IV. Health of the Troops —*cont.*	regiment at Ahmedabad was good, the diseases from which the men chiefly suffered have been fever and rheumatism. The state of health of the regiment on its arrival at Bombay was good; it arrived on the 21st March 1859, at its present station. Since its arrival at Bombay the men of the 2nd Grenadier regiment have suffered chiefly from fever, scurvy, and rheumatism. The 23rd regiment N.L.I. arrived at Bombay from Mhow, the head quarters, was stationed there 15 months, and left it on the 28th March 1860; the admissions into hospital at Mhow were 1050, chiefly from fever. The regiment reached Bombay on the 1st May 1860, since when in one year after date of arrival the sick increased to 1242, the diseases being scurvy and fever; during the above period of the regiment's stay in Bombay 300 men at one time, though doing duty in the lines, were daily attending hospital for medical treatment. Her Majesty's 2nd European regiment L.I. was at Belgaum before coming to Bombay, and has left during the preparation of this report for Neemuch. Better accommodation and ventilation are required for the troops at Colaba, and new barracks are necessary. 5. The troops at this station are not camped out. 6. Hill stations do well for healthy men and for those who are simply debilitated from fevers, &c., but they are injurious in many cases in convalescence from dysentery and structural changes of the liver, &c. 7. I have not observed that troops who have been resident for some time in hill stations are more or less liable to attacks of febrile and other diseases on returning to the plains. 8. Hill stations are beneficial to the men at certain seasons, but not throughout the year. 9. At hill stations the peculiar diseases to which the men are subjected are perhaps head affections and rheumatism, though the latter cannot be said to be peculiar; and there are what are called hill diarrhœa and dysentery; elevations above 4,000 feet are not suited to chest affections. 10. More clothing, and especially increase of protection from the sun, would be beneficial at hill stations. 11. The season best adapted for residence at hill stations is the hot season. The shortest period of residence which would enable troops to obtain the full benefit of such residence would be from the middle of March to the commencement of the rains in June, about 2½ or 3 months. 12. I am not aware that there is any period of residence beyond which injury is likely to be inflicted on the health of the troops, on returning to service in the plains, but the rains (monsoon) do not admit of hill stations, generally speaking, being resided at the whole year through. 13. I am not aware of any precautions required for protecting the health of the troops on leaving hill stations for the plains, except to allow them to return at a proper season of the year. 14. Without speaking positively, I should say that service in the plains with shorter periods of change to hill stations might be expected to be the most advantageous to the health of the troops. I consider a change of station every second or third year to be beneficial. 15. Our hill sanitaria are most at present in their infancy, but great attention is being paid to procure healthy and comfortable accommodation. 16. I have no personal experience to show at what ranges of elevation above the level of the sea the most suitable sites for hill stations may be obtained. 17. There is Malabar Point, which could be advantageously occupied as a hill station, the extremity of a range of trap rock of that name jutting out into the ocean, at present one of the seats of government. This point could be easily made to accommodate about 300 men, and would be very suitable for a sanitarium; it is upwards of 100 feet high, and has a capital road to it about 5 miles long; there is a scarcity of water, but that could be supplied by the Vehar waterworks. 18. I have never found any particular classes of surface and subsoils for stations more healthy or unhealthy than others. 19. From 18 to 20 years is the best age for soldiers to proceed to India, and they should arrive there at the beginning or end of the year. Those arriving in the cold season are generally sent at once up the country to join their corps or departments, and to preserve the health of recruits on first landing they should be sent up the country as soon as possible. 20. An intermediate station should, I think, be preferred to send the troops to previously to their going to India, and on their arrival in India they should be sent to hill stations where practicable. I may add that June and July are the best months for leaving England, viâ the Cape, for ensuring not only the best passages, but also the best time for marching into the interior on arrival in India. 21. The mode of transport of troops from the port to the interior is by steamers or sailing vessels and sometimes by country boats. 22. The number of years a British soldier should serve in India is about 7 years. 23. The manner of conducting the business of medical boards at stations or presidencies is not such as to cause conflict of opinion as regards invaliding, but the services are in a state of transition; at present there is one mode of invaliding for the local army and another for the British. 24. Invalids should leave India for home in the month of February.
Diseases.	1. There are regular inspection parades for the discovery of incipient diseases at this station. 2. No cases of scorbutus or scorbutic disease have occurred among the troops at this station, except amongst the native soldiers, who feed themselves badly in consequence of the high price of provisions. In Bombay the duty is more severe than in most stations, and the price of provisions more expensive; extra batta might be allowed, and a native regiment should be relieved after the expiration of two years service in Bombay. 3. When hepatic disease owes its origin elsewhere than Bombay, that station is a very suitable place to send such cases to. 4. The appearance of dracunculus seems attributable to the water of certain notorious places, but whether it occurs from the men drinking or bathing therein is not determined. 5. The proportion of sick from venereal diseases to the total sick in hospital varies much, but the proportion in Bombay, as is to be expected, is great. Lock hospitals have been generally abolished at this presidency.

IV. Health of the Troops—*Diseases —cont.*	6. The average strength of the European troops in the Bombay garrison for the past year amounted to 423 in number, of which 277 cases of fever have been admitted into hospital, chiefly of intermittens and quotidiana; of these 31 were of remittent fever, of which 6 died, and from continued fever there were 7 admissions and 1 death; total 7. Of dysentery there were 33 cases, and 1 death. Of epidemic cholera there was one admission, and which terminated fatally. Of small-pox 1 case was admitted, but no death, and of rheumatism there were 34 cases, but no mortality. The average strength of the native troops of the garrison amounted 2,105 in number for the past year, and the admissions into hospital from fever (chiefly quotidian) amounted to 1,330, of which number 7 died. Of dysentery there were 26 admissions and 2 deaths. Of cholera and cholera morbus, there were 11 admissions, and one death. Of small-pox there were 7 admissions, but no death, and of rheumatism there were 172 admissions, but no death.
	7. The nosological character of the more frequent zymotic diseases were:—
	Fevers { Febris ephemera. / „ intermittens tertiana. / „ „ quotidiana. / „ remittens.
	Eruptive Fevers { Variola. / Rubeola.
	Cholera, epidemic.
	Fevers prevail most in the months of August, September, and October. Eruptive fevers prevail in the months of April and May; and cholera in the months of March, April, May, and June. No particular condition of the atmosphere was observed either to precede or accompany their appearance. The sanitary condition of the regimental lines at Colaba is very indifferent; the barracks are built in a low situation, and consequently are very damp in the rainy seasons; the buildings themselves are well ventilated, the necessaries and urinals are situated to windward of the barracks, and the drains empty their contents on the beach, also to windward of the buildings; consequently the wind, which generally prevails from the west, carries the odour through the barrack rooms, which must prove hurtful to the men. The water supply is both plentiful and of good quality. The native dwellings in the neighbouring bazaar are crowded, badly ventilated, and the habits of the natives themselves are filthy in the extreme, and in my opinion predisposes them to the above diseases. As to the situation of the lines of the native soldiers, I believe it is as bad as it well can be; close upon their northern length lies a densely populated native district proverbially unhealthy; close on the eastern face is a large fish and meat market, and separated from this by little more than the breadth of the railway are butchers' shambles and public necessaries or privies washed by the sea, but extending along the whole of its margin in this direction; on the south are large railway buildings and the dhobies' tanks, where great quantities of clothing are washed, and where many of the washermen remain day and night. That which might be expected to be the best aspect of the lines, the west, looking towards Back bay, has much of the sea breeze shut out from it by the regimental bazaar, and the golundaze and gun lascars lines.
	8. Exposure to the sun and night dews when the soldier is in the field or on the march is likely to cause his general health to suffer and predispose him to epidemic disease.
	9. At this station quinine has not been tried as a prophylactic against malarial diseases, and I know of no instance in which healthy men have been put on a course of quinine with this view; as an antiperiodic quinine is found most successful in large doses.
	10. The great desideratum is to keep the regimental lines and bazaars thoroughly clean by a complete system of drainage, a liberal use of charcoal and quick lime to the urinals and necessaries, and to have the drains well flushed, and lastly, to prevent the men being exposed to the mid-day sun as much as possible (and to remove the present barracks to the higher ground on the opposite side of the road), also to have sheds and suitable workshops erected to enable the soldiers to carry on their different trades, and have their amusements without requiring them to go out in the sun.
V. Intemperance.	1. The soldiers at this station are generally temperate, only about one per cent. of confirmed drunkards.
	2. The proportion of admissions into hospital through intemperance are 3·7 per cent. I have no return from which I can prepare a statistical table, showing the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station. Drunkenness is punishable as an offence.
	3. Distilled spirits are sold both at the canteen and in the bazaar, and each man is only allowed one dram per diem of the best quality, which forms part of the ration at the station, on the march, and in the field; arrack of the best quality is alone used, and no spirits are allowed to be issued from the canteen before 12 at noon. In the field they are allowed 2 drams, but I consider it prejudicial to health, particularly to young soldiers. Spirit is never given as a ration to convalescents. No other than intoxicating drinks are sold at the canteen or bazaar which are injurious to health.
	4. I consider the daily consumption of spirits by the troops injurious to health, and certainly not conducive to the efficiency and internal discipline of the corps.
	5. It would in my opinion be highly beneficial to the health of the troops to abolish the use of spirituous liquors as part of the ration, and to prevent the sale of them in the canteen and bazaar.
	6. Good malt liquor would in my opinion be more beneficial to health than spirituous liquors.
	7. Coffee is very much used as a drink at this station, I consider if the soldiers were to drink only tea, coffee, and lemonade, they would in all probability enjoy better health, while the efficiency and discipline would be in a better state than if they drank spirituous liquors; malt liquor, however, in moderation I do not think would be in any way injurious.
	8. It would be highly beneficial as a general rule to suppress altogether the spirit ration, whether for soldiers or convalescents, and to substitute for it, beer, tea, or coffee, &c.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	9. I believe it would be beneficial to the men to prohibit the sale of spirituous liquors in the canteens, and to permit only beer, coffee, tea, lemonade, &c., to be sold to the troops; but in Bombay, where there are so many facilities and inducements to buy drugged liquor of the most deleterious kind, every possible means should be taken to prevent the necessity of a man's going outside to seek his dram. There is a penalty for selling liquor to a soldier, but the law is easily evaded so as to be almost inoperative.
	10. I would recommend that each man who may desire it be allowed two quarts of beer or porter per diem, and to be served to him half at dinner and half at night before going to bed.
	11. By the canteen regulations the issue of malt liquor is made at the rate of one quart of porter to each man, besides which they are allowed a dram of arrack per diem. The canteen is opened from 12 noon to ¼ to 1 p.m., from 2 p.m. to ¼ to 3 p.m., and from sunset to a quarter before tattoo. No man is allowed to have 2 pints of porter at one issue.
VI. Diet.	1, 2. For the Queen's British troops, a complete ration, including a due proportion of vegetables; no fruit is provided for troops at the station, and no stoppage on account of ration. The soldier has three meals a day: 1st, breakfast at half-past 9 a.m., consisting of tea, milk, bread, fish, eggs or meat, whichever he chooses to purchase; 2nd, dinner at 1 p.m., consisting of beef, rice, bread, and vegetables, such as potatoes, onions, carrots, &c.; 3rd, supper at half-past 4 p.m., this meal consisting of very little coffee chiefly, and what the soldier provides at his own expense, or what he saves from his dinner. (2.) For European troops in the Indian army, the ration is, 1 lb. of meat, 1 lb. of bread, 1 lb. of vegetables, 4 oz. of rice, 2½ oz. of sugar, $\frac{1}{21}$ oz. of tea, 1 oz. of salt., and 3 lbs. of firewood. The rations are inspected by orderly non-commissioned officers, and passed by the orderly officer, and when objected to, by a committee of two military and one medical officer.
	3. I believe it would be an improvement and conducive to the health of the troops to vary the meat, and to allow them to have mutton alternately with beef, or say two days in the week. Good mutton in quantities is difficult to be procured in Bombay. It would also be an improvement and conducive to health to increase the vegetables to 1½ lb. The existing arrangements prevent the men from disposing of any of the rations. Orderly men also are appointed daily to look after the messing, and they are responsible for the rations in every way from the time they receive them from the quartermaster's stores.
	4. The means and apparatus available for cooking at the station are copper pots tinned once a month. The cook-rooms attached to the barracks are small and close, and are badly constructed, and instead of the smoke finding a free and easy exit, it disseminates itself throughout the room, and then not only half-blinds the cooks, but renders every attempt at supervision utterly abortive. The supply of water is abundant. The food is generally boiled. The cooking is properly done, and the different messes generally manage to have a variety of dishes, such as curries, stews, &c. Tea and coffee are also properly prepared. The men always have the latter articles supplied to them about half way between halting places on the march.
	5. I do not believe that gardens could be advantageously established near the station for the cultivation of vegetables by soldiers, no ground being available for such a purpose. Where grounds and water are available, gardens should be established, and men should be encouraged to cultivate vegetables as well for profit as amusement.
VII. Dress, Accoutrements, and Duties.	1. During the cold and rainy seasons the men wear the forage cap, cloth tunic, cloth trousers, woollen socks, cotton shirt, ankle boots, and great coat. In the hot season a wicker helmet, with quilted cover and turban, khakee cloth tunic and trousers, cotton shirt, cotton socks, and ankle boots. The accoutrements consist of rifle and bayonet, with scabbard; ammunition, reserve pouch, and shoulder belt; expense pouch, waist belt, cap, pouch, and knee cap. I consider the present dress suitable to the climate at all times and seasons. The present regulation dress is well adapted for all the varieties of stations in the presidency, provided proper attention is paid to have the changes made for cold and warm weather according to temperature. I would suggest, however, that the white light clothing in garrison be substituted for the khakee.
Duties.	1. I think it would be advisable that recruits should be thoroughly drilled at home before being sent to India.
	2. The usual routine of a soldier's duties is to mount in turn any guard told off for the regiment; to escort prisoners to jail; to act as orderly to his company in turn; to keep his clothing and accoutrements clean, and to attend drill when not on duty. Drills or parades evening and morning last one hour; each man carries 10 rounds of ammunition in his pouch. The men, in my opinion, should never be kept at parade or drill more than three quarters of an hour. The best hours for drills, parades, and marches, are from daylight to a little after sunrise, and in the evening from five o'clock till a little after sunset. There are general orders on these subjects. The men have from two to three and a half nights in bed during the week.
	3. One guard is mounted about 2½ miles from the barracks, and two others in the immediate neighbourhood. Guards last 24 hours by day and night; sentries are relieved every two hours. There are roll calls morning and evening. I cannot say that I have observed any bad effect on health caused by night guards.
VIII. Instruction and Recreation.	1. There are no means of instruction or recreation at the town barracks, but at Fort George barrack there is attached one ball court, one skittle ground, covered with mats, one school, with good schoolmaster, and library and reading room sufficiently lighted at night, and a small soldier's garden. The Colaba barracks have one ball court, a skittle ground, under a temporary verandah, and a school with good schoolmaster; while the depôt barracks have only a skittle ground, covered with mats. No workshops are attached to any of the barracks. Theatrical amusements are occasionally provided at Fort George and Colaba. Cricket is a favourite game among the men. I do not think the present means are sufficient to occupy the men during the rainy season, especially for those men unable to read or write. There are no special restrictions imposed on the men in regard to exposure to sun and rain when

References to Subjects and Queries.	Replies.
VIII. Instruction and Recreation—*cont.*	off duty, but they cannot leave the barrack-yard except on pass, before five o'clock in the evening. 2. I would suggest that officers join the men in cricket, as the more they do so the better. There are now many officers who do so. In Fort George there is also a cricket club for the boys. 3. There are regimental savings banks established at Bombay, and these are of great advantage to the men. 4. No shade is afforded by trees at any of the barracks to enable the men to take exercise during the day, but there is ample shade afforded by the verandahs of the Fort George and Colaba barracks. There being only one verandah to the town barracks, the space for exercise is rather confined. There is no shade or shelter whatever at the depôt barracks.
X. Military Prisons.	1. The military prison answers its purpose very well, considering it has not been constructed *ab initio* for its present purpose, but is merely an adaptation of a portion of the House of Correction, which is essentially a jail for natives. A new building should have a more elevated site and efficient drainage, ample circulation of air all round, a verandah in front of the cells, boarded floors. and ventilators so constructed as not to tempt (as the present do) their entire closure with matting during the rainy season, when ventilation is most wanted. These arrangements might prevent the dysentery now so prevalent, and render outbreaks of cholera less frequent. With respect to lunatic soldiers, I may say that the lunatic asylum here is very unfitted for the reception and treatment of cases of this kind. It is incommodious and gloomy. But as, in my opinion, soldiers who once require restraint of this nature are ever after ineligible for the ranks, and it is an object to send these patients to England by the first opportunity, the imperfections of the lunatic asylum are of little importance in a military point of view.
X. Field Service.	1. There are no local regulations for field medical service. 2. With regard to the powers of the medical officers on the line of march, camping, &c., every attention is paid to their recommendations and representations. 3. The medical officer can suggest anything he thinks proper for the preservation of the health of the troops under his charge to his commanding officer. This is usually referred to the deputy inspector-general at the presidency, who recommends to the brigadier-commandant of the garrison any improvement he considers to be necessary. 4. Field hospitals are not required at the presidency; sick European troops arriving are taken to the Colaba sanitarium; the natives to the Marine Battalion Hospital. The sick are transferred on arrival, in buggies and palanquins, according to the nature of the case. Hospital supplies are procured on requisition from the commissariat department.

By order of the Principal Inspector-General, Medical Department,

W. C. Coles,
Assistant Surgeon, Secretary.

Office of the Principal Inspector-General, Medical Department,
Bombay, 30th January 1861.

References to Subjects and Queries.	Replies.
XII. Hospitals.	1. Plans and sections of the Fort George, Colaba, and depôt hospitals are transmitted, but there being no separate building for an hospital, a division of the upper story of the town barrack is sometimes used for that purpose. Fort George hospital is about 300 feet from the barracks to the west, and about the same distance from the stables to the south. The Colaba hospital is about 300 feet to the south-east of the barracks, and the depôt hospital about 1,550 feet to the north-east of the barracks. The European hospitals are at some distance from the bazaar, but the latter is close to the native hospitals. The sites of the buildings are generally good with the exception of the hospital of H.M.'s 56th regiment at Colaba, which has been built on low ground close to the sea. The drainage of Bombay is generally defective. 3. The water supply of the hospitals is wholesome in quality, but it has hitherto become scanty towards the end of the hot season. The wells and tanks will now, for the future, be kept filled with excellent water supplied by a large reservoir called the Vehar lake, some 15 miles distant, and brought in through cast-iron pipes. There is an intention of supplying the hospitals and barracks direct from this source. 4. The means of drainage employed for removing refuse water and other impurities from Fort George hospital are through open drains into the ditch, and through covered drains into cesspools; ordure from necessaries is conveyed away by buckets, which are emptied into the sea at the rear of the barracks at a distance of about 400 feet from the hospital. Colaba hospital is drained through open and covered drains which empty themselves into the sea, ordure from the necessaries is conveyed to the sea at a distance of from 100 to 120 feet. The depôt hospital refuse water, ordure, &c., is received into cesspools, which are emptied and cleaned when required. The refuse water from the cook-house is conveyed through a covered drain to the sea at a distance of 150 feet. 5. The lowest wards of Fort George hospital are raised above the ground about six feet, and there is free perflation of air underneath the floor. At Colaba and the depôt hospitals the lowest wards are raised about two feet above the ground, and there is no free perflation of air underneath the floors. At Fort George hospital there is no provision made for carrying away the roof water; it therefore sinks into the ground or escapes into the ditch and tanks. Wooden gutters are fixed on the roof of Colaba hospital for conveying the water into covered drains leading into a tank for use. There is no provision made for conveying away the roof water of the depôt hospital; it, therefore, sinks into the ground or escapes into the sea. There is no guttering round Fort George hospital. The ground slopes towards a tank in front, into which the water falls, and in the rear the water escapes into the ditch which is all that is required. At Colaba hospital wooden gutters are placed along the eaves from which the roof water is conveyed through wooden pipes into masonry drains, and these empty themselves into the tank; there are also open drains to convey the surface water to the sea, by which means the ground is always free from pools of water. The ground slopes from the depôt hospital towards the sea into which the surface water falls, and this is found to be sufficient. The foundations and walls below the floor of wards of Fort George hospital are built of lime and stone masonry; the walls of verandahs are of single brick six inches thick; the main walls consist of teak posts on which the roof is supported, and double bamboo plastered on both sides with chunam. The roof is of teak wood trussed with double tiles, and having dormer windows for ventilation, &c.; the roof and walls are sufficiently thick to keep the hospital cool. The foundations and superstructure of Colaba hospital are of stone and lime masonry, single walls, plastered inside and out; the roof of teak wood trussed with double tiles, and both roof and walls sufficiently thick for coolness. The foundations and plinth of the depôt hospital are of stone and mud, and plinth up to the posts of stone and lime masonry; the walls are of double bamboo plastered on both sides with chunam, the roof is supported on teak round posts, and is made of teak wood trussed with bamboo battens and double tiles; ventilators with glazed shutters, fixed close up to the wall plates, and roof and walls sufficiently thick for coolness. There is a closed verandah on the east and west sides of Fort George hospital with glazed and plank shutters. The former eight feet wide, and the latter nine feet wide, and sufficient shelter from the sun's rays is afforded. At Colaba there is a verandah 10 feet wide all round with teak plank shutters, &c., and sufficient shelter from the sun's rays. A verandah 12½ feet wide is fixed all round the depôt hospital, and is sufficient shelter from the rays of the sun. The verandahs of the military European regimental hospitals are not used for the accommodation of sick convalescents, or others, except for their own convenience or on extraordinary occasions of sickness. Fort George hospital consists of one flat or ground floor raised on arches about 6 to 7 ft. in height; Colaba and depôt hospitals of one flat or ground floor each.

