened thereby; nor should troops on returning to the plains be permitted to indulge in stimulating drinks or unduly expose themselves to the sun, from whose influence their heads should be properly protected by "shola" hats; light and loose clothing should be also provided for them. 14. I consider that the location of troops on hill stations, with short periods of service in the plains, would be the course most conducive to the preservation of their health. Frequent change of station in the plains would be beneficial, but on these points, with reference to troops, my experience is limited. 15, 16. No information on the subject of these queries. 17. There is no higher ground nearer to the station than 30 miles. A place called Noormaipoonjee has been recommended for the location of European troops. It is distant from this station 38 miles. A native doctor is now stationed there making meteorological observations; since the selection of that place a plateau of level ground in a locality called Shillong has been pointed out and a committee has reported upon it. 18. As far as my experience leads me to observe, I consider a light friable soil, not retentive of water, or such a soil as that mentioned at para. 8, Topography, as the most healthy for stations. 19. Soldiers proceeding to India should be from 16 to 19 years of age, and should land in India in the month of November. Cannot say how troops are disposed of on landing, or what precautions are necessary for preserving the health of recruits. 20. If practicable, I am of opinion that if troops were sent to an intermediate station for a certain time, it would prepare them for the climate of India. 21, 22. No experience as to the mode of transport of troops from the port to the interior, nor of number of years a British soldier should serve in India. 23. As regards the invaliding of the native sepoy, I consider the habit of obliging every candidate for the invalids to travel to Calcutta a hard and unnecessary measure; they are obliged to leave from the Sylhet Light Infantry stationed here at the most unhealthy time of the year. In some instances the broken down man is killed by the trip, and in almost every case injured by it. A medical committee composed of three medical men could always be assembled on the frontier.
Diseases.	1. There are no regular inspection parades for the discovery of incipient diseases at this station. 2. Scorbutus seldom appears among the sepoys of the regiment stationed here. 3. Hepatic disease is very rare among the troops. 4. Dracunculus is not known in this part of India. 5. Venereal disease among the sepoys bears a very small proportion to the total sick in hospital. 6. During the two years from 1st April 1858 to 31st March 1860 inclusive, there have been—

Intermittent fever	- - -	623 cases.
Remittent „	- - -	2 „
Dysentery	- - -	44 „
Cholera	- - -	4 „
Small-pox	- - -	3 „
Rheumatism	- - -	33 „

7. No zymotic diseases have been contracted at this station. The station and bazaar are always in a healthy and clean state, and the native troops are always particularly clean in their personal habits; but the native population are both in their personal habits and in their dwellings so filthy as to predispose them to many diseases. 8. Epidemic disease is not influenced by the nature of the soldiers' duties and occupations in barracks.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —Diseases—*cont.*	9, 10. Quinine has not been tried here as a prophylactic against malarial diseases, as the station is free from malaria. There has been no epidemic disease at the station.
V. Intemperance.	1, 2. The sepoys are, generally speaking, temperate; there are no confirmed drunkards. No sepoys have been admitted to hospital whose diseases were directly or indirectly caused by intemperance. 3. Distilled spirits are not sold at the bazaar; they form no portion of a soldier's ration at the station, on the march, or in the field. Spirit is never given to convalescents. No other deleterious drinks are sold in the bazaar. 4, 5, 6. I have had no opportunity of judging of the effects of the consumption of spirits on the health of European troops in India, but from my knowledge of the country I should say that total abstinence from stimulating drink would prove most conducive to the health of the European soldier. 7 to 10. The use of tea, coffee, &c. would be most beneficial to those not habituated to the use of stimulating drinks, such as spirits, beer, &c. There are no European soldiers nor any canteens at Chirrapoonjee. No recommendations to make on these points. 11. The bazaar is conducted according to the rules laid down in Section VI. of the military Regulations.
VI. Diet.	1. No reply to these queries, there being no European troops at the station.
VII. Dress, Accoutrements, and Duties.	1. No reply to this query.
Duties.	1. No reply to this query. 2. The sepoys at Cherra are on duty one day and off one day. They are drilled as recruits three times a day, and suffer much from getting wet. Drill for the regiment is totally stopped during the rain. There are no general orders particularly regulating marching hours in these hills. The inhabitants and the Sepoys always eat before starting, and the heat of the day is never too great. The average number of nights the men have in bed is three or four a week. 3. Guards are mounted close to the lines. There are three roll-calls during the day, and on occasions of sickness four. The weather here being wet and cold, the sentries require protection from it. Night duties under these circumstances do not seem detrimental to health.
VIII. Instruction and Recreation.	1. There are no means of recreation at the station, but there is a regimental school which is pretty well kept up. There is no restriction on the men as to exposure to the sun and rain when off duty, and their health is good. 2, 3, 4. No reply to these queries.
IX. Military Prisons.	1. There are no military prisons or cells at the station.
X. Field Service.	1. There are no local regulations for field medical service not included in the general presidency regulations. 2, 3, 4. No experience of the practical working of the powers of medical officers as regards the conduct of the line of march, &c.
XI. Statistics of Mortality.	1. No information under this head.
XII. Hospitals.	1, 2, 3. The military hospital at this station is only for the accommodation of native troops. It is in the immediate vicinity of the lines, and about 200 yards distant from them; it is at some distance from the bazaar and civil population. The site is open, freely ventilated, and healthy as to elevation, drainage, absence of malaria from river banks, marshes, or other nuisances. The water supply is abundant and wholesome. 4. The natural sloping formation of the ground upon which the hospital is built, combined with the heavy and constant falls of rain, renders artificial drainage unnecessary. 5. There is only one ward in the hospital, which is raised from the ground about 2½ feet and flagged. The roof water is carried away by a drain round the house; a portion of the drainage does, however, sink into the subsoil on which the building is raised. The rain-fall is carried very rapidly away, but as it rains here for weeks together without ceasing, a quantity of water penetrates the subsoil. The hospital is "pucca," *i.e.*, built of stone and mortar. The ventilation is deficient, there being no spaces between the roof and walls. The building is surrounded with a verandah which is 4½ feet wide, and affords sufficient shelter from the sun's rays; never used for the accommodation of the sick, &c. Table of hospital accommodation. Total number of wards, 1. Total regulation number of beds, 50.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patients Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
1	50	113·5	18	12	24,516	490·3	17·2	2·5	7	5·5	3·5

The hospital is so placed as to receive the full benefit of the prevailing winds. The windows open on hinges like doors: their arrangement is conducive to ventilation.

6. The means of ventilation are the windows, doors, and two fireplaces. They are not sufficient to keep the wards free from odour or closeness.

7, 8. There are no means of cooling the air admitted into wards; the wards are warmed by means of two large fireplaces. The walls and ceilings are cleansed and limewashed every three or four months.

9. There is only one privy attached to the hospital, and it is connected with the building by a covered passage. It is merely a temporary mat-house which has just been erected. The cloacæ are carried away in earthen pots.

CHIRRAPOONJEE, KHASIA HILLS. BENGAL.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	10, 11. There are no lavatory arrangements, or means of bathing the sick, save by water carried to them by the hospital water-carrier. 12. There are no means for washing and drying the hospital linen. 13. With regard to the storage, the surgery where the medicines are kept is very damp, and a loss of them is thereby entailed. 14, 15. No replies to these queries. 16. There are no diet tables or forms for keeping the statistics of sickness, mortality, and invaliding at the station. 17 to 24. No replies to these queries.
XIII. BURIAL OF THE DEAD.	1. The burial ground used by British troops is half a mile distant to the leeward of the station. 2. Its area is about an acre, and the soil is gravelly and well drained. 3. There is no particular rule as to the space between graves, but their depth is about six feet. They are only opened a second time by special request; as when one or more of a family are buried in the same grave. Interment is compulsory within 48 hours after death at ordinary times, and as soon as possible after decease during epidemics. There are not spots set apart for natives; they generally burn their dead, but when buried they are taken out of the station to any spot the relations may choose, so as no inhabited or cultivated ground is adjacent. 4. The graveyard is never offensive. 5, 6, 7. The dead of camp followers or bazaar people are taken out of camp and burned or buried, according to creed. No injury to public health accrues from the present practice. No improvements to suggest.

Major, Commanding at Cherra.
THOMAS DILLON, M.D.,
Assistant Surgeon, in Medical Charge Sylhet Light Infantry, and Civil Station, Chirrapoonjee.

19th October 1860.

MURREE.

References to Subjects and Queries.	Replies.
I. TOPOGRAPHY.	1. The country surrounding the station is very irregular and sub-alpine in aspect, in fact altogether mountainous. The hills around are for the most part well wooded with forest trees, such as oaks, horse-chesnuts, and the various genera of the natural order coniferæ, &c., on the higher hills, and acacias, euphorbias, olives, and Toon trees, &c., on the lower, whilst mountain springs are abundant everywhere. 2. The elevation of the station above the sea is about 7,800 ft., and about 2,500 ft. above the level of the adjacent country. The river Hanoo, a tributary of the river Indus, is about four miles to the west of the station, and a small mountain stream, a branch of the river Sohan, is about the same distance to the east of the station. The river Sohan empties itself into the river Jhelam; both are about from 1,500 to 2,000 feet below this station. There is no higher ground immediately adjoining the station, but there are numerous hills within a radius of 20 miles around, of various altitudes, from 2,000 feet above the elevation of Murree, to as many feet below it. The former are not adapted for sanitaria, owing to the rigour of the climate during the winter, but some of the latter are especially so from the mildness of the climate throughout the year. 3. About 24 miles south-east of Murree is the plateau of Kavor, about three miles long by two wide. Its surface is undulating and about 1,500 feet above the level of the plain. Springs are plentiful and there are two or three small rivulets on the borders of the plateau. At the north end of this plateau is the police station (a fort), and the village of Kavor, and near its centre are the ruins of an old Sikh cantonment. This plateau is well adapted for a hill cantonment, and is about 30 miles north-east from Rawul Pindi, and of easy access. About 30 miles south-west of Murree is the high hill of Nurpur, about 3,000 ft. above the plain, and 45 miles distant from Rawul Pindi. Its summit is somewhat flattened and wooded. Springs are the source of its water supply at the summit, and the river Hanoo flows at the northern base of the hill. Its site is well adapted for a convalescent depôt. On the summit are two holy shrines much resorted to by a certain sect of Mahommedans. 4. At Kavor water is obtained from numerous springs and the river Sohan flows about two miles north of the plateau. At Nurpur also springs are the source of water supply, and the river Hanoo flows along the northern base of the hill. There are neither marshes nor lakes in the vicinity of either site. The nearest water to Murree (besides the springs in the station) are the rivers Hanoo and Sohan, which flow respectively on the western and eastern bases of the hill, and about four miles from the summit; both are mountain streams. Neither vicinity is liable to overflow of water at any season. At Murree the surface is uneven, but there are no water-pits, and drainage is rapidly effected by the natural declivity of the site. 5. The upper portion of Murree is open and freely exposed to every wind. The lower part is sheltered from north-east and east winds and is somewhat encumbered by trees, but not sufficiently so materially to interfere with free external or internal ventilation, though after rains the trees hold the moisture for some time and render the neighbourhood damp. The temperature of the station is not raised by exposure to reflected sun heat, as the trees around absorb whatever heat there may be. During the winter and spring months north and north-east winds prevail, and their effect on health is invigorating. During the summer months west and north-west winds prevail, and bring with them dense fogs and rains. The effects of these are deleterious to the subjects of fevers of the intermittent type, especially to pulmonary affections and bowel complaints.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	6. The country surrounding the station is cultivated as well as the irregular surface of the ground will admit, chiefly with Indian corn and wheat, though a little of barley, rice, and cotton is also cultivated. There are no works of irrigation near the station. The cultivation of rice is prohibited within a distance of about a mile more or less of the station, at least such is nearly the average distance of the boundary line (within which all cultivation by the peasantry is prohibited) from the station. 7. The nearest city to the station is that of Rawul Pindi about 38 miles distant. 8. The mountain ridge on which Murree is situated consists of a hard grey sandstone, which at frequent and irregular intervals crops out from below a superimposed bed of indurated red clay, overlaid in most parts by a thin layer of black vegetable mould, replaced here and there by a heavy tenacious clay, the result of the disintegration of the red clay rocks. These characters belong to the main spur on which Murree is situated, as also to the numerous branches it gives off to the eastward. But on the west side the sandstone comes in contact with an extensive formation of nummulitic limestone, which constitutes the bulk of the Hazarah hills in that direction. The present site of Murree is new ground, and was never before occupied by any extensive population. 9. The depth at which water is found beneath the surface in the dry and rainy seasons is not known. There are no wells in the station, but surface springs are numerous. 10. The rain fall and water from surface springs are rapidly drained off, owing to the natural declivity of the hill sides. There is no higher ground, the drainage from which could pass into the subsoil of the station. 11. The water supply of the station is derived from numerous springs in various parts of cantonments and from two reservoirs within its limits. These latter are open stone built tanks, and contain an aggregate extent of about 2,500 feet tank surface. These tanks are at all times full more or less, and are known to contain frogs, water beetles, and a variety of confervæ; but there are no means of ascertaining the presence of other animals. No tank used for drinking purposes is also used for bathing. One tank, from its elevated and open position, is free from all chance of pollution by leaves and other matter falling into it, or from the drainage of surface impurities; but the other, situated low down the hill, is open to pollution from both these causes. No nuisance or malaria proceeds from these tanks, nor from the small ponds scattered over the station, and of which one is to be found in the grounds around almost every house. 12. The amount of water supply available for the station is not known. The qualities of the water are inferior, the colour is cloudy and sometimes muddy, the taste and smell are also; but especially after rain more or less earthy. These objectionable qualities are, however, easily removed by filtering, a process very generally practised at this station. It is sometimes necessary to boil the water, and then filter it in order to quite get rid of the peculiar taste acquired by the water during its percolation through and over the clay and vegetable mould covering the surface. These remarks apply especially to the water of those springs that issue on the surface in forest lands or well wooded spots. There are no means of ascertaining the chemical composition and microscopic characters of the water; but it is soft, its amount is sufficient, and when filtered is I believe of good quality and not injurious to health, but I have not had enough experience of this point. By the natives (principally occasional visitors) the water is considered to possess inferior qualities and is said to cause colic. The method in general practice, viz., boiling and filtering through layers of sand and charcoal, is I believe sufficient to deprive the water of the impurities it contains, and render it wholesome and fit for use. 13. During the rainy season, viz., from June 15th to September 15th, the station is more or less damp, owing to the trees and vegetation holding the moisture to a considerable extent, and on this account is prejudicial to the welfare of fever cases, more especially of the intermittent form, and bowel complaints and affections of the liver. The winter is too rigorous for cases of pulmonary disease. 14. No reply to this query.
II. Climate.	1. Hitherto the only instrument for conducting meteorological observations at the civil dispensary has been a thermometer; but within the last month a rain gauge has also been supplied. 2. There are no data available at this station from which to prepare a table of meteorological observations. [Note.—No information respecting this station is given other than that contained in the foregoing replies.]

(No date.)

(Signed) H. W. Bellew, Assistant Surgeon,
In Civil Medical Charge, Murree.

JUBBULPORE.

Accommodation—Queen's Troops { Artillery 105 / Infantry 722 }

Accommodation—Native Troops { Artillery - 14 Gun Lascars. / Cavalry - 160 / Infantry - 385 }

References to Subjects and Queries.	Replies.
I. Topography.	1. The aspect of the country surrounding the station is hilly to the south-east and west and flat to the north. There is no wood, but plenty of jungle and water in the vicinity. 2. The station has an elevation of 1,250 feet above the level of the sea, and a moderate one above the adjacent country of from 5 to 20 feet, while the site of the European barracks is 20 feet above the ordinary level of the station. There is no higher or healthier ground adjoining Jubbulpore. 3. The nearest table land is distant from the station about 10 miles on the Mundlah road, and is 350 feet above the station.

JUBBULPORE. BENGAL.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	4. The waters nearest to the station are the Nerbudda river distant four miles and a half, the Oomtee nullah distant from three quarters to one mile, and a nullah without name about 400 yards from the European barracks. Tanks are very numerous, and there is a large swamp about 600 yards to the east of the barracks. I cannot say whether or not the vicinity is liable to overflow, not having been at this station during the rains. There are plenty of ravines and broken ground in the vicinity of the station, and their effect on health is very bad. 5. The station is shut in on the western, northern and eastern sides by rocky ridges and hills. The temperature is raised by the buildings being exposed to reflected sun heat, and by the numerous rocky hills, particularly the ridge of rock 1,000 yards to the westward. The station is not exposed to cold or variable winds, and the climate is very equable. 6. The country surrounding the station is cultivated in parts. There are no works of irrigation, nor any artificial irrigation near the station beyond damming up bunds of fields. Rice is cultivated in the surrounding villages, some of which border on the cantonment; but indigo is not grown, nor the preparation of hemp or flax carried on near. 7. The native town of Jubbulpore is two miles distant from cantonments. 8. The general surface soils of the station are sand and black cotton soil, with boulders of rock (almost hills), cropping up here and there through them of black trap sandstone, or of the gravel disintegrated laterite. 9. Water is usually found in the station at from 6 to 50 feet, in the barracks at from 12 to 60 feet; but in the lower parts of the station it rises to within 6 feet of the surface. 10. The rainfall or water from surface springs generally flows readily away to the numerous small nullahs, and there is no drainage from adjacent higher ground flowing into the subsoil of the station. 11. The water supply of the station is derived from wells. The tanks are nearly dry in the hot season, some quite so. They contain duck-weed and other aquatic plants of rapid growth, and fish of various kinds. No tank is used for drinking purposes by the Europeans of the station. The wells are generally clear of trees, and cannot therefore be polluted by dead leaves falling into them. Nuisance and malaria proceed from the tanks, and the only way to remove them is to drain the tanks and fill them in, which in many instances could be easily done. 12. The water supply of the station is abundant, clear, and well tasted, and in some wells impregnated with iron. It is alkaline and soft, and no impurities can be detected by the microscope. The water is raised from the wells in accordance with the custom of the country, viz., by bheesties or water carriers in a leather musak. 13. There is a high range of rocky hills one mile to the westward of the station, and which greatly increases the heat. 14. Sites for barracks are generally selected by a committee composed of the officer commanding the station, the magistrate, the officer commanding the regiment or battery, and two medical officers.
II. CLIMATE.	1. A thermometer is the only instrument at the station for conducting and registering meteorological observations, and is kept in the hospital. 2. No reply to this query. 3. The committee having been here only 3 months cannot of their own knowledge give any information respecting the dryness or moisture, heat or cold, variability, &c. of the climate, nor its effect on the health of the troops, nor which are the most healthy or unhealthy months here. 4. In the district of Sohagpore is a plateau called "Ummurkuntuk," 6 miles long by 5 broad, at an elevation above the sea of 3,600 feet, and distant from Jubbulpore viâ Shaipoorah 130 miles. This plateau is strongly recommended as a sanitarium for European soldiers. 5. No reply to this question.
III. SANITARY CONDITION OF STATION.	1, 2, 3. Ground plans of the station, &c., and plan of the barracks, showing their construction, are forwarded. 4. Table of barrack accommodation. Date of construction. February 1858 commenced. Total number of rooms or huts. 10 ranges. Each has 3 compartments. Four rooms for non-commissioned officers.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
		Feet.	Feet.	Feet.				Inches.			
1 range	100 × 10= 1,000	303½	20	17	103,190 × 10= 1,031,900	1,000	60	15	There are no windows, as doors with ventilators are used instead.		
Outer compartment	—	97½	20	17	—	—	—	—			
Centre compartment	—	108½	20	17	—	—	—	—			
Non-commissioned officers' rooms	—	26	10	12½	—	—	—	—			
Guard room	27	96½	18	16	27,792	1,000	60	—			
10 prison cells	10	86½	7	17	10,293	1,000	60	—			

5. There are verandahs on both sides of the barracks, extending the whole length. These are occupied for sleeping when the men are very much crowded in the rooms, which has been the case ever since March 1860. There are no windows, jalousies, or jhilmils.
6. Wooden cots with string bottoms are used in the barracks for the soldiers to sleep in.
7. The tents used are made of thick country cloth; double poled (bamboos); 13 feet high; side walls 5 feet; dimensions 21 by 15 feet. There are 16 men in each tent, and the space per man is 177 cubic feet and 19 feet superficial area. The tents are all of the same size and pattern.
8. The barracks, huts, &c. are ventilated by a portion of the ridge of each building being left open, then covered and overlapped by another small roof as per sketch transmitted. The ventilation is not sufficient (with 100 men in the barracks). To keep the air cool, the door-

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	ways on the western side are covered by wet tatties, through which the wind freely blows. These tatties are frames of bamboo-work, the size of the doors, covered with the "Kus" grass; the cost is about 6 rupees each. 9. The barracks are constructed of burnt bricks in lime; flagged stone floors; sawn wood couples for the roof, which is thatched with grass 9 inches thick. The doors are battened on one side, and partly glazed on the other. The tents are made of Dosootee cloth, cotton ropes, and bamboo poles; the inner fly is lined with blue cloth, 2½ feet below the upper. The huts for native troops are of mud walls with tiled roofs. 10. The floors are of well rammed moorum and broken stones, covered with mica schist slabs set in lime. Half of the barrack floors are raised 18 inches above the level of the ground, but the remainder only 9 inches. 11. The barracks are capable of very great improvement. Repairs are executed by the Executive Engineer and Barrack Department, but they are not performed in particularly quick time. The senior medical officer and the officer commanding are responsible for the general sanitary state of the cantonment. The walls and ceilings of the barracks are cleansed and limewashed annually. 12. The wash-houses are buildings 20 feet by 15 feet, 8½ feet high, with kutcha pucka walls and thatched roof. Tubs or half casks are supplied for the use of the men. The interior is drained into a drain running round the building, which leads again into a catch drain. The buildings are 10 in number. A plunge bath is being constructed, 60 feet by 15 feet, with a depth of 5½ feet, enclosed with lattice work openings and tiled roof. 13. The barrack cook rooms are double and single kutcha pucka walls, pointed roof, tiled, and the floors of moorum. The dimensions of the double cook room are, 144 feet by 12 feet, height, 8 feet. Drains conduct from the interior of the surface of the ground around all the refuse water, pure water being supplied by the bheesties. 14. The privies are constructed partly of pucka, partly of kutcha pucka. They are single and double buildings; the former 20 feet by 14 feet, height 8 feet, and the latter 40 feet by 14 feet, with screen walls in front of the door and in the rear. They are drained from the inside into a cesspool, the contents of which are removed by the sweepers to a distance every morning. 15. These buildings are unventilated except by the doorways. The barracks are lighted at night by oil lamps, six to each barrack. 16. For drainage and sewerage of barracks, there is simply a surface arrangement of open drains, which, as the barracks stand on a slope, conduct the water to a nullah running along the western side about 30 yards from the lower ranges. There are no sewers, but the above means are sufficient for carrying away all the surface water and drainage from the men's lavatories, cook-houses, privies, urinals, &c. No part of either barracks or hospital can be said to be damp. The cesspits are about 20 yards from the nearest men's quarters, and about 100 yards from the hospital. Mahters or sweepers carry away the refuse to a distance three times a day. There are many foul ditches both in and outside the station. 17. The surface cleansing of the cantonment and its vicinity is performed by sweepers, but is not efficiently done. The refuse is removed to a distance, and burned if possible. 18. The surface of the cantonment is not kept free of vegetation, and the bazaar is very badly ventilated and requires opening out. 19. The drainage of the bazaar is insufficient, and the ventilation bad. The water supply is good, but cleanliness is almost impossible with no latrines and every hut crowded. The greatest improvements might and will be effected when funds become available. The native houses near the station are ruinous mud huts with tiled roofs. No native will keep his drains nor the precincts of his house clean unless obliged. No nuisance is experienced in barracks from wind blowing over the native dwellings, but a great one is felt from the tanks, which generally dry up in the hot weather. This, however, could be put a stop to by filling them in. 20. Animals for the use of the troops are slaughtered at a distance of half a mile from the station, and nuisance is experienced only when the place is to windward. 21. Bazaar horses, and those of camp followers, are picketed in rear of the barracks, and the manure is regularly removed and burned. 22. The picketing ground for the artillery horses is to the westward of the barracks, and about 200 yards distant, that for the cavalry horses half a mile distant to the north-west. There are no stables. The manure is burned. 23. There are at present sufficient quarters for married non-commissioned officers and men at this station: the married people do not occupy barrack-rooms with the men.
Officers' Quarters.	1. Officers' quarters at this station are the usual Indian bungalows. I would recommend as an improvement that they be placed nearer to their men's barracks.
IV. Health of the Troops.	1. As far as the experience of the committee extends, the station and the district in which it is situated are healthy. 2. The diseases most prevalent among the native population are fevers of the intermittent type, spleen disease, bowel complaints, and rapid chest affections. Epidemics are rare. 3. Attribute the unhealthiness of the neighbouring native population to the sudden and frequent changes of temperature, the numberless tanks, and large tracts of jungle. 4. The infantry arrived here from Banda, and the artillery from Umballa. The 2nd troop 3rd brigade H.M.'s Bombay horse artillery arrived at Umballa March 3rd 1859, and remained there till December 24 same year, when the troops were marched to Jubbulpore, and arrived in cantonments on March 16th, 1860. The troop was very healthy at Umballa, the mortality per annum being 20 per 1,000. Venereal diseases and fevers were the most prevalent. The troop was in good health on its arrival in Jubbulpore, and has continued so. It has had no casualties here. Venereal diseases very prevalent, and just now fevers of a mild type. H.M.'s 97th regiment arrived at Banda on the 26th January 1859, and left that station on the 10th February 1860. The five companies stationed there during that period were very unhealthy, and suffered chiefly from fevers, diseases of the bowels and stomach, diseases of the brain and venereal. The regiment arrived at Jubbulpore on the 5th March 1860 in a good state of health, and since its arrival has chiefly suffered from fever, venereal, and bowel complaints. No portion of the men's present accommodation is more unhealthy than the rest.

References to Subjects and Queries.	Replies.
IV. Health of the Troops—*cont.*	5. The troops at this station are never camped out. 6. I was quartered with H.M.'s 53rd regiment at the hill station of Dugshai (one of the Simla group of sanitaria), elevation 6,000 feet, for a period of 18 months. During the first season the mortality was large, and more than half of it was caused by hill diarrhœa. The regiment had been stationed during the two previous years at Peshawur, and the health of nearly every man was impaired by repeated attacks of severe intermittent fever, endemic to that station. It was remarked that the worst cases of hill diarrhœa occurred amongst those men who had suffered most from the fever of Peshawur. The same remarks apply to H.M.'s 32nd regiment, which was removed from Peshawur simultaneously with the 53rd, and occupied the neighbouring hill station of Kussowlie, 9 miles distant from Dugshai. The excessive cold during the winter at Dugshai hastened the fatal issue of a number of the cases under treatment for hill diarrhœa, but the health of the men greatly improved during the second year of residence, and on leaving the station for the plains in October 1855, the whole regiment was in a high state of health and efficiency. There can be no doubt that the sudden change from Peshawur to the hills in a great measure caused the sickness and mortality above noticed, and that a year's intermediate residence in some healthy station in the plains, such as Rawul Pindee, Sealkote, Jullunder, or Ferozepore, would be a more judicious arrangement than a direct move from Peshawur to the hills. I was subsequently (in 1857) in medical charge of the convalescent depôt of Darjeeling in Bengal (elevation 8,000 feet), and my experience leads me to regard it as much better adapted for convalescents than any other sanitarium in the Bengal presidency,—a pre-eminence doubtless attributable to the equableness of the climate. The mean thermometric range is less at Darjeeling than at any of the hill stations in the North-west provinces, and the bane of the latter, viz., the wasting and almost unmanageable diarrhœa, is unknown at the former. 7. I have not observed that troops are more liable to febrile and other diseases on removing from the hills to the plains. There is no reason why they should be so, provided they are removed at the proper time of the year, namely, after the cold weather has well set in. 8. From my experience, I approve of selecting hill stations for troops. 9. The hill diarrhœa before noticed is the only disease to which troops are liable to be attacked on proceeding to the hills. 10. As regards the precautions required as to diet, clothing, shelter, &c., I did not observe any errors, in the hill stations with which I am acquainted, that would be likely to increase a tendency to endemic disease. 11. The spring and autumn months are those best adapted for a residence in the hills, and convalescents cannot be expected to derive permanent benefit from a residence in a hill station under a shorter period than two seasons. 12. I am not aware that there is any period of residence in the hills beyond which injury is likely to be inflicted on the health of troops on returning to service in the plains. 13. The chief precaution necessary to be observed on removing men from the hills to service in the plains is to shift them at the proper time, viz., after the cold season has well set in. 14. There can be no doubt that if all the European troops in India could always be located in well-chosen hill stations, sickness and mortality would fall to a much lower average. It is, therefore, obvious that service in the plains, with short periods of change to the hills, cannot be equally conducive to the preservation of health and the prevention of mortality. A prolonged residence in an unhealthy station in the plains exercises a pernicious effect on both the health and spirits of the troops and convalescents; but no desirable object can be gained by moving troops frequently from stations which are found to be healthy. 15. At the hill station of Dugshai the barracks for the companies are very good in every respect; but the barracks for married soldiers are not good; they are not sufficiently commodious, and they have not proper means of ventilation. The hospital at the same station is very defective, both as to lighting and ventilation. At the sanitarium of Darjeeling both the barracks and hospital were faulty in construction. The lighting and ventilation also were defective, and the flooring, ceiling, and walls unmistakably showed that the works had been hurriedly and carelessly executed. 16. The two hill stations with which I am acquainted, viz., Dugshai and Darjeeling, have elevations of 6,000 and 8,000 feet above the level of the sea, and it has been shown that Dugshai has not proved so healthy as might have been expected, but that Dargeeling has been found to be eminently healthy, and that its salubrity is, doubtless, owing to the equableness of its climate. It is, therefore, extremely probable, though I have no personal experience in support of the statement, that a medium elevation of 4,000 or 4,500 feet in the north-west sanitaria would be found more conducive to the health of convalescents than a higher range of elevation. The extreme cold of higher elevations would be avoided, a more equable temperature secured, and probably, also, a drier climate. A climate involving a wide thermometric range is inimical to convalescents who have lost their health in the plains. Though Darjeeling stands as high, if not higher, than the north-west sanitaria, it approaches nearer to the tropics, and hence its milder climate. 17. I am not sufficiently acquainted with the district surrounding this station to enable me to say if there is any higher or healthier ground near, which could be advantageously occupied as a hill station. 18. There can be no doubt that a light sandy soil, which does not retain moisture on the surface, is the most healthy. 19. Soldiers should not be sent to India before the age of 22, and the best period at which they can land there is in the cold season, not before the beginning of November. Troops on first landing in India, if they are destined for the North-west provinces, are detained at one of the depôts near Calcutta until they have been supplied with clothing and other necessaries. They are despatched to their destinations as far as Cawnpore by bullock-train, railway, or river steamer, and beyond Cawnpore by bullock-train or regular marches. Drill is never carried on to any extent, except during the cold season, and the duties in most stations are usually light. For preserving the health of recruits on first landing in India, I would recommend sufficient and properly ventilated barrack accommodation, suitable clothing, cleanliness, athletic games, and other amusements; an avoidance of the native bazaars, and sobriety. 20. Young recruits, growing lads of weakly constitutions would undoubtedly benefit by a residence in the hills before serving in the plains.

IV. Health of the Troops—*cont.*

21. The mode of transport of troops by land is by railway, bullock-train, and marching; that by water in troop-boats, towed by steamers. Troops usually suffer less when transported by land, from the fact that the men are sometimes overcrowded.
22. A British soldier should not serve in India more than 10 years.
23. The mode of conducting medical boards, both at the station and the presidencies, appears to me to be good.
24. Invalids should not leave India, when destined for home, later than the end of March.

Diseases.

1. Health inspection parades take place at this station once a week, usually on Saturday mornings.
2. There are not, nor have there been, any cases of scorbutus or scorbutic disease among the troops at this station.
3. The proportion of hepatic disease at this station has not hitherto amounted to 2 per cent. It not unfrequently accompanies or follows bowel complaints, and its most frequent exciting causes are intemperance, excessive heat, overcrowding, and defective ventilation.
4. Dracunculus is of very rare occurrence at this station, and no case of it has occurred amongst the European troops.
5. The proportion which the constantly sick in hospital from venereal disease bears to the total sick in hospital from all other diseases is about 34 per cent. When barracks are situated in the vicinity of large bazaars and populous native cities, it is almost impossible to guard against a large proportion of venereal disease. Lock hospitals would be decidedly advantageous, in fact the only effectual means of diminishing the liability of soldiers to these diseases.

Note.—One half of the admissions into hospital are from venereal diseases; and as every bazaar swarms with native prostitutes, always more or less suffering from disease, I am of opinion these people should be brought under some health regulations, with a view of lessening the number of soldiers who are rendered unfit for service by them.

W. W. Turner, Colonel,
Commanding the station.

---

6. The following are the diseases from which the troops at this station suffer, viz.:—Ephemeral and intermittent fevers, with many cases of rheumatism. They do not suffer much from dysentery, and no case of cholera or small pox has occurred here.

The following Table shows the proportion which admissions and deaths from these diseases bear to the total admissions and deaths:—

Diseases.	Proportion of Admissions to other Diseases.	Proportion of Deaths to Admissions.
Fevers -	1 in $6\frac{16}{55}$	None.
Dysentery -	1 in $38\frac{5}{7}$	1 in $3\frac{1}{2}$
Cholera -	None.	None.
Small Pox -	Do.	Do.
Rheumatism	1 in $13\frac{11}{20}$	Do.

7. The more frequent zymotic diseases are miasmatic and enthetic. They are most prevalent during the rainy season, and after its close. In the rainy season variations of temperature are frequent, and the atmosphere is laden with moisture, and after its close a high temperature acting on decaying vegetation generates malaria. The bazaar is in a very bad sanitary condition, the drainage and ventilation are defective, and the dwellings overcrowded. The strictest personal cleanliness is insisted on as far as regards the troops, but the habits of the natives have been and ever will be the reverse.
8. Neither the duties at this station nor habits on the march predispose to epidemic disease.
9. The troops at present quartered at this station have not as yet passed through a malarial season. I am not aware that small doses of quinine have been previously tried as a prophylactic.
10. I have not resided at this station sufficiently long to enable me to judge of its epidemics, and these have hitherto been of rare occurrence.

V. Intemperance.

1. British soldiers as a rule are intemperate, but there are only a few confirmed drunkards amongst them, 1 in about every 200.
2. The total admissions into hospital from intemperance only amount to 7, and indirectly two or three.

The following Table shows the effect of total abstinence, temperance, and drunkenness on the amount of sickness and mortality at the station:—

Classes.	Strength.	Total Admissions.	Total Deaths.	Per-centage of Admissions to Strength.	Per-centage of Deaths to Strength.	Per-centage of Deaths to Admissions.
Teetotallers -	26	5	None.	$19\frac{3}{13}$	None.	None.
Temperate -	601	198	2	$32\frac{568}{1001}$	$\frac{2}{601}$	$1\frac{1}{99}$
Intemperate -	97	7	None.	$7\frac{21}{97}$	None.	None.

Drunkenness is always punished as an offence.

3. Distilled spirits are sold in the canteen, and illegally in the bazaar; the quality is very bad. Some men take one dram, others two a day. Spirit does not form part of the soldiers' ration, either at the station, on the march, or in the field. Old soldiers often take a dram before morning parade, but its effect must be injurious to health. It is never given as a ration to convalescents. No drinks are sold in the canteen except beer and spirits. Various kinds of sherbet are sold in the bazaar, which are almost all unwholesome, more especially when allowed to stand long enough to permit of fermentation commencing.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	4. The consumption of spirits by troops and convalescents is injurious to health, and is not conducive to the efficiency or internal discipline of the corps. 5. The abolition of spirituous liquors as part of the ration, would be highly beneficial to the health of troops. 6. Sound malt liquor or wine would be decidedly more beneficial to the health of troops than spirituous drinks. 7. Coffee and ginger beer are largely used here; but lemonade and soda water are luxuries too expensive. There can be no doubt that a cup of good hot coffee is the most wholesome stimulant of which a soldier can partake. 8. The entire suppression of the spirit ration would undoubtedly increase the health and efficiency of the troops. 9. It would be beneficial to prohibit the sale of spirituous liquors in the canteens, and permit only beer, coffee, tea, lemonade, &c., to be sold to the troops. 10, 11. No replies to these queries.
VI Diet.	1. The ration for Queen's British troops and European troops in the Indian army is the same, and composed as follows, viz.:—1 lb. of meat (mutton or beef), 1 lb. bread, 1 lb. vegetables, $\frac{5}{7}$ oz. tea or $1\frac{3}{7}$ oz. coffee, $2\frac{1}{2}$ oz. sugar, 1 oz. salt, 4 oz. rice, and 3 lbs. firewood. There is a responsible inspection of the constituents of the ration, by the orderly officer of the day, and after by the commanding officer and surgeon. 2. A due proportion of vegetables enters into the composition of the ration. There is no stoppage. The men here have three meals a day, viz.—breakfast at 8 a.m., dinner at 1 p.m. and tea at half-past 5 p.m. 3. The rations are generally composed of the best meat and vegetables procurable, but the cooking is, as a general rule, not sufficiently varied. The meat is almost invariably fried, and soup or broth is seldom made from it. No part of the ration is disposed of. 4. The cookhouses and cooking apparatus have been described. Tea and coffee are properly prepared for the troops, and the men generally have one or the other before a march. 5. Gardens for the cultivation of vegetables by soldiers at this station could be advantageously established, under local regulations by the commanding officer.
VII. Dress, Accoutrements, and Duties.	1. The soldiers dress at this station consists of cane helmets, khakee coat and trousers, cotton shirt, flannel cholera belt, woollen socks, and boots. They are also provided with ammunition pouch and bayonet, with white leather belts, and cap pouch. I consider the dress as suitable to the climate, and for the soldier's duties by day and night. The dress at present in use, loose khakee tunics and trousers, and the wicker helmet, are well adapted for the hot season in the plains, and the loose undress scarlet jacket recently issued, instead of the shell jacket is sufficiently warm clothing for the cold season, but the thick black cloth trousers, then issued for wear are not suited to the climate of India. Trousers of stout double-milled flannel or thick serge would be infinitely more comfortable. Flannel shirts and socks should also be used in India, more especially during the rainy and cold seasons. The guard dress is cloth or cotton according to the season, and there are wooden sentry boxes to protect the men from rain and heat.
Duties.	1. Inasmuch as men thoroughly drilled at home would be less subjected to the fatigue of constant drill on joining their regiments in India, such a practice would decidedly be beneficial to health. 2. A soldier's duties at this station consist of guards, pickets, fatigues, and regimental drills, none of which extend over an hour's duration, from 5 or 6 a.m. They are very conducive to health. The best time for drills, parades, or marches (respecting which there are regimental orders), is between 5 and 9 a.m. The men have every night in bed during the week on an average; and are on duty about one day in 20. 3. Guards are mounted about three quarters of a mile from the barracks, and last all day and night. There are always roll calls, but their number and time vary. Night duty is generally considered injurious.
VIII. Instruction and Recreation.	1. The following are the only means of recreation and instruction available at this station, viz.:—one skittle ground, one regimental school, regimental library and reading room, one armourers' workshop, and one theatre. These means are not sufficient to keep the men occupied during the wet season and heat of the day. In the hot and rainy seasons, soldiers are not allowed to leave barracks after 8 a.m., or before 5 p.m. 2. As an improvement I would suggest that ball courts, gymnasia, and carpenters' and shoemakers' shops be built for the men. 3. There are military savings banks at this station. 4. There is not sufficient shade from trees, sheds, verandahs, &c., to enable the men to take exercise without injury to health during the day.
IX. Military Prisons.	1. The military prisons at this station are as yet unfinished.
X. Field Service.	1. There are no local regulations for field medical service not included in the general presidency regulations. 2, 3. Suggestions or recommendations by the medical officer respecting the conduct of the line of march, bivouacking, camping, &c., are invariably carried out, circumstances permitting. 4. Field hospitals are established when such a step becomes necessary in consequence of the increased number of sick and maimed during war. Diets, servants, clothing, bedding, and doolies for the conveyance of the sick, are provided by the commissariat; medicines and instruments from the nearest depôt. A special field-surgeon and assistants are appointed for duty in the field-hospitals, and an officer or agent of the commissariat is attached for the purpose of procuring and maintaining the necessary supplies.
XI. Statistics of Sickness and Mortality.	N.B.—Jubbulpore is considered a healthy station. It has been a station for European troops for two hot seasons, 1858–59. They belonged to the Madras field division. There are no records of sickness and mortality to refer to.

References to Subjects and Queries.	Replies.
XII. Hospitals.	1, 2. The hospital is situated about 400 yards in the rear, and to the left of the left wing of the barracks. There are no stables in the vicinity of the hospital, while the bazaar is distant upwards of half a mile to the north-west, and the houses of the civil population generally are at a still greater distance. The site is open and freely ventilated, and there are no buildings, high walls, or trees, which interfere with the ventilation. The site generally appears to be good as regards elevation, drainage, &c.; but the hospital is not as yet completed, and has not been occupied by sick. 3. The water supply of the hospital is abundant and wholesome. 4. All refuse water is removed by means of an open pucca drain. 5. There are no wards, except those on the ground floor, which are raised on a solid plinth of masonry about two feet above the level of the ground. There is, therefore, no perflation of air whatever beneath the floors. No provision is made for conveying away the roof and rain water. The hospital is built of bricks and lime; the roof and walls are single, and the latter are of sufficient thickness to keep the hospital cool; but the roof is composed of tiles, which do not keep out the heat as well as thatch. There is an enclosed verandah on each side, 10 feet in breadth, and an outer open verandah on each side of same width, affording sufficient shelter from the rays of the sun. The hospital consists of one flat.

Table of Hospital Accommodation.

Total number of wards - - -	3
Total regulation number of beds - -	60

Wards or Hospital Huts.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
1 ward divided into 3 compartments by open archways.	20 sick in each compartment.	74 feet each.	22 feet.	22 feet.	35,360	1,768	- - -	2 feet.	There are no windows. The doors, 15 on each side, are half-glazed—a glazed ventilator being placed in every door.		

The hospital faces the west, and receives the full benefit of the prevailing winds. There are no windows in the building, but the doors are provided with a ventilator, turning on a pivot.

6. Ventilation is effected by the doors and the ventilators above them, as also by apertures near the top of the wall on each side, communicating with the roof verandah. Apertures also exist in the roof, one for each ward or compartment. These means of ventilation appear to be sufficient to keep the wards free from odour and closeness. There are no jalousies or jhilmils.
7. Tatties are used for cooling the air in the wards. They are made of a frame of bamboo, covered with layers of "khus-khus" grass, and are kept constantly wetted, by which means the hot winds in passing through them are cooled.
8. There are no artificial means of warming the wards. The walls and ceilings of the hospital are cleansed and limewashed by regulation twice a year.
9. The hospital privy is situated a few paces behind the north-east corner of the hospital, and is connected with it by a covered passage. It is well constructed and ventilated, but has no urinals connected with it. Water is supplied by bheesties. There is an open cess-pit behind, but the ordure, &c. is carried away in filth-carts and deposited at a distance. The privy has not as yet been used.
10. There are four rooms apportioned for lavatories, which are situated at the ends of the enclosed verandah, and will be amply sufficient for the purpose.
11. The bath-room is enclosed under the same room as the privy, but is separated from it by a thick wall. It is sufficient for the purpose, and very convenient.
12. The washing and drying of hospital linen is invariably performed by native washermen in the open air.
13. The store-room at present is unfinished.
14. The bedsteads are wooden frames with twine interlaced, and tightly stretched to the sides and ends. The bedding consists of one mattrass, one bolster, two pillows, two sheets, two blankets, and one quilt. Iron frameworks, with sacking bottoms, would be more suitable than wood as being less liable to harbour insects and vermin.
15. The hospital kitchen is situated a few paces in the rear of, and opposite the centre of the hospital. The diets are cooked in copper vessels, which are tinned twice a month. They are sufficient for the purpose required, and the diets are well-cooked, being varied *ad libitum*.
16. Copies of the diet tables, &c., are transmitted.
17. The provision for attendance in hospital is one hospital serjeant, and two orderlies allowed by the commanding officer, who never objects to the employment of as many orderlies as may be deemed necessary.
18. As already stated, the hospital is not completed, and has not been occupied.
19. The deficiencies with regard to the building are, a dead-house, want of accommodation for sick women and children, and quarters for medical subordinates, but there do not appear to be any deficiencies with regard to the sanitary condition of the hospital.
20. The only places of exercise for convalescents are the verandahs of the hospital.
21. There is no arrangement or provision for soldiers' sick wives or children, who can only at present be treated in their barrack rooms,—a most unsatisfactory arrangement.
22. No special local hospital regulations exist.
23. Change of diets and medical comforts within the hospital, at stations, camp, and on the march are entirely under the control of the medical officer, whose recommendations on sanitary matters are invariably promptly attended to.
24. There are no wards for convalescents at this station, but such accommodation would undoubtedly be advantageous.

XIII. Burial of the Dead.

1, 2. The burial ground for the use of the troops is in the station, and to the west of the Sudder bazaar. Its area is 28,700 square feet; the soil and subsoil being sand and loam.

References to Subjects and Queries.	REPLIES.
XIII. Burial of the Dead —*cont.*	3. The graves are 6 feet by 3 feet, and 5 feet deep, with an interval between each of from 2 to 3 feet. They are never re-opened. Interment takes place at all times as soon as the coffins can be made ready. The Mussulman troops are buried without the cantonments; the Hindoos being burnt at a distance from the station by their friends. 4. The graveyard has not as yet proved offensive. The men are buried, as soon as coffins can be got ready, in the presence of the officer commanding, &c. of the companies to which they belonged, the usual military honours being given. 5, 6, 7. The dead of camp followers and bazaar people are disposed of according to caste, in the same manner as the dead of native troops. No injury accrues to the health of the public from the present mode of disposal of the dead, and no improvement on this head can be suggested.

(Signed) W. W. TURNER, Lieut.-Colonel,
H.M.'s 97th Regiment, Commanding Station.
A. MACRAE, M.D.,
Surgeon, 97th Regiment.
FREDERICK A. HOWES, Lieutenant,
Officiating Executive Engineer, Jub. Dn. P. W.

Dated 10th July 1860.

NOTE.—All the members of the committee labour under the disadvantage of having had only four months' experience of the station.

APPENDIX.

EXTRACT of a letter No. 3,985, dated 17th August 1860, addressed by the Quartermaster-General of the Army, Bengal Presidency, to the officer commanding Saugor district, having reference to questions not properly answered on the sanitary state of the Indian Army for the station of Jubbulpore.

Question 4.—TOPOGRAPHY.—Cannot the prejudicial effect of the ravines and broken ground be remedied or improved?—*Further answer vide annexments.*

Question 6.—TOPOGRAPHY.—The local civil officers should be asked for the information which the committee express themselves unable to afford.—*Further answer vide annexments.*

Clause 7, *Question* 11.—TOPOGRAPHY.—A special report should be made on the tanks complained of, and it should be shown how they could be drained and filled in, and at what cost.—*Further answer vide annexments.*

Question 4.—CLIMATE.—Has any examination of the "Ummerkuntuk" sanitarium ever been made? If so, I will be glad to receive the report accompanied by statistical and meteorological observations for submission to the Commander-in-Chief and Government.—*Further answer vide annexments.*

Question 5, *Clause* 3.—SANITARY CONDITION OF STATION.—A more detailed return, showing how each of the barracks is occupied by the infantry and artillery, is required, as the former has a detachment absent, and it should be explained why, if the men are so crowded as to necessitate their sleeping in the verandahs, the want of barrack room has not before been brought to notice, and specially reported upon.—*Further answer vide annexments.*

Question 14.—SANITARY CONDITION OF STATION.—Could not the privies be cleaned twice a day, morning and evening?—*Further answer vide annexments.*

Question 16, *last Clause.*—SANITARY CONDITION OF STATION.—Have any measures ever been taken or applied for to remove the nuisance of the foul ditches? If not, it should be explained why the subject has been overlooked. A station order temporarily entertaining the necessary establishment for this purpose would have been sanctioned had it been attached to a representation of its urgency. A further report on this and the efficient cleansing of the station with reference to queries 17 and 18 should be submitted.

The replies to the above and following questions regarding conservancy evince a want of local arrangement and control, and the matter must be attended to, and specially reported on, if aid is required from Government, but it should be shown that this is absolutely necessary,—why bazaar establishments and local funds have not been raised, and whether the civil authorities have been applied to for prison labour and other assistance to effect these improvements.—*Further answer vide annexments.*

Question 4.—HEALTH OF THE TROOPS.—The answer to query 4 is incomplete.—*Further answer vide annexments.*

Question 1.—INSTRUCTION AND RECREATION.—Why has only 1 skittle alley been supplied, 2 per regiment being authorized? The commanding officer should refer to the executive engineer for the proper number for both infantry and artillery.—*Further answer vide annexments.*

(True extract.)
F. W. ROBERTS, Major,
D. A. Quartermaster-General of the Army.

ANSWERS to the Queries contained in No. 3,985, dated Quartermaster-General's Office, Simla, the 17th August 1860.

Query 4.—Cannot the prejudicial effect of the ravines and broken ground be remedied or improved?

Answer.—Yes, it might be improved to a certain extent by draining and filling in, but the expense would be considerable.

Query 6.—The local civil officers should be asked for the information which the committee express themselves unable to afford?

Answer.—The information has now been supplied by the deputy commissioner, and is attached to the folio.

Clause 7, *Query* 11.—A special report should be made on the tanks complained of, and it should be shown how they could be drained or filled in, and at what cost?

Answer.—Some of the tanks complained of are in the civil station. Of the two, worst in the military cantonments. estimates of the probable cost of draining and filling them in are attached and marked C.

Query 4.—Has any examination of the "Ummerkuntuk" sanitarium ever been made? If so, I will be glad to receive the report, accompanied by statistical and meteorological observations, for submission to the commander-in-chief and Government?

Answer.—A special examination has been made by Capt. Pearson. A copy of the report shall be sent as soon as obtained from the commissioner.

Clause 3, *Query* 5.—A more detailed return, showing how each of the barracks is occupied by the infantry and artillery, is required, as the former has a detachment absent; and it should be explained why, if the men are so crowded as to necessitate their sleeping in the verandahs, the want of barrack room has not before been brought to notice and specially reported upon?

Answer.—*Vide* return D., attached.

The want of accommodation was reported, *vide* letter E., attached.

Query 14.—Could not the privies be cleaned twice a day, morning and evening?

Answer.—The privies are regularly cleaned twice a day.

Query 16, *last Clause.*—Have any measures ever been adopted or applied for to remove the nuisance of the foul ditches; if not, it should be explained why the subject has been overlooked. A station order, temporarily entertaining the necessary establishment for this purpose, would have been sanctioned had it been attached to a representation of

its urgency. A further report on this and the efficient cleansing of the station, with reference to queries 17 and 18, should be submitted.

The replies to the above and following questions, regarding conservancy, evince a want of local arrangement and control, and the matter must be attended to and specially reported on, if aid is required from Government, but it should be shown that this is absolutely necessary. Why bazaar establishments and local funds have not been raised, and whether the civil authorities have been applied to for prison labour and other assistance, to effect these improvements?

Answer.—Measures have been adopted, inasmuch as they are gradually being cleaned out or filled in.

Everything is being done as far as possible, but Jubbulpore wanted much cleansing, in consequence of a large Madras commissariat depôt having been there. The funds are small.

F. Wheler, Brigadier.

Query 4.—The answer to query 4 is incomplete?

Answer.—Answered more fully.

Query 1.—Why has only one skittle alley been supplied, two per regiment being authorized? The commanding officer should refer to the executive engineer for the proper number for both infantry and artillery.

Answer.—*Vide* F., attached.

With respect to the concluding remarks made by the Quartermaster-General in the above letter, that the replies of the committee, as contained in the Sanitary Commission folio, evince a want of local arrangement and control, I beg to observe that I only took command of the station on the 5th March last, and cannot therefore be answerable for what was done prior to that date. The work which has been done since I am prepared to point out. Local funds have since that date been raised and are being worked upon, as coolies can be procured, prison labour not being available.

I have the honour to be, Sir,
Your most obedient Servant,
W. W. Turner, Colonel,
Commanding Jubbulpore.

To the Deputy Assistant
Quartermaster-General,
Saugor District, Saugor.

C.—Jubbulpore Division of Public Works, Military Department.

Estimate No. of 1860–61.

Estimate framed by Lieutenant F. A. Howes, officiating executive engineer Jubbulpoor Division of Public Works, of the probable expense of draining and filling up to the level of the surrounding ground two tanks, one of which is situated about 200 yards south-east of the artillery hospital close to the soldier's gardens, and the other to the east and close to the irregular cavalry lines at present occupied by the detachment Alexander's horse, agreeably to the accompanying copy of letter No. 490, dated the 6th instant, from the station staff officer.

Jubbulpore, 14th September 1860.

Specification.

The tanks to be filled in to the level of the surrounding ground with earth excavated from the bunds.

Detail of Work.

	ft.	ft.	ft.	ft.		
Tank south-east of the Artillery Hospital - -	600	× 550	× 5·0 =	1,650,000		
	300	× 60	× 1·5 =	27,000		
	275	× 75	× 1⅛ =	23,203		
					1,700,203	
Total cubic feet of earth work						1,700,203

Detail of Work—*cont.*

	ft.	ft.	ft.	ft.		
Tank close to the Irregular Cavalry Lines -	365	× 245	× 5·0 =	447,125		
	280	× 43	× 2·5 =	30,100		
	390	× 75	× 2·5 =	73,125		
	210	× 47	× 2·5 =	24,675		
					575,025	
Total cubic feet of earth work						575,025

Abstract of Expense.

1,700,203	Cubic feet of earth work to tank situated to the south-east of Artillery Hospital at 4r. per 100 cubic feet - - -	4,250	0	0
575,025	Do. do. to tank situated close to the Irregular Cavalry Lines at present occupied by Alexander's horse, at 4r. per 100 cubic feet - - - - -	1,437	0	0
	Total cost, rupees	5,687	0	0
	Add contingencies at £5 per cent. - -	284	0	0
	Total rupees	5,971	0	0

Jubbulpore, 18th September 1860.

W. W. Turner, Colonel,
Lieut.-Colonel, Commanding 97th Regiment.

No. 187.—E.

Sir, Jubbulpore, 19th April 1860.

In forwarding the annexed copy of a letter from the executive engineer relative to the occupation of the new military hospital at this station, I have the honour to make the following remarks for the information of the brigadier commanding the district, in view to his submitting the same to the Right Honourable the Commander-in-Chief, should he deem it expedient so to do.

It will be observed that the executive engineer anticipates that the building in question will be ready for occupation by the 20th May next. The 97th regiment arrived in the station on the 5th March, and it was then anticipated that the hospital would be ready for occupation in a month or six weeks; but as it was in very nearly as forward a state as it is now, I am apprehensive that the 20th of May will not see it fit for occupation unless more energetic measures are adopted to ensure it.

On the 5th March the hospital was floored, roofed, and all but tiled; the surgery, store-house, cook-house, and privy walls up and partially roofed; and at this present time the hospital is no further advanced, with the exception of a part of the foundation for the verandahs; while the roofing of the surgery, store-houses, cook-house, and

JUBBULPORE, BENGAL.

privy is not yet completed. The tiles of the hospital have also been shifted to substitute others of a better make.

The unfinished state of this hospital necessitated the taking up of No. 1 barrack for the accommodation of the sick, leaving only seven others for eight companies, band, drums, regimental school, reading room, and serjeants' mess, in all 651 men. These barrack buildings were built to contain 100 men each; but they are not in reality large enough for more than 80*, and as we have upwards of 100 in each, I am apprehensive of serious consequences to the health of the men.

They already show that this overcrowding is being attended with ill effects; and if they show this in the strong breezes which now prevail, and insure an ample supply of fresh air, what will they not show when the still, stifling heats of June, July, and August are upon them?

I have, &c.

(Signed) W. W. TURNER, Colonel.
Lieut.-Col., Commanding H.M. 97th regiment.

The Assistant Quartermaster-General,
Saugor district, Saugor.

(True copy.)

W. W. TURNER,
Lieut.-Col., Commanding H.M. 97th regiment.

Extra accommodation could not have been built this year; some buildings being even now, in September, unfinished.

F. WHELER, Brigadier.

SURGEON'S REMARKS.

Jubbulpore, 19th April 1860.

THERE can be no doubt that the present overcrowded state of the barracks occupied by the 97th regiment is causing steadily-increasing sickness, and that sickness will rapidly increase,† unless the evil is speedily remedied. Overcrowding of the barracks, moreover, involves overcrowding of the wash-houses, latrines, and urinals attached to them, which for this reason cannot be kept in a sufficiently clean or sanitary condition.

(Signed) A. MACRAE, Surgeon,
H.M. 97th regiment.

(True copy.)

W. W. TURNER, Colonel,
Lieut.-Col., Commanding H.M. 97th regiment.

* They are four feet narrower than is usual.
W. W. TURNER, Colonel,
Lieut.-Col., Commanding 97th regiment.

† It has not increased, except venereal.
September 1860. F. WHELER, Brigadier.

No. 407.—F.

SIR, Jubbulpore, August 10th, 1860.

I HAVE the honour to request you will bring to the notice of Brigadier Wheler, commanding Saugor district, the great want that exists of suitable places of recreation for the soldiers of the 97th regiment. There is but one skittle alley, and that so small that only one match can be played at a time; I would suggest, therefore, that a ball court, and carpenters' shop should be erected.

I am induced to bring this matter thus prominently forward, in the belief that places of recreation and amusement at the barracks, would prevent numbers from going to the bazaar to seek change from the monotony of barrack life, and considerably reduce the list of crime.

At present they have but one small table and three forms in each barrack, and have consequently to eat their meals in a comfortless fashion on their cots.

I have, &c.

(Signed) W. W. TURNER, Colonel,
Lieut.-Col., Commanding 97th regiment.

The Assistant Quartermaster General,
Saugor district, Saugor.

(True copy.)

W. W. TURNER, Colonel,
Lieut.-Col., Commanding 97th regiment.

Skittle allies have been ordered, but not a ball court, as the site for permanent barracks is not fixed on.

(Signed) F. WHELER, Brigadier.

FEROZEPORE.

Accommodation - European Troops - Artillery, 148; 1 Battery Foot Artillery.
Infantry, 1,000; including 200 for the Arsenal.
Native Troops - Cavalry, 1 Regiment.
Infantry, 5 Regiments.

References to Subjects and Queries.	REPLIES.
I. TOPOGRAPHY.	1. The general aspect of the country is sterile and desolate-looking. Very little natural vegetation. Few trees, and the villages are thinly scattered. It is a dead level; the soil for the most part consists of sand and alluvial clay; the former predominates. There is very little wood; the waste ground is thinly covered with low jungle. The Madar plant abounds. Very little water is seen.
	2. The station is 720 feet above the sea, the adjacent country about the same level; but the surface of the country appears to have a fall westward of nearly 1½ feet per mile. The nearest water is the river Sutlej, 3½ miles distant. The station occupies the highest ground in the district.
	3. The nearest mountain is Kangra, 90 miles distance, and 6,000 feet above the level of the sea.
	4. A nullah runs close to the back of the station, and is dry, excepting after heavy rain. There is no water nearer than the Sutlej. There is a considerable overflow of water in the vicinity of the station, after heavy thunderstorms, in the hot weather, lasting from 12 to 48 hours. There is broken ground and small ravines, produced by the rush of water after a heavy fall, but which rapidly run dry. No water pits are near the station, and nothing to produce disease.
	5. The station is open from without on all sides; the roads running through it are about 70 feet wide. Gardens surrounded by mud walls 4 feet high are attached to most of the bungalows; in the gardens, trees are cultivated, but nothing is allowed to interfere with ventilation. A powerful eastern sun, with a hot wind blowing during the day, will, no doubt, produce sun-heat reflection; but thatched bungalows, the prevailing mode of structure, with mud walls, well apart, will moderate the effect. There are land winds, but no sea breeze. During the summer months, frequent dust storms arise with great violence from every quarter, without rain, loading the atmosphere with dust, which, on subsiding, leaves the air pure, and contributes greatly to the healthiness of the station.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	6. The surrounding country is principally cultivated; there are no works of irrigation. Irrigation, as pursued by the native agriculturists by means of wells, is not deemed to be unhealthy, but the station is not within the influence of any. Rice is not cultivated in the district, nor is indigo, hemp, or flax.
	7. The city of Ferozepore, with a population of 14,000, is situated 2 miles from the station.
	8. The geological structure is sand and alluvial clay, free from rock and stone. The station occupies ground which was formerly cultivated by the residents of the city, but has never before been occupied by population.
	9. Water is usually found in the dry season 24 feet below the surface, and during the rains at 23 feet.
	10. The district is free from surface springs, and the rain-fall sinks into the subsoil, and so drains off, leaving the ground free from evaporation. There is no higher adjacent ground, the drainage from which can affect the station.
	11. The water supply is derived entirely from wells sunk beneath the surface to from 28 to 30 feet. Every care is taken to prevent any impurity draining into the wells. The station is particularly free from all nuisance or malaria.
	12. Water is plentifully supplied; it is remarkably pure, colourless, free from smell, almost tasteless, and very transparent. Although not free from some combination with earthy matters, it possesses the quality called softness, which renders it suitable for culinary, washing, and other purposes, and is sufficient in quantity as well as excellent in quality. It is raised by means of leathern bags, a common and very efficient way of conveyance; and, on the whole, I consider the water as good as could be wished for.
	14. New stations are selected, after a careful examination of the country by those civil, military, engineering, and medical officers who have acquaintance with the district. A mixed committee of experienced officers in the several branches is appointed to examine and report on the most desirable site, for information of the Commander-in-Chief, who submits it, with his own opinion, for the final decision of Government.
II. Climate.	1. Common thermometers and rain gauges are the only instruments used at the station for conducting meteorological observations.
	2. Table of observation.

Five Years of Observation, from January 1, 1855, to December 31, 1859.

Months.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Sun Temperature.	Rain.	Winds. Direction.	Days of Sunshine.	Remarks as to Cloud, Dew, Winds, &c.
	°	°	°	°	°	In. cents.			
January	56·	24·8	72·2	45·4	95	1·06	N.E. & S.W.	20	Frequently overcast.
February	64·6	17·2	77·4	58·2	98	1·7	N.E. & S.W.	27	Dust storm.
March	76·7	26·4	88·9	62·6	103	0·56	N.E. & W.	28	Hail storm.
April	80·8	28·6	95·4	66·8	115	0·87	N.E. & W.	28	Dust storms.
May	97·	21·2	104·8	82·8	130	0·08	Variable.	30	Dust storms.
June	95·2	22·	105·8	83·8	125	1·13	N.W.; W.	28	Dust storms.
July	90·	21·6	101·2	79·6	130	6·13	N.E., S.E., & W.	25	Hot and dry.
August	86·	19·4	95·8	76·4	115	5·30	N.E. & W.	24	
September	86·4	18·2	95·8	77·6	108	3·56	N.W.	22	Variable temperature.
October	76·8	20·4	89·	68·6	118	—	W. & N.N.E.	30	Fair.
November	68·6	24·8	81·2	56·4	96	—	N.W. & N.E.	30	Steady weather.
December	56·2	21·	71·2	51·8	79	0·04	Variable.	31	Steady weather.

3. The climate is dry, free from any great variation or miasma. The cultivation of trees within the station, and that of vegetation generally without (where at first all was bare), have increased the rain-fall, and to some extent diminished the dust storms, moderating the excessive dryness of the air, and thus improving a climate which is naturally in favour of the European constitution. It is particularly favourable, health being preserved without any dietetic restriction, or peculiar manner of clothing or shelter being resorted to. The parade duties are for 1½ hour morning and evening in the cold weather, and in the hot season for a short period each morning at daybreak, as a matter of exercise and discipline rather than drill. From December to March inclusive are the most healthy months, and August and September the most unhealthy. Fevers, particularly those of the intermittent type, are the prevailing diseases, and in severe hot weather the men may suffer, though rarely, from attacks of heat apoplexy.

4. There is no district near the station so healthy.

5. The following are the principal stations on which I have served:—1. Barrackpore; 2. Sylhel; 3. Dinapore, in Bengal; 4. Cawnpore; 5. Lucknow; 6. Agra; 7. Delhi, in Hindostan; 8. Neemuch, in Malwa; 9. Ferozepore, in Punjab. The two last were the most healthy. Neemuch is a table land, 1,400 feet above the sea. The soil is of trap rock, intersected by black mould. The country stony, undulating, and irregular; easy of drainage; no great variation of temperature; European troops were not located there in my time. Lucknow will become a desirable place of residence for Europeans. Agra was never particularly healthy; was formerly the site of an ancient city; the water brackish, and injurious to vegetation; the heat great; its proximity to a large city objectionable; visitation by cholera frequent. The old site of the station at Delhi, destroyed by the mutineers, from its proximity to pestiferous marshes, from which the prevailing winds blow, but which nothing could remove, was decidedly injurious. The present site within the city walls, and a high ridge intervening between it and the low country, is comparatively healthy. Sylhel is very similar to Moulmein in dampness, rain, and low situation, and is suited to few constitutions. Barrackpore, though too relaxing, has become, by drainage and other sanitary means, comparatively healthy for a Bengal station. Dinapore and Cawnpore have always been considered unfavourable to the European constitution, though improved under sanitary measures.

* Inner verandah not included.

5. The barracks face north-east and south-west for the benefit of the prevailing winds. They have no windows, but are well provided with doors on all sides.

A 12 feet verandah surrounds the building.

No one is allowed to use the verandah as a sleeping quarter. Jalousies or jhilmils are not necessary in the Punjab.

6. The bedsteads are wooden frames and legs, with rope or tape plaited across for the mattress.

7. Tents are of one wall with double roof, made of strong country canvass. The outer or upper roof consists of three layers of cloth; the inner of two cloths, and the walls of three.

Each tent is for 16 men. The superficial area is 320 feet, or 20 square feet to each man.

The cubical contents 2,560 feet, or about 160 cubic feet per man. (Sketch annexed.)

8. The barracks have ridge ventilation.

Skylights or upper windows are used for buildings of every description, and for tents which have no ventilators, the sides around may be raised from the ground when more air is required than four doors (one in each side) will admit of. The ventilation is quite sufficient. The air is cooled by tatties, which are universally used, and consist of screens made of the scented root, kus-kus, and sufficiently thin to admit of a current of air through it. These are placed in each doorway (previously fitted) to the windward, and kept constantly watered. The cost of each tattie is seven rupees, and 10 of these can be watered for a monthly outlay of 15 rupees. Punkahs are also in constant use during the hot season in all barracks. They are pulled by the hand, at a monthly cost of $10\frac{1}{2}$ rupees for 20 beds. The structure is a wooden frame covered with cloth, with a cotton fringe attached, and suspended from the roof.

9. Most public buildings are constructed of burnt brick, with lime and mortar. Tents are of strong country canvass.

10. Floors are constructed of brick and mortar, raised 3 feet above the ground.

11. I consider that nothing could be better than the present construction.

The executive engineer performs the principal, and the barrack-master all petty repairs, within a reasonable time after a requisition is made.

The senior medical officer present is the responsible sanitary officer. At his suggestion and recommendation, all necessary measures are carried out under the orders of the commanding officer. Walls and ceilings are cleansed and lime-washed once a year, and whenever found necessary.

12. The lavatories consist of small rooms, with floors of brick and mortar, adapted for receiving and draining off the water into the subsoil outside, so that the men may freely bathe themselves, as well as use earthen vessels for the purpose of cleanliness. The water is kept in earthen vessels, provided by water carriers.

13. The usual country mode of cooking, is by fires on the ground, with side walls of mud about a foot high and 9 inches apart for supporting the vessel. The native dhobie (or washerman) washes by the wells and dries the clothes on the spot, in the open air.

14. The contents of the privies and urinals are carried off by sweepers, and buried outside the cantonment.

15. They are ventilated by ridge ventilation as well as openings in the walls on all sides.

Country oil lamps are used for lighting all buildings requiring it.

16. No drainage is required, as all refuse is carried off by sweepers employed for the purpose. The arrangements for this purpose are quite sufficient. The buildings are free from dampness. All refuse is removed to a distance, but water from the bath room is allowed to sink into the subsoil. Pits are allowed for the temporary holding of refuse from the cook-houses, three feet in diameter, and conveniently near, but at a distance from wells. These are daily cleaned. They are between 200 and 300 yards from the nearest quarters. No foul ditches are permitted to exist.

17. An establishment of sweepers with refuse carts are kept for the purpose of daily sweeping up and removing refuse of every kind from the station.

18. The surface of the cantonment is kept free from vegetation by an establishment of coolies attached to the executive engineer's department. No old walls, thick hedges, or anything interfering with the ventilation of the station, are permitted.

19. The bazaar consists of one-story houses in lime, with verandahs in front for shop purposes, and open streets for free circulation of air. No drainage is necessary, as all refuse

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	is removed. Water is supplied from wells. Latrines (or spaces enclosed with mud walls) are kept at a distance and out of the influence of the prevailing winds, but the natives generally prefer going a distance in the country for the purpose. An establishment of sweepers is kept at the expense of the bazaar itself for removing all refuse, and preserving due cleanliness under the authority and supervision of the bazaar master. A better arrangement I could not suggest. The native houses consist of mud huts with flat roofs and an entrance door only. Native houses are not allowed sufficiently near the station to have any influence whatever on the barracks or station itself. 20. Slaughter-houses are located quite away from barracks, but within the neighbourhood of the sudder bazaar, and out of the influence of the prevailing winds. The offal is buried outside the station. 21. The number of horses kept is so very small that no particular place for picketing them is appointed, but the owners are allowed to keep their cattle in the rear of their houses, the manure and refuse being removed by bullock and buffalo keepers, or brick burners who eagerly seek it. 22. No stables are provided at the station. The horses are picketed in the open air, about 500 yards from barracks and 1,200 or more from the hospital. Dung heaps are not allowed. Manure and refuse is disposed of by the native stable assistants as explained above. The stable litter is at the disposal of the public works department, if they require it for the purpose of burning brick. The horses are arranged in double rows. The ground sloping from head for drainage purposes, the huts for the native assistants are in line close by. 23. The married men in the artillery are supplied with separate barracks, two rooms and bath room for each family. Those of the infantry occupy corner rooms attached to the barracks, and are not hutted with the men.
Officers' Quarters.	1. There are no public quarters for officers. They occupy private rented bungalows.
IV. Health of the Troops.	1. The district throughout is particularly healthy. 2. The native population suffer mostly from diseases of which venereal is the primary cause. Ulcers, cancers, diseased bones, leprosy. Fevers of the intermittent type are prevalent during the wet season from exposure, of which sleeping out of doors is too common. Splenetic diseases are comparatively few. Urinary calculi very prevalent in the male of both children and adults from the age of three years, but the cause is not very evident, unless their inveterate use of molasses in its crude and impure state accounts for it. 3. I attribute the healthiness of the population to the dry state of the atmosphere, the absence of water surface, the purity of the drinking water, and no excess of vegetation, all which are favourable to a people who habitually expose themselves at all times and under all circumstances to the open air. 4. It is two years since the whole of the European troops now at Ferozepore came from Peshawur, where the principal number had been located two and some five years. Fevers and bowel complaints were very prevalent at that station, and the men on first arrival at Ferozepore suffered from the effects of the Peshawur climate, but they are now as healthy as any troops in India. There is no perceptible difference as to healthiness in the different portions of this station. 5. The troops do not go into camp unless it is preparatory to a march, or in case of severe sickness, and when the medical authorities deem such a move to be necessary. 6. I have had no employment in hill stations. 7. I believe the constitution is better able to resist the effects of febrile and other diseases after the return from hill stations to the plains, supposing it to take place in the winter, which is the usual time. Any emergency which would recall the troops to the plains in the hot season would have an opposite effect. The purity and bracing qualities of the hill air permitting the European to take out-door exercise at all hours cannot fail to renovate the constitution. On the other hand, those in the plains at the same season must confine themselves to their quarters for eight hours daily in a temperature of 90° and upwards, or suffer exposure outside to a destructive heat with an irresistible desire for drink. 8. I highly approve of the hill stations for troops. The climate is particularly beneficial as a restorative to those from the plains who may be free from actual disease. 9. I am not aware of any diseases peculiar to hill stations. They are not considered desirable climates for chest and heart complaints, nor do I think generally speaking the hills are favourable for actual diseases of the internal organs. 10. Damp and cold are the only attacks to be guarded against, for which flannel clothing and good shoes are necessary. 11. The seasons best adapted for residence in hill stations are from the 15th April to the end of October. A residence throughout the year is found to be very beneficial for debilitated constitutions, but the difficulty in affording protection from the inclement weather, and the necessary confinement to the house, would make a winter residence in the hills unadvisable for troops. I recommend nothing short of six months. 12. There is certainly no period of residence in the hills beyond which injury is likely to be inflicted on the health of troops on returning to the plains. 13. Nothing more is necessary than the ordinary precautions for preserving health on leaving hill stations for the plains. 14. An occasional location in the hills (every third or fourth season) would be preferable, besides being equally conducive to the health of the troops; it would keep the men acclimatized and better able to resist the climate when circumstances rendered their exposure to the heat necessary. The climate varies so much in different stations in the plains that too frequent change is highly objectionable, excepting in sickly localities. The general health of troops improves by a prolonged residence, and even in stations considered sickly it is sometimes noticed that sickness decreases as the system becomes habituated to the climate. 15. I believe the barracks at hill stations to be in all respects suitable for the troops. 16. I have had no opportunity of judging at what elevation the most suitable sites may be obtained. 17. There is no higher ground near this station. 18. I have found those stations in which the surface and subsoil admit of ready percolation to be the most healthy.

FEROZEPORE. BENGAL.

IV. Health of the Troops —*cont.*	19. The best age for soldiers proceeding to India is from 19 to 22, and the period most suitable for landing is from November to the end of January, so that the troops may be comfortably settled at their quarters before the hot season commences. Every measure likely to promote the health is adopted in the disposal of troops on first landing. Exposure should be strictly avoided, and temperance in point of eating and drinking, especially the latter, enforced. 20. Troops should be sent direct to India to the healthiest stations, which experience shows to be in the Punjab. They should go to the hill districts during the hot season after landing. 21. The transport is by railroad, river steamers, bullock trains, or by regular marches, according to circumstances. 22. A British soldier should serve in India from 12 to 15 years. 23. The manner of conducting medical boards is such as to avoid conflict of opinion. I have no suggestions to make. 24. The beginning of the year is the best time for invalids to leave India, so that they may have the advantage of cool weather for reaching the place of embarkation and arrive in England at the beginning of summer.
Diseases.	1. The men are inspected once a week for the discovery of disease. 2. Scorbutic disease is scarcely known at this station. Two mild cases occurred in 1858-59 amongst 1,058 admissions into hospital. It is occasioned by impaired constitution, for which, removal to a hill station, and other suitable measures, would be desirable. 3. From the 1st April 1858 to 31st March 1859 there were 23 cases of hepatic disease out of 1,058 admissions; and, in the remaining nine months of 1859, 10 cases to 968 admissions, attributable, according to circumstances, to exposure to heat and chills, produced by sudden change of temperature, cold stages of fever, intemperance, exposure to night air when imperfectly clothed, after the sequelæ of dysentery and fever. 4. Dracunculus is seldom met with amongst Europeans, though with natives it is very prevalent in some localities; it is rarely seen in this district. Eight admissions for dranunculus appeared in H.M. 24th Foot during May and June 1858, on its arrival from Peshawur, the only cases since the regiment landed in India, on the 27th August 1846. 5. In the years 1858 and 1859, 395 cases of venereal disease were treated, out of 2,026 total admissions. 6. The troops suffer from epidemic diseases, such as fevers, principally of the intermittent type, 674 admissions to 2,026; 6 deaths. Dysentery, 48 admissions to 2,026; 1 death. No cholera nor small-pox. Rheumatism, 189 admissions to 2,026; no deaths. 7. The character of zymotic diseases differs in no particular manner from that in other localities. They are most prevalent during the hot and subsequent rainy seasons. The atmospheric conditions are those in which there is great variableness, such as intense heat by day, followed by damp and chilly nights, &c. The sanitary state of the bazaar, or native dwellings, differs in no wise from other portions of the station. Intemperance and exposure are the chief predisposing causes of zymotic diseases. 8. I am not aware that the soldier's duties, &c., at this station have any special influence in producing epidemic diseases. 9. Quinine, as a general rule, answers well as a prophylactic in 5 grain doses. 10. I have no recommendations to make with regard to the prevention of epidemic disease.
V. INTEMPERANCE.	1. The soldiers at this station, as a body, are temperate, though exceptional cases, as in all arge bodies of men, occasionally occur. From 1 to 2 per cent. is about the proportion of confirmed drunkards. 2. The admissions to hospital directly caused by intemperance were five, to a total of 2,026, in the years 1858 and 1859. It is difficult to arrive at any correct conclusion in regard to disease indirectly caused by intemperance, considering how frequently it leads to the production of other diseases. Drunkenness is punished as an offence under the authority of commanding officers. 3. Distilled spirits are sold only at the canteen. It is country distilled rum, 24 per cent. below London proof. Each man consumes two measures (about 6 oz.) of rum and 1 pint of malt liquor, or 1 of the former and 2 pints of the latter. Malt liquor is preferred in the hot season. Spirit is no part of the daily ration; the men pay for it and drink it at the canteen. It is not provided on march; and in the field it depends on circumstances. They may get it free of expense at the discretion of the officer commanding during severe exertion or exposure. It cannot be had before morning parade. Spirits are never given as a ration to convalescents. No other drinks injurious to health are sold at the canteen or bazaar. 4. Spirits in moderation, if not directly injurious to health, are certainly not conducive to it, but rather act prejudicially, promoting the habit of dram drinking, and lastly lead to excess. They are not conducive to discipline. 5. The discontinuance of the sale of spirits in the canteen and bazaar would be advantageous, provided no other means are available for procuring its substitute in shape of native distilled liquor, which of all description of drink is the most destructive. Putting an end to the use of spirituous liquors would necessitate the absolute abolishment of every sale of bazaar and country drink. 6. I consider a moderate use of beer (porter is rather heavy) to be conducive to health. The difficulty of procuring wholesome wine, free from adulteration with raw spirits, deters me from recommending it for troops. 7. Tea and lemonade are in great demand in the hot season, and coffee in the cold months. Soda water is not available for the men on account of its expense. It is desirable in every point of view that the men should be encouraged to depend more on this class of drinks during the hot and thirsty season than on spirituous liquors. 8 and 9. The supply of Government spirits is a much less evil than that the men should drink native distilled liquors. If the latter can be effectually suppressed I am confident that the substitution of beer, tea, or coffee, &c., would materially benefit the health of the troops. 10. I would recommend that a coffee and other refreshment shop on a large scale, with reading room attached, should be provided for European regiments, in which might be included workshops, &c.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	11. The following are the canteen and bazaar regulations :— 1*st Battalion H. M. 24th Regiment.* Rules for the Canteen of the above Corps. *Noon.*—1 pint of beer or 1 dram of rum. *Evening.*—1 pint of beer and 1 dram of rum. *Note.*—In the event of a soldier not drawing either beer or rum at noon he may draw 2 drams of rum in the evening, at half an hour's interval between each dram. (True copy) J. Tongue, Lieut. and Acting Adjutant, 1st Battalion H.M. 24th Regiment. Regulations affecting the purchase by European soldiers, &c., of liquor in Military Cantonments. Extract from the Abkaree lease for the sale in cantonments of spirits manufactured after the native method. No. 11. You shall never, without written authority from the officer commanding the station, under any pretence at all, sell liquor to European soldiers or non-commissioned officers, whether with their regiments, or on staff employ, such as road, commissariat, or ordnance serjeants, nor to their wives, or any members of their families, nor to any person whom you may have grounds of suspecting of an intention to convey it to such persons. The first infringement of this rule will subject you to a fine at the discretion of the superintendent cantonment Abkaree, not exceeding 500 rupees, and for the second offence you are liable to lose your contract, and forfeit your security money. C. Darnell, Capt., Superintendent of Cantonment Abkaree. Extract from the form of licence granted to merchants for the sale within cantonments of liquors of all descriptions, whether imported or country made. III. That no liquor whatever is to be sold to European soldiers, their wives, families, or servants, or to non-commissioned officers, or soldiers with regiments, or on staff or civil employ, without a pass signed by their immediate commanding officer and countersigned by the superintendent of cantonment Abkaree. (*Vide* Circular, No. 34, from the officiating financial commissioners for the Punjab, dated Lahore, 19th April 1859.) (True extract) C. Darnell, Capt., Superintendent of Cantonment Abkaree. The canteen regulations are strictly obeyed, and no man can get more than what is allowed. The bazaar rules on these subjects are also carefully attended to.
VI. Diet.	1. The composition of the ration is the same both for British and India troops, viz.:—1 lb. bread, 1 lb. meat, 1 lb. vegetables, 4 ozs. rice, 2½ oz. sugar, $\frac{5}{7}$ oz. tea, 3 lbs. firewood, 1 oz. salt. Coffee may be substituted for tea, or may be supplied on alternate days. Tea is preferred in the hot weather. In serving the meat such parts of the animal as are more than two-thirds bone are excluded from the ration. Potatoes and English vegetables are supplied when in season, at other times (in the hot weather) such native vegetables as are procurable. At this station potatoes cease on the 1st May until the new crops arrive from the hill districts about September or October. A native pumpkin is the best substitute for English vegetables. The ration is daily inspected by the quartermaster and officer on duty before issued, and if disapproved of it is changed by the supplying contractor, or should he object the articles are sucmitted for approval or otherwise to an inspection by a committee of three officers, one being medical. 2. The ration allowed already described is considered complete, but the men may supply themselves with extras at their own expense. The have three meals daily, at 7, 1, and 6 o'clock. Breakfast, meat grilled, bread, butter, eggs, sometimes soogee is preferred by the men. Dinner, boiled or roast, curry, puddings and pies. Tea, bread and butter. 3. I consider no improvement in the ration necessary. Each company is divided into a certain number of messes, and each mess is under charge of a corporal who superintends the cooking and disposal of the rations. 4. One system of cooking is in use throughout the country for officers as well as men, and consists of copper vessels covered with a thin coating of tin, the latter requires renewing twice a month at the cost of one rupee for every 16 vessels. This apparatus is more efficiently managed by native cooks than the complicated and costly English mode. Roasting is performed by a wood fire on the ground. The kitchens are clean, well ventilated, and sufficiently supplied with water. The food is boiled, roasted, or stewed with vegetables, or made into pies, according to the wishes of the men. Every attention is paid to the cooking. Tea and coffee are also properly prepared. Tea or coffee with refreshments are generally provided for the men half way on each march by the regimental cooks, who go on ahead for the purpose of preparing it. 5. A large and very productive garden is attached to the infantry barracks at this station. It is superintended by gardeners selected from the regiment with native assistants. It is supported partly from regimental funds, and partly by the sale of the surplus produce.
VII. Dress, Accoutrements, and Duties.	1. The dress and accoutrements of the Queen's British army and European troops in this Presidency are in accordance with the regulations of the Horse Guards, with the exception that in the hot season the men are clothed in a complete suit of American drill dyed khakee (earth colour), with basket-made helmets covered with the same. The present dress is suitable to the climate, and I have no improvement to suggest. The guard dress is the same as for ordinary duties. In wet or cold weather men on duty wear a woollen cloth great coat ; in the hot season European sentries are in the verandahs or under other shelter.
Duties.	1. It would be most advisable that the men should be thoroughly drilled at home, which would obviate the necessity for a good deal of exposure to the sun, which is at present unavoidable. 2. The amount, duration, and time of drill, vary according to the season of the year and other circumstances. They are not calculated to affect the health prejudicially; the best time is as soon as possible after morning gun-fire, in order to avoid exposure to the sun. Each regiment has its own orders about the hours of march. For the year 1859 each man had five nights in bed during the week, but this must vary according to circumstances.

FEROZEPORE. BENGAL.

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*Duties—cont.*	3. The regimental guards are mounted close to the barracks, and one detachment of about 120 men, European infantry, is furnished weekly to guard the arsenal, about two miles from barracks. The duration of a guard is 24 hours; each soldier remains on sentry two hours at a time, when he is relieved and gets four hours' rest; he again takes two hours, and so on. As three men are allowed for supply of one sentry, so each man has four hours' sentry duty, both day and night. The following are the usual roll calls:—1. Morning parade. 2. Breakfast. 3. In summer at 10 a.m. to warn the men not to quit barracks till evening. 4. Dinner, 1 o'clock. 5. About half an hour before sunset. 6. Tattoo. 7. Check calls, according to direction of commanding officers, to see that all men are present in bed. No particular detrimental effect is caused by night guards.
VIII. INSTRUCTION AND RECREATION.	1. The means of recreation and instruction at the station consist of ball courts; skittle grounds; schools with good schoolmasters; library and reading room, sufficiently lighted; 1 soldiers' garden; theatre; gymnasium. No day room nor workshops. The two latter combined would, I think, be an important inducement for occupying the men during the heat of the day. Strict attention is paid to prevent as much as possible the men exposing themselves when off duty. 2. The only improvement I would suggest is that previously named of providing a coffee shop with reading room, and including workmen's shops. 3. A savings' bank already exists. 4. It is not advisable that the men should take exercise during the day in the hot season.
IX. MILITARY PRISONS.	1. There are no military prisons at the station. The regimental cells (attached to the main guard) do not comprehend any defect which might be prejudicial to health.
X. FIELD SERVICE.	1. There are no local regulations for field medical service. 2. The medical officer's powers are guided by the regulations as regards marches, camping, &c. 3. Permanent camping grounds exist throughout the country, and when practicable the healthiest sites are selected with reference to all points of a sanitary nature. 4. The arrangements for field hospitals, transport of sick, &c., are laid down in the medical code.
XII. HOSPITALS.	1. Plan of hospital. 2. The infantry hospital is situated about 450 yards in rear of the barracks; the artillery hospital about 500 yards to the right of them; and the horses are picketed to the left of the barrack; and distant from the hospital about 1,200 yards. The hospitals are sufficiently removed from the bazaar and far from houses. Both are in open situations with nothing of any description to interfere with free ventilation. The infantry hospital and barracks are situated on the highest ground. Those of the artillery, though not so high, are healthy, and all are kept free from everything objectionable. 3. Wells of good and wholesome water are provided within the grounds of both hospitals. 4. No drainage is required, all refuse being removed by an establishment of sweepers and filth carts. Water from the bath rooms is allowed to sink into the subsoil. 5. The hospitals are of one story, with thatched roofs, floors of brick, raised 3 feet above the ground. The roof water sinks into the subsoil. Drainage is not necessary. The heavy rain-fall runs off to a distance, and the soil is generally so dry and of such a nature that the ordinary falls sink rapidly into the subsoil. The hospital is built of brick and mortar, with single roof and ridge ventilation; thatched of sufficient thickness to protect the hospital from heat. Twelve feet verandahs surround the buildings with always sufficient shelter from the sun's rays. The verandahs are used for walking exercise morning and evening. The hospital consists of one story only. The following table shows the hospital accommodation:— Date of construction, 1846. Total number of wards: artillery, 3; infantry, 4. Total regulation number of beds artillery, 44; infantry, 144.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.

European Infantry, No. 1	36	108	24	22	5,700	1,600	72	2	2 windows 21 doors	3 6 7 6	3 0 4 6
No. 2	36	108	24	22	5,700	1,600	72	2	Do.	Do.	Do.
No. 3	36	108	24	22	5,700	1,600	72	2	Do.	Do.	Do.
No. 4	36	108	24	22	5,700	1,600	72	2	Do.	Do.	Do.

Due attention has been paid in placing the hospital to give it the full benefit of the prevailing winds. The hospitals have no windows, but are provided with opening doors about 7 feet apart on all sides, which admit of suitable ventilation.

6. The ventilation is by means of doors and ridge ventilation, already explained, which acts efficiently. Jalousies or jhilmils are not allowed, nor deemed necessary.
7. Punkahs and tatties, as already described, are provided during the hot months, and at some stations, when the heat is excessive, a thermantidote (on the same principle as the fan blasts used for *iron* furnaces) for each ward is employed, in addition to the other means. The cost is from 50 to 80 rupees, according to size, worked by the hand at 7 rupees monthly.
8. Warming is secured by ordinary chimney fireplaces for wood, two to each ward. The walls and ceilings are cleansed and limewashed once a year, and oftener if necessary.
9. The privies and urinals are similar to those described for barracks; they are conveniently situated, and approached by covered verandahs. The filth is removed by sweepers and carts

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	employed for the purpose. No cesspits are permitted, and free use of lime and wood ashes is made for keeping the place pure and free from offensive smells. 10. Small bath rooms are constructed in the verandah corners, which in the infantry hospital are very deficient for the number of sick. 11. Warm and cold baths are ordered for the sick when the medical officer considers it necessary. 12. The native washerman requires no house, but prefers washing in the open air. 13. The storage is perfectly dry and sufficient. 14. The bedsteads are wooden frames with tape plaited across for the mattrass. (For the bedding, see medical code.) 15. The kitchen is a detached building, at a distance from the wards, with means and apparatus similar to those described for barracks. 16. Forms transmitted. 17. The attendance on the sick is performed almost solely by natives. There is a hospital serjeant to all European hospitals. In cases of extreme sickness, or whenever deemed necessary by the medical officer, a soldier is appointed to attend upon and assist in the care of a patient. 18. The sanitary condition of the hospital is excellent. No epidemic, gangrene, or pyœmia have appeared. 19. There are no deficiencies or sanitary defects, except the insufficiency of lavatory accommodation in the infantry hospital. 20. The infantry regimental garden adjoins the hospital grounds, and has seats for the use of those sick and convalescents who may have permission from the surgeon to take walking exercise. The artillery has nothing of this kind. 21. Separate wards, with a native attendant, are provided for the sick women and children. The present arrangements are satisfactory. 22. There are no special local hospital regulations. 23. The requisition of the medical officer on sanitary measures, repairs, &c., receives immediate attention from the local authorities, and on other points his powers are guided by medical regulations. 24. There are no convalescent wards or hospital, nor do I consider such necessary.
XIII. Burial of the Dead.	1. There are two burial-grounds for British troops on the boundary line of the station, favourably situated as regards the prevailing winds. One is conveniently situated for the infantry, and the other for the use of the station generally. 2. The area of the burial-grounds is 450 and 297 feet square respectively. The soil and subsoil are similar to that already described. Drainage good. The grounds are carefully kept, and decomposition takes place readily. 3. The graves are 3 feet wide by 7 long, and with 3 feet between each. They are 6 feet deep, and no grave is ever reopened. According to the season, burial takes place from 12 to 24 hours after death, and during epidemics as soon as possible. With respect to natives; Mahomedans inter immediately after death in burial-grounds of their own. The bodies of Hindoos are burnt without delay. 4. The grave-yards are never offensive. The practice of burial in regard to British troops is according to regulations. 5. The dead of camp followers and bazaar people are disposed of out of the station, as explained above. 6. No injury to health accrues from the present practice. 7. I can suggest no improvement in regard to burials.

(Signed) Chas. S. Reid, Colonel, H.M. Bengal Artillery, Commanding at Ferozepore.
G. S. Cardew, M.D., Surgeon-Major.
June 1860. Henry Blair, Lieutenant Executive Engineers.

I. Topography.	1. The general aspect of the country surrounding the station is flat, but rising towards the hills on the north, and falling towards the south. The soil is alluvial generally, but there are many barren and uncultivated parts. There is no wood, jungle, or water in the vicinity. 2. The station is elevated about 900 feet above the sea, but is almost on the same level as the adjacent country. The highest point in the station is 16 feet above the bed of the north nullah, and 14 feet above the south. There is no higher or healthier ground adjoining the station. 3. The nearest mountain land, which is 1,000 feet above the level of the station, is 30 miles distant. 4. The Chenab river is 10 miles north of the station, and the Ayke river two miles east. The vicinity of the station is not liable to overflow of water. There is a spot on the south-east where water lodges, and which becomes marshy in the rains. It has no perceptible effect on the health of the station. 5. The station is a narrow parallelogram, and is open and freely exposed to the winds. The ventilation is excellent. The temperature of the station is raised 2° or 3° by reflected sun heat. In consequence of its proximity to the hills, the station is exposed to sudden gusts and

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	to much variation of temperature. Colds and rheumatic complaints are frequent at such times. 6. The country surrounding this station is cultivated. The crops are all grown by irrigation from wells worked by the Persian wheel. Cultivation is distant upwards of one mile from the centre of the cantonment on the north and south, and nearly two miles on the east and west. Irrigation has not been observed to have any effect on the health of the station. There has never been any epidemic here since the establishment of the station in 1849. Beyond the limits above stated any crop may be grown; within these limits nothing is permitted. Indigo is not grown near the station, and hemp is cultivated beyond the above limit, so that no inconvenience is experienced from it. N.B. At this station an additional portion of ground from that usually set apart at other stations was given round the boundaries by order of Sir Charles Napier, on which only the cold weather crop is allowed to be cultivated, and during the hot season it remains fallow. This, doubtless, is one of the causes of the very great salubrity of this station. 7. The city of Sealkote is distant about two miles and a half from the station. 8. The station occupies partly new ground that had not been under cultivation, partly cultivated land from which villages were removed to make way for the cantonment. The soil is light and free, with a good deal of sand; the subsoil is sandy. 9. Fifty-three to fifty-four feet is the depth at which a permanent supply of water can be obtained. Water is met with to a small extent about 30 feet from the surface. The average depth throughout the station in the rains is 41½ feet. 10. The station is remarkable for the rapidity with which water drains off, both from its situation raised between two nullahs, always dry except when rain falls, and the nature of the soil, which does not retain water on its surface. Twenty-four hours after the heaviest rain it has almost all disappeared. No drainage from higher ground passes into the subsoil of the station. 11. The water supply of this station is derived entirely from wells, which are not liable to pollution from leaves or other impurities falling into them. 12. The water is very pure and free from colour, taste, and smell generally; some wells are impregnated with soda. It is hard, containing a considerable portion of sulphate of lime, very free from impurities, clear and sparkling when drawn, and decidedly good. The supply is abundant at about 40 feet from the surface. It is raised by means of a rope and leathern bucket. No better supply could be obtained. 13. Doubtless the proximity of this station to the hills, at a sufficient distance to avoid the reflected rays of the sun, yet near enough to benefit by the rain attracted by them, has an influence on the temperature, and then on the general health. There are, however, influences at work which are at present undeveloped, which have hitherto made this station particularly suited for European troops. 14. New stations, whether on hills or in the plain, are selected by a board of experienced officers, medical and military, under the orders of the Commander-in-Chief. There seems no better mode of selection than this, if any effort is made to come to a knowledge of the facts, and due time given for inquiry. In the selection of this station one fact was most particularly noticed by the board, the number of children and their freedom from disease of the spleen, showing an immunity from fever. This was the evidence given by the country people themselves.
II. CLIMATE.	1. The following instruments are in store at the medical depôt for conducting meteorological observations, viz., electrometer, 1 set; electrophane, No. 1; hygrometer, No. 1; and anemometer, No 1. 2. The instruments for and records of former meteorological observations were lost or destroyed at the time of the mutiny.

TABLE of Meteorological Observations.

From January 1859 to December 1859.

Months.	Mean Maximum.	Mean Minimum.	Mean Sun Temperature.	Winds, Direction.
	°	°	°	
January - -	63·	51·	72·	E. & W.
February - -	66·	51·	77·5	W.
March - -	80·	58·	98·	W.
April - - -	89·	67·	115·	E.
May - - -	94·	74·	120·	Variable.

July - - -	93·	80·	124·5	E. & N.E.
August - -	92·	78·	114·	Variable.
September - -	91·	72·	113·5	N. & E.
October - -	86·	64·	110·5	N. & E.
November - -	76·	60·	98·5	Variable.
December - -	64·	54·	86·	Variable.

5. The climate of the station is remarkably healthy and suited to the European constitution. The air generally dry, notwithstanding that a greater amount of rain falls than five miles more south. This is to be ascribed to the excellent drainage. As stated before, the climate is very variable, June, July, and August being very hot. The monsoon is not very heavy; but the cold is very great in December, January, and February, and for five months of the year. No climate in the world can be finer. The air is particularly free from dust and impurities. The troops, consequently, are remarkably healthy. It is necessary at all times to be ready to put on a cloak or great coat. Flannels are particularly called for at this station, and the men must not be too rigidly kept to the clothing of the season, as during the rains a woollen coat may at times be worn with advantage. Short drills may be given all the hot months at an early hour with advantage to the men. The most unhealthy months are August, September, and the commencement of October; the remaining months are very healthy.
4. There is no healthier district near the station.

5. The windows are on opposite sides of the main wards. An enclosed verandah runs round the building, 12 feet wide, 17 feet high; also an outer arcaded verandah, 12 feet wide and 15 feet high. The inside verandah on one side of the barracks has been since 1858 generally occupied as sleeping quarters by the men. There are no jalousies or jhilmils.

6. There are two sorts of cots in use in the barracks; tape and string bottomed cots. The former, a very complicated sort of bed, and difficult to clean; the latter, a vile description of bed, which should never have been admitted into barracks, because it cannot be kept clean, and affords shelter for bugs and all sorts of vermin. The bedding consists of a cotton-stuffed quilt, carpet, and blanket. The same remarks apply to hospital beds as to those in barracks. An iron-framed bedstead, as used in England, with canvass, laced or put on with straps, would be much better than the beds now in use at Sealkote.

7. The tents used in camp are constructed as follows:—Staff serjeant's tents, single poled, superficial measurement, 15 feet by 15 feet; cubic measurement, 1,687 feet for one staff serjeant. Private's tents, double poled, superficial measurement, 24½ feet by 19½ feet; cubic measurement, 3,819½ feet; calculated for 16 men, giving for each man an area of 14 feet, and cubic space of 238 feet.

8. There are ventilating apertures along the ridge of the barracks, &c.; also 50 upper windows in the main wards. The ventilation is sufficient to keep the air pure by night as well as by day. The only means for cooling the air of barrack-rooms are tatties or screens of kus-kus and punkahs, the former cost about 3 or 4 Rs., the latter 5*s*.

9. The barracks are constructed of sun-dried bricks, faced with pucca brick. The roofs are trussed, covered with bamboo frame-work, mats, 3-in. thatch, and tiles.

10. The floors are of paved brick, and are raised about 3 feet from the ground.

11. The materials employed in the construction of barracks, huts, and tents are very suitable to the climate, and avoid iron on account of the heat. The repairs are done by the Department of Public Works immediately the necessity for them is reported as apparent. There is a sanitary (medical) officer in the station. All buildings are whitewashed annually, and oftener if deemed necessary, as a sanitary measure.

12. Water is supplied from wells, and all waste water is conveyed into open cesspools, and thence by carts removed out of cantonment. There is a wash-room to each barrack, or 12 in the station; also three plunge baths. The water from these is generally used for gardens, irrigating purposes, &c. A sketch of the lavatories is transmitted.

13. A sketch of the barrack cook-room is transmitted. No means of cooking are provided at this station; the cooks use the native chulas on the floor. The refuse water runs into open

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	cesspits, and is removed by carts. The washing and drying of the linen are performed at a distance from the station by native washermen. 14. Sketch of the privies and urinals is transmitted. The urine is conveyed into cesspits and removed by carts. The ordure from the pans is emptied into filth carts and removed. 15. The barrack doors, which have a glass fan-light, and the upper windows, afford ample light by day, while at night oil lamps are used. 16. The drainage of the lines is by means of channels, leading into side drains of the roads. There are no sewers, cesspools, &c., every offensive matter being removed by carts. The drainage is ample for all purposes. No part of any building used as a barrack or hospital is damp. There are no cesspits or foul ditches near the station. 17. The arrangements for the surface cleansing of the cantonment are most efficient. All refuse is removed by means of carts to a distance from the station. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c. interfering with the ventilation of the station or bazaar. 19. The sanitary condition of this bazaar, which has been laid out on a very large scale, with broad streets, admitting of a thorough ventilation, is excellent. It drains itself by a great slope, carrying off everything into the nullah running south. It is well supplied with numerous large masonry wells, filled with good water. The bazaar, from its great size, and owing to the mutiny, is only half filled, so that there is no possibility of crowding. It is very clean, being kept so by sweepers and water carriers. On the right and left have been erected large and commodious latrines for males and females. A large number of sweepers and bheesties, employed at the expense of the shopkeepers in keeping the bazaar clean, are daily inspected by a non-commissioned officer (the bazaar serjeant), who reports to the officer in charge, who himself frequently inspects the bazaar in every direction, All filth, rubbish, and sweepings are carried away beyond the cantonment limits. No improvement whatever in any respect is practicable in this bazaar with reference to the financial difficulties of the state. The native houses are constructed of dried mud, and are very well adapted to the wants and means of the class of people they are occupied by. There are no dung-pits, heaps, or cesspits. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. The slaughter-house is half a mile from the infantry barracks. It is superintended by a a warrant or non-commissioned officer, and inspected constantly by the executive officer. The offal is buried, and the blood, after being mixed with water, is run off into a cesspit with a narrow mouth. The slaughter-house is kept quite clean, and I have had no hint that it proves a nuisance to any one. 21. There is no stabling for bazaar horses. There are about half a dozen horses belonging to shopkeepers, who keep them picketed in their respective compounds. The camp followers' horses amount to about 20 or 25. They are picketed in the open plain, half a mile from the station. These places are kept perfectly clean by the bazaar sweepers, and are under the supervision of the bazaar serjeant and European officer in charge. The manure is burnt as fuel by the camp followers, who are very poor. 22. There are no stables or dung-heaps, all manure being removed. Picketing grounds for horses consist of raised earthen terraces, about 100 yards in front of their respective barracks, and away from the hospital. 23. There are sufficient quarters for all the married non-commissioned officers and privates to live separately. No married people occupy barracks with the men.
Officers' Quarters.	Officers are not provided with quarters at Sealkote.
IV. Health of the Troops.	1. The station, district, and adjoining native population are healthy. 2. Rheumatic disease is the most prevalent among the native population. Spleen disease is not at all common, and, except small-pox, epidemics are unknown. 3. I attribute the healthiness of the native population to the absence of exciting causes of malaria and the openness and dryness of the country generally. 4. The 7th Dragoon Guards arrived at Kurrachee from England on 7th January 1858. From thence they proceeded by camel train to Hydrabad, from Hydrabad by river Indus to Mooltan; from Mooltan by bullock waggon to Mean Meer, where the last detachment arrived on the 31st March 1858. After remaining 14 days at Mean Meer the regiment marched from thence on the 15th April 1858, and arrived at Sealkote on the 21st. The health of the regiment at Mean Meer was pretty good, fever being the prevalent disease. The health of the regiment since it arrived at Sealkote, with the exception of the first hot season, when there were many deaths by fever, diarrhœa, and apoplexy, has been very good. The 52nd Light Infantry landed at Calcutta in October 1853. They were quartered at Chinsurah till all the detachments had landed, when they went to Allahabad by river steamers, arriving there in November 1853. The regiment marched for Umballa on the 19th December 1853, and was quartered there for six months, leaving on the 1st August 1854 for Subathoo. At Subathoo five months, from 10th August to 1st December 1854; at Umballa three months, from 6th December 1854 to 10th March 1855; at Meerut, nine months and a half, from 26th March 1855 to 8th January 1856; at Lucknow, two months in camp and nine months in quarters, from February 1856 to 27th December 1856; at Sealkote, from 14th March 1857 to 25th May 1857; two months and a half moveable column, from 25th May 1857 to 14th August 1857; before, and in Delhi from 14th August to 4th October 1857, six weeks; at Jullundur from 30th November 1857 to 22nd April 1858, five months; at Sealkote from 30th April 1858, two years and three months. The state of health has been generally good since the arrival of the regiment in India, except in Lucknow, when it suffered severely from cholera, and also when before Delhi. The prevailing diseases have been fever, ophthalmia, and venereal; at Lucknow cholera; and at Delhi wounds. The average daily number of sick for the seven years has been 63, the lowest average being for the present year, $58\frac{2}{3}$; and the highest in 1857–8, viz., 68. The number of deaths since landing is 455 men and 7 officers; average $5\frac{50}{81}$ monthly, greatly increased, of course, at Lucknow and Delhi. No portion of the men's present accommodation is more unhealthy than the rest. 5. The troops at this station are never camped out. 6, 7. I have never been in charge of troops at hill stations. 8. Troops do better in the plains than hills where the station is healthy. The men are more efficient and less liable to bowel affections.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	9. Bowel complaint is peculiar to the hills, and with which troops are liable to be attacked on going to them. 10. More attention to the water and the avoidance of chills by the use of flannel and other warm clothing are the precautions to be observed by men going to hill stations. 11. From the 15th April to the 15th October is the season best adapted for residence in the hills. Troops should remain above six months, except for particular cases in which advantage may be obtained from a residence in the winter. 12. Troops should always return to the plains before winter, unless under particular circumstances. 13. Troops should have clothing adapted to the plains on leaving hill stations. 14. Where stations are healthy in the plains, it is no advantage to quarter troops in the hills. An occasional change to a hill station may certainly benefit a regiment, especially one which has been some time in India. It has, however, not yet been shown that European cavalry corps, which never are quartered in a hill station, are less efficient in any way than infantry corps, which take their tour at these stations. Frequent change of station is doubtless beneficial to convalescents; but unless a regiment proves sickly, not to the troops in general. 15. The only hill station in this circle is Dhurmsallah, where the accommodation is sufficient for the number of troops sent. 16. Cannot say what ranges of elevation above the sea are most suitable for hill stations. 17. Ludda, a most desirable spot two nights' dak, or 50 miles in the Himalaya range, might be advantageously occupied as a hill station. 18. I have no experience to say what classes of surface and subsoil are the most healthy for stations. 19. The best age for soldiers to proceed to India is from 20 to 25 years, and they should land there at the end of October. The 7th Dragoon Guards, on landing at Kurrachee on 7th January 1858, were quartered in a thatched barrack, and it being the cold season, the men were exercised morning and evening in the usual cavalry drills. Suitable clothing was issued to each man. Generally, on first landing, troops, after being placed in barracks, are provided with the light clothing suitable to the country. There is usually scarcely any drill on first arrival; but the duties are taken as they always are, and it depends chiefly on the season of the year as to whether a regiment marches up the country, or stays at the port of disembarkation. In order to preserve the health of recruits on first landing in India, I should send them up without loss of time to join their regiments. 20. There is no advantage in sending troops to intermediate stations instead of direct to India. They should be sent to the most healthy stations first. 21. The 7th Dragoon Guards marched from Kurrachee to Hyderabad by camel train, and this mode of conveyance was generally liked by the men, as being both safe and comfortable. From Hyderabad to Mooltan the regiment was conveyed by steamer up the Indus, and from Mooltan to Mean Meer by bullock waggon. The latter mode of conveyance was particularly disliked by the men as being tiresome, dusty, and unpleasant. Generally troops landing at Calcutta are sent by rail to Raneegunge, thence to Allahabad by bullock train, and from thence they march to their destination. From Kurrachee they are sent in steamers up the Indus to Mooltan and march from there. On the steamers the men are continually on deck, there being no place below for them, except a small one in the flats generally used as a hospital. If a man catch any infectious disease, there are no means of separating him from his comrades. 22. A British soldier should not serve more than eight years consecutively in India, without a change to a more temperate climate. 23. The manner of conducting medical boards is such as to cause no conflict of opinion as regards invaliding. 24. Invalids should leave India for home in the months of December, January, and February.
Diseases.	1. Once a week the men parade by troops and companies for doctor's inspection, with their shirt fronts, open sleeves rolled up above the elbow, and trousers above the knee, and bare feet. The hour varies with the season of the year, at present it is 6·30 a.m. 2. Little or no scorbutic disease is traceable in the records of the regiment over a period of two or three years. 3. About one case in 50 of those treated is the proportion of hepatic disease at this station. It is not the result of other diseases, but of intemperance or climate. 4. No cases of dracunculus have occurred at this station. 5. The proportion which venereal diseases bear to all other diseases is about a fourth. If marriage must be limited, I would suggest the passive recognition of measures such as obtain in continental Europe. The establishment of lock hospitals would be decidedly advantageous. 6. The troops at this station suffer from ephemeral fevers, and slight attacks of dysentery and rheumatism. Of 948 cases treated in hospital for the year, there were of the diseases of the epidemic and endemic class one in 2·87. The mortality was one in 110. 7. Of the zymotic class of diseases, rheumatism is the most common at the station. Fevers of the typhus or typhoid type are almost unknown, and the same may be said of cholera, small-pox, and the exanthemata generally. Diseases of the above class are more likely to prevail in the hot and wet season, when want of occupation may probably render the men more liable to attacks. No striking atmospheric changes have been observed to precede or accompany these diseases. The sanitary condition of the bazaar is good in every way, and the buildings are not crowded. These diseases chiefly arise from negative causes. Want of occupation may probably offer weak points to the assaults of the above diseases, also a want of sufficient care in guarding against sudden changes of temperature. 8. The duties in cantonments are not such as would be likely to operate unfavourably on the health of the troops. In reference to field duties, they must necessarily in a great measure be beyond control; but I am not aware of any deficiencies which affect the soldiers' comfort while so employed. 9. Fever is not so in excess at this station as to call for the use of quinine as a prophylatic, so with this view it is not used. 10. The ordinary hygienic precautions so familiar to all are strictly carried out here. Beyond these the present crude state of sanitary science admits of no suggestions of any practical use.

References to Subjects and Queries.	Replies.
V. INTEMPERANCE.	1. The men at this station are decidedly temperate, and the proportion of men who may be called confirmed drunkards is about three per cent. 2. Intemperance exists to a very small extent in the regiments at this station, and cases of delirium tremens are very rare. Hepatic and other diseases supposed to be influenced by intemperance are few, and seldom have been found to have any apparent connexion with previous intemperate habits. Drunkenness is always punished as an offence. 3. Only rum supplied by Government is sold at the canteens, and native spirits in the bazaar only. Rum is issued at 24 per cent. below London proof, that is, 76 parts spirit and 24 parts water. The average amount consumed by each a man a day is one dram, but some men never drink spirits. Spirits form no part of the ration in the station, nor on the march as a rule, though a dram is sometimes served out to the men after a wet march, when waiting for the tents to come up. In the campaign in 1857 the men used to get either rum or coffee half way on the march. Before Delhi it used to be served out to the men going to the trenches before starting, about 4 a.m., and to the others at 6 a.m. In either case hot rice water was given with it to those who liked it, and was found very beneficial on account of the hard work the men had to go through. In station or on the march no man as a rule can get spirits till after evening parade. Some convalescents are allowed to the canteen, and others not, according to the surgeon's instructions. They never get spirits as a ration. No drinks other than intoxicating drinks are sold in the canteen or bazaar. 4. The consumption of spirits by troops and convalescents is most injurious to health. It should never be offered for sale at all, as men are induced to take spirits who never would if it were not handy to them. It is prejudicial to the efficiency and internal discipline of a regiment. 5. I would abolish the sale of spirits, undoubtedly, as part of the ration, as it tends to drunkenness. Under no circumstance, except those of extraordinary fatigue, should it be issued to the men. 6. Malt liquor or wine is good in comparison with spirits, when taken in moderation. 7. A great deal of coffee is drunk by the men; nearly all take a cup before going to morning parade. This weather a good deal of "pop" is consumed, but tea, lemonade, and soda water are not much in requisition. Their influence on the health is good, but care must be taken to make all these of good quality and palatable to the men. 8. Spirits might be issued with good effect under particular circumstances, such as exposure to damp, cold, or extraordinary fatigue. 9. It would be decidedly beneficial to prohibit the sale of spirits in the canteen, and to permit only beer, tea, coffee, &c., to be sold, if so doing does not induce the men to look after and drink bazaar spirits. 10. The price of beer should be lowered, as at present a dram of rum costs 1 anna, while a pint of beer or porter costs 1½ annas. It would be well at any rate to cheapen malt liquor, as now the men are often induced to take rum in consequence of the price. Some system ought also to be introduced to compensate for the profit (8 annas a gallon) which now arises from the sale of rum, the commissariat furnishing it at 2 rupees per gallon, and the men drinking it at 2 rupees 8 annas, thereby forming a fund out of which the canteen establishment is kept up, games of all kinds and newspapers be furnished for the men, the extra expenses of married soldiers on the march defrayed, &c. &c., the loss of which would be severely felt. Beer being retailed at cost price does not produce any fund. 11. The canteen regulations prohibit the sale of any spirits in the canteen, except those furnished by the commissariat. The canteen is opened from after evening roll call until tattoo; but malt liquor is allowed to be drawn daily at the rate of one quart per man for dinner. No intoxicated or disorderly soldier is allowed in the canteen. Two drams of rum or one quart of beer can be drawn by each man during the evening; but no man is permitted to get rum and malt liquor at the same time, nor is any liquor allowed to be taken out of the canteen, except that furnished to the men at dinner or that supplied to the serjeant's mess. By the bazaar regulations all persons residing in the bazaars, together with a list of their occupations, are registered by the interpreter of the regiment for the time being, in whom the charge of the bazaar is vested. The ground for the bazaar in camp is to be allotted in rear of the troops, but within the rear guards if possible; but in a station the regimental bazaar is never to be near the Suddar bazaar. The chowdrie is responsible that sufficient carriage is kept for the conveyance of four days' supplies for the regiment. Soldiers found ill-treating a shopkeeper or taking away his goods by force are immediately punished, and all disputes between the men of the regiment and the inhabitants of the bazaar are brought to the notice of the interpreter, who may, if he thinks proper, refer them to the commanding officer. The regimental police preserve order in the bazaar, whenever the men are allowed out of barracks, and prevent them from committing irregularities. Any native belonging to the bazaar found selling country spirits to the soldiers is to be immediately turned out.
VI. DIET.	1. The rations issued to European troops consist of 1 lb. meat, 1 lb. bread, 1 lb. vegetables, 2½ oz. sugar, 1 oz. salt, 4 oz. rice, $\frac{5}{7}$ oz. tea, and 3 lbs. firewood. The men get mutton twice a week, and beef on the other days, tea and coffee alternate days, 1$\frac{3}{7}$ oz. of coffee per man, when issued. The vegetables vary with the season of the year; at present no potatoes are issued. The men get doll-pumpkins, onions, and others, according as they are procurable. The quartermaster and subaltern of the day inspect the rations, and the former sees them issued. Should any part be bad, the contractor is allowed to replace it by good rations. If he does not do so, the rejected material is condemned by a committee, and the contractor has to replace it, and he is fined by the commissariat officer for every committee held. 2. The soldier get his ration without any stoppage. He takes three meals a day, the hour of which vary with the time of year. Breakfasts from 7·30 to 9 a.m.; dinners from 1 to 2 p.m., and teas from 5 to 6 p.m. At breakfast and dinner the men get tea or coffee, meat and vegetables, and at tea, tea or coffee and bread only. An equal quantity of meat and vegetables enters into the constitution of the ration. 3. The ration is very good, but the men would prefer mutton oftener. An orderly man from each company receives the rations, stays in the cook-house all day, sees them cooked and issued, and is responsible that the cooks give the full amount to the men. Men are told off for the purpose of seeing that the rations are not improperly made away with. 4. Each company has a set of cooking utensils, which are tinned twice a month, consisting of boilers, frying pans, gridirons, and ladles. A side of a cook-house is allotted to each

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	bungalow. The natives, of course, cook the things in their own way. The cook-houses answer their purpose very well, and are washed out once a day and kept as clean as possible. The bheesties allowed are sufficient for bringing water from the adjoining wells. The men get their rations dressed any way they like, generally roast or boiled. The cooking is very fairly done and sufficiently varied. The tea is usually well prepared, but the coffee is not so good, as it is issued green. Stalls with coffee and biscuits are always prepared half-way on a march. 5. It would be a very good thing to establish gardens for the men. Before the mutiny there were very good ones here, and the men used to get plenty of vegetables. Now, there are only small strips along one side of each bungalow, where the men of each company cultivate what they please, and some have obtained a fair amount of vegetables and flowers. If a general garden were established, one or two men per company (gardeners by trade, if possible) would be struck off duty and put in charge, being allowed to sell the produce at a certain fixed rate to remunerate them for their labour. This would benefit the men and give them employment.
VII. Dress, Accoutrements, and Duties.	1. In the cold weather the cavalry wear woollen clothing; in the hot weather khakee; on guard, a dragoon wears his pouch, pouch belt, and waist belt, and carries his carbine on sentry. On mounted parades he wears his sword in addition. The infantry wear a cloth tunic or serge tunic and black trousers, calico or flannel shirt, according to taste (nearly always flannel, or at least a flannel belt). His accoutrements consist of pouch and waist belt and pouch, the latter to contain 50 rounds, though only 20 are carried in quarters. The belts and pouch weigh 4 lbs., and 50 rounds and caps 4 lbs. 10 oz. Taking the dress as a whole, it is very suitable to the climate and to the soldiers' different duties. Khakee is the most serviceable dress ever invented for the hot weather. It is the present guard dress, night and day, from 8 a.m. to 5 p.m. In the hot weather the guards are allowed to undress and the sentries mount in the verandahs of the guard houses. During the night, if it is wet, each sentry has a post assigned him under the nearest cover, and they wear their great coats.
Duties.	1. It would not be advisable to drill the men at home before sending them to India. 2. The following exercises, which are most beneficial to the health of the dragoons, take place at this station. Field drills, riding drills, and watering order parades, the latter for an hour, the drills from 1 hour to 1½ hours. Evening stables for an hour and a general parade once a week in the afternoon, which lasts an hour. Grooming is a very healthy exercise. No special orders or parade. The best time for drill in the hot season is before sunrise. Evening parades or drills ought to be specially prohibited during the hot season. On the march troops should always reach their ground before sunrise, from 1st April to 15th October, but during the other months it is immaterial. The men at this station have six and seven nights in bed during the week. 3. The farthest guard is about half a mile from barracks, the other quite close. The guards are relieved every 24 hours in the morning, sentries are on two hours at a time. The roll-calls are as follow, if there is no parade: one in the morning, and always at breakfast, dinner, and tattoo, roll-calls in the bungalows, with a roll-call parade every evening. There are none at night, except when any men are suspected to be absent, in which case the orderly serjeant goes round the bungalow. Night guards have no bad effects upon the men generally, though in the long run they may be trying to the constitution. The men ought all, I consider, to be made to wear flannel.
VIII. Instruction and Recreation.	1. The following are the means of recreation and instruction at this station, viz.: Ball courts, skittle grounds, schools with good schoolmasters. A library is provided by Government for each regiment, embracing books on general reading in history, biography, travels, and fiction. There is a reading-room, provided with chess and backgammon boards and dominoes, and 16 newspapers and periodicals are taken in. It is very well lighted at night. The library is open during the morning; the reading-room all day in winter, and in summer from 6 p.m. to tattoo. There is a large garden attached to the cavalry regiment, of which a serjeant has the charge. Each bungalow also has a garden alongside it and at the ends, the seeds and garden tools being provided by Government, who also grant prizes for the best cultivated. There are armourers', saddlers', tailors', and shoemakers' shops in work, and one man carries on the trade of a watchmaker. There is a theatre in the lines of both European regiments. There are no gymnasia, but I strongly recommend that these should be built. There are also cricket clubs in every company, and a regimental one; the men play a great deal in cold weather. The companies are supplied with foot-balls and quoits, the latter being a very favourite game. If the men choose to avail themselves of the means provided, they will have enough to keep themselves occupied during the wet season and heat of the day. 2. The men might be made to contribute much more largely than they do towards the equipment of a regiment, with great benefit to themselves. As there are men of every trade to be found, workshops of all kinds might be instituted. 3. Soldiers' savings' banks have been working for many years, and much to the benefit of the men. The amount at present deposited by the 52nd Light Infantry is certainly 8,000*l.*, if not more. 4. There are good double verandahs to every bungalow, where the men can take exercise when wet; and, except just in the middle of the day, there is always shade enough to allow the men to play skittles or quoits on one side or the other.
IX. Military Prisons.	1. The prevost is a very well-arranged building. The cells are clean, lofty, and well ventilated, and during the hot season the prisoners are allowed into the centre hall, into which all the cells open, and where there are punkahs swung. There is more room a great deal than is ever required.
X. Field Service.	1. There are no local regulations for field medical service not included in the General Presidency Regulations. 2. There being established camping grounds and hours for marching laid down by Government, the medical officers have not much power in the choice of them, nor is it necessary, except under unusual circumstances, for them to suggest alterations. 3. The general regulations as regards camping grounds, &c. &c., as laid down by Government, are good and efficiently carried out. The medical officer can suggest officially to the com-

References to Subjects and Queries.	Replies.
X. Field Service—*cont.*	manding officer any changes he may think fit, and the latter can accept or reject them, on his own responsibility. 4. When it is found necessary to establish a general field hospital, and the site has been fixed upon by the commanding officer and superintending surgeon, the commissariat is ordered to supply forthwith all necessary stores and the proper proportion of servants; and the regimental hospitals being of course reduced, there are taken as much as possible from them, and such medical officers as can be spared are attached for duty. Doolies and hackeries are always supplied in this country for the conveyance of the sick, and accompany the rear of the column. Carriage for the conveyance of hospital stores is supplied by the commissariat, and camels are employed when procurable.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1. Plan of the hospital is transmitted. 2. It is about 300 yards from the hospital to the nearest barrack in the infantry lines, and 200 in the artillery lines from the artillery or dragoon stables. The hospital is well removed from the bazaar in the infantry and alongside of the regimental bazaar in the artillery lines. The site is perfectly ventilated and healthy as regards elevation, drainage, absence of malaria, &c. 3. The water supply is abundant and wholesome. 4. The refuse water and other impurities are removed from the hospital by carts, as in the barracks. 5. The floors of the wards, which are of brick masonry or terraced, are raised three feet above the ground. The roof water is carried out into the drains of cantonments. The drainage is ample, and water never lodges about the buildings. The hospital is constructed of brick masonry (kiln burnt). The walls are single, two and a half feet thick. The roof is trussed, of purlins, battens, flat tiles, concrete, and tiles. There is an inner enclosed verandah, 12 feet wide and 17 feet high. All round the outside there are open arcaded verandahs, 15 feet high and 12 feet wide; these afford ample shelter to the building. The inner verandahs might hold men if necessary. The buildings are on the ground floor.

Table of Hospital Accommodation.

Date of construction, 1852–53.

Total number of wards, 10.

Total regulation number of beds, 160.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
				Under truss of roof.				Ft.		Ft.	Ft.
No. 10 - -	16	52	24	24¼	30,888	1,930	78	1½	84	1¾	5¾

The hospital is placed so as to receive the full benefit of prevailing winds. The windows open on central pivots of the best construction for ventilation and coolness.

6. Open ventilators along the ridge, and the windows are ample to keep the place sweet and clean. There are no jalousies or jhilmils. Outer chicks are supplied to the verandahs, and chick doors to the building.
7. Punkahs and tatties are used to cool the air admitted into the wards. Thermantidotes have been recommended, I believe, and are being constructed by the commissariat—design not known.
8. Fire-places are in each of the inner verandahs of each ward. The whole building is white-washed twice a year, and four times to the height of six feet.
9. A sketch of the privies is transmitted. They are separate from the hospital, and only connected with it by an arcaded corridor. They are not offensive, all filth being daily removed by carts.
10. Washing-rooms are attached to each wing of the hospital. These have a plentiful supply of water laid on from the wells, from which the men get water for their basins and for the purposes of ablution.
11. In each room there are full-length baths for bathing the sick, and slipper baths are also furnished.
12. The clothes are washed and dried by native washermen at a distance from the hospital.
13. The storage is sufficient and dry.
14. Tape-bottomed beds only are being supplied now, but wooden cots in this country so harbour bugs that they are constantly broken by the men in their efforts to expel the vermin, and the repeated repairs required are most expensive. An iron cot made in England would prove economical to Government and a comfort to soldiers. I understand that new hospital bedding has been fixed on lately in Calcutta, although patterns of the new kind have not yet reached this.
15. The kitchens, which are separated from the hospitals, are similar to but smaller than those of the barracks.
16. Copies of the diet rolls, diet tables, &c. are transmitted.
17. One hospital serjeant is allowed in each regiment for attendance on the sick; but the number of permanent hospital orderlies should be increased. A requisition to the commanding officer for extra orderlies in severe cases is always attended to. Nurses are not employed at present, but I would strongly recommend their being so.
18. The sanitary state of all the hospitals at this station is highly satisfactory. There has been no epidemic disease in either of them.
19. Of the ordinary familiar sanitary measures, drainage is perhaps the only one which admits of further development, but even this may be said to be very fair, and water runs quickly off.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	20. Convalescents are carried out in doolies for air and exercise, and those who are able walk in the large enclosed hospital grounds. Elephants are also supplied for the convalescents. 21. There are excellent hospitals set apart for the treatment of women and children. There is also an establishment of native female servants in addition to the European nurses. The present arrangements are perfectly satisfactory. 22. There are no special local hospital regulations not included in the General Presidency Medical Regulations, such not having been found necessary. 23. With reference to the powers of the medical officer in all matters appertaining to the sanitary state of his hospital, repairs in buildings, diet, medical comforts, &c., every facility exists through the commanding officer of regiments and the superintending surgeon. 24. No separate buildings exist for convalescents discharged from hospital, nor do I think such necessary, but a portion of the hospital is always set apart for the treatment and isolation of any infectious disease.
XIII. Burial of the Dead.	1, 2. The burial-grounds used by British troops are on either flank and within bounds of cantonment, but are not to windward of the station. The areas are, infantry, 9,700 square yards, soil clay; artillery, 8,909 yards, subsoil light clay. They are drained by means of side channels to roads, which are carefully looked to. 3. Each grave is about 7 feet by 3 feet, and the space between them, which, however, varies, is generally 3 or 4 feet. They are 5 or 6 feet deep, and are never re-opened. In the winter burial takes place within 18 hours after death, and in the hot season within 12, and less if possible; during epidemics, as soon as possible after the heat of the day is over, and coffins can be prepared. 4. The grave-yards are never offensive. 5. The Mussulmans are buried in a grave-yard beyond the station boundaries, near the city. Hindoo corpses are burnt on the banks of the nullah outside the bazaar. 6, 7. Not the slightest injury accrues to the public health from the present practice, nor are any improvements to be suggested.

(Signed) P. M. N. Guy, Brigadier,
Commanding Sealkote.
W. S. Dicken, Deputy Inspector-
General of Hospitals, Sealkote Circle.
J. T. N. O'Brien, Major H.M.'s 20th Regiment,
1st Battalion Ex. Engineer,
Sealkote Division, D.P.W.

21st December 1860.

RANEEGUNGE.

Accommodation { Queen's Troops—Infantry - - 1,120
Native Troops—Infantry - - 500

References to Subjects and Queries.	Replies.
I. Topography.	1. The country surrounding the station is generally bleak, undulating, sandy, and occasionally swampy, with very little wood, jungle, or water in the vicinity. 2. The elevation of the station above the sea is 370 feet, but it is on the same level as the adjacent country, and about 30 feet above the nearest water. There is no higher or healthier ground adjoining the station. 3. The nearest mountains are a range about 30 miles off, the height of which is from 2,000 to 3,000 feet. 4. The nearest water is the river Dumooda, about two miles distant from the station; the vicinity is liable to overflow during the rains. There is no broken ground, ravines, or water-pits near the station worth mentioning. 5. The station is open, and freely exposed to the prevailing winds, and the temperature is not raised by exposure to reflected sun-heat. The winds also to which the station is exposed are generally salubrious. 6. The surrounding country is partially cultivated. There are no works of irrigation. The cultivation of rice is only prohibited in the cantonments. No cultivation of indigo is carried on near the station, nor is there any preparation of hemp or flax. 7. There is no large city, town, or native population in the vicinity of the station. 8. The surface and subsoil of the district consist of gravel, sandstone, and coal. 9. Water is usually found during the dry season at about 50 feet below the surface, and during the rainy season at a depth of 40 feet. 10. The rain-fall flows off readily, and there is no adjacent higher ground the drainage from which can pass into the subsoil of the station. 11. The water supply of the station is derived from wells, no tanks existing in the district. None of the wells are liable to pollution from any source. 12. The water supply of the station is equal to the demand, and the quality of the water is excellent, but it is rather hard. It is free from microscopic infusoria. Water for use is raised by buckets and so distributed. 13 & 14. No reply to these queries.
II. Climate.	1. The instruments available at the station for meteorological purposes consist of a thermometer, aneroid barometer, and rain guage. 3. The climate is generally healthy, with no great or unusual variability, but is subject to heavy storms of sand and dust. It has, however, no perceptible deleterious influence on health. The usual East Indian diet and clothing, with proper precautions against exposure,

References to Subjects and Queries.	REPLIES.
II. Climate—*cont.*	are all that are necessary in this climate in the way of precautions. We have no statistics with regard to the most healthy or unhealthy months, but the end of the rainy season in Bengal is usually the most unhealthy. 4. There is no district near the station the climate of which is more conducive to health. 5. With the exception of Raneegunge, the stations (all civil) at which I have served were positively injurious, viz., Hoogly, Jessore, and Howrah.
III. SANITARY CONDITION OF STATION.	1, 2, 3. Plans of the cantonments and district are transmitted. 4. Table of barrack accommodation. Date of construction—No. 1, 1858–9; No. 2, 1854; No. 3, 1857, 1858. Total number of rooms. Total regulation number of non-commissioned officers and men.

		Measurement of each Cell.			Total.	To each Cell or Man.	To each Cell or Man.		To each Cell.		
Prison cells† -	20	15	7	15	31,500	1,575	105	18	1	9	4

* This measurement excludes dry room, serjeant's room, and verandah on three sides.
† Roof and side ventilation given extra.

5. The doors of the barracks are on the four sides of each building. There are verandahs five to six feet wide to each temporary barracks, but neither verandahs nor shelter of any description to the iron barracks. Verandahs are seldom used for sleeping quarters by soldiers or others except in the warm season at night. There are no jalousies or jhilmils.
6. Wooden cots laced with iron hoops are used in the barracks.
7. No reply to this query.
8. In the iron barracks sufficient ventilation is afforded by four openings. Open doorways ventilate the rest of the buildings. These means are sufficient to keep the air pure by night as well as by day. There are no artificial means used for cooling the air of barrack rooms.
9. The outer walls of the iron barracks are built of mud mortar and stone masonry, while the walls of temporary huts and barracks are of sun-burnt brick. The roofs are generally thatched.
10. The floors, which are of earth, are of an average height of three feet above the country level.
11. These buildings are only suitable for troops *en route*. More permanent buildings are required for a longer residence. The iron barracks require verandahs all round them to render them fit for permanent barracks. Repairs to barracks and cantonments are done quickly when urgent, and are executed by the cantonment magistrate, barrack master, or engineer officer. The walls and ceilings of barracks are cleansed and lime-washed once a year, or oftener if required.
12, 13, 14. No information is afforded in reply to these queries in reference to privies, wash-houses, and cook-rooms. The cleansing and drying of linen is performed at the tanks in the vicinity of the cantonment.
15. The buildings at this station are lighted by lamps, and in the barracks lanterns are used, having round open-topped edges.
16. The drainage of the barracks is easily effected from the sloping nature of the ground surrounding them. No part of any building used as hospital or barrack is damp. The fluid refuse of the barracks is carried away in filth carts and buckets. No cesspits exist near the station, nor any foul ditches within 1,000 feet of it.
17. Filth carts and sweepers are employed for the surface cleansing of the cantonment; extra hands being engaged when necessary.
18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c., interfering with the ventilation of the station or bazaar.
19. No drainage exists or is required in the bazaar, which is kept clean. The latrines are at a distance, and are not offensive. Water is supplied by water-carriers from the tanks. The small depôt bazaar is kept clean by sweepers. The condition of the native houses near the station is indifferent; pits and dirt heaps abound. No nuisance, however, is experienced in barracks from wind blowing over these native houses.
20. The slaughter-house is at a considerable distance from the barracks.
21 & 22. No replies to these queries.
23. There are no quarters at this station for married non-commissioned officers or men.

Officers' Quarters. 1. The officers' quarters are not good, but improvements are about to be made, and when these are effected, good doors, with glass, &c., ought to be supplied.

References to Subjects and Queries.	Replies.
IV. Health of the Troops.	1. The station, surrounding district, and adjoining native population are generally healthy. 2 & 3. Fevers, with occasional outbreaks of cholera, are the most prevalent diseases among the natives, which are attributable to their mode of living, and neglect of all sanitary precautions in cases of sickness. Their general healthiness may be ascribed to the clear and open aspect of the country. 4. There are no troops at the station. No portion of the men's accommodation is more unhealthy than the rest. 5. No reply to this query. 6 to 16. No experience of hill stations. 17. There is no higher ground within 30 miles of the station, and it is doubtful whether this hill (Pachete) could be occupied as a hill station. 18, 19, 20. No replies to these queries. 21. The mode of transport of troops from the port to this station is by rail, and on to the north-west by bullock train or marching. 22 & 23. No replies to these queries. 24. Invalids should leave India for home at such time as will land them in England in April or May.
Diseases.	1. There are no inspection parades for the discovery of incipient diseases at this station. 2. No cases of scorbutic disease have occurred here. 3. There are no statistics to show the proportion of cases of hepatitis usually under treatment, and since my incumbency there have been no cases of decided hepatic disease among the passing troops. 4 & 5. No reply to these queries. 6. This station is only used as a resting-place for passing troops, consequently this query does not apply to Raneegunge. 7, 8. No replies to these queries. 9. Small doses of quinine have not, I believe, been used as a prophylactic against malarial diseases at this station. 10. No reply to this query.
V. Intemperance.	1. The troops while here are temperate, but as they merely rest at the station *en route* no information can be afforded as to the proportion of confirmed drunkards. 2. No reply to this query. 3. Distilled sprits are sold in the bazaar, but there is no canteen at this station. Spirit is never given as a ration to convalescents. Beer and rum are provided by the commissariat, and ginger beer, but of indifferent quality, is sold in the bazaar. 4. The consumption of spirits in moderation is not injurious to the health of troops. 5. No reply to this query. 6. Malt liquor is the best beverage for troops. 7 to 11. No replies to these queries.
VI. Diet.	1. The ration for Queen's British troops and European troops in the Indian army is the same, and consists of 1 lb. meat (beef five times and mutton twice a week), 1 lb. bread, 4 oz. rice, 2½ oz. sugar, 5-7th oz. tea, or 1 3-7th coffee, 1 oz. salt, 1 lb. vegetables, 3 lb. firewood. A daily inspection of the rations is made by the orderly officer and the mess-men of the companies. 2. A complete ration, including 1 lb. potatoes, yams, onions, pumpkins, &c., according to the season, is provided daily for the troops, the stoppage for which is 3 annas 4 pie a day. 3. No improvement in the ration is necessary, since the men themselves are satisfied both with the quantity and the quality. No arrangements are necessary for preventing the disposal of the ration by troops. 4. Native cooks are employed to cook the ration, and pots are supplied for the purpose by the commissariat. The kitchens are built near the barracks, and the food is cooked according to the taste of the men, the mess-men see that it is properly done. No refreshment is given to troops before a march. 5. Gardens for the cultivation of vegetables by soldiers on a small scale could be advantageously established near the station.
VII. Dress, Accoutrements, and Duties.	No information under these heads.
VIII. Instruction and Recreation.	1. The only means of amusement at this station are two skittle-grounds. 2, 3. No replies to these queries. 4. There is not sufficient shade to enable the men to take exercise without injury to their health during the heat of the day.
IX. Military Prisons.	1. Some cells have lately been built at this station, and they seem well adapted for punishing the men without endangering their healths.
X. Field Service.	No information under these heads is afforded.
XI. Statistics of Sickness and Mortality.	
XII. Hospitals.	1, 2. There no stables or other offensive buildings near the hospital, which is distant 1,000 feet from the bazaar and houses of the civil population. The site is open and freely ventilated, and is healthy as to elevation, drainage, &c. 3. The water for use is good, but has to be brought from a distance. 4. Refuse water and other impurities are removed from the hospital in filth-carts and buckets. 5. The floors of the hospital are of solid earth, and the lowest portion is raised 18 inches from the ground. The roof water sinks into the subsoil, but the rain-fall is carried away by the natural slope of the ground. The hospital is built of brick, stone, and mud mortar masonry; the roofs are single, but the walls being thick and ventilation good, the building is sufficiently cool. There are verandahs all round, 6 feet wide, but they are never used for the accommodation of sick. The hospital consists of one flat.

RANEEGUNGE. BENGAL.

No. 3 - -	14	55	18	12·	11,880	848	70	18	10	7	4

Verandah measurement is excluded.

The hospital is so placed as to receive the full benefit of the prevailing winds. The doors are battened, and open outwards; Venetians would be much better for the purpose.

6. The morning and evening draughts keep the hospital cool both by day and night. There are no jalousies or jhilmils.

7, 8. There is no apparatus for cooling or warming the air admitted into hospitals. The walls and ceilings of the wards are cleansed and lime-washed every six months, or oftener, if required.

9. The privies have no cesspits; they are naturally drained, and are not offensive.

10, 11. The lavatory arrangements are sufficient for the sick, but no regular baths are provided for patients.

12. The washing and drying of hospital linen are done by native washermen at a distance.

13. The storage is very imperfect. A pucka building may become available, but at present it is not so.

14. Wooden cots, with crossed-iron hoops, are used in the hospitals, the bedding consisting of a mattress and cotton quilt.

15. The hospital kitchen is very imperfect; cooking is performed over fireplaces of kutcha-work.

16. A copy of the diet-tables is transmitted, those used are of the ordinary kind for European Indian hospitals.

17. A hospital serjeant with a native establishment is the attendance provided for the sick, but orderlies are also attached if specially required.

18. The sanitary condition of the hospital is good; no epidemic has ever appeared in the wards.

19. The hospital is sufficient for temporary purposes, but is far from being complete, the ventilation and lavatory arrangements being very bad. It is, however, very difficult to obtain good ventilation in a kutcha building.

20. No provision is made for exercising convalescents at this station.

21. Soldiers' sick wives and children would be treated in a separate building, which arrangement is satisfactory for the present small requirements.

22. There are no special local hospital regulations enforced at the station.

23. The powers of the medical officer in regard to matters appertaining to the sanitary state of the hospital, repairs of the buildings, change of diet, medical comforts, &c., are considered in the station as paramount.

24. There is no convalescent ward or hospital at Raneegunge.

XIII. BURIAL OF THE DEAD.

1, 2. The burial-ground for British troops is on the outskirts of the station, and to the leeward of it. The soil is gravelly, and the ground slopes well for drainage. This burial-ground will shortly be enclosed.

3. The grave space allowed is about 7 × 3 ft., with about 4 feet interval. The graves are about 6 feet deep, and are never re-opened, one body only being interred in each. Interment is compulsory at ordinary times within 24 hours, and during epidemics as early as practicable. There is no burial-ground for native troops.

4. The grave-yard is never offensive. In the absence of the clergyman an officer performs the burial service over a British soldier.

5. The dead of camp followers or bazaar people are burnt at a distance.

6, 7. No injury accrues to the public from the present practice, and no improvements in the disposal of the dead are required.

(Signed) R. C. GERMON, Brigade Major, Commanding.
C. PALMER, M.D., Surgeon.
EDW. ROOKE, Executive Engineer, 1st Div., Grand Trunk Road.

ROORKEE.

Accommodation—Queen's troops, Infantry, strength of 2nd Bengal Fusiliers - - - 487

References to Subjects and Queries.	Replies.
I. Topography.	1. The surrounding country is a dry sandy plain, with low hills, occasional cultivation on three sides, and the Himalayas to the north. No wood or jungle exists in the vicinity of the station, but a canal runs through the cantonment. 2. The station is elevated only a few feet above the adjacent country, and no higher or healthier ground is to be found near. Roorkee is the highest spot in the neighbourhood, and is very healthy, except in September and October, when the houses nearest the low ground suffer. The native servants, especially, suffer from ague. 3. The Himalaya mountains are about 40 miles from the station, and the snow range is always visible in clear weather. 4. The canal which runs through the station is the nearest water, but there is some low ground to the north, which is marshy in the rains. It is now, however, and through the dry season, cultivated and dry. There is no broken ground or any water pits near the station except the low marshy ground already mentioned. 5. The station is generally very open, especially the barracks, but some of the private houses are too much enclosed with trees. The station is not exposed to an elevation of temperature by exposure to reflected sun heat, being too small and open on all sides. A cool wind in the hot weather, at night, comes from the hills on the north, and is very pleasant and healthy. 6. The country surrounding the station is cultivated. There is no irrigation near, except in private gardens, where it injures no one but the occupants of the houses adjacent. The soil of the station being sandy, no rice is grown in the vicinity, neither is there any preparation of flax or cultivation of indigo carried on near it. 7. There is a small native town about one mile from the station. 8. The soil of Roorkee is sandy on a substratum of coarse gravel. It has never been occupied by a population. 9. Water is never found nearer the surface than 40 feet, and during the dry season the wells farthest from the canal dry up. 10. The rain-fall sinks quickly into the soil, and does not lie on the surface. It drains off very quickly, and no drainage from higher ground passes into the subsoil of the station. 11. The water supply of the station is derived from the canal and the wells supplied by it; it is not stored in open tanks, none existing in the vicinity. 12. Plenty of excellent water is obtained from the canal, which is always very cold in the hottest weather, the water being derived from the snow which melts on the hills. It is soft, good, and very pure. Any well dug near this canal is plentifully supplied with pure water, by filtration through the intervening gravel and sandy soil. 13. The peculiarity of Roorkee is that its nearness to the snowy range brings it within the influence of the cool breezes and storms from the hills, which greatly temper its climate during the hot weather. A day hotter than usual is sure to be succeeded by a refreshing storm, which cools the air for many successive days. The cold wind which blows from the hills at night in the hot weather is also very refreshing and healthful. 14. New stations are too often selected only to protect civilians in the exercise of their duties near the larger towns; Peshawur, Kurnaul, Lahore, Delhi, Jhansi, Patna (*i.e.*, Dinapore) are all instances of unhealthy cantonments from this cause; it is, however, unavoidable.
II. Climate.	1. The means and instruments available for meteorological purposes are a rain gauge and a thermometer. 2. The following meteorological table is the result of observations taken from April 1860 to November 1860. 3. The climate of Roorkee is very healthy and quite equal to that of England, if estimated during the cold as well as hot months. From the 1st November to the 1st April nothing can exceed the healthiness of the climate, and during the hot months the heat is moderate and the sickness trifling. During 6 months of the year the open air can be enjoyed in a verandah or house with open doors both night and day. It is hot in the middle of the day in the sun, but exercise can be taken in the morning in the hottest weather, and our recruits were always at drill morning and evening without injury all through the past hot season. September and October at the drying of the rains are the most unhealthy months, fevers both intermittent and continued of a mild type being then prevalent. 4. There is no district near the station the climate of which is more conducive to health than that of the station. 5. I have served in almost every part of Bengal from Cabul to Burmah. The most unhealthy places have been Lahore, Delhi, and Fort William. Dinapore is also in some years, when the river overflows more than usual the surrounding country, very sickly.
III. Sanitary Condition of Station.	1, 2, 3. No replies to these queries. 4. There are 21 barracks, each 100 feet long, 10 feet wide, and 20 feet high, each holding without crowding 30 men. There are no windows, only wooden doors 8 feet by 4 feet. The regiment is not provided in Roorkee with regular guard rooms, &c. 5. The doors are on opposite sides and open inwards. There is a verandah on the east and west sides 10 feet wide, but I have never seen them used as sleeping quarters by soldiers or other persons. There are no jalousies or jhilmils to the barracks, only wooden doors with glass panes in the top. The hospital, however, has in addition to these doors, purdahs. 6. The bedsteads used in barracks are wooden frames with cotton tape weaved, for the centre. This can be washed, and these beds are the best possible for India, but when iron frames could be procured cheaply they would be an improvement, for bugs harbour in the joints of the wood, and cannot be dislodged without difficulty. 7. The tents are double poled, 16 feet by 12 feet area, 12 feet high to a slope of 5½ feet, which is the height of the side pieces. Each tent is calculated to hold 16 men. 8. Ventilation in the barracks, &c., is effected by means of holes in the ridge of the roof, which are covered by a raised thatch, sloping on both sides from the centre, also by small

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	windows at the top of the walls on each side, east and west. In this station the ventilation is sufficient; in other stations I have seen it often very imperfect. The air admitted into the barrack rooms is cooled by means of punkahs and tatties, which latter are very badly watered and often quite dry. 9. The barracks are built of mud bricks, the roofs being thatched with grass to the junction of the verandah roofs, which are tiled. 10. The floors are paved with burnt bricks and raised 4 feet, but there is no passage of air beneath. 11. The materials used in the construction of barracks, &c., are suitable for the mild climate of Roorkee, but not for any other place. The barracks and cantonments are kept in repair by the executive engineer under the orders of the officer commanding the station. There is often great delay in executing repairs. No one is responsible for the sanitary state of the cantonment. The walls and ceilings of barracks are cleaned and lime-washed once yearly. 12. The men have small tiled sheds for washing houses with a wall on each side, having depressions to hold the washing basins. 13. There are no proper cooking houses; they are mere sheds with places on the ground for the fires. The linen is cleansed and dried by washermen in the fields at a distance from the barracks: quite sufficient for the wants of the station. 14. The privies have seats along the wall on one side with pans under each seat, which are removed by the sweepers from behind outside the building. All filth is carried away morning and evening in filth carts, and flung into the canal, which has a strong current. 15. The privies are open in front with a wall as a screen, and are each provided with a small native lamp. The barracks are very imperfectly lighted at night, by oil lamps in lanterns hung at intervals from the ceilings. These lamps are glass tumblers with coarse cotton wicks floating in the oil. 16. There are no regular drains, trenches being merely cut to carry off the water from the barracks during the heavy rains. The filth is carried away in carts, and no drains are required. The drainage of the privies, &c. is sufficient for conveying away the surface water, &c. the urine being removed in filth carts. No part of any building used as a barrack or hospital is damp. The fluid refuse of the barracks is carried away in tubs, no cesspits being near the barracks or hospital. No foul ditches exist. 17. The surface cleansing of the cantonment is efficiently performed, and the refuse thrown into the canal. 18. The surface of the cantonment is kept free from vegetation, except in private gardens. No old walls, thick hedges, &c., exist to interfere with ventilation. 19. The bazaar is 1½ miles from the barracks, and I have no information as to its state. No nuisance is experienced in barracks from wind blowing over native dwellings. 20. Animals are slaughtered not far from the barracks, but in India where dogs and vultures are watching to clear up instantly all offal, no nuisance is ever experienced. 21. No horses or only a very few ponies are kept in the bazaar; they are tied up in the open air. There is no nuisance experienced from them. 22. There are no artillery or cavalry stables or picketing grounds at this station. 23. There are sufficient quarters for married men; none of them ever live with the men in barracks.
Officers' Quarters.	1. There are no officers' quarters at Roorkee.
IV. HEALTH OF THE TROOPS.	1. The station and district together with the native population are healthy. 2. Small-pox is very common and destructive to the natives in the spring when inoculation is practised by them. Cholera occasionally, but not in a very bad form, visits the villages in the district. Spleen disease is rare. 3. The healthiness of the natives in the neighbourhood is to be attributed to the dry sandy soil and mild climate. 4. The regiment stationed here came to Roorkee from Delhi in April last. They had been there since May 1857, and their health was bad and continued so till their arrival here. They left Delhi in March 1860, while there having suffered from the worst forms of dysentery, cholera, and obstinate intermittent fevers, which continued through the cold weather, and were incurable except by leaving Delhi. Abscess of the liver and enlarged spleen were very frequent. No portion of the men's present accommodation is more unhealthy than the rest. 5. Troops are not camped out. 6. I have been in charge of two European regiments in the hills, one at Dugshai, the other in Subathoo; I have also had charge of the sanitarium of Simla. My experience of the effect of a hill climate on troops is very favourable. 7. The 1st and 2nd Bengal Fusiliers came down from the hills to the siege of Delhi in the hot weather and rains of 1857, other regiments joined us from the plains, but no regiment was so healthy as the above two; some of the regiments who had always been in the plains suffered very severely. 8. I much approve of hill stations, and after great experience believe that they save hundreds of lives. Regiments that have suffered from bad climates in the plains have been usually sent to the hills, and their mortality and sickness there has often been great, but this is to be attributed not to the hill climate, but to the diseases which the regiment acquired in the plains, and which it requires a long residence in a good climate to eradicate. Both the 1st and 2nd Bengal Fusiliers went to the hills from Burmah. They had considerable mortality the first year from abscess of the liver and other Burmah diseases, but became very healthy the second year. This mortality on first arrival for the first 12 or 18 months has been the cause of much of the prejudice against the hills, which has increased with the custom of sending to the hills those regiments which have suffered most in unhealthy stations, Burmah, Peshawur, &c., in the plains. I had charge this year of some convalescents (about 15) going to Landour. Among these there were two with abscesses already formed in the liver, and another in the last stage of phthisis; such hopeless cases are too often sent there, and cause a high mortality. My experience is very much against depôts; entire regiments ought to be located in the hills, and not depôts. The machinery of a regiment is formed solely for preserving its order and discipline, and the loss of even one non-commissioned officer must necessarily be followed by corresponding want of order.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	How then can a depôt be properly regulated when the men are collected with scarcely any machinery for preserving discipline, and the men consequently drink and indulge in every kind of excess. If these men were attached to a regiment in the hills they would be subject to its excellent discipline with the rest, and thus have the full benefit of the good climate, which is too often counteracted by hard drinking. 9. Diarrhœa is very common during the rains in hills, but in the two regiments I have not seen one case of death from this cause. The cold weather always removes it, and those who reside always on the hills are not subject to it. New comers only have it. 10. The principal want for the troops in the hills is fresh vegetables and pure water. The men might cultivate their own vegetables if proper arrangements were made; and the drinking water ought to be purified by boiling and filtration. I believe it is the water which causes the diarrhœa. In the rains it is loaded with rotten vegetable matter. I have often prevented my patients from drinking any water but rain water collected in a tub by stretching a sheet on four poles, and always with the result of stopping the diarrhœa. 11. The rains are the worst season in the hills, but even then they are preferable to the plains. The rest of the year, not excepting the winter months, is delightful. Troops, however, can be in the plains in the cold weather, and return to the hills for the hot season. Two years is the shortest period of residence to obtain the full benefit of the hill climate. If a regiment has suffered much from former residence in the plains, I would recommend their remaining for the winter in the hills. A winter in the hills has great effect in restoring men who have suffered from tropical diseases. 12. Regiments have not hitherto been kept more than two years in the hills, which makes them more fit for service in the plains. The effect of long residence there can only be seen among the European inhabitants of Simla and Mussoorie, where those who have lived there for many years appear very robust and healthy, also their children. There are large schools at both Mussoorie and Simla for Europeans, and the health of the boys and girls is excellent. 13. No special precautions are required for troops on leaving hill stations for the plains. 14. The longer regiments can be kept in the hills the better for their health. If the station on the plains is unhealthy, the troops ought to be relieved yearly; if not unhealthy it is much better both for officers and men that they should remain in the same place three or four years, and a great saving of expense to Government. 15. The barrack and hospital accommodation provided at hill stations is sufficient for the health and comfort of the troops. 16. With regard to the elevation above the sea level the most suitable for hill stations, Dugshai, 7,000 feet high, is more healthy than Subathoo, which is only 5,000 feet. I have had charge of regiments in both places. The low ranges of hills are often more deadly than the plains. 7,000 feet I consider to be the best elevation. 17. Mussoorie, about 60 miles from Roorkee, might no doubt be selected as a hill station for a regiment with advantage. 18. Sand with a substratum of gravel I have always noticed to be a healthy class of soil, &c., for stations. Clay, though covered with a surface of sand, although appearing dry and arid, is often very unhealthy. 19. No soldiers ought to be sent to India till they are 21 years old, and have attained their full strength and growth, and they should land in Calcutta in the month of November. There is no uniformity in the mode of disposal of troops after landing in regard to barrack accommodation, as much depends on accident and commanding officers. Strict discipline, and preventing them wandering in the sun into the bazaars in search of liquor, are the precautions necessary to be observed in order to preserve the health of recruits on first landing in India. 20. Troops can be sent direct to India without risk. On landing, a regiment ought never to be kept in Lower Bengal, but sent at once up country to some healthy station, such as Umballa, Meerut, Roorkee, and Sealkote. I would reserve the hills for regiments which have suffered from the climate, though no doubt they would be good intermediate stations for new regiments to acclimate in. 21. There is no uniformity in the mode of transport of troops from the port to the interior. 22. The longer a soldier serves in India the better he is able to do his duty, provided he is not affected by organic disease from previous sickness. The most active and athletic man in my regiment has never been out of India. 23. There is no conflict of opinion in medical boards in reference to invaliding. Numbers of European soldiers are yearly invalided from the Indian local service, who, though not able to serve in India, soon become strong and healthy men in a cold climate. This must be a cause of much unnecessary expense to Government. These men ought not to be invalided, but drafted into a Queen's regiment serving in England, Ireland, or Canada. Many of them, after residing for three or four years in a cold climate, would be able to come back and serve in India. 24. Invalids leaving India for home should depart at such a time in the year as would enable them to arrive in England in the warm weather—not earlier than the 15th of April.
Diseases.	1. There are weekly inspections at the station for the discovery of incipient disease. 2. No case of scorbutus has occurred among the troops at this station. 3. The proportion of cases of hepatic disease is about one per cent. in this station; in others, two and three per cent. Spirit drinking causes a disease of the liver, but it is a contracted liver; pale, and usually called nutmeg colour, never abscesses or enlargements. These in India are always caused by the congestive influence of the malarious poison. Abscesses are often the result of the ulceration of the bowels in dysentery, and are then not single, but many small abscesses scattered through the substance of the organ. Fever and congestion of the liver always form one solitary large abscess. 4. I have never seen a case of dracunculus among Europeans. 5. Syphilis is the bane of the European troops in India. It usually forms one half, sometimes more, of the diseases in hospitals. Unfortunately, the injury caused by it is never brought to the notice of those in authority, and can only be fully appreciated by a surgeon who has been long in the same regiment. Few die of syphilis, but numbers are annually invalided from its effects, and far more die when attacked with other diseases which they would have recovered from, had not their constitution been ruined by this disease. Large sums are spent yearly in vaccination, while this more serious evil remains unchecked. Government

IV. Health of the Troops —*Diseases—cont.*	has the power, if it will use it, to eradicate this disease from the army. The cantonment magistrate ought to have women, well paid, under his orders, and their duty should be to inspect constantly all the prostitutes in the bazaar; and the magistrate ought to have full power to fine, and if a recurrence—for a second offence—imprison any woman who diseased a soldier. The soldiers would always willingly point out the woman who diseased them; but in the present state of the law a magistrate has no power to interfere or prevent the same woman from infecting as many as she pleases. When a prostitute is found to be diseased, a proper hospital ought to be provided for her cure. In India the prostitutes are more easily controlled than in any other country. They are not, as in England, outcasts from other classes, but bred and educated for prostitutes, as for any other trade. Women whose trade it is, and whose parents have carried on the same for generations, buy the girls when quite young, and they thus become the bawd's slaves. She feeds and clothes them, and receives all the profits. These bawds are regularly registered by the kotwal, or head man of the bazaar, and are as much under control of the magistrate as a grain seller or cloth merchant. So long as the bawds are not interfered with, it is of course to their interest to allow their girls to cohabit with the soldiers whether diseased or not, as she pockets their earnings; but if she is liable to fine and punishment if she does not withdraw her girls when diseased, she will soon find it her interest to do so. I write the above with the confidence of practical knowledge, for on many occasions my regiment has been encamped at a distance from towns, and where no women could be procured, except from the regimental bazaar, which is under the quartermaster of the regiment and military laws, and through him merely by threatening the bawd with punishment, I have always been able to keep the men free from any fresh infection. Nothing is easier than to detect the girl who causes the infection, for, as before stated, the men will always gladly point her out, but near a town, where the magistrate is controlled by civil regulations for the liberty of the subject, syphilis has always been a most serious evil, and destroys and invalids, if calculated by its after results, more men than cholera. 6. The troops at the station suffer slightly from intermittent and continued fever, but not much from dysentery. No case of cholera has occurred, and only two cases of small-pox were seen last year. Rheumatism, however, is common. The total admissions from all causes have been 711, and from the above five diseases 236, or one-third nearly. The total deaths from all causes have been eight, six of which, or three-fourths, have been caused by the first-mentioned diseases. 7. There are no zymotic diseases in Roorkee except small-pox, which is caused by native inoculators, who practise it in the month of April, at which time the disease is most prevalent. No peculiar condition of station, bazaar, &c., or any personal habits or conditions among the troops, predispose to these diseases. 8. The prevalence of epidemic disease is very little affected, if at all, by the soldiers' duties, occupations, or habits. 9. Small doses of quinine were tried at Delhi, during the siege, as a prophylactic against malarial disease with great benefit. 10. I can suggest nothing towards the mitigation or prevention of malarial disease at Roorkee.
V. INTEMPERANCE.	1. The soldiers at the station, in comparison with other regiments, are temperate, but still there is much disease and crime caused by spirit drinking. There are confirmed drunkards in the regiment, but I have no means of knowing how many. Numbers of men, and even non-commissioned officers, drink hard, without actually getting drunk and coming under the notice of the adjutant. 2. I have no materials to construct a table showing the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station. Drunkenness is always punished as a crime. 3. Distilled spirits are sold both in the canteen and bazaar. The quality is good, but I cannot say the amount consumed. Spirit is no part of the ration at the station, but it is so given on the march and in the field. The quality is good. It is not given before parade, but when the men have arrived, after their march, in camp. All spirit drinking is injurious to health. Spirit is never given as a ration to convalescents. No drinks injurious to health other than intoxicating drinks are sold in the canteen or bazaar. 4. The consumption of spirit is injurious to health, efficiency, and internal discipline. Almost all crime in a regiment is caused by spirit drinking. 5. Spirits ought to be abolished, both from canteens and bazaars within the reach of troops, as far as possible. At present the collectors encourage the sale of spirits as much as they can for the sake of the revenue it produces, but magistrates ought to have full power given them to prevent the sale of liquor to Europeans. 6. Spirits are in every way injurious, while malt liquor is in some cases very beneficial. During my campaign in Burmah I had many opportunies of observing this. When malt liquor could be procured the health of the regiment always improved, and there was a marked change for the worse when spirit rations were issued instead of it. I have good reason for thinking that malt liquor acts as an anti-scorbutic, and corrects the want of vegetables, which could not be procured in Burmah. It is also a very general opinion, and I think with good foundation, that malt liquor in moderation prevents attacks of malarious fevers. Numbers of old residents in India of temperate habits will assert that they were constant subjects of fever till they took a bottle of beer daily. I do not wish to infer that many do not injure themselves by excessive beer drinking in India, but its effects on the constitution *comparatively* with spirits are harmless. Since the introduction of beer into canteens the tremulous, yellow-skinned, emaciated spirit drinker, who is fit for nothing till he has drank his morning dram, is rarely met with. In former days at least one-third of every regiment in India were in this condition, and I state this from personal experience. 7 to 11. Coffee and tea are much used morning and evening by the men, and are very beneficial. A kind of effervescing drink, much like imperial, made with cream of tartar, flavoured with sugar, lemon-peel, and ginger, called "pop," is made in the bazaar, and much drank by the men in hot weather, without injury, and, perhaps, good. Spirit drinking, as before stated, is the cause of at least half the crime in regiments, and it is remarkable that some forms of spirits have the effects of rousing the evil passions of the men more than others. In Cabul this was notorious; spirit is manufactured there from raisins, and the men themselves said that this spirit made them mad. A man of excellent character, in the 13th Light

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	Infantry, who had never before been known to misbehave, went to visit a friend in the city of Cabul, who gave him a glass of the native spirit; on coming home he passed the officers' mess-tents, lighted up for dinner; he fired his musket through the tent, and the ball passed between the legs of the colonel. He said he felt, though not drunk with the spirit, an uncontrollable inclination for mischief, and his plea was admitted as true by the officers on his court-martial, and he was pardoned. I mention this to show, that though drunkenness may continue in a regiment (to be stopped, of course, if possible), yet what a vast difference depends in the crime of a regiment, on the form of liquor which the men get drunk on. Now a man who drinks too much beer gets stupid, sleepy, and plethoric. If he gets drunk on this liquor he goes to bed and sleeps it off, but does not become mad, make a row in the barrack, or wander about seeking some one to fight with. Moreover, beer drinking is easily cured; it never, as spirit drinking, becomes an incurable habit, rarely, if ever, overcome even by educated gentlemen. Our canteen system in regiments formerly educated the men in this habit. It encouraged them in acquiring a liking for spirits by daily issuing it as part of the ration. Spirit rations ought, therefore, totally to cease. No spirit ought to be sold in canteens, but plenty of good beer, as the men will drink spirits if not supplied with beer; also, especially, the sale of native spirits, which are invariably drugged with hemp and other native drugs, ought to be stopped by the Government, where they are vended in the neighbourhood of European regiments, with the most anxious care. Magistrates ought to have full power to punish persons selling liquor to Europeans, and collectors ought to be warned that, though zeal in collecting the revenue is desirable, yet the Government value far more the lives of the European soldiers.
VI. Diet.	1, 2, 3. A pound of bread and a pound of meat is the standard ration, with half a pound of such vegetables as can be procured cheaply in the bazaar. But as there are frequently none there, the soldier has to subsist on lean, tough meat and bread, with tea or coffee morning and evening, without milk. The quantity of animal food is far too great, and a fruitful source of disease in a hot climate, where the men cannot take exercise. I have often heard the men complain that the diet is too strong for them. The diet scale of the navy is far better, and has been proved by large experience to be enough for robust health. The scale there is 31 to 35½ ounces of solid food, and of this only 5 to 9½ ounces are animal, and the remaining 26 ounces, vegetable. How different this is from the 16 ounces of meat that our soldiers live on daily. The Burmah soldiers and sailors were often employed on the same expedition inland, and it was the general remark how much less the sailors suffered from the climate and diseases than the soldiers, though the former were exposed to the climate night and day in open boats, and the latter usually housed, but the sailors carried their ship rations with them, and our soldiers, who receive nothing but lean, tough beef and bread, often looked with longing eyes on the pea-soup and plum-puddings which the sailors cooked, just as if they were on board ship. The result of this diet scale (which is almost perfect, and might easily be introduced for the troops in India, substituting fresh meat for salt) is, that three ships can be now kept afloat with only the same number of men which was formerly required for two. The sailors on this diet are contented and robust; why not, then, the soldiers? Much has been done to improve the diet of the soldier since I have been in India, by the introduction of vegetables, tea, coffee, and sugar. All changes are for the better on the eternal beef and bread of former days, but much still remains to be done. The wonderful effects of good diet on the health of soldiers may be seen by comparing the history of the first Burmese war at Rangoon, with the second in the same place. In the first the army was almost destroyed by sickness caused by bad provisions; in the second war, in the same place, through the same seasons, the troops retained excellent health, because they were liberally supplied with excellent provisions from Calcutta, by the wisdom and foresight of Lord Dalhousie, and it was well known that the soldiers always became sick when they left Rangoon, and could not carry with them into the interior their proper rations. My own regiment lost heavily from sickness on two occasions, when it left Rangoon on service towards Pegu, and there was no cause that I could discover for the change but the inferior provisions. Potatoes, with a little care, can be kept all the year round, and officers always have them. A little trouble is required in the rains, when they rot if not kept dry; but this trouble ought to be given and potatoes supplied to the troops the year round. The rations are inspected every day by the quartermaster and officer of the day. 4. The cooking apparatus is sufficient, but the cooks ought to be better paid, and taught a little of the art of cooking. The kitchens are mere sheds, and not as good as they ought to be. The food is mostly boiled, for the meat is so tough and lean that if roasted it is so hard that it cannot be eaten. The only way a soldier can make his meat eatable is by stewing it till it becomes softened. The tea and coffee are good, but a little milk, which can be procured very cheaply in India, ought to be allowed for them. The men usually have coffee half way on a march. 5. Vegetable gardens ought to be established in every European station, not to be cultivated by the soldiers but by natives, under the commissariat officer. European soldiers cannot, in the hot weather, work as labourers. In the cold weather even the sun is too hot for them to work during the day, and their mornings and evenings are occupied in drill. I have seen many attempts to persuade the soldiers to work in gardens, but they have all failed. A good vegetable garden, however, worked by natives, under the commissariat, would be invaluable and save expense to Government, as the cost of a garden worked by natives is very trifling, and the produce large.
VII. Dress, Accoutrements, and Duties.	1. On the subject of dress I have, I think, valuable information to communicate, viz., how to waterproof the men's clothes, boots, and bedding; the rest I must omit from want of space. In Burmah, but especially during the siege of Delhi, in the rainy season, I was much struck with the suffering of the men from wet clothes. The constant history of the most severe cases of fever and dysentery on admission into hospital was, "I was quite well, sir, till I "got wet, and was obliged to lie in my wet clothes all night on picket." A large proportion of these cases, of both officers and men, terminate fatally. It was the same in the Crimea; numbers of officers who were there have told me it was not the cold, it was not the heat they cared about, or which hurt them, but it was the wet, and being obliged to remain in their wet clothes without the possibility of changing them. Since the Delhi siege I have occupied my leisure in trying carefully every receipt I could find for waterproofing cloth and leather in the old as well as the most recent works, particularly the *Mechanics' Magazine*. I have

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*cont.*	tried several hundred receipts, some good, others entire failures, and after repeated experiments, I can recommend the following, as scarcely admitting of improvement, either in cheapness, simplicity, or thorough waterproofing power. 1. *For Woollen Cloth.*—Burnt alum and sugar of lead, of each 4 oz. to be dissolved in two gallons of rain water for 24 hours, and kept stirred occasionally. Then drain it off once or twice till clear; put the cloth in and let it soak 48 hours. Then take it out and wash the cloth in repeated changes of fresh water, till the water it is washed in becomes quite clear, and free from alum. Do not during the process squeeze or forcibly rinse the cloth. When the alum is thoroughly washed out, then hang it up to dry, but not before a fire, or in the hot sun. This receipt was invented in Paris, and is very valuable, as the colour and appearance of the cloth remain unaltered. I have a cloak thus prepared which I have frequently put across a chair, and poured water in a small pool on part of it, and allowed it to remain for 24 and 36 hours without a drop or even damp passing through, and yet no one on examining the cloth could detect any difference in it from common blue cloth. The wool seems to absorb and chemically combine with the solution. The latter part of the process, viz., thoroughly washing the cloth in clear cold water till all remains of alum not absorbed is dissolved away is a very essential part of the process. I always failed till I learnt this, but if my receipt is followed accurately it will be found very simple and easy. 2. *Boots and Shoes.*—To waterproof leather, take of linseed oil 16 oz., mutton suet 8 oz., white beeswax 6 oz., resin 4 oz., and melt them together over a slow fire. Rub the boots well with this ointment, also rub it carefully into the soles and seams, and put them out of doors in the hot sun. In a cold climate this must be done before a fire, and the heat must be sufficient to keep the ointment soft, so that it may soak through the leather, and appear on the inside. This is readily done in India in about three hours, by exposing the boots to the sun and applying fresh ointment as it soaks in. The commonest leather treated in this way becomes waterproof, and very durable. I have boots thus prepared, of which the upper leather appears never likely to wear out, though I have worn them for a long time in constant walking. I also, as an additional protection to the sole from wearing and wet, soak them in one part of resin dissolved in eight parts of turpentine. This makes the soles, if it be repeated once or twice, as hard and durable as stone. The application ought to be renewed after walking in the boots for three weeks or a month, and well soaked in, but this resin and turpentine must not be put on the upper leathers, or they become too hard to be comfortable. This resin and turpentine will make the seams, called the welt, where the sole is sewn to the upper leather, quite waterproof, even in badly sewn native shoes. The ointment soaked into the upper leather makes it soft and pleasant to wear. The leather never cracks, and appears to me to last a very long time. This once done, never requires renewal; the leather is saturated and continues so. It may be thought that any grease, and that many proportions of resin, oil, &c., will do as well, but it is not so. I have tried, I believe, almost every receipt ever published, by the infallible tests of taking pieces of common native leather, soaking them in the preparations from different receipts, and then putting a pool of water over them over a tumbler, and trying how long the water remained on the surface without running through and damping the under surface of the leather. Fat and oil thus tried let the water through the leather in half an hour, and I find all the receipts thus tested inferior to the above, and No. 3, which I will give below. Both these are perfectly watertight, and will hold water for 24 hours, and probably much longer, for that was my limit of trial. I obtained No. 2 from a Canadian traveller, who tells me the settlers use it there, and that it keeps out even snow. There is one disadvantage in applying the above receipt to shoes, that they will not polish when blacked for some 14 days after they have been thus treated. After this time, if worn constantly they will gradually take the blacking. A strict adjutant might object to dull boots on parade, and officers especially dislike their own boots to be so. The following receipt is free from this objection, and boots saturated with it will, if dried for two days in the sun, take a more brilliant polish than before. No. 3.—Drying oil, two pints, india-rubber 1 oz. Cut the india-rubber into small shreds, and dissolve it by boiling the oil on a moderate fire, then strain after all is dissolved. The drying oil can be obtained from any house painter, as it is the basis of their paints, or it may be made at home very easily thus :— Pure linseed oil - - 1 pint. Litharge - - - 1½ oz. Boil for three hours, stirring it well, then take it off the fire and put it aside to settle for 2 days, pouring off the clear oil for use. All the materials for the above three receipts can be obtained in the native bazaars very cheaply, and the quantity required to soak the leather and cloth is not much. No. 3 is even more waterproof than No. 2, and will render, for I have tried it, even a piece of white kid glove water-tight, and it makes the leather take a better polish than without it. No. 3 is also an excellent waterproof for cotton cloth and common fine calico, such as is used for shirts. In the rains when it is hot and cloth clothing oppressive, the soldier might be provided with waterproof calico blouse leggings and cap cover, which with waterproof boots would render him impervious to rain. This calico clothing will roll up into a bundle half the size of a knapsack, which the soldier can carry with him and put on over his other clothing when exposed to rain. No. 3 dyes the cloth a red brown colour, and looks well. Calico steeped in it dries in the Indian sun in 12 hours, and the calico remains flexible, as before, without stickiness, and is very waterproof. The soldier's bedding is at present entirely unprotected from rain when on a march or moving even to their guards. They ought all to have a calico cloth to wrap it in, waterproofed by No. 3. I always use myself on a march a common sheet dipped in No. 3 to tie up my bedding in. It has often struck me as wonderful, that in these days of chemistry and improvement nothing has yet been done to protect the soldiers from wet, and that they are still sent on service in shoes, which do not resist wet much better than brown paper, and with their clothes and bedding liable to be soaked by every passing shower. Even on a common relief march I have often seen the unfortunate soldier, if it rains for a few days, with wet clothes and wet bedding, which he is unable to change until the sun again shines. In London we provide waterproof covering for our hack horses, and yet in India our soldiers are entirely unprotected. The woollen cloth would be better waterproofed in Calcutta before it is made up, and hung up in open sheds in the shade to dry. After steeping, the cloth might be conveniently washed in the running water of the river, and hung upon the sheds, without

References to Subjects and Queries.	Replies.
	squeezing or forcible wringing, to dry. The expense of drying is less in Calcutta than in England. Cloth thus waterproofed is not in any way altered in appearance, durability, or colour. I have a cloak thus prepared, and which, as I have before stated, resisted the action of water for from 24 to 36 hours. For boots and shoes and calico clothing the waterproofing material ought to be supplied by Government to quartermasters, and the men taught to apply it themselves. I trust that the Commission will not think that I have given too much space to these details, as I may call them, of domestic economy in a regiment. Any statistics I could give for the few months (seven) we have been in Roorkee could be of little value, and the barracks, hospital, and other buildings are little better than sheds, which were run up by order of Lord Clyde during the mutiny, for the temporary shelter of the regiment forming part of his Oude army. Their measure therefore can be of no value as a model for other places, for out of Roorkee, with its mild climate, they would not be habitable. But I have been many years in charge of European regiments in many a battle, and many unhealthy climates from Cabool to Burmah, and have seen more service with them than perhaps any other medical officer in India, and I am convinced that should I be so fortunate as to attract by these remarks the attention of the Commission to these important points, the benefit resulting to the soldier will be very great, far more indeed than any one can even imagine who has not lived so long with them as I have done.
VIII. Instruction and Recreation. IX. Military Prisons. X. Field Service. XI. Statistics of Sickness and Mortality.	No information under these heads.
XII. Hospitals.	1 to 5. The hospital is one of the 21 barracks, and exactly the same in dimensions, &c. 6. The ventilation is effected by holes in the roof thatched over; and these means are sufficient. There are no jalousies or jhilmils. 7, 8. There are no means of cooling or warming the wards artificially. The walls and ceilings are whitewashed yearly. 9. The privy is a shed outside the building, where the men also make water. Those who cannot walk can use copper pans, which are provided for the purpose. Both these and the privy are cleaned by sweepers with lime and charcoal, and they are not offensive, though not supplied with water. 10, 11. A small shed is used as a washhouse for the sick, which is sufficient. A bathing tub and foot bath are also provided, which are also sufficient. 12. The washermen carry the hospital linen to a distance, where it is washed and dried. 13. The storage is sufficient and dry. 14. The cots in the hospital are wooden with white tape wove for the centre. They would be better made of iron, as the wooden ones harbour bugs in the joints. 15. The kitchen is simply a hut, and the cooks prepare the food on the ground. This arrangement is not good; but we are accustomed to it in India. The hospital diet is, I think, sufficient. 16. No reply to this query. 17. The attendance on the sick is not sufficient. Healthy men are detached for this duty from the barracks; but they dislike it, and often neglect their patients. 18. In Roorkee the sanitary condition of the hospital is good. The doors are kept open day and night, and no epidemic has occurred. 19. The attendance on the sick ought to be improved, as it is now very deficient. 20. Convalescents take a walk morning and evening, and a few ride on two elephants, which are sent daily for their use by the commissariat. A few extra doolies would be a great benefit for those who are not able to walk or ride on the elephants. 21. A hospital is provided for the sick wives and children of the soldiers, with two native female attendants. The present arrangements are sufficient. The women nurse each other, and they are better off in this respect than the men. 22. There are no special hospital regulations not included in the general presidency medical regulations. 23. The medical officer has no power in matters appertaining to the sanitary state of the hospital, &c., and his advice is seldom attended to, except he be the personal friend of the commanding officer. 24. No convalescent wards or hospitals exist, and I do not think they would be advantageous. A patient when well enough returns to his company, and is there under the usual discipline, is inspected daily by the surgeon, and when recovered returns to duty. It would be very difficult to keep up discipline in a separate convalescent barrack, as the men would get liquor and wander out of bounds.
XIII. Burial of the Dead.	1, 2. The British burial-ground is a mile distant from the station, to the south-west, and the prevailing wind does not blow over it. The soil consists of dry sand, and the ground is carefully kept. 3. There are no regulations as to grave space; but the graves are generally 10 feet deep, and are never re-opened. Interment takes place at ordinary times, and during epidemics within a few hours, rarely more than 12, after death. 4. The graveyard is never offensive. The regulations as to the burial of British troops are the same as in England. 5, 6, 7. Camp followers and bazaar people burn or bury their dead according to caste. No injury accrues to public health from the present practice, nor are any improvements in the disposal of the dead to be suggested.

18th November 1860.

I. Topography.	1. The country surrounding the station is richly cultivated, flat, dry, and in parts sandy, with no wood, jungle, or water in the vicinity. 2. The station is elevated, is between 800 and 900 feet above the sea, but it is on a level with the adjacent country. There is no higher or healthier ground in the vicinity of the station. 3. The low range of hills beyond Pathan Kôte, in the neighbourhood of Noorpore, is about 62 miles distant from the station, and is about 1,200 feet above its level. 4. The branches of the Huslee Canal skirt the cantonments, and one branch leads directly into the gardens and grounds belonging to Rajah Tej-Sing, which are situated within the cantonment pillars, or rather ought to have been within cantonment limits. At times the cantonment is partially inundated during the rainy months, namely, July and August, but the inundation seldom lasts beyond 48 hours, and at all other seasons the drainage carries off the rain-fall very readily. I have only seen the cantonment under water once during a residence of upwards of three years, and then the rain was very heavy, and continued with scarcely any intermission for seven days. There are no ravines, water-pits, or broken ground near the station. 5. The station is open, and freely exposed to the prevailing winds. The walls and hedges of cantonments, by a recent order of the late C. C. General Anson, are never permitted to exceed four feet. The houses and bungalows have been built with considerable intervals between, a compound being attached to each. The barracks are also well situated, so as to leave free space for external ventilation. The internal ventilation is also good, as, in addition to a free circulation of air below, a range of upper windows on both sides is provided. The temperature of the station is not raised by exposure to reflected sun heat. The prevailing winds blow about north-west and south-east; those from the north and west are commonly designated the hot winds during the months of April, May, and June, and prevail generally, with occasional intervals, the whole year. The south-east winds prevail in the rainy months, namely, July, August, September, and part of October. The north-west winds are healthy, even when the heat is excessive, and this can be easily accounted for by the air being so dry and free from moisture. The south-east winds are loaded with moisture, and when they begin to blow, towards the end of June, are indications of the rainy season, and certainly act, from this cause alone, on the general health, as well as being the medium through which malaria is conveyed into the lines, intermittent fevers making their appearance shortly after the setting in of these winds. 6. The surrounding country is in a high state of cultivation, but there are no works of irrigation near the station. Rice is not grown within a distance of 50 or 60 miles of cantonment limits, neither is indigo cultivated near the station. There are a few fields of flax, however, within three-quarters of a mile of cantonments, but so very small that no injury or nuisance can result from its cultivation. 7. About a mile and a half from cantonments, and in a direct line with them, is the largest city in the Punjab, containing a population of 120,000 souls. 8. The surface soil is composed principally of clay, mixed with a small proportion of sand, which hardens and splits, leaving small fissures in every direction, except when the ground is prepared for cultivation. The subsoil is composed of clay to a depth of four or five feet, terminating upon kunkur beds. The station occupies new ground. 9. Water is usually found during the dry season at a depth of 36 feet, and there is a difference, I believe, of four feet during the rains. 10. The rain-fall and water from surface springs flow readily away, except during unusually heavy rains. The water generally drains off without sinking through a pervious subsoil, that which is left being carried off rapidly by evaporation. No drainage from higher ground passes into the subsoil of the station. 11. The water supplying the station is derived from wells; there are no tanks. The wells are kept remarkably clear from matter falling into them, no foul drainage or impurities being allowed to pass into them. 12. I am unable to state the amount of water supply further than this,—that each compound is provided with an excellent well, and the barracks and hospital each with a large well. The water is colourless, and without taste or smell; but I am unable to state its chemical composition, though there may be a small trace of nitrate of potash, as some of the wells in the neighbourhood are impregnated with this substance. I look upon the water as holding an intermediate character between hardness and softness, being well adapted for all purposes. The water is very good, and the supply is ample; it is drawn by means of large leathern bags, and no better supply could be obtained. 13. I consider the two gardens belonging to Rajah Tej-Sing as very objectionable. One is situated close to the officers' quarters, surrounded by a high wall, thickly studded with trees, and is frequently submerged by the water of the Huslee Canal; it is, or rather ought to be, within the cantonment pillars. The other garden is situated on the right flank of the station, is thickly studded with orange trees, also surrounded by a high wall, and the surface of the soil is constantly submerged by the water of the canal. I consider them both nest-beds of fever during the rainy season. 14. Sites of stations, both on the hills and plains, are selected, I believe, rather on political and strategical grounds than with reference to their topography, climate, diseases, or sanitary conditions, troops being generally cantoned in the neighbourhood of large cities. When a

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	committee does select a site, two medical officers are generally members. Before permanently selecting a station for troops, either on the hills or plains, I would suggest that two experienced officers—one a military engineer and the other a medical officer—should occupy the ground, whenever practicable, for a period of 12 months, in order to draw up an elaborate report upon everything connected with the site; that they should be provided with instruments necessary for the investigations; and that the medical officer should send in to Government at the same time a report of the various diseases incidental to the region, their frequency or non-frequency amongst the natives, their likelihood or not to attack the European soldiery, means of prevention, &c., as well as everything that will bear directly or indirectly on the well-being of the European soldier.
II. Climate.	1. The only instruments at this station for conducting meteorological observations are a thermometer and a rain gauge. 2. Table of meteorological observations.

Three Years of Observation, from 1st January 1857 to 31st December 1859.

Months.	Barometer mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temp.	Rain. Inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks as to Cloud, Dew, Wind, Storms, &c.

November -		61	—	72	51			90	—	Do.	Moderate.		Bracing weather; cloudy.
December -		55	—	65	44			77	0 0·60	Do.	Do.		Very cold uncertain weather.

3. The climate of this station, comparatively speaking, is very healthy. The dryness is remarkable for many months in the year, but heavy falls of rain occur during July, August, or September, constituting what is technically called the rains. During the cold season, about the end of December or beginning of January, some heavy showers of rain generally occur, but cannot always be reckoned on. The heat during the hot months, from about the 15th of April to the beginning of October, is intense. During the cold months there is considerable variability of temperature, especially after a shower of rain, when the thermometer sometimes falls to the freezing point, after having stood steadily at 15° and 18° above it previous to the rain. The cold is severe in the winter months, ice forming readily at night in December, January, and the early part of February, a sufficient quantity being obtainable then, as a general rule, to supply the residents and hospitals during the six hot months of the year. Fogs are very rare, and the damp never appreciable except after heavy rain; when they do occur, it is generally at the end of the hot and cold seasons. When the hot winds blow, the air is loaded with fine particles of dust, and during the dust-storms, which prevail from time to time in April, May, and June, the air becomes densely loaded, and at mid-day, during a dust-storm, a candle is often necessary in order to enable one to carry on his ordinary avocation. The air is not loaded with any other admixture or impurities; no irrigation or tree planting influencing the climate generally. The cold season, after it fairly sets in, and the hot winds are not unhealthy, provided that in the hot winds the men are not exposed, but kept under shelter. The hospitals begin to fill after the first fall of rain, and the season goes on increasing in unhealthiness until the cold weather begins to brace up the men. The diet should be light and nourishing during the hot months; animal food admissible but once a day; all alcoholic drinks should be avoided, and no malt liquor served out in the heat of the day; the clothing as light as possible, each man being obliged, however, to wear a thin flannel jacket next his skin, which ought to descend low enough to protect his abdominal viscera. All men who have suffered from dysentery or hepatic affections ought to wear flannel binders, and this, I think, should be compulsory, as it is undoubtedly one of the greatest safeguards against either of these affections. Collars should be worn low and loose in summer and winter, but stocks never; and everything tending to interfere with the free circulation of the vessels about the neck should be removed. I would recommend the wearing of light wicker helmets, both in summer and winter, as the sun is at all times powerful. Drills and exercises of every kind ought to be reduced to a minimum in the hot months, especially in June, and should cease almost immediately after sunrise, with only a roll-call in the evening. In the cold months the men should have warm clothing, good nourishing diet, meat twice a day, and drills and exercises at the discertion of the come manding officer. Dram drinking I condemn at all seasons. The barracks ought to be lofty, well ventilated, and each man ought to have at least 1,800 cubic feet of space. In th- hot winds tatties should be used. December and January are the two healthiest months

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	in the year; next after them February, March, and November; then April, May, and June; more unhealthy still, July and August; and the two most unhealthy September and October. During the unhealthy months, continued and intermittent fevers, diarrhœa, dysentery (acute and chronic), hepatic affections, and occasionally epidemic Asiatic cholera, prevail. In June and July, solar apoplexy is most apt to occur. 4. There is no district near the cantonment with a climate more conducive to health than that of this station. 5. I have visited the hill stations of Landour, Mussoorie, and Dhurmsala, but have only served at Calcutta, Meerut, and Umritsir and Govindghur. Of Calcutta I am unable to speak, having remained there but some 14 days. Meerut is a very favourite station, but not so healthy as the Punjab. In 1854 the artillery recruits suffered severely from "*coup de soleil*," the 81st Queen's still more. Dysentery and hepatic affections prevail with much greater intensity there than here; the fevers are developed in the rains with greater intensity, being frequently accompanied by violent purging and incessant vomiting. The falls of rain are much heavier, the cantonment not so well drained, and the water lies for days between the barracks and on the parade ground. Govindghur is the large fortress situated about one mile from the cantonment, and erected by the Sikh powers to overawe the city. It is tolerably healthy, although the ventilation is imperfect within the walls, and, I think, will bear comparison with most stations. Amritsar was not occupied by European troops before 1857. The official year, which has just closed, shows the mortality in the artillery division (composed of two European companies) under one per cent., which, I think, will bear comparison with any station in the presidency.
III. Sanitary Condition of Station.	1, 2, 3. Plans of the station, surrounding country, and barracks are transmitted. 4. Date of construction of barracks, 1st April 1859. Total number of rooms in each, 15. Total regulation number of non-commissioned officers and men, 110 for each barrack. [No table of accommodation has been filled up.] 5. The windows of the barracks are on opposite sides, and open by means of a rope and pulley. There are verandahs all round the building, generally about 10 feet wide and 12 feet high. These are sometimes occupied as sleeping quarters by native servants, but very seldom by soldiers. Chicks and purdahs are employed instead of jalousies and jhilmils. 6. Bedsteads of dyar, and broad tapes stretched across for sacking, are generally in use in the barracks; but I would suggest iron bedsteads, with thin iron laid across in strips, fitting into studs, as far the best. 7. The tent in use in cantonments, is that called European Private N.P. It is a double pole tent, with a double fly, single walls, 6 feet high, 22 feet by 14 feet, and constructed to accommodate 16 men each. Several methods of ventilation exist in the barracks, tents, &c. An open ventilator along the ridge of roof is common, as also skylights fitted with windows to open and shut; but I think this latter arrangement insufficient for the purpose. The air of barrack rooms is cooled,—1st. By means of punkahs, that exert a refreshing influence, but do not lower the height of the thermometer. They cost about 8 annas (one shilling sterling) per superficial foot; 2nd. By means of tatties and thermantidotes, which really lower the temperature. The latter apparatus costs about 50 or 60 rupees, and about five are required for each barrack. 9. Some of the permanent barracks are constructed of bricks and mortar, some of brick and mud, while the temporary are of unburnt bricks and mud. 10. The floors are composed of brick and mortar, fine masonry, and are raised about two feet from the ground. Ventilation under the floors exists only in two-story barracks, of which there are none at this station. 11. The materials of which the barracks, tents, &c. are constructed are the best that I could suggest; but I would point out that if hollow bricks were employed the barracks would not retain the heat so long after sunset; at present the walls are very hot six or seven hours after the sun has gone down. The barracks and cantonments are kept in repair by the executive engineer of the station, and the officer of the quartermaster-general's department is responsible for their general sanitary state. The walls and ceilings of the barracks are cleansed and lime-washed once a year, or oftener if required. 12. The men's lavatory consists of an oblong building, with a masonry stand in its centre, upon which are placed earthen jars and basins of water. 13. The cookhouses are square rooms with native chulahs or fireplaces, and are of no particular design, beyond four walls and a roof. Dhobies, or native washermen, wash and dry the linen in their own way. 14. No reply. 15. Privies, cookhouses, and lavatory are lighted and ventilated by openings at the top of the walls, and the barracks are lighted at night by oil-lamps. 16. No drainage is required for barracks, as all filth is removed by conservancy carts, and the natural drainage is sufficient to carry away all surface water. I believe no dampness exists in the buildings at this station. The fluid refuse of the barracks, if not removed by conservancy carts, evaporates. There are no cesspits of any consequence that I am aware of, and the distance of those which do exist, from the nearest men's quarters, and from the hospital, varies from 30 to 50 yards. The Umritsir city ditch is about 1½ miles from the station, and to leeward of it. 17. All filth is daily removed, or ought to be, from the surface of the cantonment, and its vicinity. 18. The surface of the cantonment is kept as free as is necessary from vegetation, and no complaints have been made on this head. I am not aware that any old walls, thick hedges, &c., exist to interfere with the free ventilation of the station or bazaar, &c. 19. The bazaar is in the charge of the station staff officer, and, I believe, is tolerably clean for a native bazaar. The quartermasters of regiments superintend the bazaars, and sweepers and water carriers are employed to keep them clean. I cannot suggest any improvement. The condition of the native houses near the station is good. They are small, and suitable to the natives, and no dunghills or cesspits are allowed within them. The barracks being situated to windward of all native dwellings, no nuisance is experienced from wind blowing over the latter.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	20. Animals for the use of the soldiers are slaughtered about one mile from the barracks. 21. There are no bazaar horses. 22. Cavalry horses are kept in open stables, not in a building at all. The litter is removed daily, either for fuel, or for spreading in the riding school. The stables do not appear to act injuriously on the men, nor are they offensive in the barracks. The picketing grounds are arranged in rows, generally by troops in cavalry, and divisions in artillery. The distance of these grounds from the men's accommodation and the hospital is variable. 23. There are no barracks at present for married non-commissioned officers or men, the married men of the 2nd company, 1st battalion, Bengal artillery being in the same barrack with the unmarried men of the company, as well as some men of the 51st Queen's, a purdah, or cloth, being the only separation between them.
Officers' Quarters.	1. The officers occupy detached bungalows, which are their private property. The sanitary condition of these quarters is good, as are also their drainage and ventilation. I would suggest the purchase of bungalows by Government. No officer on leaving a station likes to leave his house unsold, and very often will not rent it to the officers of the relieving corps, and the consequence is great inconvenience, as many officers have not the means of purchasing; this is the case here with the 51st Queen's. The officers are crowded together because they decline purchasing, and the owners belonging to a corps which has left the station having been obliged to purchase, decline renting. Many of the houses here are, therefore, unoccupied and empty.
IV. Health of the Troops.	1. The station, surrounding district, and adjoining native population are generally healthy. 2. Small-pox, chicken-pox, measles, cholera, and intermittent fevers are the diseases most prevalent amongst the natives. Spleen diseases rare. 3. I attribute the prevalence of the above diseases to the utter ignoring of all sanitary arrangements in the city, and, in the country, to the dirty habits of the population, the close, overcrowded, ill-ventilated buildings in which they live, and, in the rainy season, to sleeping outside exposed to the night air loaded with moisture and malaria. 4. The 2nd company, 1st battalion, Bengal artillery were in Jullundur from 2nd November 1851 to 15th October 1853, when they left for this station, where they arrived on the 19th October 1853. The state of their health at Jullundur was good, the diseases from which they suffered being principally dysenteries and fevers. They were in good health on arrival here, and have since suffered from continued and intermittent fevers, dysenteric and hepatic affections. The 2nd company, 2nd battalion, Bengal artillery were at Phillour from 5th July 1857 to 8th April 1859, when they left that station for this, and arrived here on the 17th April 1859, in good health. The diseases from which they suffered were dysenteric and hepatic complaints and fevers, but on the whole the state of their health was good. They have suffered since arriving here from hepatitis, dysentery, and fevers. The left wing of H.M. 51st Light Infantry were at Mean-Meer from 6th December 1858 to 5th January 1859; they left on the 6th January 1859, and arrived here on the 8th of the same month. The state of health of the men at Mean-Meer was good, the principal diseases being continued and intermittent fevers. They were in good health on their arrival here on the 8th, and have since suffered from fevers, bowel complaints, and "coup de soleil." The left wing of the extra Goorkha regiment were at Philebut from September 1859 to 26th January 1860, when they left for this station, and arrived here 17th March 1860. They were in good health at Philebut, where the principal diseases were fevers and dysenteries. They were in indifferent health on arriving at this station, and have since suffered severely from continued and intermittent fevers, with a few isolated cases of dysentery and small-pox. The gun lascars of the two companies of artillery have been remarkably healthy, both at their former stations and here, and the same may be said of the Ordnance drivers of No. 16 Light Field Battery, to which the 2nd company, 1st battalion, is attached. The principal diseases at both stations have been diarrhœa and intermittent fevers. The gun lascars always move with their respective companies. The old hospital of 43rd Native Light Infantry is now used as a barrack for European troops. I attribute the greater unhealthiness of this building to its narrowness, want of ventilation, no outer verandah, and increased heat from the roof being covered in with tiles. 5. The troops at this station have never been camped out, with the exception of the 2nd company, 1st battalion, Bengal artillery, during the epidemic cholera in 1856, for a few weeks, and then they derived little or no benefit from the change. 6. I have never been in charge of troops at hill stations. 7. I have observed that the convalescents on rejoining from hill stations are less liable to febrile diseases on returning to the plains. The change from a relaxing to a bracing climate, and the complete absence of malaria in the hills, enables the constitution to recover itself before being again exposed to its influence. From other diseases little or no benefit is derived by a residence in the hills. 8. I approve of hill stations for troops. 9. Chest affections, diarrhœa, and dysentery are the diseases peculiar to hill stations, and by which troops are liable to be attacked on going to them. 10. At hill stations, during the rains, I would suggest greater precautions with reference to dry warm clothing, especially guarding against the men being allowed to remain in the barracks with their feet wet after duty; any men liable to or suffering from hepatic and dysenteric affections to wear flannel binders. The diet, shelter, duties, and exercises, as far as I am able to judge, are good at hill stations. 11. From the beginning of April to the middle of November is the period best adapted for a residence in the hills, and in order to confer benefit on the troops, such residence should last at least one year. 12. There is no period of residence in the hills beyond which injury is likely to be inflicted on the health of the troops on their return to service in the plains. 13. No special precautions are necessary for protecting the health of troops on leaving the hill stations for the plains. 14. I consider it to be conducive to the health of troops to locate them on the hills with short periods of service on the plains. Frequent change of station in the plains is, I think, objectionable both to troops and convalescents.

	IV. Health of the Troops—*cont.*	15. Both the barrack and hospital accommodation at hill stations are tolerably good, and I am not acquainted with any deficiencies in the accommodation of the hill stations which I have visited. 16. I would recommend no hill station under 6,000 or above 8,000 feet above the level of the sea. 17. There is no higher ground near the station which could be advantageously occupied as a hill station. 18. I cannot say what particular classes of surface and subsoils are more healthy or unhealthy for stations than others. 19. Soldiers should not be sent to India under 19 or 20 years of age, nor above 30, and they should land in this country at the commencement of the cold season. For preserving the health of troops on first landing in India, I recommend the duty to be as light as possible, clothing light, and easy, guarding against exposure, total abstinence from spirits, and a reduced allowance of malt liquor, with tea, coffee, or cocoa as a substitute. The head to be well protected from the sun by a light wicker helmet, and every man to wear flannel, sufficient to protect his chest and abdomen. 20. I think it would be better always to send the men to an intermediate station for a certain time before despatching them to India. If they have served at such intermediate station, I should consider them fit for duty on the plains on landing, but if not a short sojourn on the hills would be preferable before encountering an Indian climate. 21. Troops are transported from the port to the interior in country boats or river steamers, when water carriage is available; when proceeding by land, marches from 10 to 14 miles per day, with occasional halts, is the mode adopted. I do not consider any additional precautions necessary on the line of route. 22. I consider that a British soldier should serve in India not more than 17 years. 23. A conflict of opinion does, I believe, sometimes on medical boards occur as regards invaliding, as the invaliding committees at the presidency have the power of reversing the opinions of the standing medical committees. I would suggest that the opinion of the station invaliding committee be final (as it is composed always of five experienced medical officers), and would lessen the duties of the medical officers at the presidency, who have almost always more work on their hands than they can possibly get through, and who would, I am sure, consider it a great boon to be relieved of these duties. 24. Invalids should leave India for home during the months of January and February.
	Diseases.	1. In the Bengal artillery regular inspection parades every Monday morning at sunrise are only ordered when men suffering from venereal diseases neglect reporting themselves at hospitals immediately after being affected. There is an inspection parade of H.M.'s 51st regiment every Monday morning at 10 a.m.; such parades are never ordered for native troops. 2. No case of scorbutus has occurred among the troops of Her Majesty's Indian forces at this station. 3. The proportion of cases of hepatitis to all other diseases is 4·66 yearly, and this is to be attributed to intemperance and dysentery. It is not generally the consequence of other diseases, but when complicated with dysentery, hepatic disease is, as a general rule, secondary. The complete withdrawal from canteens of the spirit ration would, in my opinion, be the best prophylactic measure against this disease. 4. No case of dracunculus has occurred here, either in my European or the native hospitals. 5. The proportion which the constantly sick from venereal diseases bear to the total sick in hospital from all other diseases is 0·07 to 1. I would suggest that a larger proportion of non-commissioned officers and men be permitted to marry. I do not think that the establishment of lock hospitals would be advantageous to the health of the army. 6. The following are the diseases from which the troops at this station suffer, viz.:— *Fevers.*—Continued fevers in April and May, but not usual. Quotidian intermittent fever is very common at all seasons, but tertian intermittent is seen only from time to time; quartan very uncommon. *Dysentery.*—Acute, sub-acute, and chronic. *Cholera.*—The men suffered slightly from this disease in the epidemic of 1856, and more severely in 1857, but there has been no case since. *Small-pox.*—The modified, distinct, coherent, and confluent, in fact every form of this disease. *Rheumatism.*—Rarely idiopathic, generally complicated with syphilis and gonorrhœa. The proportion which admissions from the above diseases bear to the total admissions is 0·40 to 1; that of deaths to total deaths, 0·44 to 1. 7. The nosological character of the diseases is sharp, clear, and well defined. These diseases are most prevalent in the winter, spring, and summer, increasing in virulence during the hot winds, but the number of cases decreasing; generally disappearing after the first heavy fall of rain at the end of June or beginning of July; unusual dryness of the atmosphere generally precedes or accompanies their appearance. There are only a few isolated cases among the European soldiery at this station, and these almost always arise from the men entering the city without leave, and coming in contact with those who have suffered and are suffering from these diseases. I mention this because the sanitary condition of the barracks is good. The bazaar is carefully looked after, but the native dwellings in it are very defective as regards cleanliness and ventilation, and are overcrowded. The drainage and water supply are good. The personal habits of the European troops do not predispose them to these diseases, and the native troops are cleanly in their habits, but from living in close, over-crowded, and ill-ventilated dwellings, are certainly more predisposed to these diseases than they otherwise would be. 8. I consider that the soldiers' occupations and duties in barracks exert a direct influence on the prevalence of epidemic disease, by checking its advance and lowering its intensity; his habits on the march and in the field render him more liable to the prevalence of epidemic disease. 9. Small doses of quinine have not been tried at this station as a prophylactic against malarial disease. 10. For the prevention or mitigation of epidemic disease I would recommend the never overcrowding of men, avoiding long tedious parades in the rainy season (at which period epidemic cholera almost always makes it appearance), giving the men as much liberty as possible, and providing them with rational amusement and recreation, in which, I think, the officers ought to join, in as far as the discipline admits of.

References to Subjects and Queries.	Replies.
V. Intemperance.	1. The soldiers at this station are rather intemperate, but there are no confirmed drunkards amongst them. 2. The proportions which admissions into hospitals from diseases caused directly by intemperance bear to the total admissions is perhaps one-sixth, and indirectly from this cause, half. There is no statistical table kept to show the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at this station. Drunkenness is always punished as an offence. 3. Distilled spirits are sold in the canteen, but are not allowed in the bazaar. Quality is good, and the average quantity consumed by each man per diem may be two drams. Spirit does not form part of the soldier's ration at the station, on march, or in the field. I consider its effect on health injurious to the last degree, as nothing tends to inculcate drunkenness more than the morning spirit ration. Spirit is never given as a ration to convalescents. No other drinks injurious to health are sold at the canteen or bazaar. 4. The consumption of spirits by troops and convalescents is injurious to health, and not conducive to the efficiency and internal discipline of the corps. 5. It would be most beneficial to the health of troops to restrict or abolish the use of spirituous liquors. 6. I consider the influence of malt liquors and wines as conducive to health, but the use of spirituous liquors as most detrimental. 7. Coffee, tea, lemonade, soda-water, and similar drinks are not used at this station. Their influence on health, discipline, &c., is far superior as compared with spirits, and they exert an equally beneficial influence when compared with malt liquor. 8, 9. It would be beneficial to suppress altogether the spirit ration, and to prohibit the sale of spirituous liquors in the canteens, and to permit only beer, coffee, tea, lemonade, &c., to be sold to the troops; but it might be injudicious, as the men who wanted spirits would get the country liquor, which is very deleterious, if they could not get the other. 10. I have no other recommendations to make on these points. 11. No reply to this query.
VI. Diet.	1. The daily ration for British troops consists of bread, 1 lb.; meat, 1 lb.; rice, 4 oz.; sugar, $2\frac{1}{2}$ oz.; tea, $\frac{5}{7}$ oz., or $1\frac{3}{7}$ oz. of coffee; salt, 1 oz.; vegetables, 1 lb.; and firewood, 3 lbs. Beef should be issued five times, and mutton twice a week, and the bread should be equal in quality to that used at the officers' mess; the rice and salt should be equal to a fixed muster, approved of by the commissariat department in communication with the regimental authorities. When tea, which is $\frac{2}{3}$ black, $\frac{1}{3}$ green, is not procurable, or coffee preferred to it, the latter is supplied. The firewood is dry, split, and ready cut for immediate use. There is an inspection of the ration by the quartermaster and quartermaster-serjeant every morning at sunrise; when there is no quartermaster, by the commanding officer or subaltern on duty. 2. Such vegetables as are in season are issued to the troops, and no pecuniary compensation is allowed in lieu, as they form part of the ration. Fruit is not supplied to the troops. Soldiers at this station have three meals a day, namely, breakfast at 8 a.m., dinner at 1.30, and tea at 6 p.m. At the two first the men eat meat, at the third, tea, bread, onions, radishes, or anything they like or can get. The stoppage is 5*d.* per day, or Rs. 6. 5. 4. per month, that is to say, this is the allowance each man gets when not supplied with rations. 3. The ration can hardly be improved, and no arrangements are necessary for preventing the disposal of any part of it, as the men consume it all. 4. Government supplies the cooking utensils available at this station. There are four messes in a company, and each mess is supplied with:— 1 Copper boiler of 8 gallons, with cover, weighing $21\frac{1}{2}$ lbs. 1 „ „ 7 „ „ „ $20\frac{1}{2}$ lbs. 1 „ „ 2 „ „ „ 9 lbs. 1 Copper frying-pan 12 in. × 10 in. × 2 in., with iron handle, 10 in. long. 1 „ ladle, diameter of bowl, 5 in., „ „ 18 in. „ 1 „ „ „ „ 3 in., „ „ 13 in. „ 1 Gridiron of same dimensions as frying-pan. 1 Chopper, blade 11 in. × 4 in.; handle, 6 in. 3 Baskets, each 30 in. diameter, and 9 in. deep. The copper boilers should fit into one another so as to form a compact nest. Carriage is allowed for the cooking utensils on a march, and the commissariat department renews or repairs them when necessary. They should be tinned twice a month, and should be marked before issue with the regimental and company mark of the regiment and company to which they are issued. The kitchens are tolerably clean, and sufficiently supplied with water, but are badly lighted and ill ventilated. The cooking is properly done and sufficiently varied, and tea and coffee are also properly prepared for the men. The troops do not have any refreshment before a march, but generally make arrangements for having tea or coffee half-way. 5. Gardens for the cultivation of vegetables by soldiers could be advantageously established near the station, under the regulations lately laid down by H.E. the Commander-in-Chief.
VII. Dress, Accoutrements, and Duties.	1. The dress of the soldier at this station is the same as at other stations, being the regulation dress of the various services, and is suitable to the climate, and for the soldier's duties by day and night. I consider that the light wicker helmet ought to be worn at all seasons, whether on the hills or plains, flannel under-clothing summer and winter, collars low, free and easy about the neck, and on the hills worsted socks the whole year.
Duties.	1. I consider it would be advisable, as regards the health of the men, that they should be thoroughly drilled at home, or at some intermediate station, before being sent to India. 2. In the very hot weather the men certainly suffer from drill, and the medical officers of the artillery, as well as the commanding officers, have seen repeatedly so much benefit arise from discontinuing drill, that all duty in this corps is reduced to a minimum. There are no drills, only a roll-call every morning and evening, and the men are kept in barracks from seven in the morning till half an hour or an hour before sunset. The best time for drills and parades, in the hot season is from half an hour before sunrise to half an hour after the sun is visible, and in the cold season from sunrise till 9 a.m. For marches, from 1 a.m. to 5 a.m.

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*Duties—cont.*	or from sunset to midnight, during the hot months, and in the cold weather from sunrise till 9 or 10 a.m., are the best times. The average number of nights the men at this station have in bed is about five. 3. Guards are mounted at a distance of less than 50 yards from the barracks; they are relieved daily. The native guard in the fort, and the civil court guard are relieved once a week. At times, after heavy falls of rain, in the hot and cold seasons, I have seen the men on guards suffer from rheumatism and intermittent fevers; I should recommend the guards to be relieved as frequently as possible.
VIII. INSTRUCTION AND RECREATION.	1. There are very few means of instruction or recreation at the station, there being only one ball-court in the fort, none in cantonment; no skittle-ground in the fort, two in the cantonment; there are, however, schools with good schoolmasters; there is a library belonging to the artillery company in the cantonment, but the room is in the barracks, and quite unsuited to the purpose. There is neither day-room nor soldiers' club, soldiers' gardens, workshops, theatre, or gymnasia, consequently the men are not sufficiently occupied during the wet season, or during the heat of the day. There is a restriction during the hot weather against exposure to the sun, and it is supposed to be beneficial to health. 2. Too much cannot be done to increase the means of recreation and employment. This subject is under the consideration of H.E. the Commander-in-Chief, and reports have been called for in a general order dated 6th October 1860. 3. Soldiers' savings banks are in existence. 4. During the hot season the men are confined to their quarters, as any exercise would prove detrimental. The means of shade from trees, verandahs, &c., are quite sufficient during the cold season.
IX. MILITARY PRISONS.	1. The sanitary condition of the military prison at this station is highly defective. The cells are much too low, badly ventilated, being shut in on every side, and situated near the fort ditch, which is too close, and are occasionally overcrowded. I would suggest that cells well ventilated, with a large open yard should be built in cantonments, as I conceive it next to an impossibility to remedy the defects of the present building.
X. FIELD SERVICE.	1, 2. There are no local regulations for field medical service not included in the general presidency regulations. The practical working of the powers of the medical officers is good, as their suggestions are almost invariably attended to. 3. The practical operation of the regulations in camp for the preservation of the health of the troops, as to the selecting of camping-grounds is good, as to cleanliness, water-supply, &c. Every means are taken to keep a camp clean, and the water is supplied by carriers, who are always sufficient in number. All recommendations of medical officers are attended to when practicable. I have no improvements to suggest. 4. The arrangements for the formation of field hospitals are carried out by the deputy inspector general, who accompanies the force, and who generally selects the medical staff, he countersigns all the indents, the commissariat supplying all the bazaar and country medicines, linen bandages, and other necessaries. European medicines are indented for on the public stores in camp, or the nearest depôt, and to each field hospital a medical storekeeper is appointed of the rank of assistant surgeon. The proportion of doolies for the sick and wounded is 10 per cent. All these arrangements require the sanction of the officer commanding. Copies of the medical regulations are forwarded.
XI. STATISTICS OF SICKNESS AND MORTALITY.	1. There are no returns under this head.
XII. HOSPITALS.	1. Plans of the elevation of the hospital have been forwarded. 2. The hospital is situated on the left rear of the barrack, and is about half a mile from the stables; the bazaar and the houses of the civil population are about 200 yards distant. The site of the hospital is open, freely ventilated, and generally healthy. 3. The water-supply is abundant and wholesome. 4. There are no sewers for removing refuse water and other impurities from the hospital, but other means are employed. 5. The height of the lowest wards is 2 feet from the ground, or natural surface, and there is no ventilation under the floors. The roof water evaporates or is absorbed. Arrangements are made to prevent water from standing near any buildings, and I believe they are efficient. The hospital is built of bricks and mortar, the roofs and wall are single, it is kept I believe tolerably cool. Similar verandahs to those of barracks afford shelter from the sun's rays; but I have never had occasion to use them for the accommodation of the sick, convalescents, or any others. The hospital consists of one flat only.