References to Subjects and Queries.	REPLIES.
XII. Hospitals—*cont.*	The ramparts of Fort George hospital partially obstruct the south-west wind. The Colaba and depôt hospitals each receive the benefit of prevailing winds; the windows in all these hospitals open outward on hinges with opening hooks and eyes, and their arrangement is conducive to ventilation and coolness. 6. Fort George hospital is ventilated by dormer windows in the roof, and by the doors and windows in the walls; these, with the punkahs going, are sufficient to keep the wards at all times free from odour or closeness. Colaba, by ventilators on the roof, and by the doors and windows in the walls, and also supplied with punkahs. Depôt, by ventilators in the walls, and also by the doors and windows; the wards are always free from odour or closeness by these means. There are no jalousies or jhilmils to any of the hospitals. 7. The means of cooling the air admitted into the wards are by punkahs or large swinging fans. 8. In the damp chilly weather means of warmth are supplied by charcoal burners, which are used also in the barracks. The walls and ceilings of the hospital wards are cleaned and whitewashed every three months. 9. At Fort George hospital the privy is about 10 feet to the south-west, and consists of a row of seats with covers, having earthenware pots underneath, which are emptied twice daily into buckets, and the contents thrown into the sea behind the barracks; water-closets are about 10 feet to the south-west of the hospital. The urinals, which are tubs with iron handles, are carried behind the barracks and there emptied. The water from the washing of the pots is allowed to run into the ditch. They do not appear to be offensive, no water is supplied to them, nor are they placed over cesspits. The privies at Colaba hospital are from 40 to 80 feet south-west, with plank seats, under which buckets are placed which are emptied into the sea daily. The water-closet is about 30 feet to the south-east. The urinals are of a similar description to those at Fort George, and are also emptied into the sea daily. They are not supplied with water, nor placed over cesspits, nor are they offensive; they are properly drained. At the depôt hospital the privies abut against the verandahs on the south and north sides, and have plank seats and a masonry trough underneath to hold water; the contents are received into cesspits, which are emptied daily. Water-closets are about 10 feet from verandah, and under the same roof as the bathing rooms, the waste water from the latter running through the urinaries. The contents of the urinals, &c., are received into cesspits, which are emptied when full. They are not placed over the cesspits, but near them. They are not offensive. 10. The bathing places at Fort George are four in number with terraced floors, off the south-west verandah, where the patients can bathe themselves from water-barrels; these are sufficient. At Colaba there is one lavatory near the rear verandah with flagstone floor. A large wooden trough lined with zinc is fitted up next one of the walls, which is supplied with water from an iron tank outside the ball-cock. From this trough the patients take the water to bathe themselves with; this arrangement seems sufficient. There are two lavatories detached from the depôt hospital, which are divided into several small compartments with mats nailed on wooden framework, so that each patient may bathe himself without being exposed to the gaze of the others. The water is supplied in barrels or tubs. The floor is terraced. 11. The sick generally pour the water over themselves with a tin pot. The water is supplied in troughs or tubs placed in the lavatories. 12. The washermen take the clothes to a distance, where they wash and dry them. Outside Fort George hospital in the neighbourhood there are public washing places; which answer the purpose well. 13. The storage is sufficient and dry. 14. Iron cots laced with cotton tape are now in use in the hospitals; there are some older ones banded with flat iron bars. The former construction answers the purpose well. 15. The hospital kitchens are generally to leeward of the hospital, and sufficiently large. Cooking pots, gridirons, and other appliances sufficient. The diets might be more varied; mutton might be allowed twice during the week as a change.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	16. Copies of the diet-tables, diet-rolls, and all other returns required for working the internal economy of the hospital, &c., are forwarded. 17. The provision for attendance on the sick consists of a hospital serjeant, and a nurse or native boy generally for each bedridden patient. There is also a European female nurse or matron for the sick females and children. 18. The sanitary condition of the hospitals is generally good, and no epidemic disease, hospital gangrene, or pyæmia, have appeared in the wards. 19. There are no other deficiencies or sanitary defects which have come under my notice as medical attendant. 20. There is no special provision made for convalescents taking exercise, but an allusion to Fort George artillery hospital will show certain accidental advantages in this respect. The floor of the wards is on a level with the ramparts, which lie against the rear of the hospital, and looking far out on the esplanade afford a cheerful and airy place of resort for the patients. There is also space on the other side of the hospital where the convalescents take exercise without being able to reach the barracks unobserved. Trees have been planted during the last two or three years. Fort George, as well as being the artillery quarters, was till lately the depôt of all the company's European troops. An invalid, though he may not require treatment, is never allowed to live in barracks excused from all duty. If he is not fit for light duty, he is always kept in hospital. 21. The arrangements made for the treatment of soldier's sick wives and children are quite equal to those of the men, and at present quite satisfactory. 22. There are no special local hospital regulations enforced which are not included in the general presidency medical regulations. 23. In matters appertaining to the sanitary state of the hospitals, to repairs in buildings, to change of diet, and to medical comforts within the hospitals at stations, camps, and on march, the medical officers have full powers, subject to the sanction and control of the deputy inspector-general of hospitals of their division. 24. There are no convalescent wards or hospital for convalescents at the stations, and allowing men convalescent in barracks does not answer well. Patients are better kept in hospital till they are fit for duty.
XIII. Burial of the Dead.	1. There are four burial grounds used by British troops, viz., one Roman Catholic and three Protestant; of the latter two are more especially episcopalian and one presbyterian; they all lie on the ocean side of the island, and have nothing intervening between them and the sea beach, except the presbyterian, which is crowded in by native hospitals and dwelling houses all round. 2. The area of the burial ground in charge of the trustees of the cathedral church is 16,648 square yards, soil sand, subsoil sand; drainage good; decomposition rapid; the ground is well kept under trustees. 3. The regulations as to burial are as follows:—The graves are made according to the size of the coffins, with about 3 feet between them, and between 5 and 6 feet deep; in the monsoon water prevents any deeper digging, and in the dry weather the sides fall in; graves are now never re-opened, except to receive the bodies of relatives of the family. The whole ground has, however, many times been covered with graves. Compulsory interment ordinarily takes place within 24 hours; when necessary, within 12 or even 6 hours. The same rules are in force with reference to burial grounds used by native troops. 4. The grave yard is never offensive. The practice as regards the burial of British troops is this, viz., the bodies of non-commissioned officers and privates are taken from the place where they died direct to the burial grounds. Those of commissioned officers first to the church, and then to the burial ground; all funerals take place in the cool of the morning and evening. 5. The dead of the camp followers or bazaar people are burnt; some few, including Mussulmen, are buried. 6. No injury to the public health accrues from the present practice. 7. I could not suggest any improvements in the way of regulation or otherwise in the burial or disposal of the dead.

(Signed) C. S. Stuart, Brigadier.
J. J. Hamilton, Deputy Inspector General of Hospitals.
Edm. Southey, Captain, Garrison Engineer.

I. Topography.	1. The country surrounding the station is undulating, partly cultivated and partly covered with small bushes. It is hilly and dry. There is no wood, jungle, or water in the immediate vicinity. 2. The elevation of the station above the sea is 1,862 feet, and from 100 to 200 feet above the adjacent country. Two rivers, dry in the hot season, bound the cantonment. The nearest river is the Nerbudda. There is no canal, nullah, nor marsh near the station. The edge of the Ghaut is higher than the station, but no better site for the camp exists. 3. The station is on table land. The edge of the Jam Ghaut, 12 miles distant from Mhow, is 2,328 feet above the level of the sea. 4. The Nerbudda is the nearest river; it is 27 miles distant at Burwai, the nearest point. The river does not overflow its banks. There are ravines and broken ground near the station. 5. It is open and freely exposed to winds, and nothing interferes with the ventilation. The temperature is not raised by the buildings being exposed to reflected sun heat. The station is exposed to variable winds, which, in the cold season, are cold and northerly. The pre-

I. TOPOGRAPHY—*cont.*	vailing wind, however, is from the west, and is more agreeable to the feelings and more healthy than from any other quarter. 6. The country is only partly cultivated near the camp. There are no works of irrigation nearer than 12 miles. Rice is not cultivated in Malwah, nor any hemp nor indigo near the station. 7. Indore, 14 miles distant, is the nearest city. 8. The geological structure is a trap formation, with a surface of water-worn pebbles and clay. Morum and black soil are found in the depressions; the latter is seldom more than three feet in depth. No former town existed on the site of the cantonment or near it. 9. During the dry season water is usually found at from 40 to 50 feet below the surface, and in the rainy season at from 10 to 15 feet. 10. The rainfall runs off readily. There is no adjacent high ground, the drainage from which passes into the subsoil. 11. The water supply is derived from wells, and there are no tanks near the station. 12. The supply of water is not plentiful, but it is good. Its composition varies in different wells; but good, pure, and wholesome water can always be procured. It has not been examined microscopically nor chemically. It is drawn and distributed by bheesties in the usual manner. No better water is to be obtained near the station. 13. There is no other topographical point of consequence to be mentioned. 14. No new stations have been selected within the Bombay Presidency for the last 20 years.
II. CLIMATE.	1. The means and instruments available for meteorological observations are the pluviometer, barometer, and thermometers, with wet and dry bulb. 2. The following Table gives the observations from April 1859 to March 1860:—

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Rain Inches.	Winds. Direction.	Winds. Force.	Day of Sunshine.

Dec. ,,	28·1	71	6	74	67		E.N.E.	Calm.	

Thermometer kept in a substantial building, highest 98°, lowest 62°, aneroid barometer.

3. The climate has always been considered good, dry, and cool. Few trees have been planted lately, but in some parts of the camp there are fine old trees. Except in gardens, there is no irrigation. The atmosphere is seldom loaded with dust. The health of the troops is affected at the change of the season, when fevers and bowel complaints prevail. The diet should be generous, without being over-stimulating, and with a good proportion of vegetables. The shelter is as yet imperfect, but is improving. The loose clothing is a great improvement. Drills, duties, and exercises are not excessive, and the drills are suited to the season of the year. The monsoon month, and more especially towards its termination, when fevers and bowel complaints prevail, are the most unhealthy. The end of the cold season and the beginning of the hot are the most healthy.
4. There is no adjacent district more conducive to health than the station.
5. The stations I have served on are Sholapore, Poona, Kurrachee, Baroda, and Aden, in the Bombay Presidency, and Peshawur and Gwalior in Bengal. Sholapore and Poona were the most healthy.

III. SANITARY CONDITION OF STATION.

1, 2, 3. Maps and plans.
4. The barracks at present occupied by the troops being temporary buildings, it is impossible to fill up the annexed form correctly.
5. The windows are on opposite sides of the rooms, and open windwards. There is a verandah 10 feet wide on an average. It is not occupied as sleeping quarters. There are properly constructed jalousies or jhilmils.
6. The regulation bedstead, used by the troops at Mhow, consist of 3 plain boards, each 6¼ feet long, 10 inches broad, and 1 inch thick, supported on 2 iron trestles 18 inches high. For durability, cleanliness, and comfort, it is considered they cannot be surpassed. The bedding consists of 1 pair of blankets or cumblies, 1 cotton rug, 1 cotton quilt, 2 cotton sheets, 1 cotton pillow with 2 pillow-cases. This bedding is found not to be sufficiently warm in the cold season. Instead of 2 cumblies, 1 good English blanket should be substituted; and mattress and pillows of hair, or cocoa-nut fibre, would be preferable to those now in use.
7. The structure and dimensions of the tents used in camp are as follows:—

	Cubic Contents.			Superficial Area.			Cubic Space per Man.	Superficial Space per Man.	Number of Men in each.
	Yds.	Ft.	Ins.	Yds.	Ft.	Ins.	Feet.	Feet.

III. Sanitary Condition of Station—*cont.*	8. Ventilation is obtained by openings in the roof of the barracks, and is sufficient to keep the air pure by night as well as by day. The climate of Mhow renders any contrivance for cooling the air unnecessary. 9. The troops are at present in temporary barracks, constructed with either burnt or sun-dried bricks, and with tiled or thatched roofs. 10. The floors are of lime, raised 1½ feet above the surface of the soil on an average. There is no passage for air beneath. 11. The new barracks will be constructed with stone, a better material than brick for resisting heat. The executive engineer is responsible for the buildings. The officer in command for the general sanitary state. The repairs are made quickly, and the barracks are cleansed and lime-washed every 9, 10, or 12 months, seldom at longer intervals. 12. The baths are drained into a cesspit, and the water taken away by bheesties. Three wash-houses of this description are in camp. 13. The cookhouses are temporary buildings drained in a similar manner. No conveniences for washing linen exist in the Mhow cantonment. 14. The contents of the privies are removed behind. Some of the urinals have cesspits similar to the washhouses. 15. All the buildings are ventilated by openings in the roof. They are generally sufficiently light in the day, and at night oil lamps are supplied. 16. No made drains or sewers exist, but the buildings are on sloping ground. They are kept clean by means of carts and bheesties. No part of the barracks or hospital is damp. The drainage is received into cesspits in some instances and removed. None of the cesspits are nearer the wells than 200 yards. They are 50 feet from the nearest quarters, and are cleaned every morning. There are no foul ditches. 17. The surface cleansing is done by the barrack-master, who has an establishment *constantly* employed for the purpose. 18. The surface of the cantonment is kept free from vegetation. There are no old walls, hedges, &c., interfering with ventilation. 19. From the fact of there never being any sickness in the bazaar of a serious nature, it does not appear that the sanitary measures at present in force could be improved on. The drainage is good, and water plentiful. The ventilation would be better if the street had been built endways towards the prevailing wind, instead of laterally. Sweepings of all descriptions are put into heaps and carried away by the conservancy carts. The houses are for the most part well built and airy. There are no dungheaps or cesspits within them. No nuisance is experienced from wind blowing over the native dwellings. 20. Animals are slaughtered well to leeward of the station, about half a mile. The kites and vultures carry off the offal, and the place is clean and no nuisance experienced from it. 21. Any horses belonging to residents in the bazaar are picketed in or near the Dhurrumsula. There are no horses attached to the bazaar. The manure heaps are carried away by the conservancy carts. 22. The horses are placed to leeward of the men's barracks. Those of the cavalry and artillery are not in stables. Dungheaps are a quarter of a mile distant. It is sold to the brick-makers, and by them removed. 23. Married soldiers are in temporary patcherries.
Officers' Quarters.	1. The officers' quarters, which are in low situations, are damp during the rains. The houses are well ventilated and generally healthy. The dampness in some parts of camp during the rains might in some measure be obviated by improved drainage, and this measure is about to be carried out.
IV. Health of the Troops.	1. The station, the district, and the adjoining native population are healthy. 2. The prevalent diseases are fevers, with occasional spleen affections, small-pox, and occasionally cholera. 3. I attribute the healthiness of the natives to the elevated site, dry and cool climate, and the abundance and cheapness of the necessaries of life. 4. The European part of the garrison is recently from Europe, and these enjoyed good health. They arrived in good health, and have suffered chiefly from fevers and bowel complaints since arrival. There is a deficiency of accommodation at the station, but no part is considered more unhealthy than the rest. 5. The troops are never camped out. 6. I have never been in charge of tropical hill stations, and have no experience of them. 7, 8, 9. As stated above, I have no experience. 10. Great precautions must be necessary for troops at hill stations, but I cannot speak from experience. 11, 12, 13. No reply. 14. Undoubtedly it would be desirable to locate troops on the hills as much as possible. 15, 16. No experience. 17. There is no higher ground near this station which could be advantageously occupied. 18. A friable, light, porous soil is the most healthy for stations. 19. A mature age is the best for soldiers proceeding to India. Troops are disposed of on arrival in every respect as the regiment to which they are posted. At the sea port on first landing they have not always these advantages, and suffer accordingly. The best precaution for preserving the health of recruits, if the season will permit of it, is to remove them as speedily as possible and send them to join their regiment. 20. If there were proper intermediate stations, it would be well to locate troops in them for a time before proceeding to India. They should be prepared gradually to encounter the heat of the plains. 21. The mode of transport for troops from the port to the interior varies. Some must proceed by water, others by land, to join their regiment, according to the station it may be at. 22. If every European soldier has the benefit of a furlough to Europe after 10 or 12 years, he will complete 20 years' service with ease. 23. I never saw any bad consequences arising from difference of opinion on medical boards. The majority always forms a fair judgment. 24. The spring is the best time for invalids to leave India for home.

MHOW. BOMBAY.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.* *Diseases.*	1. There are inspection parades once a week for the discovery of disease. 2. There is no considerable amount of scorbutic disease at this station. I attribute its occurrence to a deficiency of vegetables and fruits such as European soldiers are accustomed to and care for; and I recommend potatoes as the best anti-scorbutic, and which soldiers never tire of, to be issued as part of the ration throughout the year. 3. The sea-side predisposes less to hepatic diseases than high and dry climates. Stimulating food and drink also predisposes to them, and these form strong reasons for improving the vegetable portion of the ration, and substituting malt liquor for ardent spirits. The proportion of hepatic disease to other diseases usually under treatment is 3 per cent. 4. Dracunculus is rare, and not of much importance at this station. 5. Venereal cases have been as high as 60 per cent. of the sick, and as low as 8 per cent. Lock hospitals, with a good conservancy police, should be established wherever there are European troops. 6. Troops at this station suffer both from epidemic and endemic disease, chiefly the latter. Cholera, however, often appears as an epidemic, and also small-pox. Fevers are intermittent and remittent, and occasionally continued. Dysentery prevails to no great extent, and is endemic; it yields about 2 per cent. of treated and 5 per cent. of deaths. Cholera appeared epidemically last year, but not in any alarming degree. One half per cent. of cases treated, and 25 per cent. of deaths. Small-pox is neither observed as an epidemic nor endemic disease. Rheumatism is about 4 per cent. of treated and 4 per cent. of deaths. 7. The more frequent zymotic diseases are febrile complaints and disorders of the alimentary system. Fevers prevail from June to November; bowel complaints from July to October. A high temperature precedes their appearance, and damp weather, with considerable alternation of heat and cold accompany them. The station has always been considered a healthy one, and zymotic diseases are never unusually prevalent. The sanitary condition of the native dwellings in the bazaar and elsewhere may be considered satisfactory; the water supply, cleanliness, and drainage are well attended to. The crowding of native houses is always great, and their ventilation might be improved. There is nothing remarkable in the habits of either troops or natives to predispose them to zymotic disease. 8. Epidemic disease is always aggravated by irregular habits, crowding in barracks, and inferior accommodation, and the barracks here are very indifferent. 9. Quinine has not been given as a prophylactic against malarial disease. 10. Every caution is now taken in preserving cleanliness, improving the ventilation and drainage, and above all in providing the troops with proper shelter from the elements; and these should all be sedulously persevered in. Proper barracks are now in course of erection.
V. INTEMPERANCE.	1. There are no incorrigible drunkards at this station, although a few men are much addicted to drinking. 2. There are no data from which a table could be prepared to show the proportion of admissions to hospital caused directly or indirectly by intemperance. Drunkenness is punished as an offence. 3. Spirits are sold at the canteen to European soldiers, and in the bazaar are only permitted to be sold to natives. Europeans are permitted to purchase two drams of arrack daily at the canteen. Spirit is not used as part of the soldier's ration, but he is allowed to purchase in quarters from the canteen, and from the Commissariat when there is no canteen. No spirits are issued before the usual dinner hour. Spirits are not given as a ration to convalescents. No other drinks injurious to health are sold at the canteen or bazaar. 4. Spirits are seldom under any circumstances conducive to health, and not rarely very injurious. They are not conducive to discipline. 5. It would be very beneficial to restrict or abolish the use of spirits; malt liquor is far better. 6. Malt liquor or wine would be certainly beneficial as compared with spirits. 7. Coffee, tea, and soda-water are in general use, and their influence is beneficial to health and discipline as compared with spirits and malt liquors. 8. It would be beneficial to suppress altogether the spirit ration. 9. It would be beneficial to permit only beer, tea, coffee, lemonade, &c. to be sold to the troops. 10. I would recommend the substitution of malt liquor for spirits. 11. No spirits are allowed on any account to be issued at the canteen before the dinner hour; no man is allowed more than two drams per diem, and these two drams are never to be issued at the same time. The maximum issue of malt liquor to any one man is three quarts per diem without spirits, or two quarts with one dram of spirits, or one quart with both drams. The liquor contractor in the bazaar is compelled to keep up a preventive police in the bazaar and cantonment to prevent liquor being sold to European soldiers, but soldiers will contrive to obtain spirits in spite of every precaution.
VI. DIET.	1. The composition of the ration for British troops is,—1 lb. of bread, 1 lb. of meat, 4 oz. rice, $2\frac{1}{2}$ oz. sugar, $\frac{5}{7}$ oz. of tea, 1 oz. salt, 1 lb. vegetables, 3 lbs. firewood. Mutton is usually issued twice a week and beef five times. The quartermaster, orderly officer, and the quartermaster-serjeant inspect the rations daily. 2. A complete ration with vegetables is provided, but does not include fruit. No stoppage appears in the mess accounts for the above, but its value is estimated at 5*d*. The soldier has three meals daily, viz., breakfast, consisting of bread and tea, at 7 a.m.; dinner, consisting of bread, meat, and vegetables, at 1 p.m.; and tea, consisting of bread and tea, at 4 p.m. The proportion of vegetables is 1 lb. when procurable; at present they are scarce, and a half a pound is issued with a half a pound of flour. 3. During the cold weather, when vegetables are procurable, the rations are all that could be desired, and being cooked in messes, the soldier could not dispose of any part of them without detection. 4. The Commissariat supply copper kettles and saucepans for cooking, and the men pay for their cooks eight annas per mensem. There are two master cooks, two assistants, and four boys per company. The kitchens being temporary are indifferent. Water is sufficiently supplied. The food is cooked according to the wish of the men of the mess. It is properly done, and tea and coffee are to be had at coffee shops in the lines, of which the men avail themselves. They are seldom able to procure refreshment before a march.