Table of Hospital Accommodation.

Wards or Hospital Huts, No.	Regulation No. of Sick in each Ward or Hut.	Dimensions of Wards.				Cubic Feet per Bed.
		Length.	Breadth.	Height.	Cubic Contents.	
2	20	72	20	20	28,800	1,420

The hospital is so situated as to receive the benefit of the prevailing winds. The windows open the same as in barracks.

6. The wards are ventilated by punkahs and open ventilators at the ridge; I think they are hardly sufficient. There are neither jalousies or jhilmils.

7. The means employed for cooling the air are the same as in barracks, by means of punkahs tatties, and thermantidotes.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	8. The hospital is warmed by stoves and woodfires in the winter months. The walls and ceilings of the hospital are generally cleansed and limewashed once a year. 9. The privies are detached and situated 10 yards from the building; no water is used for flushing, as it would increase the nuisance; if the filth is removed directly, which it should be, they would not be offensive. 10. The lavatory arrangements are sufficient for ordinary purposes; long earthen vessels are used, well filled with a constant supply of fresh water. The sanitary arrangements are amply sufficient. 11. A large moveable bath is available for the sick when necessary; it is amply sufficient. 12. There are washermen attached to every hospital for the purpose of washing and drying hospital linen; they are amply sufficient. 13. The storage is sufficient and dry. 14. There are no bedsteads in use in the hospital; large cots, with wooden framework of sufficient strength are substituted; coarse Indian cloth, lacing with strong Indian twine to the framework, forms the portion of the cot on which the mattrass rests; the mattrasses are are lined generally with tow and covered, with Sālû bolsters, pillows with linen pillow cases, sheets, and what are called "resais," formed of a good substantial woollen material and lined inside with wool, constitute the beddding. I have no improvements which I can suggest. 15. The hospital kitchen is a large square building, after the style of the natives, with the apparatus used by native cooks, and consists principally of small fireplaces, called "chulas." The cooking is effected by dry wood and charcoal, and is amply sufficient. A medical officer has very seldom to find fault with the cooking. The building is situated about 30 yards from the wards. 16. No reply. 17. The attendance on the sick consists of an apothecary, assistant apothecary, hospital apprentice, a hospital surgeon, native compounder, native dresser, and ward coolies; such attendance is sufficient. 18. The sanitary condition of my hospital is good. No epidemic disease (with the exception of cholera in 1857), hospital gangrene, or pyæmia has appeared in the wards. I am unable to account for the cause of epidemic cholera appearing here in 1857. 19. There are no sanitary defects. 20. The hospital compound is large, and there is plenty of ground for convalescents to take exercise in. No shaded walks exist as they would impede the free circulation of air around the hospital. No seats are available, as the men generally sit on the edges of the verandah. 21. A small detached bungalow has been made available for the soldiers' sick wives and children. The present arrangements are very unsatisfactory, as the building is low, unusually hot from being tiled, ill-ventilated, and contains but little space for the sick; the building is simply the quarters of a non-commissioned officer, and never was intended for a hospital. I would recommend a proper building being erected. 22. There are no special local hospital regulations, which are not included in the general presidency medical regulations. 23. In the internal economy of the hospital, its sanitary state, dieting, and other comforts, the medical officer has full power. The repairs of building are carried out on his requisitions, countersigned by the officer commanding the station. 24. There are no wards for convalescents. At large stations, such as head-quarters of divisions or where there is a large general hospital for the troops, a hospital for convalescents would be advantageous, but at small stations, such as Govindghur, I should not think such an arrangement necessary.
XIII. Burial of the Dead.	1, 2. The burial ground is a mile and half from the station and is to the leeward; it is about 100 yards square, and is, I believe, properly kept. 3. As regarding the burial regulations, I am not aware of any specified space, as much ground as is required is generally taken up, The grave is about 6 ft. deep, it is never reopened, and contains one body only. At ordinary times the interment takes place within 24 hours in the cold season, and in the hot weather as soon as the necessary preparations are effected, as a general rule, about 12 or 18 hours after death. In epidemics, coffins are kept ready, so that no time may be lost, they are buried within 8 or 12 hours after death. There are no burial grounds for native troops. The soldiers of the Hindoo caste burn the bodies of their comrades, and the Mussulmen generally remove the bodies of their comrades some two or three miles from the station for interment. The removal of the body from the lines or hospital requires the sanction of the medical officer; generally the corpses of the native soldiery are removed between six and eight hours after death, whether at ordinary times or during epidemics. 4. The graveyard is never offensive. No precautions are necessary, as both Europeans and natives respect its precincts, and from this being a new station for Europeans troops, the graveyard is to a great extent unoccupied. The rules for the burial of the dead are laid down at page 80, sec. xiv., par. 19, of the military regulations. Funerals, therefore take place either at sunrise or half an hour before sunset. 5. The dead of camp followers or bazaar people are removed by the bazaar people themselves, and are either burnt or buried according to caste. The bodies are always inspected by the medical officer before removal. 6. No injury accrues to the public health from the present practice. 7. I consider the present system works remarkably well, and would feel unwilling to make any alterations in the disposal or burial of the dead.

I. Topography.	1. The aspect of the country surrounding the station is mountainous. There is a great deal of wood in the station and its vicinity, and numerous running streams, which become mountain torrents in the rains, but nearly dry up in the summer. 2. The elevation of the lake above the sea is 6,409 feet above the sea. Round the lake rise hills on all sides. The highest Cheenur is 8,750 feet above the sea, and 2,241 above the lake. Over the one ridge the country gradually slopes down to the plains; over the other continues the mountainous district of Kumaon. In the centre of the station, and the most striking feature in it, is a lake three-quarters of a mile long by a quarter of a mile broad. It is fed chiefly by springs, but in the rains the mountain torrents pour into it on all sides. The houses are studded over the hill side from a few yards to 1,200 feet above it. The site fixed on for the cantonment for invalids is at the east extremity of and beyond the limits of the old station of Nynee Täl; it is an excellent position. The elevation of the permanent barracks will be a few hundred feet above that of the lake. The temporary ones are lower. 3. The station is a valley in the heart of the mountains. 4. The lake is in the centre of the station; but the vicinity is not liable to overflow, and the natural drainage is perfect. The station is full of ravines and broken ground, but with good natural drainage, and at this elevation they are not of much consequence, except as affording facilities for concealing filth. 5. The station is perfectly open. The high hills do not prevent free circulation of air. The temperature of the station is not raised by exposure to reflected sun heat. The station is exposed to winds which are bracing and conducive to health. 6. The country surrounding the station is very little cultivated, and there are no works of irrigation in the neighbourhood. Rice is not cultivated within several miles of the station, the ground not being suitable, but it is largely grown in the valley, where water is available for irrigation. Indigo is not cultivated, nor the preparation of hemp or flax carried on near the station. 7. The nearest native population is a small bazaar in the centre of the station. 8. The mountains are of limestone with a very thin coating of light gritty soil. In the valley the soil also is very spare, and mixed with large quantities of débris. 9. There is only one well in the station, and that is in a small valley. The water there lies at a depth of 11 feet below the surface in the dry weather; but during the rainy season at not more than one foot. 10. All rain water, and water from surface springs in the district, is rapidly carried into the lake, and this at one extremity feeds a mountain stream. There is no adjacent higher ground, the drainage from which can pass into the subsoil of the station. 11. The water supply of the station is derived partly from springs, and partly from the lake. There are no tanks. There are plenty of fish in the lake, and along its margin a luxuriant water plant. The lake is used both for drinking and bathing purposes, and also for washing; but the body of water is too large to be deleteriously affected by this. A separate ghat, which might easily be made at a slightly lower level than the lake, ought to be constructed for the dhobies, and no washing allowed in the lake itself. 12. There is available for the station an unlimited supply of pure and wholesome water, soft and excellent. The water is raised by bheesties who fill their "musuks" either from the lake or springs. The supply for the barracks is conveyed from the eastern extremity of the lake in a wooden water-course. Before leaving the lake it ought to be filtered through a series of charcoal beds. This might easily be managed, the fall of water allowing every facility for it. 13. No reply to this query. 14. New stations are selected by a committee composed generally of the officer commanding the division, the deputy assistant quartermaster-general, a civil officer, the executive engineer, and one or more medical officers. Before any site is determined on for a cantonment, in the plains especially, an engineer and medical officer should be appointed with, say, one regiment of natives to reside on the spot for one year, to watch the natural drainage, the meteorological phenomena, and above all the health of the troops, and of the surrounding inhabitants.
II. Climate.	1. An ordinary thermometer and a rain gauge, are the only instruments available at this station for conducting meteorological observations. 2. The following register was kept with great care by General Sir W. Richards, K.C.B., from the 1st January 1846 to 31st December 1853.

Range of the Thermometer and State of the Weather at Nynee Täl from the 1st January 1846 to the 31st December 1853, Eight Years.

II. Climate—*cont.*	3. The climate of Nynee Täl is excellent. In the rains the air is damp; but at other times it is remarkably dry and pure. There are too many trees in the station; one-half might be cut down with advantage. The general residents of the station enjoy excellent health, and go out at all hours of the day. In the summer the sun is very powerful; but as the air is generally cool a good protection for the head removes all inconvenience. The winter months are most healthy and bracing, and best adapted for invalids. In the rains, generally from imprudence on the part of mothers, bronchitis is not uncommon among children; but I have found the cases do well. Nynee Täl is not subject to any endemic diarrhœa, which is so prevalent and intractable at some of the other hill stations. 4. There is no district near the station the climate of which is more conducive to health. 5. I have served at Wuzeerabad, Sealkote, Delhi, Jhansi, Umballa, Mean Meer, Umritsir, Jutogh, near Simla, Seharunpore, Meerut, and Nynee Täl. At some of these my experience was very short. Wuzeerabad has since been abandoned. Sealkote, Umballa, and Meerut, I consider excellent salubrious stations. Delhi, Jhansi, and Seharunpore, very inferior, and fever very prevalent. Jutogh has an unrivalled climate, and would form an admirable site for a European regiment or depôt. *Mem.*—The sanitary station of Nynee Täl was originated in 1842, and has since proved a favourite resort during the hot months for the residents in Rohilcund and adjoining districts. The station consist of a valley about two miles in length by one broad, surrounded by high hills on all sides, excepting at the east and south-west, where the roads from the plains enter the one communicating with Huldwanee, the other with Kaleedoongee. Each of these places is about 15 miles distant from Nynee Täl. In June 1858, owing to the increased number of Europeans, Nynee Täl was selected as a depôt for invalids. The site chosen for the military station is a rising ground, about one mile from the easterly end of the Nynee Täl valley; the ground is open, and in every way well adapted for the purpose. As yet the barrack and hospital are of only a temporary description—very inferior, and badly situated. Plans and estimates for permanent buildings were sent to Government a year ago, but owing to the expense the idea of erecting them has for the present been abandoned. The number of invalids in the depôt this season is upwards of 400. The sanitary station is under my medical charge; the depôt under that of Assistant Surgeon W. P. Pinkerton, R.A. As the military stations, therefore, with all particulars regarding the barracks, the hospital, and all the other matters relating to the troops, do not fall within my observation, Dr. Pinkerton has kindly undertaken to reply to the questions on these heads. Jno. M. Cuningham, M.D., Assistant Surgeon, H.M.I.S.
	The following replies are by W. P. Pinkerton, R.A., in medical charge of convalescent depôt, Nynee Täl:—
III. Sanitary Condition of Station.	1, 2, 3. The invalid station of Nynee Täl consists of two sets of huts, of temporary construction, the cantonments and permanent barracks not being as yet sanctioned. The lake which forms the chief object in the landscape, is surrounded by hills, covered with foliage; on the sides of which are situated bungalows and the bazaar of the civil station. This sheet of water, one mile long, and half a mile broad, lies due north and south. On the north Cheeny shelters it, while between "Cheeny and Ayapatta," on the west, a narrow gorge lets in the west and south-west winds. On the south the water escapes downwards towards the plains on the north of Bareilly. The gorge which then opens on the plains is narrow and full of rocks, banks of earth, &c. It is in this defile that the men's huts are built. This site is every way objectionable, as many of the huts lie lower than the surface of the lake. There is often a violent rush of wind up and down, and the earth is always more or less damp, and, especially during the rains, a perfect marsh. Table of barrack accommodation; date of construction, 1858; total number of rooms—21 barracks, containing 42 rooms, 50×18, with verandah in front. Total regulation number of non-commissioned officers and men, 840.

Barrack Room.	Regulation Number of Men in each Room.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.

42 - -	20	50	18	$\frac{11\times17}{2}=14$	12,600	630	45	14	240	4	3
Guard rooms,3	12	30	20	—	—	—	—	—	—	—	—
Prison cells -	Estimated for, and will soon be constructed.										

5. Most of the windows are on the side opposite the doors, opening in the centre. There is a verandah in front 6 feet broad and 8 feet high. This is never used as sleeping quarters by soldiers or any other persons. Jalousies are used in the huts occupied by married men.
6. Simple rope charpies, with blankets and sheets for the bed accommodation at the station.
7. There are no tents used in camp.
8. There are two ventilators on the roof of each large hut, and one on the smaller ones. Owing to the bad construction of the chimneys constant smoke exists in the huts, otherwise the air is pure. No means are required for cooling the air of barrack rooms.
9. The walls of the barracks are of stone, and the roof is thatched.
10. The floors are constructed of pucka, and raised from 1 to 2 feet above the ground, but there is no under current of air.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	11. The huts being merely temporary are not sufficient for the use of the troops. The plan proposed for the permanent barracks would give ample accommodation. They are kept in repair by the Public Works Departments under a sub-contractor. The walls and ceilings are cleansed and lime-washed once a-year. 12. There are no lavatories for the men, who wash in the verandahs, where accommodation is afforded them. 13. The cook-rooms are all temporary, and built of different sizes, as well as the barracks and temporary choolahs. As the buildings are all on the hill-side there is ample fall for all refuse water. 14. The privies and urinals are of different sizes, and being temporary there is no standard plan. A sketch of one, therefore, would not afford a true description. 15. The buildings are ventilated by means of a wooden ventilator, and lighted at night by glazed lanterns. 16. As the barracks are all built on the hill-side there is little or no drainage required. No washhouses exist. The hospital and "near" half of the barracks are very damp, owing to the bad state of the hospital-roof, and its exposed position, and to these huts lying too low and confined. The fluid refuse of the barracks flows down a steep declivity to the plains below. Cesspits do not exist, nor are any required. There are no foul ditches near the station. 17. The surface cleansing of the cantonment is efficiently done. The refuse is thrown down the "khud" and carried off by the water from the lake. 18. The surface of the cantonment is not kept free of vegetation. There are no old walls, thick hedges, &c., interfering with the ventilation of the station or bazaar. 19. Both bazaars are in a filthy and crowded state. No proper drainage nor latrines existing, the stench is at times overpowering. There are no means taken to preserve cleanliness; latrines should be enforced. The native houses near the station are small and badly ventilated. Dung, &c., is generally burnt. The want of public latrines occasionally causes a nuisance in the barracks, which would be of course removed by their adoption. 20. The slaughter house is 300 yards distant from the barracks, and is washed out by a stream of water running from the lake. 21, 22. There are no horses, stables, or picketing grounds at this station. 23. Married men use the same barrack rooms as the rest, divided only by a partition.
Officers' Quarters.	1. The officers live in separate bungalows of their own. There are no improvements to be suggested.
IV. HEALTH OF THE TROOPS.	1. The station, surrounding district, and adjoining native population are generally healthy. 2. Intermittent fever with enlargement of the spleen and variola are the diseases most prevalent among the native population. 3. I attribute the prevalence of the above diseases to sudden and extreme variations of temperature, the presence of dense underwood during the rains, their living in hollows exposed to the sun, and the want of free ventilation. 4. Before their arrival at Nynee Täl the troops were stationed at Lucknow, Allahabad, Cawnpore, Futteghur, Saugor, Gondah, Seetapore, Roy Bareilly, Bareilly, Moradabad, Shahjehanpore, Meerut, Delhi, and Agra. The near half of the barracks lie too low, and are too much hemmed in. 5. The troops at this station are never camped out. 6. I was never in charge of troops at a hill station before coming here; certain improvements in certain diseases, not organic, result from a residence in a hill station. 7. I do not think that troops are more liable to feverish attacks on leaving the hills, save such as are brought on by their own wilful intemperance or exposure to a mid-day sun. 8. I approve most decidedly of selecting hill stations for troops. 9. There are no diseases peculiar to this station to which troops are liable on coming to it. 10. No reply to this query. 11. The periods best adapted for a residence at hill stations are the autumn and winter, and the shortest period of such residence for troops to receive any benefit from it is 12 months. 12. There is no period of residence beyond which troops are likely to receive injury to their health on returning to service in the plains. 13. Troops on leaving hill stations for the plains should be sent so as to arrive at their destination by the middle of January at the very latest. 14. It would be most conducive to the health of troops to send them to head quarters in the hills with detachments doing duty on the plains, and these relieved every cold season. Frequent change of station in the plains is beneficial to the health and spirits of the troops. 15. At present the temporary barrack and hospital accommodation is not sufficient. 16. The most suitable sites for hill stations are obtained at ranges of elevation above the sea varying from 4,000 to 6,000 ft. 17. The proposed new site for permanent barracks is situated close to the far away huts at the height of 100 ft. above, and is freely exposed to all winds, excepting the north, and tolerably free of brushwood. 18. Retentive clay soils are unhealthy for stations, sand and gravel soil more healthy. 19. Soldiers should be sent to India after they have completed their preliminary drill at home, and not under 22 years of age. The best period for them to land in this country is from the 15th October to the end of February. Recruits on first landing in India should be restricted to small quantities of stimulants, have a light diet, and daily baths, and be kept in confinement to barrack rooms during the heat of the day. 20. Troops might be quartered in the Mediterranean previously to their coming to India, and on landing here should be sent immediately to a hill station for two years. 21. Troops on landing are conveyed from the port to the interior by flats up the rivers and bullock carts. 22. I consider ten years the number of years a British soldier should serve in India. 23. The manner of conducting Indian boards is not such as to avoid conflict of opinion as regards invaliding. 24. Invalids should leave India for home in December and January.
Diseases.	1. There are occasional inspection parades at this station for the discovery of incipient diseases. 2. There is no scorbutic disease among the troops at this station.

References to Subjects and Queries.	Replies.
IV. Health of the Troops. —*Diseases—cont.*	3. The majority of cases of hepatitis arrive from the plains. 4. No case of dracunculus has occurred here. 5. The establishment of lock hospitals would be advantageous. 6. The troops at Nynee Tal suffer from the following diseases, viz.:— *Fever.* Intermittent quotidian. *Dysentery.* Not local, but originating in the plains. *Cholera.* No case of this disease. *Small-pox.* One case. *Rheumatism.* Chronic form, originating in the plains, and not improved by this hill station. Acute, originating here from exposure to cold and wet, occurred last rainy season. The following is the proportion which admissions and deaths from the above diseases bear to the total admissions and deaths.

Diseases.	Admissions.	Deaths.
Feb. Quot. Intermittent	1 to 16·464	None.
Dysentery - -	1 to 14·818	1 to 244·5
Small-pox - -	1 to 489·	None.
Rheumatism - -	1 to 11·929	None.

	7. Intermittent fever is the prevailing disease in wet seasons from June to August. Hot moist air and chilly air generally precede or accompany their appearance. They are most prevalent in the native houses near the edges and below the level of the lake. Exposure to the sun during mid-day predisposes to these diseases. 8. No duty at this station can interfere with the general health of the troops. 9. For fever cases arriving from the plains five grains of quinine a day are generally used with good results. 10. For the prevention or mitigation of epidemic disease at this station I would recommend diminishing the amount of vegetation all round the cantonments, the formation of a large tank for bathing purposes, and the introduction of public latrines among the natives.
V. Intemperance.	1. The soldiers at this station are temperate, and there are no confirmed drunkards among them. 2. Only one case of delirium tremens took place last year. All the men at this station being invalids, require a daily amount of stimulant. Drunkenness is always punished as an offence. 3. Distilled spirits are sold both at the canteen and bazaar. The former supplies each man with one quart of beer and one dram of rum daily; spirit forms part of the soldier's ration at this station. The quality is good, but none is served before 12 at noon. Native spirits sold at the bazaar are very injurious to health. 4. The consumption of spirits in the amount above specified is conducive to the health, efficiency, and comfort of the men. 5. It would be injurious to deny the men their daily allowance of spirit; but its sale at the canteen should be kept under proper restrictions, and that in the bazaars entirely suppressed. 6. The use of malt liquor or wine is much less hurtful than that of ardent spirits. 7. Coffee and tea are used here. The use of these alone, if practicable, would certainly improve the general health. 8, 9. Generally speaking, the suppression of the spirit ration would be beneficial, but there are exceptions, many men labouring under abdominal diseases, not being able to drink beer without inconvenience. 10. Beer only should be drank in the forenoon, if required, and spirits not till after sunset. 11. Copies of the bazaar and canteen regulations are not to he had.
VI. Diet.	1. The rations for Queen's British troops and European troops in the Indian army is the same, and consists of beef, bread, potatoes, onions, rice, and "longee." The rations are served out every morning before the officer of the day. 2. The soldier here has three meals a day, at 9 A.M., 1 P.M., and 5 P.M., and meat once a day. One pound of vegetables enters into the ration. 3. It would be an improvement to have the dinner served at between 4 and 5 P.M. instead of during the mid-day heat, breakfast with meat having been previously served at 9 A.M., with bread and tea at 7 P.M. There is no arrangement to prevent the disposal of the rations. 4. For cooking purposes "dagchees" and wood fires are furnished. The kitchens are well lighted and kept clean, and for temporary purposes they are well provided. The food is generally boiled, and the cooking is satisfactorily done. The men occasionally have coffee before a march. 5. Gardens for the cultivation of vegetables by soldiers could be advantageously established near this station. A supply of seeds of different sorts for kitchen gardens should be given. "Good conduct" and "steady" men should alone have charge of them.
VII. Dress, Accoutrements, and Duties.	1. The soldiers at this station have the usual warm clothing during the winter, and light clothing in the summer. The dress is quite suitable to the climate and to the soldiers' duties by day and night. Solar helmets should be used always during the mid-day sun, even in the hills, and men on guard at night should be compelled to wear flannel belts around their bodies. Loose jackets are worn in the day, great coats at night.
Duties.	1. Troops should not be sent to India before being thoroughly drilled at home. 2. The best times for drills, parades, and marches is from 5 to 7 o'clock in the morning. 3. The guard-room is in the centre of the barracks, and the men are on 24 hours at a time. There is one parade in the morning and one roll-call at 4 in the afternoon. There are occasional complaints of slight rheumatism or diarrhœa after a night's duty, which would be easily obviated by proper attention to warm clothing.
VIII. Instruction and Recreation.	1. The following are the only means of instruction and recreation at the station; two skittle grounds, one school, with schoolmaster, and one library, well supplied with books and well

NYNEE TÄL. BENGAL.

References to Subjects and Queries.	Replies.
VIII. Instruction and Recreation—*cont.*	lighted. These are hardly sufficient to keep the men occupied in the wet season and during the heat of the day. The men are confined to barracks during the heat of the day. 2. I would recommend soldiers' gardens, soldier's clubs, and occasional examinations on Fridays for the best drawings or military sketches and knowledge of any specified kind or description, according to the inclinations of the individual. 3. There is a soldiers' savings' bank in operation at present, and it appears to be advantageous. 4. The shade afforded by verandahs is not sufficient for the exercise of the men.
IX. MILITARY PRISONS.	1. There are two well-built cells at this station, scarcely ever required.
X. FIELD SERVICE.	1. There are no local regulations for field medical service not included in the General Presidency Regulation. 2. The only power a medical officer has is to advise as to any choice of site for a camp, and the occasional moving after two or three days living on one piece of ground. 3, 4. No replies to these queries.
XI. STATISTICS OF SICKNESS AND MORTALITY.	No information under this head.
XII. HOSPITALS.	1. Sketch of the hospital is transmitted. 2. The hospital is close to the nearest huts, and one mile from the farthest, one mile from the big bazaar, and close to the small one. The site, which is on top of a mound, is healthy and freely ventilated. 3. The water supply is abundant and wholesome. 4. No drainage is required. 5. The lowest wards on the south side are 6 inches above the ground, and those on the north side ten feet. The roof slants on each side, the rain running off by gutters. The hospital is built of rubble stone and lime cement. There are open verandahs ten feet wide on all sides not used for sick. The hospital consists of two flats, with four wards above and seven below. Total number of wards - - - - - 11 Total regulation number of beds - - - - 45

11 - -	4	17	17	10 0				,,	,,	,,	,,

The hospital is too freely exposed to the prevailing winds. The windows open in the centre; but there are too many in this hospital, and owing to the exposed position they cannot always be open.

6. It is scarcely possible to ventilate these wards properly, as the draught caused by open windows and doors is too strong. There are no jalousies or jhilmils.
7. There are no means in use for cooling the air of the wards.
8. Fires used for warming the wards. The walls and ceilings are cleansed and lime-washed once every 12 months all over, and every three months six ft. high.
9. The privy is a simple stone hut, with seats enclosed, and kept clean by sweepers. It is not offensive.
10, 11. Chatties and tubs are provided for lavatory purposes, and are sufficient for the sick, who are, however, bathed in the lake.
12. The washing and drying of the hospital linen are performed by the regular establishment of native washermen.
13. The storage is sufficient and dry.
14. Cots, with string and newar bottoms are generally used in nospital.
15. The kitchen is on the north of the hospital, below the level of the wards.
16. Copies of the diet tables, diet rolls, &c. are transmitted.
17. The establishment for attendance on the sick consists of one hospital sergeant; one European barber, and one European orderly.
18. The hospital is in a healthy position, and no epidemic has appeared in its wards. During the rains, however, open surfaces of blisters &c., do not heal kindly.
19. Besides the hospital being too much exposed there are too many doors and windows in the wards, which again are too small.
20. There are 2 "jampanns" or chairs at this depôt, in which the sick are placed to take the air, and are carried by 4 coolies. There are walks shaded and cool on the west side of the lake, and also the verandah for the exercise of convalescents.
21. There is one room kept solely for sick women and children. All the present arrangements are temporary and unsatisfactory.
22. There are no local hospital regulations not included in the General Presidency Medical Regulations.
23. The medical officer has power to have any nuisance removed, and repairs done, and in camp the hospital removed any number of yards, by application to his commanding officer. In the diet, &c., of patients, &c., he has supreme power.
24. No convalescent wards. All the men here are invalids.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is 2½ miles from the farthest huts. The drainage is good, and decomposition takes place rapidly. The ground is well kept. 3. The grave space is eight feet by four, with an interval of three feet between each. They are six feet deep, and have never been re-opened as yet. Interment at ordinary times takes place within 24 hours after decease, and during epidemics within 12 hours. 4. The grave yard is never offensive. If possible British troops are always buried during early morning in the consecrated cemetery. 5. The dead of camp followers and bazaar people are burnt or buried according to caste. 6, 7. No injury accrues to the public health from the present practices, nor are any improvements to be suggested. Memorandum. In reply to the memorandum affixed to this book on its return, I beg to state that the questions contained in that small portion of the report, which it fell within my province to to answer, were not replied to concurrently by the commanding officer, the engineer and myself, because the sanitary station of Nynee Täl to which alone I refer has no commanding officer, but under the jurisdiction of the municipal committee, and because there was no engineer officer present above the rank of a sub-conductor in the P. W. D. whose opinion I did not think would be of sufficient value to record." Nynee Täl, 5th December 1860. (Signed) Jas. M. Cunningham, M.D., Assistant Surgeon. Memorandum. "The questions were not answered by me concurrently with the resident engineer, there being no officer at the station belonging to that department above the rank of a sub-conductor. In a convalescent station like this several questions put down can be answered only partially." Nynee Täl, 2nd December 1860. A. W. Pinkerton, Assistant Surgeon in Medical Charge of Convalescent Depôt. "Dr. Cunningham's report extends only to page 197 (end of "climate.") The remaining questions are replied to by Dr. Pinkerton, R.A., in charge of the depôt."

(Signed) John Drysdale, R. H. Commanding.
Jas. M. Cunningham, M.D. Assistant Surgeon, H. M. I. S.
A. W. Pinkerton, M.D., in Medical Charge of Depôt.

16th June 1860.

I. Topography.	1. The surrounding country is sandy, flat, and open, and generally dry. There is no jungle, and but little wood or water in the vicinity of the station. 2. The elevation of the station above the sea is about 900 feet, and from 1 to 100 feet above the adjacent country. The elevation above the nearest water—the Kalee Nuddee, about four miles distant—is 110 feet. There is no higher or healthier ground adjoining Meerut. 3. The nearest mountain or tableland is the Sewalik range of hills under the Himalayas. The height of this range above the level of the station is 3,123 feet. They are distant about 70 miles. 4. The nearest water is the Kalee Nuddee, about four miles distant to the south-east. The vicinity is liable to overflow during extraordinary floods in the rainy season, but not for more than a few hours. There is no broken ground nor any ravines or water-pits near the station. 5. The station is open, and freely exposed to the winds. Free internal ventilation exists generally, but varies according to the locality. The temperature of the station is probably raised by exposure to reflected sun heat, but to what precise extent cannot be said, as no register of the comparative temperature with that of the open country has been kept. The station is exposed to cold winds in the months of November, December, January, and February. There are land winds also, generally from east or west, the latter being most prevalent and most healthy. 6. The surrounding country is cultivated, and irrigated by the Ganges canal, about nine miles distant from the station. Artificial irrigation does not, however, affect the health of the station. The cultivation of rice is strictly prohibited within cantonment limits. No indigo is cultivated or prepared near the station, but hemp is prepared in all directions out of the station and cantonment limits.

References to Subjects and Queries.	REPLIES.
I. Topography—*cont.*	7. The town of Meerut is situated to the south about a mile distant from the lines of the European troops. 8. The surface of the district is a pervious sandy loam, with a subsoil, at some depth, of white sand and kunkur nodules. In some places beds of kunkar exist. The station was built originally on new ground. 9. Water is found during the dry season at a depth of 18 feet below the surface, and at a depth of 16 feet during the rainy season. 10. The rain-fall flows readily away. There are no surface springs in the district within which the station is situated. No drainage from higher ground passes into the subsoils of the station. 11. The water for drinking purposes is obtained from wells. There are also tanks for bathing (used only by natives) and for washing. The extent of tank surface within the station and within half a mile of it is about 2,229,397 feet superficial. The tanks are never dry, but are fullest at the close of the monsoon. No tank used for drinking purposes is also used for bathing, nor are any of the tanks liable to pollution from leaves or other matter falling into them or from any other cause. Nuisance and perhaps malaria proceeds from some of the tanks near the station, the only effectual means of preventing which would be to fill them up. 12. The amount of water supply for the station is unlimited, and it is soft and excellent in quality. It is raised by leathern buckets and bags, varying in size according as it is raised by hand or by cattle. 13. There are no other topographical points bearing on the health of the station not included in the above replies. 14. New stations are selected by special committees convened for the purpose under the orders of the Government, and composed of medical officers, aided by the executive engineer. Every practicable inquiry is made as to topography, climate, diseases, sanitary condition, &c. &c.
II. CLIMATE.	1. The instruments available at the station for conducting and registering meteorological observations are a barometer, thermometer unattached, wet bulb thermometer, thermometer in the sun's rays, and a pluviometer. 2. Table of Meteorological Observations for one year, from the 1st January 1859 to 31st December 1859.

Months.	Barometer. Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain. Inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks as to Clouds, Dew, Wind, Storms, &c.

3. The climate of the station is good, being dry for a great portion of the year, and not variable. Fogs are very rare, and the climate is not affected by the canal and well irrigation. There is much dust during the dry seasons, but it does not render the atmosphere unhealthy. The climate has no bad influence on health, and no peculiar diet is required for the troops. Tatties, punkahs, and free ventilation are, however, absolutely necessary. Light clothing is required in the hot season, and warm during the cold. Drills should be light and enforced very early in the mornings only, so that the men may return to quarters by six or half-past six a.m. during the hot weather. The most healthy months are December, January, February, and March, and the most unhealthy August, September, and October, when intermittent, remittent, and continued fevers prevail, as well as catarrh, diarrhœa, dysentery, and hepatitis.

4. There is no district near the station the climate of which is more conducive to health.

5. I have served at several stations in the North-west provinces, Punjab, and Bengal, and in my opinion the comparative salubrity stands as noted above.

III. SANITARY CONDITION OF STATION.

1, 2, 3. All the plans of the station, district, and barracks were submitted with the original copy of this report through the Deputy-Assistant Quartermaster-General's office. If copies of these plans are indispensable a delay of some months must ensue, as the office draughtsman of the executive engineer has his hands constantly employed in current work, and the original copy will be required back again.

4. Table of barrack accommodation :—

Date of construction of barrack, 1810, 1819, 1828, 1830, 1832, 1833, 1834, 1842, 1845, 1847, 1854, 1858, 1859.

Total number of rooms - - - - - - 705

Total regulation number of non-commissioned officers and men - 4,227

III. Sanitary Condition of Station—*cont.*	5. The windows and doors of the barracks are on opposite sides, and open inwards their whole length. There are verandahs on both sides of the buildings, which upon occasions of great emergency only are used as sleeping quarters. The rule is, that the centre ward only be occupied as sleeping quarters, one verandah for messing and the other for recreation. There are no jhilmils to the barracks. 6. The bedsteads used in barracks are wooden frames with a lacing of tape or cane for the bed. No bedsteads are used in tents. The men are supplied with a mattress of quilted cotton for barracks or camp. It would be a great improvement to substitute an iron band lacing to the beds in lieu of tape or cane. 7. Tents used in camp are of two sizes, one 12 ft. by 12 ft. for staff serjeants, occupied by one man only; the other 20¼ ft. by 15 ft. 10½ in., occupied by 16 non-commissioned officers rank and file, giving 20 superficial feet per man, and about 150 cubic feet of air. The tents are made of three cloths of country canvass, lined with blue, with two flies; in all, six cloths. 8. Besides the ventilation obtained by doors and windows, barracks are ventilated by openings in the roof. Tents have no ventilation beyond that afforded by the door openings. Guard-rooms are ventilated in the same manner as the barracks, and generally the buildings at

References to Subjects and Queries.	REPLIES.
III. Sanitary Condition of Station—*cont.*	Meerut are sufficiently ventilated to keep the air pure both by day and night. The means employed for cooling the air in barrack-rooms and hospitals during the hottest months are tatties or screens, made up of kus-kus grass over frames the size of the doorways. These screens are kept constantly wet by an establishment allowed for the purpose, and the breeze passing through them becomes cooled. Punkahs are also employed for increasing the circulation of air. 9. Barracks are generally built of brick set in limemortar, the roofs being supported on timber trusses, and covered with thatching grass, or tiles, chiefly the former. The construction of the tents have been already described, and there are no huts for soldiers at Meerut. 10. Floors are constructed of stone, brick on edge or brick flat, with concrete terracing over They are generally raised two feet above the ground, in some cases more and in others less There is no passage of air underneath. 11. The materials of which the barracks are constructed are suitable to the climate, and the barracks themselves could hardly be improved, as they are among the best in India. The cantonments, &c. are kept in repair by the executive engineer, and repairs are executed without any unnecessary delay on requisitions of the authorities of the station or regiments by which the buildings are occupied. The officer commanding the station is responsible for the general sanitary state of the cantonments. The walls of the barracks are cleansed and limewashed as a rule annually, and as often as may be deemed necessary on sanitary grounds. 12. The lavatories are permanent buildings, built of burnt bricks and lime-mortar, and are supplied with water from wells. Their number is one per company, besides which there are two plunging-baths to each regiment. 13. The means of cooking are those ordinarily adopted in India, metals pots and pans. Water is supplied by bheesties from wells; the refuse water being collected in small sinks and cleared out daily by the conservancy establishment of the corps. Washing and drying of linen is undertaken by native washermen, whose operations are carried on in the open air in the vicinity of the tanks or wells. These means are sufficient for the wants of the station. 14. The privies and urinals are permanent buildings, built of burnt bricks and mortar. They are drained into cesspools, and the contents of the privies (which are received into copper pans) are removed to a distance from the station in filth carts daily. 15. The buildings are ventilated by roof ventilators, and lighted by windows. The barracks are lighted by oil lamps at night. 16. The mode of draining the barracks is by wide open masonry drains, gradually increasing in depth, and having two outlets, one 1,700 ft. from the barracks, which is a large tank, and the other a nullah, 5,000 ft. distant. The drainage is sufficient for carrying away all surface water, &c., efficiently. No part of any building used as a barrack or hospital is damp to my knowledge. No complaints on the subject have ever been made. The fluid refuse of the barracks is drained into cesspools, which are close to the wash-houses and urinaries. Their dimensions are 4½ ft. diameter by 40 ft. deep. They are distant from the wells 670 ft., and from the nearest barrack 60 ft. They seldom require cleansing, but when this is necessary it is done by opening the tops and drawing out the fluid in buckets. There are no foul ditches in cantonments, but there are some near the city, about a mile from the barracks. 17. The surface cleansing within the cantonments is done by sweepers, but the establishment for this purpose is insufficient. Refuse, manure, &c. is carried away in filth carts beyond the precincts of the station. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c. interfering with the ventilation of the station, &c. 19. The streets of the bazaar are provided with drains, are well ventilated, and there is a sufficient supply of water from the numerous wells. Cleanliness is strictly enforced, and each bazaar has self-supporting public latrines. Every individual shopkeeper is responsible for the cleanliness of his own shop front. The condition of the native houses is generally filthy, dung-heaps being frequent. The existence of cesspools is probable, and pits are common, as in all native towns, villages, and bazaars, these receptacles being kept for all kinds of refuse. There are no native dwellings sufficiently near the barracks to be a cause of nuisance by the wind blowing over them. 20. There are two slaughter-houses in the centre bazaar of the cantonments. One recently erected for the butchers of the station works well, and is clean. It was built out of the bazaar funds, and will repay the outlay in about two years. The fee for killing a bullock is four annas; for a sheep or goat, one anna. What is considered to be offal is almost entirely consumed by the lower orders. The other slaughter-house is the property of the Government meat contractor, and is kept clean, being inspected daily by a commissariat serjeant and occasionally by the commissariat officer. No offal is allowed to remain on the premises. 21. The bazaar horses being very few, are picketed on the owner's premises, and the litter is disposed of for burning bricks. 22. The artillery and cavalry stables are large sheds supported on pillars, light being only admitted from the open sides. Ventilation is effected by means of ventilators in the roof. The stables are situated to the front 100 yards from the barracks, and upwards of 800 yards from the cavalry hospital. There are no dung-heaps, the manure being disposed of in the riding school manége. The picketing grounds are arranged in the immediate vicinity of the stables. 23. The quarters for married non-commissioned officers and men are sufficient. No married people occupy barracks with the men.
Officers' Quarters.	1. Officers do not live in quarters, but occupy well-ventilated houses with gardens and out-offices, in properly drained situations within their respective lines. They are rented from private individuals. No improvement whatever is required.
IV. HEALTH OF THE TROOPS.	1, 2. The station, district, and native population may be considered healthy. The most common diseases among the latter are fever, diarrhœa, dysentery, small-pox, and spleen disease. Cholera is not so frequent here as at other places. 3. The healthiness of the neighbouring native population may be attributed to the porous nature of the soil, to the country being well cultivated, there being fewer sources of malaria, and to free ventilation.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	4. H.M.'s 6th Dragoon Guards arrived here in January 1860 from Muttra, where the corps suffered from fever, but since arrival at this station their health has been good. H.M.'s 35th Regiment arrived on the 20th December 1859 from Dinapore, their health there having been indifferent, cholera, dysentery, and fever prevailing among the corps. Since their arrival at this station the health of the regiment has been good, the prevailing diseases being venereal diseases, a few cases of variola, and old cases of hepatitis. The 4th Reg. N. I. came from Noorpore in March 1860. No portion of the men's present accommodation is more unhealthy than the rest. 5. The troops at this station are not camped out. 6 to 9. No experience with troops at hill stations, but soldiers on first going to such stations are liable to be attacked with diarrhœa. 10. No special precautions are required at hill stations with reference to diet, duties, or exercise, but warm clothing is necessary to guard against vicissitudes of temperature. 11. The seasons best adapted for residence in hill stations are the hot and rainy reasons, and the shortest period to obtain benefit from such residence is eight months, or from March to November. 12. I am not aware of any period of residence beyond which injury is likely to be inflicted on the health of the troops on returning to service on the plains. 13. No special precautions are required on leaving hill stations for the plains, except to avoid fatigue and exposure to the sun. 14. In my opinion the location of troops on the hills, with short periods of service in the plains, would be the course most conducive to the preservation of the health of troops serving in India. Frequent change of station in the plains is also beneficial to the health and spirits of troops and convalescents, provided the change of stations is effected during the cold season. 15. At Landour the barrack and hospital accommodation appear to be sufficient for the limited number of troops located there. 16. I have no experience to show what ranges of elevation above the level of the sea are most suitable as sites for hill stations. 17. There is no higher ground near this station which could be advantageously occupied as a hill station. 18. A porous surface and a sandy subsoil is the most healthy for stations. Black soil, clay and kunkur beds, whether cropping out to the surface or composing the subsoil, are unhealthy sites. As a general rule, wherever sugar canes grow luxuriantly it may be taken for granted that the soil is healthy. 19. Soldiers proceeding to India should be 22 years of age, and they should land there in the cold season, November, December, and January being the best months. The precautions necessary to preserve the health of recruits on first landing is to prevent them exposing themselves to the sun by day, and the dews and fogs of night and early morning, and to totally prohibit the use of spirituous liquors. Care is also necessary with reference to clothing, as the variation of temperature is very great during the cold season in Calcutta. 23. Troops should be sent direct from the home depôts to India, and as residence on the hills does not acclimatize them for service on the plains, I should recommend recruits being sent to join immediately their respective regiments after landing in Calcutta, while regiments just arrived ought to be stationed in the upper provinces and not in Bengal. 21. Troops are transported to the interior by marching, bullock wain waggons, and by troop boats towed by steamers. 22. A British soldier should serve 12 years in India. 23. Special invaliding boards are composed of five medical officers, and although conflict of opinion is possible, I have never met with any instance of it. 24. Invalids leaving India for home should depart in the cold season, and not later than the end of February.
Diseases.	1. There are regular inspection parades once a week, on Saturday, for the discovery of incipient diseases. 2. Cases of scorbutus occur at the station, but are rare. They do not exceed 1 in every 2,000 admissions, and in the generality of these cases even the disease was contracted elsewhere. It can hardly be attributed to any peculiar cause of local origin. 3. The proportion of admissions from hepatic diseases to all other admissions for three years were 18 per 1,000. The disease was caused by intemperance, exposure, a sequel of cachexia from long residence in India, and from repeated attacks of malarial fever. 4. Dracunculus is of very rare occurrence, and is not of local origin. 5. The proportion of admissions from venereal diseases is about 8 per cent to the total admissions. Lock hospitals would be decidedly advantageous in diminishing this disease, particularly if combined with proper police supervision to provide for the diseased being sent in for treatment. 6. The troops at the station suffer from diseases both of the epidemic and endemic form, viz.:— *Fevers.*—Intermittent, remittent, and continued. *Dysentery.*—Acute and chronic. *Cholera.*—Bilious and spasmodic. *Small-pox.*—Distinct and confluent. *Rheumatism.*—Acute and chronic. The following is the proportion which admissions and deaths from these diseases bear to the the total admissions and deaths :—

Diseases.	Per-centage of Admissions to total Admissions.	Per-centage of Deaths to total Deaths.
Fevers - - -	56·00	25·00
Dysentery - - -	2·75	24·00
Cholera - - -	0·09	0·04
Small-pox - - -	0·09	0·08
Rheumatism - -	3·24	0·04

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	7. The more frequent zymotic diseases are intermittent, remittent, and continued fevers, influenza, small-pox, measles, and cholera. Fevers are most prevalent at the end of the rainy season. Small-pox prevails in March and April, when the atmosphere is in a highly electrical state, indicated by the frequency of dust storms. The other diseases occur at uncertain periods, but great variation of temperature produces influenza, and sometimes cholera. These diseases are most prevalent in the bazaar and native houses, which are dirty, badly drained, ill-ventilated, and crowded. The causes of the prevalence of these diseases among the troops are exposure and intemperance; whilst among the natives insufficient clothing, bad food, and dirty habits are the predisposing conditions. 8. I cannot give a decided opinion as to how far the nature of the soldier's duties and occupations in barracks or habits on the march and in the field influence the prevalence of epidemic disease. 9. Small doses of quinine have not been tried at this station as a prophylactic against malarial disease. 10. I have no recommendations to offer on any of the preceding points towards the prevention or mitigation of epidemic disease at this station.
V. INTEMPERANCE.	1. The soldiers at the station are temperate, the number of confirmed drunkards being very few indeed. 2. The proportion of admissions into hospital from diseases caused directly or indirectly by intemperance is very limited in number, and it would be impossible with any degree of accuracy to prepare a statistical table showing the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at this station. Drunkenness is always punished as an offence. 3. Rum is sold at the canteen. Native spirits are sold in the bazaar, but not to soldiers; they get it, however, smuggled into barracks occasionally. The quantity of Government rum allowed to each man is two drams per diem, on payment, if no beer is drank, or one pint of beer and one dram of rum. Spirit is no part of the soldier's ration, but he is allowed to buy one dram at noon and one after sunset, but never allowed to purchase the two drams together. The effect of spirits upon health depends upon the man's habits. Spirit is never given as a ration to convalescents, but they are sometimes allowed to have beer. No drinks injurious to health otherwise than intoxicating drink are sold in the canteens or bazaar; only tea and coffee are allowed besides. 4. The consumption of spirits is injurious to health, and cannot be said to be conducive either to the efficiency or internal discipline of the corps. 5. The sale of spirits in the bazaars is restricted under severe penalties, but it cannot be altogether abolished. 6. The use of malt liquors and wines would, in my opinion, be less injurious than that of spirits. 7. Tea, coffee, lemonade, and similar drinks are much used at the station, and they are more salubrious in hot climates than spirits or malt liquors. 8. There is no spirit ration either for soldiers or convalescents at this station. 9, 10. It would be beneficial in tropical climates to prohibit the sale of spirituous liquors in the canteens, and to permit only beer, coffee, tea, lemonade, &c. to be sold to the troops. No recommendations on any of these points are offered. 11. By the bazaar regulations a penalty bond is taken from wine and spirit dealers not to sell liquor to British soldiers, and a pass is required, signed by the superintendent, for more than one quart bottle of country liquor leaving the Abkar's premises. Smuggling is punished by fine and imprisonment.
VI. DIET.	1. The ration for European troops consists of—bread, 1 lb.; beef or mutton, 1 lb.; rice, 4 oz.; sugar, $1\frac{3}{4}$ oz.; black tea, $\frac{5}{7}$ oz., or coffee, $1\frac{3}{7}$ oz.; salt, 1 oz.; split firewood, 3 lbs.; and vegetables, 1 lb. Potatoes are supplied when available, otherwise the vegetables consist of such as are procurable in the local markets. An inspection of the rations takes place daily by the regimental authorities and by the medical officer. They are also frequently inspected by the commissariat officer. A daily inspection is made by the commissariat officer at the ration stands, and the bakery, slaughter-house, and cattle are viewed every day by the commissariat serjeant. 2. Fruit is not issued to troops, only to the hospitals when sanctioned. The stoppage for rations is 3 annas 4 pie, while the cost to the Government is 8 annas. The proportion of vegetables entering into the constitution of a ration is 1 lb. per man per diem. 3. No improvement is required in the ration, nor has it been found necessary to adopt any measures for preventing the disposal of the ration by the troops. 4. Native cooks are employed to cook the rations, the cooking being performed in copper and iron vessels served out by the Commissariat Department. The copper vessels are tinned monthly. The kitchens are clean, light, and well ventilated, and sufficiently supplied with water. The food is boiled or roasted in turn, and the cooking is properly and sufficiently varied. Tea and coffee is also properly prepared for the men. It depends on regimental arrangement whether the men have tea or coffee before a march, but it is now becoming a general thing to do so. 5. Soldiers' gardens for the cultivation of vegetables would be advantageous if there was ground near the barracks, as the men could not be expected to go far to work at them.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldier's dress and accoutrements at the station consist of a basket helmet, coat, trowsers, *no stock*, waist-belt, one shoulder-belt for pouch, ammunition, and boots. This dress is very well adapted for the climate and for the soldier's duties by day and night, and at different seasons. The men's kits are now well adapted to meet all vicissitudes of seasons. In the wet weather he has his cloak, and sentries are never exposed to the sun.
Duties	1. It would be a great advantage if the men came out ready drilled from home, particularly for the mounted branches of the service in India. 2. The routine of a soldier's duties is drill morning and evening for an hour or an hour and a half during the cold season, which does not affect their health. The best hours for drills in the cold season is up to 10 o'clock in the morning and after 4 p.m. In the hot season they should take place before 6 or half-past 6 a.m., and after 5 p.m. Only general instructions are issued under this head; there are no general orders on the subject. The average

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*Duties—cont.*	number of nights the men have in bed during the week varies. At present they have 14 nights in bed without mounting guard. 3. Guards are mounted close to the barracks, and relieved daily. Roll calls take place morning and evening, and at night when circumstances require it, which is rarely the case.
VIII. Instruction and Recreation.	1. The means of instruction and recreation are as follows:—There are balls courts, covered in skittle grounds, schools with good schoolmasters, and a theatre. Neither library, day-room, or soldiers' clubs, soldiers' gardens, workshops, or gymnasia exist at the station, and the present means are not sufficient to keep the men occupied during the wet season or heat of the day. The men are strictly prohibited from going out from 8 a.m. to half-past 4 p.m. during the hot weather, but there is less restriction in the cold season, and with the best possible results. 2. In order to improve the existing means of recreation and instruction I would recommend in-door employment of the men, if possible, in their several trades, and the erection of a gymnasia of approved construction. 3. Savings' banks are already in existence, and are attended with the best results possible especially to married men. 4. The shade from trees, verandahs, &c., is very limited, and quite insufficient to enable the men to take exercise without injury during the day.
IX. Military Prisons.	1. The sanitary state of the prison cells is good with respect to space and ventilation, but they are defective as regards temperature, which could, however, be advantageously lowered by tatties and punkahs.
X. Field Service.	1. There are no local regulations for field medical service not included in the General Presidency Medical Regulations. 2. With regard to the practical working of the powers of medical officers as regards the conduct of the line of march of troops, bivouacking, camping, &c., the commanding officers generally are glad to avail themselves of any sanitary suggestions made by medical officers in the positions noted. 3. The medical officers make sanitary recommendations in reference to the selection of camping grounds, general sanitary regulations, &c., which, when carried out, are attended with the best results. 4. No reply to this query.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1, 2. The hospitals are situated at convenient and proper distances from the barracks. The stables to the north-east are about 800 yards distant, and those to the north-west about the same distance. They are situated to the north of the bazaar and civil population, the sites being open, freely ventilated, and healthy as to elevation, drainage, and absence from malaria from all sources. 3. The water supply is abundant and wholesome. 4. The means employed for draining, removing refuse water and other impurities from the hospital are wide open masonry drains, gradually increasing in depth. There are two outlets, one about 1,700 feet from the hospital into a tank, and the other about 5,000 feet distant into a nullah, the water of which flows readily away, and is dry in the cold season and hot weather. 5. The height of the lowest wards above the ground is from one to two feet, but there is no perflation of air underneath. Not required; no dampness. The roof water is partly carried away and partly sinks into the subsoil. The surface drainage and guttering round the hospitals is good, and quite sufficient for carrying away the rain-fall rapidly. The hospitals are built of brick and mortar, with single tiled roofs over grass thatch. The walls and roofs are sufficiently thick to keep the buildings cool. The hospitals have verandahs all round, some of them being double. They are 10 feet broad, and afford sufficient shelter from the sun's rays. The single verandahs are never used for the accommodation of the sick or others, but in double verandahs the inner one is so used in cases of emergency. The hospitals consist of one flat only.

XII. Hospitals—*cont.*	The hospital receives the full benefit of the prevailing winds. The windows are glass doors opening inwards, and are conducive to ventilation and coolness. 6. Ventilation in the wards is effected by means of doors, windows, and circular holes in the side walls. The ventilation from the roof also is ample. There are no jhilmils, but there are chicks to keep out the flies, and quilted cotton purdahs for the cold season. 7. Screens of kus-kus grass are fixed on the doorways and kept wet to cool the air admitted into the wards, and besides these artificial cool currents of air are established by means of thermantidotes or blowers. 8. No means exist for warming the wards. The walls and ceilings of hospitals are cleansed and limewashed annually, or whenever the medical officer thinks fit. 2. The privies and urinals adjoin the hospital, and are connected with it by a covered passage. They are permanent buildings of burnt brick and lime mortar. They are properly drained and supplied with water, the soil being removed in pans and by filth carts, as in barracks. The urinary has a cesspool with a covered top attached. These out-offices are not offensive. 10. The lavatory arrangements are the same as for barracks (par. 12, Sanitary Condition of Station), and are quite sufficient for the purpose. 11. In the lavatory there is a bath for the sick, which is both sufficient and convenient. 12. The washing and drying of hospital linen is efficiently performed by native washermen at a distance from the hospital. 13. The storage is sufficient and dry. 14. The bedsteads used in hospital are of wood, some having laced canvass bottoms and some with two-inch tape. The bedding consists of a mattress stuffed with hemp, sheets and blankets, covered with chintz. I would suggest that iron bedsteads be substituted for wooden ones. 15. The hospital kitchens are detached buildings, but situated close to the hospitals. The means and apparatus for cooking are those in common use, viz., metal cooking pots on native grates, which are sufficient for the purpose. Diets are properly cooked, and can be varied to any extent. 16. Copies of diet tables, diet rolls, separate statements, &c. &c., will be found in the Bengal Medical Regulations, 1851. 17. One hospital serjeant is attached to each hospital, and the sick are attended by a native establishment sufficient for the purpose. There are no nurses, but orderlies are employed in special cases as required by the medical officer. There are female native attendants for female hospitals. 18, 19. The sanitary condition of the hospitals is excellent, and no epidemic disease, hospital gangrene, or pyænia have ever appeared in the wards. No improvements are suggested. 20. Convalescents go out for an airing on elephants and in doolies. There is also sufficient ground about the hospitals for them to take exercise, and there are seats with backs in the outer verandah. 21. There are separate female hospitals for the treatment of soldiers' sick wives and children, the arrangements in which are satisfactory. 22. There are no special local hospital regulations enforced at the station which are not included in the General Presidency Medical Regulations. 23. The medical officer has full power in all matters appertaining to the sanitary condition of the hospital, medical comforts, change of diets, &c. 24. There are no convalescent wards or hospital, but a convalescent ward attached to each hospital would be an advantage.
XIII. BURIAL OF THE DEAD.	1. The burial ground for the use of British troops is to the north of the station and about 400 yds. from the nearest barrack. The prevailing winds are westerly, and consequently out of the direct track of the station. 2. Its area is about 56,000 sq. yds., the subsoil being sandy; the drainage is excellent. The ground is carefully kept. 3. The grave space allowed is 2½ ft. in width, with an interval between each grave of 2 ft. The depth is 4½ feet below the surface. If the graves are of earth, they are never re-opened, but brick graves are occasionally opened. These, however, have seldom or never more than two bodies buried in them. Interment is compulsory at ordinary times within 12 hours after death, and during epidemics often in less than 6 hours after decease. 4. The graveyard has never been known to be offensive, being well watched by Government servants for that express purpose, and hence no nuisances have been committed. The British soldiers' burial is regulated by the medical officers of regiments; as a rule those who die in the morning are buried the same day at sunset, and those who die in the evening about sunrise next morning. 5. The dead of camp followers or bazaar people are disposed of according to caste. Their relations or the police either burn them or bury them at some distance from the station. 6, 7. No injury accrues to the public health by the present practice, and no improvements in the disposal of the dead can be suggested.

(Signed) J. WILKIE, M.D., Deputy Inspector-General of Hospitals, Meerut Circle.
G.H. SWINLEY, Colonel, Commanding the Station.
F. ALEXANDER, Captain, Offs. Exve. Engineer, Meerut Division.

I. Topography.	1. The country round the station is open, flat, sandy and dry. A ridge which is the right bank of the old bed of the Jumna, runs in a crescent shape round the cantonment at about ¾ of a mile distant. The arc is about 8 miles long, and it terminates in a marsh at Bād. There is no wood nor jungle of any size in the vicinity. The river Jumna passes close to the station, many of the officers houses being situated on its banks. There is no other running water near. During the rains the river overflows the country, extensively on the opposite side, and to some extent on this side, leaving as it subsides an extensive alluvial deposit.
	2. The height of the station above the sea is not known. The greater part of it is lower than the surrounding country. Besides the river Jumna there are two marshes, one at Māth, 6 miles west, and one at Bād, 6 miles east. There is a large nullah close in rear of artillery lines, and numerous small nullahs all over the station. The ridge mentioned above affords higher and healthier ground for a station, about 2 miles south of the present station, This ridge expands into a fine open plain, about 30 feet higher than the present station, with an ample fall for drainage on every side. It is well away from river and city. Surface sandy, subsoil kunkur (limestone nodules). It has been pronounced by two committees to be the proper site for this station.
	3. The nearest range of hills is 70 miles distant near Deig, commencing near Delhi, and running is a S.E. direction into Central India. Probable height, 2,000 feet.
	4. The station is partly bounded on the east by the Jumna, and partly on the N.W. by a deep nullah, which is dry except during rains, when the river suddenly rises; the nullahs become choked by back water from it, and as a consequence the low lying ground is overflowed, especially the plain to the S.E. of the cavalry lines. Last year this occurred only once and lasted 12 hours, when the flood began to drain off. The station and its vicinity is full of broken ground, and nullahs that carry off the surface drainage of the country. In part, the cantonments are built in the confluence of them, and during the dry season they are receptacles of all manner of filth. There is also a large excavation, say 200 yards square, about 400 yards south-west of cavalry barracks, which is full of water during the rains, but is now dry and fissured. It is close to two brick-kilns, and the clay for them is taken out of it. All this must be very injurious to health.
	5. The station is encumbered with trees, interfering with ventilation, and the large filthy city of Muttra is on the N.W., from whence the hot wind blows, and on all sides it is surrounded by higher country. The temperature of the buildings is considerably raised by their being exposed to reflected sun heat. The station is not more exposed to winds than other inland stations.
	6. The surrounding country is cultivated, but the land on this side the river being poor, only the hardiest crops are sown. Across the river the land is rich and bears all kinds of grain. There are no works of irrigation near the station. Water is obtained for the ground from wells. The quantity used is not excessive nor injurious to health. The country is not a rice country, and neither hemp, flax, nor indigo are cultivated.
	7. The large city of Muttra is three-quarters of a mile distant.
	8. The surface of the ground occupied by the station is sandy. The subsoil is kunkur (nodules of limestone). The officers lines are those which have been occupied during the last 50 years by the officers of native cavalry regiments, and the barracks are built on the site of the old native lines or huts.
	9. During the dry season water is found at 15 or 20 feet below the surface. The depth to which it rises in the rainy season is not known.
	10. Water lies on the surface until it evaporates to the front of Artillery Park, and on one or two places near the Delhi road, also between cavalry and artillery lines, and in several parts of the nullah to rear of the artillery. Water runs freely off the remainder of the station. The drainage from the ridge around the station passes through the station en route to the river.
	11. The water supply of the station is derived from wells. It is not stored in tanks.
	12. Any amount of water is available from the river, and also from numerous wells. In the west of the city and in the Sudder bazaar the wells contain large quantities of sulphureted hydrogen. This is, I believe, owing to their low situation, and consequent imperfect surface drainage. The natives drink the water from these wells, and do not appear to suffer from it. In the station some of the wells contain good, clear, wholesome water, whilst others perhaps close to them are impregnated with salts, and are avoided by the natives as causing eczema and other skin diseases. There is abundance of good water from the pure wells. The others are known and easily avoided. Water is raised and distributed for use by ropes and leather buckets, partly by manual labour and partly by bullocks. It is quite good enough.
	13. No other topographical points require to be stated.
	14. New stations are selected by a committee of two military, one civil, two medical, and one engineer officer. As far as my experience goes in the plains (I know nothing of the hills), the examination is a very superficial one, and I never heard of a committee being called to account for a careless selection, although there are but too many instances of such all over the country; this station for instance. I would insist on the committee stating in their report the number of miles they had travelled round the proposed site; the number of hours they had been so employed; the number of villages they had examined; their condition as regards the health of the inhabitants; the number of inhabitants subjected to medical examination, and the results; and I would hold the committee severally responsible for any glaring oversight. If there should be no wells on the proposed site, one or two ought to be sunk to ascertain the quality of the water before it is finally fixed upon.

MUTTRA, BENGAL.

References to Subjects and Queries.	REPLIES.
II. CLIMATE.	1, 2. There are no meteorological instruments nor records at the station. 3. With regard to the climate, since I have been at the station (I arrived in January last) there has hardly been a drop of rain. During January, February, and March, high westerly and northerly winds prevailed. There has been neither fog nor damp, nor excessive cold. It is now excessively hot. *Lowest* range of a thermometer in a good house, 93° F. In the hospital it is seldom below 98° F., and in the barracks much higher. There is neither tree, planting, nor canal irrigation to affect the climate. Just now the air over the entire district is a mass of dust, sometimes obscuring the sun even. But this is the normal state of the plains of India before the rains. The climate produces heat apoplexy, hepatitis, and continued fever. As a precautionary measure the men ought to be confined strictly to barracks, or under a good roof from 8 a.m. till sunset. Their diet ought to be lighter, less meat, light puddings, and plenty of fruit and vegetables being substituted for it. At this season of the year there cannot be too little drill. The most healthy months at the station are from October to March inclusive, and the amount of sickness is pretty equal and moderate. April and May are the sickliest months; continued fever and hepatitis being the prevailing diseases. 4. The healthiest adjacent district is that already described. The drainage is natural and the water supply would be from wells. As an illustration of the influence of elevation in the present station, the artillery are higher than the cavalry, and the sickness per cent. in the latter is more than 5½ times as great as that of the former; and the mortality is 2·38 per cent. to 0·99. As the whole station is low and in every way faulty in situation, the change could not be otherwise than advantageous. I know of no reason against its adoption, save the necessity of abandoning the cavalry temporary barracks, and the artillery antiquated permanent ones. 5. As regards the comparative healthiness of other stations at which I have served:—In 1842 the rice fields of China became unhealthy, when, owing to the irrigation being stopped, the land began to dry up and fissure. As long as the fields were under water there was but little sickness. *Berhampore* in 1843:—Station lower than the river: covered with tanks, bounded on one side by the river Hoogly, and on the other by extensive swamps; it was a very deadly place for Europeans: principal disease, remittent fever. *Benares* and *Ghazepore* in 1844; the former inland, sandy soil, and very healthy; the latter on banks of river, stiff clay soil, and that year very deadly: principal diseases, cholera and remittent fever. *Shahjehanpore*, all 1845 healthy. City of *Lahore*, first half of 1846, bad accommodation. City filthy and drainage very defective. Very sickly; remittent and intermittent fever, bowel complaints, large boils, and hospital gangrene prevailed. *Loodiana*, 1847:—Sandy soil, open country, was then healthy. *Moherim* (Jullundur Doab) 1848–49:—Open country; station on rising ground; soil sandy; subsoil boulders; very healthy. *Peshawur*, from December 1849 to July 1858:—Station on lowest part of the valley, with an extensive marsh close to it. Soil, stiff yellow clay, without a particle of sand in it. The entire valley extensively irrigated by large rivers and canals, and the station itself too freely irrigated by canals. The station was very unhealthy, but since a belt of trees has sprung up between it and the marsh, a decided improvement has taken place. Principal diseases, continued, remittent, and intermittent fevers, hepatic complaints, bowel complaints, and heat apoplexy. *Meerut*, 1859:—Sandy soil, tolerably healthy. *Muttra*, since January 1860:—Sandy soil, tolerably healthy, and with a proper site would, I believe, be remarkably so.
III. SANITARY CONDITION OF STATION.	1, 2, 3. Plan of station and barracks. Artillery barracks constructed previous to the mutiny; cavalry barracks in 1859–60. 4. The following table gives the accommodation:—

	Regulation Number of Men.	Dimensions of Barrack Rooms.				Cubic Feet per Man.	Superficial Area of Floor Space per Man.	Height of Beds above Floor.	Windows.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	5. The barrack-room windows are on opposite sides; hung on hinges, opening at the centre inwards. There are inner verandahs to each barrack 8 feet wide and 12 feet high. The verandahs are not used as sleeping places. There are no jalousies. 6. Ordinary cots with twine bottoms are used for barrack bedsteads. In tents on the march men are supposed to have dry straw to spread their bedding on, but the allowance for its purchase, 8 annas a day per troop or company, is so small that the men usually have to go without it, and spread their carpets on the bare ground. Such was the case when this regiment marched here. To remedy this, allow a certain weight of straw per troop or company, without respect to its price, which varies much. The barrack bedding consists of a cotton lined quilt, a blanket, two sheets, and a small carpet. 7. Tents are constructed with double poles and double roofs, with a space of 12 inches between them. Tents are made of cotton canvass; they are 10 feet high to the ridge poles. The side walls are $5\frac{1}{4}$ feet high; they are 21 feet long and 18 feet wide. Cubic space per man 180 feet. Superficial area per man $23\frac{3}{4}$ feet. Each tent holds 16 men. 8. Barracks and guard rooms are ventilated by saddles carried along the ridges their entire length. The only means of ventilating tents is by throwing the doors open. These means of ventilation are not sufficient for any of them by night. In tents, where the doors are closed during dust storms or very cold weather, there is no ventilation. Tatties made of kus kus, a scented fibrous root, and costing 8 rupees each, are used for cooling the air. 9. The materials used for constructing barracks are chiefly unburnt bricks and cement. 10. Various materials are used for flooring. Nos. 2 and 3 barracks in the European cavalry lines have lately had their floors raised two feet above the level of the ground, and a flooring given of stone slabs $1\frac{1}{2}$ inches thick over two courses of burnt brick. No passage of air beneath. 11. The materials and construction are tolerably suitable. The barracks might be better ventilated by having a row of small windows just below the eaves of the roof; they should be hung on pivot hinges, and opened and closed by pullies and ropes. The ventilation of tents is a more difficult question; they might, however, be ventilated by means of canvass tubes, something like wind sails on board ship suspended from the ridge poles, and passing through the inner roof down into the tent; the upper mouth of the tube should open between the roofs where there is almost always a draught of air. In executing repairs of barracks, mason's work is promptly done by the executive engineer. Minor repairs to doors, windows, &c. are done by the barrack master or serjeant, not very promptly. The senior medical officer is supposed to be responsible for the general sanitary state, but he can only represent, and his representations are frequently attended to very tardily. The walls are swept down once a fortnight, and limewashed once a year, or oftener, if recommended by the medical officer. 12. The lavatories, three in number, are only temporary sheds built on poles (what is commonly styled wattle and dab), and there is one plunge bath of similar construction, only lighted and ventilated by the doors. 13. The cook-houses are of masonry with tiled roofs. Copper cooking vessels, iron roasting spits, water supplied by water carriers. Refuse water collected in reservoirs and carried away by hand. Linen is taken to the river, washed there, and dried in the sun. It is the usual plan in India, and answers very well. 14. The privies are merely tiled sheds. The contents are removed by mehters. 15. The outbuildings, except the cook-houses, which have grated windows, are only lighted and ventilated by the doors. Barracks lighted at night by oil lamps, four per troop. 16. The drainage arrangements consist of temporary drains varying from $1\frac{1}{2}$ to $4\frac{1}{2}$ feet deep. They are quite sufficient for readily conveying away surface water. The drainage from lavatories, baths, and wash-houses, fluids from cook-houses, privies, and urinals, are carted away in vessels. There is no part of the barracks damp. There are no cesspits. 17. As regards surface cleansing, about the barracks the surface is kept tolerably clean. It is swept twice daily, and the refuse, &c. is taken to the brick-kilns. But in the officers' lines sweeping is unknown, and the roads and compounds are very filthy. 18. Of late the surface of the cantonment has been kept free of vegetation. The station is full of old walls of dwelling-houses and outhouses, destroyed during the mutiny, which ought to be removed. 19. The bazaar is an accumulation of huts without any attempt at order. The drainage is bad; the ventilation worse; water supply execrable. All the wells are brackish from nitre oozing into them from the surrounding earth, which is contaminated with all sorts of impurities, tanners' refuse included, as a host of these people carry on their trade in the midst of the bazaar. Latrines are hardly known. In short the bazaar is a mass of filth. The bazaar is in charge of a native Kutwale, but his means are inadequate for enforcing cleanliness. Indeed I do not see how cleanliness could be enforced in such a place. It ought to be razed to the ground, and a new one properly laid out, built on a new site. There are not any native houses nearer than this bazaar. There is no nuisance from winds blowing over native dwellings. 20. Cattle are slaughtered not 200 yards N.W. from artillery barracks. No regulations. Offal taken away. No nuisance experienced. 21. Horses are picketed in rear of the bazaars on sloping ground, about 400 yards from the nearest barrack. The manure is sold or burnt. 22. The stables of the station consist of open sheds on brick pillars, tiled roofs. Cavalry stables due west, not more than 100 yards distant, and about 120 yards south-west of hospital. Artillery stables are 200 yards north of barracks and hospital. No ventilation in the roofs of any of them. There are no dung-heaps; the manure is burnt in brick kilns hard by, or used for riding-school, and for exercising ground for sick horses. Picketing grounds are close to the stables. 23. The married quarters are sufficient for married non-commissioned officers. Married men of cavalry occupy old cavalry barracks on bank of river. They do not occupy barrack-rooms with the men. In the artillery, married people occupy barrack-rooms with the men.

MUTTRA.
BENGAL.

References to Subjects and Queries.	REPLIES.
Officers' Quarters.	1. Cavalry officers' quarters are between barracks and river, amongst the confluences of the ravines described above. In the heart of them are situated two burial grounds, one Christian and one Mohammedan. The artillery officers' quarters are between the barracks and the filthy Sudder bazaar, close to the latter on low raviny ground, and the roads and enclosures of both are in a filthy neglected state. Both burial grounds ought to be closed up, cleanliness enforced, and all ruined houses levelled.
IV. HEALTH OF TROOPS.	1. The station has only been re-occupied for a year. The artillery have been healthy; the cavalry not so. District is healthy, and the villagers living on the banks of the marshes, not 100 yards from them, are healthy, and spleen disease is rare amongst them. 2. During the months of March, April, May, and December, small-pox rages in the city, which is very filthy, and there is great mortality amongst children. 3. Sandy soil, open country, and freedom from excessive irrigation, are causes of healthiness of the district. Dirt, crowding, and the absence of all precautions against spread of contagion, are causes of the great prevalence of small-pox in the city. 4. The following stations were occupied by the troops before coming here:— *Cavalry.* Meerut, 16 months. Left, December 28th 1859. Their health there was tolerable. Fever, bowel and hepatic complaints were the principal diseases. Health good on arrival here on January 8th, 1860. Ephemeral fevers and venereal complaints the principal diseases since arrival. *Artillery.* Bareilly, 4 months. Left, October 10th 1848. (Query 1858.) Health there, indifferent. Arrived here, 3rd April 1859. Good health. Chiefly intermittent fever since arrival. The cavalry lines here are more unhealthy than the artillery, from their lower position. 5. Troops are not camped out at this station. 6, 7. No experience. 8. I approve of hill stations for troops. 9, 10. No experience. 11. The best period for residence at hill stations is from April to the end of November. A three years' residence at such stations would enable troops to derive the most benefit from them. 12, 13. Not aware of any period of residence at hill stations beyond which troops would be more exposed to disease on returning to the plains, nor of any precautions being required on returning. 14. With reference to the best manner of combining the advantages of hill stations with service in the plains, I am decidedly in favour of locating troops on hill stations, with short periods of service in the plains. As regards change of station in the plains, if the station be a healthy one, it does not conduce either to the health or happiness of the troops to remove them quickly. With an unhealthy station, as a general rule, the converse holds good. I say as a general rule, because in some malarious climates, Peshawur, for example, I believe the troops become acclimatized and reconciled to them. 15, 16. No experience. 17. There is no ground for a hill station near Muttra. 18. The most healthy stations I have been at have had sandy surfaces, but I cannot say what the subsoil of all of them was. One of the healthiest had flint boulders, and this station has kunkur (limestone nodules). 19. The best age for soldiers proceeding to India is between 20 and 30, and the best period for arriving in India is early in October. They should be sent at once up country, or (20) to the hills. 21. Troops are transported to the interior by railway, bullock train, and river. Marching would be preferable, say 12 miles a day. According to the present system, the men are frequently sent up country in small detachments; they sometimes travel *day and night during the hottest weather;* sometimes without any medical aid, and sometimes in charge of a hospital apprentice of *three months' standing.* Many of my fatal cases last year were attributable to this cause solely, namely, to exposure and want of proper treatment. 22. I consider from 12 to 15 years as the period a British soldier should serve in India. 23. In my experience I have found medical boards anxious to act conscientiously, and when there has been a difference of opinion, the majority decided. 24. February is the most desirable month for invalids to leave India for home.
Diseases.	1. There are health inspections every alternate Saturday for cavalry, none for artillery. 2. There is no scorbutus. 3. The proportion of hepatic disease usually under treatment is about 2·84 per cent. of the admissions. On the accession of hot weather it becomes much greater. This, I believe, is owing to the excretory functions, particularly those of the skin, not having adapted themselves to the sudden change; for although the heat increases their affections do not increase with it. Thus, in May 1859, the proportion per cent. of hepatic affections to all admissions was 10·31; in June, 3·49; and in July, 3·29. The majority of acute hepatic affections are, I believe, idiopathic. Though doubtless some depend on obstinate or neglected cases of remittent and intermittent fever, inducing congestion, &c. The prophylactic measures are avoiding direct solar exposure, guarding against chills at night by wearing flannel belts, and other appropriate clothing, and cutting short these fevers by active treatment. 4. No experience. 5. The proportion of constantly sick from venereal disease to the sick from other diseases is 14·10 per cent. or 1 in 7·5. To diminish this evil, no cantonment ought to be nearer than four miles to a city, for as long as the men have access to one no precaution will preserve them from infection. Make them dependent on the cantonment bazaar, and then, I believe, lock hospitals would be highly advantageous. 6. As regards the occurrence of epidemic disease, the station has only been re-occupied for a year, and there have been no diseases among the troops of an epidemic or endemic nature. Cases of fever which have occurred are such as are met with all over India. The proportion of admissions from these diseases to the total admissions have been, fever common continued, 1 in 52·8; intermittent, 1 in 6·6; dysentery, 1 in 6·6; cholera, none; small pox, 1 in 155; rheumatism, 1 in 17·6. From all of them the admissions have been 1 in 3·7 of the admissions, and there have been no deaths.

References to Subjects and Queries.	Replies.
V. Health of the Troops: *Diseases—cont.*	7. No information, except that the city is very filthy, and that small-pox prevails in it in March, April, May, and December. 8. No information. 9. Quinine has not been tried as a prophylactic at this station. 10. For the prevention or mitigation of epidemic disease at this station, enforce strict cleanliness throughout cantonments, including officers' compounds; close the present graveyards, and have others outside cantonments; establish an efficient sanitary police in the bazaars, or, better than all, remove the station while you can, *i.e.*, before permanent buildings have been erected, to an eligible site, for a reference to the topography of the station ought to convince any one that one worse than the present could not possibly have been selected; and if a new site should be determined upon, make the engineer forfeit his commission if he places a single brick or lime kiln within two miles of the boundary pillars. When a new station has been decided on, the first thing an engineer does is to commence to burn his bricks, and to save the expense of carriage he places his kilns as near to his work as practicable. By-and-bye when the kilns have been well lighted, the community is surprised at their noxious exhalations. Stable litter, the bones of dead animals, such as horses, camels, elephants, and dried ordure, human included, being the ordinary fuel used in them. The engineer is appealed to, but he pleads, and generally successfully, the loss to Government, and the delay in the construction of the barracks, their removal would entail, and so they are allowed to remain, poisoning the cantonment. At Peshawur, they thus burnt all round cantonments for 7½ years, and it is worthy of remark, that since they were allowed to burn out in 1857, the health of the troops there has considerably improved. Whilst I am now writing, the smell from the kilns at this station is very disagreeable; but it is during the cool still night that it is most intense, often entailing the necessity of closing the doors to keep out the abomination.
V. Intemperance.	1. The artillery soldiers at the station are very intemperate, the cavalry temperate. About 10 per cent. in the artillery are confirmed drunkards. There are no confirmed drunkards in the cavalry. 2. One in 91·5 of the admissions into hospital are caused directly by intemperance, none indirectly. There are no materials for a statistical table on this subject. Drunkenness is punished as an offence. 3. Spirits are sold in the canteen, and also in the bazaar, surreptitiously. Two drams of rum, 24 per cent. under London proof, may be had at the canteen. Any amount of bazaar spirits is obtainable. Spirits form no part of the soldier's ration, except on occasions of extraordinary exertion, such as sometimes occur on active service. No spirits are sold in canteen before dinner. They are seldom given as a ration to convalescents, except to confirmed drunkards; if any, it is brandy, from four to six ounces. No other drinks injurious to health are sold in the canteen or bazaar. 4. The consumption of spirits is not as a general rule conducive to health, but at times it is absolutely necessary for convalescents. It is not conducive to discipline, but it would not do to withhold it from men long accustomed to its use. 5. It would be beneficial to abolish the use and sale of spirits; but it is a measure that should be gradually introduced, for there are many confirmed dram drinkers who would not exist without it. Prohibit its use to all men under 30 years of age, and to all men who may *hereafter* arrive in the country under 30 years of age. 6. Malt liquor and wine are decidedly the best for men who have not been long used to spirits. 7. Coffee, tea, lemonade, and similar drinks are much used at the station. I consider their influence good as auxiliaries to malt liquors. 8. It would be beneficial to suppress altogether the spirit ration, but for reasons before assigned, it ought to be done gradually. 9. It would be beneficial to permit only beer, coffee, tea, lemonade, &c., to be sold to the troops, except in the case of men long used to spirits. 10. I have no recommendations to make on these points. 11. There are no canteen or bazaar regulations. Only beer and spirits are allowed to be sold.
VI. Diet.	1. There are no Queen's British troops at the station. For the European troops in the Indian army the ration is— 1 lb. bread; 1 lb. meat, generally beef; 4 oz. rice; 2½ oz. sugar; ⅝ oz. of tea, or double that quantity of coffee, alternately; 1 oz. salt; 1 lb. vegetables; 3 lbs. firewood. Mutton is substituted for beef occasionally. The ration is inspected by the orderly officer and quartermaster. 2. A complete ration is provided at 3 annas 4 pice, and, in addition, the men mostly pay 1 anna each a day for extra necessaries. They have three meals: breakfast of tea or coffee, bread and rice, at 8 a.m.; dinner of meat, soup, and vegetables, at noon; and supper of tea or coffee and bread, in the evening. 1 lb. of the vegetables of the season are included in the ration. 3. It would be beneficial to reduce the quantity of meat during the hot weather, substituting light puddings, fruit, &c. There is no arrangement for preventing any part of the rations being disposed of. 4. There is a cookhouse to each troop, supplied with a certain number of copper cooking pots, &c. The kitchens are clean, and inspected daily by the orderly officer. They are badly lighted and ventilated. There is plenty of water. Food can be boiled, baked, stewed, and roasted. The cooking is tolerably done; but there is great difficulty in procuring good cooks at this station. The men have no refreshment before the march, but half way the regiment is halted, and coffee and biscuits are ready. 5. Very few of the men would work in gardens, unless Government insisted on their supplying themselves with vegetables, and then potatoes, their staple vegetable, cannot be grown at many stations, Peshawur, for instance. These gardens should be under a regimental, station, or bazaar committee.

References to Subjects and Queries.	Replies.
VII. DRESS, ACCOUTREMENTS, and DUTIES.	1. The soldier's dress consists of jacket, a tunic, and overalls of cloth and cotton, according to season, with the usual accoutrements. The dress is suitable to the climate and duties. No suggestions as to improvement.
Duties.	1. Men should, most decidedly, be thoroughly drilled at home before being sent to India, especially mounted soldiers. 2. The usual routine of duties is one hour in the morning five times a week, and one hour in the evening at either drill or stables four times a week. Trained soldiers do not suffer from this, but recruits suffer much. The best remedy is to drill them at home. Daybreak and sunset are the best times for drills and parades during the hot weather. For marches, the men ought to arrive on their new ground by sunrise in hot weather. The men have usually four or five nights per week in bed. 3. Guards are mounted close to the barracks. They last 24 hours. Sentries relieved every second hour. There are check calls every hour from 9 a.m. to 5 p.m. during the hot weather, in order to keep the men from roaming about in the sun. Roll calls at watch setting, at 9 p.m. No roll calls by night. The night guards, with proper precautions as to clothing, *i.e.*, that the men are not too warmly nor too coolly clad, are not injurious to health.
VIII. INSTRUCTION AND RECREATION.	1. At this station there are neither ball courts, skittle grounds, schools, library, reading room, nor day room. The two first proposed, but not decided on. There are no workshops, theatre, nor gymnasium. There is one soldier's garden for the artillery, but there are no European garden tools, although indented for a year ago, and the men cannot use the native tools. There are hence no means of instruction or amusement. 2. To supply means of occupation, establish commodious well-lighted and ventilated workshops provided with ordinary turning lathes, carpenters and other tools, and encourage the men by purchasing their work at a fair price. Work of this kind is in great demand, as is also saddlery, cooper's work, &c., and as European workmanship is confessedly superior to native, the state would be doubly benefited by thus employing the men; first as regards the health and morals of the men, and next as obtaining more durable work. 3. I am not prepared to say whether savings banks would be beneficial; their establishment has been ordered, however. 4. There is not sufficient shade at the station to enable men to take exercise during the heat of the day without injury to health.
IX. MILITARY PRISONS.	1. The prison consists of four cells, about 14 feet square and 12 feet high, arranged in pairs, and entered from a common passage. They are ventilated by loop holes about 9 feet above the ground. There is no verandah round the building, which being of burnt bricks laid in lime cement, and faced with white lime cement, absorbs the heat and renders the place uninhabitable during the hot months. A new one on improved principles has been sanctioned for the cavalry, but its construction is in abeyance, pending a reference for a new site for the station.
X. FIELD SERVICE.	1. I have no local regulations on this head. 2. I have never been consulted on the conduct of the line of march, bivouacking, camping, &c. 3. The usual practice is that the quartermaster goes ahead and selects the camping ground. I know of no general sanitary regulations on this head. There is generally an abundance of water. The medical officer has no power in these matters, and he would lay himself open to a rebuke if he interfered. I have known a superintending surgeon to be most severely reprimanded by a general officer for presuming to remonstate against his sending a party of soldiers as *a sanitary experiment* from one station to another, distant 100 miles at the hottest time of the year. Give the medical officer power in these matters, and when his services can be spared, let a medical officer go ahead with the quartermaster to select camping ground, and let him have power to enforce the selection. 4. No information.
XI. STATISTICS OF SICKNESS AND MORTALITY.	1. No information.
XII. HOSPITALS.	1. Plans. 2. The new female hospital is used as a male one for cavalry. It is due north (nearly) of the barracks, and distant 200 yards from them, and 400 yards from the stables. The artillery hospital is close to the barracks, distant about 30 yards from them and 200 yards from the stables. Both hospitals are some distance (say 400 yards) from any bazaar or non-military dwelling. The cavalry site is well open and freely ventilated. The artillery not so well off, being too near the city. The site of the cavalry hospital is the highest spot in their lines, much higher than any of their barracks. It is well drained (naturally), there is a very large excavation, and a good deal of raviny broken ground to the N.E. of it, and not 200 yards from it. The artillery has a large nullah dry, except in the rains, close to it due west. 3. The water supply is abundant and wholesome. 4. The refuse water and other impurities are collected in cesspools and removed daily. There is no drainage. 5. The hospital wards are 2½ feet from the ground, and there is no perflation of air under the floors. The roof water flows off by natural drainage. The whole drainage is natural and quite sufficient. The cavalry hospital is built partly of burnt and partly of unburnt bricks, the walls and roofs single, the latter tiled and not sufficiently thick to keep the building cool. The artillery hospital is thatched and cooler. There is an outer verandah all round both hospitals 8 feet wide. It constitutes a fair shelter. The inner verandahs are very frequently used for sick. The hospitals are single storied.

XII. Hospitals—*cont.*	The following table gives the ward accommodation :—

Date of construction of Artillery Hospital, before the mutiny :—New Cavalry Hospital, 1858. New Female Hospital, 1859.

Wards or Hospital Huts.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patients' Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Ft.	Ft.	Ft.			Ft.	Ft.			
Artillery Hospital -	16	43	24	22	22,754	1,422	64½	—	6	5	4
Temporary Hospital, European Cavalry, two wards.	16	50	24	18	21,600	1,350	75	—	12	6	4
New Female Hospital, European Cavalry, two wards.	—	31	24	21	15,645						
Three wards - -	—	16	24	21	8,064						

The cavalry hospital is placed so as to receive the full benefit of the prevailing winds. The artillery is too close to the city.

There are no windows. All the doors open at the centre, are opposite to each other, and well calculated for ventilation.

The wards are ventilated by the doors and saddles on the roof. Dormer windows would be a great improvement.

There are no jalousies or jhilmils.

7. During the rains thermantidotes are usual for cooling the air. They are a species of huge winnowing machine, fixed to every third and fourth doorway on one side of the building, and the air has to pass through wet kus-kus tatties, fixed to holes in their sides, before it enters the machine, and is blown into the building.
8. No means of warming are required here. The walls are swept down weekly, and white-washed annually, or as often as the medical officer requires it.
9. The position and structure of the privies are shewn in the plan of the female hospital. Copper stool pans are used in the privies; these are emptied as soon as used, and the contents carted away every morning for combustion in one of the many brick kilns that surround the station, and help to poison the air.

   The drainage from the privies runs into a cesspool close by, as seen in the plan of the female hospital. It is not allowed to accumulate there, but is baled out. There is no supply of water save what the water carriers (bheesties) afford, and at times the privies are offensive.
10. There is a lavatory room, as shown in the plan of the female hospital, supplied with earthern pans or basins, and some earthen vessels filled with water, towels, rollers, &c. It is not a convenient arrangement. There ought to be fixed basins with plugs in their bottoms, and cocks above to supply water from a cistern.
11. There are no means of bathing save a moveable warm bath and a slipper bath. There ought to be a plunge bath.
12. The foul linen is generally boiled in a large copper pot. It is subsequently taken to the river, and washed, and then dried in the sun. The plan answers very well.
13. The storage is sufficient and dry.
14. The bedsteads in use are common cots with nawai (broad tape) bottoms. Mattresses and pillows, some stuffed with tow, others with cotton, sheets, blankets, quilts, pillow cases, and a small bedside carpet for each bed.
15. The kitchen is due north of the hospital, 40 yards distant, a building of brick and lime, with tiled roof, and brick on edge flooring, a separate fire-place for each cooking vessel, the usual arrangement in this country; copper pots, frying pans, gridirons, skillets, &c. All copper vessels are tinned twice a month. The means are quite sufficient and the cooking is properly done and sufficiently varied.
16. No reply.
17. An hospital serjeant is provided for each hospital, and waiting men when required for bad cases; also native ward coolies. The attendance is not sufficient. More European supervision is desirable to keep the natives to their work. It is impossible for one man to be always on the alert, and in times of increased sickness the apathy and laziness of the natives is always embarrassing, and a source of complaint and discontent to the patient.
18. The sanitary condition of the hospital is fair, and no epidemic disease, hospital gangrene, nor pyæmia, has appeared in any part of it.
19. As a general rule, for I know of no exceptions in the hospitals in this country, they are badly lighted and gloomy. They are usually lighted, and that indifferently by the doors; these are battened, with a couple of panes of glass in them, near the top, and when from any cause they are closed the building is in almost complete darkness. Have the doors glazed down to the centre, have windows above the verandahs, as recommended for the barracks, and also have dormer windows in the roof. A hospital cannot be too cheerful or comfortable in appearance.
20. The sick are taken out on elephants, *i.e.* those who are equal to the exertion, others stroll about the outside of the building, and any very weakly man whose case requires change of air, is taken out in the dooly, if not otherwise engaged, which it seldom is in ordinary times. There is no fence nor any trees near the hospital; the men walk in the shade of the building, where the ground is level, and they have forms with backs and arms to sit upon.
21. For the women and children of the cavalry a portion of the old male hospital has been set apart; but for the artillery there is no arrangement. There ought to be a hospital for artillery women and children.
22. There are no special local hospital regulations.

References to Subjects and Queries.	REPLIES.
XII. Hospitals—*cont*	23. At stations the powers of the medical officer are complete; he has full control over his hospital, and it is his own fault if it is not properly kept. His requisitions for repairs, whitewashing, &c., are generally promptly attended to, and his resources as to diet, comforts, &c., are only limited by the resources of the station. He can order champagne if he deems it absolutely necessary. In camp the sanitary position of his hospital depends upon the position taken up for the general camp, and about that I was never yet consulted. 24. There are no such buildings as convalescent wards or hospitals in India that I am aware of. I do not think they would be an advantage, but quite the contrary. When a man is convalescent his great anxiety is to get back to his barracks, his box, and his comrades. Such a building would be looked on as a sort of penal settlement.
XIII. BURIAL OF THE DEAD.	1. The burial ground at the station is nearly in the centre of the cavalry officers' lines. It is to leeward of all barracks, but well to windward of some of the officers' houses, many of which are close to it. 2. It is 140 yards square. The soil stiff alluvial, of great depth. The river most probably flowed over it at some former period. The drainage is natural. I cannot say if decomposition takes place readily. It is tolerably well kept. 3. The graves are 8 feet long, 2½ feet wide, and 7 feet between each. They are 8 feet deep, and are never reopened. At ordinary times interment is compulsory from 12 to 16 hours after death. During epidemics it is never longer than 12 hours, often under 4 hours. The native burial ground, which abuts on the European, is not often used. I have not seen a grave opened. The graves are much about the same distance apart as in the European. The ground is about 40 yards square. 4. I am not aware that the burial ground is ever offensive. In the hot weather, if a man dies, say at 1 P.M., he is buried, if possible, that evening; if he dies in the evening he is buried next morning. In the cold weather there is not so much haste. 5. The dead of the camp followers, or bazaar people, are disposed of according to caste. They are either burnt, thrown into the river, or buried in native burial grounds, at a distance from the station. They are not kept long after death. 6. No injury to the public health accrues from the present practice. 7. I would recommend the closing of the present burial grounds, European and native, and establishing others outside the station.

(Signed) R. A. MASTER, Colonel, 2nd Regiment European Light Infantry, commanding at Muttra.
ARTHUR W. OWEN, Captain, Assistant Executive Engineer.
C. L. COX, F.R.C.S., Surgeon, 2nd European Light Cavalry.

I. TOPOGRAPHY.	1. The country surrounding the station is moderately wooded, and for the most part under cultivation. It is, generally speaking, flat and dry, with much kunkur; but to the west of the station it is low and swampy. There is a fair amount of trees, but no jungle that I know of in the vicinity of the station, which lies on the banks of the Ganges. 2, 3. The station and adjacent country are on about the same general level, and the nearest mountain range is the Kymore, distant about 60 or 70 miles. 4. The station lies on the left bank of the river Ganges, and the low ground to the west of the station is liable to overflow, I believe, during the rainy season; but I am unable to furnish any particulars on my own authority. There are numerous ravines and much broken ground to the west and north of the station, and several tanks in and around it, but I have no experience of their effect on the health of the inhabitants or troops. 5. The station is open. There are the usual gardens, but nothing to impede free ventilation. The temperature of the station is not raised by exposure to reflected sun-heat. The wind varies much between the east, north-west, and west. The station is quite out of the influence of the sea breeze. The east wind, according to my experience, affects the health of the native population very much, by bringing on attacks of fever, disease of the lungs, &c. 6. The country surrounding the station is chiefly cultivated, but there are no works of irrigation near the station. Rice is cultivated on the low ground close to the north side of the station. There is no law to prevent the cultivation of indigo or the preparation of hemp or flax near the station, but I have not seen them carried on myself. 7. The city of Ghazeepore is about one mile to the east of the station. 8. Underlying the surface earth of the station is a bed of kunkur, of greater or less thickness. The ground on which the station now stands was previously unoccupied by population. 9. Water is usually found during the dry season at a depth of from 18 to 100 feet below the surface; and at from 6 to 100 feet in the rainy season. 10. The rain-fall in the higher portions of the station flows readily away, but in the low lying grounds it remains until it evaporates. The ground surrounding the station being, as a rule, a little lower than the station itself, no drainage can consequently flow into the subsoil of the latter. 11. The water supply of the station is derived from wells, which are very numerous and contain good water. Open tanks are very numerous, as in all Indian stations, but the water they

References to Subjects and Queries.	Replies.

I. Topography—*cont.*

contain is not used for drinking purposes. I am unable to state the area of tank surface. Most of the tanks are dry, or nearly so, towards the end of the hot season. Tanks are not used both for bathing and drinking purposes, excepting those used by natives; in fact, tank water is not drank by Europeans. The water in the wells is very good and sweet, and does not seem contaminated by the amount of leaves that necessarily fall into open structures. Great nuisance proceeds from a large tank partially drained near the Gora bazaar, which must prove prejudicial to the health to a certain extent. The only means of preventing it is either to fill it up or thoroughly clean and arrange it and prohibit its use by natives for bathing and the many other purposes they are so fond of putting tanks to.

12. The water supply available for the station is very abundant, wells existing in all compounds. The water is clear, colourless, sweet, and without smell in general. The amount is perfectly sufficient, the quality good, and it is mostly soft, but no means for analysing it are available. It is raised by the usual bucket and rope, and distributed chiefly by bheesties in mussucks.

13. The existence of a large sand bank on the left bank of the Ganges, at the western end of the station, enclosing puddles of water in the hot weather, seems to render that portion of the station more unhealthy than the eastern end, where the current flows free under the bank. I know of no other points worthy of mention.

14. I have had no experience to enable me to say what amount of inquiry, as to topography, climate, diseases, sanitary condition, &c. is gone into before new stations, whether on the hills or plains, are selected.

II. Climate.

1. The following instruments for conducting meteorological observations, provided by Government, are in use at this station:—Thermometer, rain gauge, and within the last few months the aneroid barometer.

2. Table of Meteorological Observations from January 1856 to December 1859:—

Months.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Sun Temp.	Rain, Inches.	Remarks.
January	67·5	22·	78·5	56·5	90·26	·75	
February	71·8	23·75	83·75	60·	98·49	1·68	
March	82·	28·25	95·	66·75	111·3	·42	
April	88·1	21·75	99·	77·25	121·12	·42	
May	93·6	23·	105·	82·	125·41	·52	
June	92·	20·5	102·75	82·25	119·02	7·42	
July	89·75	14·	96·75	82·75	111·64	8·55	
August	89·1	19·	100·25	81·25	107·92	14·37	
September	86·7	13·5	93·	80·5	111·09	8·23	
October	82·37	17·25	91·	73·75	109·22	4·2	
November	73·75	23·	85·25	62·25	101·8	·3	
December	64·75	17·5	73·5	56·	89·88	·37	

3. From my limited experience I can give no authoritative opinion as regards the climate of this station; but as far as I have observed, it is not very variable. The cold season is very bracing. During the hot season, when the wind is from the west it is dry and hot, and there is much dust in the air, as is the case in all parts of this country. With respect to the effect of this climate on the health of European troops, I have had no experience. September and October are undoubtedly the most unhealthy months, from the prevalence of fevers of all kinds, dysentery, and affections of the lungs; this is my experience as regards natives alone. From January to April are the most healthy months.

4. There is no district near this station with a climate more conducive to health than that of Ghazeepore.

5. The following are the stations at which I have served, viz.: Chinsurah, Subathoo (in the hills), Umballa, Gorruckpore, Bustee (Gorruckpore district), Ghazeepore, Azunghur, and Jaunpore. Of these Subathoo was the most healthy, and of the others I have no reasons to form an opinion in favour of any one over the other.

III. Sanitary Condition of Station.

1, 2, 3. No replies to these queries.

4. Table of Barrack Accommodation.

* Nos. 8 and 9 were partially destroyed by fire on 28th March 1860. The roof has been raised since.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	5. Numbers 5, 6, 7, and 10 barracks are old stables fitted up for the accommodation of European troops, but are not provided with windows; numbers 8 and 9, lately destroyed by fire, are being re-roofed and provided with windows on opposite sides. All the barracks are furnished with verandahs on both sides, averaging 8 to 10 feet broad. These are never occupied as sleeping quarters by the soldiers. Two rooms for non-commissioned officers at each end of each building are provided with jhilmils. 6. Each man has a charpoy, a blanket, seleeta, sheet, and setringee. 7. The tents used here are of the usual regulation pattern, 16 being the number of men accommodated in each privates' tent. 8. The old stables used as barracks are provided with roof ventilators along the ridge, about three feet apart. The new barracks, numbers 8 and 9, are provided with one ventilator each, occupying the central third. These means of ventilation are by no means sufficient. The barracks are provided with punkahs for cooling the air, the average cost of which is five rupees. 9. The barracks are pucka buildings, with tile roofs, and the two new barracks, numbers 8 and 9, are provided with doors and windows. 10. The floors of the old stables used as barracks are partly of kunkur and partly of brick, and are raised about one foot above the level of the ground. It is proposed to floor numbers 8 and 9 with stones, raised one foot above the ground. 11. The old stables used as barracks are not at all adapted for that purpose, and to render them so it would be necessary to raise the roofs considerably, and supply them with doors and windows. Annual repairs to the barracks and cantonments are executed by the department of public works; petty repairs by the barrack department. The commanding officer is the person responsible for the sanitary condition of cantonments. The walls and ceilings of the barracks are cleansed and lime-washed once a year, or when the commanding officer considers it necessary. 12. Each barrack is supplied with a wash-house, the water being supplied from a reservoir behind the outer wall. Leading from each is a pucka drain, which empties itself into a reservoir outside, and this again is emptied twice a day by the filth cart. 13. The cook rooms are provided with fire places (choolahs). Water is conveyed to them by bheesties, and the refuse water is collected in a large reservoir, which is emptied twice a day by the filth cart. The clothes are washed by the dhobies at the various tanks and on the river's banks, and dried in the open air, and for this there is both water and space sufficient. 14. Each barrack is provided with a privy, drain, and reservoir, which is cleaned twice a day, the filth being removed by carts. 15. The barracks are ventilated by roof ventilators and lighted by means of the entrances by day, and at night by the ordinary oil lamp. 16. There are temporary drains running parallel to and between the barracks, with a breadth varying from one to three feet, and are only of use during the rains to carry off the water. The present drainage is not sufficient for carrying away readily and efficiently all surface water, and the drainage from the lavatories, cookhouses, privies, &c., but it is in contemplation to provide a sufficiency of pucka drains. There is not, that I am aware of, any part of any building used as a barrack or hospital that is damp. The fluid refuse of the barracks mostly sinks into the ground and the solid is removed by the proper attendants. There are no cesspools or foul ditches that I am aware of near the station. 17. The station is always clean, but I do not know that there is any special service for its surface cleansing. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c., interfering with the free ventilation of the station, bazaar, &c. 19. The bazaar at Ghazeepore is like all native villages. It is drained by surface drains, and the streets are moderately wide and are kept clean. There are no latrines, but the water supply is good, and the bazaar chowdra is held responsible that it is kept clean. As usual there is the mixture of good houses and dilapidated ones, but I do not know of any dung heaps or cesspits being in any of them. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. The slaughter-house is about a quarter of a mile from the station to the south-east, and no nuisance comes from it that I am aware of. 21. The European bazaar is a regular village a quarter to half a mile from any of the barracks. The manure of the bazaar horses is carried off and used by the natives. 22. The stud stables are close to the barracks, but well separated from the hospital. Their construction is the same as the barracks which were formerly stables. The manure, I believe, is used for the stud lands. There are no picketing grounds at this station. 23. The quarters for non-commissioned officers are sufficient. There are separate barracks for married men and non-commissioned officers.
Officers' Quarters.	1. The officers live in separate bungalows belonging to private individuals. I have no suggestions to make in regard to them.
IV. Health of the Troops.	1. Since I have been here there has been a great amount of fever, which during October, November, and December 1859 proved fatal to the native population to a most fearful extent. The prisoners in the jail, on the contrary, are in general very healthy. 2. Fevers, intermittent and remittent, dysentery, diarrhœa, small-pox, spleen diseases, and affections of the lungs are frequent diseases among the native population. 3. I attribute this unhealthiness entirely to the malarious nature of the climate. 4. The troops at this station before arriving here were stationed at Sasseram, Karomdah, and Dehree. During the thirteen months ending February 23, 1860, their health was good. The most prevalent diseases were fever and dysentery. They arrived here in good health on 1st March 1860, and cholera, fevers, and dysentery have been prevalent since that time. There is no portion of the men's present accommodation more unhealthy than another. 5. The troops at this station are never camped out. 6. I have been in charge of troops at the hill station of Subathoo. My experience of the effects on the health of troops of a residence there is most favourable, gained as it was from troops who had just returned from Burmah, viz., the 2nd Bengal Fusiliers in 1856. 7. No experience. 8. I approve most decidedly of selecting hill stations for troops.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	9. There is a form of diarrhœa and dysentery prevalent in Kussowlie and Subathoo most difficult to treat or cure, and I believe it is the same at most other hill stations. 10. The precautions to be observed in order to guard men on going to the hills from such attacks are those which protect them from sudden variations, especially proper clothing and the constant wearing of a non-conducting medium, such as flannel, next the abdomen. Diet should also be most carefully attended to as respects the nature of the vegetables supplied, which ought to be such as are readily digested, and the greatest care should be taken that all things are properly cooked. 11. With respect to the seasons best adapted for residence in the hills, much depends on the nature of the case, but as most benefit is to be expected from avoidance of the hot and rainy seasons in the plains, such seasons are the best for hill residence. I consider two or three years is the shortest period that would enable troops to obtain the full benefit to their health from a residence in a hill station. 12. There is no period of residence in the hills, that I am aware of, beyond which injury would be likely to be inflicted on the health of troops on their return to service in the plains. 13. There are no special precautions, that I know of, required for protecting the health of troops on leaving hill stations for the plains beyond such as are always necessary in the plains. 14. I am of opinion that it would be most conducive to the health of troops to locate them permanently in the hill stations. Frequent change of station in the plains is most beneficial to the health of troops and convalescents. 15. At Subathoo the barrack accommodation was most deficient, and the barracks were mostly built in positions that prevented proper ventilation. The hospital was very good in most respects. 16. I have no experience to show at what ranges of elevation above the sea the most suitable sites for hill stations may be obtained. 17. There is no higher ground near the station that could be advantageously occupied as a hill station. 18. No observations. 19. The best age I consider for soldiers to be sent to India is from 20 to 24 years, and they should land there either in November or December. The precautions for preserving the health of troops on first landing in India that I would recommend are a proper attention to their clothing, so as to prevent sudden chills so likely to arise during the great variations of temperature in the cold season, and the utmost precautions to prevent their drinking the common country liquor, and also a strict attention to diet so as to prevent over feeding. 20. I think that troops should be sent from the home depôts to India direct and not to any intermediate station, as much of their future health depends on the care and precautions taken on their first landing. It would be as well to send them to a hill station for the first hot season. 21. The mode of transport of troops from the port to the interior is from Calcutta to Allahabad, generally by steamer, and then by marching, or occasionally in the hot season by bullock train. 22. I consider from eight to ten years as a fair average for the service of a British soldier in India. 23. No experience. 24. Invalids about to proceed home should leave India in January, February, or March.
Diseases.	1. There is a medical inspection every Saturday at this station for the discovery of incipient diseases. 2. There has been no case of scorbutus among the troops at this station. 3. My experience at this station has been entirely amongst natives in the jail and military police hospitals, and in them I only remember in 13 months to have seen one case of hepatitis. Amongst the class of natives who come under my care it is a very rare disease. 4. I have never seen a case of dracunculus during a residence in India of 5½ years. 5. I have no experience with Europeans; but in the police hospital the cases of venereal disease are in the proportion of 1 to 12·6 of the other diseases amongst natives. No precautions against this disease are possible beyond punishing the patient himself. Amongst European troops my opinion is that the only way to keep venereal disease down is the careful supervision and licensing of women in the bazaar. In January 1856, before such regulations were introduced into the bazaar of the 2nd B. E. F., two thirds of the men in hospital were suffering from venereal. 6. The following are the diseases from which the troops at this station suffer, viz.— *Fevers.*—Intermittent, of the quotidian, tertian, and quartan types, remittent, and ephemeral. *Dysentry.*—Both acute and chronic. *Cholera.*—This year (1860) most severely amongst the Europeans; but lightly among the natives. *Small-pox.*—Very prevalent among the natives owing to their preference to inoculation. In the year ending 31st March 1860, there were in the M. P. Battalion 1,159 cases treated; 43 remaining from the previous year, and 1,116 fresh admissions, and of these 10 died. The following were the diseases treated, and the number of deaths from each disease:

Diseases.	Cases treated.	Deaths.
Fevers - - - -	547	1
Dysentery - - -	31	2
Cholera - - - -	6	4
Rheumatism - - -	34	0

7. The only zymotic disease I have met with is small-pox, and measles also is occasionally met with; but I have had no experience of it. Small-pox is most prevalent in April, May, and June. Great heat and in general east winds are the climatic and atmospheric conditions, which generally precede or accompany the appearance of the above diseases. In the native town

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	where these diseases prevail, the houses are nearly all alike crowded, ill-ventilated, and undrained; but the water supply is good. The prevalence of small-pox is undoubtedly due to the superstitious adherence of the natives to inoculation, whereby a constant hot bed of infection is maintained, which breaks out in the hot season into an epidemic of greater or less severity. 8. The total want of healthful occupation by the soldier when off duty must predispose him to anything like infection whilst in barracks; but whilst on the march or in the field I have generally found them more than ordinarily healthy, except when over fatigued by long marches. 9. Small doses of quinine have not been tried as a prophylactic against malarial disease. 10. General sanitary arrangements are the best prophylactic for the prevention of epidemic disease. As regards small-pox, nothing but the substitution of vaccination for inoculation will do good, and that must be a work of time or civilization, unless compulsory measures are introduced, an impossibility as regards the native population in general; but as respects residents in regimental bazaars compulsory vaccination would be a great benefit.
V. Intemperance.	1. The men of the right wing 77th regiment have been on the whole very temperate since their arrival at this station. There cannot be said to be any confirmed drunkards, as many, who in former days might have been deemed such, have become greatly reformed. 2. My duties being entirely confined to the civil department and the military police, I am unable to furnish information from any other source, and therefore cannot give any satisfactory answer to this query. Drunkenness is always punished as an offence. 3. Government rum is sold at the canteen; but none is authorized to be sold in the bazaar. Each man is allowed 2 drams a day by purchase. The spirit is of good quality; but none is taken by the men before morning parade, and such a habit would be most deleterious to health. It is never given as a ration to convalescents. No drinks other than intoxicating drinks are authorizedly sold in the bazaar or canteen. 4. The consumption of spirits in moderation can have no deleterious effect, especially after two or three years' residence in India; and in no way interferes with the efficiency or internal discipline of the regiment. 5. The sale of spirits in bazaars ought by all means to be abolished, but as sold in the canteens it can in no way be injurious. 6. Good malt liquor is preferable to spirits in any form, or any wine that could be supplied to troops at a similar price. 7. Coffee and ginger beer are much used at this station. The former taken in the early morning is, without doubt, best for the soldier in all points, but at other times, a moderate amount of stimulant is of great benefit, more especially to those some years resident in the country. 8. Beer, &c., might with advantage be substituted for spirits. 9. If beer of good quality could always be supplied as a rule, it is better than spirits, but I do not think that the total abolition of the sale of spirits would be advisable. 10. I have no recommendations to make on these points. 11. Each man is allowed to draw one dram of rum at 2 p.m., one pint of beer at 12, and one dram of rum at 7 p.m. There is no open canteen, the spirit and beer being obtained by indent, and issued at once from the tub.
VI. Diet.	1. The ration for European troops in the Indian army consists of meat, vegetables, and bread, of each 1 lb. Mutton is issued to the troops two days in the week, and beef the remaining days. The rations are inspected by the officer of the day, and the quarter-master. 2. A complete ration is issued to the troops. The men at this station have three meals a day, viz.:—Breakfast at 8 a.m., consisting of bread, coffee, and meat; dinner at 1·30 p.m., of meat and vegetables; and supper at 6·15 p.m., of bread and tea. 1 lb. of vegetables enters into the composition of the ration. 3. According to my experience the rations are sufficient. There are no special arrangements made for preventing the disposal of the men's rations, but the soldier's appetite is generally a guarantee for his consuming it himself. 4. There are two cook-houses at this station, and company cooks according to the strength of the companies, are provided. The kitchens are clean, and the water supply sufficient, but the ventilation and light are bad. The food is boiled and fried, and the cooking on the average is good, but much depends on the proper supervision of the cooks. The men complain at times that the coffee is imperfectly roasted. The men usually have coffee at the half-way halt when on a march. 5. The establishment of gardens for the cultivation of vegetables by soldiers near the station would be very desirable under the usual regulations for soldiers' gardens.
VII. Dress, Accoutrements, and Duties.	1. From March to November the troops at this station wear the khakee tunic and trousers, flannel shirts, woollen socks, and ammunition boots, wicker helmets with pugaries and covers; during the remainder of the year the ordinary English regimental clothing. It would be advisable to introduce clothing of an intermediate thickness for use during the night guards in the rains and at the commencement of the cold season. The present guard dress is the full dress of the season. The protection from sun and wet for guards when on duty is that of verandahs and great coats.
Duties.	1. It would be advisable to drill the men at home or at some intermediate station before sending them to India. 2. The routine of a soldier's duties is reveillé before daylight, parade at daylight with drill, varying from half to one hour in duration; evening parade in the cold season three times a week, and during the hot and rainy seasons, roll-call in barracks. The men do not suffer from the drill. The best time for drills, parades, and marches, is in the early morning. At present the men have four nights in bed during the week, but this is from increased duty on account of rifle drill, ordinarily it is eight or nine nights in bed to one out. Guards are mounted in the barrack square, and last from one morning parade to the next. There are roll-calls every evening in the hot and rainy seasons, and four times a week in the cold season.
VIII. Instruction and Recreation.	1. The only means of recreation at the station are one ball court and two skittle grounds, which are by no means sufficient to occupy the men during the wet season and heat of the day. In the hot and rainy seasons the men are restricted to barracks from 8 a.m. to 5 p.m. 2. The means of recreation, &c. at this station are so very limited, that almost everything in this way has yet to be done.

References to Subjects and Queries.	Replies.
VIII. Instruction and Recreation—*cont.*	3. A regimental savings' bank has already been established. 4. There is not sufficient protection from trees or other means to enable the men to take exercise without injury to health during the day. The verandahs, where existing, are too small, and are under water in the rains, and the only avenues are at such a distance from the barracks that the men, in order to reach them, must walk in the sun.
IX. Military Prisons.	1. The cells at this station are in a good condition.
X. Field Service.	1. There are no local regulations for field service that I am aware of not included in the General Presidency Regulations. 2. According to my experience, the medical officer has little or no power as regards the conduct of the line of march, &c. He is at liberty to offer suggestions, and that is all. 3. In most routes there are Government camping grounds set apart; otherwise, the quarter-master chooses the ground on the most elevated spot, near water and shade if possible. The medical officer may suggest or recommend alterations. 4. The sick are transported in doolies, which are allowed in the proportion of one to every ten men. If not sufficient, any means of conveyance that can be obtained, as carts, &c., are used for this purpose. Hospital supplies are carried on camels and carts. I have had no experience of the arrangements of other than regimental field hospitals, and the regulations by which I have been guided are those printed at length in the Bengal Medical Code.
XI. Statistics of Sickness and Mortality.	No information is conveyed under this head.
XII. Hospitals.	1. Plan. 2. The hospital is from a quarter to half a mile from the barracks, and still more from the stables, and entirely away from the bazaar and native houses. The site is open, and perhaps as good an one as could be chosen with a reference to the position of the barracks. 3. The water supply is good. 4. Pucka drains are used to convey away the refuse water and impurities of the hospital. 5. The buildings consist of single stories raised two feet from the ground on a solid base. The roof water runs into the drains, and the surface drainage is ample for all purposes. The roofs of the hospitals are tiled. No. 1 is built of pucka, Nos. 2 and 3 of kucha bricks, the plinths being pucka, as also the foundations. The walls are sufficiently thick to keep the hospital cool, the ventilation being effected by the roofs. All the buildings have verandahs of sufficient breadth to afford shelter from the sun's rays. The verandah of No. 1 is used for the accommodation of sick, &c., but not those of Nos. 2 and 3. The hospitals are single-storied buildings.

Table of Hospital Accommodation.

Total number of wards, 3.
Total regulation number of beds, 156.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.

„ 2 -	28	$83\frac{1}{2}$	25	$15\frac{1}{2}$	36,660	1,309	68·1	—	28	$6\frac{1}{2}$	4
„ 3 -	28	$83\frac{1}{2}$	25	$15\frac{1}{2}$	36,660	1,309	68·1	—	28	$6\frac{1}{2}$	4

	The hospital is so placed as to receive the full benefit of the prevailing winds. The windows open inwards, and their arrangement and construction are conducive to ventilation and coolness. 6. The buildings are ventilated by means of roof ventilators and jhilmils, which keep the wards free of odour and closeness at all times. 7. No reply. 8. The walls and ceilings of the hospitals are whitewashed whenever required on the requisition of the medical officer. 9. The privies, &c. are similar to those used in barracks. They are properly drained, and provided with reservoirs, and are not offensive. 10, 11. The lavatory arrangements are similar to those in the barracks, and the means of bathing the sick are sufficient and convenient. 12. The washing and drying of hospital linen are performed by dhobies. 13. The storage is sufficient and dry. 14. The bedsteads used in hospitals are similar to those used in barracks. 15. The kitchen is about 80 yards to the rear of the hospital. The food is cooked in the ordinary way, and is well done, and can be sufficiently varied. 16 to 24. No replies to these queries.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is about one mile from the station. The soil is sandy, the subsoil being kunkur. The ground, which is carefully kept, is drained into a neighbouring nullah and low ground. 3, 4. No replies to these queries. 5. The dead of camp followers and bazaar people are disposed of according to their religion, Hindoos thrown into the Ganges and Mahomedans buried. 6, 7. No injury accrues to the public health from the present practice, nor are any improvements necessary.

14th December 1860.

(Signed) Alexander Parden, M.D.,
Civil Assistant Surgeon.

HAZEEPORE. BENGAL.

GHAZEEPORE.—FURTHER REPORT.

Accommodation :—Queen's Troops.—Infantry - - 848.

References to Subjects and Queries.	Replies.
I. Topography.	1. The country surrounding the station stands directly on the left bank of the Ganges, and slopes gently from both sides, probably in the degree of seven or eight inches in a mile, from N.W. to S.E. It is flat and interspersed with but few trifling elevations, and in localities is dry, sandy, or swampy. It abounds in jheels or water courses; but no great extent of jungle exists. 2. The station's greatest elevation above the sea is towards its west extremity, and is about 260 feet, and probably nowhere exceeds 350 feet, owing to the extremely flat and undeviating nature of the ground.—There is no higher or healthier ground adjoining the station. 3. The nearest mountain lands are the Nepaul Hills, at a distance of 184 miles. 4. The station is directly upon the left bank of the Ganges, which, with several other rivers, —as the Gogra-Karamnassa, Tons-Bisu, and the Maughi,—intersect the country, the first three being the most important. The Ganges overflows the vicinity during the wet season, from the middle of July to near October. Ravines, water-pits, and broken ground abound in every direction, and from the filthy habits of the natives, and absence of public latrines, they are very offensive. 5. The station is open, but the free ventilation is somewhat impeded by proximity to the native city and an over-grown bazaar to the eastward. With but very few exceptions the buildings are on a level with the ground, and thus doubtless the temperature of the station is raised by exposure to reflected sun-heat. The winds are often very variable, but the S.W. and N.E. are those which mostly prevail, sudden changes of which, conjoined with other atmospherical phenomena, produce their usual effects on health. 6. Nearly every available plot of ground in the country surrounding the station is in a state of cultivation. There are no works of irrigation near, only the usual native mode of irrigating their fields from wells, &c., and this, as at present managed, has not, it is presumed, any effect on the health of the station. All objectionable cultivation can be prohibited by the commanding officer. No rules exist forbidding the cultivation of rice beyond the limits of the station; but it is not largely grown here. Indigo, hemp, and flax, with opium, maize, and sugar-cane are extensively cultivated in the surrounding district; but not with any apparent injurious effect on health. 7. The tolerably-sized town of Ghazeepore stands about 1½ miles lower down, and upon the same side of the river as the station. 8. The soil of the station may be said to consist of an upper surface of pale, light-coloured clay, resting on kunkur or calcareous conglomerate, covered by a deposit of fine sandy soil, slightly impregnated with salts of potass, while the bed of the river is composed of fine sand, intermixed with particles of mica, except at its edges, which are more clayey. 9. Water is usually found at a depth of from 12 to 25 feet below the surface in the dry, and a little less distance than that in the rainy reason. 10. The rain-fall is rapidly absorbed, and in about two or three hours the ground is fit to walk upon, even after the heaviest showers. The majority of the nullahs conduct the water-surface to the Ganges. There is no drainage from higher ground passing into the subsoil of the station. 11. The water supply of the station is derived from the Ganges, and numerous wells which abound; but it is not stored. These tanks are full or dry, according to the season. The impurities contained in the water are dissolved organic matter, suspended algar infusoria, and other offensive materials, which evolve carbureted and sulphureted hydrogen and carbonic acid gas. No tank water is used for drinking or bathing purposes by Europeans, though natives employ it for both purposes. These tanks and wells are liable to pollution from the filthy habits of the natives, pigs, &c. All the tanks, without exception, are nuisances, and the filling them up could be easily effected. 12. The water supply available for the station is most abundant. The colour is pure and clear, the taste slightly of salts of potass; it will not keep any length of time. The Ganges water is, however, free from this fault. The means for correct chemical and microscopical examination are not at hand. The quality of water has not appeared in any way injurious to health, and the amount is always sufficient. It is raised in leather buckets by native water carriers and bullocks. 13. The completeness of the foregoing queries leaves little room for additional remarks. 14. New stations, whether in hills or plains, are selected by committees of professional and non-professional officers, as laid down in the Bengal Regulations. An independent "sanitary officer" should decide such matters.
II. Climate.	1, 2. There are no means or instruments attached to the military department at this station for conducting and registering meteorological observations, all these being made by private instruments. 3. The climate of Ghazeepore is highly salubrious. Few stations possess such a cheerfulness of aspect, and it is celebrated for the wholesomeness of its air, and dryness of its soil, which never retains the moisture. It has also a noble reach of the river to the south-west. From the middle of October till the end of April the climate has been denominated the "Heavenly." Except during the prevalence of epidemics the health of the troops does not appear otherwise than good, but of course, during the prevalence of these, the unhealthiness is much the same as at most other Indian stations. The cool mornings and evenings are the proper times for drills, &c. During January, February, and March, the comparatively cold and dry months, remittent, intermittent, and ephemeral fevers of a mild type prevail, and, from careless exposure at night, &c., diarrhœa and colic are induced. In April, May, June, and July, when the greatest degree of heat is felt, various forms of these fevers occur, the "continued" not unfrequently assuming the character of "ardent fever" of Indian authors. Dysentery, with and without hepatic complication, cholera, and other intestinal affections amongst Europeans and natives, are met with alike. In August, September, and October, bilious remittent fever and diarrhœa most commonly prevail. During November and December unless the rains have continued far into October, sickness decreases, and slight ailments of a general character only exist.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	4. There is no higher ground whatever in the neighbourhood of Ghazeepore. 5. The following is a list of the stations at which I have served :—Bengal, North Western Provinces, and the hill sanitarium of Darjeeling, but chiefly at Ghazeepore, and none have appeared particularly inimical to health.
III. Sanitary Condition of Station.	1, 2, 3. Plans of the station and surrounding country, with ground plan of barracks, &c. are transmitted herewith. 4. For table and barrack accommodation *vide* the preceding report. 5. The doorways in the barracks serve as windows, and are placed at intervals along each side, and at each end (where only small windows exist), and have Venetian shutters. Verandahs run along each side of the building and across the south end, but they are never permitted to be occupied as sleeping quarters by soldiers or other persons. There are no jhilmils in the barracks, but they exist in the hospital, are of proper construction, and renewed as often as as is necessary. 6. The bedsteads should be of iron, with cane bottoms, as the present wooden ones are infested in a few weeks with bugs and other vermin to such an extent as to defy sleep. Pillow cases would be of great service, for the pillows soon become saturated with perspiration, and consequently dirty, and offensive to sight and smell. The material of which the sheets are made is too thin, and the supply is inadequate. 7. The tents supplied to Europeans are made of country material, and are intended to contain 20 men each. They are generally about 15 feet square. 8. The barracks at Ghazeepore are ventilated by raised and covered openings along the centre of the roof. These means are sufficient for the present style of buildings. No permanent cooling apparatus or other means are used here. During the hot winds the doors and windows are covered with a framework or "tatties" of grass called kuskus, which are kept constantly wet, and thus considerably lower the temperature of the apartments. 9. The barracks, &c., are constructed of kiln and sun-dried bricks, mud, plaster of brick-dust and lime; bamboos, suchoo wood, &c., with layers of straw and mud underneath the tiles. Tents are made with bamboo-poles and cotton cloth of country manufacture. The native huts are of mud with bamboo and grass, and grass or mud roofs. 10. The floors of the barracks, &c., are constructed of bricks, Chunam flags, concrete of brick-dust and lime, mud, &c. The barrack floors are level with the surrounding ground, and there is no passage of air beneath them. 11. Barracks should be constructed on arches not less than 5 feet from the ground, with grated openings along the centre of each room, side openings along the upper part of the wall; both to open and close during the hours the hot winds blow. Upper stories should be built, and used for sleeping apartments only (open gratings should be placed along the centre of the floor communicating with the external air by tubes, &c.), and they should be double-roofed with permanent openings along the centre, and placed at such an angle as to benefit by the prevailing winds, S.W. and N.E. Tents should have openings at the top; at present they merely collect and retain a most vitiated atmosphere. The barracks and cantonments are kept in repair by the officer commanding the station, assisted by the quartermaster. The senior medical officer is designated "Sanitary Officer," and reports weekly to the head of the medical department. The walls and ceilings of the barracks are cleansed and limewashed annually, or as often as may be certified to be necessary by the medical officer. 12. A sketch of the men's lavatory is transmitted. There is a good-sized lavatory to each barrack, supplied by water-carriers. The drainage of these is imperfect, and their contents merely run out upon the ground. This, however, will shortly be remedied. A large swimming bath is still a desideratum. 13. A sketch of the barrack cook-houses is transmitted. The means of cooking are ample, according to the simplicity and fewness of the culinary wants of native cooks. The water is brought by the native water-carriers from the adjoining wells. The refuse will shortly be made to run into reservoirs, and be carted away. The washing and drying of the linen are performed by dhobies, or native washermen, who are always to be had in abundance. 14. A sketch of the privies, &c., is transmitted. Each privy has a water-tight reservoir, with a lid, and the contents are carted away twice a day to a large tank about two miles from the barracks. 15. The barracks, &c., are lighted at night by oil lamps, suspended from the roof at regular intervals; but these means are very deficient, and compel the men to buy their own candles or oil. 16. No system of drainage and sewerage, properly so called, exists at this station; but shallow, saucer-like drains are cut around each barrack and other buildings, merely to carry off surface water, and empty themselves into tanks, nullahs, or the Ganges. In the rainy season the barracks must necessarily be damp, from being upon a level with the ground outside. The hospitals are not so, owing to their being somewhat raised, and to having a flag flooring, which the barracks (with the exception of the "married quarters") have not. Urine tubs are placed along the verandahs at night, and are emptied next morning into the privy reservoirs, and thence carted away. The place of deposit is about two miles distant from the barracks, and is merely a large excavation caused by making bricks, &c. It is clear of all wells. The privies are placed at convenient distances from the men's quarters, varying from 20 to 50 yards, and, as before stated, their contents are carted away by the conservancy department, morning and evening. The extreme cleanliness observed keeps them as free from smell as possible, and the liberal use of charcoal and lime is attended to. Ditches exist in every direction round about the station, and, from the want of public native privies, the dirty habits of the people, and other causes, they cannot be otherwise than foul. 17. The general surface cleansing of the cantonment and its vicinity is as good, if not better, than is usually found in cantonments, particularly where native troops are in proximity. The cleansing staff is sufficient, and can always be increased, temporarily, be requisition to the commanding officer. 18. The surface of the cantonment is kept free of vegetation, but might with advantage by laid out as a garden, &c. As before stated, the ventilation of the whole cantonment would

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	be improved by the total removal of the overgrown bazaar at the east extremity to the S.W., where a much better site could be obtained. 19. For sanitary condition of the bazaar as to drainage, ventilation, cleanliness, water supply, &c., *vide* Appendix to this report. The regulations and police arrangements are those laid down in the Bengal code. The whole bazaar should be removed as recommended by a medical committee. The native houses near the station are everywhere surrounded by filth of every description, to which the natives are indifferent, notwithstanding the strictest watchfulness of both civil and military police. Nuisance is experienced in barracks in the hot weather from wind blowing over the native dwellings, and also more particularly after slight showers of rain. This nuisance could be prevented, that is, to a limited extent, by the erection of public privies, but Asiatics will defile the country in spite of any regulations. 20. Animals for the use of the soldiers are slaughtered at about a mile away from the barracks. No particular regulations regarding the slaughtering places exist, the offal is thrown into the Ganges or tanks. No nuisance is experienced in the station from these places. 21, 22. There are no picketing grounds or stables whatever in or near the station. 23. There are two ranges of quarters for married non-commissioned officers and men, and these, recently erected, are somewhat small but sufficient. They are considered "temporary," "and according to standard sanctioned by Government." A few married families occupy small rooms at either end of each building occupied as a barrack, but none are in the rooms used by the unmarried soldiers.
Officers' Quarters.	1. The officers' quarters at this station are the ordinary bungalows of the country. I would suggest as improvements, that new ones be erected so as to catch the prevailing winds, and that water-tight reservoirs be placed for the refuse from the cook-houses, stables, &c., and which ought to be regularly carted away.
IV. HEALTH OF THE TROOPS.	1. The station and surrounding district are generally very healthy in every direction. 2. The following are the diseases of the native population. Small-pox, intestinal affections, remittent and intermittent fevers during the hot season, and at the changes of the monsoon. Pleuro-pneumonia, bronchitis, and sore throats are common in the cold season, and enlargement of the spleen and mesenteric glands prevail everywhere. 3. Malaria, want of sanitary arrangements, and poverty of food are the chief causes to which I attribute these diseases. 4. The troops at this station served 10 years in the island of Ceylon, and arrived in Bengal June and November 1857. During their service in the former place they suffered from epidemic cholera, three times from the endemic remittent fever, dysentery, diarrhœa, and enlargement of the spleen chiefly; but the general state of their health was as usual with white troops serving in that island, as detailed in the valuable statistical reports. On their arrival in Bengal, at a time when troops were so urgently needed, they were little fitted for the exposures and fatigues of an Indian campaign, for there is no 'cold season' in Ceylon to recruit the health of the soldier. They reached the station of Ghazeepore in August 1857 and March 1858, and have suffered from endemic dysentery, remittent and intermittent fevers, sporadic cholera, diarrhœa, hepatic derangements, obstinate enlargement of the spleen, and from primary, secondary, and tertiary syphilis. No portion of the men's accommodation at this station is more healthy or unhealthy than the rest. 5. The troops at this station have not as yet required to be camped out. 6. I have been in charge of troops at the Hill Sanitarium of Newera Ellia,—the intermediate station of Kandy in the Island of Ceylon,—and that of Darjeeling in Bengal. Experience has taught that they are not sufficienty availed of for the residence of European troops. Both the above sanitaria are placed at too high an elevation. The Pusilawa range in the former, and Curzeon in the latter seem preferable sites. 7. Ample observation proves that though the change to these hill stations suspends for a time organic disease, and also the accompanying fever, always of the remittent or intermittent type, yet on the return of men to the plains they appear more readily to suffer from fever, &c., and existing disease is accelerated to an incurable degree, or fatal termination. 8. Of the great advantage and permanent good of locating troops in hill stations of proper elevation there cannot exist two opinions, particularly if ample employment by gardening, working at trades, agriculture, &c., &c. be given to the men, without which intemperance and its results will always prevail to a greater extent than in the plains. 9. Troops on going to hill stations are liable to be attacked chiefly from diarrhœa. At Darjeeling this and remittent, and intermittent fevers are not unobserved. 10. Ample employment should be given to the men located in hill stations to enable them to benefit by such residence, and of the marked good of this proofs are not wanting; the benefits will vary accordingly. 11. At the elevation named in reply to query six, benefit is derived during the whole year. At the higher elevations the avoidance of the heavy rains has appeared advisable, and the colder season there from October to April is better suited to the younger soldiers than to those who have become debilitated by long residence in the plains and from other causes. The best preventive to disease is the constant employment of both body and mind by executing every want, as butchering, tailoring, baking, shoemaking, flour grinding, &c. To enable troops to obtain the full benefit of a residence in the hills their stay should not be less than two years, but even a twelvemonth's residence in correctly selected cases is extremely beneficial. 12. If the above precautions be attended to there is no period of residence in the hills beyond which injury is likely to be inflicted on the health of troops on their return to service in the plains. 13. Troops should not be marched from hill stations to the plains later than February, but this depends of course upon the distance to be marched. 14. Both service in the hills with short periods in the plains, and service in the plains with short periods of service at hill stations, would be productive of the most beneficial results to the health of troops serving in India, provided the before named "precautions" were adopted. Frequent change of station in the plains would unquestionably be beneficial to the health and spirits of troops and convalescents—two years at one station should be the limit. If much or unusual sickness prevails at any time, immediate removal should take place, and with soldiers will always act beneficially. 15. At both the hill stations I have referred to the accommodation is very defective, and the position of the barracks, &c., bleak and cheerless. A more positively objectionable site for barracks than that selected at Senchal near Darjeeling could not have been made. For

References to Subjects and Queries.	Replies.
IV. Health of the Troops Troops—*cont.*	nearly two-thirds of the year it is enveloped in mists, or deluged with rains, is difficult of access for supplies, and is somewhere about 7,500 feet high. These barracks, however, have not as yet been occupied (February 1860). 16. Martin has correctly stated at what ranges of elevation above the sea the most suitable sites for hill stations may be obtained, and no one judging from actual personal observation can disagree with him on this point. 17. There is no higher ground near this station which could be advantageously occupied as a hill station. 18. See MacClelland on the particular classes of surface and subsoils more healthy and unhealthy than others, and whose opinions on this subject are concurred in. 19. Troops should not be sent to India until they are well formed, and have been "made soldiers" for at least three years at home. Both officers and soldiers now sent to this country are mere boys, whose whole strength is wanted to mature their manhood, and from being unable to withstand the enervating effects of climate, must, and too often do, resort to objectionable habits. The men should land at Calcutta never later than November, so as to give ample time to reach up country stations before the oppressively hot season begins. For this Presidency, troops land at Calcutta, and are thence despatched up country by river steamers and flats, or floating wooden barracks, and by bullock train along the Grand Trunk road, and by stated marches. The following are the precautions I would recommend for preserving the health of troops on first landing in India, viz.:—That the detention at Calcutta be no longer than positively required; less crowding in the barracks of the place; the supervision of an officer from each corps to which the men belong; the marching in lighter clothing than the European uniform; distinctly informing each individual by printed forms of what he is entitled to immediately on landing, and while serving in India; and the insertion in the end of his small book of a few "simple precautions against sickness," so as to warn the inexperienced against that which is so positively injurious in this country. 20. Troops destined for India should be sent direct from the home depôts, and not to any intermediate station for a certain time. With larger barracks, a more cheerful aspect of cantonments and buildings, the establishment of workshops, libraries, reading-rooms, coffee and smoking-rooms, and other modes of keeping their time employed, soldiers might without disadvantage serve first in the plains. 21. The following seem to be the only precautions needed for the preservation of the health of troops "*en route:*"—The less crowding of the men on board the river steamers or flats, and in the bullock trains; the greater attention to personal ablution, and cleanliness of linen and other garments, and, above all, the supervision of an officer from the regiment to which the men are proceeding. 22. British soldiers should serve in India seven years, and officers ten, by which greater efficiency, better health, and actual gain to the State would result. Speaking generally, the ailments of European soldiers for the first five years are slight, and easily overcome; after this, dysentery and diarrhœa become more severe, and less amenable to treatment, and enlargements of the spleen also continue to be obstinate. From this time to nine years, hepatic affections and enlargements are of more frequent occurrence, and after nine years the soldier appears but little able to bear up against disease, and the results of anæmia become apparent. 23. With respect to invaliding, greater weight should be given to the opinions of local medical committees. Men often apparently improve by river voyage or transit train to such a degree as to mask, or often conceal, the serious nature of the disease for which they were invalided, and are often sent back only to enter the regimental hospital on the return of the hot or wet season, and there remain until the cold or invaliding period returns. 24. Invalids should certainly leave India for home before the setting in of the "hot season."
Diseases.	1. Inspection parades, for the discovery of incipient diseases take place regularly once a week at this station. 2. Scorbutus occasionally occurs as an accompaniment or sequel to dysentery, or long-continued diarrhœa; but, so far as has been observed, to no very great extent. 3. The proportion of cases of hepatic disease under treatment for the past 12 months has been 38, and in nearly every case was traceable to indulgence in spirituous liquors, and exposure to solar influence. It has not by any means been observed to be commonly complicated with any other disease. Malt liquor should be sold cheaper in preference to spirits. 4. Dracunculus has not been observed at this station. 5. Venereal is unquestionably and unfortunately the disease of military hospitals, and prevention of its evils of the utmost importance. The proportion of venereal diseases to the total treated in hospital for the last 9 months (ending December 1859) has been one in 5·93. I would recommend as a step towards the prevention of these diseases that the old practice of registration, periodic examination of women, and re-establishment of lock hospitals, be resorted to at every station. The latter can be easily conducted without in any way interfering with the prejudices of caste, &c. 6. The following are the diseases from which troops at this station suffer, viz.:— *Fevers.*—Remittent and intermittent fevers prevail both endemically and epidemically; chiefly of the bilious and tertian types. *Dysentery*, *Cholera*, } Both prevail here. *Small-pox* is confined almost entirely to the natives. *Rheumatism* occurs, but only as the result of previous syphilis or gonorrhœa. The following is the proportion which the admissions and deaths from the above diseases bear to the total admissions and deaths for 9 months ending 31st December 1859:—

Diseases.	Admitted.	Died.
Fevers	1 in 1·82	1 in 4·85
Dysentery	1 „ 15·55	1 „ 3·09
Cholera	1 „ 114·42	1 „ 3·40
Small-pox	None.	None.
Rheumatism	1 in 77·21	Do.

	7. The nosological characters of the more frequent zymotic diseases are now so well known, and in no way differ at this station, so perhaps a mere enumeration may be omitted. These diseases are most prevalent during the hot season and changes of the monsoon. The climatic and atmospheric conditions which accompany or precede them are also well known,

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	and do not offer any peculiarity worthy of note. But the longer the rains continue, so does disease increase generally; and the same may be said of any unusual degree of lowness of the Ganges. The habits and customs of all natives invite this class of diseases. These subjects, however, are now receiving great attention from the magistrates and municipal authorities. The personal habits among the troops and native population which predispose to these diseases have already been pointed out. 8. The prevalence of epidemic disease among the troops may be said to be influenced by exposure at night particularly, the want of occupation while in the barracks, perhaps the indulgence in intoxicating drinks generally, and needless exposure to solar influence. 9. Small doses of quinine have not been tried as a prophylactic against malarial disease at this station.
V. INTEMPERANCE.	1. The soldiers at this station are by no means intemperate, considering the many depressing influences, and there are certainly not more than half a dozen "confirmed drunkards" among 848 men. 2. There have been 21 admissions for delirium tremens during the past 9 months (ending December 1859), and of these 3 died. I cannot state with sufficient accuracy to be of any use the number of admissions from diseases caused indirectly by intemperance, neither can I (from want of correct data) furnish a table to show the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station. Drunkenness is always punished as an offence, as directed by general orders on the subject, and 51 men were punished for this alone during the past 9 months (ending December 1859). 3. Distilled spirit is sold in the canteens as permitted by regulation, and surreptitiously in the bazaars, and other places. Every care is taken to have it of good quality, and the amount allowed to each man by regulation is 2 "tots," or about 6 oz. per diem. Spirit of good quality is issued, as per regulation, at the station, on the march, and in the field. Men are not supposed to take a dram before morning parade, as hot coffee is provided for them, and recommended to be used. Spirit is not given as a ration to convalescents, but where the health of the soldier requires it, malt liquor is permitted to the extent of 1 or 2 pints daily. No injurious drinks other than intoxicating ones are permitted to be sold in the canteens; but highly intoxicating and injurious drinks can always be readily procured from the natives, and this it is impossible to prevent. 4. Whether the consumption of spirits by troops and convalescents is conducive or injurious to health must of course depend on the quantity taken, and at what time. At this station the men are encouraged to take it with, or immediately after, meals. There is no doubt of the injurious effects of spirit drinking in all hot climates, and it should be discountenanced as much as possible. Without the sale of good spirit and cheap malt liquor, under responsible supervision, the soldier will only consume the very highly injurious and often poisonous liquors concocted by natives, which would, no doubt, tell most materially on the internal discipline and efficiency of the corps. 5. I would recommend its use to be discountenanced by every legitimate means; but until drinking becomes less than a national vice, and means for the employment of the soldier's mind and body while off duty are provided, the issue of good spirits, or better still, of cheap malt liquors, ought to be continued under responsible supervision. Its sale in the native bazaars should be entirely prohibited. 6. Good malt liquor has been rarely observed to produce disease. Few men can get drunk on this, and its moderate use appears advisable, especially during the hot season, and under certain circumstances of fatigue, debility, &c. The substitution of a good, light, and cheap wine for spirits would also doubtless be of advantage. 7. By a very great many at this station, coffee, tea, lemonade, ginger beer, soda water, and similar drinks are preferred to spirits, and the sale and use of these should be encouraged in every way. 8. The use of tea and coffee before parade of a morning for all, and again at midnight for those going on and coming off sentry, ought to form part of the diet for troops, and not be left optional as at present, in which case half a loaf might be issued at evening meal with advantage. The use of a cup of hot coffee and a crust of bread at midnight has been attended with marked benefit at this station. 9. The benefit arising from the prohibition of the sale of spirituous liquors has been fully pointed out in answers to previous queries. 10. In addition to the recommendations already indicated, the canteens should be better furnished, have coffee and reading rooms attached, be better lighted, increased permission given to friends of the soldier to visit these places with him; a larger stock of actual and all small necessaries kept for sale, and the incumbents of canteens be permanent. Discharged married soldiers with families might be usefully employed in this way. 11. Canteen and bazaar rules are all laid down in the Bengal regulations, and, as far as can be ascertained, they are strictly adhered to. The following is Sir Charles Napier's "Advice to Soldiers":— "Let me give you a bit of advice, that is, don't drink. I know young men do not think much about advice from old men. They put their tongue in their cheek and think they know a good deal better than the old cove that is giving them advice. But let me tell you you are come to a country where, if you drink, you are dead men. If you be sober and steady you will get on well, but if you drink you are done for. You will be either invalided or die. I knew two regiments in the country, one drank, the other did not drink. The one that did not drink is one of the finest regiments, and has got on as well as any regiment in existence; the one that did drink has been all but destroyed. For any regiment for which I have a respect (and there is not one of the British regiments I don't respect) I should always try and persuade them to keep from drinking. I know there are some men who will drink in spite of the devil and their officers, but such men will soon be in hospital."
VI. DIET.	1. The ration for Queen's British troops and European troops in the Indian army is the same, and is composed as follows:—on land, viz., 1 lb. bread, 1 lb. meat, 4 oz. rice, 2½ oz. sugar, $\frac{5}{7}$ oz. tea or 1$\frac{3}{7}$ oz. coffee, 1 oz. salt, 1 lb. of vegetables, and 3 lbs. firewood. The same rations are issued on board river steamers, except that salt-beef or pork is substituted for fresh meat, and instead of salt being given weekly, 2 oz. ground mustard seed, 1½ pint of split peas, and 1½ pint of vinegar are issued per man. A responsible inspection of the ration is made daily before it is issued, and receives the attention of an orderly officer, medical officer, and quartermaster, also of non-commissioned officers and men from the companies.

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	2. A complete ration, in which the proportion of vegetables is 1 lb. per man, is issued daily. The men at this station have three meals a day, viz., breakfast at 8 o'clock a.m., dinner at 1 p.m., and evening meal at 6 p.m., consisting of tea or coffee, bread, and their rations divided into portions. 3. As an improvement in the ration, fish might be given, and the men allowed to procure game, &c., so very abundant at every station. Disposal of any portion of the ration by the troops is forbidden. 4. The means of cooking are ample enough; but the present system of issuing copper vessels to be tinned twice a month seems very objectionable. The kitchens are clean, light, sufficiently supplied with water, well ventilated, and daily inspected by orderly and medical officers. The meat for the most part is made into good soup with the vegetables. The cooking is properly done and sufficiently varied; but fish is so abundant and cheap that it might be given in addition. It is almost uniformly a rule that the men have tea, coffee, or other refreshment before a march, but this should be made a strict regulation. 5. Gardens for the cultivation of vegetables by soldiers could be advantageously established near the station and would be of the very greatest good, Government supplying the necessary tools and seeds, and allowing a fair proportion of water carriers. Canteen funds might also perhaps do much in the way of up keep.
VII. Dress, Accoutrements, and Duties.	1. The men at this station wear the usual uniform and accoutrements as laid down by regulations, together with a light summer one of American drill, dyed khakee or dust coloured, and a cane helmet covered with the like material. Generally there is little objection to be made in the present dress, as the altered style and material have been a great boon to European soldiers. The red serge tunics issued for winter wear should be lined with thin flannel or American drill. Good sized and very light waterproof caps should be used by the men on guard when moving during reliefs, &c. During the wet and cold seasons the European clothing and great coats are worn by the men on guard.
Duties.	1. It is unhesitatingly asserted, after much thought and observation on the subject, that each man should be a "made soldier" at home for at least three years before being sent out to this or any other tropical climate. 2. The usual routine of a soldier's duties at this station is very light, and the greatest care is taken in no way to prolong or have them at such times as are likely to prove injurious to the health of the men. The best time for drills, parades, and marches is the "early morning" as directed by general orders. The men at this station have on an average five or six nights in bed during the week. 3. Guards are all mounted in the immediate vicinity of the barracks. Day guards last 24 hours, night guards from sunset to sunrise, and sentries are relieved every two hours. Roll calls are made six times during the day and once at night. If night guards *could* be altogether discontinued the sickness among soldiers would doubtless be very small indeed.
VIII. Instruction and Recreation.	1, 2. The following are the means of recreation and instruction available for the men at this station.—1st. A good ball court, which should be roofed and correctly ventilated.—2nd. Two skittle grounds near the barracks, which are very much too short.—3rd. A school with good schoolmasters; and, 4thly, a very good theatre belonging to the station officers, but the use of which is sometimes permitted to the men. There are however neither day rooms or soldiers' clubs, soldiers' gardens, workshops, gymnasia, nor room available for a reading room for the men. The above means are not sufficient to keep the men occupied during the heat of the day or in the wet season. The strict regulations respecting restriction to barracks when off duty during the wet weather and heat of the day, are properly adhered to, with corresponding advantage to the health of the men. 3. The institution of soldiers' savings banks at this station would be very advantageous. 4. There is not sufficient shade from trees, sheds, or verandahs to enable the men to take exercise without injury to health during the day.
IX. Military Prisons.	1. Cells for eight prisoners have been recently erected here according to the standard plan sanctioned by Government. They are suitable enough for the cold weather; but are somewhat confined for the hot season.
X. Field Service.	1. No local regulations for field medical service exist. 2. The powers of the medical officer as regards the conduct of the line of march of troops, camping, bivouacking, &c., of course depend entirely upon the appreciation of sanitary police possessed by commanding officers. If they appreciate this, the recommendations of medical officers are always properly attended to and carried out. 3. The perfect nature of the regulations in India for the preservation of health, as to the selection of camping grounds, ventilation, and generally sanitary regulations, &c., &c., are too well-known to need description here. 4. The regulations adopted in the Presidency for field hospitals, ambulances, transport of the sick and hospital supplies, &c., will doubtless be furnished by the head of the medical department.
XI. Statistics of Sickness and Mortality.	No information under this head is transmitted.
XII. Hospitals.	1. Ground plan of the hospital is transmitted. 2. The three hospital buildings stand at the western extremity of the ranges of barracks, at a distance of about 150 yards, while the bazaar, and houses of the native population generally, are quite at the opposite end of the cantonment. The site is open and generally healthy as to elevation, drainage, &c., but the buildings are so placed as not to benefit by the prevailing winds, and a better site is where the old military hospital formerly stood. 3. The water supply is ample in every respect; but good and tolerably large baths are still wanted. 4. There is a mere surface drain to convey the drippings of the roof away. 5. The wards are raised about two feet above the ground; but there is no perflation of air beneath the floors as there should be. One building has a masonry drain all round it for conveying away the roof water, but the other two buildings have no such provision. The hospitals are constructed of kiln and sun-dried bricks, plaster of brick dust and lime, roof of country wood and bamboos, and tiled with a layer of straw underneath. The walls, &c., are all single, but of sufficient thickness to keep the hospital cool. There are verandahs on both sides of the hospitals 9 feet broad, but they are never used for the accommodation of sick, convalescents or others. The hospital consists of one flat. For table of hospital

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	accommodation, *vide* preceding report. The hospital buildings being in echellon receive benefit from prevailing winds. There are no windows, properly so called, the doorways answer for these for ventilating and cooling the hospitals. 6. The wards are ventilated by raised and covered openings along the roofs. Perflation of air under the floor, and along its centre would be a great improvement. The jalousies and jhilmils are of the ordinary construction. 7, 8. The means for cooling the wards will be best seen by the section of the hospital roof on the plan. The wards do not require warming. The walls and ceilings of the hospital are cleansed and limewashed once a year by regulation, but on requisition can be repeated as necessary. 9. The plan of the privies and urinals annexed to the hospital is transmitted. Their contents are removed twice a day, while the daily washing and use of charcoal and lime keep them tolerably free from smell. 10, 11. The lavatory arrangements of the hospital consist of fixed washhand basins and bathing tubs, and have generally proved sufficient for the purpose. 12. The washing and drying of the hospital linen are performed by the natives at the river side, by their usual simple but efficacious plan, the clothes being previously well boiled with wood ashes. 13. The storage at present is sufficient and dry. 14. The bedsteads used in hospital are of common country wood, and infested with bugs and other vermin to the great distress of the sick. They should be of cast or wrought iron, with cane bottoms. Scalding the bedsteads with a solution of turpentine, corrosive sublimate, &c., is resorted to to destroy these insects, but with very partial success. 15. Pots and pans, &c., are supplied by Government for cooking purposes, and are quite sufficient, for a native cook requires but little aid of any kind beyond firewood. 16. Copies of diet tables, diet rolls, &c., will doubtless be forwarded by the head of the medical department. 17. The hospital attendance is liberal, and performed by natives with European supervision, according to the Bengal regulations. 18. The sanitary state of the hospital is as perfect as the means will allow. Of course all the buildings generally are most unsuitable for hospital purposes in this climate; but no better are available in the station. 19. I would recommend that a new hospital be built on the site of the old one. 20. Convalescents exercise on the unshaded space of ground in front of the hospital, where there are seats. Those who can bear it are permitted the use of elephants and doolies, night and morning, for rural rides. 21. The sick wives and children of the soldiers are generally treated in their own quarters, and there is nothing at present to suggest in this respect. 22. There are no local hospital regulations. 23. The powers of the medical officer as regards the sanitary state of the hospital, repairs, change of diet, &c., are considerable, if requested with discrimination, and clearly shown to be useful and necessary. 24. Wards or hospitals for convalescents might be established here; but, as a rule, men are not discharged till fit for duty.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is about 1½ miles to the S.W. of the barracks. The N.E. wind blows over it to the open country. Its area is about two acres, and the nature of the soil is similar to other parts of the station already described. The drainage is merely superficial, and conveys the surface water to a nullah, and thence to the Ganges. The ground is carefully kept, and decomposition takes place readily. 3. The graves are dug large enough to admit of one coffin each, and there is the width of a grave between each. They are about 6 feet deep, and are never re-opened. The time of interment after death is decided by the medical officer. Early morning, or a little before sunset, is the usual period of burial. 4. The grave-yard is upwards of a mile from the barracks, and is not offensive. 5. The dead of camp-followers and bazaar people are disposed of according to caste; burnt, buried, or thrown into the Ganges. 6. Injury to the public health doubtless generally accrues from the present practice; for the pollution of Indian rivers is beyond the conception of those who have never witnessed it. 7. No improvement can be made, at least without, perhaps, interfering with the religious prejudices of the people.

(Signed) Henry Kent, Major, 77th Regiment, Commanding Station.
J. W. Fleming, F.R.C.S., Surgeon, H.M.'s 37th Regiment.

10th June 1860.

APPENDIX.

Sir, Ghazeepore, December 1858.

As it appears to me that what is now called the "Station Bazaar" has entirely lost the purposes for which it was originally sanctioned, and as contemplated by Government Regulations, I would, as intimately connected with the general health, cleanliness, and appearance of the cantonment, most seriously call your attention to the propriety or safety of permitting its existence as at present.

A very cursory survey of the place will at once convince any one that a more perfect hot bed for the production and dissemination of disease could not exist. From having originally occupied ordinary space, it has now increased to such an extent that there is barely a square yard of ground uncovered. Its inhabitants, streets, and lanes are crowded to excess, and beyond safety, a very large body of persons, having no right whatever to reside therein; improper trades are carried on; filthy pigs, donkeys, and wretched and diseased beggars, &c., are observed in almost every lane; obnoxious pits exist in nearly every street; drains are uncut, the ground unswept, filth unremoved, ventilation rendered utterly and totally impossible, the oppressiveness of the stench almost unbearable, even at this season of the year, and, above all, there exist pestiferous tanks at its northern and southern extremities.

I would, therefore, suggest for your consideration the advisability of assembling a medical committee, to report as to its influence on public health, and to consider the advantage of total removal to a more appropriate site, or the demolition of such houses, lanes, &c., as may be in its opinion necessary.

Further to show the necessity of immediate steps in the matter, I may mention the additional fact of there being actually crowded in a space of ground 2,210 long, with a mean breadth of 851 feet, certainly not less than 5,000 human beings, to say nothing of cows and other animals. I have not been able to ascertain the exact number of

persons, as no "registry" exists, but the calculation stated is, I have no doubt, under the mark.

I have the honour to be, Sir,
Your most obedient Servant,
J. W. FLEMING, F.R.C.S.

To the officer commanding the station, Ghazeepore.

EXTRACT of a letter, No. 3,612, dated 27th July 1860, addressed by the Quartermaster-General of the army, Bengal Presidency, to the officer commanding at Ghazeepore, having reference to questions not properly answered on the Sanitary State of the Indian Army.

QUESTION 4.—TOPOGRAPHY.—"Is there any broken ground, or are there any ravines or water pits near the "station? and what is their effect on health?"

Answer.—"These abound in every direction, and from the "filthy habits and absence of public latrines are very "offensive."

"I presume that natives are alluded to in this remark, and "beg you will inform me whether public latrines for their "use could not be adopted at Ghazeepore, as is the custom "in almost every other station, cantonment, and bazaar in "the Presidency."—*Further answer, vide letter annexed.*

QUESTION 5.—TOPOGRAPHY.

Answer.—"It is open, but the free ventilation is some-"what impeded by proximity to the native city, and an "overgrown bazaar to the eastward."

"With reference to former correspondence on the subject "of this Gora bazaar, I beg you will inform me what is "being done to remedy the evil complained of."—*Further answer, vide letter annexed.*

QUESTION 2.—CLIMATE.

Answer.—"There are none attached to the military depart-"ment, all such observations are made by private instruments."

"Are not thermometers, barometers, rain gauges, and "other instruments supplied by Government for use and "record in hospitals of European troops?"—*Further answer, vide letter annexed.*

QUESTION 1.—SANITARY CONDITION OF STATION.

Answer.—"Herewith annexed."

"This has not been sent, though the reply states, 'here-"with annexed,' the only plan received is one of the "station alone."—*Further answer, vide letter annexed.*

(True extract.)
HEN. ROBERTS, Major,
D.A. Quartermaster General of the Army.

SIR, Ghazeepore, August 25, 1860.

IN reply to your letter No. 3,612, dated 27th ultimo, on the subject of my answers to queries issued by the Royal Sanitary Commission, I have the honour to report further, for the information of His Excellency the Commander-in-Chief.

TOPOGRAPHY.—1st. That I purpose having public latrines constructed for the use of the natives in the Gora bazaar, similar to those in use at other stations in India, part of the expense to be borne by the natives themselves, and part by the bazaar fund. These, which will probably occupy about a month or six weeks in building, are much needed, and will be a great improvement to the station in a sanitary point of view when completed.

Question 5. TOPOGRAPHY.—2. No steps have been taken yet to raze any portion of the Gora bazaar. The recommendation of the Station Committee, as you are aware, have received the sanction of Government; but without a grant of public money, or an order to me or whatever officer may be in command to pull down the houses, without reference to the vested interests of the natives, I do not see how they are to be carried out. In the latter case, prison labour might be made available, but, at present, I believe there is an order against the magistrate employing prisoners outside the prison walls.

Question 2. CLIMATE.—3rd. I am not aware whether thermometers, barometers, rain gauges, and other instruments for conducting and registering meteorological observations are usually supplied by Government to hospitals occupied by European troops, but there are none attached to the military department at this station. All such observations, if any, are made by private instruments.

Question 1. SANITARY CONDITION OF STATION.—4th. I have applied to the Executive Engineer, Public Works Department, through the Deputy Assistant Quarter-Master-General of the division, for a map of tracing of the station, with the country round, showing the position of the bazaars, public buildings, villages, &c., &c., but have failed to obtain what I want, his excuse being that he has no establishment of surveyors to make maps of the country round each station in his division, and that he is too much occupied with his other duties to make them himself.

I have, &c.
(Signed) HENRY KENT, Major, 77th Regt.,
Commanding at Ghazeepore.

The Quarter-Master-General of the Army, Simla.

UMBALLA.

I. TOPOGRAPHY.	1. The aspect of the surrounding country is level, well cultivated, and studded at intervals with trees. The view is bounded on the N. and E. by hills; the country is flat, sandy in some places, and dry. There are no swamps near the station. There are a considerable number of trees both isolated and in clumps, but there is very little jungle or water. 2. The elevation of the station above the sea is 1,050 feet; but it is on a level with the adjacent country. The Gujgur river is the nearest water; the exact elevation of the station above it, however, is not known. There is no higher or healthier ground adjoining the station. 3. The nearest mountain land is the Himaleh, about 35 miles from the station. The crest of the nearest range at Kussowlie, attains a general elevation of 6,250 feet above the sea, and 5,200 feet above the station. 4. The Gujgur river, which is the nearest water, is about 5 miles from the station. The nullahs in the vicinity, as a general rule, contain no water except immediately after rain; the vicinity is liable to overflow of water. This occurs generally in the rains; but it runs off rapidly, sometimes in a few hours. There are ravines and broken ground in various directions in and near the station; but their effect on health is not perceptibly injurious. They ought, however, to be filled up, and one clean cut waterway established, especially in the vicinity of the Native infantry hospitals. 5. There is much tree vegetation in the station; but there are regulations in existence which are from time to time enforced to prevent it from interfering with free ventilation. There are no other impediments of any moment either within or without the station. The temperature of this station is less raised by exposure to reflected sun heat than that of most other stations in India. There is a grassy surface for the greater part of the year, that modifies the amount of reflected heat. The station is not exposed to cold or variable winds, or to the sea breeze, and the hot land winds that prevail at one season of the year are not unhealthy.

I. Topography—*cont.*	6. The surrounding country is cultivated. There is no irrigation beyond that from the wells, and that is not allowed within a mile of the station; this is not observed to have any effect on the health of the station. There is very little rice cultivation in this part of the country, and none within several miles of the station. Neither indigo, hemp, nor flax is cultivated or prepared near the station, consequently there is no nuisance or injury to health experienced from them. 7. The large native city of Umballa lies about 3 miles to the westward of the station. 8. The geological structure of the surface is light clay and loam, with a sandy admixture, in some places pure sand, and in others sufficiently argillaceous to retain the water, and cause considerable evaporation. The subsoil is composed of alternate beds of light clay and sand, not sufficient to prevent percolation. The station occupies new ground. 9. Water is found at an average of about 30 feet below the surface both in the wet and dry seasons, and at some places within half that distance. 10. For the most part the rainfall of the district flows readily away; there are no surface springs. In some of the sandy spots the water sinks into a pervious subsoil, and so drains away; it nowhere oozes out again near the level of the station. In some spots there is considerable surface evaporation. There is no higher ground near the station, and the bases of the hills are at too great a distance to drain into the subsoil of the station. 11. The water supply of the station is derived from wells. The tank surface in the station approaches 400,000 square feet. Only two of these tanks, however, were intended for storing the water, the rest are excavations from which materials for building have been taken. They contain more or less water generally throughout the year, but two of them are liable to get dry during May and June. They contain no plants, and few, if any animals; and none of them are used for drinking purposes. The wells are not liable to pollution from leaves or other matter falling into them. All stagnant water gives out malaria under certain conditions of the atmosphere, and the alternate filling and drying of these earthen tanks must to a certain degree produce it. The remedy is to fill up all that are not required, and make the rest of solid masonry. 12. The amount of water supply available at the station is very limited indeed; it varies with the seasons. In the hot weather the majority of the wells are nearly dry. The water in its sensible properties is for the most part pure, free from colour, taste, and smell. No complete chemical analysis of it has ever been made; it is hard and contains carbonate of lime in considerable quantity. It is good and not injurious to health, but its amount is very far from sufficient. It is raised by Persian wheels and by the hand, and distributed to the European troops by a masonry channel, and to them and the station generally by men employed for the purpose. A better supply could be obtained from the Gujgur river, and it would be a matter of great importance to the station to have it done. 13. No answer to this question. 14. With respect to the manner of selecting sites for new stations some rules are to be found in the Public Works Code of 1858, page 82, and also in the General Order G.G. of 8th August 1853. The committees for this purpose are directed to consist of 2 military, 2 medical, and 1 civil officer, with the executive engineer. All intelligent medical officers are aware of the conditions necessary for a healthy site, but no selection should positively be made till an officer of scientific acquirements has lived a year on the spot. He ought to keep during that time a complete series of meteorological observations, and he ought to be able to report that the site is well raised and easily drained, the surface of green sward, the surface soil porous, the water level at least 20 feet from the surface, with an intermediate subsoil that admits of ready percolation. Also that there are no evidences of previous malaria in the inhabitants, that the vicinity is free for miles from swamps, floods, rank vegetation, and objectionable cultivation, or that there are ready means of getting rid of all these. That the water supply is pure, wholesome, and abundant, and that large trees to a wholesome extent exist.
II. Climate.	1. There are no instruments for conducting meteorological observations at the station except the thermometer and rain gauge. 2. Twelve meteorological registers are transmitted. The following Table is from June 1851 to May 1852.

3. The climate of the station is a generally healthy one. It is dry and hot for three months of the year, moist and hot for three more, temperate for two, and cold and bracing for the remaining four; it is neither variable nor foggy, and is not influenced either by irrigation or tree planting. The atmosphere, however, of the entire district is more or less affected by dust from April till July. Like all Indian climates its influence on the health of the troops from April till October is debilitating under all restrictions and provisions. The diet during

II. Climate—*cont.*	that period should contain less animal food, and the clothing ought to be of the lightest description, with flannel next the skin during the rains. Parades and drills should be confined to the first hour and a half after daybreak, and large airy buildings should be erected for the indoor recreation of the men, both physical and mental. February is the most healthy, and July the most unhealthy month. The prevailing diseases are fevers, rheumatism, bowel and liver complaints. 4. The hill districts are generally more healthy than the station, and their distance may be said to extend from 40 miles upwards. Their facilities for drainage are complete, but the water supply generally limited or difficult of access. There are many reasons for their adoption (the chief of which is reduced temperature), and few against it which will not disappear when they are better understood and more easily reached. 5. The following are the stations at which I have served, viz., Calcutta, Barrackpore, Dum-Dum, Dinapore, Mullye, *Ghazapore, *Benares, *Mirzapore, Cawnpore, *Meerut, *Dehra-Doon, *Umballa, and Lahore. Those marked with a * were comparatively healthy, but Dinapore, Cawnpore, and Lahore were positively injurious.

III. Sanitary Condition of Station—*cont.*	5. In the main rooms there are no windows, they are all doors on opposite sides opening inwards. In the non-commissioned officers' rooms there are windows, which also open inwards. There are double verandahs on both sides, the dimensions of which will be found in the plan transmitted; one of the inner verandahs is used as a sleeping apartment. There are neither jalousies nor jhilmils. 6. The cots are usually of salwood, 2 ft. high, with bottoms of country tape or canework. The bedding consists of cotton sheets, a quilt stuffed with cotton, a blanket, and a carpet, the size of the cot. In barracks there ought to be substantial iron cots, 20 inches high, 3 feet broad, and 6½ feet long. In tents straw ought always to be supplied as bedding, and a piece of painted canvass, or something impervious to moisture, ought to be laid over it for each man. 7. The tents are rectangular in form, and made of cotton cloth. The dimensions are, length, 20 ft.; breadth, 16 ft.; height, 10 ft. Sixteen men are the complement for each tent, and the above dimensions would give 200 cubic and 20 superficial feet per man. 8. The barracks and guard rooms are ventilated by the doors and by roof ventilators only. Tents in India have no artificial ventilation, nor have the huts of the native soldiers. The ventilation in the barracks at Umballa is tolerably efficient, but it could be improved by raising the walls of the centre rooms, and placing ventilators in them between the roof and the verandahs. A judicious system of ventilating crowded tents is still a desideratum. The barracks are cooled by tatties, which are light bamboo frames made to fit the doors, and over them is spread a thin aromatic root. This, when moistened and exposed to the hot west wind, which blows through it, cools the air agreeably inside. They are only available, however, for cooling purposes from the time the hot winds commence till the rains set in. The cost is 8 rupees per 100 square feet. 9. All the barracks at Umballa are built of burnt brick and lime mortar, except those of the infantry, some of the inner walls of which have mud cement. Tents are constructed of cotton cloth, tape, bamboos, and rope. The roofs of the barracks are either tiled or thatched, and the verandahs are terraced. 10. The floors of the barracks are principally of burnt brick, an objectionable mode of construction; they are raised above the ground about 1½ feet, but there is no passage of air beneath. 11. Burnt bricks and lime mortar are the most suitable materials for the construction of barracks in India. The floors ought to be raised on arches and flagged with stone, and there should be wall ventilation high up, which is wanting in the Umballa barracks. A non-absorbent material as plaster is also a desideratum both in barracks and hospitals. The materials of which tents are constructed cannot be improved; they want nothing but means of ventilation in bad weather when overcrowded. The barracks and cantonments are kept in repair by the executive engineer, and repairs are executed whenever called for. The senior medical officer at the station is *ex officio* sanitary officer, and the quartermaster-general's department is responsible for the sanitary state of the cantonment. The walls and ceilings of the barracks are cleansed and limewashed annually. 12. A sketch of the men's lavatories, &c. is transmitted. There is to be one lavatory with urinal attached, for each barrack. The greater number are now being built, and they are supplied with water from the wells. 13. A sketch of the barrack cook-houses is transmitted. The means provided for cooking are copper utensils tinned inside monthly by the commissariat. The whole question of cooking for the European soldiers is open to much improvement. Water is carried to the cook-houses from wells, and the refuse water is sometimes carried away, but more generally is thrown outside, and is absorbed or evaporates according to the season. The artillery have a tank about 400 yards from the barracks, where much of the washing is done. The washermen of the other regiments carry the clothes to the Gujgur river, where they are washed once a week. The means are sufficient. 14. A sketch of the privies and urinals is transmitted. They are drained into a shallow masonry cesspit just outside the building, which is cleaned every day and the contents conveyed in carts beyond the limits of the cantonments. 15. The privies and cook-rooms are ventilated by doors and openings in the walls. The barracks at night are lighted by oil lamps enclosed in lanterns, and hung from the ceiling. The regulation allowance is six of these lights per 100 men. Two lamps in each barrack are supplied to burn all night. 16. The barracks are drained by surface drains; but they are not of masonry; there are no masonry drains or sewers at Umballa. There is a natural fall in the country from right to left, and also in front and rear of the barracks, and the surface drains are merely kept open and free from rubbish and vegetation. Surface water and the drainage from the lavatories, baths, cookhouses, &c. disappear with tolerable rapidity, by the drains and by percolation. That from privies, urinals, &c. is carried away in carts, but increased conservancy means are required for this latter part. No part of the barrack buildings or hospitals is damp; in the former some leakage occurs from the roof ventilators, but this can be remedied. There are no cesspits properly so called; the only approach to them are the masonry receptacles for the urine, &c. Their contents are carried away daily and never absorbed into the soil. The distance of the urinals and wash-houses from the men's quarters is about 150 yards; they are cleansed daily and their contents removed in carts. There are several nullahs in and near the station which can never in my opinion be kept in a satisfactory state, till their bottoms are metalled as you would do a road. Almost every fall of rain cuts them away in some part, destroys the slope, and permits water to lodge; their extent, too, is so great that their conservancy is a matter of the greatest difficulty. 17. The general state of the surface cleansing is satisfactory. The refuse, manure, &c., are carted out of the station daily, or every second day, to the extent that the conservancy establishment can effect. Improvements in that respect affecting officers' compounds, &c., have lately been proposed. 18. The surface of the cantonment is kept free from all rank vegetation. There is nothing that obstructs ventilation in any material degree in the station. The numerous trees are what require most attention, and they are looked to from time to time. 19. The station bazaar is regularly laid out in squares or rectangles, and intersected with broad roads, which admit of tolerable ventilation in it. The drainage might be improved, but, on

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station —*cont.*	the whole, it is clean as a bazaar, and well kept, though crowded in some parts. The water supply is defective. There are 2 large public latrines, but two more are required. The regulations having reference to bazaars are to be found in the Public Works' code. The sanitary establishment consisted of 28 sweepers, paid by the inhabitants; but it was doubled in one day at the request or order of the cantonment magistrate without a complaint, showing the elastic nature of his resources. Native houses can never be kept perfectly clean; but in the bazaars of the station cesspits or dungheaps found without them subject the owners to fine, and they are consequently kept tolerably clean. There is no nuisance experienced in the barracks from wind blowing over the native dwellings. 20. Only one place is allowed for the slaughtering of animals. It consists of two divisions: one where the cattle and sheep for the soldiers are killed, and the other for the station and bazaars generally; it is about 400 yards to the rear of the Suddur bazaar. The regulations regarding it are that animals shall only be killed over-night or in the early morning; that the blood and offal shall immediately be removed by sweepers, two of whom are entertained for each division; and that everything offensive shall be carried beyond the cantonment boundary. All this is done, but the offal is thrown into a nullah, and left to be disposed of by birds and beasts, the bones remaining on the surface; it would be an improvement to bury it. There is no nuisance experienced in the station from this place. 21. There are no regulations for stabling or picketing bazaar horses, or those of camp followers. All that is looked to is that the owners of these horses shall allow no dung or filth to accumulate where these animals are kept, or be fined in default. 22. The stables for the artillery and cavalry belonging to the station are open sheds with tile roofs supported on pillars, with roof ventilation from end to end. In the artillery, they are 220 yards in the rear of the men's barracks, and 480 yards from the hospital; in the dragoons, they are 300 yards in the rear of the barracks, and 400 yards in front of the hospital. The light and ventilation are ample. The dungheaps are close by the stables, and the manure is carted away every day, or, at latest, every second day, out of the limits of the cantonments. The picketing ground for the artillery and cavalry horses belonging to this station are arranged just outside, and between the rows of stables, and are, consequently, at the same distance as the stables from the barracks and hospitals. 23. In the artillery and 27th regiment of foot there are sufficient quarters for married non-commissioned officers and men; but in the dragoons, not quite enough for all the married men. No married people at this station occupy the same barrack rooms with the men.
Officers' Quarters.	1. The officers' quarters are for the most part good bungalows, ventilated by large doors. The compounds or grounds surrounding them are well drained. Arrangements are required to ensure the soil and filth of these compounds being conveyed out of cantonments, for this, if done at all, at present is done imperfectly. I would recommend that a small monthly sum should be levied on the occupant of each bungalow, to defray the cost of filth carts for this purpose, and that the officers should be held responsible that all impurities are removed.
IV. Health of the Troops.	1. The station, district surrounding it, and the adjoining native population are, as a general rule, healthy. 2. There are no statistics to show what diseases are most prevalent among the native population; but endemic fevers with spleen disease occur, though in a modified degree, as compared with other districts. Epidemics are rare. 3. The district is naturally well drained by rivers; the soil and subsoil favourable to percolation; there are few swamps; the extreme hot weather is short in duration, and the cold weather is bracing and healthy. 4. The H. A. came from Mean Meer. They had been there 11 months, and had been healthy, and are so still; their principal diseases were, and are, fevers and venereal. The F. A. came from Saugor; had been there two and a quarter years; suffered much from intermittent fever and spleen disease; arrived here on the 19th May, 1859 and suffer still from the sequelæ of those diseases. The 7th hussars landed from England on 30th November 1857, and were in the field till their arrival here on 8th April 1859; the most prevalent diseases are fevers, venereal, and diarrhœa. The 27th foot had been at Peshawur from December 1856 till March 1858, and suffered much from fevers of malarious origin. They arrived here in September 1858, and suffer still from the same diseases, but are much improved in health. The Loyal Poorbeah regiment were at Palam for eight months, and arrived here in February 1859; they were healthy there, and are so still. The Kelat-i-Ghilzie regiment from Jullundur arrived here September 1859. The 6th irregular cavalry are from Mooltan. The European infantry barracks have been the most unhealthy, caused by inferior buildings and greater crowding; they have been much improved recently. 5. The troops at the station are not camped out at any period of the year. 6. I have never been actually in charge of troops at a hill station, but I lived for nearly seven years within a few miles of the hill stations of Mussoorie and Landour. I am of opinion, that to troops arriving in health the climate of those stations is highly favourable, provided they are lodged in good barracks. The effects in some states of disease are not favourable, but that is too wide a question to be answered here. 7. I do not believe that residence in a hill climate predisposes men to any diseases on their return to the plains. All the instances bearing a semblance of it that have come to my knowledge, are capable of a much more rational explanation otherwise. I have no proof, however, that it is protective beyond the temporary effect that more robust health would produce. 8. I approve of selecting hill stations for troops, and I believe, under proper precautions, they are destined to be of the greatest advantage to European troops in India. 9. There are no diseases that can be strictly called peculiar to hill climates, with which troops going to them are liable to be attacked; but diseases prevail in some of them at certain seasons, from which troops have often suffered severely. 10. Dry, spacious, and well-ventilated barracks have been the great want up to the present time, a want which is only now commenced to be remedied; this is the first and most essential point calling for attention. Arrangements also are required for a full supply of vegetables for the men, another want that has been productive of much mischief. Flannel next the skin, and especial attention to warmth about the abdomen and extremities, in the rains, with many other minor points, can be arranged by the local authorities.

IV. Health of the Troops —*cont.*	11. To healthy men none of the seasons in the hills are inimical. To men who have suffered from disease in the plain, the hot and cold seasons as a general rule are the best adapted. The period of such residence which would enable troops to obtain full benefit to their health depends much on the state of health in which the men are sent up, and the disease. I would recommend that accommodation should be provided in the hills for at least one-third of the number of European troops serving in India. I would give every regiment 3 years out of 9 in the hills at least. 12. So far as my experience goes there is no period of residence in the hills likely to prove injurious to troops on returning to service in the plains, but they have never been allowed to remain long enough to test this; on the contrary short and interrupted residence of sickly regiments has been the rule, and the results have unfairly been allowed to stand as evidence that such is the case. I would point to the prolonged lives and the physical and mental energy that have returned to the shattered constitutions of our invalid officers who reside there as a proof to the contrary. 13. There are no special precautions for protecting the health of troops on leaving hill stations for the plains beyond what is enforced for protecting the health of the men cantoned in the plains. 14. To preserve the health of troops serving in India I would locate them in the hills with short periods of service in the plains. The march I believe to be generally beneficial, but frequent change of station has no other advantage. The excitement and novelty are said to interest the men, but they are too short lived to be of any benefit. 15. Both barrack and hospital arrangements have hitherto been utterly insufficient, but improvements in this respect are now going on. The new barracks and hospitals at Subathoo and Kussowlie leave little to be desired but their completion. 16. Elevations of from 7,000 to 8,000 feet above the level of the sea are the most suitable for hill stations for healthy men; at such an elevation it is almost immaterial what kind of country the site overlooks. The climate is temperate in the hot and bracing in the cold weather, but in the rains, no doubt, such a site is obnoxious in an increased degree to the evils of clouds and damp, and in some parts of the hills to bowel complaints also, but, as I have said before, under proper precautions healthy men would not suffer much from any of these. Suitable sites, as far as accessibility is concerned, and other military reasons, must be looked for at lower elevations, and probably convalescent stations also such as would suit diseases of the bowels and confirmed organic disease generally. 17. The various ranges of the Himalayah mountains are near the station, and many parts of them could be advantageously occupied as hill stations. No survey or selection of new sites has recently been made, but many are doubtless available at different elevations. 18. I have found stiff and retentive surfaces unhealthy unless thoroughly drained, but it is fair to say that other causes may have been at work at the same time. A soil and subsoil that will admit of ready percolation to a depth of 10 or 15 feet at least, is however, the one to be selected. 19. Soldiers should not proceed to India before the age of 20 or 21, the latter is preferable, and they should land in India in November. To preserve the health of the recruit when landed in India, I would move him off at once from presidency towns, which are hot-beds of all that is injurious to the young soldier, and avoid great fatigue and exposure at first to the sun. If they march, ascertain that the commanding and medical officers are alive to the following evils, viz. late marching, a crowded column of march, deficient or excessive clothing, irregular and unwholesome diet, and intemperance, especially with bazaar spirits. Above all have lock hospitals at every station, and keep them as nearly free as possible from diseases which ruin the constitution 20. With respect to the advisability of sending troops direct from home depôts to India, or first to intermediate stations, we must refer to the health statistics of regiments that have come to India, after service at the Cape, at Australian Colonies, Ceylon, the Isle of France, &c., to decide. I have some doubts of any acclimatising benefits from intermediate service, but I have not sufficient personal experience to enable me to speak decidedly on the point. Experience does not show that the death risks to the young recruit are greater in the earlier than in the succeeding years of service. The points to be avoided are exposure and hard service before his frame is consolidated, and sending him at first to an unhealthy station. My experience points to the latter as the great danger to be avoided. I speak moreover from analogy, when I say that the two first years spent in the hills would be advantageous to all troops recently arrived, especially to the young. 21. The mode of transport from the port to the interior is by steamer to Allahabad and Mooltan, or intermediate stations, from thence by rail, bullock-train, or dak-carriages; very few troops have of late been allowed to march up. The chief precautions necessary are to move them in warm weather only during the night, and provide them good shelter during the day, and to have regular establishments at each halting-place, to provide good food, and all other requisites for them. 22. Experience goes to prove that a regiment of infantry would die out and be renewed in 20 years' continued service. Some improvement is now to be hoped for; but I would for the present confine the service of the British soldier in India to one-third of the above period, or under great emergency to half at the very utmost. 23. In stations, the mode of conducting medical boards is such as to avoid conflict of opinion as regards invaliding. At presidencies, it gives boards there the power to upset all previous decisions, while they have in all probability less information on the case to guide them, the surgeon of the man's regiment being absent. I have not, however, found the evil of sufficient magnitude to call for a remedy. 24. Troops leaving India for home, if going by the Cape, should leave in all January; if overland, before the middle of April.
Diseases.	1. In the 27th foot, there are inspections every Saturday; in the hussars, at irregular intervals; in the artillery, when specially ordered; and in the Native troops, none. 2. There has been no case of true scorbutic disease at this station. In a few isolated cases, a spongy state of the gums has been detected; but it cannot be classed as scorbutic. There are no preventive measures I could suggest. 3. The proportion of cases of hepatic disease usually under treatment, is between two and three per cent. generally. It very frequently succeeds to fevers, and in some cases is traced to direct exposure and intemperance. The state of fatty degeneration doubtless succeeds to

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	too high living, and too much animal food, without exercise in the hot weather. The prophylactic measures necessary are, the means of taking in-door exercises in the hot weather; occupation, mental and physical; freedom from all crowding in barracks; a scale of diet adapted to the seasons; and the absence of exposure and spirituous liquors, &c. 4. There is no case of dracunculus at Umballa. 5. The proportion which the constantly sick from venereal diseases bear to the total sick in hospital, is 27·38 per cent. among the European troops. It would be highly advantageous if a larger proportion of married men were allowed. Lock hospitals would in the highest degree be advantageous, and to aid them, let the women select one of their own number as their head. Make her position desirable by good pay, and make her responsible that no diseased woman goes undetected. 6. The troops at this station suffer from fevers. Endemic fevers of miasmatic origin, and intermittent and remittent. Dysentery. Often one of the sequelæ of the above. Cholera. Sporadic cases, rarely epidemic. Small-pox. Ditto ditto. Rheumatism is frequent. 7. The more frequent zymotic diseases are fevers, intermittent in character, and quotidian and tertian in type. Profluvia and impetigines. The two former are prevalent mostly in and after the rains, and the latter at all seasons. Moisture, cold, and terrestrial exhalations generally accompany their appearance. We have no statistics to prove that these diseases prevail more in one part of the bazaar than in another, and there is no trustworthy testimony to be obtained. The vital statistics of bazaars and native dwellings are entirely wanting. Among the poorer part of the native population there are many conditions that predispose to these diseases; they are ill fed, ill clothed, exposed to all the vicissitudes of climate as well as such malarial influences which exist, their personal habits also all tend in the same direction. The troops are exposed to none of these. 8. Epidemic disease is seldom seen in the station, and is little influenced by the soldier's duties or occupations in barracks, though his personal habits may, and doubtless in many instances do, determine the severity of individual attacks. 9. Small doses of quinine as a prophylactic have been tried only by one medical officer at present at the station, and he reports unfavourably of the practice, or, to speak more properly, he has been disappointed in the results. 10. No answer to this question.
V. Intemperance.	1. As a general rule the soldiers at this station are temperate. There are three or four confirmed drunkards in the artillery, the same number in the 7th hussars, while in the 27th foot only four men have been tried in two years for habitual drunkenness. 2. The proportion of admissions into hospital from diseases directly caused by intemperance is about 3 per cent., and indirectly about 15 per cent. There are no available statistics to show the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station. Drunkenness is invariably punished as an offence. 3. Rum is sold in the canteens and native spirits in the bazaars by a contractor. The quality of the former is good, but that of the latter highly injurious. The artillery consume three-quarters of a gallon per month per man, and the hussars at the rate of $1\frac{51}{91}$ drams per man daily. Spirit forms no part of the soldiers' ration in any situation; they can purchase it at the canteen, but not before 1 p.m. No dram is allowed before morning parade. In the artillery brandy has been given in minute quantity, and largely diluted, to convalescents in cases of impaired digestion, but very rarely. In the other regiments distilled spirits are not given to convalescents, they are allowed at the utmost to draw an allowance of beer or porter. No injurious drinks other than intoxicating drinks are sold in the canteens, but a kind of ginger beer is often procurable in bazaars, which becomes injurious in cholera seasons, or when a tendency to bowel complaints exists. 4. The consumption of spirits by troops is injurious to health, and is not conducive either to the efficiency or internal discipline of the corps. 5. Spirits form no part of the ration, but it would be beneficial to the health of the troops to abolish the sale of them in canteens and bazaars, and allow nothing to be sold but malt liquor. 6. The abstract question as to the comparative effect on health of spirits and malt liquor or wines is a wide one, but in a practical point, as regards the soldier, and used as he uses them, there can be no doubt of the evil effects of spirituous liquors as compared to the other two. 7. Tea, coffee, lemonade, soda water, &c. are much used at the station, and the effects of all as compared with spirits may safely be pronounced favourable, but as compared with malt liquors in moderation I am not prepared to say that they can claim the same superiority. 8, 9, 10. There is no spirit ration, but I am of opinion that it would be beneficial to suppress the sale of spirits and substitute beer, tea, coffee, &c. 11. Copies of the canteen and bazaar regulations are transmitted. The canteen regulations are enforced; but it requires constant supervision to see those of the bazaar anything like obeyed.
VI. Diet.	1. The composition of the ration for Queen's British troops and European troops is the same, and as follows:—viz., meat (beef or mutton) 1 lb., bread 1 lb., rice 4 ozs., sugar $2\frac{1}{2}$ ozs., tea $\frac{5}{7}$ oz., or coffee $1\frac{3}{7}$ oz., salt 1 oz., vegetables 1 lb., and firewood 3 lbs. The periodical changes are from beef to mutton, and *vice versâ*, in the vegetables as the seasons change, and the men vary their own diet occasionally by the purchase of fowls and other items. There is a daily inspection of the ration in all the regiments by the orderly officer and regimental quartermaster, and by the commanding officers at intervals. There is also a monthly inspection of the things that are kept in store by a board of officers. 2. A complete ration with vegetables is provided, but no fruit. The stoppage is 5*d.* or 3 annas 4 pie per man. The soldier has three meals a day, viz., breakfast at 8 a.m., consisting of tea or coffee, and bread and meat, generally fried or curried. Dinner at 1 p.m., consisting of soup, meat, (roast, boiled, or curried,) rice, potatoes when procurable, bread and vegetables. Tea at sunset, consisting of tea and bread. The allowance of vegetables to the daily ration is 1 lb.

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	3. I would modify the ration by reducing the amount of animal food to one half its present allowance from May till October, and substituting a milk diet for the part retrenched. I would give all encouragement for the production of such native vegetables as can be grown during the hot months, when the want of vegetables is much felt. The rations for a company or mess are for the most part made over to a non-commissioned officer or mess orderly; but no precautions are found necessary for preventing the rations being disposed of. 4. There are two cooking-houses for the artillery and one for each troop or company of the rest of the troops at the station. The apparatus consists of copper vessels tinned inside, iron or copper frying pans, and iron spits. As regards cleanliness, light, and ventilation, the kitchens are open to improvement. The water supply is sufficient for cooking purposes only. The food is generally roast, stewed, or eaten as steak, but each man can order his food to be dressed as he likes it. Commanding officers at present at this station report the cooking as satisfactory, but it cannot in reality be considered so. The great majority of the cooks are ignorant of the first principles of the art, and I am satisfied it would add much to the health of the soldier in India if a class of men were properly taught and trained for this purpose. The men have tea, coffee, or other refreshment either before a march or half way, generally the former. During a march in the hot weather it has been found advantageous to give the men a substantial meal at two and three in the morning before march. Some regiments during the late service in the hot weather ate a hot breakfast at that hour with good effects. 5. Gardens could be advantageously established near the station in the cold weather, but so far as my experience goes, soldiers will not work voluntarily in them to an extent that would render the exercise healthful or the products valuable to themselves. Regulations might be framed, rendering the work in the garden an offset against some other part of the soldier's duties, and all be obliged to take it in turn. As regards health, the regulations would effect the following points:—1st.—Situation, so as not to be too near the barracks to affect the health of the men, or too far to be conveniently reached; 2nd.—Avoiding excessive irrigation; 3rd.—Keeping down excessive vegetation, especially in the rains; 4th.—Forbidding manure heaps and other causes of unwholesome emanations; 5th.—Appropriate times for the men to work, both as regards seasons, and the hours of the day, &c. &c.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress is as follows:—Flannel shirt, shirt, cotton drawers, cotton and worsted socks, boots, braces, tunic, jacket, helmet, or shako, helmet forage cap, cloth forage cap, gloves, overalls, great coats. In the cold weather the outer garments are of cloth, and in the hot of light cotton cloth dyed kaki. The accoutrements are a pouch, and pouch and sword belts. I consider the present dress as suitable to the climate, and for the soldier's duties by day and night. The present loose dress is well adapted for India. A light helmet with a double crown, and a white cover would be desirable for the hot weather, as the pith helmet, though a good protection against the sun, is none against rain unless supplied with an outer cover impervious to wet. Men on guard have the protection of guard rooms against sun and wet. Sentries have generally a verandah or some cover in their beat.
Duties.	1. Recruits should be thoroughly drilled at home before proceeding to India. Enlist them at 18 or 19, drill them for two years at home, and send them out men, capable of bearing fatigue and ready to take their place in the ranks, instead of boys unfit for the working duties of actual service. The drill necessary for the recruit has to be undertaken in the first hot weather, and they stand it badly. 2. The duties consist principally of guards and parades, and stable duties for the mounted branches. The drill is confined to 1 hour or 1½ hours in the early morning, from half an hour before to an hour after sunrise (in the cold weather this period is increased), and in the evening three-quarters hour. The men do not suffer in health from the drills and duties at this station. The best hours for drills, parades, &c., are from 7 to 9 in the cold weather, and from 5 to 6 in the hot, with half an hour in the cool of the evening. March so as to reach your ground by 9 in the cold weather, and about sunrise in the hot. General Order, March 21st, 1846, sec. 2, page 361, Military Regulations. The artillery have 5 nights in 6 in bed, Hussars, 7 out of 8, 27th foot, 10 out of 11, Kelat-i-Ghilzie regiment, 5 out of 7, and the Loyal Poorbeah regiment 6 out of 8. 3. Guards are all mounted close to the men's barracks, and they are 24 hours on duty. There are generally three roll calls during the day, but none at night; in some instances check roll calls on uncertain days. Night guards are not injurious to health if the men have five nights in bed. Flannel next the skin is necessary during the rains and cold weather, and the only other precautions required are against cold and wet.
VIII. Instruction and Recreation.	1. The following are the means of instruction and recreation at this station, viz., ball-courts, skittle-grounds, schools (but no trained schoolmasters), library and reading-room, well lighted, but no day room, or soldiers' clubs. There is a soldiers' garden; government provide tools and seeds, but few men take much interest in it. There are neither workshops, theatre, nor gymnasia. Lofty spacious buildings for these as well as for a day-room, are much required. They would add greatly to the health, comfort, and amusement of the men during the hot weather. With the exception of the library, none of the means at this station are available for the occupation or amusement of the men, during the heat of the day in the hot season. There are restrictions on all the European troops exposing themselves during the heat of the day, on pain of confinement, in the hussars, between breakfast and 5 p.m.; artilleay, between 9 a.m. and 4 p.m.; and 27th foot, between 7½ a.m. and 5 p.m. These restrictions are beneficial to the health of the troops. 2. I would erect large airy buildings near the barracks for the indoor recreation of the men, during the long days of the hot weather. A part ought to be set aside for games of all kinds, and a part for a library, reading-room, coffee-room, workshops, theatres, &c. In the coffee-room, tea, coffee, beer, to a limited amount, and a pipe ought to be procurable. Plunge baths under the same roof would be a great advantage. 3. The institution of soldiers' savings banks here would be advantageous. 4. There is not sufficient shade from sheds, verandahs, &c., and exercise during the day in hot weather cannot be taken under the shade of trees without injury to health.

References to Subjects and Queries.	Replies.
IX. Military Prisons.	1. There is no uniformity in the military prisons in the station; the cubic space allotted to prisoners, extending from below 800 to above 3,000 cubic feet. Improvements in the ventilation of some have recently been made, and are still required in others. Verandahs in some have also been applied for to modify the heat, and others are quite uninhabitable in the hot weather, and are not used.
X. Field Service.	1. There are no local regulations for field medical service not included in the general presidency regulations. 2. The actual powers of the medical officer as regards the conduct of a march, &c., are, I believe, *nil*; but I have always found the practical working of his recommendations satisfactory. It depends much, however, on the officer commanding, for he has the power of setting aside those recommendations, and acting in direct opposition to them. In this case, of course, he takes an increased responsibility on himself, and is held solely answerable for any evils that may ensue. 3. In ordinary marches in this presidency, encamping grounds are marked out along all the principal lines of road, and no other selection allowed. Their conservancy is well cared for, but they become impure to a certain extent after long use under any regulations. Where camping grounds have to be selected, it would be an improvement, if a medical officer were directed to accompany the officer who selects the ground the day before, and to advise with him in this duty. It would also be an improvement, if medical officers had the power of interdicting absolutely unhealthy spots, unless there were the strongest military reasons against him. 4. The arrangements for field hospitals are made by the principal medical officer with the army. Doolies are the general (and by far the best) mode of transporting the sick; ambulances also are supplied, and the hospital supplies are generally transported on camels. Copies of regulations bearing on these matters are to be procured from the presidency office.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1. A sketch of the ground plan and elevation of the hospital is transmitted. 2. The position of the hospitals, as regards the distance from barracks and the stables, is as follows:—In the infantry, on the left rear of the men's barracks, about 400 yards distant; in the cavalry, on the left rear angle, and 300 yards from the stables; in the artillery, in rear of the park, and quite detached; and in the native regiments in the rear of each. They are at a distance from all bazaars, but not at a great distance from officers' houses. The sites are open and freely ventilated, and there are no buildings or other obstructions to interfere with ventilation. The sites are healthy as regards elevation, drainage, absence of malaria, &c., with the exception of the native infantry hospitals, where foul nullahs run in close proximity. These require to be filled up, and one clear cut for the water made. 3. The water supply is wholesome, but very limited indeed. A small canal, brought into cantonments from the Gujger river, would appear to be the only feasible remedy. 4. The facilities for drainage require little artificial assistance. There are surface drains cut in the soil, but the refuse water of hospitals is carried away. 5. The lowest wards of the hospital are raised 3½ feet above the ground, but there is no perflation of air below. The ground being metaled on a slope all round the building, the roof water is rapidly carried away into side channels, which communicate with a natural nullah, 1,500 yards from the building. This surface drainage is sufficient for carrying away the rain-fall rapidly from around the hospital. The hospitals are built of burnt bricks and lime cement, but in some portions the cement is mud. The walls and roofs are not double, but are sufficiently thick to keep the hospital cool. The main wall is from 2 to 2½ feet thick, and the others 1½ and 2 feet. The artillery and cavalry hospitals are thatched, and the infantry one is tiled over two layers of bricks. There are verandahs on both sides 10 feet wide, but an additional 2 feet in width would have added much to the shelter they afford from the sun. The inner verandahs are frequently used for the accommodation of sick, convalescents, and others. The hospitals consist of one flat.

XII. Hospitals—*cont.*	The hospitals are so placed as to receive the full benefit of the prevailing winds. There are windows to one hospital only, and they are constructed on the revolving principle on a central axis. The arrangement is highly conducive to ventilation, and ought to be extended to the other hospitals and the barracks also. 6. In the new infantry hospital the ventilation is effected by doors and the windows above mentioned, in the others by doors and ridge roof ventilation. The wards are always kept pure from odour and closeness, but the addition of windows would aid ventilation much. There is also a ventilating shaft in the new infantry hospital, of which a plan is transmitted. Jalousies or jhilmils have not been supplied to all the hospitals. Those in existence are 8 feet by 5; a double row of imbricated boards, that admit the air, and modify the glare, wind, &c., when required. 7. Tatties, as before described, are the means used for cooling the air admitted into the wards, together with the thermantidote, a circular arrangement of fans for throwing in fresh air, previously cooled by passing through a tattie at the side of the machine; they are worked by manual labour. 8. The walls and ceilings of hospital wards are limewashed to the height of 6 feet every quarter, and entirely once a year, but it can be done oftener, if considered necessary, and an application made for it. 9. The privies are detached buildings from the corner of the rear verandah in each hospital, and communicating by a covered way, and are constructed of the same materials as the hospital. A plan is transmitted. The fluids are received into shallow masonry cesspits, which are cleaned twice a day, and the whole soil and filth are carted out of cantonment daily. Much attention is given to keep them clean and free from all offensive smells. 10, 11. The lavatory arrangements of the hospitals are as follow:—Bathing rooms with basins ranged all along the wall, some of brass, some earthenware, and bathing tubs are supplied, in which cold and warm baths are given. Inexpensive means of giving hot, cold, and vapour baths might be arranged in every hospital. The above applies also to the means of bathing for the sick. 12. Washermen to the required number are kept up by Government for the hospitals. The clothes for the most part are washed and dried out of the station; the work is efficiently performed, and I do not know that it could be improved upon. 13. In the artillery hospital there is properly speaking no store room, but a spare room is made available without interfering with hospital arrangements. In the hussars the storage is sufficient, but in the 27th regiment rather confined. 14. The cots supplied are not of a standard or uniform pattern; they are generally of wood with tape or cane bottoms. The bedding is of red cotton cloth filled with country tow. Substantial iron bedsteads with tape bottoms would be a great improvement on the wood. The covering consists of sheets and country blankets, as many as may be necessary. 15. The kitchens are detached buildings in the rear of the hospitals, and from 40 to 60 yards distant. The means of cooking consist of copper vessels tinned twice a month, and kept very clean; means of boiling, roasting, frying, stewing, &c. are provided, and puddings and extra diets also. Much cannot in general be said in praise of the cooking, but it is sufficient. 16. The diet tables, diet rolls, &c. are the same in all regiments, and copies can be supplied from the head offices at presidencies for the two services respectively. Copies of all the returns recently called for in the royal army are not yet available at this station. 17. One hospital serjeant is allowed to each European hospital, and sick orderlies are also furnished from regiments to attend on serious cases. No nurses are provided in regimental hospitals beyond two native women for the female wards, and in smaller hospitals such as those of brigades and battalions of artillery they are not allowed to be permanent but are indented for when required. One European nurse at least ought to be allowed for every female hospital. With this exception the attendance for the sick is ample and liberal. 18. The sanitary condition of the hospitals is satisfactory. No epidemic diseases have appeared in the wards. 19. The deficiencies which have come under my notice are, 1st, a left wing hospital for the infantry regiment; 2nd, means of isolating infectious cases in all the hospitals; 3rd, a privy for each of the female hospitals; and 4th, baths as before mentioned. 20. The commissariat furnish carts, elephants, and extra doolies on requisition, or on indent for the exercise of convalescents. There is also sufficient ground round each of the hospitals, but shaded walks and seats are not in existence. 21. There are separate buildings (females' hospitals) for the treatment of soldiers' sick wives and children. A privy is required for each, but estimates have been sent in for this necessary addition. 23. The powers of the medical officer in matters relating to the sanitary state of the hospitals consist in representing improvements required, and the same as regards repairs of buildings. These representations, bearing the signature of his commanding officer and of the deputy inspector-general of hospitals, are passed on to the proper department to be carried out. As regards diet and medical comforts, his powers within the hospital are complete, under the supervision of the deputy inspector-general of hospitals. 24. There are no wards or hospital for convalescents; they would be useful as enabling the surgeon to regulate the diet, exercise, and exposure of convalescents; but they cannot be said to be urgently required.
XIII. Burial of the Dead.	1. The burial ground for British troops is in the station, in the rear of the dragoon bazaar and to leeward as regards the prevailing wind. 2. It is 900 feet by 700, giving an area of 630,000 square feet. The soil and subsoil are those of the station generally before mentioned; it is well drained, and the ground carefully kept. 3. With regard to grave space and the interval between the graves, there are no specific regulations; no depth for the graves is laid down. They are never re-opened, and not more than one body is interred in the same grave. Interment is not compulsory at any time, but is seldom delayed beyond 24 or 48 hours. There are two burying grounds for native troops, about 400 yards in the rear of the native hospitals; and a space close beside them for burning the dead. One is a Mussulman, and the other a Hindoo burying ground. 4. The grave yards at this station are never offensive. British troops are generally buried within 24 or 36 hours after death.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead—*cont.*	5. There are four Mussulman burying grounds altogether, but only one for Hindoos, and many of the latter burn their dead in a nullah outside the cantonments. An additional burying ground ought to be marked out for the Hindoos of the Sudder bazaar. 6. No perceptible injury from the present practice accrues to the public health of this station. 7. The improvements I would suggest with regard to the disposal of the dead are, that the place of incremation for the Hindoo dead be removed to a greater distance, and the Mussulman graves should be much deeper.

(Signed) R. Garrett, Major-General, Commanding Division.
H. A. Bruce, M.D., Deputy-Inspector-General of Hospitals, Sirhind.
A. K. Moffat, Captain, Executive Engineer, Lower Sirhind Division.

1st August 1860.

PESHAWUR.

Accommodation
- Queen's Troops
  - Artillery: 2 Troops Horse Artillery (Bengal), 5 Companies Foot Artillery - } 732 non-commissioned officers and men.
  - Infantry: Barracks for 2 Regiments, but 2½ Barracks in each lines are unfinished, so that there is actual accommodation for - - } 1,919 non-commissioned officers and men.
- Native Troops
  - Cavalry: Lines for 1 Regular and 2 Irregular Native Cavalry.
  - Infantry: 5 Regiments of Native Infantry, 1 Company Sappers and Miners.

I. Topography.	1. The general aspect of the valley of Peshawur is flat, with sufficient undulation to render the drainage lines marked and decided. In its natural state, the country would be dry, but the free use of water for irrigation renders the cultivated parts of the valley moist. There are no woods or jungle near the station; even single trees are scarce, except near the irrigation canals. There is a good deal of water in the vicinity, which is drawn from the larger rivers for the purpose of cultivation. 2. The station of Peshawur is 1,056 feet above the level of the sea; Nowshera is 1,014 feet, and the cold weather level of the Indus at Attock is 874 feet above the sea level. The ridge on which Peshawur cantonment is located is about 68 feet above the depression which separates it from the next undulation, and about 70 feet above the jheel or marsh, which is the nearest body of water. There is no higher or healthier ground adjoining which would be available for a station, as most of the neighbouring hills are beyond British territory. 3. The mountain of Tarturrah, to the right of and overlooking the Khybor Pass, is about 16 miles distant from the station, and about 5,600 feet above it. 4. The nearest standing water is the jheel, which is mostly within the cantonment boundary, and about three quarters of a mile from the inhabited part. The nearest running water, independent of the small canal which runs through the station, is the Barah river, distant about four miles. The Cabul river is about six miles off. The vicinity is not liable to overflow of water. There are ravines and broken ground beyond the limits of the station; when these are made receptacles of filth and stagnant water they cannot but be injurious to health. None exist within the limits of the cantonments, and those that exist outside the station are so far from it that the health of the troops is not affected by them. 5. The station is open and freely exposed to such winds as circulate in the valley. The trees within the station are trimmed to such a height as to allow free circulation of air, and there are no high walls to interfere with ventilation. The temperature of the station is raised by reflected sun heat. This fact can be sensibly felt by going some distance out of the station after sunset in the hot weather. It is not exposed to cold or variable winds. During the cold season the wind blowing off the snow is naturally sharp, but it has no injurious effect on health. 6. In the immediate vicinity of Peshawur the country is cultivated, but throughout the valley there is much uncultivated land. There are numerous water channels or irrigation cuts from the Bara river intersecting the country to the very boundary of the cantonment. Indeed, the stream which supplies water to the station is one of these. When not carried to any great extent, artificial irrigation is not injurious, but if carried to the extent required for the cultivation of rice, maize, or bajra, it would probably affect the health of those living near. The cultivation of rice is prohibited within three miles of the cantonment boundary. The cultivation of indigo, flax, and hemp is not carried on in the Peshawur valley, or if it be, it is so distant from the station as not to have any effect on health. 7. The city of Peshawur, which is large and populous, is within 1½ miles of the station. 8. The soil of the district is a peculiarly stiff non-absorbent clay; underneath are beds of gravel and small shingle, which overlie a bed of boulders. In this last stratum water is found. The cantonment was formerly cultivated land, and remarkable for its fertility; rice was the principal crop raised. Two small villages stood on the site of the present left irregular cavalry lines, but they covered a very small portion of the present cantonment area.

I. Topography—*cont.*	9. The water level in the wells does not vary in the wet or dry season. The depth of those in the station to the water line is about 102 feet. Those wells are on the ridge, not in the valley. 10. The stiff clay soil of the station is almost impervious to water, but the slope of the ridge is sufficient to carry off all rain fall. Unfortunately, most of the natural drainage lines in front of the cantonment lead into the jheel, which is formed by the embankment of the Sheikh ka Kutta canal crossing and closing the drainage outlet of the country. No drainage from higher ground passes into the subsoil of the station. 11. The principal water supply is derived from the river Barah, and is conducted into the cantonment by a small open canal. This river is never totally dry, much of the water is probably derived from the melting of the snow on the Sooféd Koh, under which it takes its rise. Most of the native lines have a small tank, about 30 feet square, in which they allow the water to settle before using it; this gets rid of much of the impurities which the water holds in suspension. These tanks are filled every day. They contain numerous frogs, but there are very few plants either in them or the water-courses, as they are frequently cleaned, Typha angustifolia, Potamogitons, and Confervæ. The following statement is made by Dr. J. L. Stewart, 14th P. I. "The higher grounds in the immediate neighbourhood of the marsh are abundantly covered with several species of Salsolacæ (anabisis Suædah), Frankinia pulverulenta, and similar species of plants that affect saline soils, and there is a profuse saline efflorescence on the surface of the ground in these places, the water of the marsh at one place being quite salt. The willow, which is abundantly propagated by means of shoots in many places near the marsh (and with a shrubby salt-loving Tamarix is the only tree) is probably Salix Babylonica. The ordinary plants which grow in and about the marsh are as follows:— " Epilobium; occasional. " Lycopus; abundant in parts of marsh. " Lippia nodiflora and Herpetis monneira about ditches. " A species of Utricularia; rare. " Eclipta erecta; not uncommon when not stagnant. " Ranunculus aquatilis and R. Sceleratus; common in places. " Limnanthemum cristatum; in one part of marsh only. " A species of Lium; common in some ditches. " Typha angustifolia; abundant. " Nelumbium; common (cultivated) in some parts. " Butomus; rare. " Sagittaria sagittifolia and Alisma Equisetum debile; occasional. " Two species of Juncus; rare. " Of sedges the following are common:— " Cypicus exaltatus and C. Mucronatus, Malacochæte pectinata, Scupus Maritimus, Carix Wallichiana (rare), and Eleocharis palustris. "The common grasses about and near the water are Agrostis alba, Polypagon monspeliensis, Andropagon Bladhii, and Cynodon dactylon, with an Arundo and a Saccharum. "The following are the floating and submerged plants:— " A species of Ceratophyllum (C. demersum?), Potamogeton crispus, common in streams; P. Pusillus, not common; and P. Plantageneus (?), rare. " Hydrilla verticillata; Marsilea quadrifolia; Chara, most abundant; and Nitella (?), occasional. " Confervæ; profuse. " Two species of Riccia, a Semno, and an Argolla; in abundance in various parts of the marsh." Owing to constant stirrings and renewal of the water in the tanks and canals of cantonments, almost the only plants that are to be found in them are the Typha angustifolia, two Potamogitons, and Confervæ, and these are very uncommon. No tank used for drinking purposes is used for bathing, great care being taken to prevent the water from anything tending to defile; leaves of trees do fall into the tanks, but they are cleaned out so frequently that no harm ensues, and the water is not injured. Drainage is never allowed to flow into the drinking tanks. No malaria proceeds from the drinking tanks, because they are always kept full of water, and free from decomposing vegetable matter. 12. The supply of water at the station is about 15 cubic feet per second: the water has no peculiarity, in either taste or smell, but the colour is affected by the quantity of earthy particles held in suspension, and varies from pale grey to a deep red, the latter being caused by heavy rain in the hills. There are no means available for analysing the water to ascertain its chemical or microscopic character. No artificial means are used for raising and distributing the water; it flows in earthen channels on the surface of the ground. Better water could not be obtained, but a system of filtration should be adopted to purify it by mechanical means. The filtering strata might be boulder stones, kunker, gravel, and charcoal. 13. With regard to other topographical points not included in the above, may not the basin-like position of Peshawur have some effect on the health of the valley? Being completely surrounded by hills, it has not the advantage of a free circulation of air, and any one who has been there for some time cannot but have remarked the stagnation of the atmosphere at certain times. Again, the latitude of Peshawur, 34′ 4″, is considerable, and change in temperature from day to night very great. In September and October this cannot fail to affect the men exposed to night duties. 14. In former years sites for cantonments appear to have been selected without much regard to the topography of the country. If the position were relatively high, it was supposed the station must be healthy, as it had facilities for drainage, but at the present time, other points formerly deemed of little importance, receive due consideration, such as nature of the soil, whether light and absorbent, or clayey and retentive of water, nature of vegetation, quality of drinking water, depth from the surface, prevailing winds, medical statistics gathered from the local inhabitants, &c. In choosing sites for hill stations, elevation, climate, differences produced by different aspects, and the disposition of the surrounding hills, humidity of the atmosphere, &c., have their weight.

References to Subjects and Queries.	Replies.
II. Climate.	1. There is a set of instruments at the station for meteorological observations, which were supplied by Government about two years ago, and a register of the temperature is carefully kept by the staff surgeon. 2. The following is a table of meteorological observations.

From 1st January 1859 to 31st December 1859.

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain, inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks.
	Inch.	°											
January -	28·95	51	17	59·5	42·5	51	43·5	—	1·4	E.,S.E.& N.W.	—	—	Cold, cloudy, and several showers of rain.
February -	28·77	51	13	57·5	44·5	51	47·5	—	3·1	N.,N.E.& S.	—	—	Cold, generally cloudy, with rain.
March -	28·775	65	14	69·	55·5	65	63	—	1·2	E.,N.E. & N.W.	—	—	Beginning of month cloudy, with drizzling rain, latter part clear, hot during the day.
April -	28·75	74	15	79·5	64·5	74	73	—	0·7	E.,N.E.&W.	—	—	Several showers of rain during the month.
May -	28·615	85·5	18	91·	73·	85·5	72	—	0·9	Variable	—	—	Dust storms and rain first part, latterly close and oppressive.
June -	28·325	93	16	99·	83·5	93	85·5	—	0·9	E.,N.W. & W.	—	—	Hot and oppressive up to 15th, rain on 16th, 19th, and 20th.
July -	28·415	91	14	95	81·5	91	82·5	—	2·39	N.E. & Ny.	—	—	Heavy clouds and strong wind at times.
August -	28·472	88·5	16	96·06	80·3	88·5	78·5	—	0·02	Nrly. & N. Easterly	—	—	Cloudy in middle of month, days cooler than usual.
September	28·462	84·9	17	90·5	73·9	84·9	71·2	97·8	0·11	N.,N.W. & N.E.	—	—	Days hot and oppressive, nights cool, cloudy at times.

November	28·583	59·5	16	65·75	49·5	58·7	51·5	87·25	1·5	S. & S.W.	—	—	Cloudy,particularly latter half.
December	28·80	48·6	16	57	41·75	48·5	44·81	74·75	1·01	S.,S.W. & N.W.	—	—	Rather cloudy.