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	5. Water is not sufficiently abundant for the cultivation of gardens, except in low situations at a distance from the barracks. If there were gardens the men would work in them themselves, and if necessary might subscribe a small sum monthly for seeds, &c. A small allowance from the canteen fund would cover all expenses after the garden had been established.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress consists of cloth tunics, woollen trousers, and forage cap; shoulder and waist belt, two pouches, knapsack, havresack, and water bottle; serge frock, khakee clothing and wicker helmet, ammunition boots, great coats, &c. I consider the dress suitable to the climate. During the rains and cold weather woollen clothing is worn, and khakee during the hot weather. European soldiers are never exposed in cantonments to the sun or rain.
Duties.	1. The men should be thoroughly drilled at home or in a more temperate climate than that of India. 2. The usual routine is one hour's drill daily at sunrise, except on the garrison holiday, Saturdays and Sundays. Occasional evening parades, with drill in the cool weather. The above does not appear to be injurious to the health of the men. The best hour for drill is at sunrise, and for marches, during the night and early morning. There are general orders respecting these. The men have on an average seven nights in bed. 3. Guards mount as far as half a mile from barracks; they usually last 24 hours. Rolls are called at morning parade, breakfast, dinner, tea, and tattoo. The barrack rooms are also visited during the night by the orderly serjeant to see if the beds are occupied. Night guards are not injurious when they do not come oftener than once a week.
VIII. Instruction and Recreation.	1. There is a ball court in the R.H.A. lines. Each corps has a skittle ground, but only the R.H.A. one is built by Government. There is a school, but the schoolmaster of the Bombay Artillery is untrained. There is a library and reading room, but the 3rd Dragoon Guards is the only corps which has the reading room well lighted at night. There are no day rooms, clubs, or gardens. There are regimental artificers, but no regular established workshops, except in mounted corps. There is a station theatre, but no gymnasia. There is not sufficient employment to keep the men occupied in wet weather or during the heat of the day. They are not allowed to go out in the heat of the day, and are generally healthy. 2. I would recommend that there should be ball alleys to all the barracks, with covered skittle alleys. Reading rooms well supplied with newspapers and lighted at nights. 3. The present system of savings' banks answers well. 4. The space in the verandah is insufficient for exercise, and there are no trees near the barracks.
IX. Military Prisons.	1. The military prisons in the cantonment are temporary buildings. Cells properly ventilated are to be constructed; those at present in use are not well ventilated, and are ill adapted for the purpose.
X. Field Service.	1. There are no local regulations of any consequence in regard to field medical service. 2. The medical officer has the power of objecting in regard to the line of march, camping, billeting, &c. 3. In the late campaign rules were proposed for the preservation of the health of the troops in camp by the principal medical officer, and sanctioned and published for general information by the general officer in command. 4. The orders relative to field hospitals are bad. For the transport of sick and of hospital supplies they are excellent. Copies of all regulations bearing on these matters will probably be furnished by the director-general.
XI. Statistics of Disease and Mortality.	1. The following Table gives the sickness and mortality of British and Native troops:—

MHOW.

XII. HOSPITALS.	1. The building used as a hospital by the 72nd Highlanders was formerly used for native soldiers, and the hospital of the 3rd Dragoons was formerly an officer's dwelling house. They will both be abandoned as soon as proper hospital accommodation can be provided. To give any detailed description of them would be therefore superfluous. They are about 100 paces to leeward of the barracks and stables, and about 300 yards from the bazaar. The site is tolerably open, but is low and indifferently drained, though at a good distance from any river or nullah. 3. The water supply is abundant. 4. Refuse water is carried off by surface drains. 5. The wards are scarcely at all raised from the ground in one hospital, and in the other about two feet, but there is no perflation of air underneath the floors. The roof water runs into the surface drains. There are open drains, which are sufficient to carry away the rainfall. The walls of the hospitals are of sun-dried bricks and mud. The roofs are thatched. Both being thick, the hospitals are tolerably cool. They have verandahs about 10 feet wide, which afford sufficient shelter. The verandahs are sometimes used for the accommodation of sick, but never when it can be avoided. The hospital consists of one flat. The date of construction is unknown. There are 2 wards, and the number of beds is uncertain. The hospital is not judiciously placed. The windows open inwardly, and when open permit free ventilation. 6. They are ventilated by opening the doors and windows. One building has cowls in the roof. There are no jalousies or jhilmils. 7. There are no punkahs, but kuskus tatties are used in the hot season. 8. No means of warming are required. The walls and ceilings are limewashed every three months. 9. The privies and urinals are at one end of the buildings, running to leeward. Deodorizing agents and effective sweeping prevent their being offensive. 10. The lavatory arrangements answer the purpose, but are all of a temporary description. 11. The means of bathing is by tubs, and is sufficient. 12. The linen is washed by washermen at a distance from the hospitals. 13. The storage is dry and sufficient, but all is temporary. 14. The bedsteads are iron, the mattresses stuffed with rice straw; sheets and blankets are provided, and are all good. 15. The kitchen is conveniently situated, but temporary, like the rest. The cooking apparatus is sufficient; the diets are well cooked, and can be sufficiently varied. 16. Diet tables, &c. will most likely be furnished by the Director-General. 17. For attendance on the sick there is a hospital serjeant and ward boys, who make excellent nurses. 18. The hospital is healthy, and no epidemic diseases, gangrene, or pycemia have had their origin in it. 19. I have already mentioned the improvements required. 20. In such hospitals as these no arrangements could be made for convalescents taking exercise. There are no suitable fenced nor shaded walks and no seats. 21. The sick wives and children of soldiers are always treated in female hospitals, but here there are none. As neither the dragoons nor Highland regiments have their families with them, the want is little felt. 22. There are no special local hospital regulations worth sending. 23. In regard to repairs, alterations, and improvements, the medical officer can only recommend. In regard to diets and medical comforts, nobody but his professional superior can interfere in the field or in camp. 24. Convalescents are kept in hospital till fit for duty, but not in separate wards.
XIII. BURIAL OF THE DEAD.	1. The burial ground for British troops is within the cantonment limits, but situated on the S.E. side of camp, to leeward of the prevailing winds. 2. Its area is 17,100 yards laid morum, subsoil decayed trap; it is situated on sloping ground, and the drainage good. Decomposition does not take place readily, as the soil is impregnated with lime. 3. The grave space allowed is what is necessary, so that no ground be wasted. Two feet is the interval between the graves. The depth depends on the soil; 4½ feet deep is the average. Graves are never reopened, and only one interment takes place in each. Early decomposition prevents the body being kept longer than from 24 to 30 hours. On one occasion during an epidemic, funeral parties attended twice a day at hospital, and took away all bodies they found in the dead house. Native dead are soon removed. 4. The graveyard has not been observed to be offensive. Funerals take place at sunrise and sunset. If notice be received before 3 p.m., the funeral takes place in the evening; if after that time, in the morning. 5. The dead of camp followers and bazaar people are buried and burnt. 6, 7. The present practice is the best that can be pursued, and I have no improvements to suggest.

(Signed) R. W. HONNER, Brigadier, commanding Malwa Division.
F. S. ARNOTT, M.D., Superintending Surgeon, M.D.A.
G. J. MELLISS, Lieut. Executive Engineer, M.D.

I. Topography.	1. The station is in a valley, the surrounding hills bare at their summits and bases, lightly and partially wooded on their slopes. It is intersected by two rivers, well cultivated (crops light) and moderately wooded. It has a general slope from the base of the hills, where the soil (the débris of decomposed rock) is dry and poor. In the flat part of the valley and near the river there is black soil, but no swamp. There are trees scattered or in clumps and single, but no jungle. Besides the water of the rivers, there are a few small tanks and nullahs here and there dammed for irrigation (which is very limited).
	2. The elevation of the station above the sea is 2,320 feet. The general valley level is about the same, the surrounding hills varying from 600 to 1,500 feet higher. The nearest notable amount of water is that of the river, distant a mile at the nearest point. There is a nullah running through, and another forming a boundary of the camp, but both are dry in the hot weather. There is somewhat higher ground a little beyond the camp, to be preferred to any other as a site for barracks in my opinion.
	3. The fort hill is distant about $1\frac{1}{2}$ miles from the station. It is 1,000 feet high, with an area on the top of about one-eighth of a square mile. Utishwur, a spur of the Mahableshwur range, is 1,500 feet high.
	4. A nullah runs through camp, dry in the hot weather, and the river is within a mile. Inundation is unknown. There are no ravines or broken ground which can be considered prejudicial to health.
	5. The station is quite open, the hills being too distant to obstruct ventilation. The temperature of the station is not raised by reflected sun heat: but the barracks are hot, being temporary and kutcha. The station is subject to land winds (E. and N.E.) and to the sea breeze (W.S.W.), the latter modified by distance from the ocean; both prevail with tolerable regularity, according to the season and time of day, and neither seem to exert any marked influence on health generally, but the former prevailing at night is sometimes charged with a small amount of marsh poison from the river, as has been lately evidenced.
	6. The surrounding country is cultivated. There are no works of irrigation near the station worthy of note, and garden irrigation only very near the camp. Irrigation in its present extent is not believed to have any effect on the health of the station. There is no rice cultivation, and neither indigo, hemp, nor flax are grown in the district.
	7. The city of Sattara, with a population of 30,000, is within 2 miles.
	8. The whole of the district is of "trap" formation, the sides of the hills presenting many parallel and horizontal layers of basalt and amygdaloid, capped here and there with laterite. The station is situated on the hard swelling flank of one of the hill ranges, and occupies new ground.
	9. In the dry season water is usually found at a depth of from 15 to 45 feet, and in the rainy season at from 5 to 10 feet.
	10. The surface water flows readily away: the slope is great and the soil hard. There is no drainage from higher ground passing into the subsoil of the station. There is no water bearing subsoil.
	11. The water supply of the station is derived principally from wells, but there are two or three small tanks, which, as well as the wells, are all in rock. The extent of tank surface is 29,165 square yards, or about 6 acres. The tanks are filled during the rains, and fall low towards the hot weather, and are then nearly, if not quite, dry. There are a few aquatic plants in the tanks not requiring botanical description, and the only animal to be noted is the guinea worm. No tank used for drinking purposes is used also for bathing, nor are the wells in general use rendered impure by decaying vegetable matter or surface drainage. No nuisance or malaria proceeds from any tanks within or without the station.
	12. The water supply consists of about 15 wells and 3 tanks, and the nullah running through camp, which affords water for bathing 8 months in the year. In most of the wells the water is colourless, somewhat hard and inodorous. Its chemical composition or microscopic character have not been ascertained. As a rule, it is rather hard, though soft in the monsoon, good enough not to be injurious to health, and sufficiently abundant in most years. It is raised by means of buckets and ropes. The quantity and quality of the supply could be improved by bringing water from a large reservoir on the neighbouring range of hills, and surveys for a project having this end in view are already half complete, but their further prosecution is delayed for the present, owing to the suspension of public works.
	13. A malarious fever has prevailed this hot season, the marsh poison cause of which could only have proceeded from the river. This is the most important if not the only influence bearing on the health of Europeans at this station to be considered.
	14. I do not know the kind of data, or by whom collected, on which are founded the establishment of new stations. I think, however, that common sense and local experience, as well as scientific knowledge, should be made available on these medico-military occasions.

SATTARA. BOMBAY.

II. CLIMATE.	1. The means available for conducting meteorological observations at the station are the common thermometer, rain gauge, and weather-cock in the cantonment, and in addition to these a hygrometer and barometer in the civil hospital. 2. The following table contains the observations :— Years of Observation from 1855 to 1859 (4 years).

Months.	Barometer Mean.	Mean Daily Temp.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain.	Winds.		Days of Sunshine.

The above is filled in from the records of the civil hospital, which afford a more extended period of observation (including that of the barometer) than those of any hospital in camp. I think they must not be valued beyond an "approximation," but an extract of observations under Surgeon Murray, quite trustworthy, is appended. See opposite page.

3. The climate, generally considered, is good for three months. The air is hot and dry, but not very exhausting. In the rains, it is fresh, not damp or chilly, and the temperature very equable. The cold in the winter months is not invigorating. I think there are no influences (except the river in some years) prejudicial to health. The station is proved to be healthy for natives, and with good and well-placed barracks, would be no less so for Europeans. Light early morning drill is desirable in the hot weather. As to diet, clothing, &c., there is nothing special required by the climate.

From June to December, comprising the rains and the beginning of cold weather, is the unhealthy season for natives, when fever, bowel complaints, and rheumatism prevail. October, with the hot months of March, April, and May, are unhealthy for Europeans, when they suffer from fever principally of a mild type.

4. There is no district on the same level as the station more conducive to health, and the hill sites, adverted to under Topography, are not habitable all the year round.

5. The stations on which I have served are the following :—Bombay, Shikapore, Sukkur, and Hyderabad (in Sinde), Surat and Deesa (in Guzerat), Sattara (in the Deccan). Of these stations, according to my experience, Deesa is the healthiest.

III. SANITARY CONDITION OF STATION.

1, 2, and 3, maps and plans.

4. The following table gives the accommodation in the barracks :—

Date of construction of barracks, January to July 1858.

Total number of rooms, 13.

Total regulation number of non-commissioned officers and men, 520.

Barrack Rooms.	Regulation Number of Men in each Room.	Dimensions of Rooms or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
				To wall plate.	Including vacuity of roof.			About		Feet.	Feet.
13	40	100	20	10	29,000	735	50	2 feet.	18	4½	3
Guard Room	1	25	12	10	3,900	557	43	2 „	6	4½	3
Prison Cell	1	8	6½	10	676	676	52	2 „	1	2¾	2½

5. The windows are on opposite sides, and open as casements. There is a five feet verandah on both sides, and at the ends also. The verandah is never occupied as sleeping quarters. There are no jalousies or jhilmils.

6. The bedsteads for hospital patients are of iron. For the barracks, iron trestles with wooden boards. No bedsteads are used in tents. I have no improvements to suggest.

7. The tents used in camp are bell-shaped, with double flys. They are 14 feet 6 inches by 14 feet. The number of men, 13; superficial area per man 15.7.4; cubic space per man, 123. 7. 5. Double poled tents, with double flys, are 22·6 feet by 14 feet 6 inches, to contain 22 men. Superficial area per man 14. 9. 11; cubic space per man, 124.

8. There is no appliance in the barracks for ventilation, which is not sufficient unless the windows are opened. No means are used for cooling the air.

9. The barracks have wattle and dab walls, and grass thatches, and are of a merely temporary construction. Tents are made of cotton cloth.

10. Floors are constructed of beaten earth. They are raised from one to five feet above the ground, according to the slope of the surface, and there is no passage of air beneath.

A Synopsis of Four Years' Meteorological Observations (from 1st January 1844 to 31st December 1847), at Sattara.

Latitude 17° 40′ N., Longitude 74° 2′ E. Height above the sea, 2,320 feet.

III. Sanitary Condition of Station—*cont.*	11. The European barracks being temporary, are of course defective in all respects. The huts of the native lines are good enough. Barracks and cantonments are kept in repair by the engineer department, and are quickly executed. The commanding officer is responsible. There is no specific period for cleansing and lime-washing, which are performed, when needed, at intervals of from four to six months. 12. There are no baths. 13. The cooking is conducted by the soldiers' servants on wood fires. Water is brought by bheesties. Linen is washed and dried by dhobies (washermen). 14. The urinals and privies are not drained. They are cleansed in the manner usual in India, by a class of men called bhungies or sweepers. 15. The ventilation is spontaneous by the doors and windows. The barracks are lighted at night by oil lamps. 16. There are no sewers. The surface drainage is readily and efficiently carried off by open trenches. No part of the barracks or hospitals is known to be damp. There is no stagnant drainage. There are no cesspits. One nullah on the east side of the camp is occasionally offensive for short periods. 17. The system of surface cleansing (lately improved) is good. It is performed daily, and the refuse manure, &c., carried to a safe distance from and to leeward of camp. 18. The surface of the cantonment is kept perfectly free from vegetation. There are no old walls or hedges interfering with ventilation. 19. The sanitary condition of the bazaar is in every point good. A sufficient number of sweepers are employed, and a cart to carry away refuse, &c. No improvement has to be suggested at this station. There are no native houses near enough to require description. No nuisance is experienced from wind blowing over native dwellings. 20. Animals are slaughtered near a watercourse (nullah) to the eastward of cantonments. There are no regulations in force further than that they are obliged to be to leeward of camp. The offal is removed daily, and no nuisance is experienced from the slaughtering places. 21. There are no bazaar stables. The few tattoes in the bazaar are picketed in an open space in rear of the bazaar, and the manure is carted away daily. 22. There are no artillery or cavalry stables. The horses are picketed in double lines. The cavalry horse lines are distant about 100 yards from the men's quarters in a south-westerly direction. The artillery horse lines are distant from the men's quarters 60 yards, in an easterly direction. The dung is deposited in a nullah in rear of the barrack, at a spot which is 200 yards distant from the nearest barracks, and 600 yards from the hospital. 23. There is separate accommodation for the married non-commissioned officers and privates, and they do not occupy the barrack rooms with the men.
Officers' Quarters.	1. The sanitary condition of the officers' quarters (which are separate houses) is good. No general recommendation would apply to dwellings no two of which are alike.
IV. HEALTH OF THE TROOPS.	1. The district in which the station is situated is healthy. 2. The diseases most prevalent among the native population are fevers (chiefly mild intermittent), sub-acute rheumatism, and guinea worm. Spleen disease is rare; cholera prevails in some seasons. 3. I attribute the healthiness of the native population chiefly to the elevation of the district and the scanty vegetation of a somewhat poor soil. 4. Before coming to this station, the European troops were at Ahmednuggur. Their stay was 2 years and 11 months, and they left on the 12th July 1857. Their general health there was good. There is no record of the prevalent diseases. They arrived here healthy on the 25th July 1857, since which intermittent fever of a mild type is the disease they have chiefly suffered from. The native regiment had been at Baroda 3 years and 3 months, and left by wings on the 31st March and 25th April 1859. Their general health there was bad. The prevailing diseases, fever and rheumatism. They arrived here in an unhealthy state on the 27th April and 31st May. The men have suffered here from fever and rheumatism in the sub-acute or chronic form. The barracks (temporary as they all are at this station) occupied by the artillery stand on a low site, and are therefore nearer and more exposed to the malaria of the river. 5. The troops have never been camped out. 6. I have never been in charge of troops at a hill station. 7. My experience scarcely justifies an opinion in regard to the health of troops at hill stations. I once sent a few men from a troop of horse artillery to Mount Aboo, in whom little tendency to relapse was shown on their return. 8. I approve of selecting hill stations for troops. 9. I have no experience as to diseases peculiar to hill stations, but men there would doubtless be subject to capillary congestive forms of disease of both kinds (æsthenic in old soldiers with enfeebled organs). Dysentery and diarrhœa are said to prevail. 10. At hill stations, I should give diet according to the increased assimilating power, holding inflammatory tendency in view; and warm clothing, especially a flannel belt over the belly or any weak organ, with protection from the night air, avoidance of wet feet, and exercise strong enough to excite perspiration in the strong and increase action in the weak. 11. I have no experience, but am of opinion that the hot months are best adapted for the hill stations, to avoid cholera and exhaustion; September and October should be selected to avoid malaria. With my avowed inexperience, I could not define the time necessary for troops to obtain the full benefit of a hill station. 12. I think any period beyond the acquirement of moderate tonicity would be injurious. This period would apply differently to young and old soldiers. 13. The special precautions for protecting health on leaving hill stations are avoidance of sun, and all stimulating influences, diminished food, lighter clothing. 14. Long periods of residence on the hills, and short on the plains, would in my opinion most conduce to the health of the troops. Moderately frequent change of station in the plains is beneficial, and before intolerance of the climate contemplated in the transfer has been acquired (as from Guzerat and the coast to the Deccan). 15. Mount Aboo and Poorrendhur are the only hill stations with which I am acquainted, and in these the barrack accommodation is limited. 16. I have an opinion in regard to the level most suitable for hill stations, but no experience. 17. There is higher ground near this station at Utishwur, four miles to its summit from the station, accessible by a good enough road for beasts, but not carts. Its height is 1,500 feet

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	above the plain, with a climate described by occasional residents to be good; but I think the rain-fall is too great for residence in the monsoon. 18. I have found light surface and porous subsoils most healthy; black soil, as containing vegetable matter decomposing under heat and moisture, excepted. 19. I consider from 20 to 25 the best age for soldiers proceeding to India, and the best time of landing the beginning of the cold weather. I have no knowledge how troops are disposed of on landing, beyond a general one that the barracks at Bombay, into which most of the troops are at first received, are all bad, either in site or construction. I should recommend that troops should be sent straight to a plateau or hill station of moderate elevation. 20. If the Cape, Australia, or the Mauritius are the intermediate stations referred to for troops proceeding to India, they might be sent there now, but not, I think, when hill stations are organized. I should advise their being sent to hill districts on landing. 21. In Bombay, the mode of transporting troops to the interior is chiefly by land marching. The first great precaution is the selection of a proper season; the next to keep the men from liquor. 22. I consider about 15 years as the length of time for a soldier to serve in India. Longer, if the hill sanitaria plan is carried out. 23. In my own experience I have found no conflict of opinion on the subject of invaliding. If, however, opinion is invited as to other boards, I am strongly against them for passing recruits, and think that at least the final power of rejection should be vested in the regimental surgeon. 24. Invalids should leave India so as to arrive at home in early summer.
Diseases.	1. There are regular inspection parades of European soldiers for the discovery of incipient disease ordinarily once a week. 2. There has never been scorbutic disease amongst the European troops, and only an occasional case of taint amongst the present natives of the brigade. 3. The ratio of cases of hepatic disease to all others has been only 1·03 per cent. for three years. 4. The primary cases of dracunculus (that is not brought here) amongst the Europeans under observation have only been 0·62 per cent. on all others. Amongst the native troops it has been more common, and avoidance of the tanks and wells known to produce it is the only preventive I know of, and this cannot be carried out with the natives to any useful extent. 5. On a three years' estimate, venereal cases amongst the Europeans have borne a ratio only of 8·22 per cent. to all others, and no precautionary suggestions have to be offered as to this station. 6. As regards epidemic diseases, both European and native troops are most subject to fevers, chiefly mild quotidian intermittents. Dysentery is so rare as hardly to be called an endemic disease. The troops, European especially, suffer little from it. Cholera and small-pox prevail amongst the population most years; the troops are protected by prophylactic care and vaccination; they suffer little. The native troops suffer much from rheumatism, the Europeans scarcely at all. In the European battery, average strength 74 (the only detail susceptible of correct observation), there have been two deaths only, one from dysentery, and one from cholera; the ratios therefore would be of no practical use. 7. Very few zymotic diseases have come under my observation at this station; their invasion might be expected at the beginning and end of the rains. Cholera and small-pox generally prevail in the hot weather, when the air is hot and moist; in the station bazaar and native lines this class of diseases may be looked for. The former is small, and stands on a slope; the houses are not crowded, and no organic remains are allowed to accumulate. The lines are open; in both the best sanitary means available are in force. The troops and natives are for the most part cleanly in their persons, but the latter are opposed to ventilation in their dwellings. 8. Some of the soldier's duties and occupations favour epidemic disease, but there are no personal habits conducing thereto which cannot, I think, be controlled. 9. Doses of quinine as a prophylactic have been tried at the station to a small extent; I tried them some years ago on the malarial banks of the Indus without much effect. 10. The only morbific cause to be guarded against at this station is marsh poison, chiefly from the river. It is small in quantity, but brought by the night wind on the soldier at the susceptible time of sleep, producing fever, as has been evidenced this hot weather. This applies to the Europeans only, and might, in my opinion, be obviated by good barracks.
V. Intemperance.	1. The soldiers at the station to whom observation has been extended are temperate; there are no confirmed drunkards. 2. Admissions to hospital from drunkenness and its sequelæ have been so very rare that a scale of proportion would be too small for statistical usefulness. Drunkenness is punished as an offence. 3. Rum or arrack received from the commissariat on indent is sold to the soldier only at the canteen. Bazaar shopkeepers are prohibited from selling liquor to soldiers. Spirits are procured from Government of the first quality, and issued to the troops on payment, diluted with one-fourth of water. The quantity varies in different regiments and seasons, usually it is about a dram a day to each man. Spirits form no part of the ration of the soldier. It is never or very rarely indeed given to convalescents. No other drinks are sold at the bazaar or canteen injurious to health; fresh toddy is not obtainable. 4. The consumption of spirits is injurious to the health of troops and convalescents; it is neither conducive to health nor to the efficiency and discipline of the corps. 5. I think it would certainly be beneficial here to abolish the use of spirituous liquors. 6. I consider malt liquor and wines less injurious than spirits. 7. Coffee, tea, lemonade, and similar drinks are used at the station to a considerable extent; I consider that as a rule they are preferable. Malt liquor is *sometimes* necessary. 8. It would be highly beneficial to suppress the use of spirits altogether. 9. It would be beneficial to restrict the canteen supplies to malt liquor, porter, &c. 10. I would recommend that in restricting the sale of spirits in the canteen, the most rigid means be adopted to prevent the purchase of them in the bazaar, &c. 11. There are no local canteen and bazaar regulations; they are laid down in Jameson's Code and its appendices, and are strictly enforced and implicitly obeyed.