3. The climate of Peshawur is exceedingly trying to weak constitutions, chiefly from the great alternations from heat to cold, and from dryness to moisture. Tree planting appears to have done a good deal towards equalizing the temperature by preventing that fierce heat which used to mark the station, but without carefully registered data for several years past, all remarks on this point must be received with caution. The canal which runs through this station does not appear to be conducive to malaria; nor is irrigation from it allowed to produce rank vegetation. The presence of water doubtless tends to increase the humidity of the atmosphere, but in the present case not to an injurious extent. The air is generally free from dust. It is the variableness of the climate that chiefly affects the health of the troops. The diet at present given to the men is excellent, and requires no change. Every attention is paid to clothing. It is very advisable that the times of drill should in the hot season be confined to the very early morning between gunfire and sunrise, but in the cold weather the troops should not be turned out until after breakfast. The most healthy months are December, January, February, March, and April, and the most unhealthy months September and October, fevers and bowel complaints prevail.

4. There appears to be no more healthy spot near the cantonments where a station would be advantageously placed. Cherat, in the Khuttak range of hills, about 20 miles distant, was at one time much talked of as a desirable site, but the civil authorities objected to its occupation.

5. The following are the stations at which I have served, with observations on their comparative salubrity :—

Calcutta, Dum Dum.—Generally healthy, but no crowding in barracks should be allowed.
Cawnpore.—Fevers and dysentery prevail.
Agra.—Generally fairly healthy.
Delhi.—Formerly healthy, but latterly not so.
Ferozepore.—Generally healthy.

III. Sanitary Condition of Station.

1, 2, 3. Map and plans of the station, with ground plan of the barracks, are transmitted.

III. Sanitary Condition of Station—*cont.*	5. In the European barracks the doors are opposite each other, and open down to the ground. The ventilating windows in the upper part of the wall swing on horizontal pivots, and are opened and shut by ropes. The barracks are surrounded by a closed verandah 12 feet wide, and an open outer verandah of the same width. The verandahs are never occupied as sleeping quarters during the hot months, but in the winter it is sometimes found necessary to put a few men in the inner verandah. There are no jalousies or jhilmils. 6. The bedsteads are of wood, strung with hempen twine or a sort of grass rope; both of which materials are good. No alteration appears necessary in these or the bedding, which consists of a mattress stuffed with cut hemp (in hospitals only), wadded quilts, sheets, and a country blanket, with a suttringee. 7. Sixteen men occupy each tent. The tents are all of the same pattern, and are known as the "European privates' tent;" they are composed of canvass supported by two uprights and a ridge pole, and have a door on each side. The cubical contents are 2,280 feet, and the superficial area, 320 feet. The cubic space per man is 142½ feet, the superficial area per man is 20 feet. 8. The flat roofed buildings have generally ventilating shafts or chimneys at the corner of the rooms, as well as upper windows, opening and shutting by a string. Pitched roofs have ventilators under the ridge pole, as well as upper windows. The ventilation is in every case sufficient. In the barrack rooms tatties are the only artificial means employed for cooling the air. The proportion of tatties for a barrack or guard-room is one tattie to every two openings. 9. The Peshawur barracks are built of bricks, either burnt or unburnt, according as the barrack is termed a permanent or temporary building. Tents are generally made of three folds of white cotton canvass, and lined with blue. 10. The floors are all of brick, the main ward floors being three bricks, or 9 inches thick; the dining wards, two bricks, or 6 inches thick; and the outer verandah, either one brick over lime rubbish, or refuse of kilns 9 inches thick beaten to 6 inches. This makes a very good verandah floor. All floors are raised; never less than 2 feet, and in some instances as much as 5 feet, but this is due to the inequality of the ground. There is not a free passage of air beneath. 11. It is an undisputed point that unburnt brick buildings are cooler than burnt brick ones; and in this station the barracks with mud roofs are undoubtedly cooler than those with tiled roofs. The materials best suited for buildings in this station are burnt bricks for walls, and pitched roofs covered with mud. The barracks are kept in repair by the executive engineer. Repairs are here not so quickly or so readily executed as at other stations where there is a greater command and consequent competition of skilled labour. The deputy assistant quartermaster-general is, under the brigadier commanding, responsible for the sanitary state of the cantonment. The walls and ceilings of barracks and guard-rooms are cleansed and lime washed annually; those of the hospitals, once in six months. 12. There are as yet no wash-houses for the European soldiers at Peshawur, but a plunge bath is made in each set of lines. 13. Water is readily supplied to the cook-rooms from the nearest channel. The refuse water runs into cesspools, which are emptied out daily. The washing and drying of linen is performed by native washermen outside the limits of the cantonments. 14. The privies are cleaned out daily, and the urine runs into cesspools which are emptied every day. The urine and ordure are carried beyond the limits of the cantonments, and there buried. 15. The cook-rooms and privies are ventilated by openings under the roof, and by several openings in the walls. Those at present in the station have neither doors nor windows, consequently there is a free circulation of air. The barracks are lighted at night by lanterns suspended from the roof. 16. There is no system of sewerage at Peshawur. Offensive matter is received into cesspools which are daily cleaned. Rain water is carried away by surface drains into the natural drainage outlet of the country. Situated on a ridge, as Peshawur cantonment is, the surface drainage must needs be good, and where it is not so, the cause is traceable to local holders; these are being gradually filled up or efficiently drained. The drainage may be considered

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	good. There is no dampness in any of the buildings. The fluid refuse of barracks is received into cesspools, which are daily cleansed. The cesspools are about 3 feet deep and 3 feet wide. It is impossible to state their position from the nearest well or tank, as each building which requires it has one of its own, but in no case is the cesspool sufficiently close to taint the water; moreover, they are to be made more absorbent, which will remove all possibility of such a thing happening. There are no foul ditches in or near the station. 17. The surface cleansing is satisfactorily performed by a conservancy establishment kept up for the purpose. It is done daily, and the refuse manure, &c., are carted to a sufficient distance from the cantonments, and thrown into existing pits or ravines. 18. The surface of the cantonments is kept free from vegetation, except grazing grass, which is permitted and even encouraged. There are no old walls, thick hedges, &c., sufficiently high to interfere with the ventilation of the station. 19. The station bazaar enjoys the same advantages from situation as to drainage as the rest of the station. The ventilation is free, water supply ample, and cleanliness strictly enforced. There is but little crowding, as a large portion of it is unoccupied. Every attention is paid to cleanliness and sanitary measures in the Sudder bazaar generally, for which an establishment is kept up. The drains are not good, but are kept clean, and no accumulation of filth is allowed. The native houses in the villages round the station are not dirtier than native villages usually are, and it is probable they have dung-heaps inside their enclosures. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. The slaughter shambles are at the extremity of the cantonment, as far as possible from the inhabited part. Offal is not allowed to become offensive, as it is generally eaten by pariah dogs and other natural scavengers. The shambles are not a nuisance to the station. 21. The horses of camp followers, if residents of the station or regimental bazaar, are picketed in those bazaars. The ponies belonging to the irregular cavalry grass cutters are tethered in the rear of the horse lines. It would not be possible to picket horses outside the cantonment unless a strong guard were furnished, for the people of the neighbouring hills are great horse thieves, and succeed occasionally in taking them even from officers' compounds. The picketing places are kept clean according to the conservancy rules of the station. 22. There are no artillery or cavalry stables at Peshawur; the horses are picketed within 100 yards of the artillery barracks. Most of the stable litter is used in the riding school, and the remainder is carried beyond the cantonment boundary. 23. There is sufficient accommodation at the station for the married families; they do not occupy the same rooms with single men.
Officers' Quarters.	1. There are no officers' barracks. Officers live in detached houses, each having a small garden round it. These compounds are generally well drained, and the houses are ventilated by upper windows. Rank vegetation is not permitted in the gardens. No improvements are suggested.
IV. Health of the Troops.	1. During the past two years and up to this time (July 1860), the station has been comparatively healthy; there is no European population out of the station. I believe also that the native population of the surrounding district has been in a more healthy condition than formerly, but it is difficult to obtain any reliable information on the latter point. 2. Intermittent fevers, bowel complaints, and rheumatism are the most prevalent diseases among the natives. Small-pox generally prevails as an epidemic towards the end of the cold season. In the Ensufzae and Hazara districts a severe form of remittent, assuming a typhoid type, and attended with jaundice, occurs at times as a severe and fatal epidemic. Spleen disease does not prevail to any great extent. 3. Judging from the physical appearance of the natives of the district, I consider them a well-grown, healthy race. I allude to the rural population: it is different with the inhabitants of the large densely crowded city of Peshawur, with its narrow dirty streets and ill-ventilated houses. 4. The following table will show the stations at which the troops were before coming here, with the length of their service there, and date of arrival at this station; also the state of health and diseases from which they suffered there, their state of health on arrival here, and the prevailing diseases since then.

Regiments.	Name of former Station.	How long there.	Date of leaving it.	State of Health there, and Diseases from which chiefly suffered.	Date of Arrival here.	State of Health on Arrival.	Diseases from which chiefly suffered since Arrival.
7th Batt. 11th Brig. R.A.	Rawul Pindi.	5 months	7 Oct. 1858	Not good; fever; dysentery.	28 Oct. 1858	Improved	Fevers; dysentery; venereal.
3rd Troop 2nd Brig. B.H.A.	Mean Meer	4½ years	7 April 1858	Good; cholera -	—	Good -	Fever.
3rd Comp. 2nd Batt. B.F.A.	Lahore -	5 years -	10 Jan. 1854	Good; none recorded -	—	Good -	Intermittent fever and bowel complaints.
3rd Comp. 6th Batt. Ditto.	Ferozepore	5 years -	4 Mar. 1858	Very good; fever; rheumatism.	—	Good -	Ditto, ditto.
Right Wing 7th Royal Fusiliers.	Jhelum -	1 year -	25 Oct. 1859	Good { Fevers; bowel complaints; venereal and liver diseases.	{ 8 Mar. 1859 / 5 do. }	Very good	{ Fevers; bowel complaints; venereal.
Left ditto, ditto -	Rawul Pindi	1 year -	28 Oct. 1859	Good			
98th Regiment -	Nowshera -	½ year -	—	Good; common continued fever.	—	Excellent	Ditto, ditto.

The eastern end of the cantonment has been by some people pronounced more unhealthy than the western, but the ratio of sick between the corps stationed at opposite ends varies so that it is impossible to say with certainty that one part is more unhealthy than another.

5. The artillery generally move out into camp at Chum Kunnie, about eight miles from the station, for practice, during part of the cold season. They usually remain in camp for six weeks or so, and I believe the men are all the better for the change.

6. I have never been in charge of troops at hill stations.

7. Data are wanting to show whether troops resident for some time in hill stations are more or less liable to attacks of febrile disease on returning to the plains, but men who have gone to

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops —*cont.*	hill sanitaria labouring merely under debility after an attack of fever or other acute disease, and who have derived full benefit from the renovating climate there, will, it is believed, be less liable to those attacks. 8. I highly approve of hill stations for troops. 9. The diseases which troops are liable to be attacked with on going to hill stations are chiefly bowel complaints. 10. No reply to this query. 11. From April to November is the best season for residence in hill stations, and that is the shortest period of residence to obtain any benefit therefrom. 12. Experience seems to prove that a residence in the hills protracted beyond two years tends to injure the constitution. 13. The troops should not leave hill stations for the plains until the cold weather has decidedly set in. 14. As a rule it appears that it would be more generally conducive to health to locate troops in the plains, giving them short periods of service in the hills. Frequent change of station is very desirable. 15. With regard to barrack and hospital accommodation, the experience of any of those deputed to reply to these questions only extends to Murree, and there the accommodation is ample. 16. The most suitable sites for hill stations are obtained at an elevation of from 4,000 to 7,000 feet above the level of the sea. 17. There is no higher spot near the station that could be advantageously occupied as a hill station. 18. No answer to this question. 19. I consider 20 the best age for a soldier proceeding to India. The best period of the year for troops to land in India is about the end of October or during November, as the heat has become moderated by that time, even in the southern parts of India, where the ports are situated, and there is ample time for the men to arrive at the most distant stations during the cold season. Recruits on arrival should join their regiments at once. 20. The Cape of Good Hope would be a good intermediate station to which to send troops. It might be beneficial to locate young regiments on landing on hill stations for the first two years. 21. Troops arriving at Kurrachee for Peshawur usually travel by river steamer as far as Mooltan, and thence by regular marches 10 or 12 miles a day. They are well looked after and are healthy on march. 22. Men arriving in India at 20 years of age may, I think, serve efficiently for at least 22 years. A furlough of two years to Europe, including the passage home and out, after 10 years' service would be beneficial. 23. No experience of invaliding boards. Those convened at stations for selecting invalids act harmoniously, and, I think, efficiently. 24. I consider that invalids leaving India for home should embark at any time from the middle of January till the middle of February; they would thus arrive in England after the severity of winter had passed over.
Diseases.	1. Weekly health inspections of Europeans are made. Natives are not inspected. 2. Scorbutic disease is now rare; only three cases are recorded amongst the European troops of the station during the past year. In some previous years, 1855, 1856, and 1857, H.M.'s 87th Regiment suffered a good deal from scorbutic disease. This is attributable to the want of fresh vegetables formerly. The supply is now abundant. 3. The proportion of hepatic diseases under treatment varies much. When other diseases prevail extensively it is low, sometimes as low as 0·76 per cent. During the past year, which has been a generally healthy one, the proportion of hepatic to all other diseases treated has been 4·133 per cent. The average of five years is 1·847 per cent., and from this circumstance it would appear to be not generally the consequence of other disease. The natives do not suffer much from hepatic disease. Abstinence from spirituous liquors would, I conceive, be the best prophylactic. 4. Dracunculus is almost unknown amongst Europeans at the station, only one case being on record during a period of ten years. The natives suffer occasionally from it. 5. The proportion which the constantly sick from venereal disease bear to the total sick from all other diseases, of course varies much, being small during otherwise unhealthy seasons, and *vice versâ*. I have seen it as high as 28·50 per cent. The average per cent. of venereal cases to strength is 1·015. I consider that the establishment of well regulated lock hospitals would be advantageous. At present the women have no place of refuge to which they can resort when diseased, and therefore cannot forego the only means they have of obtaining a livelihood. 6. Fevers generally prevail to a considerable extent; but less during the two past years than formerly. The most common forms are— Fevers.—Febris inter. quot. „ „ tert. remittent. contin. com. Dysentery.—Dysentery, acute and chronic, is of frequent occurrence. Cholera rarely appears as an epidemic. Small-pox is of rare occurrence amongst the European and native troops; but it frequently appears as an epidemic in the city of Peshawur and the neighbouring villages. Rheumatism is of frequent occurrence amongst both European and native troops at the station. The following shows the proportion which admissions and deaths from these diseases bear to the total admissions and deaths :—

Diseases.	Admissions.	Deaths.
Fevers - - -	44·90	22·85
Dysentery - - -	3·34	14·28
Cholera - - -	0·17	10·11
Small-pox - - -	0·35	4·31
Rheumatism - -	2·45	„

IV. Health of the Troops —*cont.*	7. Fevers of the intermittent, remittent, and continued types, which form by far the most numerous class of diseases at Peshawur, are remarkable on account of the extreme prostration that often attends them, in former years assuming frequently the typhoid form. Small-pox, dysentery, diarrhœa, &c. exhibit no peculiarities at this station. In May ephemeral and simple continued fevers sometimes prevail; but the admissions from the more severe forms of fevers and dysentery are generally most numerous in August, September, and October, sometimes extending over the cold months of November and December. Rheumatism is most frequent in the cold season, at which time there is usually a good deal of rain and stormy weather. Sudden changes of temperature, also a long continued high range of temperature, accompany or precede the appearance of these diseases. The sanitary condition of all parts of the station is pretty much the same as regards cleanliness, drainage, water supply, &c. The personal habits and conditions among the troops or native population do not appear to have any effect in predisposing to the above diseases. 8. If the soldier is exposed to excessive fatigue or harassing duty in the field, he will certainly, it is presumed, be rendered thereby more susceptible of an attack of any prevailing epidemic; but his ordinary duties and occupations in barracks, with the exception of night guards, do not produce liability to such attacks. 9. Small doses of quinine have not, as far as I can learn, been tried as a prophylactic. 10. Doubtless the draining of the marsh in the vicinity of the station, and for effecting which a plan and estimate have, I believe, been prepared, will tend to prevent, or, at all events, mitigate the prevalence of epidemic disease, having malarious origin. Any other supposed or probable causes, such as stagnation of the atmosphere and climatic changes, are beyond control.
V. Intemperance.	1. The soldiers at the station are temperate. There are very few confirmed drunkards, and a drunken soldier is seldom seen at Peshawur. 2. The proportion of admissions into hospital from diseases caused directly by intemperance varies. During the past medical year it was 1·113 per cent. to the treated in all the European troops at this station. The proportion of those diseases caused indirectly through intemperance is not known. There are no records available from which a table, showing the effect of abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station, can be prepared. Drunkenness is always punished as an offence. 3. Government rum only is sold in the canteen; but none in the bazaar. The average quantity of good rum consumed by each man per diem is $0\cdot\frac{47}{51}\frac{4}{45}$ of a dram. Spirit forms no part of the ration for soldiers. The men cannot obtain a morning dram, as it is contrary to regulation for spirits to be issued before evening parade. Spirit is never given as a ration to convalescents; they have medical comforts at the discretion of the medical officer. No injurious drinks other than intoxicating drinks are sold at the canteen or bazaar. 4. When there is no malt liquor a moderate quantity of spirits is actually necessary to some men. The consumption of spirits certainly cannot be said to be conducive to discipline, for what is conducive is improving, and spirit drinking cannot improve while it may injure a regiment's internal discipline. 5. The sale of spirit at canteens is restricted by regulation. To abolish the sale altogether would not be advisable, for there are doubtless some old soldiers who could not do without it, and were it not procurable at the canteen they would by some means get it elsewhere, and of a far less wholesome quality. If an unfailing supply of malt liquor were available it might be that spirits could be entirely done away with; here the supply of malt liquor is very uncertain. 6. Malt liquor is undoubtedly more wholesome than spirits. 7. Coffee, tea, lemonade, soda water, &c. are considerably used at this station. Malt liquor (or failing that, spirits in moderation) is far better than total abstinence. Tea and coffee give no stamina. 8, 9, 10. It would be better to suppress entirely the sale of spirits, and to permit only beer to be sold in the canteens, if beer could be supplied unfailingly. 11. The canteen regulations are that a man may draw one quart of malt liquor and one dram of rum per diem, or he may have two drams of rum and no malt liquor. The man may take his quart of malt liquor at dinner, or he may divide and take part at dinner and part after evening parade. The bazaar regulations are that the sale of all spirituous liquors is strictly forbidden, and the Abkaree and regimental police are on the look out for offenders. These regulations are strictly acted up to. See section X. Bengal Military Regulations and the Punjab government rules for Abkaree.
VI. Diet.	1. The composition of the ration for Queen's British and European troops in the Indian army is as follows:—Bread, 1 lb.; meat, 1 lb. (beef five times, and mutton twice a week); tea, $\frac{5}{7}$ oz. (or coffee, $1\frac{5}{7}$ oz.); sugar, $2\frac{1}{2}$ oz.; rice, 4 oz.; salt, 1 oz.; vegetables, 1 lb. (potatoes, 8 oz.; mixed vegetables, 8 oz.); and firewood, 3 lb. An inspection of the ration is made daily by the captain and subaltern on duty, frequently by the commanding officer of the regiment, and occasionally by the brigadier commanding the station. 2. There is a complete ration provided for the troops, with a due proportion of vegetables (no fruit). The stoppage for rations per diem is 3 annas 4 pie; and, besides, the infantry regiments in the Peshawur district pay 1 anna per diem, and the artillery about 2 annas per diem, for the purpose of bettering their mess, and this has been found of great advantage. The soldier takes three meals a day, viz., breakfast at 7 a.m., dinner at 1 p.m., and supper at 5 p.m. The proportion of vegetables which enters into the composition of the ration is 1 lb. per man. 3. The rations are excellent at Peshawur. To prevent the troops disposing of their rations there is an orderly to each mess, whose duty is to see the rations of the mess properly used. A soldier discovered making away with his ration would be severely punished. 4. The means and apparatus available for cooking at the station are the ordinary Indian fire-places and copper vessels; the latter are tinned at stated times. The kitchens at Peshawur are only temporary buildings; they are as clean as possible, sufficiently light, and well ventilated. There is abundance of water. The food is boiled, roasted, stewed, fried, &c.; in fact, the men may have it dressed any way they like. The cooking is excellently done, and varied in every possible way. Tea and coffee are properly prepared. When on a march the men generally have coffee half way between the old and new camp. 5. Gardens for cultivation by soldiers must of necessity be close to the barracks, and this was tried at Peshawur, but did not answer. There is here an excellent Government garden, from which vegetables are purchased by the Commissariat for the soldiers.

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties.	1. In winter, the soldier's dress at this station consists of cloth tunic and trousers, forage cap or wicker helmet, and boots; in the summer, cotton (khakee) tunic and trousers, wicker helmet, and boots. The ordinary accoutrements. The present dress is admirably adapted to the climate, and every precaution is taken to guard against the alterations from heat to cold. Men on guard here in the winter have their great coats, to which a serge lining is added. The European troops here at Peshawur have, in addition to their ordinary dress, a wadded coat for winter wear.
Duties.	1. It is advisable that the men should be thoroughly drilled in England before being sent out to India. 2. The ordinary routine of a soldier's duties is as follows. Morning and evening parades, guard mountings, roll calls, ordinary fatigue duties, &c. In the hot weather regimental parades last about three quarters of an hour, and are over by sunrise; in the cold weather, from one to two hours' time, varying from 8 to 10 a.m. Brigade drills are of frequent occurrence, and occasionally very long, but the men do not suffer from this. The best part of the day for drills, marches, &c. is, in the hot weather, between daybreak and sunrise; and, in the cold season, after breakfast. The average number of nights which the European troops have in bed during the week is from five to six. The guards furthest from the barracks are the rear-guards, distant about half a mile. There are roll calls at all the customary hours, but should irregularity be suspected there would be check roll calls at uncertain hours. The effect of night guards on health is considerable at some seasons of the year,—spring and autumn chiefly, and also all through the winter; but every possible precaution is taken.
VIII. Instruction and Recreation.	1. The following are the means of recreation and instruction at this station:—1. Ball court (Left European Infantry lines); 2. Skittle grounds; 3. Schools with good schoolmasters; 4. Libraries and reading rooms, well lighted at night. There are no soldiers' gardens. No workshops have been built for the men, but they work at their trades if so disposed. There is a theatre, but no gymnasia; but there should be a gymnasium in each regimental barracks. In the hot weather, men are restricted to barracks from 10 a.m. to 4 p.m. 2. To improve the existing means of recreation and amusement there should be a gymnasium for each regiment, a large reading room separate from barrack rooms, serjeants' mess, and school-room. These should all be separate buildings, instead of, as now, being taken from the barrack accommodation. 3. Soldiers' savings-banks already exist, and are found highly advantageous. 4. There is no shade for trees close to the barracks, and it is too hot in the daytime to take exercise in the verandahs.
IX. Military Prisons.	1. The only cells at Peshawur are those attached to the guard-rooms of regiments, and these are defective in ventilation. An experimental alteration is about to be made in one set of cells.
X. Field Service.	1. No local regulations for field medical service exist which are not included in the General Presidency Regulations. 2. Any suggestions made by the medical officer would, as a general rule, meet with the attention of the commanding officer. 3. There are no regulations existing here which provide for selection of camping grounds general sanitary arrangements, ventilation, &c., in huts, tents, and hospitals. 4. No answer to this query. Could be answered by Inspector General of the Presidency.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1. Plan of hospital, &c. has been transmitted through quartermaster-general of the army. 2. The European infantry hospitals are situated close to their barracks. The artillery hospital is about a quarter of a mile from the nearest part of artillery barracks, and at least half a mile from the horse lines. The hospitals are clear of the bazaars, but close to the officers' houses, separated merely by the breadth of the road. The sites are open, and nothing interferes with free ventilation. The sites are generally well drained, and not exposed to the evil influence of malaria. 3. The supply of water for the hospital is abundant and wholesome. 4. Refuse water and other impurities are removed from hospital, as from barracks, by carts with barrels. 5. The lowest wards of the hospital are raised 2 feet above the ground, but there is no perflation of air underneath the floors. Roof water is conveyed by surface drains into the general drainage of the cantonment. The surface drainage, and materials of which the hospital is constructed, are the same as those of the barracks. The hospitals are supplied with outer open and inner enclosed verandahs, 12 feet broad; they afford good shelter. Along the outer verandah reed chicks are suspended to ward off the heat and glare. The inner verandahs afford excellent accommodation for the sick when required, but it has not been found necessary to use them of late. The hospital consists of one flat. Table of Hospital Accommodation:— Date of construction, 1851 to 1857. Total number of wards, 21 (6 wards for men and 1 for women in each hospital). Total regulation number of beds for each European infantry hospital, 300. There are three hospitals for Europeans in this station.

Wards or Hospital Huts, Number.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Ft.	Ft.	Ft.	Ft.			Ft.		Ft.	Ft.
21	24	66	24	20*	31,680	1,320	66	2	26	2	4

* This height includes the gable.

N.B.—Observation or admission wards and inner verandahs are not here shown, as they are not occupied unless the number of sick is very great.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	6. The replies to queries regarding barrack ventilation apply equally to hospitals. 7. Thermantidotes are employed for cooling the hospitals. One is allowed for each ward, and even when the atmosphere is such that they do not cool by evaporation, they throw in a current of fresh air which is beneficial. 8. There are fireplaces at each end of the wards. The walls and ceilings of the wards are cleansed and lime-washed once every six months, but if recommended by a board of medical officers as a sanitary measure more frequently. 9. The privies and urinals of the hospitals are the same as those of the barracks; they are not over cesspits, but are daily cleansed, and are not allowed to become offensive. 10. The lavatory arrangements of the hospital, as well as the barracks, are incomplete and insufficient; no permanent washhouses have yet been built. A portion of each of the outer verandahs is enclosed and partitioned off; these are supplied with earthenware basins. 11. Cold baths, when required, are given by means of mussucks (leather bags), or waterpots; appliances for administering hot baths are available in every hospital. 12. The washing and drying of all hospital linen are done by the washermen out of the station 13. The storage is crowded, first, because there are no quarters for medical subordinates, who consequently occupy what would otherwise be used as storerooms; and, secondly, double quantity of bedding is allowed at Peshawur, and no extra provision made for storing it. 14. The bedsteads are the same as those used in the barracks, and so is the bedding, with the exception that a mattress stuffed with chopped hemp is allowed. 15. The hospital kitchens are conveniently situated as regards the wards, but being merely temporary mud buildings without doors or windows, are of course much exposed in storms and rainy weather. An ample stock of kitchen utensils is provided by the Commissariat Department, and the mode of cooking is varied, as directed by the medical officer. 16. Copies of diet tables, diet rolls, &c., forwarded by Surgeon N. H. Stewart, H.M.'s 98th, along with copy of report transmitted through quartermaster-general of the army. 17. The hospital servants are natives; there is a hospital serjeant in each regiment, and if a man's case requires it, an orderly is told off to attend on him. 18. With the exception of the scanty accommodation for ablution purposes, the sanitary condition of the hospitals is good. No hospital gangrene or pyæmia have appeared in the wards. 19. It is suggested by Dr. N. Stewart, 98th regiment, that in future barracks and hospitals should be built on open arches elevated at least 6 ft. above the ground; this, however, appears hardly necessary at Peshawur, where the foundations are well raised, and the buildings show no sign of dampness. 20. Convalescents are either carried out in doolies, or else ride on elephants. 21. A ward in a separate building from those occupied by the men is appropriated for the use of soldiers' wives and children. A matron and native female servants are employed to attend them. The arrangements are very satisfactory. 22. There are no special local hospital regulations in force at this station, not in the General Presidency Medical Regulations. 23. Repairs affecting the sanitary state and general comfort of the sick in the hospital are executed by the executive engineer upon the requisition of the medical officer, who has also ample powers with reference to the change of diet, and the issue of any medical comforts that may be required for the treatment of the sick in his hospital, at stations, camps, and on the march. 24. There are no wards or hospitals for convalescents, nor are such required.
XIII. Burial of the Dead.	1. There are two graveyards half a mile distant from barracks; one is to the west front, the other to the north-west front of the station. There are no prevailing winds at Peshawur. 2. No answer to this question. 3. Hindoos and Sikhs burn their dead; Mahomedans bury, but their graveyards are out of the station limits. 4. The graveyards have never been offensive. 5. The bodies of camp-followers and bazaar people are disposed of according to caste. 6, 7. No injury accrues to public health from the present practices, nor are there any improvements to be suggested.

(Signed) T. J. Galloway, Brigadier, Commanding Peshawur District.
A. Wilson, Deputy Inspector General of Hospitals.
Charles Pollard, Captain, Bengal Engineers.

16th August 1860.

JULLUNDUR.

Accommodation - European Troops - Artillery - 100 horse; 100 foot.
Infantry - 1,000 men.
Native Troops - Cavalry - 1,000 irregular.
Infantry - 2,000 men.

References to Subjects and Queries.	Replies.
I. Topography.	1. The country round the station is flat and sandy, with very little jungle, wood, or water in the vicinity. 2. It is elevated 937 feet above the sea level, and is slightly higher (1 to 12 feet) than the surrounding country. 3. There are a few large excavations within the boundary of the station, in which water lies, none of which are offensive. There is a jheel on the S.E. boundary of considerable size, which receives about a third part of the drainage of the station. There is no higher or better ground near the station.

JULLUNDUR. BENGAL.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	3. The nearest mountains are 28 miles north; a broken ridge extending for 70 miles northwards, and varying from 2,000 to 5,000 feet in elevation above the sea level. 4. The nearest water to the station is the Bain Nullah, which runs within five miles on the south-east. The ground being level, is liable to temporary slight overflows, which subside within 24 hours, owing to the sandy nature of the soil. There are no ravines or broken ground near the station, except the excavations above referred to. 5. The station is open and freely exposed. The temperature of the station is not raised by the buildings being exposed to reflected sun heat. The station is open to all the winds that blow, and their effect upon health is good. 6. The surrounding country is generally cultivated. The crops are watered from wells all round the station, also the gardens in the station. No effect is observed from artificial irrigation on the health of the station. Rice is not cultivated. Neither are hemp, flax, or indigo cultivated near the station. 7. The city of Jullundur is three miles from the cantonments. 8. No reply. 9. Water is usually found during the dry season at 17 feet below the surface, and during the rainy season at 16 feet. 10. The rain fall generally sinks into the soil. There is no adjacent higher ground the drainage from which can pass through the station. 11. The water supply is derived from wells. No tanks are used for drinking purposes. Tanks are full or nearly dry according to the season and the quantity of rain that falls. "Singarahs," a sort of vegetable much used by the natives, are grown on some of the tanks. No tank used for drinking purposes is also used for bathing. There are no trees near the tanks, but the bazaar is drained into some of them. Malaria and foul smells proceed from the tanks; the best means of preventing such nuisance is to have the large one deepened and the small ones filled up. 12. The amount of water supply is plentiful, and of a good wholesome description. No better supply is obtainable. 13. No reply. 14. New stations are selected by committees appointed by Government. There is no copy of any special regulations on the subject.
II. CLIMATE.	1. There is a thermometer in each hospital. 2. There are no data for preparing a meteorological table. 3. The climate is good, with only three months of rainy season, July, August, and September; the other months are generally dry, with occasional dust and thunderstorms. A change of clothing is required about the beginning of October, when the nights become cold. September and October are generally the most unhealthy months, and the prevailing disease is intermittent fever. 4. I do not know any station in India more conducive to health than this; I have always considered it the most healthy. 5. I served at Meerut for a short time in 1842–43; Umballa, in 1843–44; Loodiana, 1844; Shikapore, Sinde, in 1844–45–46; Muttra, 1846; Phillour, 1847; Lahore, 1847; Mooltan, 1847–48; Loodiana, 1848–49; Kurnool, 1849; Hissar, 1850 to 1855; and Jullundur, from January 1857 to the present time. From the short period I have been located at most of the above stations, I am unable to offer an opinion as to their comparative salubrity. Hissar is not conducive to the health of either European or native.
III. SANITARY CONDITION OF STATION.	1, 2, 3, maps and plans. 4. The following table gives the accommodation:— Date and construction of barracks:—E. I. Lines, Nos. 1 to 10 in 1848, No. 11 in 1850, and No. 12 in 1855–56; Foot Artillery Barracks, in 1850–51; Horse do., 1848; Horse do., married, 1851; Foot do., married, 1856–57–58.

III. Sanitary Condition of Station—*cont.*	5. The windows of the barracks are on opposite sides, revolving on their centres, and are opened by ropes from below. Verandahs are built round all barracks, and are generally 10 feet wide. There are no jalousies or jhilmils. 6. The bedsteads are of wood, with rough coir bottoms. The bedding consists of a mattrass, blankets, sheets, and cotton resai. No cots or mattrasses are used in camp. I can suggest no improvement. 7. No reply. 8. The means of ventilation in barracks and guard-rooms are by air openings along the ridge. The ventilation is sufficient to keep the air pure by night as well as by day. Punkahs and tatties are used for cooling the air. 9. Barracks and other public buildings are constructed of Pucka and Kutcha bricks, laid on lime or mud cement; the roof generally thatched, and, in some cases, tiles over thatch, and in a few instances Pucka tiled roofs. 10. Floors are generally of brick or flat tiles laid over a bed of concrete, and raised from 1 to 2 feet above the level of the ground. There are no passages for air beneath the floor. 11. The barracks for Europeans are chiefly built of Pucka brick with thatched roofs, and are of a good description, but at present considerably out of repair. The tents are of strong cotton cloth. I have no improvements to suggest. The barracks and cantonments are kept in repair by the executive engineer of the station, on requisition of the commanding officers through the barrack masters. The repairs are quickly executed. The walls and ceilings of barracks are cleansed and limewashed annually, and at any other time, on emergent requisition of the commanding and medical officer. 12. I have attached a sketch showing the lavatory for one company of 100 men. The water is kept in ghurrees or tubs. No baths for troops exist on the station. 13. Water for cooking is supplied from a well. Refuse water is drained into a cesspool, whence it is carried away by carts. The linen is washed by dhobies, and dried in the sun. 14. A sketch of the urinals is attached to the wash-house plan. Sketch of the privies is also attached. They are drained into cesspools; solid filth is carried away in carts. 15. The buildings are lighted by windows, and ventilated by openings in the roof and by windows. 16. There are open drains throughout the station kutcha; there are no station sewers, and drainage is only for rain water. The drainage for surface water is sufficient to carry away 6 inches in 24 hours, and owing to the sandy soil no inconvenience is felt from excess of moisture. The barracks and hospitals are perfectly dry. The refuse from cook-houses is carted away, and the liquid refuse from privies, urinals, and wash-houses is received into cesspools. The cesspools are underground, and connected by short underground drains with the wash-houses which they drain. They are 8 inches in diameter and 14 deep, and never within 60 yards of any well. The wash-house cesspools are about 50 feet from the barracks, but covered over, and no smell is perceptible. They are cleansed whenever required on requisition from the commanding officer. There are no foul ditches near the station. 17. The conservancy of the station is in charge of the barrack master, who has an establishment of carts and sweepers, who constantly perambulate the station, and remove all filth to the outside of the cantonment boundary pillars. 18. The surface of the cantonment is kept free from vegetation. There are some old buildings and walls in the European infantry bazaar, which could be advantageously removed, the bazaar being much too large for the requirements of one regiment. 19. The bazaars are clean and generally well drained, with free circulation of air, and are not overcrowded. Privies are erected for the natives. No native houses are near the station, except in the bazaars, nor is any nuisance experienced from the wind blowing over the native dwellings. 20. The slaughter-houses are in the bazaar; they are well regulated, kept clean, and the offal removed daily outside the precincts of the cantonment. No nuisance is experienced from them. 21. The horses belonging to the bazaar and camp followers are kept in a space set apart for them in the sudder bazaar. Some keep their horses in private stables; sweepers are hired for keeping these places clean, and the manure is carried away on donkeys every day, and sold to the villagers outside the cantonments. Any one allowing filth to accumulate is fined and compelled to remove it. 22. The cavalry and artillery horses are picketed; there are no stalls, except for sick horses, and the manure is disposed of by allowing potters to carry it away, or it is conveyed beyond cantonment boundary on the requisition of the commanding officer. In the irregular cavalry each man's horse is close to his hut. In the artillery lines the barracks of the men are 600 feet distant from their horses, and the hospital is distant 2,000 feet. 23. There are sufficient quarters for married non-commissioned officers and men at present, but this depends entirely on the number of women with the regiment. I know no case where the women occupy barracks in common with the men.
Officers' Quarters.	1. Officers occupy separate houses in their own enclosures, of every size, height, and plan. All of them are private property.
IV. Health of the Troops.	1. The station and adjoining population are most healthy. 2. The prevalent diseases are intermittent fevers and dysentery. No epidemics prevail, and spleen is by no means common. 3. I attribute the healthiness of the station to the small quantity of rain which falls at regular intervals in the early part of the season. Where there is unhealthiness it generally has happened that the rains were heavy and late in the season. 4. The 46th Regiment was stationed for 10 months at Mooltan and left it in January 1860. Their health there during the hot season was indifferent, and they suffered from fever, sunstroke, and scorbutic sores. They arrived at Jullundur in February 1860 in good health, but still suffering from the Mooltan sores. No particular disease has been prevalent since they arrived at Jullundur.

References to Subjects and Queries.	Replies.
IV. Health of the Troops—*cont.*	The 4th Company Artillery arrived at Jullundur 1st April 1859 from Lahore, where they had been stationed three months. They were in good health. The site of the artillery barracks being much higher than that of the infantry, the former are more healthily situated. From the same cause the right wing of the infantry barracks is healthier than the left. The ground surrounding the latter is flooded after a moderate fall of rain, and from the drainage being imperfect, remains so till absorbed. 5. There is no general rule for troops being camped out, but the effect it had was good when in 1858 the cholera broke out in Her Majesty's 87th Fusilier hospital. 6, 7. I have never been in charge of troops at hill stations, and have had no opportunity of observing the effects produced by them. 8. I disapprove generally of selecting hill stations for troops. 9. Diarrnœa, dysentery, and rheumatism are diseases to which troops are liable in hill stations. 10. Diarrhœa and dysentery are generally attributed to the water in hill stations, and I am not aware of any precaution likely to guard the men from attacks. 11. The hot season and after the rains till the end of November are the best seasons adapted for residence in hill stations, and in most cases a residence of six months would enable troops to obtain the full benefit of it. 12. I am unable to judge beyond what period injury to health is likely to be inflicted by residence at hill stations on the return of troops to the plains. 13. The chief precautions for protecting the health of troops on their return from hill stations to the plains, are to guard against exposure to the sun and over-indulgence in spirituous liquors. 14. I would keep the hill stations merely as convalescent depôts, and medical officers in charge of troops ought to be able to send men at any time to the hills for whom they might deem such a change necessary. If a station is unhealthy, a change each year would be beneficial. 15, 16. I do not know whether the barrack and hospital accommodation provided at hill stations is sufficient; nor do I know at what ranges of elevation the most suitable sites may be obtained. 17. There is no high ground suitable for a hill station within 120 miles of this station. Dalhousie, 120 miles distant, is 8,000 feet above the sea, and the climate is excellent. 18. I have not found any particular classes of surface and subsoil more healthy or unhealthy than others. 19. The best age for soldiers proceeding to India is between 18 and 25, and the beginning of November is the best time for troops to land. I have no experience as to the manner in which troops are disposed of on landing. They should guard against exposure to the sun, sleeping in the open air, and the use of ardent spirits. 20. Troops should be sent direct to India from home. I have no faith in acclimatizing. Strict supervision within and out-door amusements are the best safeguards. 21. I do not know what is the mode of transport from the port to the interior. 22. I consider that about 10 years is sufficient for a British soldier to serve in India. 23. The manner of conducting the business of medical boards is good. 24. Invalids should leave India about the end of February.
Diseases.	1. Inspection for the discovery of incipient disease in this station are made once a week, and oftener if required. 2. There have been some few cases of scurvy among the troops at the station this season, but I am unable to state the proportion to other diseases, the regiment (Her Majesty's 87th) in which they occurred having left for China. I attribute these cases to the want of potatoes as an article of diet during a portion of the year, and I would suggest a regular supply of vegetables, particularly potatoes, as the best preventive. 3. I am unable to state the proportion of hepatic diseases under treatment, not having sufficient data to go on, there being only 100 European troops at the station who have been here during a hot and rainy season. Her Majesty's 46th Regiment arrived only last month from Mooltan. 4. There has not been a case of dracunculas among the Europeans at the station since I have been in charge. 5. During the last year 16 per cent. of the Europeans and about 7½ of the native troops have been constantly sick from venereal disease. I would suggest regular inspection of the prostitutes by a competent female, and registration of all such persons in each bazaar, and also that a heavy fine be inflicted on any person concealing the disease. Lock hospitals would be most advantageous. 6. The troops at the station suffer from diseases of the endemic class; fevers of the intermittent type, and dysentery. Cholera has only once visited the cantonment (in 1858), and that in a very limited degree, being confined to the sick in the infantry hospital. It was, however, prevalent all over the district during the same year, and also during the year 1857. Of small-pox I have never seen a case among the Europeans at the station, and rheumatism is by no means common. Since the 1st of April 1859, the date on which the 4th Company, 3rd Battalion, Foot Artillery arrived at the station, there have only been 26 admissions for fever, 6 for dysentery, and 7 of rheumatism, out of a total of 176 admissions into hospital. 7. Zymotic diseases are most prevalent after the rains till November. The climatic peculiarities attending them are a hot sun by day with cold damp nights. In general the sanitary arrangements of the bazaar are good, and nothing in the cantonments show cause for the prevalence of these diseases, unless in one or two places, where the drainage may be deficient from the nature of the ground. The bazaars are not overcrowded, and there is a free circulation of air through the entire station. There are no peculiar habits or condition of the troops which appear to predispose to these diseases. 8. There are no duties which the soldier has to perform likely in any way to cause epidemic disease, either on the march or in cantonment. 9. Quinine has not been tried by me or any other medical man on the station as a prophylactic against malarious diseases. 10. In former reports I have brought to the notice of the authorities the existence of large excavations in the centre of the station, but without any effect. Of these there are three

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	close together, and in my opinion much benefit would accrue to the health of the community were one of these deepened, and with what would be taken out of it, the others might be filled up at a trifling cost. At present the banks are in a very irregular state, and there is a large malarial surface.
V. Intemperance.	1. The soldiers at the station are temperate; we have no confirmed drunkards. 2. There are no statistics to go on as to the proportion of disease, directly or indirectly caused by intemperance. Drunkenness is always punished as an offence. 3. Distilled spirits are sold both at the canteen and the bazaar. The quality is good, and the quantity consumed varies, but is always less than a dram for each man per diem. Spirit is no part of the soldier's ration, but he can obtain it in the canteen at the station, or from the commissariat in the field or on march, by paying for it. The quality is good, and the amount is never allowed to exceed two drams per diem. The men are not allowed to take a dram before morning parade. Rum or brandy are given to convalescents only when thought necessary. No drinks injurious to health are sold at the canteen or bazaar. 4. The consumption of spirits by troops and convalescents is injurious to health, nor is it conducive to discipline. 5. It would be beneficial to the health of the troops to abolish or restrict the sale of spirituous liquors in the canteens and bazaars. 6. Malt liquors would have a beneficial effect on the health of the troops. 7. Coffee, tea, lemonade, soda water, and similar drinks are not much used at the station. I am of opinion that spirit rations ought to be suppressed entirely, and malt liquors and coffee substituted. 8. It would be beneficial both for soldiers and convalescents to do so. 9. It would be beneficial to permit only beer, coffee, tea, lemonade, &c., to be sold in the canteens to the troops. 10. I would recommend that coffee be issued to the troops each morning before leaving for parade, and that beer should be allowed at dinner, and also at night, which latter allowance ought to be drank at the canteen to ensure that no man gets more than his proper allowance. 11. No reply.
VI. Diet.	1. The ration for Queen's British troops, and for European troops in the Indian army, consists of 1 lb. of bread, 1 lb. of meat (mutton twice a week), 4 oz. of rice, $2\frac{1}{2}$ oz. sugar, $\frac{5}{7}$ of an oz. of tea, or $\frac{1}{7}^{3}$ of coffee, 1 oz. salt, $\frac{3}{4}$ lb. of potatoes, $\frac{1}{4}$ lb. mixed vegetables. The rations are inspected daily by the quartermaster and the orderly officer: frequently by the commanding officer. 2. A complete ration, with the proportion of vegetables mentioned above, is issued daily. A soldier has three meals a day: dinner at 1 p.m., breakfast at 8 a.m., and tea at 4, 5, or 6 p.m., according to the season. The stoppage for the ration is 3 annas and 4 pice the day. 3. An improved ration would be conducive to the health of the troops. A man is stationed in each cookhouse to prevent any part of the rations being disposed of. 4. The apparatus for cooking consists of 1 copper camp kettle, 1 copper tea kettle, 1 camp kettle lid, and 1 baking dish for every ten men. There is a cookhouse for each company, The cookhouses are good, and there is a well to each. The food is boiled or roasted at the option of the men. The cooking is good and sufficiently varied. The men have coffee before a march, and half way. 5. I do not think gardens could be advantageously established; soldiers do not like gardening.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress consists of a cloth tunic, cloth trousers, and forage cap in the cold season; khakee jacket and trousers, with bamboo frame-work helmet in the hot season. I consider the present dress suitable to the climate, and have no improvement to suggest. On guard the men wear khakee during the hot, and cloth during the cold season. They have also a cloth great coat, which is worn when required. Sentries are protected from the sun and rain by verandahs and sentry boxes.
Duties.	1. It would be advisable that all soldiers should be drilled thoroughly in England previous to landing in India. 2. The soldier attends all drills and parades, takes his turn of guard and fatigues, keeps his arms and accoutrements in good order, and looks after the cleanliness and order of his barrack room. During the hot season there is one drill on parade a week, immediately after daybreak. In the cold season, one parade in the morning, the other in the evening. The European troops at Jullundur have at present 20 nights consecutively in bed. 3. All guards are within three-quarters of a mile of the barracks, and are mounted for 24 hours. There is one roll call at tattoo, and two during the day if there are no parades. The men do not suffer in health from night duty.
VIII. Instruction and Recreation.	1. There is a ball court, four-sided, in the European infantry lines, and a single ball court in the artillery lines. There are two skittle alleys in the infantry lines, and one in the artillery. There is a regimental school. A library and reading room, sufficiently lighted at night. Two gardens, one out of order, and not used by the 46th Regiment, the other used by the artillery. There are no workshops. There is one private theatre, not at present in use. No gymnasia. None of the above except the reading room could be used during the heat of the day. No man is allowed to go out during the heat of the day, and the result is favourable to health. 2. I would suggest as an improvement the formation of a skittle ground, and more skittle alleys, and ball courts. 3. Savings' banks have been instituted, and are decidedly advantageous. 4. There is no sufficient shade, and no amount of shade would enable soldiers to take exercise in the heat of the day during the hot season without injury to health.
IX. Military Prisons.	1. The cells are in good condition, not overcrowded, and are well ventilated.
X. Field Service.	1. I am not aware of any local regulations for field service, not included in the general Presidency regulations. 2. From my experience the present system, as regards the power of the medical officer in the conduct of the line of march, bivouacking, camping, billeting, &c., appears to work well. 3 and 4. No replies.

JULLUNDUR. BENGAL.

XI. STATISTICS OF SICKNESS AND MORTALITY.	No replies.
XII. HOSPITALS.	1. I have sent a ground plan of the hospital, with a copy of these questions, to Government. 2. The European infantry hospital is dismantled, and No. 1 barrack is used as a temporary hospital. The Artillery hospital is 900 feet from the nearest barrack, and 2,000 feet from the stables. It is 750 feet from the bazaar and 300 feet from the nearest private bungalow. The site is open and very healthy. 3. The water supply is abundant and wholesome. 4. No means of drainage. Solid filth is carted away. 5. The wards are 3 feet above the ground, and there is no ventilation beneath the floors. The roof water sinks into the soil, but not within 10 feet of the hospital verandah, as there is a metal slope round the outside 10 feet wide. The drainage is effected by shallow open drains, which would hardly be sufficient for the purpose but for the sandy nature of the soil, which prevents any water lying more than a few hours on the surface. The hospital has mud wells, 2½ feet thick, enclosed verandahs and outer verandahs. Thatch, 9 inches thick. Verandahs all round, 10 feet wide. The verandahs are never used for sick. The following table gives the ward accommodation:—

Artillery Division Hospital.

Date of Construction, 1847–48.

Total No. of Wards, 3. Total Regulation No. of Beds, 58.

Wards.	Regulation Number of Men in each Ward.	Dimensions of Wards.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
		Ft.	Ft.	Ft.				Ft. In.			
2 -	24	72	24	24	41,472	1,728	72	1 8			
1 -	10	24	24	24	9,024	902	57	1 8			

N.B.—The European Infantry hospital is dismantled, and Nos. 1 and 2 Barracks are used as a temporary hospital. *See* Measurement of Barracks.

Cubic contents do not include the portion of roof above wall plates, nor verandah.

The hospital is so placed as to receive the full benefit of the prevailing winds.

There are no windows, only ridge ventilation.

6. The hospital is well ventilated. There are no jalousies or jhilmils.
7. The air is cooled by means of punkahs and tatties.
8. There are no means of warming.

The walls and ceilings are cleansed and limewashed annually, and as often as the medical officer requires.

9. A sketch of the privies is sent with the Government copy.

They are well drained, and seldom offensive.

10. Large basins are fixed in masonry with gurrahs for douche baths, and tubs for warm baths.
11. The means of bathing for the sick are by douche and hip baths.
12. The washing is done by a dhobie.
13. The storage is dry and sufficient.
14. The bedsteads are a wooden frame, with grass-rope bottoms, easily cleaned and repaired. The bedding is good and suited for the seasons.
15. The kitchen is a Pucka building, situated on the east side of the hospital, and about 60 feet from it. The diets are cooked in copper vessels, which are considered sufficient. The cooking is generally good, and can be sufficiently varied at the will of the medical officer.
16. The "Bengal Medical Regulations" include all forms used in hospital.
17. In the principal European hospitals there is a hospital serjeant, one apothecary, whose duty it is to see that the wants of the sick are attended to in the absence of the surgeon. There is also a hospital steward, who regulates the dieting of the sick, and other subordinates to attend to their wants; and in the case of a man being very ill, his comrade is generally selected from the ranks to attend him. The amount of attendance is sufficient.
18. The hospital is most healthy, and to my knowledge no epidemic or hospital gangrene has ever appeared within it.
19. There are no deficiencies or sanitary defects, or improvements to be suggested.
20. There is not any provision made for convalescents taking exercise further than taking a walk in the hospital compound, which is an open plot of ground, surrounded by a mud wall about 6 feet high. There are no trees in the enclosure.
21. A ward is allotted for women and children in all hospitals, and an ayah is kept to attend on them when required. A permanent ayah ought always to be allowed on a European hospital establishment, no matter how few the strength, as long as there are women belonging to the detachment.
22. There are no special local hospital regulations.
23. The medical officer has full power in all sanitary arrangements; also as regards repair of hospitals, diet, and medical comforts, subject always to confirmation, which is invariably given when cause is shown for the necessity.
24. There are no convalescent wards or hospital for convalescents, nor do I consider such necessary at this station.

XIII. Burial of the Dead.	1. There is a burial ground 2,750 feet from the nearest building, and it is situated on the western boundary of the station. Its size is 200 feet by 200 feet. A second burial ground for the infantry is 2,100 feet from the nearest barrack, and is at the south-west boundary of the station. It is 300 by 450 feet. 3. No grave is allowed to occupy more than 10 feet by 7, and the interval between the graves is 3 feet. No grave is of less depth than 5 feet, and is not permitted to be reopened for the interment of a second body in the same grave. In the hot weather, if an individual dies before 2 P.M., the funeral takes place that evening about sunset. If death takes place after 2 P.M., the funeral is at sunrise. Native Christians are buried in the station or Artillery burial ground. 4. The grave yard is never offensive. 5. Camp followers and bazaar people, if Mahomedans, are buried near a village about half a mile from the Artillery lines. If Hindoos, they are taken to the river, about four miles distant, and the bodies burned, and the ashes thrown into the river. 6. No injury accrues to health from the present practice. 7. I would recommend that a hearse should be provided for the use of the station.

(Signed) C. A. Campbell, Lieut.-Colonel, 46th Regiment, commanding at Jullundur.
C. W. Nightingale, Executive Engineer, Jullundur.
S. A. Homan, Surgeon, 3rd Battalion Artillery, Senior Medical Officer.

Jullundur, 19th May 1860.

RAWUL PINDI.

Accommodation
- European Troops
  - Artillery - 4th Troop, 2nd Brigade B.H.A.; 4th Co. 2nd Batt. B.F.A.
  - Infantry - H.M. 81st and 93rd Regiments.
- Native Troops
  - Cavalry - 18th I.C.
  - Infantry - 21st N.I.

I. Topography.	1. The cantonment is bounded on the north by a fine alluvial plain, running to the foot of a considerable range of mountains at 15 miles distance, the height of which is from 2,000 to 3,000 feet; on the east by low hills and undulating ground, and on the south and west by arable land, occasionally broken by deep ravines. The barracks and public buildings are generally placed on the water-shed of a high strip of ground, and are well drained to the south into a ravine, and to the north into the Leh nullah. There is not much wood jungle or water in the vicinity. 2. The approximate height of Rawul Pindi cantonment above the level of the sea is 1,500 feet, the adjacent country being a few feet lower. The nearest running stream, the Leh, being about 70 feet below the level of the old, and 100 feet below the level of the new barracks. There is no adjacent higher ground which would have suited better for a station. 3. The nearest mountains are those already mentioned, about 15 miles in a direct line from the station. These are unfitted for the location of troops; but at a distance of 39 miles, by an excellent road lately constructed, is the Sanitarium of Murree, with accommodation for 300 invalids, of whom 36 may be married. The Murree Hill is nearly 6,000 feet above the station and 7,200 above the sea. 4. The Leh nullah bounds the station on the north. The Sohan, a larger stream (both mountain torrents), is 4 miles distant. The banks of the Leh are high, and though the torrent swells greatly in heavy rain it never floods the cantonment, but occasionally does the low lands towards the city. There is a great deal of broken ground and many ravines to the south of the station, but no stagnant water, as all drains into the nullahs and eventually into the Sohan. 5. The station is open and freely exposed to winds. There are no trees, hedges, &c., to interfere with the ventilation. The radiation of heat from the buildings in the station, which are anything but crowded, does not tend to increase the temperature. The winds that prevail are wholesome dry winds, not damp nor unhealthy, and as a rule are steady from N.W. or S.E. They are mostly from N.W.; the S.E. winds indicate rain. 6. The surrounding country, where the ground is tolerably level, is well cultivated;—that portion towards the hills being particularly fertile. There is no irrigation, or but very little. It is not much required, as from the vicinity of the station to the hills a fair amount of rain falls, particularly in the cold season. The irrigation has no effect on health. No rice, indigo, or flax is grown in the vicinity. 7. The city of Rawul Pindi is about a mile from the north boundary of the station, and is the only town near it. There are three villages, viz., Adrah, Ruttah, and Murreer, immediately on the outskirts of the cantonment. 8. The geological structure of the district is as follows:—A base of conglomerate of limestone boulders, occasionally varied with veins of sandstone which crop out in several places, superlaid with pure red clay, over which is a stratum of fine loam. Most part of the station occupies new ground, though there were one or two villages which were moved for space, and a few graves near the outskirts indicate the prior occupation of a portion of it. 9. Water is found at a depth of from 70 to 100 feet, according to the elevation of the wells, and differs but little during the rainy or dry season.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	10. The natural drainage is so fine that rain water never lodges in the station. It does not, as a rule, penetrate far, but flows off to the natural drains over the surface, without percolating through. There is no adjacent high ground, the drainage from which can pass into the subsoil of the station. 11. The water supply is derived from wells. The river water is very good, and is useful for watering cattle. It is not stored in open tanks. The wells are not liable to pollution from impurities passing into them. 12. The water supply is ample, both from wells and from the Leh nullah; but the wells being deep it is troublesome to raise in large quantities. Bullocks are used for this purpose. The water, as a rule, is very clear, tasteless, and without smell. It is "hard," and not injurious to health. The quantity of well water is sufficient for the station. It is raised and distributed by bheesties and bullocks. No better water is to be obtained. 13. I have no other topographical points to state. 14. Stations are generally chosen in the following manner:—The political necessity is in the first instance determined by Government for placing a certain force in or near a certain town or locality, after which a committee composed of two military, two medical officers, and an engineer, are usually deputed to select an eligible and healthy spot. Provided the members of the committee are all men of known experience, not any improvements could be made in this procedure.
II. Climate.	1. In the artillery division we have only thermometers. Every station should have a set of instruments for meteorological observations. 2. I am unable to furnish a meteorological table. 3. The climate of Rawul Pindi has been proved by 10 years' experience to be decidedly the finest in the plains of India. The station is situated on high ground, with fine natural drainage, and with good roads, which are much required, it would be as perfect as it is to be expected any tropical climate can be. For seven months in the year ordinary winter clothing is necessary, accompanied with a generous diet. During the remaining five, the lighter the clothing and the less stimulating the food the better. A liberal supply of vegetable food is most desirable during the hot weather. During the cold season the drills, &c. could be carried on in the daytime, but in the warm season must be in the early morning. According to the admissions into the artillery hospital during the year ending 31st March 1860, the months of May, June, July, and August are the most unhealthy; December, January, February, and March the most healthy. The principal diseases during the unhealthy months are generally fever and diarrhœa. 4. I know no district near the station the climate of which is more healthy.
III. Sanitary Condition of Station.	1, 2, 3. Maps and plans sent with another report. 4. The following table shows the barrack accommodation:—

Artillery Barracks.

Date of construction, from October 1858 to July 1859.
Total number of rooms, 8.
Total regulation number of non-commissioned officers and men, 200.

Barrack Rooms.	Regulation Number of Men in each Room.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
				Under roof framing.							
8	24	66	24	24	38,016	1,584	66	2	6 6	2¼ 2½	4 6
Non-commissioned Officers' Room.	1	14	13	24	4,368	4,368	182	2	2½	2½	6
Guard Room - -	16	41	18	16	11,808	738	46	2	6	21	4

No prison cells are ready.

5. The barracks have door panel windows, ventilating and dormer. Both open on pivots. The windows are on opposite sides. The doors double, and open on hinges. There are outer and inner verandahs on both sides of the entire length, outer, only, at the ends. The inner, 12 feet wide, outer 10 feet wide. The inner verandah is not used as a sleeping apartment, but merely to mess in. There are no jalousies or jhilmils.
6. The bedsteads are of wood, 7 × 3¼ feet, with cotton tape bottoms. I should recommend iron as less likely to harbour vermin, more durable, and neater in appearance.
7. Tents (privates') are made of country canvass, and consist of kanats and double roofs. Their dimensions are 20 feet × 16 ditto. 25 men are allowed to each tent. The occupants have about 100 cubic feet of air each; when the tents are shut up, as they have to be in cold weather or during rain, they become overcrowded. Tents for serjeants are made of similar materials, and in their shape resemble the hill tents of officers.
8. There is both ridge and dormer-window ventilation, and ridge and side lights in the barracks. Tents are ventilated by means of the doors, 4 in each privates' tent, and 2 in the staff serjeant's. The ventilation is quite sufficent to keep the air pure, as well by night as by day. Tatties and punkahs are used for cooling the air in the hot season.
9. Barracks are constructed of good kiln-burnt bricks, cemented with mortar. Tents are made of the strong country canvass. Huts are generally made of mud.
10. The floors are not yet laid down in the artillery barracks, but will be of brick placed on edge. The floors are well raised above the level of the ground, and are particularly dry. There is no ventilation beneath.
11. The materials of which the barracks are constructed are the most suitable the country affords. Barracks are kept in repair by the executive engineer, and the repairs are always executed at once on the requisition of the barrack master or of the regimental authorities.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	The barracks are whitewashed once a year, but oftener if deemed necessary by the medical officer. 12, 13. Sketch of lavatories and cookhouses forwarded but not received. Linen is washed in the Leh nullah by the dhobies. The nullah is conveniently situated, and is sufficient for the wants of the station. 14. The contents of the privies are carted away and buried outside the cantonment daily. 15. The barracks and privies are lighted at night by oil lamps. All the out-offices have ridge ventilation. 16. There are no sewers, all sewerage being collected in masonry cesspools and removed daily. The drains for carrying off the rain water are merely trenches, and are quite sufficient for carrying it away, without allowing any water to become stagnant in the barracks or their neighbourhood. The drains for carrying off rain water are open and well arranged. The water from the men's lavatories runs into a masonry cesspool, also the water from the cook-rooms, and is emptied daily and carried away by the conservancy carts. The filth from the privies is also carried away daily in the conservancy carts. None of the buildings are damp, and the drainage is sufficient. There are no foul ditches. 17. The surface cleansing about the barracks is done daily by sweepers, and the refuse taken away in the conservancy carts. 18. The surface of the cantonment is kept free from vegetation. When any excessive vegetation springs up it is removed by the executive engineer. Officers have to keep down vegetation in their own compounds. There are no old walls, hedges, &c. to interfere with the ventilation. 19. This being comparatively a new station the bazaars are not crowded. The sudder bazaar is well laid out, with broad thoroughfares that allow of free ventilation. It has masonry drains in nearly all the streets, and these are kept clean and free from garbage, &c. by a good staff of sweepers. Latrines are some distance from the bazaar. The bazaar is under the control of the cantonment magistrate, who enforces cleanliness, &c. There are no native houses near the station, and no dung pits or cesspits. No nuisance is experienced from winds blowing over native dwellings. 20. No nuisance is experienced from the slaughter-house, which is in the cantonment, though at a considerable distance from the barracks. Such offal as is not sold for dog's-meat is buried. 21. The manure of the Government stables is burnt by the executive engineer in his brick kilns. These stables are about 1,000 feet from the artillery barracks. There are no other horses picketed on the cantonment, and but few animals in the sudder bazaar. The grass cutter's ponies are kept in their lines, which are behind the artillery horses, and at a greater distance from the barracks. The officers on troop and battery duty are responsible that the lines are kept perfectly clean. 22. There are no cavalry or artillery stables. All the horses are picketed in the open air, and are about 1,000 feet distant from the barrack, and out of the direction of the prevailing winds. The horse lines are kept very clean; the litter, &c., being carted away by the executive engineer to be burnt in the brick kilns. Picketing ground for artillery horses is arranged in three divisions to the west of the barracks, and 1,000 feet distant from them. The horses of the H. Artillery and Light Field Battery are separate, and are arranged similarly with respect to distance, &c., from the respective barracks. The horses are about 1,000 yards distant from the hospital. 23. There are as yet no quarters for married people built specially for the artillery; they do not occupy barrack rooms with the men.
Officers' Quarters.	1. The officers live in private bungalows, which are found to be healthy.
IV. Health of the Troops.	1. The station, the district, and the adjoining native population are generally healthy. 2. Almost every year there is an epidemic of variola amongst the native population, generally at the commencement of the hot season. Rubeola is also common; calculous affections are very commonly met with, particularly those natives who live near and on the hills. I am not aware that the natives in this district suffer from spleen disease. 3. The objection of the natives generally to vaccination no doubt adds much to the number of cases during an epidemic of variola, also to their severity and mortality. Want of cleanliness, in their persons, houses, and villages, adds to the severity and fatality from other diseases, and I believe the water they use, which is generally through the district "hard," is a principal cause of calculous affections. 4. The 4th troop, 2nd Brigade H.A. was at Peshawur before coming to this station; also the 4th Company, 2nd Battery F.A. The men of the troop joined it in Peshawur in August 1857; they were volunteers from the several Queen's regiments there at the time, and the majority of them had been there for two years. The battery had been in Peshawur for five years, and arrived here on the 7th April 1859. The troop marched from Peshawur on the 15th September 1857, and arrived here on the 25th September 1857; the men suffered severely from intermittent fever in Peshawur, and for the first year after arrival here. The men of the F. artillery, who are principally old soldiers, did not suffer in Peshawur much, and have been healthy here. All parts of the men's accommodation at this station seem equally healthy. 5. The troops are not camped out at this station. 6. I have not been in charge of any hill station. Judging from my own experience of Murree convalescent depôt as a residence for convalescents, I would say that for the few months preceding the rains, and for the few months after their termination, a residence for those free from organic disease is of the greatest benefit, but for the great majority of people I do not believe it is healthy during the rains. 7. My experience of the hills is founded on the observation of men of the 4th troop, 2nd Brigade H.A., who were sent up to Murree as convalescents at the commencement of the season. A residence there certainly helps to get rid of the intermittent fever contracted in Peshawur, which depends on malaria, but I do not think it affords any protection against the liability of attacks of fever of other kinds when the soldiers return to the plains, or against the attacks of other diseases. 8. I decidedly approve of hill stations, but I do not believe that every altitude will be found equally healthy. 9. At Murree convalescent depôt, diarrhœa (diarrhœa alba) is prevalent during the rains, and the convalescents all suffer more or less from it.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	10. As the diarrhœa attacks officers and soldiers indiscriminately, I am not prepared to say what precautions are necessary, but as the disease generally comes on during the rains, I would recommend that each man going to the hills should have under-shirts and drawers of flannel, and that regular exercise be enjoined. 11. My only experience of hill stations is Murree, and I should say that the best seasons for residence there are from the 15th April to the commencement of the rains, and from the termination of the rains to the latter end of October or early in November. I am not prepared to say what is the shortest period for enabling the troops to receive the full benefit of a residence at the hills. 12. So far as my experience goes there is no period beyond which injury to health is likely to be inflicted. 13. There are no special precautions on returning required that I am aware of, beyond the ordinary ones for soldiers serving in the plains. 14. For troops serving in the Punjab and in some of the stations of the N. W. Provinces, I do not think there is any necessity for sending an entire regiment for change to a hill station, except possibly in some emergency, such as where a regiment has suffered severely in Peshawur; but even in such a case I believe that a change to some other healthy station, such as Rawul Pindi, Jullundur, Sealkote, Umritsir, which are conveniently situated with regard to any of the more unhealthy ones, would be attended with as favourable results, and I think that in the Punjab and N. W. Provinces, the present practice of selecting those men from each regiment for whom a residence at a hill station is considered necessary, as fully ensures the efficiency of a corps, as if the entire regiment had been sent to a hill climate. For troops serving in Bengal, I would think that a residence at a hill station with short service in any of the Bengal stations, would be most conducive to the health of the men. I do not think frequent change on the plains is necessary, except from unhealthy stations, in which case a change of station is certainly beneficial to the health and spirits of the troops. 15. I have not sufficient knowledge of the accommodation afforded at Murree convalescent depôt to say whether it is sufficient. 16. I do not know at what elevation the most suitable sites may be obtained. 17. I believe there is no high ground near this station better than Murree. 18. Deep loamy soils, retentive of moisture, are generally found to be unhealthy for the accommodation of large numbers of men. 19. Soldiers proceeding to India should never leave England under 20 years of age, and the cold season is the best period for them to land. I had charge of the recruit depôt at Chinsurah in 1856, and the barrack accommodation for the recruits was good, they were well provided with clothing, and their duties were in no way severe. Recruits should not be allowed to remain in any of the presidency towns, but should be marched up at once from the ship to some of the neighbouring stations. Especial care should be taken to prevent exposure to the sun or the use of bazaar spirits, fruits, &c. The allowance of rum should be stopped altogether, and beer only given in moderate quantity, and never early in the day. 20. If recruits were selected specially for Indian service, and not sent out under age, I do not think there would be any necessity for sending them to any intermediate station. I think the present way of disposing of them on landing answers well; I believe the great sickness and mortality amongst young soldiers to be caused in the great majority of cases by their own imprudence, either from exposure to the sun, unnecessary exposure at night, or the immoderate indulgence in spirits. If the young soldier would be restrained from these exposures, I am sure the sickness, &c. of their earlier years of service would be much diminished. 21. I had charge of a party of recruits from Calcutta to Allahabad conveyed up the river by steamer and flat. The commissariat supplies were very good, there was sufficient room for the men, and a sufficiency of medical stores and hospital clothing. 22. As a rule a soldier should not serve in India more than 10 years. 23. The manner of conducting medical boards is such as to avoid conflict of opinion. I have no suggestion to offer on the subject. 24. The best time for invalids to leave India is in January or February, so as to arrive in England after the termination of the winter months.
Diseases.	1. Weekly inspections for the discovery of disease are made at the hospital in the morning at the visit of the medical officers. 2. There has been no scorbutic disease among the troops. 3. Out of 282 cases admitted into the artillery division hospital during the past year ending 31st March, there were 11 cases of hepatic disease. The disease in the majority of cases was of a chronic nature; the old soldiers were principally affected with it, and it did not seem to depend on other diseases. Men who had been at some time of their lives free livers were the principal sufferers. As I believe hepatic disease is produced as readily by habitual free living and the excessive use of animal food, as by intemperance, I think that in a tropical climate soldiers should as far as possible be prevented from consuming the amount of animal food they do. 4. I have never seen a case of dracunculus in a European soldier. 5. During the past year the proportion of venereal cases to the total sick in the hospital of the artillery division was 48, out of 282 admitted. With a view to diminishing venereal diseases, I would suggest that the prostitutes, both in regimental bazaars and in the sudder bazaar in cantonments, should have their names registered, be examined by a medical officer, appointed specially for this purpose, and receiving a special salary; the examination to be made at least weekly in stations where there are European troops, and those women found diseased, to be admitted into hospital, treated, and not to be discharged till cured. The cantonment magistrate ought to have authority to punish prostitutes (other than those registered) found in regimental or sudder bazaars, as also those women who are reported by the medical officers as trying to conceal the disease. If means such as these were taken, I believe there would be but little venereal, and a number of men who are annually invalided for chronic rheumatism, generally dependent however on former venereal diseases, would still be serviceable soldiers. 6. The following are the epidemic and endemic diseases arising at this station :— Those who have suffered at Peshawur from intermittent fever have it also here for some time after their arrival. Any other fevers are generally of the continued form, and are the result of imprudence or exposure.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	*Dysentery* is generally produced by exposure, but is not either epidemic or endemic here. *Cholera.*—There was an epidemic of cholera in this station in June 1858, principally, however, attacking natives, amongst whom the disease was very fatal. *Small-pox.*—There has been no small-pox since I have been here, not since 1857. *Rheumatism.*—There has been very little rheumatism, either epidemic or endemic; the great majority of rheumatic cases are dependent on former venereal disease. The native syces and grass cutters suffer from rheumatism a good deal, but this might be expected in any station, the nature of their duties being attended with much exposure. During the year ending 31st March 1860, the total number of admissions into the artillery division hospital was 282; out of these there were admitted, of fever cases 26; dysentery, 4; cholera, none; small-pox, 1; rheumatism, 40; but no deaths from any of these causes. In allusion to these cases of rheumatism, I may add, that I believe every case almost without exception was of venereal origin, as was easily found out by the history and symptoms. 7. I have had no experience of zymotic diseases affecting the European troops at this station. Small-pox and measles are generally found at the commencement of the hot season. I have no experience of the atmospheric conditions which precede or accompany zymotic disease. 8. The duties, &c. of the troops at this station do not predispose them to epidemic disease. 9. Quinine has not been tried as a prophylactic; this station is free from malaria. 10. Should any epidemic appear amongst Europeans, the best way of mitigating it, as proved by experience, is to send the men, so far as can be done, into camp, and let them continually change their ground.
V. Intemperance.	1. The soldiers at this station are temperate, and there are no confirmed drunkards in the 4th troop 2nd Brigade H.A. A case of habitual drunkenness has not occurred for nearly two years. 2. The proportion of admissions into hospital directly caused by intemperance is 7 out of 282 during the last year, and indirectly 1 out of 282 in the same period. I cannot obtain sufficiently accurate returns for a table showing the effect of intemperance on sickness, mortality, and crime. Drunkenness *per se* is punished as an offence. 3. Rum is sold at the canteen, not in the regimental bazaar. Two drams of rum is the limit per man, and then only provided no malt liquor is drunk. Spirit is not part of the ration, and is not given to convalescents. No drinks injurious to health are allowed to be sold in the canteen or bazaar. 4. I should say the consumption of spirits is more injurious to health than otherwise; it is not conducive to discipline or efficiency. 5. It would not be beneficial to restrict or abolish the use of spirits, as the European soldier would then procure bad liquor from the natives. On a campaign or line of march it is most necessary. 6. Malt liquor is preferable to spirits. 7. Coffee, tea, lemonade, &c. are drunk at the station. 8. For the reason already given it would not be beneficial to suppress the use of spirits. 9. I do not think it would be beneficial to permit only beer, tea, coffee, &c. to be sold in the canteens. 10. I would recommend that the use of tea, coffee, &c. be encouraged as much as possible, and that a good supply of malt liquor be kept up. 11. Rum is issued at 1 anna per dram, and malt liquor at 1½ annas per imperial pint. No rum is issued before sunset. No man is allowed more than 2 imperial pints of malt liquor daily, the second pint being issued after sunset; and 1 dram of spirits, or 2 drams of spirits, and no malt liquor.
VI. Diet.	1. The ration for European troops in the Indian army consists of bread, meat, vegetables, rice, sugar, salt, tea, and coffee, namely, 1 loaf of bread, 1 lb. of meat, 1 lb. vegetables, 4 ozs. of rice, 1 oz. salt, 2 oz. sugar, $\frac{5}{7}$ oz. of tea, $1\frac{3}{7}$ oz. coffee. Tea and coffee on alternate days; mutton twice a week; beef other days. The ration is inspected by the subaltern officer on duty. 2. A complete ration is issued, including a due proportion of vegetables, but no fruit. The stoppage is 3 annas, 4 pice. The soldier has 3 meals a day; breakfast consists of bread, tea or coffee, and milk; dinner, of meat, potatoes, soup, vegetables, salt, and rice; tea, of bread, tea or coffee, and milk. Breakfast is at 8 a.m.; dinner at 1 p.m.; tea after evening duty. The vegetables constituting part of the ration are,—potatoes, ½ lb., cabbage, onions, and turnips, ½ lb. 3. An increase of potatoes, and a superior description of vegetables, would be conducive to the health of the troops. The rations are given over to the charge of a mess corporal and orderly, who are responsible for them. 4. Three pounds of wood are furnished per man for cooking, and the apparatus consists of cookhouses, dekchies, frying pans, gridirons, ladles, and choppers. The kitchens are clean and well ventilated, and sufficiently supplied with water. The meat is both boiled and roasted. The cooking is well done, and sufficiently varied, and the tea and coffee are properly prepared. The men have refreshment before a march if they choose to purchase it. 5. Gardens would be an advantage if the men could be induced to work in them. A piece of ground might be told off and placed under the superintendence of the officer commanding the troop or company.
VII. Dress, Accoutrements, and Duties.	1. The parts of a soldier's dress are a full-dress helmet, jacket, undress jacket, overalls, gloves, boots (2), wicker helmet, cloak, forage cap, 2 khakee tunics, 2 khakee overalls, 6 white shirts, 3 flannel waistcoats, 6 pairs socks. I consider the dress suitable, with the exception of the full-dress helmet; the men are sufficiently protected while on guard.
Duties.	1. It would be most advisable that the men should be thoroughly drilled at home before being sent to India. 2. The routine of duties consists of morning and evening parades. The length of drill varies according to the season. Far from suffering in health from drill, a moderate amount has the best possible effect. The best hours are early in the morning, and there are general orders respecting them; the average is 9 or 10 nights in bed (between guards?). 3. Guards are mounted close by the barracks, and last 24 hours. There are roll calls by day and night; night guards in some localities must be injurious, but not at this station.

References to Subjects and Queries.	REPLIES.
VIII. INSTRUCTION AND RECREATION.	1. There are no ball courts, skittle-grounds, day rooms, gardens, workshops, theatre, nor gymnasia. There are schools in the European regiments, and in the 4th troop, 2nd Brigade H.A. No library is yet built, but some portions of the barrack are divided off for a school room, library, and reading room. Workshops and places of amusement for the men are much wanted. During the hot season the men are prohibited from exposing themselves to the sun during the day; this is in my opinion attended with the best results, as some, indeed nearly all, the cases of fever are in this station found to be produced by exposure of some kind or other, fevers caused by exposure to the sun being generally the most serious. 2. Workshops, skittle-grounds, ball courts, and gardens would be beneficial. 3. There is a savings' bank. 4. The verandahs in the barracks are good for enabling the men to take exercise in the shade; trees are small and few.
IX. MILITARY PRISONS.	1. The military prison is not completed.
X. FIELD SERVICE.	1. There are no local regulations for field medical service. 2. Any suggestion the medical officer may offer with regard to the sanitation of troops, whether in cantonments, in camp, or on service, always meets with prompt attention from the military authorities, and is carried out as far as practicable. 3. Any suggestions of the medical officer with regard to military regulations in camp is always acted on. It is the duty of the medical officer to report any circumstance in camp likely to affect the health of the troops, and such report always receives due attention. 4. A field hospital is formed at the rear of the force, and in the most eligible position, and under the charge of the senior medical officer, assisted by a sufficient number of medical officers. I believe there are no special regulations on this subject.
XI. STATISTICS OF SICKNESS AND MORTALITY.	1. No information.
XII. HOSPITALS.	1. There is no hospital specially for the artillery. The sick from the division occupy one ward in the European infantry hospital. 2. There are no stables near the infantry hospital, which is situated on the left rear flank of the barracks. It is 500 yards from the bazaar, and there are no houses near. The site is open and freely ventilated. There are no buildings, trees, or walls to interfere with ventilation. The site is healthy as to elevation, drainage, &c. 3. A well in the hospital compound affords an abundant supply of most excellent water. 4. No rain water collects. The water from cook rooms and bathing room runs into cesspools, which are emptied daily. 5. The building is one-storied, and raised two feet from the ground. There is no ventilation under the floors. No provision is made for carrying away the rain water, but from the natural fall of the ground it soon runs off even after the heaviest rain. The hospital is built of similar materials to the barracks. The walls are single, 2 feet thick, sufficiently so to keep the wards cool. The roof is also single, with ridge ventilation. There is an inner verandah 12 feet in breadth, and an outer one 8 feet, which, with the help of chicks, are sufficient shelter from the sun's rays. The inner verandahs are never made use of except in special cases, as the ward is sufficient for the accommodation for the sick from the division. The hospital is only a one-storied building. The following Table shows the hospital accommodation:— Date of construction, 1853 to 1857. Total number of wards for artillery division, 1. Total regulation number of beds, 20.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
1	20	66	24	24 Under roof framing.	38,016	1,900	95	2	6	Ft. In. 2 3	4

The hospital is so placed as to receive the benefit of the prevailing winds; the windows open on a pivot hinge by ropes attached to them. They afford good ventilation.

6. There are doors on each side and opposite each other. There are windows and ridge ventilation. The wards are always well ventilated. There are no jalousies or jhilmils.
7. Tatties are used for cooling the air admitted into the ward in the hot season, and also punkahs.
8. There is a fire-place in each verandah of the ward. The walls are whitewashed once a year, at the commencement of the hot weather, but oftener, at the requisition of the medical officer, should he consider it necessary.
9. The privies are in the rear of the ward, and at a sufficient distance from it. The passage to them is roofed over. They are not over cesspits, but the filth is carried away daily, and as a rule they are not offensive.
10. There is a small washing room in each wing of the hospital; they are not in my opinion sufficient for the sick, nor are the utensils nor the furniture in these rooms of such a kind as to afford facilities or comfort for the patients in washing themselves.
11. There is a plunge bath in each wing of the hospital, but it is never made use of, as it is not considered beneficial to the patients in hospital.
12. To each of the hospital establishments of the troop and battery there is a dhobie attached; he washes and dries the clothes, and is always able to have a sufficient quantity clean and ready for immediate use.
13. At present the storage for the clothing, medical stores, &c., of the artillery division is not sufficient; they are placed in the verandahs of the ward occupied by the sick, and in the plunge bath room.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	14. The bedsteads are made of wood with tape stretched across; both these are highly objectionable as beds for hospital or barrack use. Those furnished are cumbersome, unsightly, and after a short time become filled with bugs, which are a cause of the greatest discomfort to the patients, and in some cases, from the loss of sleep they produce, occasion positive injury. The tape is objectionable as being easily dirtied, and in case of an epidemic, requires to be destroyed. Light iron bedsteads, similar to those used at home, both in military and civil hospitals, are the proper ones, being lighter, cleaner, and just as comfortable. The bedding I consider well suited to the climate, and quite sufficient for all the wants of the patient. 15. The hospital kitchen is well to the rear of the ward; its construction is similar to those in barracks. 16. There is no annual return of sick in store. The number of men invalided is forwarded in the annual return. The diet rolls, &c., are forwarded. 17. In the artillery division hospital there is a hospital serjeant, besides the usual allowance of native servants. The attendance thus afforded is quite sufficient for the wants of the sick. 18. The sanitary condition of the hospital is good. No epidemic, gangrene, or pyœmia have appeared in this hospital since I have been in Rawul Pindi. 19. I consider that bath rooms, such as have been recently erected at the rear of each barrack, would be of the greatest use to the patients in hospital. 20. For ordinary cases of convalescence the hospital compound and verandahs afford sufficient room for patients taking exercise, but there are no shaded walks or seats set apart for them. Trees have lately been planted. In special cases, on the recommendation of the medical officer, doolies and bearers are supplied by order of the brigadier, for such patients as may require them. 21. The wives and children of soldiers when sick are admitted into the hospital where there is a ward specially for them. The present arrangements are satisfactory. 22. There are no special local hospital regulations. 23. All matters relating to the sanitary state of the hospital and its repair are attended to on the requisition of the medical officer. The liberal allowance of diet and all medical comforts for the patients in hospital saves the medical officer from all trouble on these subjects. 24. There are no wards for convalescents specially, and except in contagious or infectious diseases, I do not think they would be necessary.
XIII. Burial of the Dead.	1. The burial-grounds are in the station, but at a considerable distance from the hospital and barracks; they lie out of the direction of the prevailing winds. 2. The area is 321 × 176 feet. The soil, &c. is the same as the station generally. Decomposition takes place readily, and the ground is carefully kept. 3. The grave space allowed is 6½ × 2½ feet. The interval between the graves is 2 feet. The depth is 5 feet, and no grave is re-opened. Burial takes place in ordinary times in 24 hours, and during epidemics as soon as possible. 4. The graveyard is never offensive; funerals take place early in the morning, or in the afternoon when the sun has lost power. 5. The dead of camp followers or bazaar people are burned or buried outside the station. 6. No injury to the public health accrues from the present practice. 7. I could suggest no improvements.

(Signed) C. L. Cox, Major, Commanding 4th T. 2nd Brigade H. A. and Artillery Division.
James Brown, Assistant-Surgeon in Medical charge of Artillery Division.

Rawul Pindi, 14th May 1860.

(Captain Davies, Executive-Engineer, is on duty at Murree. The Topography and part of the Sanitary State of the Station, also that part relating to the Public Buildings, have been furnished by him.)

MEAN MEER.

Accommodation	European Troops	Artillery	- -	301	Head Quarters and 1 Troop.
		Cavalry	- -	476	1 Regiment.
		Infantry	- -	1,437	1½ Regiments.
	Native Troops	Cavalry	- -	627	1 Regiment, Irregulars.
		Infantry	- -	638	1 Regiment, lines for 4 Regiments.

N.B.—With these numbers the barracks are crowded.

References to Subjects and Queries.	Replies.
I. Topography.	1. Surrounding country a flat arid plain, sloping towards the river Ravee (Hydraotis) as it approaches it to the N.N.E. The country around the cantonment is partially cultivated with wheat, millet, dour, Indian corn, mustard, cotton. Beyond this is a low jhow jungle, *Tamarix Indica*, and the common wild plants and shrubs, saline and others, usually found in the arid, waste saline tracts of the Punjab, viz., *Aloe*, *Salvattora Persica*, *Currile*, *Capparis Aphylla*, *Lana*, a creeping shrub, a *salsolaceous* plant, prickly camel-thorn, some scattered shrubs of the mimosa species, &c. The country is sandy and dry. There is only low jungle, very few trees near. The Ravee is about seven miles distant from the centre of the cantonments. The Baree Dooab canal (lately opened) is about 2½ miles distant.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	2. Mean is 1,128 feet (ascertained) above the level of the sea. It is 8 feet 6 inches higher than the civil station at Lahore. There is no higher or healthier ground near the station. 3. The nearest mountain range is about 100 miles distant. 4. The Ravee, seven miles off, overflows its banks in some seasons in July or August, and floods the surrounding lands. The highest flood recorded was to a level 11 feet 6 inches below that of Mean Meer. The inundation usually subsides in a few days. The only broken ground has been caused by railway earth-works and digging a canal, in the course of which high roads and pathways, and heaps of earth, have been made, and hollow excavations left where rain-water may accumulate for a time. 5. The station is remarkably open. Trees planted along the road sides are as yet small. There are one or two gardens only with trees and shrubs of any size. The garden boundaries are low mud walls, 3½ to 4 feet high. The houses are one-floor bungalows; the outer walls, 22 feet high, surmounted by a flat roof, in a few instances with a pent thatched roof. There may be some little heating of the air from the reflected sun's rays off the barracks and bungalows, but the effect of this cannot be much in so large a plain with unimpeded ventilation. The warmth of the atmosphere is most sensibly increased by the greatly heated state of the hot, baked, and hard metalled roads, after any continuance of drought. A cold north-east wind blows during the cold weather months, which augments considerably the sensation of cold to the feelings. 6. The country surrounding the station is scantily cultivated; in the vicinity of the Ravee there is more cultivation. The noble canal lately opened, and running two miles distant from the station, is intended for irrigation. Its effect on health has not yet been tried. There is no rice cultivation in the neighbourhood, nor is there any of indigo, flax, or hemp. 7. The nearest large city is Lahore, six miles off. The cantonment Sudder bazaar, with a population of 7,338 men, women, and children, is nearly two miles from the centre of cantonments. There are four or five other bazaars within cantonments placed near to their respective regimental lines; these are small excepting the bazaar of artillery. 8. As regards the local geology:—The soil is alluvial. The subsoil consists of layers of loamy clay, suited for brick making; of sandy loam; of pure white micaceous sand, resting on a bed of bluish, ochery, ferruginous, stiff clay, through which the well water rises up from a bed of dark sand. The upper stratum of clay, at a depth of two or three feet from the surface, and extending to a depth of 10 or 12 feet, is embedded with nodulated limestone or kunkur in small pieces, very like fragments of coral formation. The surface is much covered with a white efflorescent salt, with which the soil is much impregnated. This appearance is increased on ground which has been saturated with water, during and after the drying process. The soil has been professionally analyzed, and found to be constituted like the water; to contain, in pretty much the same relative proportions, carbonate of soda and lime, sulphate of soda, chloride of sodium, and carbonate of magnesia. The environs of the city of Lahore, with its buildings, approached originally very near to the site of Mean Meer. There are very few vestiges of the city now nearer than four or five miles. 9. The depth from the surface at which water stands in the wells averages 40 feet in the dry season. On an average there are about 15 feet (varying from 8 or 10 to 20 feet) of water in the wells, except during periods of great drought. There is a slight increase of depth of water after much rain. 10. The rain-water, for the most part, runs off rapidly by means of a well-arranged system of drain cuttings. It lies, however, in places for some hours, not disappearing very rapidly through the loamy soil. Its clearing off is facilitated by small cuttings directed towards the nearest drain. There is no higher ground the drainage of which passes into the subsoil of the station. 11. The water for the station is obtained from wells, and is filtered before drinking. It is not stored in tanks. There are two water-tanks only near the bazaar. They are hollows, the results of excavations for buildings. Filled by rain-water, partially dry during the dry season. The bazaar people bathe in these, and may drink the water. The water supply from the wells is not liable to pollution from leaves, &c. No nuisance is experienced from the tanks alluded to. 12. As regards the amount and quality of the water:—It may be stated generally that there is a well to each bungalow. Sometimes there are two within the garden enclosure. For the infantry barracks intended for one regiment there are five wells, besides a well within each cook-room enclosure, used for the cooking of two companies. The water is, for the most part, good in quality, but some of the wells are brackish saline. The following is a professional analysis of the well-water:— 1,000 parts of water, after evaporation and incineration of solid residuum, yielded—

	Grs.		Grs.
Carbonate of soda	0·494	Chloride of sodium	0·095
„ lime	0·140	Sulphate of soda	0·178
„ magnesia	0·080	Silica	0·013

The quantity of organic matter traced in the water is very small. The water I should call soft, from its ready admixture with soap. It agrees well ordinarily, and is sufficient.

Water is raised from the wells by the Persian wheel, or else in large skins drawn up by manual labour lightened by pulleys. Small masonry reservoirs have been built by the side of the well's mouth in some places for keeping a large supply of water ready for use, to supply the barrack wash-houses or plunge baths. These reservoirs, together with the well's mouth, are raised above the surface level. For ordinary domestic purposes, the water is brought from the well in leather skins by water-carriers or bheesties.

The vicinity of the canal would afford a water supply in case of need.

13. The roads are intolerably dusty, and should be watered as a sanitary measure. Considerable outlay would be needed in digging wells and making masonry conduits by the roadside. More care should be bestowed on the watering and culture of the trees by the roadside, and in replacing them when fading.

14. In selecting new stations, mixed committees of civil, military, engineer, and medical officers are appointed, who, after careful survey and investigation into all points of locality, topography, climate, diseases of its inhabitants, and all matters of hygiène, recommend the particular site or otherwise.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	The appointment of a well-selected medical officer as sanitary officer to each division of the army, whose business it should be to inform himself of all progress in all such matters, and whose recommendations should be imperative and unquestioned when not politically inconvenient, is most desirable, and would much expedite the present sluggish and often obstructive proceedings in these matters. This advice has reference to the selection of new sites for cantonments and encampments, as well as to ordinary requirements of hygiène and conservancy at stations.
II. Climate.	1. The station is wanting in meteorological instruments, and in the proper machinery and arrangements for keeping a reliable register of phenomena. There is a common thermometer at every European hospital, but I believe that it is carelessly observed. Representations on this head have been made to the principal inspector-general, medical department. 3. The climate is dry; in hot weather, within a room, the wet bulb falls 19°. The dew point stands at 46° 45′ F. Degree of saturation, ·236. The thermometer in a northerly covered verandah stands at 107° F. at 4 P.M. The range of the thermometer is 16° to 18° ordinarily; after a dust storm the fall may be 19°. In the hot weather the thermometer falls 20° in 24 hours, after a heavy fall of rain. During the cold weather months, the diurnal range is much greater. Fogs during the cold weather are rare. A cold easterly wind prevails during the cold weather months, much increasing the sense of cold. Tree planting along the road side, and in clumps here and there on the plain, is salutary, in a bare arid spot like Mean Meer; irrigation has not been tried; trees are planted along the road sides. The atmosphere is loaded with dust. The soldiers are attacked with simple ardent fever at the setting in of the hot weather, and by heat-apoplexy in May, June, and July. Light cotton clothing of a greyish dusty colour is now generally adopted in the hot weather. The diet allowed is suitable. Drills should be light and finished soon after sunrise in the hot weather. The men should be strictly confined to their barracks from 8 o'clock A.M. to 6 o'clock P.M. A light basket work well-covered helmet should be worn to protect the head. From an analysis of the returns of European troops at Mean Meer, for four years up to 1858–59, I find that the hot months of May, June, and July are the most unhealthy months. The men suffer from fevers, common, continued, and intermittent; from hepatic and bowel complaints. September and October again are unhealthy months. Fevers continued and intermittent are rife, especially when malarious causes of diseases exist. In 1856, in August, a fearful cholera epidemic appeared, and continued until November. The deaths were very numerous. 4. There is no district near the station, I have ever heard of, the climate of which is more conducive to health than that of the station. 5. I have served for short periods at the following stations and cantonments:—*Ghazeepore*, for one year. *Dinapore*, for five months, during the rainy season. *Lucknow* cantonments, three months, cold season. *Dum Dum*, six months, during the rains. *Ferozepore*, six months, cold season. *Cawnpore*, for five months, hot weather and rains. *Meerut*, seven months, January to August. Of civil stations I have served at *Mymunsing*, in Eastern Bengal, 4½ years. *Moradabad*, north and south, for one year. *Hourah*, near Calcutta, 6½ years. *Midnapore*, two years. *Dacca*, eight years. As regards their comparative healthiness, I can only speak superficially. *Ghazeepore*, generally a healthy station. The troops of Her Majesty's 44th suffered much from cholera in 1836–37, while I was there as civil surgeon. Their barracks were bad, confined, ill-ventilated; the conservancy was bad. Situated on the banks of the Ganges. *Dinapore*, in 1847, considered unhealthy. Is on the river bank. Dysentery prevailed much among the troops. The cantonment parade ground is flooded, and a good deal under water during the rains, and high rise of the rivers. Fevers abounded among the sepoys at that season. *Lucknow*, then three or four miles distant from the city upon a sandy plain, was healthy. *Dum Dum* was not remarkably unhealthy during my residence there. Deaths from apoplexy and fever occurred largely among the recruits, in consequence of reckless exposure to the sun, and excess in liquor. *Ferozepore* is a healthy station. *Cawnpore*, a notoriously unhealthy station in 1849; some localities were more unhealthy than others. Cholera prevailed fearfully among the European troops, infantry, while I was there. The hospital and barracks were placed on the banks of the river. The drainage of the native town, which stood on a higher level inland, ran down into the river close by the barracks. Amongst the European artillery of which I had charge, whose barracks were higher and better placed in every point of view, cholera did not prevail nearly to the same extent. *Meerut* was healthy during the time I was there (1850).
III. Sanitary Condition of Station.	4. The following is a Table of the barrack accommodation:— Date of construction, between 1850–57. Number of barrack houses, 16, with 8 married barracks and two iron-framed barracks.

Number of Barrack Rooms.	Regulation Number of Men per Room.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Contents in Cubic Feet.				Number.	Height.	Width.

References to Subjects and Queries.	REPLIES.
III. Sanitary Condition of Station—*cont.*	There is a dining-room for 104 men in the centre of each iron-framed barrack. It is 60 feet long, 26 feet wide, 26 feet high in the sides, and 33 feet high to the ridge. 5. As regards windows:—The windows or lights are situated high up in the two main inner walls of the barrack, along the whole length of the building, on either side and opposite each other. They swing open on a central pin or rod. The arched openings between the central apartment, or nave of the barrack, and the inner verandah, as well as the large doorways, and the arcaded outlets of the outer verandahs are all opposite, so as to favour the passage of free currents of air through the barrack from east to west. There are outer verandahs on both sides lengthwise, and at the ends, 10 feet wide, and 14 feet 9 inches high, flat-roofed. They are not occupied as sleeping quarters by the soldiers. There are no jhilmils, the doors are panelled, with a glazed arch above. 6. The bed-cots are of wood, bottomed by a close interlacing of broad cotton tape, or nawar. The bedding (mattress and pillow) is made of stout country cloth, either dyed red or not, stuffed with hempen fibre or sunn. Cot well made, strong and comfortable. 7. Tents are made of stout cotton cloth. On the inner side, the roof is dyed blue. Dimensions:—Length of floor, 20 feet; length of ridge, 6 feet. Width, 16 feet. Height to the top of the two poles at the ridge, 12 feet. Height of the tent sides or kanats, 5 feet 4 inches. There are two roofs or flies; the outer one three cloths thick; the inner are two cloths thick. The kanats or side walls are three cloths thick. There are four doorways with cotton canvass screens or falling doors. The number of cubic feet, reckoning 9 feet as the height throughout, is 180 for each man; 20 superficial feet per man. Each tent holds 16 men. Ventilating and lighting by doorways, or by lifting up and laying open the side walls. 8. Ventilation in barracks is provided for through the ridge of the roof, by swing windows high up in the inner main walls, by holes in the roof of the inner verandah, covered over on the outside by the entrance doors. When the barrack has only its proper complement of men, and is not crowded, this ventilation answers the purpose. The ordinary means of cooling the air are punkahs, and *Kus kus* grass tatties. These last are thinly laid grass screens on a framework of bamboo, made to fill up and fit the doorway to windward, and kept wetted. The external heated air becomes cooled in passing through them. Punkahs, 20 feet long, and 2 feet deep, cost 20 rupees. A Kus kus grass tattie costs 4 rupees 4 annas. The erection of thermantidotes in all the barracks, by which currents of fresh air would be driven through the room and foul air expelled, would be a great improvement. A thermantidote set in brickwork costs 130 rupees. 9. The barracks are built of burnt brick with a cement of lime, sand, and pounded brick. Tents are made of cotton canvass. Temporary barracks may be built of sun-dried bricks, with a mud cement. Iron-framed barracks are now erected with a pent roof surrounded by masonry walls, with a verandah all round. The roof is overlaid with mats, upon a framework of split bamboo, and over this a thatch. 10. The barrack floors are made of kiln-burnt brick, set on end and resting on a concrete made of broken burnt brick, or of kunkur (nodulated limestone). Square or hexagonal tiles are also used for barrack and hospital floors. The floors are raised three feet above the ground level. There are no flues beneath them. 11. Barracks built of burnt bricks are hotter than those of sun-dried bricks, but, of course, more durable. The iron framed barracks are good, capacious, and airy. The executive engineer repairs barracks, and keeps roads and drains in order. The cantonment magistrate looks after the public gardens, watering roads, &c. The quick execution of repairs seems to depend on the amount of important work on hand at the time. The directing authorities in cantonment repairs are the chief engineer and the officer commanding the station. The cantonment magistrate has the charge of the Sudder bazaar. The regimental quartermaster has the charge of regimental bazaars. In sanitary matters, the commanding officer is advised by the senior medical officer at the station, Queen's and Indian army. Petty repairs of barracks and equipments not involving building are made by the barrack master, who is subordinate to the quartermaster general's department, under whose care all barracks are placed. Repairs and whitewashing take place annually. 12. The lavatories are about 60 feet distant from the barracks, with a covered way to them, and about 180 feet from the supplying well. Water is conveyed from an elevated reservoir at the well's mouth by a drain underground to the lavatory reservoir, part of the masonry platform, into which the basins are let. The water is turned into the basins by spring cocks: underneath the basins are pipes for conveying away the foul water to a drain. The bathing accommodation consists of a long shallow tank, with low walls, in which the men can lie down and bathe. The refuse water runs off by the general drain. Plunge baths of large size are now in progress of erection. The lavatories are of solid masonry, one to each barrack nearly. 13. Each cooking house has two rooms, with an open space between them within one enclosure; serves for one company. The buildings are of masonry, with tiled roofs. The rations are cooked by cook boys, who prepare stews, soup, and bouillé, fryed and baked meats. The cooking is done by low brick fire-places on the ground, and also by higher ones with gratings set in masonry and flues beneath. The refuse water is carried off by a drain to a shallow tank, whence it is removed daily. In some instances the refuse water is drained into covered cesspits. Clothes are washed by washermen in the river Ravee, and are returned daily, prepared. 14. The best description of recently erected privies, called surface privies, are partitioned off into seats, with moveable pans underneath, which are taken away by holes in the wall behind, and emptied into large iron air-tight cylindrical vessels, to be removed. All the vessels should be cleaned with wood ashes twice a day. The ground beneath has to be swept clean, but this ought not to be necessary, everything should go into the receptacles. Beneath the latrines are now placed, in some cases, newly adapted vessels with an outer iron casing, having an earthenware pan fitted into each, which is perforated with holes in the bottom, through which the urine passes into water, between the iron casing and the earthenware pan. 15. The barracks are lighted by oil lights, either affixed against the wall or suspended from the roof. Lanterns or lamps are used. 16. Barrack drainage. There are no drains immediately about the barracks. There are servants employed to sweep the barracks, and remove all accumulations of refuse from their

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	vicinity. The lines of barracks are drained by two shallow saucer drains of masonry running the whole length of the barrack frontage, and emptying themselves into the roadside drain which skirts the barrack ground. These drains, running one between each two rows of barracks, are distant about 250 feet from each line of barrack, and are intended to drain the ground and to carry off quickly rain water. In some parts, where the level is unfavourable, rain water lies for some hours; small shallow cuttings, however, are made from the barracks into these saucer drains. The rest of the drainage has been described. The lavatory cesspools sometimes overflow, and the ground around becomes saturated, and the atmosphere is tainted. The cesspool plan is universally condemned, and is being exchanged for small surface reservoirs, whence the fluid is removeable. No part of the buildings is damp. Rain lies on the surface for a few hours, till it evaporates or is absorbed. The cesspits for receiving foul water are just outside their respective buildings. They are from 30 to 40 feet deep, and 8 feet in diameter. They are situated 64 feet from the barracks and 180 feet from the wells. Occasionally they are opened and emptied. There are no foul ditches near the station. The drains are, upon the whole, kept clean. There are a number of paid men, under the orders of the executive engineer, whose occupation is to keep the drains clear. 17. Besides the men stated above, people are employed upon the roads to remove dung, &c., daily. The cantonment is kept clean. 18. As regards vegetation, the cantonment is very bare and arid. There are a few officers' gardens. There are no hedges, walls, &c., to interfere with external ventilation. 19. The bazaars are arranged, with reference to ventilation, with good broad roads, intersecting each other at right angles. The houses are of mud, with brick facings, two chambers deep, open in front, in some cases with neat wooden verandahs, in rows along the roadsides, low and flat roofed. The bazaar is kept clean. One of the main drains runs through the Sudder bazaar. The drainage is about to be improved by masonry saucer drains on the roadsides, which can always be kept clean. There is a plentiful supply of good water from deep and wide wells. There are three public privies outside the bazaar, well looked after. There are from four to five residents per house, of all ages. The artillery bazaar has a well. There are public wells near all the bazaars. The regimental bazaars have their own conservancy arrangements, under the control of the quartermaster. The Sudder bazaar is in the hands of the magistrate. The people are compelled each to keep his part of the bazaar clean, under penalty of fine, and they contribute towards paying an establishment for the purpose. There are ten public privies placed in different parts of cantonments. The inner apartments of the native houses must be dark and ill-ventilated. There is an upper story, consisting of small rooms, over some of the houses. There are private privies to the houses, which the owners are compelled to keep clean. There are no dung heaps within the bazaars. The only nuisance of any kind is smell from a small rum distillery, in the Sudder bazaar. This smell reaches the hospital and barracks at times. The removal of the distillery is the only remedy. 20. The Mean Meer slaughterhouse is under the commissariat. It is two miles from the centre of cantonments, consisting of the necessary sheds and buildings. Offal is carried away to a distance from the station, and does not create any nuisance. 21. With reference to bazaar horses, the grass cutters have lines assigned for their ponies near their regimental bazaars. They are kept systematically clean. The artillery lines have good broad streets, with the grasscutters huts along their sides. All manure is removed outside, and then collected and taken away by the people for their land. These lines are about 700 feet distant from the nearest artillery barrack, and from the hospital, to the westward of the latter. The conservancy is under the artillery bazaar authorities. 22. Horses are picketed in the open air, in double lines, with a low wall running along in front of their heads. They stand on a slope on raised ground. The lines are kept very clean. All manure is carried away from the lines. The horse lines are about 372 feet from the nearest barrack, which is to the east. They are about 330 feet north of the hospital. There are wells belonging to the lines, and masonry aqueducts for watering the horses. The horse lines of the two troops of artillery, and two regiments of European cavalry, run along the line of the barracks on the east towards the open plain, distant about 372 feet from the men's accommodation. 23. There being few women with the artillery and cavalry, the married quarters are large enough at present. Some married non-commissioned officers occupy the corner rooms of the men's barracks.
Officers' Quarters.	1. Officers live in detached bungalows, with enclosures or gardens around them of ample size arranged in double or single rows, forming the sides of a street. The drainage is a part of the general cantonment drainage.
IV. Health of Troops.	1. Mean Meer is ordinarily a very healthy station, that is, to troops at all acclimatized and not suffering from the effects of hard service. Judging from the only source available, viz., the Government dispensary returns, sickness in the neighbourhood and district is not met with in an exaggerated degree among the native population. In the crowded city of Lahore epidemics of small pox and measles appear almost annually. Small-pox is continually rife in some districts of the Punjab. 2. The most common diseases among the native population are fevers, intermittent for the most part, lung diseases, bowel complaints, acute and chronic dyspeptic complaints, ophthalmia, ulcers, and boils; rheumatism, venereal complaints. 3. The cheapness of food and the fine climate of the Punjab are conditions of healthiness among the native population. The amount of sickness varies in different stations, and would seem to be much influenced by the character of the seasons. Dry seasons are found to be the most healthy, and those in which the fall of rain is moderate and opportune in breaking long-continued drought and heat. Sickness follows in the neighbourhood of inundations, when the waters recede and leave a swamp under the action of the sun. The river Ravee near Lahore causes much sickness in this way.

IV. Health of Troops —*cont.*	4. Her Majesty's 51st King's Own Light Infantry were nine months at Kurrachee and Scinde before coming here. The regiment suffered much from a low type of Scinde fever, particularly a detachment stationed at Shikapore. There was a good deal of fever in the regiment after its arrival here in December 1858, during the hot months. Many cases occurred in men who had suffered at Shikapore. Otherwise the regiment has been ordinarily healthy at Mean Meer. The principal diseases have been fevers, chiefly intermittent, acute dysentery, and diarrhœa. The 79th Highlanders were in the field in Oude and Rohilcund during the hot season, 1858. Many deaths from heat apoplexy occurred. Remittent and common continued fever prevailed during the hot season, and increased when the regiment went to Futtyghur in June. At Cawnpore, to which the regiment moved, it suffered much from fatal hæmorrhagic dysentery. Since the regiment arrived here on April 9th 1859, it has been on the whole healthy. The common forms of disease being fevers, diarrhœa, hepatitis a few cases, rheumatism, and of pulmonary complaints, acute catarrh. E., battery R. H. A., having previously been engaged in service, were at Setapore from April to September 1859, occupying temporary thatched huts, where they suffered from fevers and dysentery. They arrived here in February 1860. 3rd European Light Cavalry was seven months at Allahabad, occupying bad quarters in sheds, huts, and bungalows, part of the time surrounded by indigo and other cultivation. They suffered much from Paludal fever, continued and intermittent, and from diarrhœa, The regiment has been healthy since its arrival at Mean Meer on March 27th 1859; but there were cases of heat apoplexy in June and July of that year, partly from high temperature, partly from crowding in barracks, and there were many recruits. 5th European Light Infantry were at Campbellpore nearly a year. Left 26th March 1860. Common continued fever was the prevailing disease. The regiment was not unhealthy otherwise, although the barracks were temporary raised buildings and confined. Have been healthy since arrival here on April 18th 1860. The state of the 51st, 79th, and 3rd European Light Cavalry on arrival here may be judged of by the numbers invalided a few months after arrival, viz., 51st, 12; 79th, 39, out of full corps. Convalescents were sent to the hills, of the 51st, 26; 79th, 4. The Mean Meer barracks are generally salubrious, but the neighbourhood of an offensive cesspool or drain has been known to bring on sickness and fever in one particular barrack. 5. Troops are not usually camped out here. 6. As regards hill stations, I append the remarks of an officer of some experience in them:— "As assistant surgeon with the 2nd Bengal Fusiliers, I spent the autumn of 1846 and summer of 1847 at Subathoo. During summer of 1854 in medical charge of hill station of Murree. In medical charge of hill sanitarium, Simla, for 1858 and 1859. The population of both these stations consists of retired officers and civilians on sick or other leave, with their families. At Subathoo my regiment, full of organic disease contracted in Scinde, suffered severely; there was also bad barrack accommodation, no sanitary measures, and indifferent rations. As a general rule, troops which come from a station where the seeds of organic disease have been laid are sure to suffer; otherwise a regiment, under proper precautions, is sure to be healthier in the hills than in the plains. The last three years, 1858, 1859, 1860, during which healthy regiments have been quartered at Subathoo and Dugshai, with good barracks, rations, and a better system, will be the best test of the value of these stations. 7. "Men leaving their barracks and the cool air of a hill station for ordinary camp life in the plains, suffer from febrile attacks at first, under the same causes as men entering the tropics from temperate climates; but this casual acclimatization passed, a regiment remains much healthier than one that has passed a hot weather in the plains. I should say the higher the hill station, the more men would be liable to these attacks in descending to the plains. For instance, I believe that troops making an ordinary march on the plains, after residing at Subathoo (4,000 feet), would suffer less than men leaving Kussowlie (6,500 feet), all sanitary measures being equal, and the season, with reference to the sun's power, being taken into consideration. 8. "I approve most strongly of selecting hill stations for troops. 9. "The disease peculiar to the 'Simla group' of hills used to be 'diarrhœa.' I believe statistics of the last three years, 1858, 1859, 1860, would show it much less prevalent now. In my two years' experience of Simla, under improved sanitary arrangements, the type of bowel complaints that used formerly to exist was very rare indeed; and when it did occur, it was much less formidable and more tractable than formerly. "All men, on first arriving at a high elevation from the plains, are liable to suffer from internal congestions, particularly of liver and bowels (children, of the chest), unless proper precautions be taken. "No hill station has yet been found to have perfect immunity from Indian diseases, cholera, bowel complaints, and fevers. 10. "As regards diet, &c., at hill stations, the rations should be, and I believe now are, of the best; quantity cannot be altered; vegetables are more plentiful than formerly. "Great care should be taken about clothing; nothing but woollen should be worn, except perhaps during May and June. A flannel belt should never be left off round the abdomen. The feet should be guarded by woollen socks during the rains, &c. As the sun's rays are very powerful during April, May, and June, good protection for the head is necessary. "Barracks should not be too exposed. A southern aspect for the higher ranges, and a northern for the lower would be best. They should be so built as to afford good shelter from the night air, and from drafts at all seasons, and yet have good ventilation. "Regular exercise should be insisted on; but the usual custom of men wandering down ravines, and to the bottom of the vallies, where the sun's power is intense, and the jungle always thick, should be interdicted. And again, a man walking in light clothing to the top of a high hill, meets a cold blast of air, which is often a cause of disease, and which soldiers of themselves are thoughtless about. 11. "At stations of the elevation of Subathoo (4,000 feet), residence is safe during the whole year. At the more elevated stations, from 1st April to 15th November. A hill residence of 7½ months, or from and to the above dates, would be sufficient for health. Troops would then have two months of bracing weather, from 15th September to 15th November, such as is hardly to be equalled in any country. The rainy season is always a trying one, and thus time would be given to recover from it. From neighbouring stations in the plains

References to Subjects and Queries.	Replies.
IV. Health of Troops—*cont.*	there are many men who would be saved much sickness, or a long convalescence, if they could have short leave to the hills for two months during the hot season. 12. "I do not think that troops would be injured physically by length of residence on the hills, but troops get weary of the monotony of the hills. Officers cannot be said to share this feeling, but it certainly exists among the men. I have, however, noticed many men of mature age, who have been resident for some years at 7,000 feet and upwards, to have the capillaries of the face injected, and otherwise to present a very florid appearance, but their numbers are too few, and their periods of residence too uncertain, to form any certain conclusion upon. I have not noticed any diseases peculiar to this class. 13. On leaving hill stations for the plains all camp comforts should be provided; not too long marches taken at first; guarding as much as possible from cold at night and from direct exposure to sun in day time. 14. "As regards the manner of using hill stations, I think service in the plains, with short periods of change to hill stations, would be most conducive to the health of the troops, mentally and physically; I mean a period of two or three years, the former, or even less, at an unhealthy station in the plains, and one year, or one year and a half, at the lower elevation, or the 7½ months at the higher elevation. "Change of stations on the plains would be decidedly beneficial; but I would say let troops remain at favourite stations for three years, at others for two. 15. "I am not acquainted with the present barrack and hospital accommodation of the hill station I formerly served in. At Subathoo in 1846–47 both were very bad. 16. "Medical officers have rarely dwelt long enough in the hills to be able to state what elevation is best for health from personal experience. "Statistics would probably give the truest information. I have always held the opinion that elevations of from 4,000 to 4,500 feet are the best localities for troops, for at this height there is cold enough to renovate the system, and the extremes of wet and cold are not so much felt, while at higher elevations few constitutions can stand the extreme and penetrating cold for at least four months in the year with impunity. But barrack accommodation, with reference to space, heat, cold, and ventilation, must be of the best, and good sanitary arrangements carried out. "The station of Subathoo is the only one in the presidency which answers to the above height. It may be described as an isolated level plateau, being drained nearly all round by steep descents, with the higher ranges of hills in a circle round it, varying in distance from 10 to 30 miles. A plateau of this elevation, without the higher hills round, would perhaps be better. It is hotter in summer and warmer in winter than the higher elevations; but the heat in a moderate building is rarely above 86° Fahrenheit. The nights are always cool, and out-door games and amusements can be carried on throughout, except perhaps for three weeks before the setting in of the rains, towards the end of June. The winter is not too cold. Snow falls about once in four or five years, but seldom lies more than three or four days. During the rains the station is under clouds, without being in them, or in fog, and the rain-fall is moderate. Up to the end of 1858 the station never had a fair chance, barracks and conservancy arrangements being alike deficient. "J. T. C. Ross, F.R.C.S., "Surgeon, 3rd regiment, Bengal European Light Cavalry." 17. There is no higher ground near Mean Meer which could be occupied as a hill station. 18. With regard to the comparative healthiness of different subsoils for stations, I have found a stiff clayey soil, retentive of moisture, particularly if drainage be neglected, productive of intermittent fever, followed by enlargement of the spleen. I have found sandy or light pulverizable loamy surface soils healthy, *per se*, independently of other associated causes of disease. 19. The best age for soldiers proceeding to India, about 20 to 23 years of age. Troops for the Bengal presidency should arrive during the two first weeks in November. On landing, troops are immediately sent off to the depôt at Dum Dum, Barrackpore, or Chinsurah. It is the custom to send off by steamer to the upper provinces, as quickly as possible, troops arriving early in the cold season. The barracks at the above depôts are good brick European barracks. Light clothing or otherwise according to the season is provided for and worn by the men on landing. Flannel waistbands are distributed in the cold season. Drills and duties are made light for the recruit. He is not exposed to the sun. The marches during the cold season, if he leaves Calcutta in that way, are not exhausting, but rather invigorating. The most necessary measures for preserving the health of the recruit on first landing, are preventing access to or excess in the use of spirits; preventing exposure to the sun; providing suitable clothing and airy commodious barracks; giving the men exercise; providing them with beer in lieu of spirits; and taking care that their rations are wholesome and good. 20. In sending healthy troops out to India, they should come out direct. If they arrive in India at the approach of the hot season, then send them to a hill station, provided the barracks there are good. If they arrive at the proper season of the year, they have the cold season before them to acclimatize in, whether they be moved upwards by steamers, or whether they march; in which latter case, the daily morning exercise is salutary and bracing. 21. The marches are from 10 to 12 miles, halting on Sunday. The men are supplied with regulation tents, each holding 16 men, giving 20 superficial feet to each man; a commissariat agent accompanies the troops, or else the men travel by a Government covered bullock cart train, travelling 30 to 40 miles during the cool of the day and at night; stopping during the day at caravanseras prepared for them. The carts hold six men each, and allow of their sitting or reclining. River steamers are used for transport from Calcutta to Allahabad, and intermediate places. The men on board are often crowded, and their comfort and convenience not sufficiently attended to in a sanitary point of view. 22. A moderately well conducted man should be able to serve in India from 10 to 15 years. 23. I have generally seen the business of invaliding committees consisting of five members satisfactorily carried on, and without any impediment in working. 24. Invalids should leave India throughout January.
Diseases.	1. Inspection parades for the detection of incipient disease are or ought to be held every week by surgeons of European corps. There may be more or less laxity in this respect.

References to Subjects and Queries.	Replies.
IV. Health of Troops—*Disease—cont.*	2. Scorbutus is not a disease of this station. It has been spoken of as slightly indicated by the state of the gums, debility, &c., at the time when vegetables, more particularly potatoes, become scarce, as during very hot months. A provision of potatoes all the year round is desirable, if possible, but potatoes become unsound after June. Limejuice is plentifully supplied to the troops. Fruits of some kind are to be had at almost all seasons. 3. During the past three years the average occurrence of hepatic disease among European troops has been in the proportion of 3·86 per cent. of the strength, and in the proportion of 1 to 48·66 of all other diseases. Experienced surgeons attribute hepatitis ordinarily to exposure on sentry, or in the field to the extreme heat of the sun. Hard drinkers are undoubtedly predisposed to it. It is often co-existent with ulceration of the colon, but not invariably so. Evidence of disease in the portal system of veins and of the presence of pus in them has been looked for in vain, in many instances. It has been observed that soldiers conceal their hepatic disease, and come into hospital to die very shortly afterwards, sometimes in a few days; post-mortem examination showing large abscesses of the liver. These instances are generally found in drunkards. 4. Dracunculus is an uncommon disease here. During the past three years there is not one case recorded among European troops. 5. Upon the average of the past two years the proportion of venereal disease to all other diseases has been as 1 to 13. A lock hospital has been established at Mean Meer. The bazaar women have been all registered, and every week they are collected and examined by a surgeon, and if diseased are removed to the lock hospital. The returns of hospital of the last year show a diminished per-centage of syphilis among the men. 6. The prevailing fevers at Mean Meer are common, continued, intermittent (of various kinds), and remittent. Acute, chronic, and hæmorrhagic dysentery, sporadic and epidemic cholera, small pox, and rheumatism also occur. The following Table gives the proportions, in comparison with *all other diseases.*

Years.	Fevers.		Acute Dysentery.		Cholera.		Small Pox.		Rheumatism.	
	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.	Admissions.	Deaths.
1857–8 - -	1 to 3·3	1 to 5	1 to 25	1 to 3·3	Nil.	Nil.	Nil.	Nil.	1 to 17	1 to 10
1858–9 - ..	1 to 2	1 to 4	1 to 29	1 to 4	1 to 500	1 to 19	1 to 322	1 to 32	1 to 48	Nil.

	7. As regards nosological characters, the intermittent fevers are not commonly accompanied by spleen enlargement. The remittent fever is the ardent remittent, or ardent continued, often of short duration, and produced by heat. Bilious remittents are met with occasionally. Dysentery is of the acute kind. When small pox occurs, it is often observed to be imperfectly eliminated, and the vital powers sink under the disease. This is more especially noticed amongst the native population. The most unhealthy months are April, May, and June, and again September and October. In these, fevers and bowel complaints most prevail. According to common observation, the invasion of the hot weather ushers in fevers. Exposure to heat in barrack life and on duty introduces them, and brings on hepatitis. Vicissitudes and extremes of temperature tend to dysentery.. I have no reason to attribute the appearance of disease to sanitary defects in the bazaars. The want of exercise and the inertia of mind of barrack life are causes favouring the inroad of epidemics and other diseases. 8. Under the conditions of a free and frequently changed atmosphere, and active exercise in the camp and field, and the pleasurable and energetic operation of the faculties of the mind at such times, the health of the soldier is observed to be more vigorous. 9. Small doses of quinine as a prophylactic in malarial diseases have been tried, and in the opinion of the regimental surgeons with effect. The men come up to the hospital for their dose every morning. 10. As regards local measures for preventing epidemics, these diseases are uncommon at Mean Meer. The outbreak of cholera at the station in 1856 is the only epidemic heard of here of late years. The cause of this remains unfathomed.
V. INTEMPERANCE.	1. The soldiers at this station are temperate on the whole. They consume a great deal of malt liquor in lieu of spirits. Crimes from drunkenness are certainly not numerous, nor is the occurrence of delirium tremens common. 2. The admissions from this disease among European troops during the past year have been 1 to 204 of the admissions from all diseases. The baneful effects of dram drinking are the growth of bad habits of years. The present corps here are mostly newly raised. Drunkenness, *per se*, is punished as an offence. 3. Spirits are sold in the canteen, but prohibited and guarded against in the bazaar. The quality is good, and is passed by a committee of officers before being disposed of to the canteen. Two drams of spirits per man daily is the quantity allowed and sold to each man. At the station his ration is two drams of spirits and one pint of beer, or one dram and two pints of beer. On the march the same. In the field an extra ration of grog is given to the men. A morning dram is not now served out to the men. Brandy and other spirits are used curatively in hospital. A ration of spirits is not given to men in hospital, nor can they procure it. Pop (a sort of ginger beer), lemonade, and soda water, are procurable in the bazaar and canteen, and are bought by the men. The two first are often spuriously made, and so are injurious to health. 4. The men in my opinion would be more healthy than they are without spirits, and by the substitution entirely of malt liquor, except upon occasions of great exhaustion and depression of vital power, after fatiguing marches, chilliness from wet, &c. The use of spirits tends to the subversion of discipline and efficiency.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	5. It would, I think, be beneficial to health to restrict or abolish the sale or use of spirituous liquors. 6. My own opinion, and that of many experienced medical officers of European troops, is decidedly in favour of beer in place of spirits, as more compatible with a vigorous and healthy digestion, and more preservative of the general health. 7. There is in barracks an authorized shop for the sale of tea, coffee, &c., and these beverages are much used by the men, and may be had by them at early morning by purchase. Statistical evidence, showing the influence on health of such beverages compared with spirits, is very imperfect and incomplete. The abstinent man is, I believe, generally speaking, more endurant of fatigue, and less obnoxious to disease than the good liver, or he who is called temperate. 8. I think it would be beneficial to suppress the spirit ration altogether. 9. And to permit only beer, coffee, tea, lemonade, &c., to be sold to the troops.
VI. Diet.	1. The ration for Queen's troops, and troops of the Indian army, is as follows:— 1 lb. bread, $\frac{5}{7}$ths oz. tea, or $1\frac{3}{4}$ oz. coffee, 1 lb. beef or mutton, 1 oz. salt. 4 oz. rice, 1 lb. vegetables, varying with the season, *i.e.*, $2\frac{1}{2}$ oz. sugar, in the cold weather, potatoes, cabbages, cauliflower, turnips, carrots, lettuce, onions; potatoes fail early in June; they will not keep good longer; onions, and a species of green stuff, like turnip tops, are supplied when the others fail, as well as peas or dhal and pumpkin. The rations are inspected daily by the regimental officer on duty, and by the commissariat serjeant, and periodically by the commissariat officer himself. 2. The ration as above described is furnished to all the troops. Fruit the men must buy themselves. The stoppage is 3a. 4p., about fivepence a day for breakfast, dinner, and tea. The soldier has three meals a day; at eight o'clock a.m., one p.m., and five p.m. For breakfast meat, fried generally, bread and tea. For dinner the following, varying on different days:—Soup, or soup bouillé, stews with vegetables. Meat, fried or roast, or baked, with dressed vegetables, curries, pies. In the evening tea and bread. The men join in messes, and subscribe to procure little additions, such as butter, milk, eggs, spices, extra vegetables. 3. The beef is often lean, but is considered sound and good on the whole. Mutton is often bad, and often not taken by the men. A continuous supply of potatoes all the year round, if procurable, is desirable. Such a supply has been ordered for the hospital. Selling part of the ration is a crime not heard of in this country among Queen's troops. 4. Cook boys act as cooks, to whom each soldier pays 12 annas monthly. The men pay a trifle extra (two pice per meal) when they require their food cooked in a nicer manner, requiring extra ingredients. The kitchens are good, and as clean as they can be, with the smoke escaping by the roof from wood fires. There is a good well close by. The cooking is as varied as can be, and with a little looking after is well done. On march the men have tea and coffee distributed to them at a halting place. Each soldier on march should have his leather-cased bottle thrown across his shoulders, holding water or cold tea. No tea or coffee served before a march. 5. Gardens for the men would be very desirable, but their cultivation could not be left to the pleasure or the caprice of the soldiers. A Government establishment must be provided. Hitherto either commanding officers of regiments or stations have not been sufficiently earnest in urging their establishment, or the Government has not been liberally inclined in the matter. The former is, I believe, the preponderating obstacle. At some large stations good soldiers' gardens are now in existence, as at Ferozepore and elsewhere. There was a famous one at Lahore during Sir Henry Lawrence's time there, but it has since fallen into neglect and decay. As an instance of what can be done, the native prisoners throughout all India almost are now supplied with good vegetables of all kinds out of excellent gardens tilled by themselves. The management of any such gardens must be under the regimental authorities, with the sanction of the officer commanding the station.
VII. Dress, Accoutrements, and Duties.	1. The men wear woollen cloth in the cold season, and a light cotton cloth (khakee) in the hot months. The infantry wear a loose sort of smock and trousers in summer, and a cloth tunic and trousers in winter. The Highlanders wear their kilts, which the surgeon considers to be too hot for the country. The artillery and cavalry wear the same texture of clothing. The warm clothing being of blue cloth. They wear jackets and trousers. The accoutrements are the usual kind appropriated to each arm of the service. The head-dress now worn by each arm is a basket framework helmet, covered with wadded cloth, and surrounded by a light turban. The helmet projects behind, and protects the back of the head. The present dress, without neck stock, and loose, is suitable to the climate. Warm clothing should be worn on night duty, and at the change of the seasons, to avoid the baneful effects of sudden vicissitudes of temperature. As regards improvements in dress, the men should be provided with flannel shirts and drawers during the cold season; a flannel waistband is beneficial, as tending to avert visceral congestion, by maintaining active circulation and warmth on the surface; this especially in hill complaints and for old residents in India. The guard dress is the ordinary parade dress for the season with accoutrements. The men have their cloaks for protection against severity of cold and wet. They do not patrol in the sun.
Duties.	1. It is the opinion of experienced men that recruits, if drilled at the depôt at home, before coming out to this country, would be saved a good deal of harassing labour on their arrival, and be less liable to disease, and likely to do the Government better service. 2. With regard to duties. Drill is twice a day in the cold season. It is lessened in the hot season. Cavalry and artillery rub down their horses for a time. The royal artillery are kept a longer time at this than the Indian army artillery. The time of drill is suited to the season, so as to avoid exposure to the sun. The infantry have drills three times a week during the hot weather. They have daily target practice (one company at a time) for several hours morning and evening during the cool months. In the hot months the men are in their barracks by 6.30 a.m., and are prohibited leaving them during the heat of the day. The drills and parades are not injurious to health.

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*Duties—cont.*	The best hours for drills and parades are about sunrise and sunset. For marching through a dry healthy country, the early morning, before sunrise, is the best time, so as to finish the march two hours after sunrise in the cold season; but, through a low malarious country, and at a season of fogs, exposure to such an atmosphere before sunrise should be avoided. The troops should march later. Troops ordinarily commence their march some hours before sunrise. The number of nights in bed depends on the number of guards and the strength of the corps. The infantry here have 12 successive nights in bed, the cavalry four or five. The men do not appear to suffer from night duty. 3. Guards are mounted within the precincts of the barracks. The guards are relieved in the infantry every 24 hours. Sentries are on duty for two hours at a time. They walk under cover. There are morning and evening roll calls in the summer, at 6 p.m. daily, and at 5 a.m. every alternate morning, Sunday excepted. There are no night roll calls.
VIII. INSTRUCTION AND RECREATION.	1. The following are the means of instruction and recreation provided at this station :—Skittle grounds, schools for some of the European corps, library and reading rooms, several theatres. There is a billiard room in the serjeants' mess. The men play cricket, chess, backgammon, bagatelle. There are no ball courts, day-rooms, nor soldiers' clubs; no soldiers' gardens, workshops, nor gymnasia. The men are not sufficiently provided with means and opportunities of employment, and the above deficiencies ought to be supplied. A double fives court is much needed. The men are strictly prohibited from leaving their barracks after the heat of the day has set in. 2. Together with workshops, photography, modelling, and drawing should be introduced. 3. Savings' banks for soldiers have been established, and have been of the greatest use. 4. As regards shade for exercise. In the immediate vicinity of cantonments there is not a tree except along the roadsides.
IX. MILITARY PRISONS.	1. There is no special prison. Provost prisoners are kept in rooms at the ends of the barrack, intended for bath rooms. They are kept clean. Each room has 2,000 cubic feet of contents. Ventilation by open fanlights over two contiguous doors. The rooms being part of the outer verandah are much exposed to the sun's rays. Those which receive the afternoon sun are not used unless absolutely necessary.
X. FIELD SERVICE.	1. I do not know of any local regulations for field service. 2. The medical officer may or may not be consulted on the march of troops, bivouacking, campaigning, &c. It is his duty to point out and protest against any neglect or disregard of proper sanitary rules or precautions. But the management of them is mainly conducted by the commanding officer and by his subordinate quartermaster's department. 3. Greater care than previously has of late years been bestowed on the selection and sanitary condition of camping grounds. Large serais have been built in the neighbourhood of the termination of each march, with a good water supply from wells. Dry camping grounds are chosen if possible at a distance from swamps and nullahs, or water channels. The route is chosen away from the neighbourhood of bazaar towns and villages, so as to keep liquor and disorderly temptations out of reach. To keep the men from damp a bedding of straw or grass is provided, over which a tarpaulin or blanket is thrown. Water carriers and other servants for cleansing and clearing the ground, &c., accompany the troops. 4. In times of war, field hospitals are organized, with a field surgeon and several assistant-surgeons, and a hospital establishment, European and native, with a large number of doolies for wounded, which are upon the whole the easiest mode of conveyance. Ambulances are employed only on good made roads, and are apt to come to pieces if taken across country. Field hospitals are on the plan and scale of regimental hospitals as to establishment. Hospital stores and supplies are obtained upon indent, upon the different departments, signed by the field surgeon and superintending surgeon. Camels and elephants are used for the carriage of tents, stores, &c. The Bengal medical code of 1851 contains the field hospital regulations in force.
XI. STATISTICS OF SICKNESS AND MORTALITY.	1. No information.
XII. HOSPITALS.	1. There are two large European hospitals built on the same plan. The infantry hospital is at the north-west corner of cantonments, the artillery hospital at the south-east corner. There are besides hospitals for native infantry and cavalry on the east and west facings of cantonments. The two European hospitals are situated on the open plain, between three and four miles asunder. The hospitals in both cases are separated only from 400 to 500 feet from the nearest barracks. The hospital enclosure wall is 330 feet from the nearest stables, and 700 to 800 feet from the regimental bazaars. The European hospital sites are quite open and good. The native hospitals are nearer their lines and bazaar. The European infantry hospital occupies an area of 60,000 square yards. 3. The water supply is abundant and good, and is obtained from a well within the enclosure. 4. The drainage of refuse water from washhouses and cook-rooms is either into deep covered cesspools or else into small shallow reservoirs, whence it is carried away daily. These receptacles are close to the hospital building. 5. The floors of the wards are raised 3½ feet above the level of the surface. There are no ventilating flues under the floors. The roof water falls on the ground, and escapes towards the drain by a slight fall. Surface drainage is effected by small channels cut to carry off the rain water towards the main drain, in the infantry hospital; but there being no main drain in the artillery hospital the water is conducted to the outside of the enclosure wall. The hospitals are constructed of solid masonry. The roofs are single, with ridge ventilation, and sufficiently thick. The wards are lofty. There are outer verandahs 10 feet broad on all sides, with closely set reed chick (a hanging screen), with or without the addition of cloth purdahs (hanging curtains), as a further protection from sun heat. The outer verandahs are not used for sick or others. But on one side the verandahs are divided into small compartments, to answer as washhouses.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	This bad system is detrimental to free ventilation through the verandahs, which ought to be open spaces. The following is the hospital accommodation :—E.1. Hospital. Date of construction - - - - 1854–5. Number of wards - - - - 10. Regulation number of bed in main wards - 160.

Wards.	Regulation Number of Sick to each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area per Bed.	Height of Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
10 - - - - -	16	48	24	24	27,648	1,728	72	2	6 doors and 6 upper lights, 3 on each side and opposite.	—	—
Verandahs occupied by sick only under pressure or for purposes of separation. } 20	8	48	12	16·75	9,648	1,206	72	2	—	—	—

The hospital is placed so as to receive the full benefit of prevailing winds.

The windows swing open, and are opened and closed at will by ropes, being situated high up in the main walls. These let hot air in as well as permit the escape of air from within, and are not calculated to promote coolness.

6. Ventilation is effected by doors, windows and ridge openings. In crowded hospitals these means would not be sufficient, but ordinarily, on account of the large space, they keep the wards free of odour and closeness. There are no jalousies or jhilmils.

7. Thermantidotes have recently been introduced for ventilating and cooling the air in wards. They consist of a fan wheel, 10 feet in diameter, with an iron axle, and are composed of seven wooden fans, each 4 feet 11 inches long, and 2 feet 6 inches broad. The axle works on two small wheels, fixed on each side in the wooden frame. The whole is enclosed in brickwork, with openings for two tatties behind. The fans are revolved by one man by means of a handle on the axle. Tatties are also placed in the doors to windward and kept well wetted. Punkahs are also used.

8. For warming, each ward has a fire-place in the side of the inner verandah at each side.

Repairs and whitewashing are done annually. The hospital walls may be partially whitewashed every quarter, or it may be done after epidemics.

9. The privies are at the extremity of the hospital wings, and communicate with it by covered ways. They are rooms with front verandahs 27½ feet long by 12½ feet wide; eight seats in separate compartments. The side walls are 13 feet 3 inches high. The ridge is 17 feet high.

Pans are used like those in the barracks, and are removed and cleansed in the same way. The filth is removed morning and evening in carts. Moveable urinals of iron, with earthenware pans, are placed in the verandahs. Lately pans with airtight covers have been introduced, into which the filth is emptied previous to removal.

If the privies and urinals are kept clean they are not ordinarily offensive.

10. The lavatories are small compartments walled off in the outer verandah. They contain tables and basins, pegs for towels, and tubs of water. They are too small, badly placed, and obstruct the space in the verandah.

A drain from these lavatories runs into covered cesspools outside. In the infantry hospital masonry platforms and benches have been built with a small runlet, reservoir, or sink at the back. The basins are placed on these benches, and the refuse water is thrown into the sink, where it passes into a drain and into the cesspool. Wooden gratings are provided for the men to stand on. There is a small space walled off at one corner of the lavatory sufficiently large for a man to sit in and wash.

11. There are slipper baths and tubs in the hospital for the use of the sick.

12. The linen is washed in the river Ravee, seven miles off, and is there dried, prepared, and brought back for use almost daily.

13. The store accommodation is scanty. The infantry hospital was built for one regiment, and has two stewards' establishments. At the artillery and cavalry hospital there are four stewards' establishments, without more accommodation than in the infantry hospital.

14. The cots and bedding are the same as those used in barracks.

15. There are two cook-rooms, one to each hospital wing of the infantry hospital. They have the usual Indian cooking arrangements : low mud or brickwork fire-places with side ledges, to support pans and kettles over the fire, as well as raised brickwork fire-places with iron gratings on the top, and underlying flues or passages for creating a draft under the fire, placed on the gratings. The appliances are sufficient to cook in the required variety.

16. The diet tables are those in the regulations, but besides the printed forms, there are numerous indents and vouchers for incidental and contingent and extra wants and supplies of a trifling nature, all requiring monthly the superintending surgeon's signature.

17. For attendance, a hospital serjeant and two hospital orderlies are allowed; a native nurse for the female hospital. There are a certain number of ward coolies allowed to attend on the sick (20 to a full regimental hospital). Usually there are enough. If more are required men from barracks are allowed.

18. The hospitals are splendidly commodious buildings. Improvements in cooling the air, in latrine and urinal arrangements, abolishing of cesspits, &c., are progressing. The ventilating arrangements are defective, on account of admitting hot air and dust. This could be remedied. Epidemic or hospital gangrene or pyæmia, traceable to defective hospital conservancy, have not appeared.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	19. Daily removal of hospital excreta, and the so-called dry system should be adopted. 20. Convalescents take exercise on the open plains, morning and evening, conveyed either in carts with awnings, drawn by bullocks, three or four men in a cart, or on elephants six men to each. Men too delicate for this can be carried in a dooly by four men. 21. There is a female hospital within the same hospital enclosure, managed like the rest of the hospital. 22. The medical code contains all existing hospital regulations. Any others not found there are according to the custom or discipline of the regiment. 23. As regards the practical powers possessed by medical officers; it is the duty of the medical officer of the regiment, through the commanding officer, and through the deputy inspector general of hospitals near at hand, to point out earnestly and repeatedly any unsanitary conditions. He is the first moving agent towards bringing about the remedy, and should persevere until he succeed. He exercises the same influence in obtaining change of diet, increase of comforts, &c., in fixed hospitals, camps, and on the march. The intermediate controlling officers through whose hands his requisitions pass, secure a check over any licence of requirement. 24. There are no convalescent wards, and they are not required in such hospitals as those at this station.
XIII. Burial of the Dead.	1. There are two burial-grounds nearly half a mile from each hospital. The atmosphere over them is not perceptibly tainted. 2. The infantry burial-ground has an area of 37,500 square yards, and the artillery ground of 10,000 square yards. The soil is the same as the rest of the cantonment, and is drained in a similar way. The chaplain may keep the ground in good order by application to the commanding officer at the station. 3. According to custom, graves are 7 feet long by 3 feet wide, with 2 feet between them. The Mohammedan burial-grounds are far beyond cantonments. They allow two feet between every two graves. For Europeans the depth of graves is 6 feet, one body in each grave. For Mohammedans 4½ feet, and one body per grave. Funerals of Europeans take place at sunrise, or half an hour before sunset. The funeral should take place on the day of death, if due notice has been given. Mohammedans bury a few hours after death. Hindoo dead are burned to ashes. The burning grounds are far off, beyond the boundaries of cantonments. The air is not sensibly vitiated on their account. 4. As regards the influence of burial on health. The European burial-grounds are not offensive. In Mohammedan grounds the body is often built over with bricks, burnt or unburnt, and earth is loosely piled over, slightly above the level of the ground. This soil is often removed by rains, and the body comes in contact with the air; hence these burial-grounds even in the vicinity of large native cities are often very offensive. At this station the grounds are too distant to be noxious. The civil authorities could enforce greater precautions in the burial of native dead. There are certain people who dig graves and prepare coffins for European dead, to whom notice is given by the hospital serjeant. Two graves are always kept ready. The local paymaster is authorized to issue a sum equal to a month's pay of the deceased on account of funeral expenses. 5, 6. No injury to the public health arises from the present practice of burial. 7. The chaplain could make convenient additions and improvements to the present arrangements, if funds were placed at his disposal.

These answers have been filled up with the assistance of the Executive Engineer, so far as relates to his department, and have been shown to the Commanding Officer of the station.

July 29th, 1860.

W. A. Green, Deputy Inspector General of Hospitals, Lahore Circle.

MEAN MEER.—FURTHER REPORT.

(Much of the information in this report for Queen's troops is given in the preceding report, and only such parts are abstracted as throw additional light on the questions.)

References to Subjects and Queries.	Replies.
I. Topography. II. Climate.	*Vide* preceding report.
III. Sanitary Condition of Station.	1 to 13. For answers to these queries, *vide* preceding report. 14. Formerly cesspool privies were made, but they have been universally condemned, as they contaminate the wells and air in their proximity. The present system is that of surface privies with separate enclosed seats, with pans underneath, which are removed through holes in the rear wall, and emptied into conservancy carts, in which the contents are conveyed outside the station boundaries. The urinals drain into cesspools after being mixed with the refuse water of the washhouses. The system is very bad as it contaminates the soil. 15 to 24. *Vide* preceding report.
IV. Health of the Troops.	1. The station, with the surrounding district, and the adjoining native population, are generally very healthy. 2. The diseases most prevalent among the natives are fevers, and bowel and liver complaints. In the city of Lahore, six miles off, small-pox and measles appear annually. 3. I attribute the healthiness of the neighbouring native population to the dry climate and almost entire freedom from malaria.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	4. The large force now at Mean Meer is constantly changing stations. Commanding and medical officers of corps consider that the health of their regiments improves in coming to this station. The various portions of the men's present accommodation are all equally healthy.
	5. The troops at this station are always in barracks.
	6. I have only seen a few invalids at Dhurmsala, but I have been at that place a good deal, and I dislike it very much for soldiers in the rains. Dalhousie, also in this division, is much drier, and I think would be a much more healthy station for troops. I think that Holta in the Kangra valley, where the Government tea gardens are, is the most fitting place for soldiers that I have seen in India, it being not too high, whereas I do not approve of very high elevations.
	7. At first troops resident in hill stations are rather liable to attacks of febrile and other diseases on their return to the plains; but after this casual acclimatization has passed, a regiment remains healthier than one which has passed the hot season in the plains.
	8. I most decidedly approve of selecting hill stations for troops.
	9. Diarrhœa is the particular disease of hill stations, and with which troops are liable to be attacked on going to them.
	10. The use of woollen clothing and flannel belts is absolutely necessary for the greater benefit to the health of men resident in hill stations. Better diet than what is usually provided in the hills should also be given to the troops, and during the months of April, May, and June exposure to the sun should be avoided.
	11. The best season for a residence in hill stations is decidedly during the hot weather in the plains; but Europeans derive great benefit from a residence during winter in stations that are of moderate altitudes. The period of residence in the hills which would enable the men to obtain great benefit to their health could not be less than six months, or they would have to come from a cool to a hot climate.
	12. Provided the troops keep their health in the hills, there can be no limit to the duration of such residence.
	13. Avoidance of direct exposure to the sun and the precautions of ordinary common sense alone appear necessary for protecting the health of troops on their leaving hill stations for the plains.
	14. A regiment should occasionally go to a hill station for a hot season; but a long residence in the hills would be very wearisome to men, affect their spirits, and consequently their health. Troops and convalescents should be moved every two years when stationed in the plains.
	15. Additional accommodation at hill stations is being furnished for troops; but I cannot state whether the barrack and hospital accommodation in the hills or sanitaria generally is sufficient for the health and comfort of the men.
	16. I consider an elevation of from 5,000 to 7,000 feet above the level of the sea as best suited for sites for hill stations.
	17. There is no higher ground near Mean Meer which could be advantageously occupied as a hill station.
	18. From experience I find that a sandy soil is good for the formation of a station, while a wet clay soil is bad, more particularly as the drainage is neglected.
	19. I consider from 20 to 23 years the best age at which soldiers should proceed to India, and November the most fitting month for them to land therein. Troops, on first landing in India, are sent to depôts and put into barracks, carefully clothed and drilled, and then sent to their corps, generally speaking by steamers and bullock-carts, as opportunities may offer. For preserving the health of recruits on first landing in this country, I would recommend that they be kept from drink and undue exposure to the sun, and that healthy recreation be afforded them.
	20. Troops destined for India should be sent here direct from the home depôts, if it be arranged for them to land here in November. If landed in this month, and at once marched off up country, the exercise and air would be the best way of giving them strength, and inuring them to the climate.
	21. Troops are transported from Calcutta and Kurrachee by river steamers to Allahabad and Mooltan; thence, if in small parties, by bullock-carts travelling for 18 out of the 24 hours; but if in large parties, by regular marches of 12 miles a day on an average.
	22. Both for physical and moral reasons, I consider that the number of years a British soldier should be made to serve in India ought to be limited to ten.
	23. The manner of conducting medical boards as regards invaliding, whether at stations or at the presidencies, is believed to be satisfactory, and of such a nature as to avoid conflict of opinion.
	24. Invalids destined for home should leave India during the month of January, so as to arrive in England about the beginning of May.
Diseases.	1. In each European regiment at this station there are regular surgeons' inspections once a week for the discovery of incipient disease.
	2. Scorbutus is not a disease of this state, but when occurring, it is attributable to bad food, want of vegetables, hard work, and bad spirits.
	3. The proportion of cases of hepatic disease usually under treatment is 3·86 per cent. I attribute this disease to the following causes, viz.,—heat of climate, exposure to the sun, and changes at night. Hard drinkers are predisposed to it. As a prophylactic measure which, in my opinion, would diminish its frequency, I would recommend that spirits be stopped and the men kept from exposing themselves to the rays of the sun.
	4. Dracunculus is a disease unknown at this station.
	5. The proportion which the constantly sick in hospital from venereal diseases bear to the total sick from all other diseases, is 1 in every 13. There is an experimental lock hospital here, which diminishes the severity of the disease without actually affecting the number of cases. It is considered very advantageous, but there is a difficulty in a large Indian cantonment with regard to supervision. It has been constantly tried in India, but the Government has not yet sanctioned a permanent establishment of the kind.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	6. The following are the diseases from which the troops at this station suffer, viz.:— *Fevers.*—Common, continued; intermittent, of the various kinds; and remittent. *Dysentery.*—Acute, chronic, and hæmorrhagic. *Cholera* only rarely, at very long intervals. On the last occasion, in 1856, it was extremely severe. *Small-pox.*—Common in a mild form, and to a limited extent. *Rheumatism* very common, but not in the acute form. The following table shows the proportions which admissions and deaths from the above diseases bear to the total admissions and deaths:—

Diseases.	Admissions to Total Admissions.	Deaths to Total Deaths.
Fevers -	1 to 3	1 to 4·5
Dysentery -	1 to 27	1 to 3·6
Cholera -	Nil.	Nil.
Small-pox -	1 to 322	1 to 32
Rheumatism	1 to 32	1 to 10

7. The character of fever is common ague, with enlargement of the spleen. Occasionally it is ardent remittent, the result of heat, and also the bilious remittent. Dysentery is of the acute kind. Small-pox is attended by weakness and imperfect elimination. Rheumatism is muscular and arthritic. These diseases are most prevalent during the months of April, May, and June, and again in September and October. They generally make their appearance at the setting in of the hot season, and the atmospheric changes, heat and dampness, and the drying up of inundations in September and October. These diseases do not arise in this cantonment from want of cleanliness or proper drainage, or from imperfect ventilation and water supply. Idleness among Europeans predisposes to disease, and want of proper food and clothing among the natives.
8. The prevalence of epidemic disease amongst the troops is partly owing to idleness in barracks, and on the march and in the field to certain deprivations of food and proper places for sleeping, and to other unavoidable circumstances.
9. Small doses of quinine have been tried with success as a prophylactic against malarial disease at this station.
10. The greatest care is taken of the troops at this station as to their accommodation and food, and no particular improvements, beyond those already stated, can be suggested towards the prevention or mitigation of epidemic disease.

V. INTEMPERANCE.

1. The soldiers at this station are usually temperate. The number of confirmed drunkards among them is very few, so few indeed that the proportion cannot be stated.
2. During the year from the 1st of April 1859 to the 31st of March 1860, in a troop of Bengal horse artillery, 115 strong, the total number of cases treated were 151, and there was but one case of delirium tremens. In a regiment of Bengal light cavalry, 348 strong, 1,139 cases treated, and four cases of delirium tremens. In a wing of an English regiment of royal infantry, 556 strong, 1,532 were treated, one case of delirium tremens. In a Scotch regiment of royal infantry, 955 strong, 1,493 cases treated, with 11 cases of delirium tremens. There are no data at this station to enable me to prepare a statistical table, showing the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime here. Drunkenness is always punished as an offence.
3. Rum is sold at the canteens, and native liquors in the bazaar; but this latter is not allowed to be sold to the soldiers. The quality of the spirit is bad. Not more than an average of one dram per diem is consumed by each man. Spirit does not form a part of the soldiers' ration either in barracks, on the march, or in the field. Formerly old soldiers used to take a morning dram, and they would do so now, but it is not permitted by commanding officers of corps. Wine and beer are commonly given as a ration to convalescents, brandy very rarely, but rum never. With regard to the brandy, the quality is fair. The amount is specially prescribed in every cases by the medical officer. No drinks injurious to health, other than intoxicating drinks, are sold at the canteen or bazaar at this station.
4. The consumption of spirits by troops and convalescents is injurious to health, and not at all conducive to the efficiency or internal discipline of the corps.
5. The restriction or abolition of the sale of spirits in the canteens and bazaars would be beneficial to the health of troops.
6. Malt liquors are considered preferable to spirits for troops. Wines are never used except in the hospitals.
7. There are regimental coffee shops at this station, and they are much frequented. Coffee, &c., and malt liquors at their proper times, are considered good for the health, efficiency, and discipline of the troops.
8, 9. It would be beneficial to the health of troops to suppress the use of spirituous liquors, and to substitute beer, tea, &c., but there would be an objection to carrying this out in a Scotch regiment.
10. The general establishment of coffee shops throughout the whole army would be very beneficial.
11. Extracts from the Bengal Military Canteen and Bazaar Regulations:—" Every means are " to be adopted to induce the soldier to give a preference to malt liquor, rather than to " spirits."
" The quantity of malt liquor so supplied is not to exceed one quart per diem per man.
" The allowance of malt liquor may be issued for consumption with the dinner.
" Canteens are to be opened in the hot season, or from the 1st of April to the 1st of November, from gun-fire until 10 a.m., and again from 5 p.m. until watch setting, and during the cold season, or from the 1st of November to the 1st of April, from gun-fire until 12 o'clock, and again from 4 p.m. until watch setting."
N.B.—It is the duty of the canteen committee to give orders for wine, ginger beer, spirits, &c., and to see to their quality. " No spirituous liquor, wine, or beer is on any account to be " sold or issued from the canteen, directly or indirectly, to any native whatever, nor are any

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	" of these articles to be allowed to be taken away from the canteen except on special " occasions, when the soldier requiring them for himself or family must produce an order " signed by the officer commanding his troop or company." " The canteen serjeant is held responsible that the canteen is always kept clean, and properly " ventilated, and regularly lighted from dark until closed for the night." " No spirits are to be issued on any occasion before the usual dinner hour, nor is any man to " be allowed more than 2 drams per diem, and these 2 drams are never to be issued at the " same time." " Men who draw malt liquors are only to be permitted to receive 1 dram of spirits in addition."
VI. Diet. VII. Dress, Accoutrements, and Duties. VIII. Instruction and Recreation. IX. Military Prisons. X. Field Service. XI. Statistics of Sickness and Mortality. XII. Hospitals.	For information under either of these heads, *vide* preceding report.

I. Topography.	1. The aspect of the country surrounding the station is rocky, hilly, and barren. Ravines exist; but there is not much water, jungle, or wood in the immediate vicinity. 2, 3. The elevation of the station is about 700 feet above the level of the sea; but in the direction of Seepree, about 70 miles due west, there is a gradual ascent up to 2,000 feet above the sea. There is no higher or healthier ground near the station. 4. The river Betwa, six miles south-east, and Luchmee Tal, about a mile and a half north, are the nearest waters to the station. There are no marshes, and the vicinity of the station is not liable to overflow. There are many ravines, but they form a natural drainage, and are conducive to health rather than otherwise. 5. The station is open in every direction, and there is no obstruction to free ventilation. The soil being rocky and gravelly, with a substratum of quartz and granite, heat is retained and thrown out to a much later hour after sunset than if the soil were earthy. The prevailing wind is from the north-west. 6. At some distance from the station the country is cultivated. The nearest work of irrigation is the Kockaboor dawk, about three miles off. Neither rice nor indigo is cultivated, nor the preparation of hemp or flax carried on near the station. 7. The town of Jhansi is about one mile from the station, that of Oorcha about eight miles south-east by south, and that of Dultea about 17 miles distant north-west by north. 8. The station of Jhansi, with its vicinity, is rocky and barren, but as it stretches away, grass lands and soil fit for cultivation appear. The ground occupied by the station is partly new. 9. In sinking wells, water is usually found at a depth of from 40 to 50 feet below the surface of the earth. This is a very expensive process, as the wells have to be sunk through the solid rock. 10. Water does not lie on the surface, neither is there any drainage from higher ground passing into the subsoil of the station. 11. The water supply of the station is derived from wells, but is not stored. The Luchmee tank has always abundance of water, varying in quantity with the season. The water chesnut is cultivated, the water lily grows spontaneously, and inferior kinds of fish and tortoises are contained in the water. Tanks are not used for drinking purposes, and the sunk wells are carefully preserved from all chance of pollution. No nuisance or malaria proceeds from the tanks, as the prevailing wind carries any vapours that might arise clear of the station. 12. The supply of drinking water is sufficient, and can be increased by sinking other wells. The water is hard, slightly impregnated, agreeable to the taste, and of good quality. It is distributed for the purposes of cultivation by the Persian wheel. 13. Embracing all the topographical points, even including the heat occasioned by the rocky character of the soil, the station should be healthy. 14. Boards for the selection of sites are so inaugurated by the regulations that if their duties were carried out with ability and diligence, no improvement need be suggested.

JHANSI.
BENGAL.

References to Subjects and Queries.	Replies.
II. CLIMATE.	1. The instruments for conducting meteorological observations are rain gauges, thermometers, and pluviometer. 2. The following observations are from the Journal of the Asiatic Society, No. 5 of 1852. All other records were destroyed during the mutiny and new research is in its infancy.

Table of Meteorological Observation during the year 1851.

Months.	Mean Temperature.	Months.	Mean Temperature.	Months.	Mean Temperature.
January	—	May	96·2	September	81·1
February	—	June	94·4	October	85·1
March	80·8	July	—	November	73·6
April	88·6	August	—	December	65·7

3. The climate is healthy and bracing except during the hotter months of the year, perhaps less prejudicial and relaxing to a healthy subject than most parts of India. The station has not as yet had a fair trial, as the troops that have hitherto arrived have suffered from severe service and exposure. The cold season is the most healthy at this station. Intermittent fever prevails during the months of August and September.
4. There is no district near the station with a climate more conducive to health than that of Jhansi.
5. I have served in almost every Indian station, and regarding their salubrity, there is little choice, they are all equally relaxing during certain months. Dacca and Dinapore are most frequently visited by cholera. From this list I of course exclude the whole of the Punjab, as this has during eight months of the year a climate equal to the best. (Colonel W. W. Davidson.)

III. SANITARY CONDITION OF STATION.

1, 2, 3. Map of station, &c., forwarded.
4. Table of barrack accommodation.

Barrack Rooms or Huts.	Regulation Number of Men in each Room.	Dimensions of Rooms or Huts. Length.	Breadth.	Height.	Cubic Contents in Feet.	Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows. Number.	Height.	Width.	Remarks.
INFANTRY.												
8½ Co. barracks:—												
2 rooms	24	67	22	28	41,172	1,715·5	61·4	1′ 9″	12	2	4	
4 rooms	2	18	11	14	2,772	1,386	99·0	1′ 9″	13	8	4	
									1	11½	8	
Mess rooms	48	16	25	28	32,200	—	—	—	2	8	4	
									2	5	3	
ARTILLERY.												
8½ Co. iron-frame barracks:—												
1 room	24	40	39	18	28,080	1,170	65·0	1′ 9″	22	10	4½	
1 room	24	39	39	16	24,336	1,014	63·3	1′ 9″	4	5	3	
1 mess room	—	39	25	18	17,550	—	—	—	4	9	5	
2 non-commissioned officers' rooms	—	19	12½	14	3,325	—	—	—	2	12	8	
3 verandah rooms	—	10	10	10	1,000	—	—	—	3	8	4	Open ventilators along the whole ridge of the roof.
									6	5	3	
3 pendals (temporary)	60	160	40	14	89,600	1,493	106·6	—	(Open all round.)			
1 thatched hut	25	90	30	14	—	—	—	—	—	—	—	
1½ Co. iron-frame barrack	—	—	—	— As above, erecting for infantry in the Fort.								
Guard room	—	—	—	— Not erected.								
Prison cells	—	—	—	— Not erected.								

5. There are doors on both sides of the barracks in two leaves opening inwards, and verandahs on both sides, 160 feet by 12, which are usually in the hot season, and temporarily when the barracks are overcrowded, occupied by the soldiers as sleeping quarters. There are no jalousies or jhilmils.
6. The cots used for sleeping in the barracks are 6 feet 6 inches long, 2 feet 6 inches broad, and 2 feet high, covered with broad tape. Improvement is desirable, and could be effected by putting the head bar above and foot bar below the sides, thus giving a slight slope.
7. No reply to this query.
8. There are ventilating windows on both sides above the doors opening inwards, and generally speaking these means are sufficient to keep the air pure by night as well as by day. Punkahs are used and tatties during the hot winds.
9. No reply to this question.
10. The floors are usually of lime plaster 3 feet above the ground; stone slabs are preferable. There is no passage for air beneath the floors.
11. The barracks are well suited to this locality; but in damp situations two stories are preferable, the upper one only being occupied by troops. The barracks are repaired by the barrack department, except when large repairs have to be made, when the executive engineer does them. They are cleansed and limewashed as often as the medical officer may require.
12, 13. The men's lavatories and barrack cook-houses are not yet finished. The washing is done by dhobies.
14. The privies, urinals, &c., are on the standard plan for a company of infantry.
15. These buildings are ventilated at the top by openings that cannot be closed, and lighted from the side doors. The barracks are lighted at night by lanterns.
16. Drainage of the barracks entirely superficial. Sewage is collected directly in small open tanks close to the buildings, which are emptied and cleaned every day. These means are sufficient for the purpose. No part of the barracks or hospital is subject to dampness. The natural drainage is so good as to prevent any accumulation of surface water. The cesspits or tanks are only about three feet cube, and are cleansed morning and evening. There are no foul ditches near the station.
17. Surface cleansing is done by the barrack department. The refuse is removed in carts outside the limits of cantonments.

References to Subjects and Queries.	Replies.
II. Sanitary Condition of Station—*cont.*	18. The surface of the cantonment is kept free of vegetation. A few old buildings exist; but not in a position to affect the ventilation of the station. 19. The bazaar is new and incomplete, but is well-drained, and the arrangements as to cleanliness satisfactory. Public latrines are constructed at the expense of the bazaar residents. The police force is at present insufficient. There are no native houses, except in the Sudder bazaar, and no nuisance is experienced in barracks from wind blowing over them. 20. The slaughtering of animals for the use of troops is forbidden within the limits of cantonments, and is done outside and to leeward of prevailing winds. The offal should be burnt, but is quickly disposed of by vultures, adjutant birds, &c. 21. Bazaar horses are picketed in rear of the bazaar, and are under the inspection and control of the bazaar authorities. The manure is removed for fuel by the poorer classes. 22. There are no cavalry or artillery stables at this station. The conservancy carts remove the manure daily. The picketing grounds are upwards of 150 yards from the barracks, and to leeward of them. 23. There are no quarters for married non-commissioned officers and men. The pendals are occupied by married people as a temporary arrangement.
Officers' Quarters.	1. The officers' quarters here are inconvenient and ill-adapted for the purpose, being mere outhouses. Officers should be encouraged to build for themselves, receiving assistance from Government.
IV. Health of the Troops.	1. The station and surrounding district are generally healthy. 2. Fevers and venereal are the most prevalent diseases amongst the native population. Small-pox occasionally occurs, but cholera is almost unknown. 3. I attribute predisposition to disease among the native population to intense heat, the radiation from the rocky soil and brackish water. 4. H.M.'s 89th regiment was at Seeonee nine months, and left on the 27th of February 1860. The health of the men there was good: intermittent fever was the prevailing disease among them. They arrived here (Jhansi) on the 13th March, in a healthy condition; the prevailing disease since which time has been intermittent fever. No portion of the men's present accommodation is more unhealthy than the rest. 5. Most of the troops were in camp last year, the barracks not being ready for occupation. They suffered much during the hot season and rains. 6, 7. I have never served at hill stations, but I should say that troops that have been some time resident at them are, generally speaking, less liable to attacks of febrile and other diseases on return to service in the plains. 8. I approve of selecting hill stations for troops, as I believe them to be highly beneficial to health 9 to 12. The regiment has never been in a hill station. 13. I would recommend the use of flannel under-clothing as a precaution for preserving the health of troops leaving hill stations for the plains. 14. I should say it would be most conducive to the preservation of the health of troops serving in India to locate them on hill stations, with short periods of service in the plains. Frequent change of stations in the plains is beneficial to the health and spirits of troops and convalescents. 15, 16. I have no experience to enable me to answer these questions. 17. There is no higher ground near the station which could be advantageously occupied as a hill station. 18. A sandy surface, with a gravelly subsoil, is the most healthy for a station. 19. Troops should not be sent out to India under 20 years of age, and should land there in November. Troops on landing in India are usually sent to their regiments, and are some time on the march. Before proceeding up country they are provided with such clothing as they require. I would recommend as a precaution for the preservation of the health of troops on first landing in India, that they be kept as far as possible from exposure to the sun and from intemperance. 20. Troops destined for India should, in the first place, be sent to an intermediate station, and then on landing in India should be sent to hill districts. 21. Troops are forwarded from the port to the interior by steamer or thatched bunder boats, if by water; by railway or bullock train if by land. 22. British troops should not serve more than from six to ten years in India. 23. Medical boards are conducted in such a manner as regards invaliding as to avoid conflict of opinion. 24. Invalids should leave India for home about the end of January.
Diseases.	1. Among European troops an inspection for the discovery of incipient diseases takes place weekly at this station. 2. There have been very few cases of scorbutic disease in the 92nd regiment, and none at all in the 89th. As a preventive measure against this disease, I would recommend a greater variety in and an increased quantity of vegetables. Potatoes should invariably from portion of the daily ration. 3. The proportion of cases of hepatic disease is usually about 1 in 15, and the probable cause the effect of the climate. It is not consequent on other diseases. 4. No particulars are as yet known here of the disease called dracunculus. 5. The regiment having been on field service since its arrival in India, venereal disease has not been prevalent. 6. The prevailing diseases here are intermittent fever and a few cases of dysentery, but no cases have occurred of cholera, small-pox, or rheumatism. Having only lately arrived here, I cannot state the proportion which is borne by admissions and deaths from these diseases to the total admissions and deaths. No death has yet occurred from fever. 7. There has been no epidemic disease here since the arrival of the regiment. The station is well situated; the bazaar and native dwellings clean and well-drained, with a good supply of water, and they are not crowded. 8. The regiment has not suffered from any epidemic disease since its arrival in India. 9, 10. Small doses of quinine have not been given here as a prophylactic against malarial diseases. I have no recommendations to make on any of the preceding points.
V. Intemperance.	1. The soldiers at this station are temperate, and there are no confirmed drunkards among them. 2. There are no admissions into hospital from diseases arising, either directly or indirectly, from intemperance. Drunkenness is always punished as an offence. 3. Distilled spirit is sold at the canteen, but never forms part of the ration to convalescents,

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	nor of troops, either at the station, on march, or in the field. No drinks injurious to health, other than intoxicating drinks, are sold at the canteen or bazaar. 4. Although the use of spirits by troops or convalescents is not injurious in moderation, yet it is not conducive to health. In moderation it does not affect the internal discipline of the corps. 5. The use of spirituous liquors should be restricted, but could not be abolished. 6. Malt liquor and wines are beneficial to health, being tonics, whereas spirituous liquors are merely temporary stimulants. 7. Neither coffee, tea, lemonade, nor soda-water is much used at this station. 8, 9. Beer might be substituted with advantage and by degrees for spirits. It would not be beneficial at once to prohibit the sale of spirituous liquors in the canteens, as then men who were accustomed to it would take to country liquor, which is more injurious. 10. I would suggest as an improvement on the above points a more liberal supply of malt liquor. 11. No reply to this query.
VI. Diet.	1. The daily scale of rations for Queen's British troops and European troops in the Indian army is the same, and as follows:—Meat, 1 lb.; bread, 1 lb.; rice, 4 oz.; salt, 1 oz.; sugar, $2\frac{1}{2}$ oz.; tea, $\frac{5}{7}$ oz. ($\frac{2}{3}$ black, $\frac{1}{3}$ green); milk, 6 oz., and vegetables, 1 lb. There is a responsible inspection every day of the rations by the captain and subaltern of the day, with the quartermaster, and when in doubt, a medical officer. 2. One pound of vegetables a day such as are procurable at this station during and after the monsoon is not sufficient for the men. The men here have three meals daily, viz., breakfast at 8 a.m., dinner at 1 p.m., and the evening meal at 5 p.m.; the first and last consisting of bread and tea. 3. As an improvement in this ration, I would suggest that potatoes invariably form part of it, with other vegetables in as great a variety as possible. The rations of each company are cooked together by native cooks. 4. The cooking apparatus admits of the ration being boiled only; but kitchens are being built. The cooking is not sufficiently varied. Good tea is properly prepared for the men, and when on the march some of them get coffee. 5. Gardens for the cultivation of vegetables by the soldiers could be advantageously established near the station.
VII. Dress, Accoutrements, and Duties.	1. In the hot weather khakee clothing and wicker helmets are worn by the troops at this station, and in the winter the usual regimental clothing. The ordinary accoutrements are worn. I consider the present dress as suitable to the climate, and for the soldier's duties by day and by night and at different seasons. I would recommend the use of flannel underclothing in all seasons here. The guard-dress at this station consists of khakee clothing in summer, and warm regimental clothing with great coat in the cold season.
Duties.	1. Troops should be thoroughly drilled at home, or at some intermediate station, before being sent to India. 2. There are parades in the morning and evening here, and the men do not appear to suffer in health from the drill. The best time for drills, parades, or marches is the early morning. The men have, on an average, about 8 nights in bed. 3. There are regimental guards only at this station, so that they are quite close to the barracks. There are roll-calls day and night at uncertain hours. The men do not appear to suffer from the usual night guards.
VIII. Instruction and Recreation.	1. The following are the only means of recreation and instruction provided at this station:—School with good schoolmaster, library, reading and day room, one garden for the soldiers, but there are no funds for its proper maintenance, and workshops. There are no ball courts, theatres, gymnasia, or skittle grounds, but these last have been sanctioned, and will be provided as soon as the barracks are completed. These means are not sufficient to keep the men occupied during the heat of the day and in the wet season. During the hot season the men are not allowed to leave their barracks during the heat of the day from 8 a.m. to 5 p.m.,—a measure attended with marked benefit. 2. To increase the efficiency of the present means of recreation and employment, ball courts, roofed skittle grounds, gardens, swimming baths, &c., are strongly recommended. 3. Soldiers' savings banks exist here, and are found advantageous. 4. Verandahs only, for shade.
XI. Military Prisons.	1. There are no military prisons at Jhansi.
X. Field Service.	1, 2. No replies to these queries. 3. The principal medical officer and engineer are on the sanitary committee, and their suggestions would be followed with respect to general sanitary regulations. 4. No reply to this query.
XI. Statistics of Sickness and Mortality.	No information under this head is transmitted.
XII. Hospitals.	1 to 15. The hospitals are not yet built, but barrack No. 2 is used as a temporary hospital. 16. For copies of diet tables, diet rolls, &c., *vide* the New Hospital Regulations. 17. There are a hospital serjeant and native orderlies for attendance on the sick, but neither matrons nor European orderlies are allowed in the Bengal Presidency. European female nurses would be of the greatest advantage to the sick women and children. 18. No epidemic disease has as yet appeared here. 19. No reply to this question. 20. There are no shady walks or seats for convalescents. 21. There is no female hospital as yet erected. 22. No answer to this query. 23. All suggestions of the medical officer as regards the sanitary state of his hospital, repairs to buildings, change of diet, &c. would be attended to. 24. There is no hospital or ward for convalescents at this station, but such accommodation would be an advantage.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is about 1,800 yards from the European lines directly to leeward, and is about 350 yards square. Its soil is alluvial, about 10 feet deep, with a subsoil of rock, and it is drained into a nullah, forming one side of the ground. The ground has only recently been laid out. 3. The graves are about 7 feet 4 inches by 7 feet deep, with intervals of 5 or 6 feet between each. The graves are never re-opened, and as soon as the burial ground is full it is enlarged. Interment always takes place within 24 hours, but this is not compulsory.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead. —*cont.*	4. The graveyard is never offensive. The men are buried either morning or evening. 5. The dead of camp followers and bazaar people are disposed of in like manner as with the native troops. 6. Injury must in many cases accrue to the public through the present practices, but the cause is not always traced home. 7. The burial ground should be enclosed and interments prohibited elsewhere. Some system of registration of deaths should be enforced, as the death and interment constantly take place before the bazaar authorities are aware of the former.

(Signed) *Henry H. Maxwell, Lieut.-Col., Commanding at Jhansi.
R. Gilborne, Surgeon, 89th Regiment
John Baillie Captain, Ex. Engineer

24th April 1860.

* I have signed my name above as being at present in command ; but as I have only been in that command for two days, I have had nothing to say to answering the questions. I coincide, however, in the remarks herein entered.
Henry H. Maxwell, Lieut.-Col., Commanding at Jhansi.

MORAR GWALIOR.

Accommodation
- Queen's Troops
  - Artillery - - Two Batteries.
  - Infantry - - Twelve Companies.
- Native Troops
  - Cavalry - - One Regiment.
  - Infantry - - Two Regiments.

References to Subjects and Queries.	Replies.
I. Topography.	1. The cantonment of Morar is situated in a species of basin surrounded by stony, barren hills of small elevation, at distances of from 3 to 6 miles. These hills are covered with a coarse grass and thorny jungle, and there appears to be a good deal of iron in the soil of which they are composed. The vicinity of the station is an open undulating country, intersected by small ravines running into the Morar Nuddee, on the east bank of which the station is built. There is a good deal of cultivation to the west of the station, but none on the other side, except at a considerable distance off. There is no wood or jungle in the immediate neighbourhood. There is a jheel out on the north-east flank, but some miles away from the cantonment. The bed of the Morar river is gravelly, and contains pure running water the whole year round. 2. The elevation of the station above the sea is about 800 feet, but it is on a level with the adjacent country generally. It is about 35 feet above the bed of the river Morar, on the bank of which the station is built. There is a higher table land to the east—probably 30 or 40 feet more elevated—but, on military grounds, it could not be made use of without virtually abandoning the present cantonment, on which a large outlay has been incurred. 3. The only extensive table land in the vicinity is the Kolait plateau, about 10 or 12 miles to the westward of the present station, with an increased elevation of from 300 to 400 feet. 4. The nearest water is the Morar Nuddee, on the bank of which the station is built. The vicinity is never liable to overflow from this river. During the rains, however, one of its small feeders which runs along the east of the station overflows its banks, but this only lasts for a few hours. There are several ravines near the station which have been a good deal used by the natives for the calls of nature, and consequently emit a bad effluvia, especially after rains ; otherwise I do not think the ravines would be the cause of sickness. 5. There is great room for improvement, such as clearing away trees, otherwise the station is open and fairly exposed to the prevailing winds. The temperature is generally cooler a short distance from the station than within the station itself. The station is freely exposed to all winds, which are very variable and at certain seasons cold. The prevailing and most healthy breeze is from the west, and comes straight from the sea, which is distant, however, about 800 miles. Easterly and variable winds increase the admissions into hospital from bowel complaints, rheumatisms, and fevers. 6. The surrounding country is but sparingly cultivated, and there are no works of irrigation near the station, nor is there any artificial irrigation affecting the health of the troops. The cultivation of rice is prohibited within the bounds of the cantonment, and no cultivation of indigo or preparation of hemp or flax is carried on in the vicinity. 7. The old town of Gwalior is about 2½ miles from the station, and the Lushcar is about the same distance. They both lie to the westward. 8. The surface of the district is argillaceous, resting generally on strata of kunkur, varying in thickness and density. The station occupies ground on which were originally two or three villages and some cultivation. 9. Water is found during the dry season about 35 feet below the surface, and during the rains at a depth of about 30 feet. 10. The surface drainage flows readily away, and there is very little percolation into the subsoil of the station from the adjacent higher ground. 11. The water for drinking is obtained from wells, the natives using the water from the Morar Nuddee for cooking purposes. No tanks of any kind exist for the storage of water. 12. There is an ample supply of well water for the station, which appears generally very pure, colourless, and sweet. It is soft, abundant, and excellent, but has not been examined chemically or microscopically. It is drawn, for the troops, in the usual way by bheesties with leathern buckets, carried away in leathern mussucks, and stored in baked earthen vessels. No better water supply could be obtained. 13. No reply to this query. 14. Sites of new stations are always selected by committees, generally composed of the chief civil, military, and medical authorities, and the executive engineer. The amount of inquiry as to the points referred to is generally very limited, more heed being paid to appearances than anything else. Stations are generally selected on account of the extent of ground required ; and the necessity for their speedy selection is generally so emergent, that no time is ever allowed for proper inquiry into the nature of the surface-soil and substrata, or for a determination of cross levels, both with a view to proper drainage or relative altitude. These points should be more strictly attended to than they hitherto have been.

MORAR GWALIOR. BENGAL.

REPLIES.

II. CLIMATE.

1. There has never been a barometer at the station, but a common and wet bulb thermometer and a pluviometer were available.
2. The following meteorological table is for less than two years, comprising the time since Gwalior was re-occupied, in June 1858.

ONE YEAR OF OBSERVATION.—From January 1859 to December 1859.

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Days of Sunshine.	Remarks as to Clouds, Dew, Wind, Storms, &c.
January	No instrument.	68°·5	8°·0	76°·0	62°·0	27	1 storm.
February		74·0	18·5	87·0	60·5	19	2 storms.
March		77·5	13·4	88·5	68·5	30	None.
April		81·5	14·5	99·0	76·0	24	4 storms.
May		95·5	11·0	105·0	86·0	25	3 storms.
June		96·0	12·3	105·5	85·0	14	8 storms.
July		95·0	11·0	106·0	83·5	16	1 storm.
August		85·0	5·2	89·0	80·5	16	1 storm.
September		89·0	3·3	93·0	83·0	24	None.
October		84·5	7·3	90·5	80·5	31	None.
November		78·0	No register kept.		—	—	
December		61·5	11·5	70·5	56·5	31	None.

3. The climate is dry and hot, but is salubrious. There has been no irrigation nor tree planting since June 1858, but well-grown trees are superabundant, and require thinning. The air is often loaded with dust; no prejudicial effects, however, have been traced from it; every one, very properly, avoiding these dust storms. The troops have enjoyed a very fair share of health, considering the disadvantages they have had to contend with as regards barrack and hospital accommodation, &c. The shelter has been, and even yet is, indifferent and limited. The diets are now good as regards animal food and bread, but potatoes have not been furnished so regularly as could be wished. The men have now warm clothing for the cold season, and light loose clothing for the hot weather, and the drills, duties, and exercises are adapted to the different seasons of the year. The most healthy season is the termination of the cold and commencement of the hot weather. The most unhealthy period is the end of the hot and wet seasons. Head affections, bowel complaints, and fever prevail in May and June; fevers and bowel complaints after the rains.
4. There is no district near the station, the climate of which is more conducive to health than that of the station itself, but there is a ridge running north and south about three-quarters of a mile from the present camp, which in regard to elevation, natural drainage, &c. &c., seems a far more eligible site for a station than Morar, and I cannot comprehend why it was not selected in preference.

III. ANITARY CONDITION OF STATION.

1. No plan of the station and adjacent country exists, as no topographical survey has yet been made; but a plan of the station itself, showing the position of the buildings, &c., has been forwarded.

Date of construction of barrack 1859–60.

III. Sanitary Condition of Station—*cont.*	Extract of a Letter No. 2,982, dated 23rd June 1860, addressed by the Quarter-master-General of the Army, Bengal Presidency, to the Officer Commanding Gwalior District, having reference to Questions not properly answered, on the Sanitary State of the Indian Army, for the Station of (Morar) Gwalior. *Question* 2. The position of the native latrines, as shown in the Trace Plan of Cantonments, is objectionable; they are to the west and windward of the proposed hospitals are they permanent? *Question* 3. According to the plan of the half-company barracks, the non-commissioned officers' end rooms are certainly not fit for occupation. The sloping roof should be continued over them, and projecting verandahs, with bath-rooms in the corner, should be provided. This will be brought to the notice of Government, but Brigadier McCausland should report on the subject with reference to all the stations in the district, and offer suggestions.—*Further answer,* vide *Annexure.* *Question* 4.—Health of the Troops.—Some further explanation is required as to the selection of sites for barracks alluded to in the reply to the second clause of Query 4, p. 30.—*Further answer,* vide *Annexure.* A report should be furnished on the proposed improvements to the nullah in front of cantonments, mentioned in p. 58. *Question* 5.—Hospitals.—In the reply to Query 5, p. 59, it is said the hospital will be a one-story building, while the plan sent by Captain Basevi shows it to be of two stories. (True extract.) F. S. Roberts, Major, D.A. Quartermaster-General of the Army.

No. 640 of 1860.

From Brigadier J. K. McCausland, C.B., Commanding Gwalior District, to the Quarter-master-General of the Army, Simla.

Sir, Morar, 10th July 1860.

In reply to your "Memorandum," No. 2,982, of the 23rd June, returning the Committee* replies to the Royal Sanitary Queries, I have the honour to state—

Question 2.—Sanitary Condition of Station.—1st. Regarding the native latrines. They are in the only available spot in the cantonment to which the natives would resort, and their present position in no way interferes with the salubrity of the barracks or hospitals, being to the eastward of the former, and situated at least 20 feet below the level of the latter, and are at a distance of, I should say, 1,000 yards to the westward. They are kept perfectly clean, and can in no way affect any public building, and they may be removed at any time.

Question 3.—2nd. The serjeants' rooms in the new barracks at Morar are under the chopper, and not, as in the fort, in the verandahs. This alteration was made since the Sanitary Report was drawn up. The executive engineer having received instructions to erect choppers over the serjeants' quarters in the fortress, this will correct the evil complained of there. The present site of the barracks in Morar was selected by Lord Clyde; the Committee recommended the high ground, and no doubt it is the best, but, in a military point of view, his Lordship set aside their recommendation, at least so I am informed.

Question 4, *Clause* 2.—Health of the Troops.—3rd. With regard to the nullah, I am of opinion that any attempt at improvement would make matters worse. Almost every drop of water that falls within the boundary of cantonments is carried off by this natural drainage into the Morar river; therefore to fill it up would be impossible; and if the present grassy slopes on both sides are touched, the force of water that now passes down would very soon make a deep ravine. Half an hour after the heaviest rain the nullah is perfectly dry, unless, perhaps, a few inches of water that may be left in one or two spots that are below the level; these are easily filled up, and will be so as discovered. Nothing can be cleaner kept than the bed of this nullah. Medical men are apt to cry out at nullahs passing through cantonments, but this one, in my opinion, is not of the description that causes sickness.

Question 5.—Hospitals.—4th. In reply to concluding paragraph. At the time the sanitary report was submitted, it was intended the hospital should be one story; but since, the Secretary to Government, Public Works Department, having written to the Executive Engineer to suspend the building, as Government contemplated making an upper-storied one, it was thus the apparent discrepancy has taken place. I have not yet heard that the upper-storied hospital is actually sanctioned, but I have little doubt it will be so; I attach a plan of it to the sanitary report.

I have the honour, &c.
F. H. McCausland, Brigadier,
Commanding Gwalior District.

---

5. There are no windows at all in the old barracks. In the new ones the windows are on opposite sides, and also at the ends. They open on the revolving principle, on a pivot at each side. There are verandahs 10 feet wide running round the whole of the old and new barracks. The height on the outside, in the old barracks, is 10 feet; those in the new ones are flat-roofed, and 14 feet interval height. These verandahs are not intended to be occupied as sleeping quarters. There are doors in the main walls, but no jalousies or jhilmils.
6. The bedstead used in the barracks is a frame of wood, laced over with twine, and the bedding consists of 1 cotton settringee, 1 cotton quilt, 1 blanket, and 2 cotton sheets.
7. The tents used in camp are made of four or five thicknesses of cotton, with two upper flies and wall 6 feet high; they are 24 feet by 14 feet, giving a cubic space of 3,000 feet, and have 16 men in each, at 21 feet superficial area per man.
8. The old barracks have small ventilations, pierced in a projecting plank of wood. These planks are about 4 long and 1 high, at intervals of 12 feet, running along near the ridge of the roof on both sides. In the new barracks there will be ample window ventilation, and, in addition, ventilating tubes can be inserted in the thatch near the ridge of the roof

* Returned by Dak Bunghey.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	on both sides. The ventilation of the old barracks is imperfect, but that of the new ones will be quite sufficient to ensure pure air by night as well as by day. There is no mechanical means employed of cooling the air in the barrack rooms other than by the use of kus-kus grass tatties or frames, which are placed in the doorways on the side of the prevailing winds, and then kept well watered. 9. The temporary barracks are constructed of stone or kutcha or burnt bricks and mud mortar, according to the resources of the locality. The roofs are generally tiled over grass fascines, or entirely thatched; the walls generally plastered and whitewashed, and the floors mud plastered. The permanent barracks are constructed of stone or burnt bricks and lime mortar, the roofs being tiled over grass fascines, or else entirely thatched. The floors are either beton plastered, burnt bricks on edge, or stone slabs, according to the resources of the locality. 10. The floors of the new barracks will be 4 feet above the level of the ground, and well rammed earth is to be filled in previous to laying the flooring. There is no free passage of air underneath. 11. The materials used in the construction of barracks, huts, and tents are quite suitable to the climate. Thatched barracks are generally cooler than others, whether tiled or flat-roofed. Where sufficiently raised, there does not appear to be much room for improvement in construction, though it might be considered that they would be drier and healthier if the floors, instead of being solid, were to rest on arches, by which means a free current of air could pass underneath; but, unless these arcades were sufficiently lofty to be easily visited and cleaned, they might serve as receptacles for refuse matter, vermin, &c. The barracks and cantonments are kept in repair by the executive engineer, but petty or urgent repairs are always executed at once on requisitions from the barrack-master. The barracks are whitewashed once a year. 12. Each company is supplied with a wash-house and privy under one roof. A certain number of tubs or large earthen vessels are allowed for holding the water for lavatory purposes, which is supplied by bheesties or water-carriers from the nearest well, as required; a certain number of earthen or metal washhand basins are also allowed. The drainage is received into a cesspool four or five feet in depth, at the bottom of which is laid about a foot of gravel or sand, any filth or refuse matter being carried away from the cesspool every morning in filth tubs. 13. Cooking recesses or chulas are provided of burnt bricks or stone, on which the native cooks are enabled to perform all the cooking required for the troops; there is a well close to every cook-room, from which the cooks either draw their own water, or have it supplied to them by each company's water-carriers. The filth and refuse from washing dishes, &c., is received into cesspools, and daily cleared away as noticed for wash-houses. The washing of linen is done entirely by native washermen; there is no arrangement for the purpose on the part of Government. 14. Every company is provided with a privy and urinal, the drainage from which is received into a cesspool, and carried off daily in filth tubs or carts. 15. These buildings are ventilated through the roofs. The new barrack will be lighted by oil lamps suspended from the roof. 16. The ground around all barracks is sloped off, so that no water shall lodge in the neighbourhood; open drains intersect the blocks of barracks, so as to lead off all surface drainage to the main channels, which convey the same to the nearest nullah or river. There is no drainage at Morar, except surface drainage from rain. The surface water and the drainage from washhouses, privies, urinals, and cookhouses is conveyed into cesspools, and from thence removed in carts. There is no proper sewerage, as the term is applied in England; but the drainage in Morar is ample, owing to the great cross-slope in the site. The cesspools which receive the drainage from out-offices attached to barracks are, on the average, three feet each way in breadth, and about five feet in depth; they are never less than 50 yards from the nearest well, and are quite sufficient for all purposes, being about 100 feet from the nearest quarters, and cleaned out daily. There are no foul ditches, properly so called; and the ravines, which might get foul, unless properly watched and attended to, are about 300 or 400 yards from the soldiers' barracks. 17. The surface cleansing within the cantonment and its vicinity is performed by means of a conservancy establishment of carts and sweepers, which is maintained under the orders of the barrack-master, whose duty it is to remove all refuse, filth, manure, &c., from the surface of the cantonment, cesspool, &c., and to carry it out to some distance, where it is either used as manure by the villagers, or else burnt. This duty has been efficiently done hitherto. 18. No rank or objectionable vegetation is allowed in the cantonment, and all hedges and trees are trimmed down so as to allow of a free circulation of air. There is a little room for improvement in the ventilation of the station by the removal of trees and old walls; but this will be effected as the new barracks approach completion. 19. The bazaar is well drained and ventilated; the water is supplied from wells. Latrines are constructed well out to the front, and not at all crowded. Five sweepers are kept for the purpose of general cleanliness; and the inhabitants are required to sweep their premises clean, and to place the sweepings in a bucket in front of their houses every evening, to be emptied in the rubbish-carts (of which there are three) as they pass. The bazaar serjeant reports on the state of the bazaar daily, and any one infringing these regulations, which answer very well, is punished by fine. No native buildings are allowed within the boundaries of the cantonment, thus avoiding any nuisance in barracks from wind blowing over the native dwellings. 20. The slaughter-house is to the east of the cantonments, about 1,000 yards from the barracks, and as it is not situated on the windward side no nuisance is experienced. All refuse is carted away to a distance. 21, 22. No horses are allowed in the lines. The station being at present in a transitory state, and numerous alterations in progress, the horses are picketed wherever room can be found, but always to the east of the barracks, and some distance to the front. 23. There are only temporary quarters for married soldiers, but they are entirely separated from the barracks occupied by the single men.
Officers' Quarters.	1. The officers' quarters are what were formerly private houses. No improvement can be suggested with regard to them, as the sanitary condition is satisfactory, and the drainage, ventilation, &c., appears to be ample.

References to Subjects and Queries.	Replies.
IV. Health of the Troops.	1, 2, 3. The station and district and native population are very healthy; there has been no epidemic disease since 1858. Spleen disease exists, but to no great extent, which is attributable to a dry climate and soil, and abundant and cheap food. 4. Previous to arriving at this station, the troops were mostly engaged in the field; some were recently from Europe, where they were healthy. In the hot season of 1858, when under canvass, they suffered much from sun-stroke and exhaustion, consequent on the fatigues of the campaign; they have since suffered from ordinary complaints, but in no extraordinary degree. The barrack accommodation is not yet good, but large barracks are in course of erection, when, no doubt, the men will be healthier; but the sites of these barracks have been all selected towards the bottom of the nullah, instead of towards its origin, more to the south, and where they could have been placed on higher ground, and at twice the distance from its dirty bed. 5. The 17th lancers were sent out of camp for change last cold season, but seemed to derive little improvement from it. 6, 7, 8. I have never been in charge of troops at a hill station, nor has my experience given me great confidence in hill climates for many of the diseases for which men require a change from Central India. This season I proposed to send several men to the sea-side, instead of to the hills, but it was not considered convenient; but in future years I am sure it will be found necessary to do so. For healthy regiments no doubt stations on the hills are desirable, as far as practicable. 9, 10, 11, 12. I have no experience with regard to any diseases peculiar to hill stations with which troops are liable to be attacked on going to them; but no doubt every precaution must be taken to provide proper shelter, clothing, &c. &c., to enable them to obtain greater benefit from residence at those stations. 13. Great precautions are required for protecting the health of the troops on leaving hill stations for the plains. 14. As a general rule, regiments should be located as much as practicable at hill stations, where certainly health can be preserved, though not always restored. Frequent changes of station in the plains are beneficial to the health and spirits of the men. 15, 16. As regards barrack and hospital accommodation at hill stations, and the ranges of elevation above the level of the sea which form the most suitable sites for such stations, I have no experience. 17. There is no higher ground in the district which could be advantageously occupied as a hill station. 18. With regard to the class of surface and subsoil for stations, I prefer a loose, sandy, absorbent soil. 19. Soldiers proceeding to India should be of mature age, and should arrive at the commencement of the cold season. Recruits, on landing, are furnished with cap covers and a suit of khakee, and sent to join their regiments without delay; they undergo much drill on joining, but perform no regimental duties until dismissed drill. With regard to length of marches, they are placed on a footing with long resident soldiers. They should land in India in November, be equipped with helmets at the place of debarkation, and should reach the head-quarters of their regiment in March, but no later. 20. A short residence (one or two years) at an intermediate temperate station would be beneficial to troops proceeding to India, and on landing they should be sent to the most healthy stations, and gradually acclimatized. 21. The modes of transporting troops from the port to the interior are,—by railroad, where available; by bullock train, resting at bungalow stations during the heat of the day; or by steamers on the Ganges, as far as Allahabad. These modes of transport are generally good. 22. The number of years a British soldier should serve in India is from seven to ten. Men landing in India with good constitutions, and from 18 to 22 years of age, may retain good health much longer, but those of more mature age, and naturally delicate, or with damaged constitutions, will succumb to a long residence in so debilitating a climate. 23. I have never known any conflict of opinion in medical boards as regards invaliding. 24. It is desirable that invalids should leave India in the spring, in order that they may reach home in the summer.
Diseases.	1. Inspection parades, for the discovery of incipient diseases, are held once a week. 2. Scorbutic disease does not prevail to any great extent at Gwalior; but in my late tour of inspection I found it at Jhansi and Lullutpore, and recommended potatoes and improved diet, it being chiefly attributable to the want of proper vegetable food. 3. The proportion of cases of hepatitis varies, but is not unusually prevalent here; the causes are a hot dry climate, a heating diet, with too great a proportion of animal food and ardent spirits, and the small proportion of vegetables. The prophylactic measures are malt liquor and potatoes, for the native vegetables are never relished by soldiers for a continuance; potatoes they never tire of. 4. Dracunculus is seldom seen at Gwalior. 5. The proportion of constantly sick from venereal disease to the total sick in hospital has been as high as 80 per cent., and is seldom under 12 or 20. Lock hospitals and a good conservative police should be established wherever there are European soldiers. 6. The troops at the station suffer from diseases of the endemic class, such as fevers, chiefly of the intermittent type, which are common at certain seasons, but the mortality is inconsiderable. Dysentery is always prevalent, though most frequent before and after the rains. Cholera and small-pox has never appeared. Rheumatic affections are met with in variable weather, with east winds. The proportion of fever admissions to total admissions is 38·64 per cent., and the proportion of dysentery admissions to total admissions 5·39 per cent. 7. The more frequent zymotic diseases are fevers of the intermittent class, and occasionally continued or remittent, and bowel complaints, which are most prevalent at the end of the hot season and beginning of cold weather. The atmospheric conditions which precede or accompany these diseases are variable, being hot and dry, or cold and damp. The station and bazaar are well drained, and the supply of clean water is abundant, but native houses are very apt to be crowded and ill-ventilated; however, disease has never prevailed to any extent. As regards any personal habits or conditions among the troops or native population predisposing to these diseases, I have nothing worth recording. 8, 9. Epidemic disease has never prevailed to any extent, nor has quinine been tried at this station as a prophylactic against malarial disease. 10. I have no recommendations to make as to the prevention or mitigation of epidemic diseases at the station.

References to Subjects and Queries.	Replies.
V. INTEMPERANCE.	1. The greater number of soldiers at this station are temperate, but there are several intemperate men; the difficulty in obtaining liquor, however, prevents any intemperance at the present time. 2. The proportions of admissions into hospital from diseases caused by intemperance are,—directly, ·932 per cent., indirectly, 2·588 per cent. I have no data to guide me in making out a statistical table showing the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station; but though drunkenness has not been by any means excessive, yet the use of ardent spirits has been the cause of a good deal of sickness, and the fatal cases have occurred mostly in those men who are of intemperate habits, and drunkenness is by much the prevailing crime at this station. Drunkenness *per se* is punished as an offence. 3. Distilled spirits are sold at the canteens only, and the probable amount consumed by each man per diem is one dram of arrack, but, if there is no beer, then two drams. Spirit does not form any part of the soldiers' ration, but is purchased at option from the regimental canteen, and is never given as a ration to convalescents, nor are any injurious drinks other than intoxicating liquors sold at the canteen or bazaar. 4, 5. The consumption of spirits by troops and convalescents is very seldom conducive to health, even in moderate quantities, and soldiers are seldom moderate, except when they cannot procure it, and that is very seldom. The sale of spirits in the canteen is doubtless conducive to discipline, as liquor is not issued as a part of the rations, and soldiers not being allowed to purchase spirits elsewhere than in the regimental canteen, would, if it were not allowed to be sold there, endeavour to obtain it elsewhere, and would succeed in obtaining an inferior article of a very deleterious description. 6. Ardent spirits, except as a medicine, (which is seldom requisite,) are always injurious, but more particularly in a warm climate; malt liquor is much less so, but should never exceed a quart per man per diem. Good wine is not within the reach of the soldier at this station, but if it could be procured, and taken in moderation, it would not act injuriously. Men with naturally weak constitutions require a certain amount of stimulants in India, and they should consist of beer or porter, to be used at the dinner hour, but never arrack, rum, or brandy. Men naturally robust never require any stimulating drinks. 7. Coffee and tea are used by many of the men, and can be procured early in the mornings at the canteens. Ginger beer is a common beverage, and lemonade is also used, but soda water is too expensive a drink for the private soldier. The influence of these drinks on health, efficiency, and discipline is decidedly good, when intoxicating liquors are abandoned. 8, 9. It would be most beneficial to suppress the spirit ration for every one, and substitute beer, tea, or coffee, provided steps could be taken to prevent the men procuring the deleterious native liquor; but I fear that if the spirit ration was suppressed, many of the men would make increased efforts to procure it. It would also, under the same circumstances, be most beneficial to prohibit the sale of spirituous liquors in the canteens. 10. I would recommend in the strongest possible manner the prohibition of spirits being distilled, except for medicinal and chemical purposes. 11. The canteen rules concerning liquor are agreeable to the Bengal Military Regulations on the subject, and no deviation therefrom is allowed. By the bazaar rules, liquor is not to be sold to European soldiers on any pretence whatever. All liquor shops must be closed at nine o'clock p.m., and not opened before gun-fire in the morning, and no liquor may be brought into the cantonment except by authorized persons.
VI. DIET.	1. The ration for Queen's British troops and European troops in the Indian army is as follows:—1 lb. bread, 1 lb. meat, 4 oz. rice, 2½ oz. sugar, $\frac{5}{7}$ oz. tea, ($\frac{1}{3}$ green, $\frac{2}{3}$ black), 1 oz. salt, 1 lb. vegetables, (8 oz. potatoes, and 8 oz. onions or carrots, at present,) 3 lbs. firewood. Six days beef and one day mutton in the week; the meat is the best description of grass fed, and the bread made of Soojee. There are no periodical changes, except in vegetables, which necessarily vary according to the season; potatoes are issued when procurable at a reasonable cost, viz., from October to May; the other vegetables consist of onions, yams, egg plant fruit (Baign), carrots, and turnips. The commissariat officer inspects the rations twice a week as to their quality; the regimental authorities arrange for receiving the correct quantity, the quartermaster or other officer making the inspection. 2. A complete ration is supplied to the troops at this station, but no fruit is allowed, except in hospitals on indent countersigned by the superintending surgeon; the stoppage is 3 annas and 4 pice; there are three meals per day, breakfast, dinner and supper, the hour is a regimental arrangement. The proportion of vegetables in a ration is nearly two-sevenths of the whole. 3, 4. There is no possibility of the men making away with any of the rations, which are cooked by means of copper boilers, tinned once or twice a month, and by saucepans and gridirons. The men are allowed to have their rations cooked in any way most agreeable to their tastes, but the members of each mess must be unanimous in their choice, in order that the native cooks may be enabled to prepare the different dishes; this system has acted beneficially, and has given much satisfaction. The men are not provided by the Government with any refreshment before a march. 5. Soldiers' gardens could not be established advantageously near the station, as vegetables are cheap and abundant during the cold season, and during the hot weather the men would be too much exposed to the climate while cultivating them.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldiers' dress and accoutrements at this station consist of a helmet, cap, shirt, jacket, trousers, stockings, boots, belts, and a pouch; and these are quite suitable to the climate and for the soldiers' duties by day and night, and I can suggest no alteration. In the hot weather the guard dress is khakee clothing both by day and night; in the rains the great coat is worn loose at night, or when raining and during the cold weather the clothing is worn as usual in England. There are no sentry boxes, but the sentries are all posted so that they can take refuge in the verandahs both from the sun and rain. It is advisable, as far as regards the health of the men, that they should be drilled at home, as the wear and tear of their constitutions on first landing is very great. 2. The men rise at daylight during the hot weather, and parade half an hour afterwards, in the cold weather one hour; they have very little drill during the hot weather, occasionally half an hour in the morning. During the cold weather they are drilled four times a week,

References to Subjects and Queries.	Replies.

VII. Dress, Accoutrements, and Duties—*cont.*

generally for one hour, and once or twice a week for an hour and a half or two hours. The men do not appear to suffer in health from drill.

Breakfast in hot weather at	8	o'clock,	in cold at	8½
Roll call in barracks	„ 10	„	„	10
Dinner - -	„ 1	„	„	1
Roll call or parade	„ 5½	„	„	5
Evening meal -	„ 5	„	„	4
Tattoo roll call -	„ 9	„	„	8

Early hours are the best for drills, parades, and marches, but in the cold weather they can be done after four p.m. During the week the men have five nights in bed for one on guard.

3. There are no guards at any great distance from the barracks; the bazaar guard is a short quarter of a mile from the parade ground. Guards generally last 24 hours, and when night sentries are required, the men mount at sunset. There are no roll calls at night, the evening roll call falls in on parade, but without arms. There is evening parade with arms during the hot weather.

VIII. Instruction and Recreation.

1. The means of recreation and instruction at the station are, a skittle ground for each company, a school with a good schoolmaster for each regiment or battery, and a library and reading room, fairly lighted for a temporary building. These are sufficient, as far as they go, to keep the men occupied during the heat of the day, and during rain, when the men are all confined to barracks; but this being a new station, there are no ball courts, soldiers' clubs and gardens, workshops, a theatre, and gymnasia, which doubtless will be introduced in due course.
2. Very little means of recreation exist at present, only skittle alleys, but more are promised. A fives court ought to be built, as this game can be played during six months of the year at all times of the day, and even in the hot weather early in the morning.
3. The Government savings' banks seem to answer every purpose.
4. At present there is not sufficient shade from trees, sheds, verandahs, or other means, to enable the men to take exercise without injury to health during the day.

IX. Military Prisons.

1. The building used at present for a military prison is but a temporary one, but orders have been received for permanent buildings, which will be built in due course.

X. Field Service.

1. There are no local regulations for field medical service.
2. As regards the conduct of the line of march of troops, bivouacking, camping, billeting, &c., my experience compels me to say that the medical officers are rarely consulted on these subjects.
3. Camping grounds are laid down by the Quartermaster-General of the Army. If it happens that a camp is a standing camp, the same regulations are observed as if it were a cantonment.
4. There has been no proper field hospital in existence in this district; the sick are conveyed in doolies, which is a very excellent mode. The medicine chest is carried by bamboo coolies, and camels or carts convey the hospital stores. The regulations bearing on these matters are given in the Bengal Military Code, but I am unable to comply with the request of transmitting copies of them.

XI. Statistics of Sickness and Mortality.

No information given under this head.

XII. Hospitals.

1, 2. The present hospital is in one of the old barracks, but the proposed hospital will be on the east of the present cantonment, about 800 yards from the barracks, 400 yards from the nearest horse pickets, and about a mile from the bazaar. The site is airy, open, and freely ventilated. The buildings hitherto used as hospitals are objectionable in every respect; those about to be erected ought to be healthy, as the site is good, and the elevation, drainage, &c. unobjectionable, but the nullah in front must be improved, as it is sluggish and foul, and malaria may be expected to rise from it in its present state.

3, 4. Any supply of water is available by digging wells, and the drainage will be all carried into cesspools as described for the barracks, and from thence removed by the conservancy establishment.

5. With regard to the general structure and arrangement of the hospital, it will be of one story only, the floors of the wards being raised from 5 to 6 feet above the ground; it is not yet settled whether the floors are to be on open arches or on solid blocks as described for the barracks.

The roof water is carried off by flights of steps to a distance of 9 or 10 feet from the main buildings, and is then by means of a kunkur platform removed some 15 or 20 feet further, and the cross slope of the site from thence admits of easy drainage into the nearest open drainage channel. The plan of the hospital sufficiently shows its construction, the walls are of stone, and the main roof is thatched, the double verandah roofs being flat pucka. The roof and walls are sufficiently thick to keep the hospital cool, and there are two verandahs on each side, the use of which for the accommodation of the sick, convalescents, and others has hitherto been unavoidable, but in the new buildings there will be better accommodation.

Date of construction of temporary hospital, July 1859.

MORAR GWALIOR. BENGAL.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	In the artillery hospitals there is about as much cubic and superficial space per cot as in the infantry hospital, and the new hospital will correspond proportionately with the new hospitals for the infantry. The present hospital is properly placed to receive the full benefit of the prevailing winds, and so will the new ones be. In the present building there are no windows, but in the new ones there will be the revolving windows or fanlights, near the top of the side walls, by which, ventilation and coolness ought to be secured. 6. The ventilation of the wards is only secured by means of open doorways below, and open windows above, in addition to ventilating openings in the edge of the roof. I think that the hospital will be thoroughly ventilated and free from odour or closeness. There are no jalousies or jhilmils, but grass chicks or screens are allowed to all hospitals. 7. Tatties are always used when required for cooling the air admitted into the wards as described for barracks. 8. Fire-places will be made for the hospitals, and, if necessary, stoves will be supplied in addition. The walls and ceilings of hospital wards are cleansed and whitewashed, whenever considered necessary as a sanitary measure by the medical officer in charge. 9. The structure of the privies is similar to those attached to barracks, and they will be properly drained, and kept clean by sweepers. This is a matter of internal economy which is dependent on the care or otherwise of the medical officer in charge. 10. The lavatory arrangements in the present hospitals are all of a temporary nature, and though they have been found sufficient, they are neither so complete nor so comfortable as they will be in the new hospital. 11. The only means of bathing for the sick are bathing tubs, which are neither sufficient nor convenient. 12. The hospital linen is washed and dressed by dhobies or washermen; there are no conveniences attached to the hospital establishment for washing or drying clothes. 13. The storage has been indifferent and insufficient, no proper store having been in existence. Tents have been frequently used, but when accommodation could be afforded, the stores were placed at one end of the buildings occupied by the sick, and partitioned off. 14. The bedsteads used in the hospitals are wooden frames laced over with Newar tape, and the bedding consists of one mattrass, one quilt, two sheets, and two pillows. 15. The hospital kitchens are on one flank, and are not commodious; the cooking apparatus is abundant, and diets can be sufficiently varied. In the new hospital the kitchens will be very superior. 16. The diet rolls and tables and all other returns that have been in use for working the internal economy of the hospital are the same as those in existence throughout the Bengal Presidency. 17. Every European hospital has European serjeants; the nurses or ward boys are a most useful and efficient set of men, for whom it would be difficult to find substitutes, whether men or women (if Europeans). Every female hospital ought to have an European matron and assistant, who do many of the duties of nurses, but they are not allowed in Bengal, though found in every European regiment in Bombay. 18, 19. No epidemic disease has appeared in the hospitals; but, as already stated, they are in every respect objectionable, and the new ones are much required, and it is to be hoped that they will obviate all defects. 20. No provision has been made for convalescents for taking exercise; the buildings are not fenced in; nor is there any suitable ground. Shaded walks and seats are equally unprovided, but it is hoped the new buildings will be better provided in every way. 21. With regard to arrangements for the treatment of soldiers' sick wives and children, a building was set apart as a hospital for the women of the 3rd Bengal European regiment when stationed here; but now there are no women and no hospital. The present arrangements are very unsatisfactory, for some soldiers' wives and families may soon be expected from England. 22. There are no particular local hospital regulations enforced at this station. 23. With regard to the powers of the medical officer in matters appertaining to the sanitary state of his hospital, repairs to buildings, change of diet, &c., in repairing and altering buildings, he can only recommend; but in every other respect he has full powers, and no man can interfere with him. Changes of diet, medical comforts, and all internal arrangements are made by him, and for these he is solely responsible to his professional superior. 24. There are no convenient wards at the station, nor any conveniences for convalescents.
XIII. BURIAL OF THE DEAD.	1, 2. The burial ground at present used by British troops is on the left flank of the station. The westerly winds passing over it do not affect any of the barracks, unless the direction is almost northerly, which is very seldom the case. A new burial ground, 200 yards long by 100 yards wide, is about to be made on the right front of the European lines, which being to the east will not affect the barracks in any way. The soil is argillaceous, the subsoil on the spot unknown, and the drainage will be easily effected. 3. I have allowed 17 feet by 10 feet for each grave, which will allow at least 4 feet between two graves; they are 6 feet deep, and never reopened. Interment is compulsory, at ordinary times and during epidemics, about 12 hours after death. 4. I have never noticed anything offensive in the graveyard. Soldiers are generally buried in proper coffins, at a depth of 5 or 6 feet below the ground, and I have never known an instance of a grave used for the purpose of a second burial on the same spot. 5. The bazaar people, if Mahommedans, bury their own dead most scrupulously in the nearest Mussulman burying-ground. Hindoos generally burn their dead. 6, 7. No injury to public health arises from native interments, and I can suggest no improvements in the way of regulation, or otherwise, in the burial or disposal of the dead.

(Signed) J. K. McCAUSLAND, Brigadier,
Commanding Gwalior District.
F. S. ARNOTT, M.D., Superintendent-Surgeon,
Gwalior District.
W. S. OLIPHANT, Captain,
Executive Engineer, Gwalior Division.

30th March 1860.

SEETABULDEE.

Accommodation.—Native Troops { Artillery - 8 Havildars, 8 Naicks, and 122 Privates. Cavalry - 6 Kote Duffadars, 48 Duffadars, 480 Sowars. Infantry - 48 Havildars, 48 Naicks, 800 Privates.

References to Subjects and Queries.	Replies.
I. Topography.	1. The country surrounding the station is hilly, basaltic, and dry. There are three large tanks and two small rivers in the vicinity, but not much wood or jungle. 2. The elevation of the station above the sea is 939 feet, but it is on the same level as the adjacent country. There is no higher or healthier ground adjoining the station. 3. The nearest high land is Ramakonah, 52 miles distant. 4. The Taklee river, distant one mile from the cantonment, is the nearest water. The vicinity of the station is not liable to overflow, and there is no broken ground ravines or water pits near. 5. The station is open and freely exposed to the prevailing winds. The buildings within it are not exposed to reflected sun heat, nor to cold or variable winds. 6. The surrounding country is under dry cultivation, but there are no works of irrigation. 7. The city of Nagpore is distant two miles from the station. 8. The station occupies both new ground and ground which had been previously occupied. 9. Water is found during the dry season from 20 to 30 feet below the surface, and from 10 to 15 feet during the rainy season. 10. The rain-fall sinks into a pervious subsoil. The drainage of a few small hills passes into the subsoil of the station. 11. The water supply is derived from wells; water is not stored in open tanks. 12. The amount of water supply is moderate, but the water is of good quality. It is raised by a rope and native bucket. A better supply could be procured by sinking more wells. 13. There are no other topographical points bearing on the health of the station. 14. A portion of this station was chosen by a committee composed of two military and one medical officer in 1854. No improvement is suggested as to the manner of selecting new stations.
II. Climate.	1. There are no means or instruments at the station for conducting and registering meteorological observations. 2. The following Table is the result of 2½ years of observation at the artillery and irregular cavalry hospitals from June 1858 to December 1860:—

Months.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Rain Inches.
January - -	71	12	80	61	—
February - -	79	19	84	75	·88
March - -	83	10	88	78	·2
April - -	91	9	97	87	2·2
May - -	95	9	99	92	·8
June - -	88	6	90	86	3·82
July - -	83	2	84	81	13·07
August - -	81	2	83	80	12·42
September -	82	4	84	80	11·1
October - -	81	7	85	77	·9
November -	74	10	79	69	—
December -	69	9	74	65	1·06

3. The climate is good. It is hot from the 15th March to the 15th June; wet till the 30th September, and during the remainder of the year cool. The troops are healthy. They are all natives, and clothe and diet themselves. Immediately after the rains until the end of November, fevers are prevalent; the hot season is the most healthy one.
4. There is no district near the station which would prove more conducive to health for natives.
5. The following are the stations at which Captain Shakespeare has served, with the observations on their comparative salubrity:—Dinapore, in the Bengal presidency, moderately healthy; Berhampore, unhealthy; Mizapore, moderately healthy; and Chunar, healthy. Bolarum, Hyderabad, Deccan, healthy. In the Deccan, Mominabad, very healthy; Hingoliee, healthy; Ellichpore, unhealthy; Arungabad, moderately healthy; and Seetabuldee, Nagpore, healthy.

Lieutenant Smith has served at (1) Trichinopoly, healthy; (2) Hurryhur, healthy; (3) Secunderabad, unhealthy; and (4) Bellary, healthy.