VI. Diet.	1. The composition of the ration for Queen's British troops and Europeans in the Indian army is of meat, bread, vegetables, and groceries; 1 lb. meat, 1 lb. bread, 1 lb. vegetables, $\frac{5}{7}$ oz. of tea, $1\frac{2}{7}$ oz. of sugar, 4 oz. rice, 1 oz. salt; mutton twice a week. The rations are inspected by the quartermaster serjeants of detachments, and subsequently by the orderly officer, after having been passed by the commissariat inspector in the first instance, when submitted by the contractors. 2. A complete ration (except fruit) is provided, and the stoppage is 3 annas 4 pice per diem. 3 meals a day; breakfast at 7 a.m., dinner at 1 p.m., and supper at 7 p.m. The proportion of vegetables in the ration is 1 lb. to each man. 3. The diet scale, when practicable, might be more varied, as in fact it is at this station by the issue of mutton. There is no arrangement to prevent the troops disposing of any part of the ration; such a thing is not known. 4. Cook-rooms are attached to each barrack; they are separate buildings, and the rations are cooked in copper utensils, which are tinned monthly. The kitchens are clean and good, considering their temporary construction. Water is supplied by bheesties. The food is boiled, there being no appliances for roasting; the cooking is not sufficiently varied. Tea and coffee are properly prepared. Troops usually commence the march about 2 or 3 a.m., and are supplied with coffee half way, but have no refreshment before starting. 5. Gardens for the cultivation of vegetables by the soldiers might decidedly be established at this station with advantage; they should be on the self-supporting plan.
VII. Dress, Accoutrements, and Duties.	1. A soldier's dress consists of a tunic and shell jacket, black cloth trousers, and forage cap during the monsoon and cold weather. Khakee clothing and red serge coat, with wicker helmet and blue serge trousers, in the hot season. The accoutrements consist of a shoulder belt, waist belt, pouches, and bayonet scabbard; I consider the present dress suitable to the climate. The helmet might be made lighter; the guard dress is according to the season of the year. There are verandahs and sun-boards as a protection from the sun, and verandahs and sentry-boxes as a protection from rain.
Duties.	1. It would be advisable for the men to be thoroughly drilled at home before being sent to India. 2. They have parade in the morning for one hour with arms, in the evening one hour without arms, for four days in the week; fatigue duties and guards. The men do not suffer from drill; the best hour for drill is the early morning. There are no general orders on the subject. They have, on an average, five nights in bed during the week. 3. Guards are mounted at about one mile from barracks at the most distant guard; they are relieved every 24 hours. There are three roll calls by day and one by night; night guards are not prejudicial to health at this station, and no further precautions are required.
VIII. Instruction and Recreation.	1. There are no ball courts, skittle grounds, library nor reading room; no gardens, workshops, nor gymnasia. There is one school in the artillery, and a theatre (barrack-room). These are certainly not sufficient to keep the men occupied during the wet season or heat of the day. The men are restricted from exposing themselves to the sun during the heat of the day, and other restrictions are imposed which are conducive to health. 2. I should recommend the men having full amusement and occupation, such as ball courts, skittle grounds, school, library, day rooms, gardens, workshops, gymnasia. 3. Savings' banks have been already instituted with advantage. 4. There is not sufficient shade from trees or otherwise to enable the men to take exercise without injury during the day.
IX. Military Prisons.	1. The cells, like the barracks, being temporary, are defective.
X. Field Service.	1. There are no local regulations for field medical service. 2. As in all mixed medical and military consultations, the power of the surgeon is limited to recommending; this is enough where the commanding officer and himself, as is usually the case, are *en rapport;* if not, I appre hend there is an appeal open. 3. The practical operation of measures for the preservation of the soldier's health in camp I leave to be disposed of by men of more recent experience in the field.
XI. Statistics of Sickness and Mortality.	The following form shows the statistics:—

SATTARA.—European Troops.

Years.	CORPS.	Strength.	Fevers.		Eruptive Fevers.		Diseases of the Lungs.		Diseases of the Liver.		Diseases of the Stomach and Bowels.		Diseases of the Brain.		Epidemic Cholera.		All other Diseases.		Total.		Ratio per Cent. to Strength.

XII. HOSPITALS.	1. Plan. 2. The hospital is situated on the right front of the men's barracks, 150 yards distant from the nearest, and about 450 yards from the horse lines; it is 900 yards distant from the bazaar, and N.E. of it, and upwards of a mile from the houses of the civil population. The site is open and freely ventilated, and there are no high walls, trees, buildings, &c., anywhere near it. The sites of the present European hospitals are in my opinion objectionable, but, as before observed, they are temporary buildings. 3. The water supply is sufficient and wholesome. 4. All sewage and refuse is cleared away by sweepers. All surface water is carried off by open drains. The hospital is situated on quickly sloping ground. 5. The lowest ward is raised on an average 1½ feet above the ground; there is no perflation of air under the floor. The roof water is conveyed away by trenches and by the natural slope of the ground; it does not sink into the subsoil, the surface being quite hard. The surface drainage consists of open trenches, and is quite sufficient; the natural slope allows of no lodgment, and is such that little or no artificial drainage is needed. The hospital is built of wattle and dab walls, grass-thatch roofs, and earthen floors; the roof is thick enough, but the walls, from their construction, are too thin. There are five-feet verandahs on both sides, closed in on the monsoon side by weather frames; the verandah is not sufficient, but the building is only temporary. The verandahs are not used for the sick. The hospital consists of one flat. The following table shows the hospital accommodation:— Date of construction, January to July 1858. Total number of wards, 4. Total regulation number of beds, 78.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.

XII. Hospitals—*cont.*	The hospital has a western aspect, and is so placed as to receive the full benefit of the prevailing winds. The windows open as casements, but being like the rest of the building, only of temporary construction, are incapable of excluding the hot winds. 6. Apertures for ventilation are made in the upper part of the walls under the eaves, but they do not afford sufficient. There are no jalousies or jhilmils. 7. There are not any means of cooling the air. 8. There are no means of warming. Cleansing and whitewashing is done whenever needed, generally about three or four times a year. 9. The privies and urinals are in rear of hospital, and are approached by covered passages, as shown in the accompanying sketch. They are kept clean by sweepers. There are no cess-pits. 10. There is a washing-room at the end of each ward sufficient for the purpose. 11. There is a washing room attached to each temporary hospital, convenient and sufficient enough. 12. There are the usual means of washing linen, and they are sufficient. 13. The storage is sufficient and dry. 14. The bedsteads are iron; the bedding, rice-straw mattress and pillows. 15. The hospital kitchen is temporary, 12 yards distant from the wards, not on the side of the prevailing wind. It is furnished with the usual cooking apparatus. The cooking is properly done, and if soup is made in jars, varied enough. 16. The diet tables are kept in the laid down forms in general use. 17. There is a hospital orderly, and until lately a hospital matron, and the attendance, with the occasional help of a comrade in special cases, is sufficient. 18. The sanitary state of the hospital is good, and no epidemic disease, pyœmia, or gangrene have manifested themselves. 19. As might be inferred, the European hospitals being temporary, are defective in some points. 20. There are no fenced grounds or shaded walks or seats for the convalescents, but an airy open space adapted to morning and evening exercise. 21. Up to a late date there was a ward set apart for the reception of women and children; the arrangement at present is not satisfactory, for I think the female ward ought to be kept up. 22. There are no special local hospital regulations. 23. All alterations and repairs, whether sanitary or not, are submitted to and carried out by the military authorities. Diets and medical comforts are solely under medical control. 24. There are no convalescent wards or hospital, but where troops are treated on a large scale, such a ward is necessary.
XIII Burial of the Dead.	1. The burial ground for British troops is about one mile from the station. It is dead to leeward in reference to the prevailing winds, being to the S.E. 2. The area is 17,000 square yards. The soil throughout is *moorum* (trap-rock), decomposed in situ. It is believed that decomposition readily takes place. It is carefully kept. 3. The grave space allowed is 10 × 3, and the interval between graves three feet. The graves are about six feet deep. The ground is new, and no grave has been reopened. Only one body is interred in each grave. Burial takes place at ordinary times within 24 hours. During epidemics as soon as possible. There are no burial-grounds for native troops in camp. 4. The grave yard is never offensive. The practice of burial is according to standing regulations. 5. The dead of camp followers and bazaar people are disposed of according to caste; some burned, some buried. 6. No injury accrues to health from the present practice. 7. I can suggest no improvements.

(Signed) H. J. Pelly, Colonel commanding at Sattara.
Robert Dent, Staff Surgeon.
M. K. Kennedy, Captain Executive Engineers.

Sattara, July 19th, 1860.

1. Topography.	1. The surrounding country is an open level plain; flat and dry. There is no jungle, and but little wood in the vicinity; a river runs close to the bazaar and lines. 2. The elevation of the station above the sea is about 1,300 feet, and from 20 to 25 feet above the nearest water. There is no higher or healthier ground adjoining the station. 3. The nearest mountain or table land is about 35 miles distant, and about 3,200 feet higher than the level of the station. 4. The nearest water is only a few yards distant from the station, but the vicinity is not liable to overflow. There is no broken ground, ravines, or water pits near the station. 5. The station is not encumbered in any manner, but is open and freely exposed to the winds. The temperature of the station is not raised by being exposed to reflected sun heat. The station is exposed to all winds except that from the sea.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	6. The surrounding country is only partially cultivated. There are no works of irrigation. There is no cultivation of rice or of indigo, nor is the preparation of hemp or flax carried on near the station. 7. The town of Mulligaum is three-quarters of a mile distant from the station. 8. The surface of the district is black loam, with sub-strata of trap rock; the ground upon which the station stands was never occupied before. 9. Water is found about 20 feet below the surface during the dry season, and about 15 feet during the rainy season. 10. The rain-fall and surface water sinks into the soil, and thus drains off. There is no adjacent higher ground the drainage from which must necessarily pass into the subsoil of the station. 11. The water supply is derived from the river and wells; there are no tanks. The wells require to be cleaned out once a year; being constantly used, the water remains pure. 12. The water supply is unlimited; its colour is clear and good, but it tastes as if slightly impregnated with vegetable matter. There are no means at the station of ascertaining its chemical composition; most of the water from the wells is hard, but good and not injurious to health. It is raised by hand buckets. No better supply can be obtained. 13. There are no topographical points bearing on the health of the station not included in the foregoing answers. 14. New stations are selected by the Quartermaster-General's Department in consultation with the medical authorities.
II. Climate.	1. The only means and instruments available at the station for conducting and registering meteorological observations are a pluviometer and a thermometer. 3. The climate is generally dry; during the months of May and June very hot, but mornings agreeable up to 10 a.m. Cold weather pleasant, with very few fogs. The only trees are near the houses, a few of the gardens irrigated; the air is pure and unmixed with dust, and dust storms are very rare. The troops are generally healthy, there is good shelter, and the usual diet and clothing required. Drill during the rains and cold season can be carried on till half-past 7 a.m. and after 5 p.m. The most healthy months are during the hot season, from March to middle of June, and October is the most unhealthy month. Fevers and rheumatism are the prevailing diseases. 4. There is no district near the station, the climate of which is more conducive to health. 5. The following are the stations at which I have served, with their comparative salubrity:— Poona—Healthy. Sattara—Very healthy. Bombay—Healthy. Baroda—Unhealthy; much fever and diarrhœa. Hyderabad—Healthy, but periodical sickness prevails. Sukkur—Healthy, but climate very hot and enervating. Dadur—Unhealthy; exceedingly hot fevers prevail. Quetta—Above the Bolam Pass, unhealthy. Aden—Healthy.
III. Sanitary Condition of Station.	1, 2, 3. A map and ground plan of the station and barracks is transmitted. 4. Table of barrack accommodation.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Feet.	Feet.	Feet.	Feet.			Inches.		Feet.	Feet.
No. 1	90	264	21	19	105,336	1,170½	61⅔	22	50	4	3
No. 2	26	60¾	19	14½	16,737	643¾	44⅔	22	6	3¾	3½
		It has not been considered necessary in the answers to the following queries to describe in detail Barrack No. 2, which is an old building of pucka construction, but of smaller dimensions than would now be given to a barrack for an equal number of men.									
Total -	116										
Guard-room, 1 -	4	33⅓	15½	13½	6,862½	This guard-room is divided into three rooms, one for the guard and two for prisoners.		22	5	4 ft. 11 in.	3 ft. 6 in.
Prison Cells, 2 -	1	10	10	17⅔	1,766	1,766	100	22	1	3	[illegible]

5. The windows are on opposite sides, and open inside, with two glazed shutters. There is a verandah on both sides, and also at the ends, surrounding the barrack room. It is 10 feet wide. There is ample space within the room for the sleeping quarters of the soldiers, but it is believed that there would be no objection to their moving their cots into the verandahs if desired in the hot weather. No other persons use the verandahs. There are no jalousies or jhilmils.
6. The cots used in barracks are of iron, laced with cotton tape. A soldier's bedding consists of one humda mattress, two cotton covers for ditto, one blanket and one sheet. No improvements are suggested.
7. No tents are used in camp.
8. The barracks are ventilated by apertures in the roof, called lift ventilators; the ventilation is sufficient to keep the air pure by night as well as by day, when the windows, as usual in this station, are left open. No apparatus is used for cooling the air for barrack rooms at this station.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	9, 10, 11. The barracks are only of a temporary nature, the roof being double-tiled with teak wood trusses, and supported on teak posts. The walls are built of sun-dried bricks. The floors are constructed of moorum, and are raised about one foot above the ground. There is no passage for air beneath the floor. The barracks are only of a temporary description; should they be permanently rebuilt, they would no doubt be on an improved plan. It is thought that permanent barracks should be provided with double roofs and good ventilators, so that there might be a current of fresh air to carry away any hot air between the two roofs, and thus prevent its increasing the temperature of the room below; barrack rooms should also be raised about 15 feet above the ground, the spaces below being used as canteens, libraries, store rooms, &c. It is essential to the coolness and salubrity of a barrack that its wall should be sheltered completely from the sun by broad verandahs. No other suggestions to offer. The barracks and cantonments are kept in repair by the barrack serjeant when repairs of a petty nature are required, and by the executive engineer of the district for more extensive repairs. Repairs are quickly executed. The walls of the barracks are cleansed and whitewashed as often as may be considered requisite. There are no stated intervals for the execution of this work. The barracks are without ceilings. 12. In the lavatory common basins and tubs are used by the soldiers for washing and bathing. Water is supplied by bheesties, and after use passes through the urinals, and is conveyed away by a covered drain into a cesspool, also covered. 13. The cookhouses have no special means of cooking provided, nor any means of supplying water. There is an open drain to carry off the refuse water. There are no conveniences for washing and drying linen in the barracks. 14. There are no drains to the privies, their contents being conveyed to a suitable distance by sweepers. 15. The privies are provided with a similar ventilator to the barracks, and are lighted from an arched opening and fixed venetians. The barracks are lighted at night by hanging oil lamps. 16. The barracks and the surrounding ground are drained by natural nullahs, which find an outlet in a river about half a mile distant. All the surface water is speedily carried away, but the drainage from the lavatory and urinals is inefficient. No portion of the barrack or hospital is damp. The drainage is sufficient, with the exception of that from the urinals, which is received in an objectionable cesspit. There is no well or tank within the influence of this cesspit, which is seven feet square, and 40 feet in rear of the lavatory. The cesspit is 40 feet distant from the men's quarter, and about a quarter of a mile from the hospital. There are no foul ditches. 17. The refuse, manure, &c., which is found within or near the cantonment is removed without delay by scavengers' carts. 18. The surface of the cantonment is kept free from vegetation; there are no old walls, thick hedges, &c., interfering with the external ventilation of the station, bazaar, &c., which is good. 19. The drainage and ventilation of the bazaar is good, and water supply abundant. There are no latrines, and the streets are tolerably open and clean. A regular establishment of sweepers is kept up under the supervision of the superintendent of bazaars; there is only a small detachment of police, and no improvement is necessary. There are no native houses near the station, excepting those in the bazaar, and no dung heaps or cess-pits are allowed. 20. Animals are slaughtered about 200 yards in rear of the bazaar, and to leeward of it; there are no written rules regarding slaughtering places. No nuisance is experienced from the condition of these places, and the offal is buried. 21. The bazaar horses are picketed near the owners' residences, and the place is cleared daily, and the manure burnt. 22. There are no artillery or cavalry stables; nor any regular picketing grounds at the station. 23. There is ample and good accommodation for married non-commissioned officers and men. The married people's quarters are separate from the barrack rooms.
Officers' Quarters.	1. The sanitary condition of officers' quarters is good. The drainage and ventilation also good. No improvements to suggest.
IV. Health of the Troops.	1. The station, district, and population are healthy. 2. Fevers and rheumatism are the most prevalent diseases among the native population. Cholera is the chief epidemic, and spleen disease is rare. 3. The healthiness of the neighbouring native population is to be attributed to there being little jungle, and the country being generally dry. 4. The troops had been stationed at Poona for upwards of three years, and left there 26th September 1859; fevers and rheumatism were the chief complaints. They arrived at Mulligaum in good health on 2nd April 1860, and since then fevers and rheumatism have been the chief diseases. No portion of the present station is more unhealthy than the rest. 5. The troops are never camped out. 6. I have not been in charge of troops at hill stations. 7, 8. Cannot state whether troops who have been resident for some time on hill stations are more or less liable to diseases on returning to the plains. I certainly approve of hill stations, especially during the hot season. 9. Troops are liable to be attacked with dysentery, liver and heart disease on going to hill stations. 10. The precautions necessary to protect men from these diseases are spare diet, warm clothing, and they should not be allowed to expose themselves to the sun from 9 a.m. to 5 p.m. They should have plenty of exercise morning and evening. 11, 12. The hot season is best adapted for residence in hill stations. Cannot say what is the shortest period to enable troops to obtain the full benefit of such residence; nor whether there is any period of residence beyond which injury is likely to be inflicted on the health of the troops on returning to service in the plains. 13. The special precaution for protecting the health of the troops on leaving hill stations for the plains is to prevent their exposure to the sun. 14. Residence on hill stations, with short periods of service in the plains, is most conducive to the preservation of the health of the troops; but cannot say that service on the plains, with short periods of change to hill stations, would be equally conducive to their health; change of station in the plains is decidedly beneficial. 15, 16. Cannot say whether the barrack and hospital accommodation provided at hill stations or sanitaria are sufficient for the health and comfort of the troops. No experience to show what elevation above the sea is most suitable for hill stations.

References to Subjects and Queries.	Replies.
IV. Health of the Troops—*cont.*	17. Sufter Sing, about 60 miles distance from the station by the road, could be advantageously occupied as a hill station. Its elevation above the plain is about 2,000 feet. The range of thermometer under a chupper, from March to June, is 76° to 92°, and seldom above 88°. The climate is most agreeable, and out of the influence of the hot winds. Europeans cannot live there during the rains, it being enveloped in clouds, but it is quite accessible after October, and very healthy. 18. Gravelly soils are the most healthy for stations. 19. Soldiers proceeding to India should be from 20 to 25 years of age, and the best period for them to land there is in November. No knowledge as to the mode of disposing of troops on first landing, but to preserve their health they should be immediately sent to their regiments or depôts. 20. Troops should be sent direct from the home depôts to India; and to diminish the dangers of the earlier years of service they should not be kept out at drill too long in the morning or commence too soon in the afternoon. 21. Mode of transport of troops from the port to the interior is by railway or bullock train, or water carriage and the usual march; sufficient precautions are taken to preserve the health of the troops on the route. 22. A British soldier should serve in India from 10 to 12 years. 23. The manner of conducting the business of medical boards is such as to avoid conflict of opinion as regards invaliding. No suggestions to make. 24. Invalids should leave India for home at the end of the cold season, in February.
Diseases.	1. When European troops are present, there is a weekly inspection for the discovery of incipient diseases according to order. 2. There has been only one case of scorbutus among the troops at this station. It frequently occurs after rheumatism. The preventive measures are, a generous diet of animal food, vegetables, lime juice, and spirits. 3. Disease of the liver is very rare amongst natives; prophylactic measures necessary to diminish its frequency are, spare diet, no beer or spirits, small quantities of wine only, horse and walking exercise, flannel next the skin, and a belt also of the same. 4. Dracunculus is peculiar to those who drink or wash from certain tanks or wells. The water should be heated before used. 5. The proportion of venereal diseases to the total sick is 2·5 per cent. Lock hospitals and supervision over the women in the regimental and other bazaars would be most decidedly advantageous to the health of the army. Women should be registered, and a person appointed to inspect them once a week. This is not necessary in native regiments, where venereal disease is very rare. 6. Cholera and small-pox are the only epidemics among the troops at the station. Of Fevers—122 cases have occurred from all the common types. Dysentery—6 cases, very rare. Cholera—occasionally. Small-pox—occasionally. Rheumatism—23 cases; this disease is rather frequent. The proportions of admissions and deaths from these diseases are 65·3 per cent. of the total admissions, and 0·8 per cent. of the total deaths. 7. Zymotic diseases are generally preceded by languor, general derangement of the digestive organs, and disinclination to any occupation. Intermittent fever is the most common type. The seasons when such diseases are most prevalent is after the rains, when the weather is muggy, hot, and damp. These diseases are prevalent in the most crowded, lowest, and dampest portions of the bazaar. The personal habits predisposing to these diseases are want of cleanliness and good food. 8. The causes of prevalence of epidemic disease amongst the soldiers are, exposure to great variations of climate, excess of duty, and overcrowding of barracks. 9. Small doses of quinine taken before going out is a good prophylactic against malarial diseases. 10. To prevent or mitigate epidemic disease, bathing should be resorted to daily, flannel should always be worn next to the skin, the barracks should be well ventilated, and the men should be exposed as little to the sun as possible.
V. Intemperance.	1, 2. The soldiers at the station are temperate. There are no confirmed drunkards. There are no admissions into hospital from diseases directly or indirectly caused by intemperance. There are no European troops at this station. Drunkenness is always punished as an offence. 3. There is no canteen at this station; spirits are sold at the bazaar by the liquor contractor. There are no data to ascertain the probable amount consumed by each man per diem. Spirit is no part of the soldier's ration at the station, on march, or in the field, except when Europeans are present. Cannot say whether it has happened among the men to take a dram before morning parade. Spirit is never given as a ration to convalescents. No other intoxicating drinks are sold in the bazaar. 4. Small quantities of spirits are not generally injurious to the health of the troops, and are frequently advantageous to convalescents. Spirits are not conducive to the efficiency of the corps. 5. It would be beneficial to restrict the sale of spirits in the bazaar, and only give them as a ration to the troops on a line of march. 6. Malt liquor or wines are much more healthy drinks than spirits, and decidedly more adapted to the climate. 7. Coffee, tea, lemonade, and similar drinks are much used at the station, and their influence on health, efficiency, and discipline, as compared with spirits and malt liquor, is very good and beneficial. 8. It would be beneficial to suppress altogether the spirit ration, whether for soldiers or convalescents, and to substitute for it beer, tea, &c. 9, 10. The sale of spirituous liquors in the canteen should be restricted, and encouragement given to the sale of coffee, tea, lemonade, &c. No recommendations to make, but those already stated. The soldier should have his beer or porter after his dinner. 11. There are no canteen regulations. There is only one liquor contractor in the bazaar, who is subject to the general bazaar rules; his shop is open from sunrise to 9 p.m. No liquor is permitted to be sold to European soldiers when such are present at the station.
VI. Diet.	There being no European troops at this station, no information is given under this head.

References to Subjects and Queries.	Replies.
VII. DEESA, ACCOUTREMENTS, AND DUTIES.	1. The soldier's dress and accoutrements at this station consist of cloth jacket and trousers for the cold season, and white jacket and linen trousers for the hot season, a Kilmarnock cap, pouch and belt, and waist-belt with bayonet. The present dress is suitable to the climate, and for the soldier's duties by day and by night, and at the different seasons. No suggestions to make for dress of native troops. The guard dress is the usual dress, and the men are protected when on guard from the sun and wet by guard-rooms and sentry-boxes.
Duties.	1. Troops should be thoroughly drilled at home before being sent to India. 2. At this station a soldier goes on guard every fourth day. Drill is carried on for an hour and a half, morning and evening, at 5 a.m. and 5 p.m. respectively. The men do not suffer in health from drill. The early morning is the best time for drills, parades, and marches, and the standing orders of the army appoint this time. The soldiers have, on an average, from three to four nights in bed during the week. 3. Guards are mounted about a quarter of a mile from barracks, and the tour of guard is for 24 hours. There are roll calls every morning and evening, but not during the night. Night duty, when light, is not found to be injurious to health.
VIII. INSTRUCTION AND RECREATION.	1, 2. There are no means of instruction and recreation at the station. 3. The institution of soldiers' savings banks would be advantageous. 4. There is not sufficient shade from trees, &c., to enable the men to take exercise without injury to health during the day.
IX. MILITARY PRISONS.	1. There is no military prison, defaulters being confined in the quarter guard and cells. These are in a good sanitary state.
X. FIELD SERVICE.	1. There are no local regulations for field medical service, not included in the general Presidency Regulations. 2. The practical working of the powers of the medical officers, as regards the conduct of the line of march of troops, &c., is good. 3. The brigade major or staff officer is responsible for the regulations of camp being observed; the medical officer can only represent defects, but has no power. No improvements to suggest.
XI. STATISTICS OF SICKNESS AND MORTALITY.	4. No knowledge of the arrangements adopted in the Presidency for field hospitals, &c.

By order of the Acting Principal Inspector-General, Medical Department,

Office of the Principal Inspector-General, Medical Department, Bombay, 9th November 1860.

W. COLES, Assistant Surgeon, Secretary.

References to Subjects and Queries.	Replies.
XII. Hospitals.	1, 2. The hospital is situated in an open space of ground, quite clear of buildings of every description. It is about 100 yards outside the bazaar, the houses of which are the nearest to it. The site is open and freely ventilated, there being no high walls or trees to interfere with ventilation. It is healthy and the drainage is good, and is free from malaria. 3. The water supply is abundant and wholesome. 4. No refuse water lodges in the vicinity of the hospital; a deep nullah runs close outside the compound. 5. The wards are about a foot above the ground, and flagged with cut stone; there is no circulation of air underneath. The roof water sinks into the subsoil. The fall of rain is never heavy, and soon drains off from the slant towards the nullah. The hospital is built of burnt brick and lime. The roof is double-tiled and the walls are double, and of sufficient thickness to keep the building cool. It is supplied with verandahs all round, about 8 feet wide, which afford sufficient shelter from the sun. The verandahs are used for the accommodation of the sick and convalescents. The hospital consists of one flat.

Table of Hospital Accommodation.
Date of construction, 1826–27.
Total number of wards, 4. Total regulation number of beds, 56.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Feet.	Feet.	Feet.	Feet.			Inches.		Feet.	Feet.
2	40	$95\frac{3}{4}$	21	$16\frac{1}{2}$	$33,177\frac{3}{8}$	$829\frac{2}{3}$	$50\frac{1}{4}$	22	10	$7\frac{1}{4}$	$4\frac{1}{2}$
2 in the same building.	8	22 ft. 10 in.	21	14	$6,979\frac{7}{18}$	$872\frac{2}{3}$	62·3	22	4	$4\frac{1}{4}$	

The hospital is so placed as to receive the full benefit of prevailing winds. The windows open on hinges outwards; the ward windows have jhilmils.

6. The ventilation of the wards is effected by the jhilmils being kept open when the windows are not entirely so—and is sufficient to keep them at all times free from odour or closeness. The jhilmils are of common construction.
7, 8. There are no means allowed for cooling the air admitted into the ward, or apparatus for warming. The walls and ceilings of hospital wards are cleansed and limewashed once in six months, but oftener if necessary.
9. The privies, &c. are about 20 yards from the hospital, connected by an open passage roofed in. They are not placed over cesspits. They are kept clean by the sweepers, and are not offensive.
10, 11. There are no means of washing or bathing the sick.
12. The hospital linen is taken away to be washed and dried.
13. The storage is sufficient and dry.
14. The bedsteads used in hospital are of wood, with tape; no bedding is allowed. No suggestions to make.
15. A small shed is used for cooking, which is all that is required.
16. There are no diet tables, &c. used in hospital.
17. The attendance at the hospital consists of a hospital orderly and a cook; if a man requires it, he is allowed a comrade from the regiment.
18. The sanitary condition of the hospital is good; no epidemic diseases have ever occurred in the ward.
19. There are no deficiencies or sanitary defects requiring improvement.
20. Convalescents are allowed to take exercise in the compound, which is quite sufficient.
21. Soldiers' sick wives and children either attend the hospital treatment or are seen at their own houses. There should be a ward for women and children, otherwise the present arrangements are satisfactory.
22. There are no special hospital regulations not included in the general Presidency Regulations.
23. The medical officer can at any time get repairs done to the hospital by writing officially on the subject, and can order any medical comforts he may deem necessary at all times.
24. There are no convalescent wards at the station.

XIII. Burial of the Dead.

1. The burial-ground used by British troops is about 100 yards from the cantonment boundary, and well to leeward, and clear of all houses.
2. Its area is 7,350 square yards. In the upper half of the ground the soil is hard moorum, in the lower part there is black soil to the depth of from two to three feet. The drainage is efficient and the ground well kept. Decomposition takes place readily.
3. There are no regulations as to burial, several vaults being built close to each other; the graves are scattered. They are from six to seven feet deep, and are never reopened. Interment takes place at ordinary times, from 12 to 24 hours after death, and within 12 hours during epidemics. The great majority of native troops are Hindoos, who burn their dead on the banks of the river. The Mahomedans bury their dead outside camp limits. There are no particular regulations.
4. The grave-yard is never offensive. With regard to the burial of British troops, the regulation is:—If a soldier dies early in the morning, the burial takes place the same evening; if the death occurs in the evening, the interment takes place the next morning.
5. The dead of the camp followers or bazaar people are disposed of according to caste; the Hindoos burn their dead on the river banks, and the Mahomedans bury their dead in the place set apart for them out of camp limits.
6. No injury accrues to the public health from the present practice.
7. No improvements to suggest for the regulation of the burial or disposal of the dead.

(Signed) J. Field, Captain, Commanding at Mulligaum.
J. C. Trestrail, Surgeon, 6th Regiment, N. I.
(Only one Medical Officer is present at the Station).
1st Sept. 1860. J. M. Greig, Captain Engineers.

KOLAPORE.

- Queen's Troops
  - Artillery, 1 Company, 3rd Company 3rd Battalion Bombay Artillery.
  - Infantry, Wing Her Majesty's 83rd Regiment.
- Native Troops
  - Cavalry, 1 Troop Southern Mahratta Horse.
  - Infantry, 1 Regiment, 10th Regiment Bombay Native Infantry.

References to Subjects and Queries.	Replies.
I. Topography.	1. Cultivated valleys bounded by bare mountain ranges to the west, north, and east, form the chief features of the surrounding country. The valleys are undulating, and the soil is composed of black argillaceous mould; the elevated ridges are covered with red soil. There are no swamps. There is very little wood and no jungle in the vicinity. Water is to be found at all seasons in the rivers, and also in the wells, which are numerous, and used for the purposes of irrigation.
	2. The elevation of the station above the sea is 1,797 feet; about 60 feet above the valleys, and 60 feet above the nearest water. There is no higher or healthier ground near the station. The hill fort of Punulla, about 11 miles distant, 975 feet above the plain, however, possesses considerable advantages as to climate, excepting during the monsoon.
	3. The nearest mountain or table land is about three miles distant, and about 900 feet above the station.
	4. The river Punchgunga is the nearest permanent water, and is about half a mile from the station. It surrounds the cantonment on three sides, at an average distance of about two miles. There are two large tanks about three miles from the station. An overflow of water takes place in the vicinity of the river Kistnah during the monsoon, and lasts for a few days only. This may occur twice or thrice during the rains. There are no ravines or water pits near the station.
	5. The station is freely opened and exposed to the prevailing winds. It is almost totally devoid of trees, hedges, and gardens. There exist no impediments to free external and internal ventilation. The buildings are scattered, so that no increase of temperature is occasioned by reflected sun heat. The winds generally are high. The land or north-easterly winds blow from November to February, and give rise to fevers, rheumatism, and pulmonary affections. The sea breeze or south-westerly winds commence in March, and blow during the greater part of the day and night. They are highly beneficial to health.
	6. The valleys in the vicinity are highly cultivated. There are no works of irrigation near the station, although partial irrigation is carried on by means of wells, but is much too limited to produce any deleterious effect on the health of the station. Rice is cultivated, in small detached fields only, within a quarter of a mile of the camp limits. No restrictions appear to have been hitherto made on this head. There is no cultivation of indigo, nor is the preparation of hemp or flax carried on near the station.
	7. The city of Kolapore, with a population of between 50,000 and 60,000, is situated to the south-west, about a mile and a half from the station. The village of Bhovra is about half a mile to the north-west.
	8. The structure of the mountain ridges is principally of basaltic formation, trap-rock, covered with red disintegrated soil, moorum; the surface soil of the valleys is black and argillaceous; the subsoil is of clay of various colours. The red soil is met with on the higher slopes, and during the rains the colouring matter (an oxide of iron) is washed out of it, and carried down as a black powder, which is used as pounce.
	9. Water is found during the dry season between 40 and 50 feet below the surface, in carefully selected site, from 35 to 45 feet, but wells have been abandoned after digging 80 feet. In the rainy season, the wells fill to the natural ground level. The depth where water is found necessarily varies with the locality. In black soil in a valley, it has been met with at 3 feet below the surface.
	10. The undulating character of the surrounding district ensures free drainage. No water from rain or surface springs settles near the station. There is no adjacent higher ground, the drainage from which passes into the subsoil of the station.
	11. The water supply is almost entirely derived from wells. The artillery horses are watered at the river. There is no water for drinking purposes stored in tanks, there being none. The wells are not liable to pollution from leaves or impurities of any kind.
	12. The amount of water supply is too limited in the dry season. The quality of the water obtained from wells, with one or two exceptions, is good, wholesome, and unobjectionable. Its chemical composition and microscopic characters have not been ascertained. It is not hard, and is clear and wholesome. The water is raised by means of buckets, and is distributed by puckal bheesties; but an increased supply, by sinking additional wells, is desirable, and is recommended.
	13. There are no other topographical points bearing on the health of the station.
	14. New stations are generally selected by a mixed committee composed of one or more military officers, an engineer, and medical officer. It is highly desirable that the members for this and similar duties should be specially selected from their known attainments and previous experience.
II. Climate.	1. There are no means or instruments available at the station for conducting and registering meteorological observations except the common thermometer in use in hospitals.
	2. The following Table of ten years' observations, from 1st January 1850 to 31st December 1859, is arranged according to the means at disposal.

References to Subjects and Queries. | Replies.

II. Climate—*cont.*

Months.	Mean Maximum.	Mean Minimum.	Mean Sun Temp.	Rain, Inches.	Winds. Direction.
January - -	77·2	66·7	92·7	·43	N.E. & S.W.
February - -	81·6	69·2	95·4	—	N.E. & S.W.
March - -	87·	75·3	99·7	·58	N.E. & S.W.
April - - -	88·	76·3	100·	1·36	N.E. & S.W.
May - - -	88·8	76·6	94·8	3·64	S.W.
June - - -	81·4	75·8	84·9	6·57	S.W.
July - - -	77·	74·	88·9	11·93	W.
August - -	76·7	73·4	78·7	5·1	W. & N.W.
September - -	77·9	73·8	81·6	4·62	N.E. & S.W.
October - -	80·	74·6	86·2	4·51	N.E.
November - -	78·3	71·7	93·	·72	N.E.
December - -	76·5	66·8	93·8	·12	N.E. & S.W.

The above Table is prepared and furnished by Dr. Wicke, Civil Surgeon, Kolapore.

3. During the cold season, viz., November, December, January, and February, the climate is dry, the winds blowing generally from the north and east; dews fall in the early mornings, which are moist and fresh until an hour after sunrise. The climate generally is a very temperate one; there is no severe cold during this or any of the seasons. In the hot season, March, April, and May, there is more moisture, the prevailing winds being south-west, which blow, as a hot wind in the day, and become cool and refreshing breezes after sunset. During the rains the climate is agreeable, though damp, and is cool from strong south-westerly breezes which blow uninterruptedly. The climate is not influenced by tree-planting, canal, or other irrigation; nor is the atmosphere rendered impure by dust, excepting very temporarily. The climate is considered one of the healthiest in the Presidency. The diet and clothing require to be modified according to the seasons. No unusual precautions are found necessary to counteract atmospheric changes. Drill should as far as possible be carried on in the mornings, and in the hot season not prolonged beyond an hour after sunrise. The months of September, October, and November may be stated as those in which disease is most prevalent, with the exception of periodical epidemics of cholera and small-pox. The prevailing diseases are intermittent and remittent fevers.

4. As before stated, the hill fort of Punalla is considered to possess a climate that is likely to prove suitable for a sanitarium for sick and weakly men during a certain portion of the year.

5. The stations at which Assistant-Surgeon Wicke, M.D., Civil Surgeon at Kolapore, has served are Broach, Sattara, and Kolapore. The two latter are pretty equally balanced in point of climate, though the latter is, on the whole, to be preferred. Broach is an unhealthy station. Major Gell, 10th Regiment Native Infantry, has served at Aden, Bombay, Gharra, in Sinde, Bhoog, Tauna, Kurrachee, Deesa, Nusserabad, and Poona; as Assistant Quartermaster-General in Egypt, commanding Punjab cavalry regiment at Burmoo and Dera, Ghazee Khan, and Kolapore. Assistant-Surgeon Murray has served at Hyderabad, Kurrachee, Gharra, Jerruck, Sukkur, Sarkhana, Shillarpore in Sinde, Rajcote, Deera, Nusseerabad, Bombay, Rajpootana, and Central India campaigns, Deopore, near Seronge, Central India, Kolapore. Captain Dickenson has served at Tauna, Bhewady, Surat, Bewda, Ahmedabad, Kursole, Kaira, Bushire, Poona, and Belgaum.

The preceding meteorological observations and replies on topography were kindly prepared by Assistant-Surgeon Wicke, M.D., Kolapore, who was in medical charge of the 10th Regiment Native Infantry, during Assistant-Surgeon Murray's temporary absence with a wing of the 15th Regiment Native Infantry.

III. Sanitary Condition of Station.

1, 2, 3. A map and plan of the station and adjacent country, and ground plan of the barracks is transmitted.

4. Table of barrack accommodation.

Date of construction of barracks for European artillery and infantry, 1857–58. Native infantry lines, 1854–55.

Total number of rooms or huts :—8 barracks, 752 huts for native infantry.

Total regulation number of non-commissioned officers and men :—European artillery, 120; infantry, 348; native infantry, 752.

KOLAPORE. BOMBAY.

References to Subjects and Queries.	REPLIES.
III. Sanitary Condition of Station—*cont.*	5. The windows are on opposite sides in the European infantry barracks, and on adjacent sides in European artillery barracks. There is a verandah on both sides 5 feet broad and 8 feet high; the verandah is never occupied as sleeping quarters by soldiers or other persons; there are no jalousies or jhilmils. 6. At this station the artillery have some iron cots, and some iron with wooden boards; the remainder are entirely of wood. For reasons hereafter stated the men greatly prefer iron cots. The bedding consists of a couple of native blankets, a wadded quilt, and sheets, but the men of the artillery have, in general, provided themselves with English blankets and extra bedding in consequence of the dampness of the monsoon. 7. The structure and dimensions of the tents used in the Bombay army are as follows (they are of six kinds):—

——	Size.	Inner Walls, No. of Cloths.	Outer Walls, No. of Cloths.	Inner Fly, No. of Cloths.	Outer Fly, No. of Cloths.	No. of Men to each Tent.	Cubic Space per Man.	Superficial Feet per Man.
European soldiers' single-poled tent - -	15 × 15	—	3	3	3	13	137	$17\frac{1}{4}$
„ „ double-poled tent - -	$22 \times 15\frac{1}{4}$	—	3	3	3	22	116	$15\frac{1}{4}$
Native soldiers' single-poled tent - -	$14\frac{1}{2}$	—	—	—	3	22	$30\frac{1}{2}$	$7\frac{1}{2}$
„ „ double-poled tent - -	$14\frac{2}{3} \times 24\frac{2}{3}$	—	—	—	3	30	65	7
European hospital, double-poled tent - -	$24 \times 15\frac{1}{3}$	3	3	3	3	20	$168\frac{1}{4}$	$18\frac{1}{2}$
Staff Surgeon's single-poled tent - -	10 × 10	—	3	3	3	6	$122\frac{1}{4}$	$16\frac{1}{2}$

8. Ventilation is effected in the European barracks by the outer wall being only six feet high, and the space between the top of the wall and the roof being fitted with bamboo mat frames, which can be raised or lowered according to the state of the weather; also by doors and windows. The ventilation is sufficient for the purification of the air by night and day, from the strong breezes that prevail at this station. No means of cooling the air of barrack-rooms exist, nor is the want of such apparatus felt at this station in so excellent a climate. Huts or lines for the native infantry are generally too low, and are constructed without any regard to ventilation or adequate drainage; they are seldom in such repair as they would be were they properly built originally, and kept in good order by Government.

9, 10. The barracks are principally built of timber frame-work, the space between the posts being filled up with burnt bricks set in mud; the roofs are covered with single tiles, and the floors are of moorum, and are raised two feet above the level of the ground; there is no ventilation from beneath the floors.

11. The barracks were originally intended to be merely temporary; they were framed of timber which had returned from Persia, but by building up the walls, &c., they may be considered as permanent, and upon the whole as suitable to the climate. Double tiling would be a decided improvement, and would render them drier in the monsoon. The barracks and cantonment are kept in repair by the engineer's department. Repairs are quickly executed. The cantonment staff officer, according to separate general order, is responsible for the cleanliness of the camp. As a general rule the walls of the barracks are limewashed once a year, but oftener if necessary.