From July to September 1854 Dr. Wyndame served with the 50th Madras Native Infantry at Madras, cholera prevailing the whole time. He accompanied the regiment on the march to Secunderabad during September, October, and November; cholera still continuing until they crossed the Kistnah river, when it suddenly and entirely ceased. During November and December 1854 did duty with the 2nd Madras Europeans at Secunderabad, when dysentery was the most prevailing disease. From thence marched to Seetabuldee, and assumed medical charge of the 23rd Madras Native Infantry, remaining with that regiment till March 1855; intermittent fever was the chief disease from which the sepoys suffered. During March 1855 he did duty with the artillery at Kamptee, and in April proceeded to Chandah, and was placed in medical charge of the 2nd infantry, Native Infantry force, and also of the civil duties. The sepoys suffered chiefly from intermittent fever; the civil population from biliary intermittent fever and dysentery. Neither cholera nor small-pox had been known in the city or district for many years previously, but since then both diseases have made their re-appearance. In December 1855 he was appointed to the Nagpore Irregular Cavalry, which appointment he has held since, having accompanied the regiment on service at Raipore Sumbulpore, Chandah, Chindwana, Bintool, and Ellichpore districts, from 1857 until March 1859. In the absence of any means of information to be derived from hospital records, &c., it is impossible to give more than an opinion founded on personal recollections as to the comparative salubrity of the above-named stations. Madras enjoys a high and pretty uniform animal temperature, cooled by the sea breeze which sets in in the afternoon. Cholera and liver diseases may be said to be endemic there. The climate of Secunderabad is hot from March to June; rainy (monsoon) from June to September; cooler from October

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	to March. Dysentery is the most prevalent and fatal of all disorders amongst European troops. Both intermittent and remittent fevers occur. Chandah, whose climate is much the same, has the same prevailing diseases, but is more healthy than Nagpore.
III. Sanitary Condition of Station.	1, 2. A map of the country and skeleton plan of the cantonment are transmitted. 3 to 16. No reply to these querries. 17. The surface cleansing of the cantonment is performed generally by sweepers daily; the refuse, &c. being removed to a distance. 18. The surface of the cantonment is kept free of vegetation. 19. Sweepers keep the bazaars clean. The bazaars are healthy, and are supplied with water from wells. A sanitary police to prevent nuisance would be of great use. The native houses near the station are tiled. No dung heaps or cesspits are allowed. 20. No reply to this query. 21. There are but few camp followers' horses, and they are picketted by their owner's houses. The dung is conveyed away by sweepers. 22. The irregular cavalry stables are long open-tiled buildings, between two rows of the men's houses, and about 30 yards from each row. The dung is daily cleared away. The horse battery horses are in the open, and are not stabled. The hospital is about 150 paces from the horse lines in both. 23. The European serjeants of the infantry and horse battery have sufficient accommodation. They are married men.
Officers' Quarters.	1. The officers' houses are chiefly thatched bungalows, there being no quarters found by Government. The drainage and ventilation of these buildings are good.
IV. Health of the Troops.	1. The station itself and the district in which it is situated are healthy, and the country people free from severe endemic disease. The population, however, of Nagpore is unhealthy, and severe epidemics of cholera, biliary remittent fever, and small-pox, often occur, and prove fatal to large numbers of the inhabitants. 2. Intermittent and remittent fevers, dysentery, epidemics of cholera, biliary remittent fever, and small-pox, are most prevalent among the natives. Spleen disorder is a comparatively rare complication of the prevalent fever. 3. The healthiness of the station and district is mainly attributable to the absence of jungle, of low vegetation and swampy ground, and to the cultivation in the neighbourhood being dry. Both the cavalry and artillery lines are on open ground, with a good slope, allowing of perfect drainage. Defective ventilation, insufficient drainage, and overcrowding, fully account for the unhealthiness of the city of Nagpore. 4. The native cavalry and artillery are stationary here. The infantry regiment has recently arrived from Chandah in the province, where it has been stationed since 1855; and whilst there it enjoyed good health, suffering chiefly from intermittent fever. The right wing arrived here on January 28, 1860, in good health. The left wing arrived on March 28, 1860, and when within a day's march of Nagpore cholera broke out and prevailed for about a week after arrival; since then the regiment has suffered chiefly from intermittent fever. The infantry lines are perhaps more unhealthy than either the artillery or cavalry lines, which is attributable to the situation not being so open, nor the ground so well drained. The lines also occupy old ground, are in the proximity of a large bazaar, and the ground in the immediate neighbourhood is used by natives for the purposes of nature. The more frequent night duty may also, in some measure, account for it. 5. The troops are not camped out. 6 to 24. No replies to these queries.
Diseases.	1. There are no inspection parades for the discovery of incipient diseases among the troops. 2. There has been no scorbutus among the troops at the station. 3. Amongst the total number of sick (640) treated in the Artillery Hospital during the years 1856, 7, 8, 9, and 60, not a single case of hepatic disease has occurred. From a total of 1,341 patients treated in the Cavalry Hospital during the same period, 8 cases have occurred out of a total of 3,054. Amongst the infantry, 7 men have been admitted suffering from this disorder. Thus hepatic disease bears the small proportion of ·25 per cent. to other ailments, and being so rare, no special prophylactic measures need be referred to. It is usually the consequence of fever or dysentery. 4. Dracunculus does not prevail in the province. Out of a total of 5,035 sick, 2 cases only have occurred. In one the history is not given, and the other, which was in the Artillery Hospital, the patient had recently arrived from Bombay, where the disease is very prevalent. 5. In the Artillery Hospital venereal diseases occur in the proportion of 8·28 per cent. to other diseases; in the cavalry the proportion is nearly 3 per cent.; and in the infantry 1·47 per cent. Native soldiers, being for the most part married, are not very liable to syphilitic diseases, the artillerymen, being younger and mostly unmarried, having suffered most. Syphilis prevails to a great extent, and in a virulent form, in the city of Nagpore; and as European troops, both artillery and infantry, are to be permanently located in barracks at this station, the establishment of a lock hospital, and a system of regular supervision, &c., would be highly advantageous. 6. Remittent and intermittent fevers occur among the troops as endemics; biliary remittent as an epidemic. Dysentery (colitis) is endemic, and Asiatic cholera and small-pox as epidemics. Rheumatism also occurs chiefly among the aged. The proportion of admissions from intermittent fever to total admissions from all diseases is 31·11 per cent., and of deaths to total deaths 13.04 per cent. Remittent fevers: admissions, 1·02 per cent.; deaths, 6·52 per cent. Dysentery: admissions, 2·33 per cent.; deaths, 4·34 per cent. Cholera: admissions, ·45 per cent.; deaths, 21·73 per cent. Small-pox: admissions, ·06 per cent.; deaths, none. 7. Bilious remittent fever, cholera, and small-pox are the most frequent zymotic diseases. The former most frequently occurs during the months of September, October, and November, the drying-up season after the monsoons, the latter two being most prevalent during March, April, and May, the hot months. These diseases attack for the most part the dwellers in the crowded bazaars, and occur to a very large extent among the population of the neighbouring city, where overcrowding, defective ventilation, and want of cleaniness prevail. Drunkenness and the use of bhang and opium, which is rife among the native population, predispose them to these diseases, and greatly increase the mortality from them. Among the troops, night duty, when severe, quickly increases the number of sick in hospital.

IV. Health of the Troops —*Diseases—cont.*	8. No reply to this query. 9. Small doses of quinine have been tried successfully as a prophylactic against malarial disease. 10. In order to prevent or mitigate malarial disease at the station the infantry parade ground should be drained, and the natives compelled to proceed to a greater distance for the purposes of nature. The use of bhang and opium should also be prohibited. The latter is not sold in the military bazaar, but is procured from the city and civil bazaars.
XII. Hospitals.	1. A plan of the Artillery Hospital is transmitted. The Cavalry Hospital is precisely similar, but double the size. 2. The Cavalry Hospital is situated about 120 yards in rear of the men's huts and stables, the bazaar being in front. No houses are near. The site is healthy, well drained, and free from all sources of malaria. The Artillery Hospital is to the east side, about 100 yards from the horse lines, and on an open, well drained site. The Infantry Hospital forms a part of the other barrack buildings, which interfere to a certain extent with its ventilation. The parade ground, which is in its rear, is during the rainy season almost a swamp. 3. The water supply is abundant and wholesome from wells. 4. There are no means of drainage; the refuse water and other impurities are carried away by the sweepers to some distance in the rear of hospitals. 5. The floors of the wards are not raised, and are not ventilated beneath. The roof water sinks into the subsoil. There is no surface drainage, a sufficient slope facilitating the speedy drainage away of all water. The hospitals are built of brick and mortar, covered with chunam, the roof and walls being single. They are sufficiently cool for natives. The buildings are supplied on either side with a verandah 10 feet wide, which are used occasionally for the accommodation of the sick when the wards are full. The hospitals consist of single flats.

Table of Hospital Accommodation.

Date of Construction - - { Artillery Hospital - 1855. / Cavalry Hospital - 1856.

Total Number of Wards - - - 4.

Total Regulation Number of Beds - 102.

Wards. No.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.
		Length.	Breadth.	Height.	Cubic Contents.			
		Ft.	Ft.	Ft.	Ft.	Ft.	Ft.	Ins.
Native Artillery Hospital, Ward No. 1	24	72	20	18	25,920	1,080	60	16
Do. Cavalry do. do. No. 1	24	72	20	18	25,920	1,080	60	16
Do. do do. do. No. 2	24	72	20	18	25,920	1,080	60	16
Do. Infantry do. do. No. 1	30	107	18	11	21,186	706	64	16

	The hospital is so placed as to receive the full benefit of the prevailing winds. There are no windows. 6. Ventilation is effected by means of roof ventilators and by gratings in the lower panel of each door, which admit of being closed at pleasure. There are no jalousies or jhilmils. 7, 8. There are no artificial means for cooling or warming the wards. The walls and ceilings of the wards are whitewashed annually. 9. The privies, which are situated in the rear of the hospitals, are washed out daily, the filth, &c., being removed by sweepers. They are not offensive. 10 to 24. There are no lavatory arrangements. The sanitary condition of the hospitals is good.
XIII. Burial of the Dead.	The dead of camp followers and bazaar people are buried or burnt, according to their creed, on ground chosen for that purpose at a distance from the cantonment. No injury accrues to the public health from the present practice.

(Signed) Henry Shakespeare, Captain Commanding Nagpore Irregular Force.
H. D. B. Smith, Lieutenant, Executive Engineer.
S. Jardine Wyndame, M.D., Assistant Surgeon in Medical Charge Cavalry, Artillery, Staff, and Details, Nagpore Irregular Force.

KHERWARRAH.

Accommodation.—Native Troops - - { Cavalry, 1 Troop of Regular Cavalry. / Infantry, 7 Companies of the Mewar Bheel Corps.

I. Topography.	1. The surrounding country is irregular, hilly, and mountainous, and in most of the ravines and plateaus remarkably swampy. The country is wild, and there is an abundance of wood, jungle, and water in the vicinity of the station. 2. The elevation of the station above the sea is about 1,200 feet, but no exact data exist to show the elevation with regard to the adjacent country. It is, however, commanded on all sides by small isolated hillocks, which are higher than the general elevation of the station proper. There is no lake or canal in the immediate vicinity, but the station is intersected by a nudder

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	or river having much malaria generating ground in its track; and close alongside its leeward and highest bank are situated the bazaar, fort lines, hospital, and village of Kherwarrah. There is also much swampy ground behind or to the leeward aspect of the bazaar, part of which is now much aggravated in insalubrity by having been used as a brick field. A large drain courses through this situation, on both sides of which the ground is oozy, spongy, and swampy during the malarious season. There is no higher or healthier ground immediately adjoining the station. 3. The highest hill in the Arabulli, according to Major Brooke and Dr. Bowhill, is Kŭmmŭl-nath, about 16 miles N.E. from Soame, or about 30 or 35 miles from Kherwarrah. Those gentlemen who spent May and June 1845 upon its summit, consider that it is 4,400 feet above the level of the sea, or 3,200 feet higher than this station. Water was found during that time 15 feet from the surface. 4. The nearest water flows through the nullah or river before mentioned, which courses through and intersects the cantonment lands. During heavy falls of rain, portions of ground in and around the station are subject to overflow, but the fall being good the water rapidly disappears, except in numerous holes and hollows where it stagnates, till dried up by the slow process of absorption and evaporation. The overflow is liable to occur in and below the brickfields. The ravines near are doubtless very prejudicial to the health of those passing through them or in their immediate vicinity during the rainy and drying up months, as much malaria is produced therein. 5. The station is open, freely exposed to the prevailing winds, and not so encumbered with trees, hedges, higher ground, &c., as to interfere with the freest external and internal ventilation The temperature of the bazaar, fort lines, and village is higher than that of the less densely populated parts of the station, owing to the reflection of sun heat from tile roofs and pucka walls. The station is much exposed to land winds but not immediately to the sea breeze. When the land wind blows from the east, intermittent fever, influenza, and chest complaints increase in frequency. 6. Not more than one-sixth of the surrounding country is under cultivation. All the cold weather crops are irrigated from wells, or where conveniently placed from rivers both in and out of the station, but there are no works of irrigation near. Artificial irrigation affects the health of the station injuriously, but it appears to me that it is the abuse and not the use of irrigation, under proper conditions, that proves so deleterious. Rice cultivation within the cantonment limits is prohibited. In one or two situations to the S.W. it is cultivated up to within a quarter of a mile of the boundary. No indigo is cultivated, or hemp or flax prepared near the station. 7. There is no large city or town near, but the village of Kherwarrah adjoins the lines of the Bheel corps on the one side, and the bazaar almost adjoins them on the other. 8. The geological structure of the district belongs to the primary formation. The bazaar, fort, hospital, lines, and village, as also the quarters of the commissioned and non-commissioned officers stand on solid trap. The soil is ferruginous, and stony, or dark, and rich in organic matter. Gneiss, greenstone, trap-rock, hornblende, quartz, amygdaloid, decomposing trap-argillaceous and mica schists, granular limestone, conglomerate, have been identified. Hematite and galena exist at Jowrah on the highway to Odegpore. The ground on which the station stands was never occupied by a population prior to the raising of the corps in 1840–1. 9. The average depth below the surface in 14 wells at which water is found during the dry season is 27 feet 6 inches, and 9 feet during the rainy season. 10. The rain fall, generally speaking, flows readily away; what is not carried off directly by the nudders, &c., sinks into the soil, and near the edges of rivers it oozes out as springs. It only lies on the surface till evaporation takes place in puddle holes and similar places which abound within and without the station. The drainage from the adjacent higher ground also passes into the subsoil of the station. 11. The water supply of the station is derived from wells during the cold and hot months, and from the nullah or river during the monsoon months. There are no tanks for storing the water. Some of the wells are contaminated from leaves and other matters falling into them; as also from the percolation of foul drainage through the subsoil and their walls. 12. The supply of water is abundant at all times. That from the wells, used by the natives, is semi-transparent, moderately hard, and not unfrequently has a fishy taste and disagreeable organic smell. In our garden wells, which are worked for irrigation purposes, it is much more wholesome, transparent, tasteless, and odourless, but even here it is much the safest plan never to use any water that has not been either boiled or filtered, as guinea worm is very prevalent here. Its chemical composition cannot be given, but it contains an abundance of carbonate of lime. It is usually considered good. It is raised by hand in leathern vessels from wells or by metal vessels or lotahs, and is distributed by bheesties. I think the well in the lines is contaminated by percolation into it of the foul subsoil drainage from the village and bazaar. 13. No reply to this query. 14. New stations have been chosen lately by a mixed committee of engineer, military, and medical officers, but the majority of our stations have been selected, not from sanitary as well as military considerations, but from the latter only. No new station, whether on the hills or plains, should ever be fixed upon until the opinion of a medical committee has been obtained regarding its eligibility in a sanitary point of view. If possible, and it ought generally to be so, the committee should sit during some period of the monsoon season, where sanitary excellences and imperfections may be detected with the greatest facility. The decision of this committee should not be overruled except from military and political considerations of the highest importance. It should always be borne in mind that the best sanitary site is generally the best military situation also; there are exceptions, but these are few, and do not interfere with the validity of the rule enunciated.
II. CLIMATE.	1. The instruments available at the station for meteorological observations are one wet bulb and one dry bulb thermometer.

2. Table of meteorological observations for five years, from 1st January 1854 to 31st December 1858 :—

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain, Inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks as to Clouds, Winds, Dews, Storms, &c.
January -	—	64·37	21·09	74·03	52·94	64·37	57·73	88·06	—	S., W., E., and N.	Calm and moderate.	28·4*	Clouds, night fogs, & dews.
February -	—	70·74	24·52	82·19	57·67	70·74	62·14	93·80	—	S.E., W., E. and N.	Do.	27·0*	Occasionally cloudy.
March -	—	78·71	23·98	90·96	66·98	78·71	67·38	100·60	—	S.E., E., N.W., & W.	Moderate	29·0*	Ditto.

May - -	—	93·82	18·13	102·57	84·44	93·82	73·82	110·70	—	W. & N.W.	Do. high & stormy	30·2*	Ditto, with hot winds and thunder storms.
June - -	—	87·46	11·83	93·02	81·19	87·46	75·44	109·60	4·027	S.W., W., and S.	Do. monsoon.	27 8*	Cloudy, thunder storms.
July - -	—	82·11	8·98	86·86	77·88	82·11	74·09	97·08	12·333	S.W. & W.	Monsoon	17·2*	Ditto.
August -	—	80·17	8·90	85·10	76·20	80·17	77·64	94·30	3·862	W.	Do.	16·2*	Cloudy without storms.
September -	—	81·07	11·62	87·65	76·03	81·07	75·16	98·70	6·459	W., N., and N.E.	Do.	17·4*	Ditto, with thunder storms.
October -	—	77·10	19·33	86·98	67·65	77·10	70·26	98·80	0·835	W., E., and N.W.	Calm.	29·2*	Bright sunshine.
November -	—	68·01	25·90	80·80	54·90	68·01	61·47	92·70	—	E., N., E., and W.	Do. and moderate	29·4*	Sunshine, and occasional fogs.
December -	—	63·74	21·92	74·38	52·36	63·74	57·35	90·16	—	N.E., N.,E., & N.W.	Do.	30·2*	Ditto, fogs, and dews.

* If at 4 p.m. the sun shines, then each day in the meteorological register is counted a day of sunshine. It is at this period (4 p.m.), that the temperature in the sun's rays is directed to be taken and registered.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	3. During March, April, May, till 20th June, the climate is very hot, dry, and comparatively non-malarious; from 20th June till the 20th September, the temperature is lower, more equable, and the air loaded with malarious exhaltations; from the 20th September to 20th November the vicissitudes are marked and of daily occurrence, and intermittent fever, splenic enlargement, &c., abound; from 20th November till 1st of March the air is cold, but very variable, and fogs prevail. The trees around in March, April, May, and June, exercise a cooling effect; the air, however, is filled with dust, and July, August, and September the atmosphere is impregnated with noxious organic matter. The drill season commences here on or about the 15th October, and there can be no doubt that when the men are kept long out in the mornings or evenings, returning as they do to their lines heated and fatigued, to substitute the merest apology for efficient clothing for their uniform and accoutrements, and then go to rest, their health suffers in October and November. The drill with night and day guards, large amount of escort duties, and the habit the men have unavoidably been allowed to indulge in of going to their homes at distances varying from half a mile to six miles or more from the station, when not immediately required for duty, is, in my opinion, too severe in October and November. The exercising season should not commence here till the 20th of November.

The healthy and unhealthy months are shown in the subjoined table, for 17 years, from September 1841 to August 1858.

Months and Quarters.	Monthly Per-centage of Admissions to Strength.	Monthly Per-centage of Deaths to Strength.	Monthly Per-centage of Admissions to Strength exclusive of Dracunculus.

Malarious fevers, spleen disease, &c. prevail most during the unhealthy months.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	4. No reply to this query. 5. I have served at Dum Dum, Barrackpore, Dinapore, Ajmere, and Kherwarrah. Dum Dum appears to be more salubrious than Barrackpore, and Dinapore, more so than either. The civil station of Ajmere is located on the leeward side of a removeable swamp of a most pestilential character. Kherwarrah, the station of the Mewar Bheel corps, is the healthiest station I have seen, but none of these stations has had fair play. Nothing has struck me so much as the utter disregard which prevails regarding the commonest sanitary precautions. A large proportion of the sickness at Dum Dum, Barrackpore, Dinapore, Ajmere, and Kherwarrah, is owing to the absence of a properly organized and efficient executive sanitary department to take the charge and management of the conservancy duties, and to attend to all other sanitary matters requiring effective, prompt, and unremitting executive action.
III. SANITARY CONDITION OF STATION.	1, 2. No plans of the station, &c. have been transmitted, as there is no engineer officer present. 3 to 8. There are no barracks at Kherwarrah. 9. The serjeants' and sepoys' tents here are constructed of two layers of thick cotton cloth, with a thinner layer of blue colour inside. The cavalry lines (now unoccupied) are built of bricks and mortar, with tiled roof, and the sepoy's huts of compressed mud and tiled roofs. 10. The floors both of the Government huts for cavalry, and in the Bheel corps' lines are raised a foot above the ground, but there is no ventilation beneath them. 11. If the cavalry huts were properly ventilated, they would be great improvements upon the rude and unsubstantial mud hut or wattle and daub. Ventilation can only be effected by a single door; and upwards, during the cold season, by interspaces at the joinings of the tiles and at the joists. As, however, during the hot seasons and rains, the temperature of the air is, especially in the day time, higher outside than within these huts, instead of the foul air passing out in an upward direction it can only escape by the single door. In fact, instead of the openings in the roof, &c. giving exit to foul air at the season mentioned, they more commonly admit hot air ranging from 100° to 130°. The consequences that would result from such a state of things are much obviated by the men sleeping outside during the hot weather and the fair nights of the monsoon. There ought to be at least two opposite doors, facing towards the prevailing winds in every native hut, extending from the floor level to the joists, in order to insure free perflation and the renewal of fresh air. Somewhat similar rules may be applied to European barracks and tents. All barracks for European troops should, in plain stations all over India, be raised on arches, six or eight feet high, and double storied. The rooms should be capacious, lofty, well ventilated by doors, and swing windows at least 9 or 10 feet high, facing the prevailing winds, and extending from the flooring upwards. The cantonments are kept in repair by the engineers. The officer commanding is responsible for the general sanitary state of the station. Repairs, especially small ones of much immediate importance, are not always so quickly executed as is desirable. 12, 13. There are no lavatories or cookhouses for native corps. Natives cook their own food and wash their own clothes. 14, 15. These queries do not apply to native troops. 16. My hospital is particularly dry and free from damp. All refuse from it is collected in earthenware vessels, and either buried at a distance or burnt on the spot. There are no cesspits. The nudder is sometimes very foul, as also is the drain passing in the front of the dhurmsala from serious inequalities in its levels. A large portion of this drain has been cleaned and adjusted as regards its levels and inclines, at my recommendation, during this season, and the commanding officer has promised to continue the cleaning out and levelling right through the brickfield near the dhurmsala. Both the nudder and drain are close to the station, and rather within it, as before pointed out. 17. There is no conservancy establishment especially appropriated to preserve cleanliness in the station. The cleansing beyond the lines is left very much to the jackal, vulture, and carrion crow; patrols are, however, posted at several points of the station to prevent the inhabitants from committing nuisances, except in specified localities. This is only partially successful. The lines are kept clean, but the sweepings are deposited 30 yards to the windward side of them. 18. The surface of the cantonment is far from being kept free from vegetation; every morsel of land that can be cultivated being made use of by the villagers. This is bad in a sanitary point of view, especially with ignorant natives for the cultivators. All land in stations should be converted into grass-growing grounds, planted with fine growing trees well removed from each other, and kept well fed down during the rainy season, like an English park or pasture. There are no old walls, thick hedges, &c. to interfere with the ventilation of the station. 19. The bazaar is situated on an elevated ridge of trap-rock on a high bank of the river, having a capital descent on three sides for the escape of the monsoon water and drainage, and it is freely perflated by the prevailing winds. The water supply is not so abundant as in other parts of the station, except during the rains. The main street is kept clean, but in all other situations, in the little bye-ways, the most ordinary precautions are lost sight of practically. Every family has its own cesspool. There is overcrowding within family huts. The conservancy establishment of the bazaar consists of a couple of sweepers. The mud and wattle and daub huts around the station denote a poverty-striken and semi-barbarous state; dung-heaps are close to every hut, and also holes for ordure. Nuisance is frequently experienced in large stations from the wind blowing over native dwellings. The cause is the utter neglect by the natives of conservancy arrangements. The nuisances may, to a great extent, be prevented by levelling to the ground every native hut within a circle of 200 or 300 yards of all barracks, by converting the open space that would thus be procured into even and well fed down pasture ground, by enforcing the opening out of capacious principal and secondary streets, and by maintaining an efficient system of "dry conservancy" throughout the whole town, village, or city. 20. Animals are slaughtered here on the windward side, and in a suburb of the bazaar. There are no special rules applicable to these places. The offal is thrown outside the houses of the butchers, and there left to be consumed by the dogs, jackals, and vultures. During the rains more particularly proximity to these places is intolerable both to natives and Europeans, the stench arising from the heaps of offal, the increasing accumulations of years, being sometimes dreadful. The nuisance might be avoided here, where there are only two or three butchers, and where very little slaughtering takes place, by merely enforcing cleanliness in and around them, and the assiduous removal, burial, or destruction of all offal.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	21, 22. There have been no cavalry stationed at this place since June or July 1858. The lines of the cavalry, and of those of the Bheel corps are about 200 yards from the bazaar, and the horses used to be picketed close to the rear of the troopers' huts. No special arrangements were ever made to remove the manure and filth; it was deposited in heaps close to the leeward side of the picketing grounds, and a portion of it was removed to manure our gardens. The picketing ground is of an oblong shape, and the horses used to be arranged in lines or rows, with a passage between each. The distance of the nearest row of horses from the men's accommodation was about 30 yards. 23. The non-commissioned officers attached to this corps are the serjeant-major and quarter-master-serjeant. Their quarters consist of two isolated bungalows, each of which have two rooms, a verandah 10 feet wide on three sides, a good bath-room, and a cook-house, and necessary detached.
Officers' Quarters.	1. There are no Government quarters for officers, each living in his own private bungalow, which are built on elevations of trap-rock. The natural drainage, site, ventilation, and conservancy arrangements are excellent. The houses require no improvement, but I think it injurious to allow the grass to grow up during the monsoon to be converted into hay for horses or cattle; it would be better to keep it well fed down.
IV. Health of the Troops.	1. The station, district, and native population is decidedly unhealthy, but chiefly from causes which can be mitigated or removed. 2. The diseases most prevalent among the natives are malarious fevers, splenic enlargement, with the splenic cachexia of tropical authors, or the leucocythemia splenica of Dr. Wilks; diarrhœa, cholera, small pox, dracunculus, &c. 3. The unhealthiness of the neighbouring population is owing to the luxuriant jungle which encircles on all sides the marshy and swampy localities, in and near which the people dwell all their lives; to small, cramped, damp, and ill-ventilated dwellings; to defective clothing, bad food and water, overcrowding, sheltering cattle, sheep, and goats under the same roofs as are tenanted by the people themselves; to neglected cesspools, middens, and exuviæ of men and animals; to the absence of artificial drainage; to opium eating, tobacco and ganjah smoking, and spirit drinking. 4. The corps at this station is a local one. The village of Kherwarrah is more insalubrious than the lines or bazaar, and the reason is that it lies at a lower level, is comparatively badly ventilated, and worse attended to as regards conservancy. It is surrounded on two sides by jungly vegetation during the monsoon, and also barricaded on two sides by an immense midden, the accumulation of many years. 5. A large number of the men are always out on escort duty. With the exception of September, October, and the beginning of November, travelling about appears to agree uncommonly well with them; but during the period mentioned they suffer most severely from malarious fevers, spleen disease, and splenic cachexia. 6, 7. I have never been in charge of troops at hill stations. 8. I approve of selecting hill stations for European troops. 9. Diarrhœa and chronic dysentery are the diseases peculiar to hill stations, especially in those persons who have been debilitated by the exhausting heats and malarious diseases of the plains. 10. On going to hill stations the men's diet should be substantial, composed of a due admixture of animal and vegetable food of the first quality procurable. The water should be the object of especial attention; an adequate quantity of good beer should always be given, and every man should be supplied with an efficient number of flannel shirts. No man, whether healthy or unhealthy, can be too warmly clothed on the hills after having passed some sickening years on the plains. The barracks or huts should be large, commodious, well ventilated, and have other appurtenances, such as latrines, lavatories, cook-rooms, &c. to match. 11. The best season for residence in hill stations is from March to November, and probably a year is the shortest period of residence to obtain the full benefit of those stations. If the troops have been sickly before they were sent thither a shorter residence than a year would not afford the desired result. 12. With excellent food, water, and beer; good capacious huts or barracks; with constant occupation and amusement, such as drills, exercises, and cricket, rackets, foot-ball, &c., and with an abundant supply of clothing, the longer troops remain in the hills the better qualified ought they be to undergo the hardships inseparable from residence in plain stations. 13. Troops should never be called upon, except from state necessity, to leave the hill stations from April to October inclusive. They should leave at a period which would allow them full time to reach their destination in the plains in February. 14. To locate troops in the hills, with short periods of service on the plains, would in my opinion be most conducive to the preservation of the health and longevity of the British soldier. When the railway system is completed the practicability and advantage of such an arrangement to the soldier and the state does not admit of a doubt. Frequent change of station in the plains would be beneficial if the march can be begun and ended within November, December, January, and February. 15, 16. No experience. 17. Kŭmmŭlnath, about 30 [or 35 miles from Kherwarrah, could be advantageously occupied as a hill station. Major Brooke states, that "there is a good made road the whole way "up to the top of the hill, laid out with great skill and a very able work." Again—"The "top of the hill, about two miles long, is fortified. On the east this fortification is "Titanic, the size of the stones composing it being very great, and the height of the "scarped and built up face very considerable. Within the fortifications are the ruins of a "large town, with numbers of temples, wells, &c. The highest parts of the hill are to the "north, where there is a fine plateau with the remains of a talao." Water is abundant. The elevation of the hill is 4,400 feet above the sea. The climate is good and bracing, two or three degrees lower than that of Mount Aboo. 18. The sandy, gravelly, and porous soils of Nusseerabad and Neemuch are, according to my experience, more healthy than the black organic soils in the valley of the Ganges. Clayey soils are damp and retentive of moisture. 19. Soldiers proceeding to India should be from 20 to 22 years of age, and should land there in November or December. Troops landed at this period could be pushed from the port of

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	disembarkation up country to their destination, during the cold months of January and February, before the heats of the latter part of March, April and May set in. Troops are often on first landing badly accommodated in depôts. Their drills, duties, and marches entail too much exposure, more especially in the hot months. Recruits on arriving in India should be marched or conveyed by land or water carriage, as the case may be, to their respective regiments without delay. If landed in November or December it would always be practicable to do so, so far as climate is concerned. 20. In the absence of accommodation in the healthy hill climate of India it might be advantageous to send troops from intermediate stations, such as the Cape of Good Hope, but I think experience will prove that it will be the best plan to make hill stations take the place of intermediate colonial stations. 21. The mode of transport from the port to the interior is by steamers, with flats attached, and sometimes by boats. By land troops generally march by regular stages, or by bullock trains or railway if available. I believe the mode of transport is of less consequence to health than the season of the year chosen for the removal of troops from one place to another. For example, any of the above modes may be employed with impunity in the cold months, whilst all may be detrimental during the hot and rainy months. 22. It would be difficult to assign the limit of a British soldier's service in India from the present data, if the different regiments could spend long periods on the hills with short periods on the plains. Even with equal periods on the hills and on the plains, the number of years he might serve with comfort to himself and benefit to the State, would not be less than 25 years. Under the present circumstances 10 years is the limit. 23. I have had no experience of the mode of conducting the business of medical boards, but I have however heard of conflicts of opinion in reference to invaliding. 24. Invalids should leave India for home in February, but never after March.
Diseases.	1. There are no inspection parades at the station for the discovery of incipient diseases. 2. There has been no scorbutus or scorbutic disease at the station. 3. Hepatitis is rare among the men of the Mewar Bheel corps. During 17 years, ending September 1858, there have been admitted 35 cases, of which one died. 4. During the period from September 1841 to September 1858 the proportion of cases of dracunculus has been 1 to 6 men in the year. It appears to be caused by drinking impure water in which the germs abound. Drinkers of pure water never get the disease. 5. There are not more than two or three cases of venereal disease during the year. 6. The troops suffer from the following diseases:— *Fevers.*—Quotidian, tertian, and quartan intermittent, remittent and typhoid of Dr. Jenner. *Dysentery.*—Acute and chronic. *Cholera.*—Sporadic and epidemic. *Small-pox.*—Simple and confluent. *Rheumatism.*—Acute and chronic. The following table gives the proportion of admissions and deaths from these diseases to the total admissions and deaths:—

Diseases.	Proportion of Admissions per cent. to total Admissions.	Proportions per cent. of Deaths to total Deaths.
Fevers	39·75	21·05
Dysentery	1·20	5·26
Cholera	0·56	26 31
*Small-pox	—	—
Rheumatism	2·07	0·75

* Cases of small-pox are generally sent out of the station, and consequently out of the hospital, to avoid the spread of the disease. The disease is very common, though it does not appear so from the returns.

7. The most frequent zymotic diseases are quotidian, tertian, and quartan fevers, remittent and occasionally the typhoid fever of Dr. Jenner. The seasons when such diseases are prevalent will be best shown by the subjoined table, showing the prevalence of malarious fevers for 17 years.

Months and Quarters.	Monthly Per-centage of Admissions to Strength.	Months and Quarters.	Monthly Per-centages of Admissions to Strength.	Months and Quarters.	Monthly Per-centages of Admissions to Strength.	Months and Quarters.	Monthly Per-centages of Admissions to Strength.
17 Septembers	6·709	17 Decembers	5·93	15 Marches	2·59	17 Junes	1·62
17 Octobers	12·760	17 Januarys	3·01	17 Aprils	1·84	17 Julys	2·75
17 Novembers	8·740	16 Februarys	2·55	17 Mays	1·12	17 Augusts	4·00
1st Quarter	9·600	2nd Quarter	3·85	3rd Quarter	1·83	4th Quarter	2·79

7. Their appearance is preceded by the luxuriant vegetation and moist climate of June and July; by the same conditions and much vegetable and animal decay in September and October. In October and November there are still days hot and often oppressive, especially during the former month, with great depression of the thermometer during the night; fogs, &c. The cleanliness of the station, bazaar, and village is wretchedly attended to. The natural drainage is good, but artificial drainage should also be adopted. The supply of water is usually good, but the ventilation of the native dwelling-houses is bad, and they are much overcrowded. The predisposing causes of these diseases among the troops and native population is the want of sufficient personal cleanliness and the absence of adequate clothing.
8. The prevalence of epidemic disease has always been augmented when the duties and exposure

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	have been great, in October and the beginning of November. Heavy, prolonged, fatiguing parades, escort duty through unhealthy parts of the country and night guards, are then very prejudicial to the health of the soldier, whether native or European. 9. Small doses of quinine have not been tried systematically as a prophylactic against malarial disease, except in my own family. During the last four years I have used it in diluted sulphuric acid, in August, September, October, and November, with marked success in preventing the occurrence of malarial disease. The dose must be varied according to the locality. 10. My opinion is, that we shall never arrive at the desired sanitary perfection in Indian military stations until sanitary officers are vested with liberal, responsible, and well-defined executive powers.
V. Intemperance.	1. The Hindostanees are remarkably temperate. The Bheels or Mogiah are habitual arrack or dharoo drinkers, and many of them are confirmed drunkards, but as no record is kept the exact proportion cannot be given. 2. Drunkenness, only when it interferes with duty, is punished as an offence. 3. Distilled spirits, opium, tobacco, chuna, &c. are sold at the bazaar. 4. The consumption of spirits is not conducive to the health of troops, but it is frequently to those convalescing from disease. Spirits are by no means conducive to efficiency and discipline. 5. It would be beneficial to abolish the spirit ration altogether and also the canteens. It would also be advantageous to restrict the sale of spirits in the bazaars. 6. Malt liquors and light wines are exceedingly beneficial when, like every other article of diet, they are taken in moderation. Spirituous liquors are always injurious, except when judiciously employed medicinally, and they then prove invaluable. 7. The influence of coffee, tea, lemonade, and soda-water is very beneficial as compared with spirits. 8 It would be highly conducive to the health of soldiers and convalescents to abolish the spirit ration for ever, and to substitute for it beer, tea, coffee, &c. The allowance of a certain quantity of spirituous liquors to particular convalescents should rest with and be regulated by the medical officer. 9. It would be beneficial in shutting up the canteen, which should never again be recognized as a regimental institution, to make an adequate ration allowance of beer, tea, coffee, lemonade, of the first quality. 10, 11. No reply to these queries.
VI. Diet.	Does not apply to native troops.
VII. Dress, Accoutrements and Duties.	1. No reply to this query.
Duties.	1. Soldiers should be thoroughly instructed in drill at home before being sent to India. 2. The best hours for drills, parades, and marches, are from 4 to 8 a.m., and 5 to 6½ p.m., in the cold season. 3. There are roll calls at day break and sunset, and on emergencies as many more as the commanding officer may find requisite. During the malarious season, night guards are very prejudicial in predisposing to fevers, &c. I think men who have been on night guards, should be excused all drill on the following morning during the drill season.
VIII. Instruction and Recreation.	1, 2. Not applicable to a native corps. 3. The institution of soldiers' savings banks would be advantageous. 4. The lines of the Mewar Bheel corps are well shaded by trees, which are sufficiently removed from each other to admit of the freest ventilation.
IX. Military Prisons.	1. There are no military prisons or cells.
X. Field Service.	1. I am not aware of any local regulations for medical field service not included in the general Presidency regulations. 2. The medical officer has no power to do anything on the line of march of troops bivouacking, camping, &c.; he attends on the sick; he cannot even choose the site of his own hospital. 3. The regulations in camp for the preservation of the health of troops, as to the selection of camping grounds, &c., are very defective. The medical officer has no power whatever; he can write, represent, implore, or refer, but he has no power to enforce improvements by others, or to carry them out himself. The general sanitary state of every station and camp in India should be placed under an executive sanitary officer provided with liberal executive powers, and an efficient fixed establishment. He would act under the deputy inspector-general of hospitals and report to him only, who would report to the principal inspector-general. 4. This query will, I fancy, be fully answered by the central medical authority.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1, 2. The Bheel hospital is within 20 yards of the southern end of the line and to the windward. It stands in much the same relation to the bazaar. The site is freely open, and there are no buildings which interfere with ventilation. The elevation and drainage are naturally good, but the nullah or river is about 30 yards to the windward aspect of it, from which much malaria emanates during the rainy and drying up months. 3. The water supply is abundant, but requires to be boiled or filtered, or both, before using it. 4. There is no artificial drainage round the hospital, the slope being sufficient for the escape of the rain water. All hospital impurities are removed as fast as collected by a professional scavenger, and buried at a distance. 5. There is only one ward to the hospital, which is raised about two feet from the ground; but there is no perflation of air underneath the floor. There is no provision made to carry away the roof water. It partly flows off along the sloping ground surrounding the hospital, the remainder sinks into the subsoil. There is no artificial surface drainage or guttering round the hospital. I think if a system of tile drainage were adopted to carry away the water all round the hospital, it would be a great advantage. The walls of the hospital are built of

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	sun-burnt bricks, with mud in place of mortar; they are single, and the roof consists of a single layer of tiles. Hot air rushes through the interspaces, at the joining of the tiles, and the whole roof radiates much heat by night. The walls are 18 inches thick, and are considered cooling. A verandah 10 feet wide surrounds the hospital on all sides, and affords great protection from the sun's rays. I always keep 32 out of 56 beds in the verandahs for the moderately sick and convalescents. The men prefer the verandahs to the hospital wards. The buildings are one flat.

TABLE of hospital accommodation.

Date of construction, 1841–2.

Total number of wards, 1; total regulation number of beds, 56.

Wards.	Regulation Number of Sick in Ward.	Dimensions of Ward.				Cubic Feet per Bed.	Superficial Area in Feet, per Bed.	Height of Patient's Bed above the Floor.
		Length.	Breadth.	Height.	Cubic Contents.			
		Ft. In.	Ft.	Ft.	Ft.			In.
1	56	70 6	20	13	18,330	327·3	25·1	18

My plan is to keep 32 out of the 56 beds in the verandahs, and the remaining 24 within the Hospital Ward. In this way the cubical allowance of air to each of these 24 beds amounts to 766·2 feet., and the superficial area to about 59 feet.

The hospital faces to the north and south, and its ends are to the east and west. To receive the full benefit of the west and east winds,—the prevailing breezes in fact,—its sides should present to the east and west, and the ends to the north and south. There are no windows, but six doors opposite each other in each side wall and one in each gable wall; in all 14. Each doorway is covered by a jhilmil, and is 7 ft. by 4 ft. The ventilation is by no means bad, and the openings in the tiles assist in perfecting it in a certain way; but the tiled roof makes the hospital very hot during summer.

6. The means of ventilation are the doorways and the openings at the joinings of the tiles of the roof, and these are quite sufficient when the number of men in the ward is kept down to 24; but otherwise, or when the sick exceed this number, the ward becomes foul and close. The jhilmils are made of teakwood painted green, and are in excellent working order.

7, 8. There are no arrangements made either for cooling or warming the air admitted into the hospital. The walls and ceiling of the ward are cleansed and limewashed once a year, and at other times as a sanitary measure on the recommendation of the medical officer.

9. The privy of the hospital is made of sunburnt bricks. It is a small place with four latrines in it, and is kept thoroughly clean by repeated scouring out. There are no cesspits, but the ordure and urine are collected in earthenware vessels placed in and fitting into the latrines, and promptly removed by the mhaiter, to be buried at a distance from the hospital. The privy is seldom or never offensive; but charcoal is in constant use in it, and with the best result.

10. Each patient in a native corps makes his own lavatory arrangement, or has them made for him by his friends. It would, I think, be a good plan, if to every native hospital a proper bath-room, &c. were attached.

11. Each patient defers bathing, according to custom, till he is cured, when he retires to the nearest well, draws water, and in the proximity undergoes the bath of cure. It is a bad custom, and perhaps if to each native hospital a good bath-room were attached, bathing might be enforced whenever deemed necessary by the surgeon.

12. The only means of washing and drying the linen in a native regiment are the caste comrades of the patients, or when not very seriously prostrated, by the patients themselves.

13. The storage is sufficient and dry.

14. The bedsteads, charpoys, or cots, are constructed of teakwood. They measure 6 ft. 4 in. in length, 2 ft. 10 in. in breadth, and 14 inches in height, and are bottomed with broad substantial cotton (country made) tape. Each sepoy provides his own bedding, and the plan answers well; the surgeon insists on each man bringing as much as may in his judgment be necessary.

15. The hospital kitchen is a small building about 10 ft. wide, by 20 ft. in length, with a tiled roof; but the men often prefer getting their friends to cook their food outside, under the nearest tree. In fact, the kitchen is chiefly employed for the preparation of hot water (always in readiness), poultices, &c.

16. There are no diet tables or diet rolls in use at this station.

17. Dooley bearers are much employed to wait upon the sick, but this duty cannot be exacted from this class of servants by any regulation. The attendance may or may not therefore be so good as is desirable. Helps are granted in extreme cases on the application of the surgeon in medical charge of the corps, who will be held responsible that the men allowed to administer to the wants of their comrades in hospital, shall not be longer detained from their lines and duties than shall be absolutely necessary. In this way the attendance may always be made sufficient.

18. The sanitary condition of my hospital is good, but it is only rendered so by an unremitting self-sustaining, and permanent system of practical sanitation. The existence of an underground plan of tile, rubble, or stone drainage for some distance round to carry off that portion of the rain fall which sinks into the subsoil would be a manifest improvement. During the past two years, gangrenous and spreading sores have been frequent from the overcrowding of many cases of sores into too confined a space.

19. I think the tiled roofs should be double, with a foot of space intervening between them, or between each layer of tiles.

20. There are no special provisions for the exercise of convalescents, neither are there any seats or shaded walks; but, last rains I, at my own expense, planted trees all round the hospital, well apart from each other. Each tree is being trained with a long shaft or trunk, so that whilst there will be abundance of shade, the perflation of air will be facilitated. The arrangement is very popular with the men.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	21. The sick wives and families attached to this regiment are always treated at their own quarters. The present arrangements of the hospital answer very well upon the whole. 22. I am not aware of any written special hospital regulations, except the following:— The surgeon cannot recommend line leave to convalescents over four days, which may, however, at his recommendation, be extended. He may recommend men discharged from hospital four days light duties, but no more. The consequence is men are often detained in hospital when they might be doing some slight service to the State. 23. Beyond a controlling influence over his own hospital establishment, the medical officer has no powers. Repairs are executed on his recommendation by the engineer authorities. In a native corps in which every man finds his own food, the medical officer can have but little influence over the diet; but he can administer any medical comforts he chooses, and charge for them in quarterly contingent bills. 24. There are no wards or hospital for convalescents at this station, but I think it would be highly advantageous to the British soldier to have that accommodation, with well shaded walks and seats attached.
XIII. Burial of the Dead.	1, 2. There is a small graveyard for Europeans here, situated to the leeward aspect of the camp; but in 19 years there have been only three burials in it. It measures 40 feet × 20 feet, and the subsoil consists of gravel and kunkur. It is not carefully attended to. I fancy that decomposition takes place pretty rapidly. There is no artificial drainage. 3. The three tombs in our graveyard are fully eight feet apart. I do not think there is any forced rule as to the grave space allowed here, although there must be where European troops are quartered. The depth of each grave is seven feet, and they are never re-opened. There is one body to each grave. Interment at ordinary times takes place, if possible, on the day of death, but during epidemics without delay. There is no burial ground for native troops at Kherwarrah. 4. No data. 5. The dead of bazaar people are generally burnt; but if the deceased be a Mussulman, he is buried. 6. I think those natives who bury their dead do so most imperfectly. The graves are too shallow, and often surround wells used by the population. 7. All graveyards should be situated fully three-quarters of a mile to the leeward side of the camp, and be well drained on every side. The men should be buried as soon after decease as possible, and fully eight feet below the surface. More than one body should not be crammed into one grave till it has been made certain that the body previously deposited there has been completely destroyed by decomposition.

June 26th, 1860.

(Signed) Joseph Ewart, M.D.

APPENDIX.

A Suggestion.

The introduction of a permanent and unintermitting system of sanitary reform into our Indian military stations, is an imperative state necessity. To accomplish this great desideratum successfully and economically, sanitary officers should be vested with executive and responsible functions. The officers, who are best qualified by life-long association with disease, to discover instinctively its sources, should be empowered to eradicate or mitigate them, according to the acknowledged principles and common sense dictates of sanitary science. To entrust, as is done at present, the execution of sanitary improvements to untrained and unqualified persons, who, judging from the experience of the past, cannot appreciate or understand their vital importance, is just as unwise and dangerous to all the dearest interests of the soldier and his family, as it would be supremely unphilosophical and unsafe to confide to untaught hands and inexperienced brains the control, management, and cure of the developed diseases from which they suffer. As it has been found absolutely necessary to vest the physician with full powers and responsibility as regards the treatment of disease, so will it, it is earnestly hoped, at no distant date be found essential, both for the welfare of the soldier and for the attainment of the greatest possible physical and military efficiency of the army, to confer plenary powers upon sanitary officers to enable them to wage a successful war against death's latent and rampant legions, and also to fix upon them complete responsibility. I beg, therefore, most respectfully to recommend for favourable consideration—

1. That there be appointed an executive sanitary officer at every station, great and small, of the Indian army.

2. That the executive sanitary officer be appointed by selection, on the recommendation of the deputy inspector general of hospitals.

3. That the executive sanitary officer be directly subordinate to the deputy inspector general of hospitals, to whom he would make periodical reports.

4. That the present scavenging and conservancy establishments of stations and camps be re-organized, according to a minimum scale, to be approved by administrative medical officers, and transferred to executive sanitary officers.

5. That every executive sanitary officer be vested with full directorial powers over his sanitary establishment.

6. That a concise code of rules be drawn up, specifying in definite terms, the duties, position, responsibilities, relations to other departments, and staff allowances of the executive sanitary officer.

7. That these regulations be framed in a liberal spirit, so as to enable the executive sanitary officer to keep up a continuous and progressive system of sanitary improvement throughout his jurisdiction.

8. That the duties of the executive sanitary officer be so clearly expressed and defined as to render collisions with other authorities and departments an impossibility, and to fix on him alone the entire responsibility for the sanitary excellence of his station or camp.

Joseph Ewart, M.D.
In medical charge,
Mewar Bheel corps,
Kherwarrah.

31st May 1860.

DERA GHAZEE KHAN.

Accommodation.—Native Troops - - - { Cavalry, 4th Punjab. / Infantry, 3rd Punjab.

Reference to Subjects and Queries.	Replies.
I. Topography.	1. The country surrounding the station is well cultivated and covered with date palms, but flat and dry, unless where irrigated by canals. The vicinity of the station is thickly covered with date palms and other jungle, and is irrigated in all directions by canals from the river Indus. 2. The station is elevated above 200 feet above the level of the sea; but is on a level with the surrounding country. There is no higher or healthier ground adjoining the station. 3. The nearest mountains are the Sooliman range, at a distance of about 40 miles west. The highest elevation of this range is about 7,000 feet above the sea level. 4. The river Indus is within three miles of the station, and the cantonments are intersected by nullahs from the canals. The vicinity is inundated annually by the Indus, from July to September. There is a little broken ground to the rear of the cantonments where water is apt to accumulate and stagnate, but no known evil effects arise from it. 5. In parts of the station date trees are very thick, but the station generally is well exposed to the winds. The temperature of the station is not raised by the buildings being exposed to reflected sun heat. The station is not exposed to cold or variable winds, or to land or sea breezes. 6. The surrounding country is cultivated, and all around as well as in cantonments is irrigated by canals; but there is no injury to health from this irrigation that I am aware of. There is no cultivation of rice; but indigo is one of the commonest crops of the district, and is grown and prepared all round the station. It has no apparent bad influence on health. 7. The town of Dera Ghazee Khan is within a mile of the station. 8. The surface soil of the station, to the depth of 4 feet, is alluvial, with a subsoil of sand, below which occurs a stratum of yellow clay, about 1½ feet thick, followed again by sand or gravel. The station occupies new ground. 9. Water is usually found at a depth of 8 feet below the surface in the dry, and of 4 feet during the rainy season. 10. The rain fall and surface water sink into the pervious subsoil or remain in hollows till dried up by the sun and wind. There is no drainage from higher ground passing into the subsoil of the station. 11. The water supply of the station is derived from wells and canals. There are no tanks. 12. The water supply is unlimited, and the water clear, colourless, soft, and free of all taste or smell. When filtered it is clear and soft, almost identical with the water of the river Indus, from which in fact it percolates, except in some of the wells, where it is more or less impregnated with salts of potash and soda, which abound in some parts of the soil. The water is raised by means of Persian wheels, and no better supply could be obtained or desired. 13. The inundation of the Indus, which in 1856 rose so high as completely to swamp the whole cantonment, is always a point to be considered in relation to Dera Ghazee Khan as a station for troops. During that year the entire station was prostrated by fevers and their results; but such a rise in the river however is not common. 14. The mode of selecting sites for new stations is as follows. A site having been indicated by the Brigadier-General commanding, it is visited by the officer commanding the station, the executive engineer, and a medical officer, each of whom sends in a separate report as to its fitness or unfitness.
II. Climate.	1. The only meteorological instruments at this station are a common thermometer, and a rain gauge. 2. No trustworthy meteorological records have been kept at this station. 3. As a rule very little rain falls in the district, and the climate may be said to be dry, though the air is always more or less charged with moisture from the proximity of canals, irrigated fields, and the river Indus. For the same reason also the temperature is lower, and the air freer from dust than in other parts of the district beyond the influence of the cultivation. The troops are generally healthy, unless after unusually high inundations, or heavy falls of rain. Warm clothing for native troops is necessary from the end of October to March. The most unhealthy months are those succeeding the inundations, viz., August, September, October, and part of November, and the prevailing diseases during these months are chiefly intermittent fevers and dysentery. 4. Any district beyond the reach of the inundation would in all probability be more healthy than this, but for military reasons the station could not be removed far from the city of Dera Ghazee Khan. 5. I have served at Mean Meer, Bunnoo, Nowshera, Rawul Pindi, Asurr, and Dera Ghazee Khan, besides in many others, but not for a sufficient length of time to enable me to judge as to their effect on the health of troops. Of the above Rawul Pindi was assuredly the most conducive to health; Mean Meer, Bunnoo, and Nowshera by no means unhealthy, but Asurr and Dera Ghazee Khan decidedly prejudicial,—the former from want of vegetables and bad water, and the latter from the inundation. In 1856, when a great inundation occurred at Dera Ghazee Khan, scarcely a man in the station, either European or native, escaped fever and enlarged spleen.
III. Sanitary Condition of Station.	1, 2, 3, 4. There are no barracks, guard-rooms, or military prisons at Dera Ghazee Khan. 5 to 10. No answers to these queries. 11. Any repairs necessary to the cantonments are effected by the executive engineer. The officer commanding the station is responsible for the general sanitary condition of the cantonments, certain funds, raised from lands cultivated within their limits, being appropriated for conservancy purposes by him. 12. No answer to this question. 13. The conveniences for washing and drying the linen of the station are ample. 14, 15. There are no privies or urinals at this station. 16, 17. There are no foul ditches near the station. There appear to be no arrangements whatever for the conservancy of the cantonment and its vicinity.

Reference to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	18. The surface of the cantonment is by no means kept free of vegetation; there is a considerable quantity of uncut jungle which is used as a resort by the Sepoys and bazaar people which might with great advantage be removed, and which, I am glad to see, has recently been begun.
	19. There is no drainage, neither are there any latrines in the bazaar, but sweepers are employed to keep the bazaar clean. There is only a regimental bazaar in cantonments. There are no native houses nearer than those in the city, which is in a very filthy state. The streets are drained and kept clean by a number of sweepers, paid from the municipal funds; but there are no public privies, and all unoccupied pieces of ground and ruined houses are consequently sinks of filth. No nuisance is experienced from wind blowing over the native dwellings.
	20, 21. No replies to these questions.
	22. The irregular cavalry have no stables, the horses of each troop being picketed down the centre of the men's lines. The dung is regularly removed by sweepers and deposited in a heap at a distance from the lines, where it is either burnt, removed by the town's people for burning bricks, or used for littering roads.
	23. No answer to this query.
Officers' Quarters.	1. Officers at this station live in detached bungalows.
IV. Health of the Troops.	1. The troops at the station and the adjoining native population are, on the whole, healthy.
	2. Small-pox is of frequent occurrence, and intermittent fevers, with enlarged spleen, prevail to a large extent after the annual inundation.
	3. The general healthiness of the neighbouring population is owing, in all probability, to the dryness of the country, and freedom from jungle beyond the reach of the inundation, it being only within the influence of the latter that intermittent fevers and spleen are common.
	4. The 3rd Punjab Infantry, which had been stationed at Kohat, on this frontier, for eight years, left it for Dera Ghazee Khan on 17th December 1859. The health of the men was bad till the last year of their stay there, endemic and adynamic fevers, and chest affections being always very prevalent there. They arrived here in January 1860, and their health since leaving Kohat has been good. The 4th Punjab cavalry was stationed at Asurr, on the borders of Sinde, for nearly three years, and left for the station on the 24th March 1860. While at Asurr their health was very indifferent from the prevalence of scorbutic diseases. They arrived here on the 30th March 1860, and since then their health has been excellent. There is no difference as to healthiness in different parts of the present cantonment.
	5. There is no such arrangement as camping out the troops for a certain time every year at this station; but there can be no doubt that, when on the march, the health of both officers and men is much better than when stationary in cantonments.
	6. I have never been in charge of troops at hill stations.
	7 to 16. No experience of hill stations.
	17. There is no higher ground within our own territory which could be advantageously occupied as a hill station.
	18. I cannot say I have remarked that any particular class of surface and subsoil is more healthy than another for stations.
	19 to 24. No experience to enable me to answer these questions.
Diseases.	1. There are no regular inspection parades for the discovery of incipient diseases at this station.
	2. There has been no scorbutus here.
	3. Hepatic disease is of rare occurrence among the native troops at this station.
	4. Cases of dracunculus are rare here.
	5. The admissions for venereal disease do not form more than $2\frac{1}{3}$ per cent. of the total admissions.
	6. Intermittent fevers, dysentery, small-pox and rheumatism are common at this station, but cholera has never been known to prevail here. About one-third of all admissions during the past year has been from the above diseases, and about two-thirds of the deaths.
	7. 8. No reply to these queries.
	9. Small doses of quinine have not been given at this station as a prophylactic against malarial disease.
	10. No reply to this query.
V. Intemperance.	1, 2. The only class who drink spirituous liquors among the native troops here are the Sikhs, and they rarely carry their potations to the extent of drunkenness. There are no confirmed drunkards, nor any admissions into hospital from diseases caused either directly or indirectly from intemperance.
	3 to 11. No replies to these questions.
IX. Military Prisons.	1. There is no military prison at Dera Ghazee Khan.
X. Field Service.	1, 2. No answer to these questions.
	3. Water being frequently scarce and bad on the Trans-Indus frontier, each native infantry soldier is supplied with a tin or copper canteen, which he carries on the march, slung over his shoulder by a strap, and filled with water. Besides this there is a bheestie attached to each company, who is provided with a bullock and "pukaul," or large skin, for the conveyance of water on the march. The irregular cavalry sowars have each a small "mussuck," or skin, which they carry filled with water and tied under the bellies of their horses.
	4. For the transport of sick and wounded in the Punjab irregular force, one dooly and six bearers are allowed for each troop or company, and these are permanently attached to the regiment. One pair of light "kujawas," carried on a camel, is also allowed each troop or company on service; and as expeditions into the hills are frequent on this frontier, where the common dooly is of little use for the transport of sick and wounded, Government has also recently provided each regiment with what is termed a "dandy," to be carried on the top of each "dooly." This consists of a piece of strong "dhurrie" cloth, with a bar or iron stretcher at each end, which can be fastened on the pole of the dooly and used where the dooly itself could not be carried.

I. Topography.	1. Towards the south of the station are extensive sandy plains under cultivation by cereals. Towards the north, the land gradually sloping towards the old bed of the river Sutlej, is better and more richly cultivated. The country is flat, sandy, and dry. There is no jungle, and very little wood or water. 2. The elevation of the station above the sea is about 900 feet, and is on a level with the adjacent country. It is about 19 or 20 feet above the nearest water. There is no perceptible high ground in the neighbourhood, and I am not aware of any objection to the present site of the station on the ground of unhealthiness, as compared with the surrounding country. 3. The nearest mountains are the Himalayan range, which lie about 70 miles north-east of the station. 4. A nullah runs about a quarter of a mile from the station, and flows into the river Sutlej, which is about five miles distant. The nullah becomes extended from the size of a brook to about 300 yards of shallow water, at the same time that the bed of the Sutlej (which at other seasons consists of a great extent of sand intersected by several streams) is filled by the melting of the snow in the hills, and by the floods caused by the heavy rains which fall in July, August, and September. The overflow seldom lasts more than a few days at a time. There are several dry nullahs about the station. They are natural surface drains, and carry off the rain-fall from the surrounding country into the nullah, and thence into the river Sutlej. They are conducive to the health of the station by keeping the land free from the lodgment of water. 5. The station is open, and freely exposed to winds, and there are no obstructions to the free circulation of air. The temperature is not raised by reflected sun heat. The station is exposed sometimes to hot land winds from the west, but most frequently from the east. They are exceedingly enervating, but do not produce generally any other bad effect upon health, except by causing ophthalmia among those exposed to them. 6. The surrounding country is cultivated. There are no works of irrigation near the station. Neither rice nor indigo are cultivated in the neighbourhood, and there is no preparation of hemp or flax carried on near the station. 7. The town of Loodiana, the population of which is about 50,000, adjoins the station. 8. The geological structure of the district is partly sand and partly clay, with a stratum of kunker here and there, on an average three feet below the surface. The ground which the station occupies was not previously occupied by population. 9. Water is usually found about 32 feet below the surface in the dry season, and during the rains about 28 feet. 10. The soil being very light and sandy, water is easily absorbed, and the surplus is readily carried away by nullahs. There are no surface springs. There is no adjacent high ground, the drainage from which passes into the subsoil of the station. 11. The water supply is entirely from wells. There are no tanks in the station or near it, and the wells are kept free from impurities of all kinds. 12. The water supply is plentiful, the water colourless, tasteless, and free from smell. It is hard, the quality is excellent, and the amount sufficient. It is raised from the wells by means of leather bags, and distributed by water carriers. The supply amply meets the wants of the people. 13 and 14. No reply.
II. Climate.	1. The only instrument for conducting meteorological observations is a rain gauge. 3. The climate is very dry, and the heat very great from April to October. The seasons are tolerably regular, but there is not unfrequently a deficiency of rain. In the cold season the nights are cold, and it sometimes freezes to a slight extent. Fogs are rare. The climate is uninfluenced by tree-planting or by well irrigation. During the hot season the air is frequently laden with dust and small sand. The police force, being composed of natives, are unaffected by the climate. The most healthy months for Europeans are from November to April; the most unhealthy are August, September, and October. For natives the most unhealthy are from August to January. The prevailing diseases during the unhealthy months are intermittent and remittent fevers, spleen, dysentery, and diarrhœa. 4. I know of no adjacent district the climate of which is more conducive to health than that of the station. 5. The stations on which I have served are Calcutta, Rangoon, Thyet Myo, Meeaday, and Loodiana. The climate of Calcutta is, I think, the most relaxing of all these. Rangoon, at the time I was stationed there, in 1853, was surrounded by jungle and swamp, so that sickness, particularly dysentery, prevailed there to a much greater extent than I believe it to do now. The same with regard to Thyet Myo and Meeaday, in Burmah, each situated upon the high bank of the river Irrawaddy. They both seemed likely to make good and comparatively healthy stations when cleared of jungle and supplied with good barrack accommodation. Loodiana, in common with most other stations in India, has its healthy and unhealthy seasons and years. Fever, spleen, and dysentery in some years prevail very extensively among the inhabitants both of the station and district, and I believe it was not found to be a healthy station for European troops. The climate, generally speaking, seems to be equal to that of the majority of the stations in the plains of the Punjab.
III. Sanitary Condition of Station.	1, 2, and 3. The executive engineer states that he has no plan which would give the information required, and without the sanction of Government, could not obtain the requisite assistance for enabling him to make one. Loodiana, formerly a large military station, is now only a civil one. The buildings which composed the old station have all been demolished, except the hospital and the houses required by the civil officers

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	now resident in the station. There are no cantonments; the military police are only in force sufficient for the various guards. The hospital is for the reception of the sick amongst the military police, as well as for any sepoys who may fall ill while marching through the station, or for any who may require medical treatment when sick on leave away from their regiments. In addition to this hospital, there is, in the outskirts of the town, a Government dispensary for the treatment of the sick of the district, with accommodation and hospital establishment for in-patients, male and female. The annual attendance of out-patients is about 6,000 or 7,000. In-patients admitted, 250 to 300. There are no barracks, military prisons, or bazaars. The only public buildings besides those above mentioned are the magistrates' offices and the jail; the latter is about a mile from the station. There are no water tanks, jheels, rivers, or canals. The station being nearly 20 feet above the nullah adjoining, the land is drained by means of natural watercourses. There are no cesspits, dunghills, &c., and the station is kept clean by means of scavengers, and all offensive matters buried. The conservancy arrangements are under the supervision of the Deputy Commissioners, the engineer, and medical officers. 4. Table not filled up. 5 to 23. No replies.
Officers' Quarters.	1. No replies.
IV. Health of the Troops.	1. The native population of the station and district are, generally speaking, a healthy race; there is, however, much sickness among them after the rains. 2. The most prevalent diseases are intermittent fever, spleen, dysentery, rheumatism, ophthalmia, and scurvy. 3. Most kinds of food used by natives are cheap in this district, as it is agricultural and not very thickly populated. The inhabitants, chiefly Sikhs and Mussulmans, are without any very strict prejudices with regard to food, and this would account for their being, generally speaking, healthy. Fever is annually epidemic after the rains, owing to malarious exhalations. It is very frequently followed by enlargement and softening of the spleen, and also by dysentery. Dysentery, I have no doubt, is more frequently produced by malaria than from any other cause. Ophthalmia is occasioned by the heat and glare of the sun as well as by the fine sand with which the atmosphere is often laden. Scurvy to a greater or less extent is common among the class of people who live on the same kind of food for years together. Many of the poorer classes subsist entirely upon bread and pulse. 4. The police at this station are relieved every few months from their head quarters at Umballah. They have always been in good health on their arrival, and there has been but little sickness among them here hitherto. Good accommodation is provided for the men at the different guards, and none of the situations have proved unhealthy. 5. No reply. 6. I have never resided in the hills in India. 7 to 16. No replies. 17. There is no higher ground near the station which could be advantageously occupied. 18. No reply. 19. Soldiers should not proceed to India until they have attained their full growth, and the best period for arriving is during the cold season, from October to February. As a precaution for preserving health, on first landing, recruits should not be allowed to expose themselves to the sun more than is absolutely necessary; they should be provided with a good, and at the same time light covering for the head, their clothes should not be tight, and they should be prevented from drinking to excess. 20. As far as I have observed, I think that a European fresh from home arriving in this country in the cool part of the year would bear the climate better than one who had spent some time at an intermediate station. I think it is probable that the lives of many recruits might be saved by their being sent to hill stations, and so becoming gradually acclimated before being stationed in the plains, as it is almost impossible, on their arrival, to make them take proper precautions against exposure to the sun. 21. No reply. 22. Most Europeans require a change of climate for a time after 8, or at most 10 years' service in India. 23. No reply. 24. January, February, and March would be the best months for invalids to leave India, so as to enable them to arrive at home in the spring or summer.
Diseases.	1. There are no inspection parades for the discovery of disease. The men are all on duty, and come to hospital readily when ill. 2. I have met with no scorbutic cases amongst the police. They are common enough in the district. I believe it to be occasioned among the natives by their eating the same kind of food for years. Those who vary their diet are not subject to the disease. 3. There is but little hepatic disease among the natives here, probably owing to the unstimulating nature of their food, it being composed chiefly of vegetables. They also generally wear folds of cloth round their waists to keep off diarrhœa. I think the heat of the climate alone in many European constitutions produces hepatic disease, and that the prophylactic measures should be those ordinarily taken to preserve health, and to avoid undue exposure to the heat of the sun. 4. Dracunculus is rarely met with in this district, and no cases have been treated in the military hospital. 5. The proportion of the sick from venereal diseases to the total number of sick treated last year at the military hospital was 16·2 per cent. The hospital accommodation at this station has been sufficient for the proper treatment of these diseases. 6. The epidemic diseases at the station are as follow:—Intermittent fever, generally quotidian, was treated at the military hospital last year to the extent of 24·8 per cent. on the total number of sick; remittent fever 3·3 per cent.; acute dysentery

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	5·4 per cent. Epidemic cholera has not prevailed here for many years. Cases of sporadic cholera have occurred occasionally in the military hospital, and have generally yielded to treatment. No case of small-pox was treated in the hospital last year. Rheumatic diseases were treated to the extent of 9·2 per cent. on the total number of sick. The only death that occurred from any of these diseases last year was one from remittent fever. 7. The only infectious disease prevalent here is "variola." It appears annually among the native population of the town and district, but very rarely occurs in the station. It prevails at the beginning of the hot season, during the months of April, May, and June, and begins to disappear on the commencement of the rains. Beyond an increase of heat no peculiar climatic or atmospheric conditions have been observed to accompany the appearance of this disease. It is not confined to any particular spot, as cases occur in the towns and villages throughout the district. All classes of the people seem to be equally subject to it. Until the introduction of vaccination scarcely a person escaped the infection. As far as my experience goes most native soldiers have had the small-pox before enlisting, generally during childhood. 8. Exposure to the sun, fatigue, and lying on the, perhaps damp, ground on the march, would render the soldier more liable to the influence of epidemic disease than another not similarly exposed; but in the station, generally speaking, the soldier does not suffer more than others. 9. Many persons subject to fever are in the habit of taking quinine in small doses daily during the fever season. There can be no doubt of the protective power of quinine so taken. 10. I think that in European regiments the practice of giving small doses of quinine as a prophylactic during the prevalence of fever to soldiers peculiarly liable to suffer from the disease would be beneficial. With regard to small-pox, the extent to which the disease prevails has been very much diminished since vaccination was introduced into the district, and we can hardly expect to see a greater reduction in the amount of the disease unless vaccination be made compulsory.
XII. HOSPITALS.	1. Plan. 2. There are no barracks in the station. The hospital is three-quarters of a mile from any bazaar, but is near the houses of the civil population. The site is open and freely ventilated, and there are no buildings or trees which interfere with ventilation. The site of the hospital is on a level with the rest of the station; the drainage is by means of open gutters falling into a nullah a quarter of a mile off. There is no malaria or nuisance near it. 3. The water supply is abundant and wholesome. 4. The water is carried off from the neighbourhood of the hospital by means of open natural surface drains. All impurities are removed by sweepers. 5. There is but one ground-floor ward, on a level with the adjoining land, or but little above it; the floor is bricked. Gutters are provided for carrying off the water from the roof. Gutters run on the north and south sides of the hospital; these unite on the east, about 100 yards in front of the building, and flow into a nullah a quarter of a mile off. The hospital is built of burnt bricks, cemented together with a mixture of lime and burnt clay. The roofs and walls are single, but are sufficiently thick to keep the hospital cool. There is an enclosed verandah all round the building. When the accommodation afforded by the wards has been insufficient for the number of sick the verandahs have been used, but it has not often been necessary. The hospital consists of only one flat. It is placed so as to receive the full benefit of the prevailing winds. It is well ventilated. 6. Windows and skylights are used for ventilation, and are quite sufficient. There are no jalousies or jhilmils. 7. No reply. 8. The walls and ceilings are cleansed and limewashed whenever required. 9 to 12. No replies. 13. The storage is dry and sufficient. 14 to 16. No replies. 17. The provision for attendance on the sick consists of one native doctor, one cooly, one water carrier, one sweeper. These meet the ordinary wants of the sick. 18. The hospital is an old spacious airy building, very well adapted for native troops. No epidemic disease, hospital gangrene, or pyæmia have appeared in the ward. 19 and 20. No replies. 21. The present arrangements for the sick wives and children of soldiers meet the requirements of the station. 22. No reply. 23. The medical officer can get sanitary defects remedied and repairs to the hospital made, by requisition to the Deputy Commissioner of the district. 24. Convalescent wards are not required for native troops.
XIII. BURIAL OF THE DEAD.	1 to 7. No replies.

(Signed) W. B. RRETT, Assistant Surgeon in Medical Charge, Loodiana.

P. C. ANDERSON, Executive Engineer, 8th Division, G. T. Road.

May 1860.

MADRAS PRESIDENCY.

Native Troops — Cavalry Body Guard - 100 (find their own accommodation). Infantry - - - 841 at Perambore. Remainder variable and not fixed.

References to Subjects and Queries.	Replies.
I. Topography.	1. The country surrounding the station is flat in many places; sandy and dry in the dry season, but in the rainy season it is not swampy. There is not much wood; no jungle; water in abundance, except during the dry season. 2. The station is almost on the level of the sea. The sea is on the east. The river Cooam nearly surrounds the fort and town of Madras, and there is a continuation of tanks on the outskirts of the suburbs. There is no neighbouring ground higher and healthier combined adjoining the station. 3. The nearest higher ground is at Palmoraire, on a spur of the Mysore range, about 2,200 feet above the sea and station, and distant from Madras 120 miles; but it is said to be feverish. With the facilities of rail and transit, the Neilgherries are preferable for sanitary purposes. 4. Station is on the sea shore. The vicinity of the station is not liable to overflow of water, except on rare occasions, during the monsoon, and it rapidly subsides. There is no broken ground, ravines, or water pits near the station. 5. The station is open and freely exposed to winds. The surrounding country is open and flat. No impediments to free external ventilation. The barracks for Europeans are in Fort St. George on the seaboard. The lines of the native body-guard are open; those for the native infantry are in the districts of Perambore, Vepery, and Royapooram. Perambore lines are open, and possess free ventilation. Vepery are more enclosed, but not so much as to interfere with ventilation; Royapooram is merely occupied temporarily. It may be remarked, that native houses in general are very deficient in internal ventilation. The temperature of the station is not raised to any appreciable degree by reflected sun heat. The station is not exposed to cold winds. Winds are variable in May, June, July, August, and September. Land winds blow in May, June, and July, during the greater part of the night and early part of the day, succeeded by the sea breeze. During the remainder of the year the sea breeze is steady till March, when the long-shore wind sets in till May, during the greater part of the day; the land wind setting in during the night. The sea breeze is favourable to health. Fevers, catarrhs, and rheumatism are, generally speaking, common during the long-shore winds; but it does not appear that they are traceable to this cause, or that there is anything detrimental to health in any of the winds prevalent here. 6. The country around is cultivated. It is irrigated by large tanks on the outside limits of the town, but these are dry at the season previous to the periodical rains. The artificial irrigation is not observed to have any influence, beneficial or otherwise, on health. There is no prohibition against the cultivation of rice near the station. Indigo is not cultivated, nor are hemp nor flax prepared near the station. 7. The troops are stationed in the large town of Madras, containing a population of upwards of 700,000. This must be borne in mind when referring to the troops, with the exception of the Europeans stationed in Fort St. George, which is isolated from the town by a glacis and esplanade. 8. The surface formations are sand and clay. Primitive formation about 100 feet below the surface. The troops occupy ground formerly and still occupied by a numerous native population, except the European troops, who are stationed in the Fort formerly built for the protection of the factory of the East India Company. 9. Water is usually found from 16 to 20 feet below the surface in the dry season, and near the surface in the rainy season. 10. The rain water generally sinks into the subsoil, but it also partially drains off and what remains on the surface rapidly evaporates. There is no higher ground, the drainage of which passes into the subsoil of the station. The elevation is so slight, that it partially drains the surface, and the water is then collected into large tanks used for irrigation, and also flows into the river Cooam. 11. The water supply is derived from the "Seven wells," distant two miles, and conveyed to the Fort by water pipes. It is stored in the Fort in large covered cisterns. It is not stored in the native lines, but the troops there use the tanks and wells resorted to by the native population. The tanks are dry in the months of May, June, and July, unless there is rain abundant enough to fill them. Various species of fresh-water *algæ* are found in the tanks, besides numerous specimens of *diatomacea* and *desmidacea*. Some species of fish and crustaceans exist in the larger tanks, and in all of them batrachians are plentiful. *Acalephæ*, &c. abound in some of the tanks, more especially in the Fort ditch, and when the water is low, a most offensive odour is emitted. No tank used for drinking water is allowed for bathing in by European troops. Native troops are generally particular as to the water they drink, especially those of higher castes. The tanks are not liable to pollution from leaves or other extraneous matters. There is no evidence of distinct malaria proceeding from any of the tanks, but nuisances in the shape of most offensive effluvia are abundant, especially in the river Cooam, supplied by the sea, the banks of which are mud; but it does not appear that beyond the offensive odour, any ill consequences to health result from the nuisance. It is difficult to trace how far the effluvia may predispose to disease, but in all probability, those who reside on the banks are more liable to suffer from malarious diseases, than others not exposed to its influence. Probably "Dale's muriate of iron" would be the best deodorizing agent as a preventive. 12. There is an abundant water supply drawn from various wells and tanks. Some of the water is brackish, especially that from the wells in Black town, whilst that drawn from other sources is tolerably pure. The water from "Seven wells," which is that supplied to the Fort, is very pure and sweet, perfectly pellucid, of good taste, and free from odour. Other wells afford equally pure water. Almost all tank water has a disagreeable smell, probably due to the presence of *characeæ*, whilst the taste is rank or mawkish. Tank

FORT ST. GEORGE. MADRAS.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	water is especially liable to be impregnated with impurities in consequence of buffaloes and other cattle being washed therein, or basking in the water during the heat of the day. There is no peculiar hardness about the well water except that which has already been mentioned as brackish, and no impurities can be detected under the microscope. Generally speaking the quality is good and in no respect injurious to health, and the amount is abundant. For the Fort no better supply could be obtained. (Means of distribution not stated.) 13. There is no other topographical point requiring notice beyond the fact that the station is bounded on the east by the sea, which here presents a completely open roadstead without harbour of any kind. 14. New stations are generally selected by the officer commanding the division in which the intended station may be situated. The medical officer nearest the spot is desired to report on the eligibility of the proposed site, his attention being particularly directed to topographical circumstances, character of soil, openness and exposure to winds, freedom from marshes and malaria, climate, diseases endemic among the surrounding population, prevalence of epidemics, means of natural drainage, facilities for forming parade and exercising grounds, and for erecting barracks, lines, &c., with due reference to sanitary requirements, and the character of the surrounding country. The assistant quartermaster-general of division generally makes a report also, and the final decision rests with the General, who visits the spot accompanied by his staff, and generally by the divisional head of the medical department. Hill stations are generally chosen when sanitaria are desired, but on ordinary occasions stations are selected on the plains. It does not always happen that the recommendations of medical officers are attended to; private interests sometimes interfering with the selection of what they consider the best site. It might be probably advisable that the power of selection should be vested in a committee composed of seven members, three of whom should be medical, and one an officer of engineers; the majority to decide on the final recommendation to government.*
II. CLIMATE.	1. There is a government observatory at Madras, under the charge of a government astronomer. 2. The following table, prepared by Mr. Taylor, formerly government astronomer at Madras, is an average for any number of years, although extending only from 1811 to 1841, and has been furnished by Major Worster, acting government astronomer :—

Months.	Days.	Barometer Mean Height.	Thermometer Mean Daily Temperature.	Extreme Maximum.	Extreme Minimum.	Mean Dry.	Mean Wet.	Mean Sun Temperature.	Rain.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks as to Cloud, Dew, Winds, &c.

* The following remark on the preceding reply occurs in a printed Order, No. 3,697, 16th October 1860.

"With reference to the answer to the 14th question, his Excellency" (the Commander-in-Chief) "is not aware of any instance having occurred of setting aside the recommendations of medical officers in the selection of sites for new stations. The practice is, as suggested by Major General McCleverty, to leave the selection of sites to committee, and the proceedings are always placed before Government in extenso, with the opinion of the Commander-in-Chief."

† On 21st May 1811, during the gale that blew there fell 5·5 inches of rain; on the 8th, 9th, and 10th May 1820, 17·56 inches; on the 7th, 8th, and 9th May 1827, 23·30 inches; and on 16th May 1841, 3·0 inches.

II. Climate—*cont.*	3. The climate of Madras, is on the whole, favourable to the health of Europeans and natives In November, December, January, and February, the air is cool, dry, and pleasant, the thermometer being 78° in the first and 76° F. in the other months. The air is moist at the commencement of the S.W. monsoon in the beginning of May, and at the commencement of the N.E. monsoon in the beginning of October. The greatest heat is in May, when the thermometric maximum is 99° F. The greatest cold is in December and January, when the minimum is 65° F. The variability is greatest in June and July, when it is 22° F., and least in October and January, when it is 15° F., but the transition of temperature is at all times gradual from the highest heat between 2 and 5 p.m. to the lowest cold between 2 and 5 a.m., according to seasons. In December and January there is heavy dew, and occasionally a ground fog, which reaches 2 or 3 feet above the surface. The air is always damp during the "south" or "long-shore" wind in March, April, and May. Madras and its vicinity are moderately planted with trees, the greater part of which are *exogenous*, occupying the higher and driest loamy and laterite grounds; the *endogenous* being comparatively few, and growing in groups or "topes" on the lower or sandy localities impregnated with salt. The planting is sufficient to mitigate the severity of the hot season, but not so abundant as to cause any injury to health by acting as an impediment to the circulation of air at the close seasons before and soon after the rains, except at Washerman's Pettah at the N.E. of the town, where the cocoa tope is so thick and extensive that it keeps up a malarious condition of the air on that very low ground, the lowest in Madras, and at the south of the ice house, where the cocoa topes are also thick and the ground low and swampy. Irrigation by canals, wells, and tanks is not carried on to such an extent as to deteriorate the climate, on the contrary the aridity of June, July, and August appears to be moderated with advantage to health by the present extent of surface water. The air in Black town and Triplecane is loaded with mephitic effluvia at night, but during the day the air is tolerable except in the worst parts, such as Vepery, Triplecane, and Washerman's Pettah. While north winds are blowing in May and June the air in and around Madras is loaded with fine red dust, which finds its way into every crevice, adheres unpleasantly to the skin, and must often get into the lungs.

FORT ST. GEORGE. MADRAS.

II. Climate—*cont.*	The most fatal diseases are cholera, dysentery, diarrhœa, and fevers. The second half of the year exhibits generally a considerable increase of mortality from the first three diseases. The health of native troops is usually improved by residence in Madras, except those located in the lines at Vepery, where there is much stagnant water and some offensive burial-grounds, and where remittent fevers are often severe and fatal during the rains. European troops suffer from dysentery, during and after the October rains, and from hepatitis and fever during the hot season. In the 7 years, 1832 to 1838 (see page 74, Medical Topography of Madras) the annual per-centage to strength of acute dysentery in Her Majesty's troops was 26·707, and deaths to sick treated 4·986. The annual per-centage of acute hepatitis is as 11·196, and deaths to sick 3·524. The total fevers to the aggregate strength (of that period), 4,055, was 1,744, viz., ephemeral 76, intermittent 10, remittent 2, continued 1,656, or one-sixth of the whole admissions, and their tractable nature is shown by the fact that there was only one death to every 174 of the patients. Europeans in Madras, as in all India, require good and abundant animal and vegetable food. They cannot bear exposure during the day till after some years of acclimation, except in the afternoon of December, January, February, and March, when they are much invigorated by athletic games in the open air. At all other times drill cannot be continued with safety after 7 a.m., nor recommended with prudence before half-past 5 p.m., and duties between these times must be conducted in the shade. Athletic exercise, however, is absolutely necessary at all seasons for the preservation of health, but must be pursued without exposure to the sun. Light khakee clothing is the best at all times, except from sunset to sunrise in December, January, and February, when cloth clothing is most suitable for men on duty. The generality of Europeans derive benefit from wearing a thin flannel jacket with short sleeves, and a broad soft flannel belt round the abdomen and loins next the skin. The flannel belt is worn conveniently by men of any length of service in India, but the flannel jacket is often prejudicial from the heat and irritation it keeps up in persons of active cutaneous circulation. Some regimental medical officers insist on their men wearing flannel jackets at all times, irrespective of feelings of individuals, but it appears to be a better and safer plan to leave European soldiers to use or dispense with this article of under-clothing according to their feelings. The abdominal belt is seldom objected to, and can be more indiscriminately used and recommended. Flannel under-clothing, with flannel stockings, is often of great service in the treatment of diseases of debility, and at all seasons, and is frequently sufficient, with attention to diet, to induce the restoration of health. January and February are the most healthy months at Madras. The prevailing diseases are catarrhs and mild continued fever. To Europeans who have resided four or five years at Madras, the south wind in March, April, and May is very depressing, and occasions neuralgic and rheumatic pains. June and July are the worst months for continued fevers and hepatitis. The most unhealthy months are August and September, when the weather is cloudy, close, and oppressive before the N. E. monsoon, and dysentery is common. It is during these months that cholera has generally raged epidemically. (See Medical Topography of Madras, p. 13.) 4. There is no district near this station which can be said to be decidedly more conducive to health than Madras itself. 5. Served at Secunderabad, Kamptee, Saugor, and Ellore. The three first-named are salubrious to those who can take proper precautions. Saugor has the advantage of a long cold season, and the nights of the hot season are cool to those who can sleep in tents. Ellore signifies in Sanscrit "the place of health," and is very healthy to those born there; but as water is within 5 or 6 feet of the surface, and the soil consists of deep rich loam, and tracts of white sand, the station is hot, and loaded with moisture. Europeans suffer from serious intermittent fevers, and natives from other parts of India resident there are very subject both to intermittent and remittent. The remittent fever which attacks natives not born there approaches very closely to yellow fever, sometimes. Ellore may also be called the head-quarters of Beri-beri, as Europeans or natives, whether born there or not, suffer more from that disease in Ellore than in any other part of the northern division. It is a bad locality to send natives to on sick leave.
III. SANITARY CONDITION OF STATION.	1, 2, 3, maps and plans of station. 4. The following are the details of the barrack accommodation:— Fort St. George was constructed about 1780, and added to from time to time. Huts at Perambore lines were erected in 1858. The huts at Royapooram are temporary. Total accommodation: European non-commissioned officers and men, 1,030.

III. Sanitary Condition of Station—*cont.*	There are 81 European families living in the regimental patchery, Fort St. George. In the lower story in the S.W. corner are two bomb-proofs, included in the above estimate, as also at the south end, which are only occupied when necessary, as the ventilation is defective. They are calculated for 124 men, thus reducing the European accommodation to 906. The huts in the Vepery native lines are no two alike as regards dimensions, character, or structure. The Royapooram lines are merely temporary. The strength is not fixed in either of these native lines. The men of the native body-guard live in their own private dwellings near the stables. 5. The windows and doors in Fort St. George barracks are opposite each other generally, opening outwards. The huts of native troops have no windows. Fort St. George barracks have verandahs on all sides 11 feet broad. The native huts at Vepery and Perambore have verandahs in front 2¾ feet wide. The verandahs are not occupied as sleeping quarters by soldiers or other persons. Fort St. George barracks are provided with properly constructed Venetian shutters to the windows of the upper floor, and with pannelled ones to the lower story. The native huts have none. 6. In Fort St. George there are iron bedsteads, with canvass sacking, for European soldiers. Government supplies no bedding to native troops, who use mats or carpets, their own property. No improvements to suggest. Europeans have also issued to them a quilt, settringie, sheet, and blanket, in barracks. In tents they are furnished with the two former, and a tarpaulin or straw underneath. 7. The construction of tents is as follows :— *European tents:* 2 poles and ridge; double fly; single walls, two folds of cotton cloth. Dimensions: length of ridge pole, 6 ft. 7 in.; length within walls, 21 ft.; breadth, 15 ft.; height of poles to inner fly, 10 ft. 3 in.; height of poles between the flies, 1 ft. 6 in.; height of walls, 5 ft. These tents accommodate 20 cavalry, with saddles, or 25 infantry, on ordinary march, and 15 cavalry, with saddles, or 20 infantry, on field service. The cubic contents per man are 100 cubic feet for cavalry, and 85 cubic feet for infantry, on ordinary march, and 141 cubic feet for cavalry, or 106 for infantry, on field service. The superficial area allowed in these tents on ordinary march is 15·9 square feet per man for cavalry, or 12·6 square feet for infantry. On field service the area is 21 square feet for cavalry, or 15·9 square feet for infantry. *Native tents* have 2 poles, 1 fly, no walls, and are made of two folds of cotton cloth. Their dimensions are: top of fly from pole to pole, 10 ft.; length at bottom, 22 feet; breadth, 12 feet; height of pole, 10 feet. The same number of cavalry and infantry are allotted per tent as in the European regiments, but 50 native recruits are placed in a tent. The space per man on ordinary march is 88 cubic feet, and 13⅕ superficial feet for cavalry; and 70½ cubic feet, and 10½ square feet for infantry. On field service the space is 117 cubic feet, with 18 square feet, for cavalry, and 88 cubic feet, with 13⅕ square feet, for infantry. 8. The barracks are well ventilated by earthen pipes above in the roofs, and by half doors, the upper portions of which are generally open night and day. The huts have no ventilation, except by a single low door. Tents are well ventilated by raising the walls. During six months in the year, punkahs are used to agitate and cool the air, as a subsidiary means of ventilation in barracks. Generally speaking, the air in tents is pure. No means are provided for cooling the air in huts. No artificial means of ventilation are allowed for native corps. The huts at Perambore were recently constructed by Government on a raised basement of 5 feet, and seem well adapted for the location of native troops. Those at Vepery are exceedingly bad. They are the property of the sepoy soldier. 9. Barracks in Fort George are built of brick in mortar; the walls are plastered and whitewashed. The outer walls of the Perambore huts are of brick in mortar; in some parts of brick in clay, pointed with mortar; the inner walls of sun-burnt brick, plastered with clay; the roof of pantiles. Those at Vepery are of mud covered over with thatch or cudjan leaves. Tents are of cotton cloth, and are well adapted. 10. Some of the floors in the upper story in barracks are of teak; the rest are of square bricks laid in lime. The floor of the lower story is paved with granite slabs. The floors are well raised above the ground, from 2 to 4 feet. There is no free passage of air beneath; it is not required in this country. The floors being never damp, passages for air would be the resort of insects and vermin. The hut floors are not raised; they are formed of earth beaten down with clay by aid of water. 11. For constructing barracks, bricks and mortar are the most suitable materials at Madras. At some stations, stone can be used with advantage. In this country, the thicker the roof is the better it adds to the coolness; terraced roofs are, therefore, preferable to tiles, slates, or thatch. Asphalte does not answer in India, the heat is too great; it may, however, be used with advantage in covered wash-houses and lavatories, where the sun and hot winds do not penetrate, otherwise asphalte is always soft, and easily indented. The Perambore huts give satisfaction to the occupants. Those at Vepery are in a most dilapidated state. The walls are of mud, with roofs of cudjan leaves, supported on thin bamboos. Huts on the model of those at Perambore are recommended. The barracks are kept in repair by the garrison engineer. They are in charge of the barrack master; both under the orders of the divisional general. Repairs are promptly executed. The sanitary state of the fortress is in charge of the general. The repairs of the Perambore huts are made by the engineer department. The men receive no hutting money. The occupants repair those at Vepery. Commanding officers are responsible for the cleanliness and sewerage in the native lines. The barracks in Fort St. George are limewashed as often as required, generally twice a year or oftener, dependent on season or change of corps. On a new regiment marching in, the barracks are thoroughly cleansed and whitewashed. The same rule applies to huts. 12. The barracks have excellent and abundant baths and wash-houses, supplied with an unlimited quantity of the purest well water, brought by pipes a distance of two miles. Attached to the barracks are separate baths built of brick in mortar, plastered over with cement chunam; each bath contains about 12 cubic feet of water, and is filled with fresh water for every man separately. The water is laid on and turned off by cocks from the main water pipe. There are 82 baths and 2 lavatories open for use from morning till night. Similarly there

Fort St. George. Madras.	References to Subjects and Queries.	Replies.
	III. Sanitary Condition of Station—*cont.*	are in patchery 19 baths and 2 lavatories for women and children. None are allowed for native troops, who resort to tanks and wells near their lines. Lavatories have lately been constructed in the barracks and patchery; two ranges in each for the right and left wings; each, in the barracks, containing 50 basins; in the patchery, one containing 36 basins; another 12. They are all well drained, and the refuse water passes through the latrines, and is flushed out to sea. 13. Until lately the barrack cookrooms at Fort St. George were very bad. A new cookroom has been provided in a more convenient locality. The apparatus has been invented, or rather modified to suit local circumstances, by Dr. Duff, Madras Medical Service. One range will cook either baked or boiled meat for 150 men with ease. The food is better cooked at half the expense of fuel and attendants. Six ranges are completed, and six are in the course of construction. The cost of each range complete is about 400 rupees. The sepoys draw their water for cooking from tanks and wells near their lines. No separate cookhouses are allowed them by Government. The clothes of Europeans are washed by dhobies in tanks and watercourses three or four miles from the Fort; but the men wash their own khakee uniform in the barrack square, and dry them in the open square within the quadrangle. The sepoys generally have their linen washed in large tanks and watercourses about three or four miles distant from town. 14. The old privies in Fort St. George were as bad as they well could be. New ones are being built at a more convenient distance from the barracks, on the berm of the adjacent curtain. The new privies will be in compartments, provided with stoneware pans, which will be filled with water from self-supplying high cisterns, and the whole sewage will be flushed out to sea into five feet depth of water. At Perambore each hut has a small enclosure kept clean by toties. At Vepery there is a large open privy, but not similar to those made by the municipal department for the public. The soil from the two latter places is carried away in box carts to a distance and buried. At the body guard-lines, there are no urinals, and the privies are not sufficiently ventilated. They are provided with openings in the walls the shape of a bull's-eye. They are washed twice a day and drained into the Cooam river, distant 300 yards, by means of a covered drain. 15. The ventilation of the barracks has been before described. They are lighted with oil lamps, but 12,000 rupees has been sanctioned upon the recommendation of Professor Dr. Mayer, for lighting the rooms with gas made from oil instead of coal. The works are nearly completed, and in the course of a month it is expected they will be in useful operation. Should the project succeed it will doubtless be applied in other barracks. Native huts are not lighted by Government. 16. The sum of 50,000 rupees has been lately sanctioned for the improvement of the drainage of Fort St. George, and for the construction for public privies for troops, &c. At Perambore there are small open brick drains about one foot by six inches. A portion of these empty themselves into the Votary nullah, distant 180 yards, and others into pits, whence the earth for the basement of huts was taken. The Vepery lines appear to be perfectly uncared-for as regards drains. There are not even small surface drains round the huts. At the body-guard lines there are covered masonry drains, built underground and carried into the Cooam, on the west side of the lines, on private property. Improvements are sanctioned as above. The whole drainage will be flushed out to sea by a 12-horse power steam engine pump, with water drawn from the ditch of the Fort. When the above works are completed, the drainage throughout the Fort will be most efficient. At the body-guard and Perambore lines quite sufficient. At Vepery the rain water is carried to the Cooam, half a mile distant. No part of the barracks in Fort St. George are damp. From the materials with which all huts are constructed in this part of India, there must be great dampness during October and November when the rains are heavy. As regards the sufficiency of the drainage. In Fort George the whole will be flushed out to sea into five feet of water. At the body-guard, the fluid refuse is not left on the surface, but received into cesspits, built in connexion with the masonry covered drain. At Perambore and Vepery it is carried off by the open side street drains to the open river in the vicinity. There are no cesspits within the Fort of any consequence. There is however on the glacis distant 80 yards, a main drain, which carries all the town sewage out to sea. When the wind is in the N.E. the effluvia from it is very offensive occasionally. Government has sanctioned an expenditure of 4,000 rupees to correct this evil. The work is under execution. At Vepery and Perambore there are no cesspits. The cesspits at the body-guard lines are 2½ feet square, and situated within 100 yards of a large well, from which water is used for the horses. There is no proper means of cleansing these cesspits. There is a ditch round the fort filled with salt water, but no others. At the native lines there are none. 17. The following are the cleansing arrangements. The streets and open surface drains are cleansed every morning, in the Fort by scavengers kept solely for the purpose. The road sweepings are carried off in carts. At the native lines in a similar manner. 18. No vegetation of any kind within the Fort. Native lines free of vegetation. There are no old walls, &c. within the fort to interfere with the external ventilation. The Vepery huts are situated in the midst of a densely populated town, within the jurisdiction of the Supreme Court, and the bazaars are not under military management as in the up-country stations. The same applies also to Perambore, which however is more favourably situated, being entirely open on the north side. Brick kilns within 200 yards are springing up, a nuisance which may affect the health of the sepoy. They should be distant at least half a mile. 19. The bazaar in the Fort is well situated, but small; clean, and well ventilated; near the patchery. The bazaars at Perambore and Vepery are not under military management, but under the police and municipal department. They are not well cleaned, and in their vicinity, the atmosphere for some little distance around and about them is perfectly poisoned. The bazaar in the Fort is under the Commissioner of Police. No improvement necessary. There are no native houses near the Fort, nor dungheaps, nor cesspits. The houses at Vepery and Perambore are of all descriptions, generally belonging to a wealthy class of natives. They are free from dungheaps and cesspits. Vepery and Perambore are important towns. No nuisance in barracks from the wind blowing over native dwellings.

III. Sanitary Condition of Station—*cont.*	20. The slaughter-houses are in the suburbs on the west side of the city, about three miles from the Fort, and half a mile from the Perambore lines. They are under the municipal board, and are provided with drain, sinkholes, and stinktraps, which are cleaned out and flushed daily by means of wells within the precincts. The offal, &c., is sold. 21. In the Fort there are stables and coachhouses allotted to regimental and various departmental officers. They are swept and cleansed daily by scavengers, and the manure is removed in carts. There are no picketing grounds. The stables of the body-guard are kept clean, and the manure removed. 22. There are no artillery or cavalry stables in the Fort. The body-guard stables are constructed of bricks in chunam, with a pent roof covering composed of Palmirah rafters, and in one course flat, with pantiles. The walls are plastered with chunam, and the floors are gravelled. The hospital is in the centre of the stables, and is considered very unhealthy. The stables are sufficiently ventilated. The manure is carried and deposited on the bank of the Cooam river, bordering the lines on the west side, and it is sold. Detachments of cavalry, artillery, and infantry are occasionally encamped on the esplanade north of the Fort, and near the sea. The horses are picketed. Such detachments are distant from the barracks and hospital, and are encamped for the purposes of embarking or disembarking. 23. In Fort St. George the patchery is distant 100 yards from the barracks. The former contains quarters for 81 families; and there are also 10 for married non-commissioned officers in the barrack square. A British regiment of its full strength has 150 families to be provided for. At present, the 43rd Light Infantry is entitled to accommodation for 126 families, and, therefore, the number beyond 91 as above occupy barrack rooms intended for the men. (This has since been corrected by the removal of a company and 15 families to Palaveram.) In native corps, quarters are provided by Government for the non-commissioned staff. These are commodious and well ventilated.
Officers' Quarters.	1. The sanitary condition of the officers' quarters in the Fort is good. European officers of native corps at Perambore and Vepery live in private houses within half a mile of the lines. Officers of the body-guard live where it suits their own convenience. When the improvements sanctioned, at a cost of 132,000 rupees, are carried out in the Fort, the barracks and officers' quarters will be most healthy and commodious, both for officers and men. At Vepery there has been great difficulty in finding suitable accommodation for officers adjoining the lines. The barrack master has been instructed by Government to rent a few houses for the purpose, which have been inspected by the engineer department, and approved of.
IV. Health of the Troops.	1. The station. The district in which it is situated and the adjoining native population are healthy. 2. The most prevalent diseases among the native population are continued fevers, diarrhœa, and dysentery. There are almost daily a few cases of Asiatic cholera amongst the natives, and occasionally it is epidemic. Spleen disease is not common at this station. 3. The healthiness of the natives is to be attributed to the salubrity of the climate and the abundant demand for labour. Those who cannot work are generally poor and unhealthy, from bad and insufficient food, and are obliged to live in the lowest and worst drained localities. 4. The following have been the previous stations of troops before coming to Fort St. George:— Her Majesty's 43rd Foot.—Was at Saugor 10 months and 14 days. Left Saugor for Madras, 13th January, and arrived there 18th March 1860. Many men on the arrival of the regiment at Saugor were greatly exhausted by the previous campaign; but the general state of the regiment was good until the commencement of the rainy season. From June to December malarious fever prevailed to a very great extent; no other form of disease prevailing. On arrival at Madras, there was little actual sickness among the men; but many of them were debilitated and cachectic from repeated attacks of malarious fever in Central India. The enervating effects of Madras during the hot season has brought on relapses of that disease, chiefly in the intermittent form in a very large proportion of cases, and the state of health of the regiment has deteriorated considerably in consequence. 4th Regiment Madras Native Infantry.—Before coming to its present station, Madras, was located at various stations at Burmah, viz., Thyetmyo, Meeday, Prome, Tabaulah, Taymeet, Mengdoon, and Rangoon. The regiment was three years in Burmah, and left Rangoon 17th May 1860, arriving at Royapooram 29th May 1860. Their state of health was bad during their whole tour in Burmah, owing to their frequent movements from one to another of the above stations. The diseases from which the corps suffered were chiefly fevers of a low quotidian type accompanied almost invariably by head symptoms, dysentery, and beri-beri. The diseases since the arrival of the corps at Madras have been fever, chronic diseases of the stomach and bowels, and boils. 34th Regiment Madras Native Infantry.—Stationed at Trichinopoly for 3 years and 24 days. Left for Madras, 12th May 1860, arrived 5th June 1860. The health of the corps at Trichinopoly was generally very good; the diseases were principally fevers, rheumatism, diseases of the lungs, and cholera. These are here stated in order of frequency. The corps was healthy on its march to Madras, and very healthy when it arrived. The diseases with which it has been affected since it came to Vepery, at Madras, have been chiefly fevers, rheumatism, and dysentery. No casualties had occurred up to 29th June 1860. Since then some fatal cases of cholera have appeared in the lines. 44th Regiment Madras Native Infantry.—Before its arrival at Madras was located at Thyetmyo. The regiment arrived at Thyetmyo 1st June 1857, and left that station 7th January 1860, arriving at Perambore, Madras, 23rd February 1860. Their state of health was very bad in Burmah in 1857–58, better in 1858–59, and good in 1859–60. In the first year 41 died in hospital, 120 were sent on sick leave. In the second year 11 died in hospital and 68 were sent on sick leave. In the third year 6 died in hospital and 46 went on sick leave. The improvement in health in each year may be ascribed to acclimation and improvements in diet. The diseases from which the men suffered chiefly were fever, beri-beri, diarrhœa, and dysentery. The medical history of the regiment in

FORT ST. GEORGE. MADRAS.

IV. Health of the Troops —*cont.*	Burmah leads to the inference that the climate would be less hurtful to Madras native troops if they were permanently stationed there. The health of the regiment was pretty good when it arrived at Perambore, Madras; the number of sick in hospital being 60 to a strength of 741. The great majority of the diseases were chronic, beriberi, rheumatism, and diarrhœa. The diseases from which they have suffered since their arrival at Perambore have been chiefly of a chronic nature, contracted in Burmah. As regards the comparative healthiness of different parts of the barrack accommodation at Madras, the accommodation for European troops, now that the Fort and barracks have been better ventilated, may be considered nearly unexceptionable. The lines of native troops are also good and well situated, except those at Vepery, which locality, as already described, is low, damp, mephitic, and unwholesome. 5. The troops here are never camped out for the sake of health. One or two companies of Europeans have occasionally to be encamped on the glacis of the Fort, on account of temporary want of accommodation. Some portion will be encamped after the monsoon at Palaveram, for the purposes of rifle practice. 6. Never been in charge of troops at hill stations. 7. I have not observed, nor see any reason to infer, that troops who have resided for some time on hill stations should be liable to attacks of febrile diseases on returning to the plains. On the contrary, the constitution, braced up by a residence on a hill station, would be more likely to resist febrile exciting causes. 8. Unquestionably approve of selecting hill stations for troops. 9. On going to hill stations, troops are at first liable to attacks of fever and diarrhœa. 10. To guard men from such attacks, diet ought to be nearly as usual, but care ought to be taken not to give way too much to vegetable diet. Clothing ought to be warm. Head well covered. Duties to be carried on, as much as possible after first arrival, in the morning and evening. Great care to be taken to prevent too much exposure to the sun, as this is not to be braved even on hill stations. 11. The best season for hill stations is the season which corresponds to the hot season in the plains; and, as far as opportunities of judging are afforded, troops should pass one year on the hills at least. 12. A lengthened residence is desirable, and the longer troops remain at hill stations the better. 13. Troops in leaving hill stations for the plains should be protected by adapting change of clothing to change of temperature. 14. As regards the question of locating the troops on hills, with short periods of service on the plains, or *vice versâ*. Of opinion that it would be most desirable to locate them on hill stations in preference to the best location to be found on the plains. Am of opinion that frequent changes of station on the plains are injurious, but an occasional change, as at present, is beneficial. 15. No information. 16. No experience. 17. There is no higher ground near this station which could be advantageously occupied as a station. 18. The most healthy soils and subsoils for stations are dry laterite and gravelly soils. 19. The best age for soldiers proceeding to India is from 20 to 25 years of age. The best months for landing here are January and February. European troops on first landing are sent to Poonamallee and St. Thomas' Mount. Their barrack accommodation is the same, and they are clothed in the same manner as troops long resident in the country. For some months they have little duty to perform, except attending roll-calls and learning extension drill morning and evening. The best precautions on landing are to march them from ship to barracks without exposure to the sun; to restrict them afterwards to barracks during the heat of the day; clothe them lightly; diet them moderately, and keep them from ardent spirits. 20. With proper precautions, troops should be sent direct from home depôts to India. It is advisable to send them to hill stations on landing, and afterwards to introduce them gradually to the climate of the plains. 21. Troops proceed from the port to the interior by land. The healthy march, while the debilitated are either kept at the general hospital or conveyed with the corps in carts or doolies. The regulations at present are sufficient to secure the health of newly-landed troops, if carefully attended to. Since the beginning of 1858, troops have been occasionally conveyed to the interior in coaches provided with relays of bullocks and horses. The health of the troops has been invariably good during this mode of transit, and, although necessitating what would appear to be a considerable outlay, its effects, in reality, are a great saving of money, by preventing disease and loss of life, which is often considerable in the ordinary mode of marching. 22. A British soldier in India should have 10 to 15 years' service. 23. The medical boards, as at present constituted in this Presidency, are well adapted to their duties. Conflicting opinions are seldom entertained, but each member has full opportunity and is perfectly at liberty to express his opinion. 24. Invalids should leave India in February for home.
Diseases.	1. There are health inspections both for Europeans and natives generally weekly, but at the discretion of the medical officer. 2. There is no scorbutic disease. 3. Among Europeans in 1857–58 the proportion of hepatic disease to all other diseases was 1·42 per cent., whilst in 1858–59 the proportion was 5·25 per cent.; but the question can be answered accurately only by the Principal Inspector-General, Medical Department. Heat and free living are the principal causes of hepatic diseases. They are occasionally consequent on fever and dysentery. Shelter from the sun and moderation in eating and drinking are the best prophylactics. Hepatic disease is rare among natives.