12. The washing places are attached to the barracks outside the verandahs, they are of simple construction, being merely stone paved floors, and raised masonry platforms for the hand basins. Only one washing place is attached to each barrack; the water is kept in casks, which are filled by the bheesties as required; the waste water runs through the urinary, and from thence to a cesspool, from which it is removed by sweepers. There are no baths, and the lavatory arrangements altogether are very defective.

13. The cookrooms are provided with no other means of cooking besides the ordinary fire-places; water is kept in casks supplied by bheesties; and waste water runs from a sink through the wall into a cesspool outside, from which it is removed by sweepers. The arrangements for washing are not carried on in barracks in this country.

14. The privies are of the following construction:—The excreta fall on the floor of the privies, which is paved and slope outwards and downwards to a drain, by which fluids are carried off to a cesspool; this is emptied by the sweepers, who also remove the deposit from the paved slope through the openings in the rear wall; it is then carried by the sweepers in buckets and deposited at a certain distance from camp.

15. The ventilation of barracks has been replied to in question 8. In the cookrooms ventilation is secured by raising that portion of the roof immediately above the fire-place about six inches higher than the rest of the roof. The barracks are lighted at night by the ordinary brass hanging oil lamps, three of which are in use in each barrack room.

16. There are no arrangements for draining and sewering the barracks. The natural drainage is good. The men's lavatories, urinaries, kitchens, &c., are drained into cesspits, which are regularly emptied by the sweepers at daylight, and purified with lime. Excepting during the monsoon the barracks are airy and dry, but it is then found necessary to have charcoal pans burning, in consequence of the moisture of the air. A small cesspit is attached to each bathing room, urinary, and privy. To each married man's quarters there is a bathing room with a cesspit. The nearest well is about 200 yards from the artillery barracks; about a quarter of a mile from the European infantry ones; and about half a mile from the hospital. There are no foul ditches.

17. The surface refuse is collected in carts, and deposited at a certain distance from camp, where it is periodically burnt.

18. There is very little vegetation of any kind in the cantonment. There are no old walls, thick hedges, &c. to impede the ventilation of the station, bazaar, &c.

19. Cantonment bazaar is kept clean, is sufficiently drained, and is not overcrowded. The local arrangements are under the superintendent of bazaar and police.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	The following are the local arrangements for preserving cleanliness in the station bazaar at Kolapore:— The whole of the filth and rubbish which accumulates at the bazaar is collected by the inhabitants in baskets every morning, and is placed in front of their houses. These baskets are emptied into a scavenger's cart kept up by the Government for the purpose. The contents are deposited in an open space about 350 yards to the east of the bazaar and burnt. One sweeper is maintained by Government, and the filth collected by him is thrown into a nullah about 400 yards to the eastward of camp, where the bazaar people resort for the purposes of nature. All stagnant water is removed every morning by the bazaar sweeper, or by sweepers kept up by the inhabitants. Two bazaar peons and two of the night police maintained by the inhabitants, prevent any nuisance being committed within camp limits from 4 a.m. to 10 a.m. daily, and all offenders apprehended are fined by the superintendent of the bazaar and police. These arrangements have hitherto proved sufficient. There are no native houses in the vicinity of the station. 20. The slaughter ground is to the east or leeward of camp, and is about half a mile distant. No nuisance is experienced from it in the cantonment. 21. There are only about six tattoes in the bazaar, they are stabled with the buffaloes of the milkmen. Bullocks are picketed in an open space to the north of the bazaar. The whole of the refuse grass, manure, &c. is daily removed by the bazaar cart. 22. The artillery stables are open sheds. They are situated to the leeward of the artillery barracks, but to the windward of the infantry ones. The manure is removed daily. The dung is sold or made into fuel and taken to a distance. The urine is allowed to evaporate, and to a certain extent deodorized by means of lime. The stables are nearly a mile from hospital. 23. The accommodation for the married people is sufficient. None of them occupy barrack rooms with the men. The patcheries, however, are of a very slight temporary description, and would require improvement were it decided to locate European infantry here permanently. They are damp during the monsoon.
Officers' Quarters.	Officers reside in separate bungalows, the compounds of which are kept clean. They are, from their position on a ridge, well drained naturally. Any inattention to cleanliness would receive due notice from the station authorities. No improvements are suggested.
IV. Health of Troops.	1, 2, 3. The station of Kolapore is a very healthy one, the mortality amongst the Europeans being lower than in any other cantonment in the Bombay Presidency. From January 1830 to December 1849, out of an average strength of 292, the deaths were only 20·54 per 1,000. The entire district enjoys more or less the influence of a sea breeze, which commences in the afternoon or evening, and tempers the westerly winds in April, May, and June, and renders the hot weather much less debilitating than at most stations. It is even considered in some respects superior to Belgaum in point of climate. Amongst the native population the endemics are intermittent and remittent fevers, guinea worm, tape, round, and thread worms, and itch. The epidemics are cholera, small-pox, and measles. Its salubrity is no doubt attributable to its elevation,—1,797 feet,—to the open nature of the country in the immediate vicinity of the camp, freedom from luxuriant vegetation, and to its free exposure to westerly and south-westerly winds. 4. The only force that has been here any time is the 3rd company 3rd battalion of artillery, which is a newly raised one. The men composing it were drawn from different stations. It has been located here for two years and a half, and has enjoyed excellent health. It has suffered from intermittent fever, but not to any extent. The native infantry lines are perhaps the least healthy, the wing of the 15th Regiment N.I., that was here last year, having suffered from cholera, which, however, was attributed to defective drainage, and to the existence of concealed cesspits in or near some of the huts. 5. The system of camping out has not been practised here, as the troops have been much moved about latterly. The 10th Regiment N.I., for example, has just returned from field service in Rajpootana and Central India, and with the exception of a three weeks' halt in the first monsoon, has passed upwards of two years under canvass. 6. Our experience of hill stations is confined to a short sojourn at Mahableshwur. 7. We have no data to furnish, but consider that a residence at hill stations would not only lessen the liability to fever, but would tend generally to diminish the predisposition to climatic disease which is occasioned by a protracted residence in the plains. 8. We highly approve of selecting hill stations for troops when practicable. 9. In the Himalaya group, Kussowlie, Subathoo, Simla, and Dugshai, troops are liable to hill diarrhœa to a greater extent evidently than on the few hill stations on the Bombay side. 10. Bowel complaints might in some measure be guarded against, so far as they possibly could, by the use of flannel under-clothing, pure water, attention to cleanliness, clearing the jungle, thorough drainage, and a strict system of conservancy. 11. In the Deccan hill stations the hot weather and post monsoon are the most suitable seasons for residence there. The shortest period of residence to derive benefit from hill stations is from one to two years; but even a single hot season on the hills has a remarkable effect on individuals, free from organic disease, debilitated by service and hard work in the plains. 12. Not aware of any period of residence beyond which injury is likely to be inflicted on the health of the troops on returning to service in the plains. 13. The precautions for protecting the health of the troops on leaving hill stations for the plains are to make the transition easy and to avoid too long marches and exposure to the sun. 14. As a general rule it is advisable to have European troops located periodically on the hills, and especially to canton them as much as possible on high table lands; stations such as Belgaum, Kolapore, and Poona proving very suitable to the European constitution. Until the system of railways, however, is much more advanced, stationing troops on the hills can only be hoped for, as a large portion of the army will be required in the plains to preserve order amongst a mixed population, as well as to curb warlike robber tribes on the frontiers. It would doubtless prove most beneficial to have European children after five years of age sent to the hills, and to arrange that the European soldier should pass one year in five in a climate more suited to his constitution than the enervating one of the plains. Change of station in the plains is beneficial, and is very requisite in unhealthy localities.

IV. Health of Troops—*cont.*	15. The sanitaria on the Bombay side are very limited. Those in the Deccan were some time ago fully reported upon by Dr. Morehead, then superintending surgeon, Poona division—one of the highest authorities on Indian diseases. 16. The elevation of Mahableshwur and Mount Aboo is 4,500, but a less height would evidently prove suitable. At Poonagunee, 4,000 feet, the rains are comparatively light, amounting to about 50 inches, while Mahableshwur is uninhabitable during the monsoon. 17. Punulla, a dismantled hill fort 11 miles from this station, is 975 feet above the plains, and has a climate suitable for a sanitarium, excepting perhaps during the monsoon, when it would in all likelihood be too damp, from being enveloped with clouds. It bears a high reputation among the natives, who declare that cholera has never been known to enter the fortress. The water is said to be good and pure, and slightly impregnated with iron, which abounds on the hill. 18. The most healthy soils for stations have been sandy gravelly soils, through which water readily percolates; moorum red soil, compound disintegrated rock (trap), coloured with oxide of iron. The worst met with by me in the course of 16 years' service was the limestone formation at Sukkur, Hydreabad, and Tatta. The presence of iron in the soil has not been found injurious to health, as ironstone is met with at some of the most healthy stations in the Bombay Presidency—at Mahableshwur, Punulla, Kolapore. When the 10th Regiment Native Infantry was at Supree, in Central India, which is a very healthy station, ironstone was found to be common. 19. Soldiers proceeding to India should be about 20 years of age, or when the constitution is sufficiently formed. The best period for troops to land in India is early in November, at Bombay, Kurrachee, and Calcutta. Recruits for the Indian army are usually landed at Bombay, and thence dispatched to their different stations, being supplied before starting with light clothing and bedding. If proceeding to the Deccan, they are forwarded by rail to Poona, from which they are marched to their respective stations, and on arrival at regimental head-quarters are sent to drill. To preserve their health they should be carefully looked after at the Presidency, at once dispatched up the country to their respective regiments, and in no case detained long at the Presidency towns, where they are extremely apt to be led into vice and intemperance. 20. Troops should be sent direct from home, as no perceptible advantage would be derived from residence at an intermediate station. To diminish the dangers of the earlier years of service they should be sent to a healthy station, such as Poona or Belgaum. The former has the recommendation of easy access by rail, but the latter has the advantage in point of climate. 21. The arrangements relative to the transport of troops are made by the quartermaster-general's department. It may be stated generally, however, that water transport, when available, should be adopted—steam in preference to sailing vessels—and that sending troops by country craft should be entirely discontinued. Pattinars have long been considered as unfit for the public service, being from their form, construction, and rig unmanageable in rough weather, when, moreover, they are liable to capsize from having to wear, being unable to tack. 22. The number of years a British soldier should serve in India varies according to circumstances, from 12 to 15 years. 23. There is rarely any conflict of opinion with regard to invaliding at the medical boards, as the committees are entirely composed of medical officers, who should, however, be selected for this important duty, and not be taken from the roster. In mixed committees for the examination and passing recruits, for example, it is different. To rectify any defects in their constitution, it should be made imperatively necessary for all recruits to be finally passed by the regimental medical officer, who is more interested than strangers in selecting only thoroughly effeetive men for his regiment. 24. Invalids should leave India in January, so as to reach home in the summer.
Diseases.	1. There are regular weekly inspections in the detachment 56th Regiment for the discovery of venereal disease. 2. There has been no scorbutus among the European troops. The 10th Regiment Native Infantry has been too short a time here to enable me to form an opinion regarding native troops suffering from the disease at this station. Moreover, many of the men have brought a scorbutic taint with them from Central India, the result of long-continued over-work, hardship, and privation. As a preventive measure to this disease, greater encouragement should be given to gardening and to the cultivation of vegetables at all large stations. 3. The proportion of hepatic disease treated in the 3rd company 3rd battalion Artillery is small, only three cases of hepatitis having been in hospital in the last two years. The climate of India is the principal cause of hepatic disease, which arises from long continued exposure to a high temperature, the disease occurring on exposure to the sun, and great diurnal changes, in the most abstemious, as in the case of the French traveller Jacquemont, as well as in intemperate habits. Addiction to spirits no doubt induces organic disease of the liver, which is followed by intestinal hemorrhage and dropsy. This form of disease might in some measure be obviated by the use of malt liquor instead of spirits; by active habits and attention to the state of the skin; by the daily use of the swimming bath, which is a most important means of preserving health. 4. Dracunculus is rare among the European troops, but is prevalent among the natives here. The origin of the disease is still involved in obscurity. It arises from the use of water containing the worm or its germ, but whether from drinking or from bathing in such water, is still an open question. Her Majesty's 8th Hussars and 10th Regiment Native Infantry suffered considerably from the disease last year, and evidently contracted it in the jungles near Seronge in Central India. 5, 6. The following table shows the admissions from venereal diseases in the hospital, 3rd company 3rd battalion Artillery, during the last two years. It would be advantageous to establish lock hospitals at all large stations where Europeans are located. The troops at the station do not suffer from epidemic or endemic diseases to any extent. The only corps that has been stationed here for any length of time is the 3rd company 3rd battalion Artillery, the detachment of the 56th Regiment having been here for little more than two months and the 10th Regiment Native Infantry for a month and a half.

IV. Health of Troops: *Diseases*—cont.

7. The more frequent zymotic diseases are,—endemic, intermittent, and remittent fevers, epidemic cholera, small-pox, and measles. The former occur mostly at the termination of the rains, when there is considerable diurnal variation of temperature—hot days and cool mornings and evenings. Cholera and small-pox appear generally in the hot weather, the former in close, sultry, or muggy weather, with a highly charged electrical state of the atmosphere. The station bazaar is healthy; the dwellings are clean, and not overcrowded, and it is well drained. The native population generally are predisposed to disease from neglect of sanitary arrangements in the vicinity of their dwellings.

8. With regard to the influence which the soldiers' duties and occupations in barrack, &c., have on the prevalence of epidemic disease, it is difficult to reply more than generally. The more varied and agreeable a soldier's occupation is rendered, the better will be his health. In the field and on the march his health is usually good, from his enforced regular habits, free exercise in the open air, and the absence of means of dissipation. On his return to the routine of camp life he enjoys a less high state of health, caused to a certain extent by the less exciting nature of his employment, but more, perhaps, from the greater opportunity of indulging in intemperance in all large cantonments.

9. Small doses of quinine have not been tried at the station as a prophylactic against malarial diseases.

10. The station might be improved by sinking additional wells, so as to ensure a sufficient supply of good water during the hot season, when it is apt to become somewhat short. Planting trees might also be recommended as likely to add to the salubrity of the station. But the chief and most urgent measure as preventive of disease would be entirely to abolish cesspools and urinaries, and to introduce "the dry system of conservancy," as in Bengal, of removing all excreta in moveable iron pans, and of emptying them into filth carts morning and evening. Under the present system it is impossible, even with the greatest care and vigilance, to prevent the vicinity of cesspools and urinaries from becoming very offensive during light winds or calm weather. The only drains that it is desirable to continue are those connected with the lavatories, and those for the efflux of rain water.

V. Intemperance.

1. The soldiers of the detachment 56th Regiment are considered to be temperate. The 3rd company 3rd battalion Artillery are considered to be somewhat intemperate, and to have about five per cent. drunkards in the company, though no case of habitual drunkenness has occurred for a very long time.

3. In the hospital, 3rd company 3rd battalion Artillery, the admissions from delirium tremens were :—In 1858–59, 3 cases; in 1859–60, 3 cases. Drunkenness is always punishable as an offence.

3. In the Artillery canteen arrack is sold at 25° below proof, and is issued at the average rate of one dram per man daily. It is always paid for, excepting when artillery are serving on board ship, when it forms part of the ration. No spirits are issued in the Artillery canteen until the evening. Spirit is no part of the soldier's ration, excepting, perhaps, in the field, when it is considered necessary. When spirit is given to convalescents, it is by the special direction of the medical officer, and is always limited and of the best quality. In the bazaar an inferior description of ginger beer is sold, called "pop," which is decidedly injurious to health, and is apt to induce bowel complaints, and even cholera.

4. In moderation, spirit does not seem materially to affect health or prove injurious to discipline. The officer commanding detachment 56th Regiment distinctly states that the quantity allowed, of one dram to each man, is not detrimental to the internal discipline of the detachment.

5. It would not prove beneficial to the health of the troops to abolish the use of spirits in the canteen, as the men would very soon find a substitute in the cheaper and more deleterious spirits of the country, easily procurable at all large stations. At this station men have been known to have delirium tremens, caused chiefly, if not entirely, from the use of eau de Cologne, or what is sold at the bazaars as such.

6. The use of malt liquor is greatly preferable to that of spirits. Wines of a good quality would be beyond the soldier's means.

7. In the Artillery, tea, coffee, &c. are much used, and their consumption is encouraged as much as possible by the commanding officer. Their influence on health, efficiency, and discipline is undoubtedly beneficial.

8, 9. It would not be advisable to suppress altogether the issue of spirits from the canteen store, but something might be done by gradually substituting and cheapening the supply of beer.

KOLAPORE. BOMBAY.

References to Subjects and Queries.	REPLIES.
V. Intemperance—*cont.*	10. The use of tea, coffee, and lemonade should be freely encouraged, and, as far as practicable, the use of beer should be substituted for spirits. This can only be done in cantonments. In the field, during war, beer and porter cannot be carried about. In Central India, officers as well as men had occasionally to depend on the commissariat department for arrack, from the difficulty of getting carriage and from the nature of the country in which operations were carried on.
	11. The following is an abstract of the more important canteen regulations:—The canteen of the 83rd Regiment is open at noon for the issue of porter, and for the issues of porter and arrack from 2 to 3, and from 7 to 9 p.m.; when tattoo beating begins at 8 p.m. it is open from 6 to 8 instead of 7 to 9 p.m. The allowance of liquor to any one man is one quart of porter and one dram of arrack per diem. If he receives the quart of porter at noon he is not allowed to draw any more porter, and only one dram of arrack for the remainder of the day. If he receives only a pint of porter at noon, he can have the remaining pint and one dram of arrack in the evening; but whether he receives a pint of porter or no porter at all at noon, he can receive no more than one pint of porter and one dram of arrack in the evening, No liquor, without permission of the commanding officer, is allowed to leave the canteen except the porter at noon. No person not belonging to the regiment can receive liquor from or in the canteen. All issues from the canteen are paid for in ready money. No man on guard or picquet, or for reinforcement, or convalescent, or defaulter, is allowed in the canteen, and no liquor is allowed to be sold directly or indirectly from there to any native whatsoever. The canteen of the 3rd company 3rd battalion Artillery is opened at the following hours, 7 a.m. to 7 . 30 a.m. for the issue of one pint of porter; 12 noon to 12 . 30 p.m. for the issue of one pint of porter; and from 7 p.m. to 8 p.m., when the men can procure one pint of porter and one dram of arrack. There are no local bazaar regulations; those contained in 2nd Supplement to Jameson's Code are duly acted up to. No liquor is allowed to be sold in the bazaar to European soldiers or their wives or children, nor is liquor allowed to be brought into camp by unauthorized persons.
VI. DIET.	1. The composition of the ration is as follows:—

——	Queen's Troops.	——	European Troops in the Indian Army.
	lb. oz.		lb. oz.
Bread	1 0		1 0
Meat—Beef	1 0	Beef or Mutton	1 0
Tea (Black)	0 $\frac{10}{21}$		0 $0\frac{5}{7}$
Tea (Green)	0 $\frac{5}{21}$		
Sugar	0 $2\frac{1}{2}$		0 $2\frac{1}{2}$
Rice	0 4		0 4
Salt	0 1		0 1
Potatoes	0 8		0 8
Mixed Vegetables	0 8		0 8
Firewood	3 0		3 0

The only changes are from beef to mutton, and from bread to biscuit, and in the vegetables, which vary according to the season of the year. The ration is inspected by the commissariat officer, the orderly officer, and the non-commissioned officer on duty. That of the sick in hospital is inspected by the medical officer.

2. A complete ration, including vegetables, is provided. In the 56th Regiment the stoppage is 3 annas 4 pice a day. In the Artillery each man pays 2 pice a day for fruit and spices for puddings. Breakfast, dinner, and supper are taken at 8 a.m., 1 p.m., and 4 p.m., respectively. In the hot weather a change might be advantageously made by having a light meal in the middle of the day and the principal one in the evening; but it is not certain that the men themselves would prefer the arrangement. The proportion of vegetables in a ration is one pound.

3. The rations issued are excellent. They might be varied more from beef to mutton. In the Artillery the men change the rice for a supply of milk for their tea. A small quantity of milk might be added to the ration, and some butter, perhaps, during the rains and cold weather.

4. The kitchens are good, but the camp kettles are too large, and there are no means of roasting the meat. The kitchens are clean, open, and well ventilated, and sufficiently supplied with water. The food is either boiled or fried. It is properly done, but not sufficiently varied, from the want of roasting apparatus. Tea is properly prepared. In the Artillery arrangements are made to have coffee prepared for the men, either before a march or as a refreshment half way; but this is not the case in the 56th Regiment detachment.

5. Gardens for the cultivation of vegetables would be advantageous in many respects, by employing the men out of doors and affording an agreeable relaxation from the dull routine of camp life. They should be under the superintendence of officers selected for the duty by the commanding officer.

VII. DRESS, ACCOUTREMENTS, AND DUTIES.

1. The soldier's dress in the Artillery consists of cloth tunic and trousers, serge jackets and trousers, khakee light clothing, and helmet with turban over it. The accoutrements are, sword belts and knapsacks, the latter is only worn on heavy marching order parade. In the 56th Regiment khakee clothing is worn during the hot season, and shell jacket and cloth trousers during the rest of the year. Woollen clothing, light or thick, according to the season, should be worn by men exposed to night air, and flannel under-clothing throughout the year, but particularly during the monsoon, the neglect of which precaution is apt to occasion bowel complaints. During the hot weather the men should wear cotton socks, and woollen ones during the rest of the year. The men on guard wear cloth clothing, excepting in the day in the hot season. The helmet is by far the best and most suitable head dress for the climate. Its construction, however, is open to improvement as regards durability and lightness. The dress of the men of the 10th Regiment Native Infantry is, for parade, forage cap without cover, cloth shell jacket or tunic, and American drill fatigue trousers. In cold weather, cloth trousers are worn on all duties before 8 a.m. and after 6 p.m., and guards wear great coats during the night. For summer clothing, white clothing cut tunic

References to Subjects and Queries.	Replies.
VIII. Dress, Accoutrements, and Duties—*cont.*	fashion has been introduced, and has been directed not to be dyed until a regiment is ordered on service. This would occasion considerable inconvenience, even were it always possible to dye some 1,500 tunics khakee coloured at a short notice. A peak is very much required for the forage cap to protect the eyes from the intense glare of the sun. This could easily be introduced without any general order being issued that would excite remark. Were it intimated that its use would be permitted, the native officers would at once adopt it, and it would become generally appreciated by the men. The shoes now in use are of a bad description, and of country leather, which becomes worn out in a short time in wet weather. It would be preferable were Government to provide the article in the same way as to European troops. The want of good shoes was severely felt by the 10th Regiment Native Infantry, which underwent no ordinary hardship and privation in the Central India campaign, having in the course of two years marched 3,689 miles. The committee beg to recommend loose serge coats and khakee clothing, the same as is used by European Infantry, instead of the present dress, for regular Native Infantry. The accoutrements are, buff waist and shoulder belts, with bayonet frog and scabbard, black leather pouch, with 10 rounds of ball ammunition. The present accoutrements are badly slung, the whole weight of the ammunition being thrown on one shoulder, and the one too that has to bear the weight of the musket. This could be obviated by dividing the ammunition into two smaller pouches. The knapsack when packed is too heavy, and is, moreover, quite unsuited to the natives, for when likely to come into use on a forced march it cannot really be carried without exhausting or distressing the men. A better and more serviceable haversack is desirable.
Duties.	1. No apparent material advantage would be derived from drilling troops at home. It would seem preferable to have them drilled in this country by the officers and non-commissioned officers under whom they have to serve. 2. The usual routine of soldiers' duties at this station are:—Artillery, morning parade or drill from 5 to half-past 6 a.m. Stables, 6.25 a.m. to 7.30 a.m. Breakfast, 8 a.m. Orderly room, 9 a.m. Cleaning harness, arms and accoutrements, and barracks, until noon. Dinner 1 p.m. Supper, 4 p.m. Drill or stables, 5.30 p.m., and in evening, tattoo roll call. 56th Regiment detachment.—Guard mounting and drills, twice a day, three-quarters of an hour morning and evening. The best hours for drills are early in the morning, earlier in the hot than in the cold weather. With regard to marching, the instructions in separate general orders are as clear and distinct as could be wished. The commanding officers, however, often assume large discretional powers in marching, evidently from want of due appreciation of the importance of preserving the energy of the men from the effects of the sun, which seems to operate more quickly on a soldier, fatigued at the end of a march, buttoned up and accoutred, with a rifle and supply of ammunition, than it would do on the same individual disencumbered of his arms and lightly dressed. The Artillery have five nights and the 56th Regiment six nights in bed during the week. The 10th Regiment Native Infantry have morning parade every day, Sundays and holidays excepted, averaging about one and a quarter hours in duration. Orderly room at 8 a.m.; evening roll call and inspection parade, once a week. Evening parade for non-commissioned officers, three times a week. On weekly holidays roll call is taken at tattoo beating. The average nights in bed for privates are three; for naiques four; for havildars, five. Guards last for 24 hours day and night, and are mounted in the main street in the regimental lines. They are, with one exception, within half a mile of the lines, and the treasury is three miles distant. The European Infantry mount guard in barrack square and are relieved every 24 hours. There are roll calls at morning parade, breakfast, dinner, evening parade, and tattoo, and check roll calls when required. The night duties here are light, and do not have the same effect as in unhealthy stations. With regard to the movement of troops, by special general orders, long and distressing marches, unless under special orders or emergencies, are strictly forbidden. The hours of marching must depend on the season, climate, state of roads, distance, and service; but on ordinary occasions, when troops are not in an enemy's country or disturbed district, or in charge of prisoners or treasure, it should be so timed as to bring them to their ground by or soon after sunrise; all unnecessary exposure being sedulously avoided, as prejudicial to health.
VIII. Instruction and Recreation.	1. The means of recreation and instruction are as follows:—There are no ball courts, but the Artillery have skittle grounds in the lines. There is no adult school. The Artillery have a library, which is well lighted. There is no day-room or soldiers' clubs. There are no soldiers' gardens, but the Artillery cultivate small plots of ground during the rains. There are no workshops or gymnasia, but there is a station theatre, which is out of repair, and which has fallen down since the preparation of this report. The means are not sufficient to keep the men occupied during the wet season and during the heat of the day. The commanding officer of the Artillery does not restrict his men, but permits them to expose themselves as they please, and encourages them in getting up cricket matches. In the 56th detachment the men are not allowed to expose themselves unless on duty. 2. A ball alley should be built, and plunge baths established, as the men have no means of keeping themselves clean properly, from the defective lavatory arrangements in the barracks. Indeed in all stations where European troops are located, plunge baths should be built, as they are most essential to the health of the troops. In several stations they have been already introduced, as at Kurrachee, Belgaum, Kulladgee, &c. Their effect on the health of the troops can hardly be overrated. 3. Soldiers' savings' banks are already established at the station. 4. There are no trees in camp to afford shade, but there are good verandahs to all the barracks.
IX. Military Prisons.	1. The European cells can scarcely be considered as good, the cubic space being less than the minimum allowed in barracks for European troops in Bengal Public Works Code. There are moreover no wash-houses for the prisoners.
X. Field Service.	1. There are no local rules for field medical service which are not included in the Bombay Medical Code, Section XI. 2. With regard to the powers of the medical officers, as to the conduct of the line of march, of troops bivouacking, camping, billeting, &c., the rules for encampment on service are laid down in pages 143–4–5, separate general orders; and ordinary camping in page 81 of the same, but contain no reference to medical officers. These arrangements are entrusted entirely

X. Field Service—*cont.*	to the commanding officer. This renders it a matter of considerable delicacy for the medical officer to offer any suggestion, as such recommendations are not always well received. To illustrate the working of the present system a few instances had better perhaps be adduced. In a cavalry regiment that had a short time previously arrived in the country, the corps was marched late and kept out in the sun. The result was that the men suffered from exposure and the sick list increased. The surgeon represented to the colonel the advisability of marching earlier, but was not attended to. The next occurred in an infantry regiment, which, on account of an outbreak of cholera, was moved into tents. The colonel, from a want of knowledge of sanitary matters, had the tents so closely pitched that the ropes nearly interlaced. The surgeon ventured to suggest that the tents were too close to allow of proper ventilation, and was publicly informed that it was no affair of his. He accordingly reported the matter to the brigadier, who personally inspected the camp and ordered every second tent to be taken down and pitched elsewhere. In giving another illustration of the disregard of medical officers' opinions, there is no reason for withholding the details, as it has already appeared in print. At the end of April 1846, the 22nd Regiment Bombay Native Infantry was ordered from Mhow to Baroda, and Dr. Arnott, the surgeon in charge, remonstrated against the march being undertaken at such an advanced period of the year, and as cholera and small-pox moreover were then raging along the line of march. His representation however was not attended to, and within ten days of leaving Mhow there were 300 cases of cholera, of which 200 died. Dr. Arnott too, a good and zealous officer, fell a victim to the disease, and the regiment was left in the middle of the jungle without any medical aid. 3. The regulations for preserving the health of troops in camp are laid down in separate general orders, an extract from which is appended. Ventilation and water supply come only to a limited extent within the province of the regimental medical officer, whose duties are confined to the details of station and field hospitals. At large military stations the senior medical officer has latterly been nominated sanitary officer, and is thus permitted to make recommendations bearing on the health of the troops. The power, however, of the medical officer in the matters referred to is very restricted, being confined to submitting suggestions to the military authorities, which may or may not be received in good part. The result is that medical officers are somewhat reluctant to interfere unless obliged to do so officially through the occurrence of sickness. During the two last years on field service in Rajpootana and Central India I only recollect of having once offered a suggestion to the commanding officer, and that was in a private form to the officer now commanding the regiment, who is a personal friend of many years' standing. It would be preferable were it clearly laid down to be the duty of the medical officer to advise the commanding officer in all questions relative to the health of troops, as he is fully as responsible for the health of the regiment as the commanding officer is for the maintenance of discipline and proper interior economy, having annually to furnish a detailed statistical account of his charge to the Director-General at the Presidency. Any cases of difficulty or doubt could easily be set at rest by a reference to the Deputy Inspector-General of the division, which course would ensure attention and discretion, and would prove more conducive to the interests of the public service than the present arrangement, by which the sphere of usefulness of medical officers is in a great measure limited to the details within hospital. Since the above was written, the Director-General's quarterly sheet of general orders and medical circulars of the last quarter contains the following:—In a general order, 11th February 1860, regimental medical officers have been directed as at home to frequently examine into the state of the barracks, of their environs, and to suggest any improvements that may appear necessary to the commanding officer. Copies of such suggestions to be invariably forwarded to the Director-General's office, Bombay, and to be inserted in the annual report of the medical history of the regiment. 4. When it is necessary to establish a field hospital, a surgeon is selected, from his experience generally, and is nominated in general orders, with as many assistant-surgeons under him as may be required. The field surgeon, in concert with the superintending surgeon, makes the requisite arrangements for medical stores, commissariat supplies, and sick carriage. The rules on this subject will be found in section xi., Medical Code. During the campaign in Central India the dooly was the best, and by far the most comfortable means of carrying wounded men. The next in point of convenience was the new pattern iron kajawak on a camel, and the last, the ambulance or spring cart, which was slow and not suited for forced marches, or for operations in a hilly or jungly country. The number of dooly bearers in an European regiment might, perhaps, be slightly reduced and replaced by kajanahs, but the former can never be dispensed with in this country.

By order of the Acting Principal Inspector-General, Medical Department.

Office of the Principal Inspector-General, Medical Department, Bombay, 9th November 1860.

W. C. COLES, Assistant-Surgeon, Secretary.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1, 2. The hospitals occupied by the European troops face S.W. by S., and are about half a mile from the barracks and stables. The sudder bazaar is about 350 yards distant on the north of the hospitals. The site is open and freely ventilated, the ground being the highest in the immediate neighbourhood, and almost the highest in camp. The site is generally healthy. 3. There are wells of excellent water in the vicinity of the hospitals, which are generally sufficient. In the hot weather the supply for troops in camp is apt to become somewhat short before the setting in of the monsoon. 4. No system of drainage exists. The refuse water runs off, and is either evaporated or absorbed. Impurities from the necessary run into a cesspool, from which they are removed by the hospital sweepers. 5. The average height of the floor of the Artillery hospital above the surface of the ground is about 3 feet, and that of the European Infantry is about 5 feet. There is no ventilation underneath the floors. The roof water is partly absorbed, but a good deal runs off from the slope of the ground on which the hospital is built. No system of drainage or gutterage exists, the natural slope of the ground being sufficient to carry away any rain water rapidly. The walls of the hospital are of stone and lime, plastered with lime inside, and pointed with lime outside. The walls are single, 2 feet in thickness. The roof consists of a double layer of semi-cylindrical tiles, with bamboo matting below. Both roof and walls are considered sufficiently thick to keep the hospitals cool. The hospitals have a verandah 10 feet wide all round; the front and rear of it are open, but the ends are built up, forming dispensary and store-rooms, &c. The front is moreover protected by a second verandah of bamboo matting, which affords sufficient shelter from the sun's rays. The verandahs are never used for the accommodation of sick, convalescents, or others, excepting in an extreme case perhaps, from want of room. The hospital consists of one flat, the basement story. Table of hospital accommodation. Date of construction, 1854–5. Total number of wards, 3, one in each hospital. Total regulation number of beds.—About 48 in the European wards, and 60 in the Native Infantry hospital.

* This was originally a gun-shed, and was recently occupied by the commissariat department as cattle-shed. It was lately converted into a hospital to accommodate the sick of the 10th Native Infantry, as they were exposed in tents at the beginning of the monsoon.

References to Subjects and Queries.	REPLIES.
XII. Hospitals—*cont.*	The hospitals are so placed as to exclude the north-easterly winds, and to receive the benefit of the sea breeze as much as possible without being exposed to the south-west monsoon. The windows are made in two halves, opening from the centre inwards in the usual manner.
	6, 7, 8. In the European Infantry hospital ventilation is effected by three large iron ventilators in the roof, in the shape of revolving cowls, which, with the windows and doors, are sufficient to keep the wards free from odour or closeness. As these openings are always turned from the wind they do not admit cool air freely, though they allow of the exit of heated air. During the heavy rains, moreover, the rain beats in and renders the wards so damp that it is necessary to use charcoal in the monsoon to keep it dry. In the Artillery hospital there are two ventilators of the same description. There are no jhilmils. There are no other means employed for cooling the air admitted into wards, or warming them, than those already described. The walls and ceilings of hospital wards are cleansed and limewashed as a general rule every three months inside, and once outside annually, or oftener if necessary.
	9. There are two large necessaries in the rear of hospital under one roof, 8 feet high, connected with the wards by covered passages. They are divided by a partition wall inside; one is 30 × 12, the other is 25 × 12 feet. The walls are of stone and lime, 2 feet in thickness, with single tiled roof and roughly paved stone floor. All fluid excreta run into a cesspool behind them; all other impurities are removed by the sweepers. As the privies are cleaned out regularly, and lime daily employed for deodorizing, they are not offensive.
	10. In the 3rd company 3rd battalion Artillery the lavatory arrangements for the hospital are: 1 large bathing tub, 1 slipper bath, and basins at the rate of 1 to every 100 men. In the detachment 56th Regiment, 1 tub, and basins at the before-mentioned rate. This proportion is insufficient.
	11. There are no regular bath rooms attached to the hospitals. This is owing to the fact that the European troops now occupy the hospitals which were built for the native troops stationed here. It is understood that a site has been selected for a new hospital for the Europeans nearer the braracks.
	12. Washing and drying hospital linen, &c., are performed at a distance by hospital washermen in this country.
	13. Storage is very limited.
	14. The cots used in hospital consist of strong wooden frames with cotton tape stretched across them. The bedding consists of straw mattrass, $6\frac{1}{2}$ by $3\frac{1}{2}$, at the rate of 20 per cent. of the strength; pillow cases are of the same description, $2\frac{1}{2}$ feet by 15 inches, at the rate of 60 per cent. of the strength; cotton sheets, $7\frac{1}{2} \times 4\frac{1}{2}$ feet, at 60 per cent.; bedding quilts, gingham lined, with soft country blankets of the same size as sheets, at the rate of 30 per cent. Lately suttringees or bed carpets, $5\frac{1}{2}$ by $2\frac{1}{2}$, have been sanctioned in addition to the above. It would be advisable to substitute in all hospitals and barracks strong iron cots, painted, which would be more durable and economical, and certainly much cleaner than wooden ones, which are greatly disliked by the men from their speedily becoming infested with bugs.
	15. The cooking of the hospital diets is properly done, as far as the means at disposal permit. The apparatus for cooking, however, is insufficient; additional kettles being required and camp ovens for roasting.
	16. Diet tables, rolls, &c., according to regulations.
	17. In the detachment 56th Regiment no hospital orderly is allowed for attendance on the sick. It is evidently desirable to have a steady non-commissioned officer nominated for this duty in all hospitals, whether of a wing or only a detachment of two companies. A matron is sanctioned only for a complete battalion of artillery or infantry.
	18. The sanitary condition of the hospitals is good. The wards have been free from hospital gangrene, pyæmia, &c., from its free ventilation and excellent site.
	19. There are no sanitary defects calling for especial notice. It would be an improvement to have a small cylindrical drain with a sufficient fall to carry the fluid impurities a greater distance from the hospital than at present. This could be flushed regularly daily. But the chief and most important alteration that is necessary is the introduction of the dry system of conservancy in barracks and hospitals.
	20. When convalescents are too reduced to take exercise they are sent out for air in a doolie. In special cases in the Artillery permission is obtained to have exercise on horseback. There are no shaded walks or seats set apart for their use.
	21. At present there is special provision made for the treatment of soldiers' sick wives and children; they are attended in the married people's lines. These arrangements are temporary. A new hospital is required for the European troops, for whom the present accommodation would be insufficient in the event of much sickness occurring amongst them. A female hospital also is much needed for the treatment of sick women and children.
	22. There are no special local hospital regulations not included in the general Presidency Regulations.
	23. In reference to the powers of the medical officer as to repairs, &c., he can bring to the notice of the commanding officer any repairs required through the adjutant of the regiment, and he can have the hospital whitewashed on indent countersigned hy the superintending surgeon of the division. With regard to medical comforts, he has discretionary powers, restricting himself to the scale laid down. But his powers are rigidly circumscribed, and almost entirely confined to hospital details, his practice being strictly reviewed and expenditure controlled by the superintending surgeon of the division, while the commanding officer is authorized to see that order, regularity, and discipline prevail in the regimental hospital. The course pursued by Lieut.-General Sir Hugh Rose in Central India towards the medical department seems more likely to encourage zeal, to foster *esprit de corps*, and to stimulate to increased exertion, than frequent interference with executive medical officers. He is reported to have said, "I never interfere with you, and only wish to interfere when "you require my assistance to carry out your arrangements."
	24. There are no convalescent wards. In the event of much sickness occurring among the troops such an accommodation would be an advantage.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead.	1. The burial-ground for British troops is about a mile from the station, bearing south-easterly and to the leeward of the camp. 2. Its area is about 200 feet square, and it is surrounded by a wall 8 feet high. The soil on the east side is black, but on the west this gives place to moorum, so compact that it is difficult to excavate. There is no subsoil drainage. The surface drainage is effected by means of openings left in the plinth of the wall. 3. The burials have been so few that it has not been found necessary to make any regulations as to the space allowed for each grave. The interval between each grave depends on the season, whether it is wet or dry. In the monsoon the sides of newly-dug graves fall in so much that a much larger interval must be allowed than in the dry season. The depth of the graves is never less than 4 feet, and in the dry season it is greater. During the rains a greater depth cannot be obtained in the lower part of the graveyard on account of the water. Hitherto there has been no necessity for reopening graves, nor, according to the rate of mortality since the inclosure of the graveyard, is such a necessity likely to arise for many years. The time of interment in the case of soldiers depends a good deal on the recommendation of the regimental surgeon, and in the cases of others on the wishes of the friends of the deceased. 4. The graveyard was slightly offensive last year during the time that cholera prevailed. The cause of its becoming so was attributed to the burial of native Roman Catholics without coffins. No measures were taken in the matter, as the nuisance did not extend beyond the walls, and the situation of the graveyard with respect to the camp rendered such measures unnecessary at that time of the year, when the wind blew directly from the camp to the graveyard. There are no local regulations for the burial of British troops. They are buried according to the custom of the service. 5. The bodies of Mahomedans and certain classes of Hindoos are buried in a place set apart for that purpose. The burial-ground is situated to the north, and about half a mile from the lines of the 10th Regiment Native Infantry. No houses are near to the burial-ground except one or two bungalows, which are about a quarter of a mile from it. The bodies of the other classes of Hindoos are burnt in the river. 6. No injury to the public health has resulted from the present practice, as the ground seems to have been well selected. It is desirable that the bodies should be interred sufficiently deep. The inhabitants have, up to the present time, been in the practice of digging about 5 feet deep, but in many cases much less. 7. The only improvement in the European burial-ground would be, as far as practicable, to have the bodies buried in coffins.

(Signed) J. S. Gell, Major, 10th Regiment N. I.,
Commanding at Kolapore.

T. Murray, Assistant Surgeon,
10th Regiment Native Infantry.

W. R. Dickinson, Captain, Executive Engineer,
Belgaum and Kolapore.

15th August 1860.

APPENDIX.

Cantonments and Quarters.

Separate General Orders, par. 11.

The preservation of cleanliness is of the first importance, and to this end the encroachment of huts or shops, temporary or otherwise, beyond the space already marked out for the purpose, or extending enclosures or court-yards without the sanction of Government, is to be particularly prevented.

11. All persons residing within military cantonments are required to keep all drains and water channels in and about their premises free from obstruction; to remove all causes of malaria, to keep their hedges, inner and outer, cut to the height of 4 feet from the level of the ground, and not more than 2 feet in breadth, and branches of trees lopped off to the height of 6 feet from the ground.

38. Commanding officers of regiments are to be held responsible that the above regulations are observed within the lines of their respective corps. The work is to be performed under the immediate superintendence of the Regimental Quartermaster, and without expense to the State.

41. The Cantonment Staff Officer is responsible for the general cleanliness of camp. He will procure such assistance of carts, bullocks, sweepers, &c., as may be necessary, and prefer charges for the whole expense in contingent bills.

47. The Line or Staff Serjeant of each cantonment is daily to inspect a portion thereof, so that in the course of one week every portion shall be visited by him, and to report daily to the Cantonment Staff Officer as concerns all subjects embraced in existing orders relative to cleanliness, good order, and the removal of all preventible causes of malaria.

48. The Station Staff Officer is himself to make a similar inspection weekly, and to report in writing to the Commanding Officer, who is to take immediate measures to correct what may be wrong.

49. These reports, with memoranda of measures adopted or required to check irregularities and remedy defects, are to be sent on the first of each month to the Assistant Quartermaster-General of Division, for the information of the General Officer commanding.