References to Subjects and Queries.	Replies.
IV. Health of the Troops. —*cont.*	4. In the body-guard, composed of natives, the per-centage of cases of guinea worm for ten years, from January 1848 to 31st December 1857, was 33. The per-centage of guinea worm to all other diseases was 30·41. Washing in tank water is the cause. Throwing quick lime occasionally into the tanks would be the best prophylactic. Dracunculus is rare among Europeans. 5. The proportion of constantly sick from venereal disease to total sick from all other diseases, is about 35 per cent. But the question can be more accurately answered by the Principal Inspector-General, Medical Department. Unquestionably no preventive measure would be better than Lock hospitals. 6. The troops at this station suffer from endemic disease. *Fevers* of the ephemeral form and intermittent types are common amongst natives. The types among Europeans are ephemeral, continued, and intermittent. *Dysentery*, both acute and chronic, chiefly amongst Europeans; but not nearly so common now, and much milder than formerly. *Cholera* is endemic amongst natives, and occasionally occurs epidemically amongst all classes. *Small-pox* is very seldom met with amongst the troops, in consequence of their being protected. *Rheumatism* is sometimes very severe, both amongst Europeans and natives. The following table gives the proportion of admissions and deaths from these diseases.

Europeans, including Officers of Regiments.

7. The nosological characters of the zymotic diseases here do not differ materially from those of the same diseases in other parts of the Presidency.

As regards seasons:—*Fevers* are most prevalent in the hot season; *Cholera* towards the end of the hot and beginning of the wet season, in June and July, continuing during

FORT ST. GEORGE. MADRAS.

References to Subjects and Queries.	Replies.

IV. Health of the Troops —*cont.*

August, September, and October, and in some years till January. *Small-pox* appears at the end of the hot and beginning of the rainy season. *Diarrhœa* is met with at all seasons; but is most common when dysentery is prevalent in October, November, and December. *Hooping-cough* is most prevalent in December, January, and February.

The climatic and atmospheric conditions accompanying these diseases are those mentioned above.

The sanitary condition of the localities where these diseases are most prevalent, is very bad.

Large meals of fermentative and indigestible vegetables after long fasts appear to be the chief personal predisposing causes.

8. There is nothing in the nature of the soldier's duties and occupations in barracks which has any influence on the spread of endemic disease; but epidemics are of frequent occurrence on the march and in the field. On the march, the diseases generally arise among the camp followers, and their spread amongst the men is favoured by overcrowding of tents, and by the healthy using the same necessaries as the sick, or being exposed to the poison emanating from the excretions of the diseased.
9. Malarial diseases not being very prevalent at this station, there has been no necessity for using prophylactic doses of quinine.
10. As regards recommendations for the mitigation of epidemic diseases at this station;—there are certain difficulties in the way of draining such a town as Madras, in consequence of its level being very little above that of the sea; but should the attempts which are now being made to overcome the engineering difficulties prove successful, the sanitary condition of the town will be much improved, and epidemic invasions in all probability greatly mitigated.

V. INTEMPERANCE.

1. The troops at the station are usually temperate. There are few confirmed drunkards, the proportion cannot be stated, and the real amount of drunkenness in a corps can seldom be ascertained.
2. There are no data from which the proportions of admissions to hospital directly and indirectly from intemperance, could be ascertained. Drunkenness *per se* is invariably punished as an offence in the 43rd Regiment stationed in the Fort.
3. Distilled spirits are sold at the canteens. The quality is of the best, supplied by the commissariat. Each man is allowed two drams a day, if he drinks no porter, but if he takes his quart of the latter he is allowed but one dram. Many men do not drink spirits, and some only a portion of that allowed. Spirit forms no part of the soldier's ration. It is optional with a man to take it at the station, on the march, or in the field, or not, as he wishes. In the 43rd it is not the habit of the men to take a dram before morning parade. The canteen is not opened till 12 o'clock noon, at which time porter is given out for the men's dinner. No man is permitted to have spirits till after his dinner. Spirits are not given to convalescents, either in hospital or in quarters.

   The surgeon of the 43rd Regiment has recommended that convalescents should be allowed to get malt liquor but not spirits.

   Spirits and porter are alone sold in the canteen. There is a regimental coffee shop, where tea, coffee, and ginger beer are sold, but nothing injurious to health.
4. The surgeon of the 43rd Regiment is of opinion that the consumption of spirits as a general rule is injurious, and that it would be far better for the health of the troops, if the sale of spirits in the canteen could be altogether abolished; wine and malt liquors being substituted for them, but the easy means of obtaining elsewhere injurious spirits presents a strong objection. If soldiers would not drink spirits, the surgeon of the 43rd is of opinion that it would lead to improved efficiency and discipline. A great improvement has taken place of late years, but the British soldier, if he could not obtain good spirits such as those sold in the canteen, would, notwithstanding restrictions, obtain spirits in the towns or elsewhere far more injurious to his constitution and general efficiency.
5. It would be prejudicial to suppress the sale of spirits in canteens.
6. Some men enjoy better health when using malt liquor, some when using spirits. Malt liquor is generally more beneficial.
7. Tea, coffee, lemonade, &c., are used at the station, and their influence is favourable to health, efficiency, and discipline; but there have not been opportunities of estimating accurately the influence of simple beverages, compared with spirits and malt liquors, where the latter are used in moderation.
8, 9, 10. Opinion. It would be prejudicial to the health of troops to suppress the spirit ration. Decidedly prejudicial to prohibit the sale of spirits in the canteen. Spirits, malt liquors, and simple beverages should be sold; the spirit always good,—old Colombo arrack, to the complete exclusion of rum. None should be issued before dinner time. The state of a corps may be known by the conduct of the canteen. In a well-regulated corps, as in a well-ordered family, comforts are used but not abused, and the members of the corps are not driven to seek their comforts from deceitful and deleterious sources.
11. The following is an abstract of the chief canteen regulations of the 43rd Regiment:—

   Canteen. May be issued daily to each man—1 dram spirits, and 1 quart porter or beer; or two drams spirits, without malt liquor. Canteen open from 12 to 1 daily, to issue malt liquor for men's dinners. Names of men and quantities issued to be checked. Canteen to be opened from ½ past 1 to ½ past 2, to issue 1 dram or 1 quart malt liquor to men who had none for dinner. To be open from 5 to a quarter to 8 p.m. to issue the remaining allowance; but men who who have had none before, not to have more than 1 dram spirits or 1 quart malt liquor. No liquor to be taken away from the canteen. Sick and duty men and defaulters to have neither spirits nor beer. Serjeants not to receive liquor at the canteen. Their allowance of spirits to be received by mess serjeants.

   Bazaar. No prohibition against the sale of spirits or malt liquors.

VI. DIET.

1. The rations issued to all European troops at Madras daily is as follows:—

Bread	1 lb.	Sugar	2½ ozs.
Meat	1 lb.	Tea	⅜ oz.
Rice	4 ozs.	Salt	1 oz.
Vegetables	1 lb.	Firewood	3 lbs

The rations are inspected every morning by the captain or subaltern of the day; the quarter-master being invariably present. Should any complaint arise the commanding officer assembles a board to record their opinion, and whether the rations are rejected or not.

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	2. The ration stoppage, three annas and four pice daily, or 5*d.* The soldier has three regular meals: 8 o'clock, breakfast, tea and coffee; 1 o'clock, dinner; 4 o'clock, tea or coffee and bread. At breakfast the men have meat, fish, or eggs, besides bread, at their option. The vegetables are 12 ozs. potatoes, and 4 ozs. of such vegetables as are procurable in the market. 3. Improvement might be advantageously effected in the barrack bread, which is said to be brown, and much inferior to seconds quality. The meat is insufficient in quality for the generality of the men. Mutton day is called starvation day, on account of the meat being poor and bony. Not less than 1½ lb. should be given. The 1 lb. of vegetables is found to be rather too much, ½ lb. would be sufficient. Improvement is still much required in some corps in the dishes in which the meals are served. Men on guard frequently receive their meals in a very disagreeable state, owing to want of care in serving and transporting them. No part of the ration can be disposed of, and no such thing has occurred in the 43rd Regiment. 4. The cookhouses are clean, light, well ventilated, and sufficiently supplied with water. The apparatus has been described above. The cooking is varied, boiled, baked, roasted, and stewed. Occasionally curry and rice. The cooking is sufficiently varied, and tea and coffee properly prepared. On a march, when practicable, hot coffee and biscuit are given on starting, and the same half way. This was done when possible on active service in Bengal. It would be better that the men should be compelled to take it, paying for it as a component part of the ration. The benefit is incalculable in a tropical climate. 5. There is no ground sufficiently near Madras or the vicinity of the Fort for soldiers' gardens.
VII. Dress, Accoutrements, and Duties.	1. The soldiers has three dresses: 1, thick cloth tunic and trousers. 2, red serge frock and thick cloth trousers; both these dresses served out in alternate years. 3, a suit of khakee. A wicker helmet covered with cotton drill: the English forage cap, with a thick wadded cover, and curtain hanging behind. Accoutrements as in England; pouch to contain 60 rounds. The present dress is suitable, but it is recommended that in lieu of the thick cloth trousers issued with the serge frock, that woollen ones of a lighter texture should be issued. There would therefore be three suits; one of thick cloth for colder weather and climate: one of serge for damp weather in hot seasons, or for warmer climate; one of khakee for hot weather. It is to be regretted that one uniform dye for the khakee is not obtained. A regiment presents a motley and not uniform appearance from the different shades of colour. With the dresses above recommended a soldier might serve in any part of India. Flannel is generally indispensable, and is constantly worn by the men of the 43rd. They have also woollen socks in addition to cotton. The dress of the guard varies according to the season. They have an excellent great coat for wet weather. European sentries are kept in the shade by verandahs or shed. They have sentry boxes for wet weather.
Duties.	1. The men should be drilled at home, decidedly, in preference to any intermediate station, before being sent to India. 2. The duties are, guards, picquets, and the usual drill. The amount of drill varies considerably with the seasons. In the hot weather (May to September at Madras) there is drill for an hour in the morning as soon as it is light. Instruction drill and rifle practice are carried on in the evening for an hour. This amount is not injurious to health, as the greatest care is taken to prevent exposure to the sun. In the cooler season drill is resumed twice a day. Drills should take place as early as possible in the morning and late in the evening. Marches should commence early enough to enable the men to arrive at the camp ground before the sun has influence. This will vary according to climate. European troops here, have at present five nights a week in bed. The company at rifle practice has every night in bed, being off duties. 3. Guards last 24 hours. All are mounted within the Fort, except one small guard at the hospital, half a mile from barracks. There are roll-calls early in the morning, at 8 a.m. breakfast, 1 p.m. dinner, 4 p.m. tea, at 5 p.m., 8 p.m., at tattoo, and if necessary during the night. Night guard is not prejudicial to health at Madras, and no additional precautions are necessary.
VIII. Instruction and Recreation.	1. The means of recreation and instruction are ball court, skittle ground, school with good schoolmaster, library and reading room, temperance room. There is no space for soldiers' gardens. There are no workshops nor gymnasia. A theatre is permitted in a barrack room. With a gymnasium and workshops, doubtless Europeans might find occupation. No man is allowed to quit the barracks in the Fort from 7 a.m. till 5 p.m. They are permitted to walk out morning and evening. They are thus never exposed to the heat of the sun or to rain during the day. 2. As to improvements, a gymnasium and workshops, as already proposed. 3. Savings' banks are already established. 4. There is not sufficient shade from trees, sheds, verandahs, &c. to take exercise.
IX. Military Prisons.	1. There is no military prison, but ten solitary cells have lately been built of approved construction, well ventilated, with 1,824 cubic feet to each inmate. An alteration is about to be made by throwing three solitary cells into one associated room. These are in the Fort, and appropriated to European troops. No cells could be better adapted for their purpose.
X. Field Service.	1. There are no local regulations for field medical service. 2. The practical working of the powers of medical officers as regards conduct of the line of march, bivouacking, camping, &c. is satisfactory. 3. The selection of camping grounds rests generally with the medical officer. Fresh ground is selected in preference. A standing camp is seldom established. Ventilation is universal in camp. Water is brought by bheesties and puckally bullocks from the best springs or wells in the vicinity. The present arrangements are satisfactory. 4. Ample arrangements are made for field hospitals. Sick carts and doolies for carrying the sick. Hospital supplies carried by coolies in medicine chests, but the principal supply is carried in carts. The regulations are embodied in the general medical regulations of the Presidency.

FORT ST. GEORGE. MADRAS.

References to Subjects and Queries.	Replies.
XI. Statistics of Sickness and Mortality.	No information.
XII. Hospitals.	1. Plan of hospital for European troops. Hospitals for native troops are in the neighbourhood of their lines.
	2. The European hospital is upwards of half a mile from the Fort where the troops are. The body-guard stables are upwards of half a mile from the hospital. On the opposite side of the main road which forms the northern boundary of the hospital in a very densely-populated village. The site is well open to the S. E., the prevailing quarter for the sea breeze, for nine months in the year. It is bounded on the south and west sides by the Cooam river, from which there arise very unpleasant odours during the dry season, especially as some of the chief drains of the town and minor drains from the penitentiary and other public buildings discharge themselves into the river. Notwithstanding all this, the locality is considered healthy by the medical officer.
	3. The water in the grounds of the general hospital is brackish and unfit for drinking. Drinking water of excellent quality is brought in barrels from a well on the Poonamallee road, two miles from the hospital. There is a well of excellent water about ten yards in the front of the hospital, but it is private property.
	4. There are only two drains for all purposes at the general hospital. The outlet of each is into the Cooam river, about 100 yards from the hospital.
	5. The ground occupied by the wards is raised about one foot, and the wards are surrounded by verandahs on all sides. The floors are of six-inch square bricks, and have no free circulation of air under them. There is no special provision for carrying off the rain water from the roof, but from its proximity to the Cooam river it is easily drained off from the surface. As above stated, the rain water is easily carried off to the Cooam river without any surface drain. The walls are built of brick in chunam, and though the roof is not a double one, it is sufficiently thick to keep the hospital cool, as are also the walls. There is a verandah ten feet broad on all sides which affords good shelter from the rays of the sun. It is provided with rattan blinds. The verandahs are never used for sick, except as a place of exercise. There is only one floor of wards. The following table gives the accommodation:— Total number of wards, 12. Number of beds, 192.

Wards.	Regulation Number of Sick per Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Square Feet per Bed.	Height of Bed above the Floor.	Windows.

Regimental hospital, 6 -	16	81 6	20 8	15 6	22,360	1,397 6	101 6	1 6	4 and 3 doors	7 9	4 5

	The hospitals are under one roof. The wards are in pairs and communicate by seven arches. The hospital is remarkably well placed for receiving the invigorating sea breeze of the coast.* The windows are provided with both batten and Venetian shutters. One opens on the inside, the other on the outside. They are 3½ feet above the ground. It would be advisable to lower them, and thus add to the ventilation of the wards.
	6. There are no roof ventilators, and the wards are entirely dependent on the numerous doors and windows (not stated whether the ventilation is sufficient.)
	7. There are punkahs for cooling the air over the beds.
	8. There are no means of warming. The walls and ceilings of the wards are whitewashed as often as the medical officer may consider necessary. Generally twice a year.
	9. The privies are unfortunately placed on the south side. Tubs only are used. No urinals or water-closets. The general hospital privy is daily washed out and charcoal burned in it. The night-soil is carried away in tubs. There is only one privy drain for urine into the river. No cesspits. Privy not offensive.†
	10. There are two small bath rooms for general hospital, besides washstands holding 12 brass basins in the verandahs. The European regimental hospital has a bath room fitted with brass basins.
	11. The means of bathing consist of large tubs for cold and warm water; the latter conveyed from the cook room. There is a shower bath and douche.
	12. Hospital clothing is washed by native washermen at tanks and watercourses at the outskirts of the town.
	13. The hospital storage is sufficient and dry, but considerable improvements might be made with advantage.
	14. The cots in all European and native hospitals are either wooden frames and broad tape bottoms, or iron frames with iron straps or wooden bottoms. The bedding is of good quality. A few cots for Europeans should be furnished with posts and mosquito curtains.
	15. The cooking arrangements are similar to those already described for the barracks. They promise to act well. The kitchens are sufficiently far from the hospital, but will occupy another position when the hospital is remodeled.
	16. Diet roll, &c. annexed.

* With reference to this reply, his Excellency the Commander-in-Chief, in the Order already cited, desires to add the following sentence, "if the vile stinking river Cooam were not under the very noses of the patients."

† As regards this opinion, the Commander-in-Chief, says in the above cited Order "this can only be said of it recently, a year ago it was odiously offensive."

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	17. Sick are not attended by hospital serjeants in this presidency depôt. They superintend the general arrangements and keep order in hospital. The nurses are male coolies trained for the purpose. Orderlies are obtained when required. Attendance sufficient. 18. The sanitary condition of the general hospital is good. Cases of cholera have appeared occasionally among the patients when that disease prevailed in Madras, but it has never spread. Ulcers have once in five years shown a tendency to gangrene when whitewashing has been neglected. 19. There are no deficiencies of any moment; all minor defects will be remedied when the general and European hospitals (regimental) are remodeled, which they are about to be. 20. There is not sufficient exercising ground for convalescents, but that defect will soon be remedied. They are conveyed in doolies and bullock carts to the sea beach morning and evening, where they can walk and enjoy the sea air. 21. Sick wives and children of soldiers have a good detached ward next their regimental hospital; and midwifery cases are taken to the lying-in hospital. The existing arrangements are not satisfactory, but they will be when the contemplated improvements are carried out. 22. There are no special local hospital regulations beside the general regulations. 23. As regards the power of the medical officer over building repairs, sanitary improvements, diets, comforts, &c., the medical officer can only report to superior medical and military authorities. 24. There are no convalescent wards at present, but they will be included in the contemplated remodeling of the hospital.
XIII. Burial of the Dead.	1. The cemetery where the Europeans are buried is about a quarter of a mile from the hospital and half a mile from the barracks in the Fort. It is situated S.W. by S. of the hospital and W. of the Fort. Prevailing wind S.E. for nine months in the year. 2. The area of the cemetery is about $7\frac{1}{6}$ English acres. Sandy soil and subsoil. Decomposition appears to take place readily. There is no offensive odour, and the place is well kept. 3. The grave space is 7 feet by 3, with 2 feet between the graves. Depth of graves, 6 feet. Re-opened every third year; bodies readily decompose in that time. No compulsory time of interment. Burial takes place here 12 to 24 hours after death. Hindoos and Mohammedans always bury within 12 hours after death, and frequently immediately. Burning, when it is had recourse to, is within six hours after death. 4. The burial-ground is never offensive. The native grounds are offensive frequently, from overcrowding, as at Triplecane. 5. The dead of camp followers and bazaar people are immediately buried. 6. In camp especially, bodies are superficially buried, and succeeding troops are liable to suffer from encamping on the same ground. 7. No suggestions, except that officers should be prohibited from burying or allowing burials to take place in the immediate vicinity of permanent camp grounds.

(Signed) W. A. McCleverty, Major-General Commanding Fort St. George.

J. McKenna, M.D., Deputy Inspector-General of Hospitals.

Madras, 25th September 1860. H. W. Hitchins, Captain, District Engineer, Madras.

SAINT THOMAS' MOUNT.

Accommodation, Queen's Troops, Artillery, 600.

References to Subjects and Queries.	Replies.
I. Topography.	1. The surrounding country is an open level, with occasional small hills; the aspect is varied by villages and tanks scattered about. The hills do not form continuous ranges, but rise abruptly from the plain and stand isolated; they are covered with small shrubs, the soil not being good enough, or of sufficient depth, for the growth of trees. A small hill is in the middle of the cantonment, and the buildings are erected on the slope, from the foot towards the lower country round; it has a natural drainage and is dry. There is a swamp to the south-east, running parallel to the coast. There is no jungle or water in the vicinity. 2. The elevation of the station above the sea is 60 feet. It is 18 feet above the adjacent country, and 46 feet above the river Adyar. The ground to the west towards Palaveram is high and open, and would, in my opinion, be preferable to the present site of the barracks, viz., at the foot of the Mount Hill. 3. St. Thomas' Mount rises close behind the barracks, and is about 180 feet above the parade ground. 4. The nearest water is the river Adyar, which runs on the north and west sides of the cantonment, distant about half a mile from the west, and varying from 1 to half a mile on the north side. The vicinity is not liable to overflow of water. There are no ravines or pits near the station. 5. The station is open in many places, but in others the superabundance of trees prevents ventilation. St. Thomas' Mount, which rises close in the rear, also not only impedes ventilation, but increases the temperature of the barracks by day from reflected heat, and prevents the temperature from falling during night by radiation. The station is exposed both to the sea breeze and land wind, the former of which is conducive to health. 6. The country is cultivated in patches about the cantonment. There are numerous tanks all round, which are used for the purposes of irrigation. Artificial irrigation is probably in some instances productive of fever. The cultivation of rice is not prohibited within limits. Indigo is not cultivated, nor is the preparation of hemp or flax carried on near the station.

Saint Thomas' Mount. Madras.	References to Subjects and Queries.	Replies.
	I. Topography—*cont.*	7. The native town lies close on the east side of the station. 8. The geological structure of the district is gravelly. The cantonment has occupied its present site for 80 or 90 years, having been previously occupied by native population. 9. The depth below the surface at which water is found is 6 feet in the rainy season. 10. The rain-fall and water are rapidly absorbed in the soil. The drainage from St. Thomas' Mount passes into the subsoil of the station. 11. The water supply of the station is derived from wells, and is not stored in open tanks. The tanks outside the station are filled to overflowing during the rainy season; but are nearly all of them dried up during the hot season. No tank used for drinking purposes is used for bathing, They are not liable to pollution from leaves or other matter falling into them, or from foul drainage passing into them. There are no tanks in the station, but I consider it probable that some degree of malaria is produced by those in the neighbourhood. A belt of trees round each tank would probably obviate the effects of the malaria. 12. The supply of water from the wells is abundant. The water from some is brackish, and unfit for drinking purposes, while that of others, within a very short distance, is excellent. Those used for drinking purposes contain excellent water. It is raised by windlass and bucket. 14. The only portion of this query I am able to answer is, that new stations are selected by a committee.
	II. Climate.	1. The instruments available at the station for conducting and registering meteorological observations are a barometer, thermometer, and pluviometer. 2. (No meteorological observations transmitted.) 3. The climate is dry for at least nine months, and hot all the year round, varying from 71° as a minimum to 95° as a maximum. There are heavy rains during the months of October and November, when the north-east monsoon prevails, and occasional showers from July till September. The average annual fall is between 30 and 40 inches. The climate is very equable; fogs rare. There is considerable damp during the north-east monsoon, and in a lesser degree during the south-west monsoon; tree-planting is superabundant. There is considerable irrigation of rice grounds; but it does not perceptibly influence the climate. The air is very dusty during the dry season. The effect of the climate on the health of the troops is debilitating from the excessive heat. A moderate admixture of animal and vegetable food; the total abolition of spirituous liquors, and the substitution of a moderate quantity of malt; woollen clothing during the prevalence of the rain and cool season; drill in the morning alone, to be finished before the sun has acquired much power; and the evenings to be given to the soldier for his recreation and exercise, are the precautions necessary to avoid its influence. The most grave and fatal forms of disease prevail from October to the end of December. The healthiest months are January and February. Fever, dysentery, and hepatic disease are the most prevalent during the unhealthy months. 4. There is no district near the station, the climate of which is more conducive to health. 5. The following are the stations at which I have served:—Neilgherries, Sholapore, Trichinopoly, Saint Thomas' Mount, Rangoon, and Quilon. I have named them in the order of their comparative salubrity. I do not consider any of them to be positively injurious, except from the fact of their being tropical climates. The only one positively conducive to health was the Neilgherries.
	III. Sanitary Condition of the Station.	1, 2, 3. A map of the station, adjacent country, &c., has been forwarded. 5. There are windows on both sides of the barrack rooms, which open outwards. There are verandahs on both sides. They are never occupied as sleeping quarters by soldiers or other persons. There are no jalousies or jhilmils. 6. Both iron and wooden cots are used in barracks. 7. The tents used in camp are double-poled, to contain 25 Europeans. 8. The ventilation of the barracks, &c. is effected by an opening in the roof, and is sufficient. Punkahs hung from the roof, in shape like a door, are used for cooling the air of the barrack rooms. 9, 10. The materials of which the barracks are constructed are bricks. The tents are of canvass, and the huts are built of mud. The floors are made of chunam or brick. 11. The barracks are too low, being only 12 feet high, and therefore unsuited to the climate. Every barrack in this country ought to have an upper story, or to be sufficiently elevated on arches so as not to require it. The barracks and cantonment are kept in repair by the engineer officer. The walls and ceilings are cleansed and limewashed when required; generally annually. 12. Each lavatory contains a tub filled with water by a bheesty or water-carrier, in which the men wash; this practice should be abolished and a sufficient number of basins supplied instead. 13. Cook-houses of the usual construction. The linen is washed and dried out of barracks by washermen, quite sufficient for the wants of the station. 14. The urine is collected in tubs and thrown into a drain. The solid sewage is carried away daily to a considerable distance from the hospital. 16. With regard to the draining and sewering of the barracks, the drains are only flushed by the emptying of the bath rooms and the rain. These means, however, are insufficient, and consequently the drains are frequently in a filthy condition. No part [of the barracks or hospital is damp. The fluid refuse is conveyed away by drains to a very short distance from the barracks and hospital, where it is allowed to sink into the soil. There are no cesspits. There is a foul ditch close to the outer wall of the hospital, which the engineer officer is engaged in rectifying. 17, 18. The cantonment is kept very clean, and the surface is freed from vegetation. There are numerous hedges about the cantonment which certainly impede ventilation. 19. The sanitary condition of the bazaar is bad, being narrow, crowded, and badly ventilated. Each person is responsible for the cleanliness of the front and rear of his premises. The condition of the native houses near the station is good. There are no cesspits or dung heaps within them. No nuisance is experienced from the wind blowing over the native dwellings. 20. The animals for the use of the soldiers are slaughtered a long distance off from the station.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of the Station—*cont.*	21. There are no stables in the bazaar, nor are cattle allowed within it. 22. There are no stables in use by the artillery. The picketing ground is some distance from the barracks. Horses are picketed in lines, parallel to each other. 23. The quarters for married non-commissioned officers and men are insufficient; others are being erected.
Officers' Quarters.	1, 2. The sanitary condition of the officers' quarters is very good. No improvements are suggested.
IV. Health of the Troops.	1. The station and the district in which it is situated is healthy, as also is the native population. 2. The most prevalent disease among the natives is fever of the intermittent character. Cholera and small-pox occasionally break out in an epidemic form. Spleen disease rarely occurs. 3. These diseases are due to crowding, want of ventilation, and filth. 4. Troops are received at this station from England and all parts of the Madras presidency, it being the depôt of the sick of the Madras Artillery and Company's European regiments. The barrack-rooms known as the troop lines are greatly superior to those already described as close to Saint Thomas' Mount, being in a much more open position, and one of them very lofty. 5. Troops are camped out when the barrack accommodation is insufficient for their number. 6, 7, 8. With reference to hill stations, and their effect on health, I have no experience, for although stationed on the Neilgherries, I was not in charge of troops, but I believe it is an established fact, that long residence on those stations renders troops more liable to febrile and other diseases on returning to service on the plains. I approve of the selection of hill stations for troops. 9, 10. The diseases peculiar to hill stations are pulmonary and bowel complaints. The precautions necessary to guard against such attacks are, to avoid getting wet, by wearing warm clothing and stout boots and shoes. 11, 12. With reference to the seasons best adapted for residence on hill stations, they vary with the position of those stations in India. The shortest period of residence to obtain any benefit from them, should be not less than two years. 13. The special precautions for the preservation of health of troops on leaving hill stations for the plains are, adaptation of clothing to the climate, to avoid unnecessary exposure to the sun, and to reduce the quantity of their animal diet. 14. I am of opinion, that long periods of service on the plains should alternate with short periods of service on the hills. Frequent change of station on the plains is beneficial to the health of troops and convalescents. 15, 16. With regard to barrack and hospital accommodation on hill stations, that provided at Jackatalla, on the Neilgherries, is excellent. My experience is confined to Jackatalla. 17, 18. There is no higher ground near the station, which could be advantageously occupied as a hill station. No particular classes of surface and subsoil are more healthy for stations than others. 19. Soldiers should not proceed to India under 21 years of age, but 25 would probably be the best age. The best period for landing is January. Upon first landing, they are put into barracks, dieted, &c. To preserve their health, they should be clothed lightly in hot weather; all unnecessary exposure to the sun avoided; the stiff stock should be entirely dispensed with, and they should be prevented from having access to spirituous liquors and the unripe fruits of the country. 20. A previous period of service at the Cape or New South Wales would prepare troops for service in India. On landing in India they should, in the first instance, be sent to the coolest station on the plain, from thence brought to the hottest stations, and after a certain period of service there, sent to the hills. 21. Troops are usually marched from the port to the interior. Every precaution is taken to preserve their health. 22. As a general rule, from 15 to 20 years is the period a British soldier should serve in India. 23. The manner of conducting medical boards could not be improved. 24. Invalids should leave India so as to reach England at the commencement of summer.
Diseases.	1, 2. There are no regular inspection parades for the discovery of incipient diseases. There has been no scorbutus at the station. 3. The proportion of cases usually under treatment for hepatic disease is from four to five. It is caused by long-continued solar heat and intemperance; it is frequently the result of fevers, and the prophylactic measures are, the avoidance of stimulants and of exposure to the sun, and the careful protection of the body while on night duty. 4. Dracunculus has very seldom come under my observation. 5. The proportion of venereal disease to the total sick in hospital is 7 in 54. The precautions for diminishing the disease would be the removal of all diseased women from the cantonment, or treating them in a lock hospital. 6. The troops at the station suffer from the fevers and bowel complaints of the country, but not in an unusual proportion. 7, 8. In fevers, head symptoms prevail, and in dysentery the mucous membrane of the large intestine suffers. Fevers and dysentery are most prevalent during the monsoon, and hepatic complaints during the hot season. I have remarked no particular climatic or atmospheric change beyond those ordinarily accompanying the seasons at which those diseases occur. The sanitary condition of the bazaar is bad, as before stated. The personal habits of the troops predisposing to these diseases are, drinking spirituous liquors, exposing themselves carelessly to the night air, and eating unripe fruits. 9. Quinine has not been tried at this station as a prophylactic against malarial diseases. 10. Well ventilated and capacious barracks and hospitals, proper drainage, proper latrines, and abundance of water for the purposes of ablution, avoidance of exposure to the sun, protection from night air when on guard, wholesome and nutritious diet, abstinence from spirituous liquors and the substitution of malt liquor for the same, would prevent or mitigate epidemic disease at the station.

SAINT THOMAS' MOUNT, MADRAS.

References to Subjects and Queries.	REPLIES.
V. INTEMPERANCE.	1, 2. There are no returns to show the temperate or intemperate habits of the soldiers kept in the station; they are kept by the regiments, and there is no regiment here now to afford the information. The Europeans stationed here are all recruits lately joined. Drunkenness is always punished as an offence. 3. Distilled spirits are not sold in the canteen, but in the bazaar, under civil authority. Spirits are not allowed to be sold to Europeans. Soldiers are permitted to draw two drams of arrack at the station, and the same on march or in the field. No liquor is issued till dinner time (one o'clock). It depends upon the surgeon whether spirit is given as ration to convalescents. No deleterious drinks other than intoxicating drinks are sold at the bazaar. 4. The consumption of spirits, if taken in moderation, is conducive to health and discipline. 5 to 9. It would be beneficial to abolish the use of spirits as part of the ration, if malt liquor could always be issued. Wine and malt liquor are preferable to spirits in their influence on health. Tea, coffee, lemonade, and similar drinks, are much used at the station. There is no difference in their influence on health, as compared with spirits and malt liquor, if the latter are taken in moderation. 10. The canteen funds are insufficient to provide amusements to keep the men from drinking. 11. The canteen and bazaar regulations are prescribed by general orders. No station orders exist.
VI. DIET.	1. The rations for Queen's troops and European troops in the Indian army are the same, and consist of— 1 lb. of meat (beef or mutton). | 1 lb. of vegetables. 1 lb. of bread. | Tea or coffee. A responsible inspection is made of the constituents of the ration. 2. The stoppage is 6 rs. 5 annas 4 pie per month. The soldiers have two meals a day:—Breakfast at 8 a.m., dinner at 1 p.m. 3. No improvement is suggested in the ration. Arrangements are made for preventing it being disposed of by the troops. It is issued to the soldier cooked, at meal times, at meal parades. 4. The cooking is performed in pots and pans, which are the only means and apparatus available. There are no kitchens, only cooking houses. The food is both boiled and roasted, and is properly done and sufficiently varied. The men have coffee half-way on the march. 5. Gardens for the cultivation of vegetables by the soldier could be advantageously established near the station, under such regulations as may please the men; there should be no compulsion.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldier's dress consists of cap, coat, trousers, boots, pouch, and sword belt. It is very well adapted in all respects for the climate. No improvement is suggested.
Duties.	1. It would be advantageous if the men were drilled at home before being sent to India. 2. The usual routine of soldiers' duties is one hour drill morning and evening, but generally only in the morning three times a week. The best time for drill, parade, and marching is in the early morning. The hours are prescribed by general orders. The men have three nights and upwards in bed during the week. 3. The distance at which guards are mounted depends on circumstances. Guards last 24 hours. Rolls are called during the day, but not at night. Health is not affected by night guards.
VIII. INSTRUCTION AND RECREATION.	1, 2. The following are the means of recreation and instruction:—There are ball courts, skittle-grounds, schools with good schoolmasters, and a library and reading rooms, lighted at night. There are no day rooms or soldiers' clubs, neither are there any soldiers' gardens, workshops, theatre, or gymnasia. The means are sufficient to keep the men occupied during the wet season and heat of the day. There is no restriction on the men as to exposure to the sun and rain when off duty; few men like going out at those times. No improvement is suggested in the existing means of recreation. 3. There is a government savings' bank. 4. There is not sufficient shade from trees, &c. to enable the men to take exercise without injury during the day.
IX. MILITARY PRISONS.	1. There is no military prison, but cells and rooms are attached to battalions.
X. FIELD SERVICE.	1. There are no local regulations for medical field service not included in the general presidency regulations. 2, 3. As regards the conduct of the line of march of troops, bivouacking, camping, &c., the medical officer is consulted on these points by the commanding officer. Encamping grounds are fixed sites, so as not to interfere with cultivation. The encamping space is sufficient only for one regiment. 4. Arrangements are made for the transport of the sick according to the strength of men in the corps.
XI. STATISTICS OF SICKNESS AND MORTALITY.	I have no documents to enable me to answer questions under this head.
XII. HOSPITALS.	1, 2. The hospital is well situated, and faces the N.E. It is at right angles with the barracks, only the main road intervening. The bazaar is about 500 yards from it in a northerly direction, and the houses of the civil population are distant about 800 yards. The site is open, but imperfectly ventilated, owing to its being surrounded by a wall and outhouses; the former could be lowered with advantage to two feet, and surrounded by a railing. The hospital labours under the same defect as the barracks, being too close to the mount. The situation, with the above exceptions, is healthy. 2. The water supply is abundant and wholesome. 4. The drainage of refuse water and other impurities is effected by open drains leading into another drain outside the hospital precincts.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	5. The lowest wards are raised about 5 feet from the ground. The wall surrounding the hospital prevents the free perflation of air through the lower wards. The roof water is conveyed away by drains. There is a large open chunam drain outside the hospital, which receives the rain water from it, and carries it rapidly away. The hospital is built of bricks and chunam; the roofs and walls are single, but sufficiently thick to keep the hospital cool. It is surrounded on three sides by a jalousied verandah, 10 feet wide, and enclosed behind. The verandahs afford sufficient shelter from the sun's rays. They are sometimes used for the accommodation of sick when the hospital is crowded. The hospital consists of two flats.

Table of Accommodation.

Wards.	Regulation Number of Beds per Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
4	18 each	Lower ward 60′	Lower ward 16′ 10″	Lower ward 21′	Lower ward 21,210	Lower ward 1,178	19ft. 72in.	1ft. 4in.	Lower wards 6 on each side.	Lower wards 6 ft.	Lower wards 3′ 8″
		Upper ward 61′ 3″	Upper ward 18′	Upper ward 16′ 3″	Upper ward 17915·7·6	Upper ward 995			Upper wards 9 on each side.	Upper wards 5′ 7″	Upper wards 5′ 8″
Two side rooms.	Each can contain 4.	28 ft. each.	12′ 6″ each.	12 ft. each.	4,200	1,050					

The hospital is situated so as to receive the full benefit of the prevailing winds. The windows open outwards, and their arrangement and construction is conducive to ventilation and coolness.

6. The ventilation of the wards is effected by means of windows and ventilators in the wall. The means are sufficient to keep the wards airy.

7, 8. The air admitted to the wards is cooled by means of punkahs and grass tatties during the prevalence of the land wind. There are no means of warming the wards.

The walls and ceilings are cleansed and limewashed about once a year.

9. The privies belonging to the hospital are small outhouses, with a covered way. There are bed stools for bad cases. The privies are placed over cesspits.

10. The hospital has an outhouse for lavatory purposes, which contains a bath.

11. The sick are bathed in a bathing house; the arrangements for this purpose are quite sufficient.

12. The hospital clothing is washed and dried by a washerman outside of the hospital.

13. The storage is sufficient and dry.

14. The bedsteads and cots in use in the hospital are constructed of iron and wood.

15. There is a cooking house detached from the hospital, and the diet is cooked in pots and pans; there is no apparatus.

17. The attendance provided for the sick is as follows:—1 hospital serjeant, 1 conicopoly, or purveyor, 1 tailor, 1 cook, 1 cook's mate, 4 ward coolies, 3 first-class coolies, 4 sweepers, 4 toties, and 2 female nurses (one European and 1 native). The attendance is sufficient.

18. The sanitary condition of the hospital is good, and no epidemic disease has appeared in it.

19. The only defect is the imperfect ventilation of the lower wards of the hospital from the surrounding wall.

20. The provision made for the exercise of convalescents is by sick carts and doolies; seats are set apart for their use in the verandahs and on the top of the hospital.

21. Soldiers' sick wives are treated in hospital. The present arrangement is satisfactory.

23. The powers of the medical officer in respect to the repairs of the hospital are confined to a representation of any defects that come to his notice. In matters relating to the sanitary state of the building, change of diet, and medical comforts, at stations, camps, and on the march, he possesses full powers.

24. There are no convalescent wards, and I do not think such accommodation would be an advantage.

XIII. Burial of the Dead.

1. The burial-ground is in the station about three-quarters of a mile from the nearest barrack. It is situated on the north side, the prevailing winds being on the opposite side of the compass.

2. Its area is about 150 yards by 100. Decomposition does not take place readily. The soil is all gravel. The ground is carefully kept.

3. The grave space allowed is 7 feet by 2½ feet, and the interval between the graves is 2 feet. They are 5 feet deep. The graves are never re-opened. Only one body is interred in each grave. Interment is compulsory, at all times, at or before sun-rise or at sun-set. There are no rules with reference to burial-grounds used by native troops.

4. The grave-yard is never offensive.

5. The dead of the bazaar people and camp followers are disposed of outside the cantonment.

6. No injury to the public health accrues from the present practice. No improvements can be suggested in the burial or disposal of the dead.

(Signed) E. Amsinck, Brigadier,
Commanding Mount.
Arth. S. Moberly, Captain,
District Engineer of Chingleput.

15th April 1860.

BANGALORE.

Accommodation:
- Queen's Troops: Artillery - 215; Cavalry - 729; Infantry - 745.
- Native Troops: Artillery - 235; Cavalry - 339; Infantry - 2,090.

References to Subjects and Queries.	Replies.
	(*The following answers are by the Deputy Assistant Quartermaster-General of the Mysore Division.*)
I. Topography.	1. The general aspect of the country surrounding the station is open, with topes of trees, and tanks scattered about. It is undulating, the high ground being dry and sandy, and the low ground swampy in the rains. There is no wood or jungle in the vicinity, but numerous tanks of all sizes.
	2. The elevation of the station above the sea is 3,000 feet; and in parts it is higher, and in parts lower than the adjacent country. One part of the station is nearly on a level with the Ulsoor tank, while other parts are 200 feet above it. There is higher ground near the station, but none with any advantages over Bangalore in a military point of view.
	3. Nundydroog, 36 miles distant from the station, is 1,600 feet above its level, and is one of several small hills. The Commissioner has a house on Nundy, where there is water, which is also to be found on one other hill also.
	4. Small tanks surround the station at all distances. There are no rivers, but numbers of small nullahs, which are dry in the hot season; there is no marsh. The vicinity is not liable to overflow. There are several ravines round the station caused by the rush of surface water in the rains; but they have no bad effect on the health of the station.
	5. The station is pretty open, freely exposed to winds, and not much encumbered by trees, hedges, gardens, or higher ground. All trees and hedges are kept topped to a certain height, so as not to interfere with the ventilation. All buildings of large extent must raise the temperature of the air about them. In Bangalore this applies to barrack squares. Variable, but scarcely to be called cold, winds blow through the station. There is no sea breeze, and the land wind is not hot like that up the country. The winds are very dry, and conducive to fever diseases.
	6. The country surrounding the station is cultivated; but there are no works of irrigation further than those in general use in India for irrigating small fields and gardens. No rice cultivation is allowed in military stations; but this being a civil station, it cannot be prevented by military authorities. None worth mentioning, however, is cultivated. Neither the cultivation of indigo, nor the preparation of hemp or flax is carried on near the station.
	7. The fort and native town are distant about one mile from the station.
	8. No reply to this query.
	9. Water is found at different depths, according to the level of the surface of the ground. It is generally to be obtained at some 15 feet lower in the dry than in the wet season.
	10. What water does not come in the tanks soaks in the surface, and remains at a certain level, according to the season and the height of the water in the nearest tank. There seem to be no springs, and all wells are supplied by this surface water till used up. There is some adjacent higher ground, the drainage of which flows into two tanks in the station.
	11. The supply of water for the station is derived from wells and tanks, but is not stored at all. In monsoon time all the tanks in the country are full after a sufficient quantity of rain has fallen; but in the dry seasons they get gradually smaller. Water lilies, weeds of all descriptions, fish and frogs in great quantities, abound in the tanks and wells. All the open tanks in and about the station are used by the natives both for drinking and bathing purposes. The water for Europeans is taken from wells. These latter are open, and when they get dirty are cleaned. The Ulsoor tank, which supplies drinking water to the greater portion of the native population of the place, is the outlet for the whole drainage of a most filthy bazaar of both the cavalry, infantry, horse artillery barracks, and of the greater portion of the station. It is in a most filthy state. This tank in the dry season is a great nuisance. (*Remark by the Commander-in-Chief.*) "The disgustingly filthy nature of the source from which the water used at Bangalore is taken has been brought to notice scores of times by me within the last 4½ years, but, as usual, nothing has been done to remedy this most crying evil." (Signed) P. G.
	12. All drinking water is raised from wells, some in the compounds, some is carried on bullocks, and some in water carts. Colonel Cotton is now organizing a scheme by which water could be brought in at a high level to the station from Nundydroog, 36 miles off. Should his scheme be practicable, and succeed, it will be a great boon, as though the station is never actually at a loss for water, still in the dry seasons the supply is by no means abundant.
	13. I am not aware of any other topographical points bearing on the health of the station not included in these queries.
	14. New stations are generally selected after the fullest inquiry by Government through its officials, both civil, military, and medical. When a position is selected, the Quartermaster-General's department carries out the details. I can suggest no improvement in the manner of conducting this service.
	(*The following answers are by the Deputy Inspector-General of Hospitals, Mysore Division.*)
II. Climate.	1. Meteorological observations have been made at many of the hospitals in the station for many years past, but the instruments have in most cases been of inferior construction, and the observations not having been made upon a definitely arranged plan, it is not possible to construct from them any table of observations for a long series of years.
	2. The following very accurate table of observations can be given for the year 1859, to which certain notes are appended, which embody the most important points of the observations of previous years. (Data can be had for forming a table of observations for five years from 1830 to 1835, at page 62 of the Medical Topography of Malabar, Canara, and Mysore, compiled by the Madras Medical Board.)

TABLE of Meteorological Observations from 1st January 1859 to 1st January 1860.

II. Climate—*cont.*	This season was an unusual one, the rain being 10 inches less than the average 35·41 inches of 25 years. The rainy days, however, were more numerous, 118 to 77; but this arises probably from the use of an instrument which registered even minute falls, whilst in former years small falls were not noted. The thermometric observations were taken with a maximum and minimum instrument in the shade of an open verandah. The maximum noted was 97°, and the minimum 55°·50; the mean sun temperature was not ascertained. The average temperature during the year inside another house and by different instruments was found to be 74·53. The temperature of spring water taken from a well 63 feet deep at 9 a.m., 28th April, was 75·45. The average temperature of the years 1805–06 is given 75·13, and from Heynes' Tracts the average highest range of the thermometer when exposed was 106°·33, and the average lowest when exposed 63°·58. This was for five years (1831–35). 3. The climate of Bangalore is one of the best in India, owing to its physical situation in the middle of the open, undulating, cultivated plain, the heat of which is tempered by the light rains and clouds brought by the monsoons, and by the elevation above the sea of 3,000 feet. The sun's rays are generally powerful, but in the shade and at nights the temperature is moderate, and in November, December, January, and part of February the cold is so great as to render warm woollen clothing in the day pleasant and blankets at night necessary. The atmosphere is rarely very damp, for there are no extensive sheets of water or swamps in the neighbourhood, and the rains, though protracted in their period of falling, are rarely heavy. The natural dryness of the air in the hot months of March, April, and May is, however, lessened by the existence of numerous artificial lakes or jheels, varying from 50 yards to half a mile or more in diameter, all over the country neighbouring the station. In the wet months of June, July, and August the sky is generally so overcast with dense clouds, that exercise in the open air during the day may often be taken with impunity by Europeans if suitably clothed. Thunder storms are frequent in April, May, August, and September, and occasionally in June, July, and October. But though the climate be so generally agreeable to the feelings of a European, it is necessary that he should remember he is in the tropics, and not expose himself much to the sun, which is so hot that the alterations of temperature in the open air between day and night are very great, and must be trying to any constitution exposed to them. The climate is most favorable to the health of the troops, and, from the experience of many years, shows that the mortality among European troops stationed at Bangalore is less than in almost any other station in the south of India. Severe fevers are rare, cholera seldom commits great ravages, and though hepatic affections and dysentery are to a considerable extent suffered from, it is probable that they may principally result from indiscretions or exposure in a climate which, though pleasant, is still tropical by situation and in character. The fine cool climate permits of the cultivation of potatoes, cabbages, &c., so that the troops have at Bangalore the advantage of a plentiful supply of wholesome vegetables. Officers at Bangalore generally enjoy excellent health. European children thrive till 8 or 9 years of age, and many instances can be adduced of children born and reared in the place having attained able-bodied maturity. In consequence of the comparative coolness of the climate more exercise may be taken, and the clothing should be warmer at times than in the hotter climates of the plains of south India. The more healthy months are the dry months, viz., December, January, February, March, and April, and two in the middle of the rains, August and September. The most healthy months are February and March, and the most unhealthy are those at the commencement and end of the rains, May, June, July, and again October and November. The prevailing diseases as influenced by climate are catarrhs and fevers, hepatic affections, cholera, and dysentery. 4. There is no other district near the station the climate of which is more conducive to health, but there is a great extent of country round about, where the climate influences would be equally favourable to health; and there are a few flat-topped hills near, as Nundydroog, where small sanitaria for invalids might be established. 5. The following is a list of the stations at which I have served, viz., 1829, Trichinopoly, D.D. H.M.'s 89th regiment; a very hot and dry climate, particularly favourable to natives. 1834, Palaveram, 27th regiment native infantry, within 12 miles of Madras and Bangalore, one of the most healthy and agreeable climates in the Madras Presidency, and well suited

II. Climate—*cont.*	for troops lately arrived from Europe; still there are a greater number of diseases existing there than in most of the warmer stations, owing to the greater variety in temperature. 1837, Arcot, 5th regiment light cavalry, in the Carnatic, within 70 miles of Madras, a cavalry brigade station, generally healthy, but subject to periodical attacks of cholera. 1840, Bellary, 5th regiment light cavalry, a hot and dry station. While a European regiment was stationed there, with all its followers in the fort, the place was seldom, if ever, free from cholera, but latterly very fine barracks have been built in the open plain, and since that the station has become one of the most healthy in the Presidency for European troops. 1843, Sholapore, 5th regiment light cavalry, in the Bombay Presidency, generally considered one of the worst stations; extremely hot and disagreeable from about the 10th March to the end of May, after which it becomes tolerable enough, and in December and January is very cool and agreeable. 1847, Jaulnah, 5th regiment light cavalry, a very fine climate, situated in the Hyderabad territories, principally occupied by native troops, and generally remarkably healthy. 1850, French Rocks, 1st regiment native infantry, much the same climate as Mysore or Bangalore, garrisoned by one native regiment. 1851, Bellary, 1st regiment light cavalry. 1853, Bangalore, 1st regiment light cavalry. 1856, Vizagapatam or Waltair, as garrison surgeon; a civil station situated in an elevated rising ground, and projecting somewhat into the sea, so that a sea breeze is felt on three sides, rendering the climate delightful and healthy. 1857, Madras, as superintending surgeon. 1858, Malabar and Canara, as superintending surgeon, and from that removed to the centre division, and on that division being abolished, I was ordered to Bangalore (where I am at present stationed) as deputy inspector-general of hospitals.
III. SANITARY CONDITION OF STATION.	1. (*Answered by Deputy Inspector-General of Hospitals, Mysore Division.*) A photograph of plans of the station and surrounding country is in the quartermaster-general's office. 2. There is a photograph of plan of the station itself in the police office; but there is no plan in existence that shows all the minute details wanted, nor could one be drawn, unless after a careful survey, I believe. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) Some of the drains about the barracks are covered, some are open. Most of these are built of masonry, and all have a free outlet into the principal tank of the station, not greatly to the advantage of the native population, who use largely for drinking purposes the water of the tank in question. The wells in the different compounds are innumerable, and each house has its own dung-heaps and ashpits. There are no public privies or urinals except those in the European barracks. 3, 4. Particulars of accommodation in the various barracks at Bangalore.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	5. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) The windows of the barracks are on opposite sides, and open to inside. The Dragoon and Artillery barracks have verandahs 12 feet either side. The Infantry barracks, a verandah on each side 10 feet wide. The verandahs are never occupied as sleeping quarters by soldiers or other persons. The Dragoon and Horse Artillery barracks have jalousies and jhilmils to them but there are none to the others. 6. The bedsteads used are planks laid on wooden tressels. The bedding is good, and I can suggest no improvements, with the exception that iron bedsteads would be better than the wooden ones. 7. No reply to this query. 8. The ventilation in the different barracks varies considerably. In all new buildings, &c., there is both roof and floor ventilation; in tents there is none. Huts are not used in India. Generally speaking, the ventilation is sufficient to keep the air pure by night as well as by day, but some old buildings are defective. There are no means used in Bangalore for cooling the air of barrack rooms. 9. The barracks are constructed of stone and mortar, and bricks and mortar. The tents are made of strong country cloth. 10. The floors of the barracks are made of flags or of chunam. Some are raised from and others level with the ground. Being of stone or chunam, there is no passage underneath, though some of the floors are raised as much as three feet above the ground. 11. The material and construction of the barracks and tents are suitable to the climate, and I can suggest no improvement. The roads of the cantonment are under the Executive Engineer, the parades under the Deputy Assistant Quartermaster-General, and the whole is under the supervision of the officer commanding the division. When barracks require repairs, the officer commanding the troops occupying them applies to the Deputy Assistant Quartermaster-General of the division, who, with the sanction of the General commanding, orders the Executive Engineer to have them executed. Repairs are generally quickly done. European barracks are whitewashed once a year inside, and once every two years outside; but should it be necessary on sanitary grounds, it is done oftener. 12. No reply to this query. 13. All linen in India is washed by washermen, who do the work in their own houses, and in an efficient manner. 14. No reply to this query. 15. The privies, &c., are ventilated by roof ventilators, and are lighted at night by oil lamps hung from the ceiling. 16. All the barracks in Bangalore are drained through open drains. The distance of the outlet being the Ulsoor tank, varies, but in no case is more than half a mile. The drainage is sufficient to carry away the surface water, &c. &c., readily. Neither the barracks nor hospitals are damp. The drainage is quite sufficient; but the outlet, as before mentioned, is in a large tank, much used by the natives for all purposes. There are no cesspits in the station. The drainage from both the European and Horse Artillery barracks flows into the Ulsoor tank through open drains. 17. (*By Deputy Inspector-General of Hospitals, Mysore Division.*) The natural formation of the ground on which the cantonment is situated is so favourable to drainage, that there are no swamps or even (decidedly) damp situations within the bounds. The surface drains, &c., along the sides of the roads are quite sufficient to carry off what rainfall there is. The houses of the officers are scattered widely over a large extent of ground, and are built separately, each one in the centre of a moderate-sized garden or compound. The refuse and manure from these are perhaps not removed so regularly as is desirable, but they are from time to

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	time used in manuring the gardens, or carried off to the neighbouring country by the cultivators. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) The surface drainage is good, but all is unfortunately carried into the tanks, the water of which is, as I before stated, largely used for drinking purposes. Refuse is carted away to the country daily. 18. (*By Deputy Inspector-General of Hospitals, Mysore Division.*) The surface of the cantonment has become rather overgrown with shrubberies in the officers' compounds. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) The surface of the cantonment is kept free of all rank vegetation which might be injurious to health. (*By Deputy Inspector-General of Hospitals, Mysore Division.*) There are scarcely any old walls or hedges in the place which materially interfere with the ventilation. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) There are no old walls, hedges, &c. in the station. In the bazaar a good deal might be removed with decided advantage. 19. *By Deputy Inspector-General of Hospitals, Mysore Division.*) The cantonment of Bangalore has, according to a census in 1859, a population of 124,660 natives and 3,306 Europeans and East Indians. The native population is chiefly located in the general bazaar, and the villages of Ulsoor and Shoolay. The two former are close to the European barracks; the last is at a considerable distance. About three-fourths of the whole live in the bazaar, which is situated close to the north of the European Infantry barracks, and is a densely-crowded town, which has sprung up since the formation of the cantonment. This bazaar is situated on sloping ground, well adapted for drainage, and its main streets are lined on either side with open stone-built drains, but the various lanes are partly undrained. The main streets are of fair width, but generally the crowding of the houses must interfere with the general ventilation. Water is obtained from wells and tanks, and is generally sweet and good, though in some wells it is brackish, and in many there must now be organic impregnations by filtration from the surface. There are no public necessaries, the natives resorting to open spaces near for the purposes of nature. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) The sanitary condition of the bazaar is very bad indeed; there is neither sufficient ventilation nor drainage, and the water supply is not wholesome, owing to the amount of filth percolating into the wells from bad drainage. There are no latrines, and the houses are much too crowded. (*By Deputy Inspector-General of Hospitals, Mysore Division.*) A small scavenger establishment with carts is kept up to sweep out the street drains, &c., and remove the offal outside the town. Public necessaries have recently been ordered to be built. Tanneries and slaughter-houses to be removed to outside the town. A plan is being carried into effect for removing the sewage of the place by a large main drain to a distance, and for storing water in a tank above the town for the purpose of flushing this and other drains. A good deal might be done in increasing the number of drains, in building them properly, and in opening out the town by main and cross streets. Covered drains would not suit the circumstances of the climate or people. The native houses are built with the object of concealing the female inmates, so that the principles of ventilation are little attended to; but the climate admits of doors and windows being generally open, so that the want of a better construction is not so much felt. Many of the houses are of good size and well built, but more are low, small, and crowded together; and there are many more tiled or thatched huts. However dirty the neighbourhood of the houses may be, native habits cause the inside of them to be kept generally clean, though for the sake of the privacy of the women there are latrines in most of the better houses, and cows and other cattle are often kept inside the house enclosures. The latrines are either wells sunk in the ground, which are closed up when filled, and others opened, or small rooms adjoining the streets, occasionally cleaned, and the drainage from which is led into the open street drains; either being an objectionable arrangement. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) I have had to examine several native huts near the lines of the native regiments which are under my department, and in front of almost every door there was a dirt heap. These bazaars are all under the Superintendent of Police, who, I know, has long been trying to remedy the evil. (*By Deputy Inspector-General of Hospitals, Mysore Division.*)—Occasionally there may be a nuisance experienced in the Infantry barracks from the wind blowing over the native dwellings; but it must be rarely, as the bazaars are situated to the north-west of the barracks, whilst the prevailing winds are west and south-west, or east and north-east. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) Nuisance is experienced from this cause in the married men's huts of the Fusiliers. (*By Deputy Inspector-General of Hospitals, Mysore Division.*) The bazaars have originally been allowed to spring up too near the Infantry barracks enclosure, and now nothing short of the entire removal of one or other can prevent such occasional nuisance as may be experienced; but the nuisance may be modified by enforcing, as far as practicable, cleanliness in the native dwellings nearest the barracks. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) A bazaar is close by the barracks, and is crowded with the houses of men who keep buffaloes. The filth from these cowhouses flows into open drains, and in the dry season is very offensive. 20. (*By Deputy Inspector-General of Hospitals, Mysore Division.*) The slaughtering-places are situated at a considerable distance from the nearest part of the barracks, some 600 or 800 yards; but by the growth of the bazaars they have become enclosed in the centre of the town. They are daily cleaned out by a party of prisoners, but nevertheless are still rather offensive. Their removal to a place outside the town has been provided for. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) The slaughtering-place is in the centre of the bazaar, about half a mile from the European barracks. 21. (*By Deputy Inspector-General of Hospitals, Mysore Division.*)—There are no arrangements for stabling the bazaar horses, which, with other domestic animals, are kept in and about the houses of the inhabitants; but very few natives keep horses, and the few who do are comparatively wealthy, and their house enclosures large. The manure is sold or given to the ryots.

References to Subjects and Queries.	Replies.
II. Sanitary Condition of Station—*cont.*	(*By Deputy Assistant Quartermaster-General, Mysore Division.*) There are no arrangements for stabling horses. There are but few horses in the bazaar, and these being the property of wealthy natives, it is presumed they are housed in regular stables. 22. There are no stables for Artillery or Cavalry horses, which are picketed within 100 yards of the barracks. The dungheaps are some 200 yards distant; the manure is sold. The picketing-grounds are arranged in lines, about 100 yards distant from the men's quarters and the hospitals. (*Remark by the Commander-in-Chief.*) "After repeatedly urging the necessity of providing stables for the European mounted corps in this Presidency, sanction for their construction has at last been obtained, but no commencement has yet been made." (Signed) P. G. 23. (*By Deputy Assistant Quartermaster-General, Mysore Division.*) To the Dragoon barracks, soon to be occupied as an Infantry barracks, a sufficient number of married quarters is being built; some are already finished. In the Artillery barracks the allowed number is sanctioned. In the Infantry barracks the married quarters are insufficient in number and very bad, but this barrack is condemned, and to be given up in the course of two or three years. Some married people are located in barrack rooms, but none but married men are in these rooms, and the quarters of the different families are screened off (*Remark by the Commander-in-Chief.*) "The disgraceful state of the Infantry barracks at Bangalore was earnestly brought to notice by me in my Report of September 1856, and after much pressure sanction was obtained for the erection of new barracks, but from the impoverished condition of the finances, and delays interposed by the Government of India, the works have proceeded very, very slowly, and fully another year must elapse before the buildings can be occupied. See also my inspection tour report, March 1858, head Bangalore." (Signed) P.G.
Officers' Quarters.	(*By Deputy Assistant Quartermaster-General, Mysore Division.*) There are no officers' quarters in Bangalore.
IV. Health of the Troops.	(*The following answers are given by the Deputy Inspector-General of Hospitals, Mysore Division.*) 1. The station of Bangalore is generally considered one of the most healthy for European troops in the Madras Presidency; the native population is also healthy. 2. The diseases most prevalent among natives in Mysore are intermittent fever, chiefly of the quotidian type, dysentery, diarrhœa, rheumatism, and hepatic disease; epidemic cholera occasionally occurs. 3. Bangalore is situated in one of the most elevated parts of the Mysore country, and is about 3,000 feet above the level of the sea. The climate is generally cool and agreeable, except in the hot months, March, April, and May, and is considered healthy. 4. The European troops at present at this station are Her Majesty's 1st Dragoon Guards, the 1st Madras Fusiliers, the head-quarters of the Madras Horse Artillery, and A. company, 3rd battalion Foot Artillery. For this and several other questions relative to the health of European troops, I must beg leave to refer to the reports of the medical officers in charge of those regiments. Her Majesty's Dragoon Guards have but lately arrived from England, and I believe were healthy while in Europe. The 1st Madras Fusiliers have lately returned from field service in Bengal, where they had been ordered to assist in quelling the mutiny of the Bengal native army in 1857–58. Very few of the men who left the Madras Presidency for that purpose have returned; the regiment now chiefly consists of new or fresh recruits who are scarcely yet acclimatized. The men's accommodation in this station is very good; the barracks formerly in use have been very much improved lately, and are now in excellent order. The hospital of the Dragoon Guards was objectionable in many respects, but it has lately been put in thorough repair. 5. The troops at this station have not been camped out. 6. I have not been in charge of troops at hill stations; I consider hill stations, such as the Nielgherries better adapted for a sanitarium than for the location of troops. 7. Troops returning to the plains from hill stations are more liable to hepatic diseases, dysentery, and relaxation of the bowels, and this is attributable in a great degree to the great change of temperature, to the change of water, and to the fact that the men are less careful in exposing themselves to solar influence. 8. I consider hill stations better calculated for sanitaria than for the location of troops. 9. On first going to hill stations, such as the Nielgherries or other hills at a higher elevation, 7,000 or 8,000 feet above the level of the sea, persons very often suffer from diarrhœa, relaxation of the bowels, and febrile attacks, unless they are particularly careful in adapting the clothing to the change of temperature. 10. The chief precautions to be observed at hill stations are the use of warm clothing, generous diet, regular exercise morning and evening, and avoiding exposure to the sun during the heat of the day. 11. Persons generally go to hill stations to avoid the extreme heat of the weather in the plains during the hot months. The shortest period of residence in the hills which would enable troops to obtain benefit to their health is 12 months. 12. Persons who have been for some time resident at hill stations, and who are acclimatized, may remain for an indefinite time with advantage, but they must feel the change of temperature more on returning to the plains. 13. For troops returning to the plains from hill stations, I would recommend avoidance of exposure to the sun during the heat of the day, and of the use of hard or unfiltered water, adapting the clothing to the change of temperature, and generous diet. 14. I consider that service in the plains, adopting every means to preserve the health of the troops, with short periods of change to hill stations, would be better calculated to keep them in a fit state for general service. I consider occasional change of stations in the plains beneficial in the absence of epidemic disease, such as cholera. Troops are generally very healthy on a line of march. 15. A barrack and hospital for one regiment have lately been built at Jackatalla, a station in the Nielgherry hills, now called Wellington. I understand that in future it is to be used as a sanitarium for troops serving in the plains. 16. The most suitable sites for hill stations would be between 3,000 and 6,000 feet above the level of the sea.

BANGALORE. MADRAS.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	17. The Nielgherry hills are chiefly used as a sanitary station for troops serving in the Mysore division. They are about 170 miles from Bangalore, and can be easily reached by transit coaches. The climate is cool and bracing, and very agreeable, except in the monsoon or rainy season. 18. The black loamy cotton soil, such as is frequently found in the ceded districts, is considered unhealthy, but I am not aware that it is more so than others. 19. The best age for a soldier to proceed to India is about 20 or 21 years of age, and he should land there between the months of October and March. On first landing troops are generally located in Fort St. George, Poonamallee, or Palaveram. The barrack accommodation is good, the troops are well clothed and attended to, and not overworked. Recruits should be instructed to avoid exposure to the sun in the heat of the day; their clothing should be adapted to the climate; they should be regularly exercised morning and evening, but not overworked, and a good generous diet be provided for them. 20. I should think that a residence by troops at an intermediate place, before being sent to India, for a certain time would be desirable. If troops could be sent to hill stations on landing, and gradually accustomed to the climate, it would be a very good plan, but this cannot be always adopted. 21. Troops formerly marched to the different stations; they now usually travel to the interior by railways, transit coaches, &c. when practicable. 22. From my experience I consider the term a British soldier should serve in India should be 24 years. 23. The manner of conducting medical boards is at present very satisfactory. 24. Invalids should leave India for home in the months of January and February.
Diseases.	1. There are regular inspection parades for the discovery of incipient diseases once a week at this station. 2. There is no scorbutic disease now existing among the troops at this station. 3. During the year 1859–60 the admissions out of a strength of 1,425 from hepatic disease occurring amongst the Europeans were one in 25 of the whole strength, and of these three died. The frequency of the disease is attributable in some degree to the great variety of temperature occurring in the 24 hours. The measures which, in my opinion, would diminish its frequency are,—temperance in the use of spirituous liquors, attention to clothing, avoidance of exposure to the sun during the heat of the day and to the cold heavy dews of the early morning, and a good and generous diet. 4. There has been no case of dracunculus amongst the European troops during the year 1859–60. 5. The proportion of sick from venereal disease to the total sick in hospital from all other diseases is fully one half. Lock hospitals have been lately established at the principal stations occupied by European troops, and it is to be hoped that much benefit will be derived from them, if properly and judiciously conducted. 6. The admissions and deaths from fevers, dysentery, cholera, small-pox, and rheumatism are shown in the following table. The proportion which the admissions from these diseases bear to total admissions is about one-fourth.

Diseases.	Admissions.	Deaths.
Fevers:		
Intermittent, quotidian type	109	0
Tertian fever	9	0
Remittent „	4	2
Continued „	26	2
Dysentery, acute	55	1
„ chronic	1	0
Cholera	11	3
Small-pox	5	1
Rheumatism, acute and chronic	140	0

	7. The only zymotic disease which occurred was variola, four cases of which occurred in the 1st Madras Fusiliers, and one in the 1st King's Dragoon Guards, in the months of March and April. The sanitary condition of the barracks, &c. is good, but immediately in rear of the Fusilier barracks is the bazaar, in which are several tanneries, a slaughter-house, and other nuisances, which have been recommended to be removed. The Europeans are generally clean and healthy, but the natives are not so particular in this respect. 8. I should not suppose that the nature of a soldier's duties or occupation in barracks, which are kept clean and well ventilated, and not over-crowded, would tend to the production of epidemic disease. These diseases do occasionally occur, but it is sometimes very difficult to account for their prevalence. 9. There has been no opportunity of trying quinine as a prophylactic at this station, but it has been tried on a line of march through a jungly district, and, I believe, with good results. 10. For the prevention or mitigation of epidemic disease, I should recommend the frequent use of quicklime to drains, privies, &c., and if sulphate of iron and alum could be obtained, this might also be used with advantage in moderate quantity; and further, baskets of charcoal placed in all latrines, &c. for the absorption of gases, as it has been found to correct effluvia, and particular attention to cleanliness in every respect.
V. INTEMPERANCE.	1. (*By Officer commanding Artillery.*) The soldiers at the station are usually temperate, under existing restrictions. (*By Officer commanding 1st King's Dragoon Guards.*) I consider the soldiers of the King's Dragoon Guards, generally speaking, are of temperate habits. (*By Officer commanding 1st Madras Fusiliers.*) The Madras Fusiliers are temperate; unquestionably temperate considering the temptations they are exposed to; but in India temperance is the exception and intemperance the usual habit of the European soldiers, who become rapidly demoralized by their residence in this climate, by the idle, listless, objectless lives they are in a measure compelled to lead. But Government is much to blame; it places the poisoned chalice to their lips, bids them drink freely, and when the pernicious habit of swallowing

References to Subject and Queries	Replies.
V. Intemperance—*cont.*	raw spirits is confirmed, denounces them as a disgrace to their country, their religion, and their humanity. (*By Officer commanding Artillery.*) The proportion of confirmed drunkards is small, not more than 5 per cent. (*By Officer commanding* 1*st King's Dragoon Guards.*) There are two men in the regiment under my command confirmed drunkards out of 646 men. (*By Officer commanding* 1*st Madras Fusiliers.*) The average proportion of confirmed drunkards may, I think, be estimated at 1 per cent. of those who have been one year in the country; 2 per cent. of those who have been two years in the country; increasing throughout in a similar ratio to the period of residence in the country. 2. (*By Officer commanding Artillery.*) The average proportion of admissions to strength from diseases caused by intemperance during the past year has been 12·59 per cent. Directly - - - - - - - - 10·37 per cent. Indirectly - - - - - - - - 2·14 per cent. (*By Officer commanding* 1*st King's Dragoon Guards.*) The proportion of admissions from diseases caused by intemperance has been about one in 70 in the year. (*By Officer commanding* 1*st Madras Fusiliers.*) During the last year, 1859, there were nine admissions from drunkenness and one from delirium tremens. It is impossible to state numerically, with any approach to accuracy, the number of admissions from diseases caused indirectly or aggravated by intemperance, as other causes are in operation, but the injury done to the health of soldiers by immoderate indulgence in ardent spirits is obviously very great. (*By Officer commanding Artillery.*) The following table shows the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station.

—	Tectotalers.	Temperate.	Intemperate.
Average strength for past year 135 -	3	114	18
Average amount of admissions - -	0·33 per cent.	11·40 per cent.	22·2 per cent.
„ „ mortality - -	None.	1 in 114, or 0·87 per cent.	None.
„ „ crime - - -	None.	1 in 14¼, or 7·9 per cent.	1 in 1⅕ men.

(*By Officer commanding* 1*st King's Dragoon Guards.*) No record of the number admitted into hospital under this head has been kept, but I should say, directly and indirectly, intemperance is the cause of at least one-sixth of the admissions. No correct statistics have been kept to prepare a table of this kind.

(*By Officer commanding* 1*st Madras Fusiliers.*) Data do not exist with which to construct a statistical table in which confidence could be placed. There are few totally abstinent men, and the classes of temperate and drunkard are not sufficiently defined to admit of showing statistically the results in each class, as respects sickness and mortality. Thus much may be stated with the utmost confidence, viz., that drinking to excess of ardent spirits is, directly or indirectly, literally the root of all evil in the army. It is the cause of more than nine-tenths of the crime, and its influence on health and morals is hardly less destructive.

(*By Officer commanding Artillery.*) Drunkenness is always punished as an offence.

(*By Officer commanding* 1*st King's Dragoon Guards.*) Drunkenness is always punished as an offence.

(*By Officer commanding* 1*st Madras Fusiliers.*) Drunkenness is considered one of the greatest crimes commited by a soldier, and is always punished. It is the parent of almost every crime committed by the European soldier. It is considered a minor crime *per se*, and is punished as such. Deducting entries for drunkenness, and crimes committed under its baneful influence, I doubt if any army in the world could exhibit such a moderate defaulter sheet as the British army.

3. (*By Officer commanding Artillery.*) Distilled spirits are sold both in the canteen and in the bazaar, but illegally in the latter, and the spirit there sold is very inferior.

(*By Officer commanding* 1*st King's Dragoon Guards.*) Arrack is sold in the canteen of the King's Dragoon Guards. The daily quantity for each man is one dram.

(*By Officer commanding* 1*st Madras Fusiliers.*) The men are allowed only a certain quantity of spirit in the canteen, but any quantity of an inferior description can be obtained in the bazaar. Unfortunately spirits are sold in canteens even in garrison, and this practice should be discontinued, if the welfare of the soldier is really an object of anxiety to Government. Spirit rations mixed with three parts water might be issued on actual service; but the issue of raw spirits to the soldiery in garrison is justified by no valid consideration of economy or expediency. The normal state of man is a craving for stimulants. In the savage, as in the civilized man, this craving has developed itself, and has in every country in the world been gratified by deleterious drugs and liquids. It is the part of a civilised government to devise means to check and not pamper this morbid appetite; but to issue raw spirits to the soldiers, and to encourage its consumption by authorizing its unchecked sale in every street, and in every bazaar in a large military station, as is the case at Bangalore, is a short-sighted policy, subtracting from the revenues by the non-efficiency of its soldiers, by their premature decay, and by their rapid consumption ten times the amount realized by the unchecked sale of spirits.

(*By Officer commanding Artillery.*) At the canteen two drams of spirit is the allowance per man, or one dram with one quart of malt liquor or two drams of wine. Four drams of wine is the limit in wine, but then no arrack is allowed.

(*By Officer commanding* 1*st King's Dragoon Guards.*) The quality of the arrack is good, and the amount consumed per diem by each man one dram, with the exception of those who do not drink arrack.

(*By Officer commanding* 1*st Madras Fusiliers.*) The quality of the spirit sold in the canteen is good: but that sold in the bazaar is generally very bad. The average spirit consumed by each man is one dram per diem from the canteen. If the quality of any spirit can be said to be good, the spirit sold in the canteen may be called so. It is impossible to guess what amount is really consumed by each man per diem. The fear of punishment, but no moral control, checks its consumption. The canteen allowance is limited, but the bazaar supply is inexhaustible. No restraint is placed on the men leaving their barracks between morning and evening gun-fire. The probability is that not three men in five go to bed perfectly sober; and when pay is issued, or funds available, not two in five are completely free from the influence of liquor. Total abstinence is unknown.

V. Intemperance—*cont.*	(*By Officer commanding Artillery.*) It is not a habit in quarters with the men to take a dram before morning parade, even had they the choice, which they have not, as no spirits can be sold in the canteens before half-past 1 p.m.; but on the line of march, I am of opinion that the issue of a dram on arrival in camp, and before the men turn out to stables, would be beneficial, as it would help to keep them from drinking bad water, and the stuff sold as fire Chilli water and toddy. (*By Officer commanding* 1*st King's Dragoon Guards.*) It is not a habit among the men of the regiment under my command to take a dram before morning parade, and I believe that almost every man has a cup of coffee and a biscuit before morning parade or drill. (*By Officer commanding* 1*st Madras Fusiliers.*) It is not a habit among the men of my regiment to take a dram before morning parade, as no liquor can be purchased from the canteen before 11 a.m. Two drams of raw spirits are a recognized portion of the soldier's ration, which he can claim, whether in garrison, on the march, or in the field, by paying for it. A regimental order prohibits the canteen being opened for the sale of spirits till 11 a.m., but the habit of the European soldier is to take raw spirits at any time when he can get it, whether it is early morning, noon, or night, and the unquestionable effects of this habit are loss of health, loss of character, and premature death. (*By Officer commanding Artillery.*) Spirit is never given as a ration to convalescents. (*By Officer commanding* 1*st King's Dragoon Guards.*) Spirits are not given as a ration to convalescents; but some of them in barracks doing light duty are permitted to draw their allowance of beer from the canteen. (*By Officer commanding* 1*st Madras Fusiliers.*) No convalescent list is kept in hospital; that is, patients are not discharged (and therefore remain on hospital diet) till able to perform their duty. (*By Officer commanding Artillery.*) Soda water, lemonade, and ginger beer may be sold in the canteen, and coffee also, none of which are injurious to health when properly made at the canteen under my command. Coffee only is sold at present. (*By Officer commanding* 1*st King's Dragoon Guards.*) No drinks other than intoxicating drinks are sold at the canteen under my command. (*By Officer commanding* 1*st Madras Fusiliers.*) In the bazaars very many drinks are sold that are most injurious to health, poisonous in quality, and maddening in their effects. Ginger beer, spruce beer, soda-water, and lemonade are procurable in the canteen. Tea and coffee in the coffee shop. 4. (*By Officer commanding Artillery.*) As a general practice, the consumption of spirits is injurious to health. (*By Officer commanding* 1*st King's Dragoon Guards.*) A moderate use of spirits is conducive to health in more than the majority of mankind. The absence of it is no doubt injurious to health. (*By Officer commanding* 1*st Madras Fusiliers.*) The consumption of spirits by troops and convalescents (more especially in tropical countries) is decidedly injurious to health, excepting in particular and rare circumstances, such as when exposed to rain and fatigue on field service. (*By Officer commanding Artillery.*) The consumption of spirits is conducive to the efficiency and internal discipline of the corps, when kept within due limits. (*By Officer commanding* 1*st King's Dragoon Guards.*) I look upon spirits as conducive to the efficiency of the corps when employed on arduous and laborious duties, as a stimulant to exhausted nervous prostration, frequently met with on active service. As to its being conducive to internal discipline, I do not think it is. (*By Officer commanding* 1*st Madras Fusiliers.*) If the men could be restricted in the quantity of spirits they are permitted to obtain at the canteen, and not be able to procure it in the bazaar, I consider the quantity allowed would not be the cause of detracting from the efficiency or internal discipline of the corps. But, as the case stands, the unrestricted sale of every species of intoxicating drug and liquor being authorized and encouraged by Government, the efficiency and discipline of the corps are maintained with difficulty. 5. (*By Officer commanding Artillery.*) It would not be conducive to further restrict the sale of spirits at canteens than the present regulations provide for; any measures that could be taken to abolish their sale in bazaars would certainly be advantageous. Spirituous liquor is not and has not been issued as part rations to European troops of the Madras army since November 1836. *Vide* General Order, No. 243, November 22, 1836. (*By Officer commanding* 1*st King's Dragoon Guards.*) I do not think spirits should ever form part of the ration of a soldier, and it would be conducive to health to do away with it as a regular ration, particularly on board ship, where often the young soldier gets habituated to what he does not require; but on active service, in an unhealthy country, I think one or two drams daily would be conducive to health and to the efficiency of a corps. The small amount of spirits allowed to the men (optionally) in a well-regulated canteen can never produce any harm, and may be beneficial to many, but it is different in the bazaar, where any quantity of the worst kind of liquor can be had for a very small sum, only eight annas (one shilling) the quart bottle, and decidedly the sale of it should be abolished in all bazaars in India where European troops are located. Many young soldiers have attributed their illness to the drink they got in bazaars in nearly these words:—"I took a walk out, "and I felt thirsty, and was induced to take some arrack in the bazaar. It tasted very weak, "and I drank nearly a bottle of it, but I soon felt it overcoming me, and I did not recollect "anything more, till I awoke with a headache three or four hours after, and with a burning "in the throat." (*By Officer commanding* 1*st Madras Fusiliers.*) To restrict the sale of spirits in the canteens would be of little advantage so long as abundance is procurable elsewhere, and to limit the quantity in bazaars is impracticable. There appears to be but one remedy for the total prevention of drunkenness, and that is the entire suppression of the distillation and sale of spirits. Half measures will not do—one glass only creates a stronger desire for a second, and so on. Experience proves that the depraving and demoralising vice of intemperance cannot be cured by temporising measures. In England the carrying out of the preventive plan recommended might meet with powerful opposition, but in India the principal objection would be the injurious effects it would produce on the revenue. If ardent spirits be sold, English soldiers will obtain them in some way or other, and drink to excess. The canteen and the liquor shop possess far stronger attractions for the soldier generally than the library;

V. Intemperance—*cont.*	and so long as spirits are obtainable in such abundance, all attempts to substantially improve and elevate the character of the soldier will be but partially successful. 6. (*By Officer commanding Artillery.*) A moderate use of malt liquor or wine is calculated to produce a beneficial influence on the health of the men as compared with spirituous liquors. (*By Officer commanding 1st King's Dragoon Guards.*) The use of spirits, wine, or beer can be abused; but the moderate use of any one or all is wholesome. As a general rule the free use of malt liquor is less likely to do harm, and would be the most agreeable and wholesome beverage in a hot climate. (*By Officer commanding 1st Madras Fusiliers.*) In my opinion malt liquor in moderation, as a general rule, is beneficial to health, whereas ardent spirits are prejudicial. 7. (*By Officer commanding Artillery.*) Lemonade, soda-water, &c. are not much used under my command; but tea and coffee are, the latter chiefly in the morning before going to drill. (*By Officer commanding 1st King's Dragoon Guards.*) The men of my regiment use a great quantity of tea, coffee, and ginger beer, especially in the hot season. (*By Officer commanding 1st Madras Fusiliers.*) Coffee, tea, and ginger beer are much used, but lemonade and other drinks not so much, partly because they are beyond the soldiers' means, but chiefly because they are devoid of the stimulus a vitiated appetite craves that has early in life been innoculated with the pernicious habit of drinking raw spirits. To such an extent does this morbid appetite for stimulants prevail, that old soldiers are in the habit of adding to their rations of raw spirits both spices and Chilli seeds to improve its strength. Spirits diluted with water would be rejected by such men as liquor that had been spoilt and not fit to be drunk. (*By Officer commanding Artillery.*) As compared with the temperate use of spirits or beer, coffee, tea, &c. &c. are of no advantage to health or discipline. Comparative yearly statements showing the ratio of disease and death among temperate and teetotal men corroborate this opinion. (*By Officer commanding 1st King's Dragoon Guards.*) I believe that the men who take the least drink are in every way the best as regards their own comfort. They are seldom sick or in confinement, though I do not think that the quantity allowed to each man (one dram of arrack and one quart of beer or porter), as it is given to them, can have any effect on the efficiency and discipline of the corps. (*By Officer commanding 1st Madras Fusiliers.*) There can be no question of the incalculable advantages as regards health, efficiency, and discipline that would accrue from the substitution of tea, coffee, lemonade, &c. &c. in lieu of raw spirits. Beer and porter, in moderation, I believe to be wholesome and unobjectionable drinks. 8. (*By Officer commanding Artillery.*) No spirit *ration* is allowed or has been for the last 24 years in the Madras army. *Vide* General Order O. G., 22nd November 1836. Compensation instead of spirit ration is included in the monthly pay of all ranks. (*By Officer commanding 1st King's Dragoon Guards.*)—The climate at Bangalore is frequently cold and damp, and I do not think that the quantity of drink allowed by regulation is the least injurious to health. I think the suppression of it altogether would have a bad effect, as no doubt the men would obtain it surreptitiously in the bazaar, and the drinks sold by the natives are, generally speaking, of a bad quality and pernicious to health. On the whole it would be beneficial to suppress altogether the use of spirits as a ration in the station, and to substitute beer, tea, and coffee. The only time that I think spirits may be required is on active service, and it is more easily carried than beer. (*By Officer commanding 1st Madras Fusiliers.*) If the distillation and sale of spirits at the station were entirely suppressed, the spirit ration discontinued, and beer, coffee, and tea substituted, the influence on the health of the troops would be decidedly beneficial. 9. (*By Officer commanding Artillery.*) It would not be beneficial to prohibit the sale of spirits in the canteen, as it would be impossible to put a stop to men getting spirituous liquors somewhere when prohibited in the canteen. I made the experiment of having no spirits in the canteen at Jaulnah for nearly four years, but found those men who got drunk generally procured it in the bazaar; and there was a constant wish, even among the best behaved men, to be allowed arrack in the canteen, particularly in wet or damp weather during the monsoon. (*By Officer commanding 1st King's Dragoon Guards.*) The small quantity of spirits allowed in a well regulated canteen can do little or no harm. It is the immoderate use of spirits in the bazaars that should be stopped, where men, heated in the middle of the day, will drink anything that offers, be it never so bad. Where beer is to be had at a moderate price in the canteen, little or no spirit is ever called for by the soldiers, as they nearly all prefer beer to spirits. (*By Officer commanding 1st Madras Fusiliers.*) It would be beneficial to prohibit the sale of spirituous liquors in the canteen, provided they were not obtainable elsewhere, but not otherwise. 10. (*By Officer commanding Artillery.*) I would suggest that on the line of march the issue of one dram be allowed before the men turn out to stables on reaching new camp ground. I would suggest that all tobacco for the use of the men (*bonâ fide*), and sold in canteens, be allowed to them free of duty. I would suggest that every facility and encouragement be afforded to regiments to establish for the use of the men gymnasia and games, such as cricket, foot-ball, &c., and that fives courts be erected in every regimental lines. At stations near which there is no river, swimming baths might be built. I am of opinion that attached to the gymnasia there might be a school of arms, and that encouragement might be more generally given to the practice of sword exercise, single stick, and fencing among the men, especially those of the mounted branches of the service. (*By Officer commanding 1st King's Dragoon Guards.*) I would recommend that no abkary licences should be issued to natives by Government in any cantonment where there are European troops, or within 10 miles of it, and the sale of the worst kind of liquor will be prevented. (*By Officer commanding 1st Madras Fusiliers.*) I would urgently recommend the discontinuance of spirit rations except when on actual service, and even then I would exact that all spirits issued to troops be mixed with three parts water. I would continue canteens in regiments, but while in garrison or on the line of march no spirits should be allowed in them, but only beer, porter, ginger and spruce beer, soda-water, lemonade, and other harmless drinks, with tea and coffee. I would convert the canteen into a club house, furnished with chess and backgammon boards, dominoes, billiard and Sinclair tables. It should be located

V. Intemperance—*cont.*	within an extensive piece of ground planted with shady trees, with open glades for quoits and cricket, containing skittle alleys, a fives court, a racket court, an extensive workshop, a good library, and a large piece of water. 11. (*By Officer commanding Artillery.*) General rules for canteens as laid down by the G. O. C. C., 17th August 1855, are strictly adhered to. (*By Officer commanding* 1*st King's Dragoon Guards.*) The following copies of the canteen and coffee-room regulations are properly obeyed by the troops:— "REGULATIONS FOR THE COFFEE-ROOM. "The coffee-room having been instituted for the recreation of those men who are desirous of spending their leisure hours in reading and quiet amusement, all noisy conversation, bad language, and gambling with cards or dice are strictly forbidden. Chess, draughts, and dominoes are allowed to be played, but wagers or bets on these games are prohibited. "A number of papers and periodicals are provided from the fund for the use of the men, and the non-commissioned officer in charge is held responsible for their safe custody. "Any man damaging or destroying any journal &c. will have to pay its full value. "Coffee, tea, &c. will be provided at the following prices, and will be in readiness from 4·30 a.m. until a quarter to 8 p.m. Coffee, per cup - - - 4 pies. Tea, do. - - - 4 „ Biscuits, each - - 1 „ Cheroots, do. - - - 1 „ Ginger beer, per bottle - 8 „ "All articles to be paid for on delivery. "The serjeant on duty for the day at the canteen will frequently visit the coffee-room to preserve order and regularity, and will immediately report any breach of the same. "The canteen serjeant will exercise a general superintendence of the coffee-room, and will see that the premises are kept perfectly clean. "The coffee-room will be cleared every evening at a quarter to 8 o'clock, and will not be opened after that hour upon any pretence, without competent authority. "The orderly serjeant-major and serjeant will see it cleared as heretofore, and continue to certify the same in their reports." True copy. (Signed) J. NISBET, Major, King's Dragoon Guards. "REGULATION FOR THE CANTEEN. "King's Dragoon Guards, Fort St. George, 13th November 1857. "The Right Honourable the Governor in Council is pleased to cancel G. O. G. noted in the margin, and to notify that the issue of malt liquors will from the 1st March 1858 be regulated by the imperial measure. The price of malt liquor issued by the imperial measure will be at three annas per quart, or one anna and a half per pint, and no man is allowed to purchase more than one quart daily, and only one dram of arrack in addition. No spirits are to be issued on any occasion before the usual dinner hour; no man is to be allowed more than one quart of malt liquor and one dram of spirits per diem, and these are never to be issued at the same time. When there is no malt liquor, one dram of spirits will be allowed in lieu thereof." (*By Officer commanding* 1*st Madras Fusiliers.*) The canteen regulations are contained in the General Orders of the Army, page 379 of 1855, and General Order, 17th August 1855, which are strictly carried out. There are no private rules.
VI. DIET.	1. (*By Officer commanding Artillery.*) The rations consist of the following, viz.:—1 lb. bread, 1 lb. meat (five days beef and two days mutton), 4 oz. rice, $1\frac{3}{7}$ oz. coffee, 2 oz. sugar, 1 oz. salt, $\frac{5}{7}$ oz. tea, and 1 lb. potatoes, to each man. Coffee and tea are issued alternately. Married men draw their tea, coffee, rice, and sugar once, or at some stations twice, a month. (*By Officer commanding* 1*st King's Dragoon Guards.*) 1 lb. bread, 1 lb. meat, 4 oz. rice, $2\frac{1}{2}$ oz. sugar, $\frac{5}{7}$ oz. tea, or $1\frac{3}{7}$ oz. coffee, 1 oz. salt, and 1 lb. vegetables (potatoes). (*By Officer commanding* 1*st Madras Fusiliers.*) Mutton or beef, bread, tea or coffee, sugar, rice, salt, and vegetables. (*By Commissariat Officer.*) Bread 1 lb., meat 1 lb. (mutton twice a week, beef five times), rice 4 oz., sugar $2\frac{1}{2}$ oz., firewood 3 lbs., salt 1 oz., tea $\frac{5}{7}$ oz., coffee $1\frac{3}{7}$ oz., and vegetables 1 lb. The rations are inspected daily previous to issue by a warrant or non-commissioned officer of the Commissariat department, and by the executive officer at uncertain periods during the month. (*By Officer commanding Artillery.*) The officer of the day inspects the rations every morning when issued, and at 1 p.m. when the men in barracks dine. (*By the Officer commanding* 1*st King's Dragoon Guards.*) An inspection of the ration is made once during the week by the commanding officer, and every morning by the orderly officer and quartermaster. (*By Officer commanding* 1*st Madras Fusiliers.*) The rations are drawn by the orderly corporal of each company, and the orderly officer on duty attends and inspects the rations. If they are reported bad by the corporals to the orderly officer, he reports the same to the officer commanding the regiment, and a committee is immediately assembled to reject them or otherwise, a medical officer being always on the committee. 2. (*By Officer commanding Artillery.*) Fruit is never provided for the troops. The stoppages from each man of all ranks is daily 3 annas 4 pies. There are three meals a day in quarters, and on the line of march two generally; the first meal in quarters is at 8 o'clock a.m., second at 1 p.m., and the third at 6 p.m. On the march it all depends upon the time of arrival in camp; with artillery men, their first meal is after morning stables, say 10 or 11 o'clock, and second at $6\frac{1}{2}$ p.m. 1 lb. of vegetables is allowed for each man when procurable. (*By the Officer commanding* 1*st King's Dragoon Guards.*) A complete ration is provided at all times for the troops; the vegetables consist of 1 lb. of potatoes. No fruit is provided, nor does it belong to a soldier's ration, but the soldiers frequently buy fruit and other vegetables besides potatoes. The stoppages 3 annas 4 pies per diem. They breakfast at 8.30 a.m., consisting of tea or coffee and a portion of a pound of bread. Dinner at 1 o'clock, and in the evening at 6 o'clock tea or coffee.

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	(*By the Officer commanding* 1*st Madras Fusiliers.*) A complete ration is provided daily at a cost to the soldier of 6*r.* 5*a.* 4*p.* per mensem. There are three meals a day. Breakfast at 8½ a.m., of bread, tea, and meat; dinner at 1 p.m., of bread, meat, vegetables, and curry and rice; and tea at 6 p.m., of bread and tea; 1 lb. of vegetables is allowed per man. (*By the Commissariat Officer.*) 1 lb. of vegetables is issued daily, consisting of potatoes, brinjall, carrots, onions, pumpkins, &c., according to the season. No fruit is provided at this station; the stoppage for the rations is 3 annas 4 pies per day. The troops have three meals a day, breakfast at 8, dinner at 1, and supper between 5 and 6, consisting of the articles enumerated. 3. (*By the Officer commanding Artillery.*) The men complain that the supply of 1 lb. of bread per diem is insufficient. They should also have 1 ounce of tea instead of as at $\frac{5}{7}$ oz. No man has any opportunity or inducements to sell his rations. (*By the Officer commanding* 1*st King's Dragoon Guards.*) A ration of salt meat and biscuit should be issued to all the troops in garrison once a week; 1st, because I think it would be wholesome, and the men would like it; and 2nd, because a stock of those two articles should be always ready in every station, so that they might be issued to the troops at any moment. It has frequently happened that the bread or meat supplied to the troops has been condemned as bad and unfit for issue, and the soldiers have been kept without the rations till 4 or 5 o'clock in the afternoon; even then, as a better ration could not be procured, condemned and unwholesome rations have been obliged to be issued. This might be avoided if biscuits and salt beef or pork were kept good in store by an issue of one day's ration of these articles in a week and a fresh stock would be always on hand in store. The orderly corporals of troops receive the rations from the quartermaster, and they are by them given over to the cooks. These corporals superintend the cooking and division into messes of the rations, and are held responsible that no person purloins any portion of them. It is their duty also to see that the cook-houses and utensils are kept thoroughly clean. (*By Officer commanding* 1*st Madras Fusiliers.*) The great defect in the rations, and especially at Bangalore, is their being supplied of an inferior description. Both beef and mutton here are bad, and the bread is generally sandy. The quantity of rations is not sufficient for young and growing lads (recruits); they provide an additional supply privately. The rations I consider just sufficient for the men. No part is ever disposed of; no complaint of the disposal of rations has ever come to my notice. As there are from 10 to 20 or more men in each mess, any disposal of rations would unquestionably be complained of if detected. (*By the Commissariat Officer.*) All improvements in the rations, it is presumed, would be conducive to health. So far as I know, there is no arrangement for the prevention of any part of the ration being disposed of by the soldier, but it is presumed he would not be permitted to sell his rations with the knowledge of his commanding officer. 4. (*By the Officer commanding Artillery.*) The cooking places are very bad. It would be advisable to introduce Captain's Grant's cooking fire, as it would be cleaner and more economical in firewood, and more efficient in every way. The cook-houses or kitchens are very ill ventilated, dark, and small, and dirty from want of ventilation. The food is generally cut up and boiled into stew or curry for dinner, but in the morning the meat used by the men is fried. Cooking is very indifferent. Coffee is well prepared, better than tea, of which the allowance is small. The men have coffee on the march. (*By the Officer commanding* 1*st King's Dragoon Guards.*) The means and apparatus for cooking available: 1 copper boiler, 9½ gallons; 1 ditto, 6½ gallons, and 1 frying-pan for cooking for every 25 men. The kitchens are cleaned after every meal; they are indifferently lighted and ventilated. Cooking is done to the satisfaction of the men, and sufficiently varied, and the tea and coffee properly prepared. A sufficiency of water is supplied by the puckallies. The food is sometimes boiled, and at other times roasted. In fact, each man has his food cooked to suit his own taste. The men of the King's Dragoon Guards when on a march invariably have coffee and biscuits provided for them previous to leaving the encampment. (*By the Officer commanding the* 1*st Madras Fusiliers.*) Cook-rooms are attached to the barracks, and cooks are provided on application at the Commissariat department, or supplied by captains of companies. The rations are cooked in metal vessels supplied by Government, and in earthenware chatties purchased by the respective mess funds. The kitchens are kept as clean as the habits of the native cooks will admit of, but they are not sufficiently roomy or sufficiently ventilated. The smoke escapes through small apertures in the side walls, or through the upper part of the roof, portions of which are raised a few inches above the rest for this purpose. The supply of water is totally inadequate for cookery and cleanliness. It is brought by the puckallies from a considerable distance. The water of the only well in the barracks square is brackish. The food is sometimes boiled, sometimes roasted, according to the wish of the soldiers. The men always have tea or coffee before marching. The rations are sufficiently cooked, and the tea is also properly prepared. A coffee shop is located within the barracks square, where good coffee is procurable. A contract is granted by the commanding officer to any one—generally a native—who offers the best terms. (*By the Commissariat Officer.*) Copper boilers, frying-pans, and gridirons are supplied by the Commissariat department for cooking purposes. It is believed the kitchens are kept clean, but it is stated that they are badly lighted and ventilated, and that there is an insufficient supply of water. The food is boiled, roasted, stewed, and fried, I believe. The cooking is entirely under regimental arrangement, but is believed to be good and varied (as above stated). It is also understood that the tea and coffee, which are both good in themselves of their respective kinds, are properly prepared. In most regiments arrangements are not only made for these articles (generally coffee) being issued to the men before marching, but also for a supply on the march itself, generally half way, if practicable. 5. (*By the Officer commanding Artillery.*) It would be difficult to find suitable ground at Bangalore for soldiers' gardens, the lines being filled up with buildings. To encourage men to work in gardens, they must be left entirely to themselves. Any regulations would prove irksome to them. (*By the Officer commanding* 1*st King's Dragoon Guards.*) There is no ground near the cavalry barracks that could be advantageously converted into gardens. (*By the Officer commanding* 1*st Madras Fusiliers.*) Gardens for the cultivation of vegetables by soldiers could not be advantageously established near the station, every spot of ground

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	being crowded with houses. There is no available ground near the barracks for gardening, and unless the ground is contiguous to them, it would not be resorted to by the men. These things were not dreamed of in the days when these barracks were built. After palaces have been built for the reception of convicts and felons, the public mind awoke sluggishly to the necessity of ameliorating the condition of their natural defenders. The ground around all barracks is preoccupied. The vegetable gardens should be established, to be cultivated by married men, and annual prizes should be given for the best vegetables. (*By the Commissariat Officer.*) I think the vegetable gardens could be established here with great advantage, If the full complements of public cattle, with due proportions of servants and dooly-bearers, were always kept up, a portion of their services could be made available for the culture of vegetables. The public cattle could also be used in ploughing and preparing the ground, drawing water, &c. &c., and plenty of manure could always be had from the Karkhanah.
VII. Dress, Accoutrements, and Duties.	1. (*By the Officer commanding Artillery.*) The Artillery soldier's dress consists of jacket, trousers, and cloak, of army blue cloth, shirts, flannel waistcoats, Banyan drawers, socks, a cumbly jacket for stables in cold weather, and the new established Khakee dress. The accoutrements are belt, pouch belt, and sword belt of buck leather. I consider the present dress as suitable in every way to the climate and the soldier's duties, care being taken that the light clothing is used in the hot season by the men on duty, and the woollen clothing in the cold season. The Khakee clothing is useful on hard service. The changes lately introduced into the soldier's clothing are sufficient. In hot weather the men on guard dress in the new Khakee clothing, which is a relief to them. They also wear the new introduced wicker helmet. (*By the Officer commanding 1st King's Dragoon Guards.*) The men of the King's Dragoon Guards have in possession a wicker helmet, cloth tunic, jacket, and overalls, cloak and cape, white drill tunics and trousers, white drill forage cap and helmet covers. The latter are worn on all duties during the day in the hot season. The white clothing is to be replaced by the Khakee clothing as soon as a supply of the latter (ordered some time back) is received from England. The cloth clothing is worn at night and during the cold season. The men have also a sword and carbine and sword belt and pouch belt. The present dress is in every way suitable, except that the cloth tunic might be of lighter material. I would suggest that instead of the present wicker helmet now in use, a light cork or felt helmet, with a plume for the cavalry, as the wicker helmet does not keep its proper shape, and the plume would help to keep off the sun. The present guard dress is cloth clothing during the night, and white or Khakee clothing during the heat of the day. The men are posted near the verandahs, so that in the heat of the day or wet weather, where there are no sentry-boxes, they may walk in them. (*By the Officer commanding 1st Madras Fusiliers.*) The following articles comprise the soldier's kit, viz., a forage cap, a wicker helmet, shell jacket, 1 pair of cloth trousers, 2 pairs of Khakee trousers, 2 Khakee tunics, 4 white shirts, 2 Banyan shirts, 2 flannel waistcoats, 1 helmet cover, 1 blue puggery, 2 pairs of woollen socks, 2 pairs of cotton ditto, 1 pair of braces, 2 towels, 1 hold-all, 1 button stick and brush, 2 hair combs, 1 hair brush, 1 clothes brush, 2 shoe brushes, 1 sponge, 2 pairs of boots (Europe), 1 marking stamp, 1 regimental carpet, 1 blanket, quilt, account book, bible and prayer book, knife, fork and spoon, and stock. I would substitute in lieu of cloth trousers, 2 pairs of flannel drawers. An elderly man, or one of weak constitution, feels the heat and cold when younger and stronger men do not. Cloth trousers are worn and put off by order, to the great inconvenience and discomfort of such men. The flannel under-drawers can be worn and discontinued at the pleasure of the men to suit their own feelings; and worn under linen trousers, they impart as much, if not more, warmth than cloth trousers, and they are easier of carriage and occupy less space in packing. The mania for Khakee clothing is an egregrious mistake. It is not a fast colour, and consequently to preserve uniformity in a regiment is absolutely impossible. The appearance of a regiment dressed in Khakee is variegated, slovenly, and unsoldierlike. A light loose drab serge or flannel tunic will answer all the purposes of Khakee, will look well and uniform, and will last out half-a-dozen linen Khakee coats. The trousers should also be of brown holland, brown nankeen, or any dark-coloured stout linen of a fast colour. The above few alterations would render the kit suitable for every climate in the tropics from Simla to Cape Cormorin. The helmet is the most suitable, as it is the only head-dress fit for a soldier. The present shape is well adapted to the climate, with its 4-inch peak in front, 5-inch peak in rear, and 3-inch side pieces, connecting the front and rear peaks, but the material should be stout felt, of a drab colour, with a soft linen turban of several folds. The wicker or basketwork helmet is most objectionable, and affords little protection from the sun, the basketwork being more or less open, and admitting through the interstices the rays of the sun, the head is totally exposed. It breaks easily; is hard and unyielding and uncomfortable to the head; is pervious to rain and sun, and requires a linen cover. Felt is impervious to both rain and sun; is yielding, soft, and comfortable; requires no cover, and retains its shape and colour. I speak from experience, having worn both, and the felt helmet is immeasurably the superior head-dress. On guard the loose Khakee clothing and basket helmet are worn. The European soldier is generally well protected from sun and rain while on duty.
Duties.	1. (*By Officer commanding Artillery.*) It would be a great advantage to the service in India if recruits before leaving England were instructed at least in the preliminary portion of their drill, so that they might at once, on joining, commence upon the more important drills,—especially in the horse artillery. (*By the Officer commanding 1st King's Dragoon Guards.*) I think it advisable that men should be so far advanced in equitation, sword, and carbine drill at home before being sent to India, that after their arrival two or three weeks' drill would make them fit to take all duties as efficient dragoons. Owing to the heat of the sun, the time for riding drill in this country is very limited; and there is no covered riding school, though it is much required. (*By Officer commanding 1st Madras Fusiliers.*) The health of recruits seldom suffers materially from drill in India when drill is conducted judiciously; that is, when they are not over-drilled, or exposed too long to the sun in the hot season. I think it most advisable that the local European army should have a depôt at home with three provisional battalions,—one belonging to each Presidency, where the troops might be thoroughly drilled before being sent out. 2. (*By Officer commanding Artillery.*) The recruit in the horse artillery commences with his marching and saluting drills until dismissed cavalry foot drills; he has a full hour in the morning, or say from a quarter to 6 to 7 o'clock on six mornings in the week; this lasts generally about five weeks, the men having been partly taught the same in England; the