References to Subjects and Queries.	Replies.
I. Topography.	1. The surrounding country is bare and somewhat exposed, undulating in the immediate neighbourhood of the station; hills and mountains at a distance varying from 5 to 30 miles, with intervening valleys. There is not much wood, jungle, or water in the vicinity of the station.
	2. The elevation of the station above the sea is from 2,100 to 2,260 feet. It is on a level with the adjacent country, and 20 to 100 feet above the nearest water. There is no higher or healthier ground adjoining the station.
	3. The nearest hills are about 8 miles distant, and the nearest hill with table land about 30 miles distant. The height of the latter is about 650 feet above the station.
	4. A small nullah runs through the camp, and there is also a large tank close to the fort; both are dry during the hot season. The nearest river is 16 miles distant. The vicinity is not liable to an overflow of water. There are a few ravines and water pits near the station, but they do not appear to have affected the general health of the troops.
	5. The station is open, although there are some trees adjacent; but with the exception of the fort, which is somewhat shut in, there is free circulation of air throughout the camp. The temperature of the station is not raised by reflected sun heat; it is exposed to both land and sea breezes. The land winds of the cold season injuriously affect the health of the troops; the sea breezes, however, are beneficial.
	6. The higher tracts close around are uncultivated; the lower land is all cultivated; their extent is perhaps the same. The large tank near the fort is an irrigation work, and several of the wells may be said to be the same, as fields are irrigated from them. Artificial irrigation has no effect on the health of the station, it is so very limited. The cultivation of rice is not prohibited. No indigo is cultivated, nor is the preparation of hemp or flax carried on near the station.
	7. Shahpoor is distant about half a mile from the station, and the town of Belgaum is between the fort and the camp; the latter, it is said, numbers some 18,000 inhabitants.
	8. The ground of the district is undulating, its geological structure is trap and laterite here and there cropping out. The general surface of the higher ground is composed of laterite detritus, that of the valleys is composed of negur or black soil. The camp is on new ground, but the fort, which is also included in the camp limits, is supposed to be 600 years old.
	9. Water is found during the dry season from 10 to 70 feet below the surface, according to the site of the well. The difference in depth between the dry and rainy season varies to the extent of 47 feet.
	10. The greater part of the rain-fall flows very readily away; on the lower ground some sinks into the soil, but much of it lies on the surface until it evaporates. There is no higher ground the drainage from which passes into the subsoil of the station.
	11. The water supply of the station is derived from wells; there are no tanks for the water supply of the station. The wells are liable to pollution, both from leaves and other matter falling into them, and yearly cleansing is desirable. No nuisance or malaria proceeds from any tanks within or without the station.
	12. In camp the supply of water is somewhat defective, owing to the wells being at a distance. The water is good, and has no unpleasant taste or smell. Indications of the presence of chlorides are found when chemically tested, also of sulphates of lime or magnesia, or both; carbonic acid is also present, and probably a salt of iron. It has not been microscopically examined, but it is clear from taste and smell, soft, good, and not injurious. The supply in camp is rather limited; the water is raised in leather moats (skins) by bullocks and emptied into troughs, and thence conveyed by water carriers. More wells might be sunk, or tanks might be built, to improve the water supply.
	13. We can suggest no other topographical points bearing on the health of the station not included the previous answers.
	14. New stations are sometimes selected by a commanding officer, but we believe more generally by a committee, of which the commanding officer, the senior officers of the medical, engineer, and quartermaster-general's departments are members. Elevated ground appears to have been generally preferred. We recommend that officers should be specially selected to determine so important a question, and that time, opportunity, and every facility should be afforded them of forming a proper opinion. We would also strongly recommend that no barrack or hospital be built till the climate of the station at which it may be intended to erect it may have been duly considered and the plans have been approved of by officers competent to judge, as the climate at different stations varies greatly, and the same kind of barrack or hospital will not suit for all.
II. Climate.	1. The means and instruments available at the station for conducting and registering meteorological observations are—

Anenometer	1
Pluviometer	2
Barometer, standard	1
,, mountain	1
Hygrometers, Daniell's	2
,, Regnault's	1
Thermometer, standard air	2
,, ,, wet bulb	2

References to Subjects and Queries.	Replies.

a, for four years; *b*, for two years; *c*, for one year.

3. The climate is generally good, there is no excess in either dryness, moisture, heat, cold, fog, or damp, but it is variable. The trees growing in the station affect the climate beneficially. The irrigation in the neighbourhood is not injurious. Dust storms occasionally occur in the hot season, but do not affect the salubrity of the air. The general influence of the climate on health is good. During the cold and rainy seasons warmer clothing is required, and places to live in that are roomy, well-ventilated, and easily kept dry. Duties cannot be avoided, but drill and exercises should be avoided, so far as possible, from the middle of June to the end of August, on account of the ground being wet. Drills should take place generally in the morning, but during the monsoon the evening is preferable. The healthy and unhealthy months vary somewhat in different years; but for a period of 8 years the most healthy months for the European soldiers were January, February, September, August, October, and July; and the most unhealthy, May, June, March, November, April, December, and in the order stated. For the natives the healthy months were January, September, August, February, October, March, and the unhealthy, April, May, June, July, November, and December, and in the order given. The healthy season may however be stated to be from the beginning of August to the end of February, and the unhealthy from the beginning of March to the end of July, as it is during these months that epidemics usually prevail. During the unhealthy months the prevailing diseases are fever, intermittent principally, but also remittent and continued, affections of the stomach and bowels, and hepatic diseases; there are also occasional outbreaks of cholera, small-pox, and measles.

4. Not aware of any district near the station, the climate of which is more conducive to health than that of the station.

N.B.—*a* The number of men is calculated at 5 running feet along each wall inside per man, excluding doors.
b Height under the tie beams. } The roofs are open to the ridge; no ceilings.
c Height of side walls inside. }
d Spaces taken up by the pillars have been deducted.
e The usual strength of these Guards.
f This is the height to the plank ceiling, which has an air hole in its centre; and above it, the walls are carried 3 feet, having in each of its four sides, between the ceiling and the roof, a circular ventilating hole 1½ feet in diameter.

* The sepoys' huts are of native construction; a number built end on constitute a "pendall," which is of various lengths. It will average, say, 20 to 22 feet broad, 5 feet high at the sides, and 11 at the ridge. The interior being partitioned off with wattle and daub into separate cabins, giving, perhaps, an average of 80 to 100 square feet to each man; one small door, about 3 by 4, is all that admits light and air into each den. The pendall is usually single-tiled.
† There are other guards of less strength; but it is, perhaps, not intended to insert all.

5. The windows are on opposite sides and open inwards. Every barrack has a verandah on both sides extending its whole length. In one artillery barrack it is 8⅓ feet broad, in the other 12 feet. In 9 of the infantry barracks it is 10 feet 7 inches broad. In the remaining 3 the inclosed verandah is 9½ feet in the clear.
The verandahs are occasionally used as sleeping quarters in the hot weather. Three

III. Sanitary Condition of Station—*cont.*	of the infantry and one artillery have the front verandah enclosed by Venetians and glass—the rest are open. 6. The bedsteads used in barracks are boards and iron trestles. The bedding consists of coverlids, sheets, bolsters, and cotton mattresses in barracks, and the same are used while marching or on field service, minus the boards and trestles. 7. There are six descriptions of tents in use in the Bombay army. All are made of a cotton cloth manufactured in this country called durgaree.

—	Size.	Inner Walls, Number of Cloths.	Outer Walls, Number of Cloths.	Inner Top, Number of Cloths.	Outer Top, Number of Cloths.	Number of Men to each Tent.	Cubic Space to each Man.	Superficial Area per Man.

Staff Serjeants, single-poled tent	10 ×10	0	3	3	3	6	$122\frac{1}{4}$	$16\frac{1}{2}$

8. The barracks and guard rooms have small ventilators on the ridge. Tents and sepoy huts are not ventilated. The ventilation is sufficient for the purification of the air whenever they are not crowded. There are no means of cooling the air of the barrack rooms.

9. The walls of the barracks are built of laterite and lime, doors and windows, plank shutters, and the roof is double-tiled. The tents are constructed of durgaree cloth. Huts have mud walls and single-tiled roofs.

10. The barrack rooms are paved with stone; the floors are raised to various heights from 0 to 8 feet, according to the fall of the ground. They are solid, with no passage of air underneath.

11. The materials used in the construction of the barracks, huts, and tents are suitable for the climate. We would recommend that the floors should be planked, and if the barracks were more lofty, and had a continuous ventilation along the ridge, it would increase their salubrity. The barracks and cantonment roads are repaired by the department of public works, and repairs are quickly executed. The officer commanding the station is answerable for the sanitary state of the cantonment. The walls and ceilings of barracks are cleansed and whitewashed at no stated intervals, but whenever the commanding officer of the troops occupying the barrack consider they require it.

12. There are one or more washing rooms to each barrack. The water is kept in casks filled by the water carriers, from which the men help themselves. The artillery have one plunge bath in the fort, and the infantry two in the camp. They are supplied with water raised by bullocks from adjoining wells. The water is let off through a hole in the bottom of the bath, from which a drain leads to the lower ground, where it runs to waste. The artillery can use their waste water in their gardens, if they choose.

13. A cooking range extends the whole length of the barrack cook rooms, and is topped by a number of small cooking places, open to the front and top, and of a sufficient size for a camp kettle to rest on. The fuel used is wood. There is also an oven in each cook room. Men from Goa are employed as cooks, paid by the soldiers. Water is supplied by carriers, and the drainage is led into the adjoining cesspool, which is emptied whenever necessary. There are no conveniences for washing and drying linen, nor are they necessary, the work being done by washermen generally beyond the cantonment limits.

14. The solid matter is removed from the privies daily by sweepers, the liquid finds its way into cesspools, which are cleared out whenever necessary.

15. The barracks are ventilated by the doors and windows, and ventilators in the roof. At night they are lighted by 3 lamps in each barrack. The washing places are ventilated by loopholes in the walls, the privies by doors and holes. The cook rooms are open in front, and have loopholes in the walls, and a portion of their roofs is raised. The urinals are attached and under the same roof as the barracks. None of the above subsidiary buildings are lighted at night.

16. The cesspools are cleaned out by sweepers as often as required. The drainage is sufficient, but some of the drains open too near the barracks. There is no dampness in any of the buildings beyond that caused by the weather in the monsoon. There are no foul ditches.

17. The surface cleansing is for the most part daily and efficiently done; some is burnt and the rest removed and used as manure.

18. The surface of the cantonment is kept free from vegetation. There are no old walls, &c. interfering with the ventilation of the station, bazaar, &c.

19. The bazaar is well drained. Its ventilation, as in all station bazaars, is deficient; the houses being low and crowded. The water supply is good, and there is no want of cleanliness. There are sweepers and scavenger carts to carry away rubbish and burn it. There are public privies and cesspools, but the better classes have privies near their houses, and they pay for sweepers to keep them clean, but at times they are very offensive. The bazaar is too crowded. Houses should be pulled down and the streets widened. The native houses near the station are generally low, mean, and dirty looking, there are dung-heaps and cesspits near them as well as within the enclosures. No nuisance is experienced in barracks by the wind blowing over the native dwellings, but only because they are at a distance.

The native town affects the general health of the station from bad conservancy.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	20. Animals have hitherto been slaughtered within bazaar limits, and the offal has been carried away about a mile and a half beyond the camp limits. Very little nuisance is experienced, but a more distant place for the purpose would be better, and one has lately been selected.
	21. The bazaar horses, buffaloes, and other cattle are kept on the owners' premises. All the manure is carted away, except the cow-dung, which is kept for fuel.
	22. In constructing the stables, the roof has been carried up to a greater height along the centre of the stable. The spaces between the upper and lower roof and the pillars that support the former, being open, thorough ventilation is secured, assisted by the large entrances at either end, which also admit a sufficiency of light. The stables are outside the Fort, and away from any barracks or hospital. The dung-heaps are in the first instance near the stables, but are afterwards sold for manure. There are no picketing grounds.
	23. There are not sufficient quarters for married non-commissioned officers and men. Some of the end verandah rooms are occupied by married men; they are separated from the unmarried.
Officers' Quarters.	1. There are no public quarters for officers. They occupy private hired bungalows, which are generally well ventilated and drained.
IV. HEALTH OF THE TROOPS.	1. The station, district, and adjoining native population are generally healthy.
	2. Intermittent fevers, bowel complaints, ulcers, and affections of the air passages are the prevalent diseases among natives. Diseases of the spleen are not very frequent. Cholera and small-pox are often epidemic.
	3. The diseases from which the natives suffer are chiefly caused by imperfect ventilation, want of personal cleanliness, as well as about their dwellings, errors in diet, and ignorance and disregard of all hygienic laws.
	4. One of the European regiments at this station was at Kurrachee from April 1859 to January 1860, their health there was not good as they were suffering from scurvy which originated at Aden, Mooltan, and Sinde. They arrived at Belgaum, 29th January 1860, and their health since has much improved. Venereal has been the chief disease among them since arriving. The other regiment was at Nusserabad for 2½ years, and left it on the 17th February 1860. Their general health was good, but they lost many men from sunstroke while in pursuit of the rebels in 1858. They afterwards suffered from intermittent and remittent fevers; hepatic and abdominal affections also prevailed, and often proved fatal. They arrived at Belgaum, 16th April 1860, since which slight cases of fever and venereal affections have been the chief complaints. Of the two native regiments, one was at Aden three years; they left on the 23rd December 1857, they suffered much from scurvy, which carried off a number of men. The regiment arrived at Belgaum, 6th Februry 1858, in very indifferent health, and has since principally suffered from scurvy, intermittent fevers, and bowel complaints. The other regiment was nearly two years at Jhansi and the neighbourhood, they left 3rd January 1860; but while there, suffered much from intermittent fever. They arrived at Belgaum, 13th April 1860, since which bowel complaints of a mild type have been chief diseases. No part of the men's present accommodation is more unhealthy than the rest in a marked degree, but some of the European barracks are lower and not so well ventilated as the others, consequently they are not so healthy.
	5. Troops are not camped out except when epidemic disease such as cholera breaks out among them. The result is generally beneficial, and the disease soon disappears.
	6, 7, 8. No experience regarding hill stations.
	9. Troops going to hill stations are liable to head attacks, hepatic affections, and rheumatism.
	10. Warm clothing, good shelter, no night duty, plenty of exercise and recreation, and abstinence from ardent spirits, are the precautions necessary to guard against these attacks.
	11. The hot season before and after the monsoon is the season best adapted for residence in hill stations, and the shortest period to derive benefit from such residence is 7 months.
	12. Not aware that there is any period of residence beyond which injury is likely to be inflicted on the health of the troops on returning to service in the plains.
	13. The precautions necessary for protecting the health of the troops on leaving hill stations for the plains are, that they should leave in the beginning of the cool season; their marches should be easy, and encamping grounds should be carefully selected; supplies, especially water, should be good and plentiful; they should not, except it be altogether unavoidable, be brought to the plains at an unhealthy season, and above al when an epidemic prevails.
	14. Long residence on the hills and short residence on the plains is likely to be most conducive to the health of the troops. Long residence in the plains is injurious; long residence at hill stations does not benefit much. Frequent change of station plains is beneficial.
	15, 16. No experience.
	17. Not aware of any higher ground near the statien which could be advantageously occupied as a hill station.
	18. We think the laterite detritus, with rock, is as healthy for stations as any we have experience of; light sandy soil is also good; black and clayey soil is objectionable.
	19. Soldiers proceeding to India should not be under 20 years of age. They should land there in the months of November, December, or January. Troops landing in Bombay are generally quartered in the town barracks, and the men are provided with suitable bedding, &c., but as soon as arrangements can be made, if a regiment, it is sent to one

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	of the healthier stations ; if recruits, they join their regiments, in either case proceeding by ordinary marches. Since the late alterations the clothing is unobjectionable. The drills are light and the duties seldom very heavy. Recruits should never be quartered, or even landed in Bombay, but be sent to Kurrachee, Poona, or some other healthy station at once. Their drills should be light, and also their clothing, exposure to the sun avoided, personal cleanliness observed, and abstinence from spirituous liquors enforced; intemperance and debauchery of every kind should be provided against as much as possible. 20. We see no objection to troops being sent direct to India, provided they arrive in the early part of the cold weather, are well looked after during the earlier periods of their residence, and are sent to a healthy station. We do not think any material benefit would be derived from a residence at an intermediate station. If possible it would be advisable to send them to a hill station, and where it cannot be done they should be sent to the coolest and most healthy station on the plains. 21. The mode of transport of troops from the port to the interior is by marching, rail, bullock-train, steamers, and country boats. As a general rule, troops should be exposed to the sun and rain as little as possible, and they should never be moved from one station to another while any epidemic prevails along the line of march, when it can be avoided. The cool season should, if possible, be always selected for moving troops. 22. Ten years is the period a British soldier should serve in India; but many think this too long, while others would extend the period to 14 years, or even more. 23. The manner of conducting the business of medical boards is generally such as to avoid conflict of opinion as regards invaliding. The present system works well, and we have no improvements to suggest. 24. Invalids should leave India for home in the months of December, January, or February, when going round the Cape. But there should be invaliding committees, and invalids should be sent home oftener than once a year.
Diseases.	1. In some regiments there are weekly inspection parades, and in others quarterly inspections, for the discovery of incipient diseases. 2. Scurvy is of rare occurrence at this station; from 1850 to 1858 inclusive, 224 were admitted with this disease, and 8 died. Of these, 25 admissions and 1 death were among the European, and the remainder among the native soldiers. They were nearly all from other stations, principally from Aden. The proportion which this disease bore to other diseases was 223 to 26,452, or 0·84 per cent. In the few instances in which it does occur at the station, it is mainly attributable to inferior or insufficient diet, owing to the restrictions natives sometimes impose upon themselves. The remedies are sufficient and nourishing food, vegetables, fruits, and other anti-scorbutics. 3. During the 9 years from 1850 to 1858, the proportion of admissions for hepatic disease, including jaundice, was 744 to 26,452, or 2·81 per cent., and of deaths 33 to 287, or 11·5 per cent. Of the admissions, 693 were Europeans, and 51 were natives; and of the deaths, 24 and 9 respectively. The principal causes of the disease are the variable nature of the climate, exposure to the sun, and intemperance, when the disease occurs by itself; but it is a very frequent concomitant of fever and dysentery, and attributable to them. The prophylactics we would recommend are regular and temperate living, suitable clothing, and careful avoidance of exposure; but the climate of the station is very unsuitable for hepatic affections, and no regiment which has suffered much from fever or bowel complaints should be sent to it, if it can be avoided. 4. Dracunculus is a very rare occurrence at this station. The total admissions during 9 years were 331, but they were nearly all from other places, such as Dharwar, Kulladhee, and Kolapore. The fact of the disease ever having been contracted at Belgaum is doubted. 5. The proportion of the constantly sick from venereal diseases to the total sick, from 1850 to 1858, was 2,943 to 26,452, or nearly 11·13 per cent. Of these, 2,542 were European, and 401 native soldiers. To the above might, there is very little doubt, be added half of 447 cases of orchitis and stricture, and at least a third of the most severe of 2,341 cases of rheumatism has been of venereal origin, as well as some cases of ophthalmia. Venereal, especially syphilitic, diseases are frequent and formidable at this station, and often seriously impair the efficiency of a regiment. The most effectual means of diminishing the liability of the soldiers to this disease, would be to allow them to marry in larger proportions than at present. Were all the loose women in or near the bazaar, whether within the military or civil limits, registered and subjected to periodical medical inspections, a lock hospital might be of use, but not otherwise. The restrictions necessary to render a lock hospital useful, hardly accord with British ideas of the liberty of the subject, and hence in a great measure their inutility hitherto, and their having been generally abolished. 6. The troops at the station suffer from the following diseases:— *Fevers.*—Intermittent, remittent, continued, and ephemeral; also eruptive fevers. *Dysentery.*—Acute and chronic. *Cholera.*—Sometimes mild, but often of a most severe type. *Small-pox.*—Mild and virulent. *Rheumatism.*—Acute and chronic, idiopathic and of syphilitic origin. The proportions of admissions and deaths from the above diseases to the total admissions and deaths were 10,359 and 102 to 26,452 and 287 respectively, or 39· per cent. of the total admissions; and 35·54 of the total deaths, during a period of 9 years. Of those admitted, 7,358 were Europeans and 3,001 natives; and of the deaths 80 and 22 respectively. To show the proportion of admissions and deaths among the Europeans compared with the native troops, it may be stated that the total strength of the former during 9 years was 9,519, and of the latter 13,437, or an average of 1057·66 of Europeans and 1493·0 Natives for each year. 7. Intermittent fevers are very tractable, and remittent and continued generally so when not complicated with hepatic, pneumonic, or cerebral affections. Measles are generally mild and seldom fatal. Small-pox is very often fatal, especially among infants.

References to Subjects and Queries.	Replies.
IV. Health of the Troops: *Diseases—cont.*	Chicken-pox is generally a trifling complaint. Cholera, when prevailing epidemically, is rapid in its progress, and extremely fatal. Dysentery and diarrhœa are often severe, but generally manageable if uncomplicated; but at this station hepatic affections are common concomitants. Hooping cough is generally mild, but of long duration. Erysipelas generally requires stimulant treatment. Catarrhal affections are frequently severe but seldom fatal. The hot season and the first part of the monsoon, that is, from the beginning of March to the end of July, are the seasons when such diseases are most prevalent. The climatic and atmospheric conditions which precede or accompany their appearance, are hot, close, and oppressive weather, with variable and irregular winds, and frequent calms. The sky is generally clear till about the end of March, and there are few electric disturbances, but afterwards it is more or less cloudy, and sometimes overcast, and storms, with rain, thunder, and lightning, are not infrequent, till about the middle of June, when it becomes settled monsoon weather. The sanitary condition of the station is upon the whole good. But the bazaar and native dwellings are greatly wanting in cleanliness and ventilation, as the houses are close, crowded, and confined. The water supply is very fair, both as regards quantity and quality; but the drainage is bad or very indifferent. The European troops are at present too crowded, and the natives always so. The crowded state of the native population, their want of cleanliness, both personally and in and about their dwellings, and their apathy and disregard of all sanitary measures, no doubt predispose them to disease. 8. The nature of the soldiers' duties, and occupations in barracks have very little influence on epidemic diseases, but their habits of exposing themselves to the sun, frequenting the bazaar, and their irregularities and intemperance, tend to excite disease, and to render it more severe when they are attacked by it. 9. Small doses of quinine have not been tried at this station that we are aware of, as a prophylactic against malarial diseases. 10. To prevent or mitigate epidemic disease, the troops should have more space, the Europeans in their barracks and the natives in their huts; both should be loftier and better ventilated dwellings. Every inducement should be held out to the European soldier to eschew the bazaar, and the irregularities there committed, by providing him with reading rooms, and all rational means of occupation or amusement. The conservancy of the cantonment might be improved, and in the bazaars and native population it should be far more insisted upon. If it could be done the streets should be widened, and proper ventilation in the dwellings enjoined, as well as the removal of all impurities. Vaccination should also be more generally practised.
V. INTEMPERANCE.	1. The soldiers at the station are generally temperate. The confirmed drunkards are about 1 per cent. 2. The proportion of admissions into hospital from diseases directly caused by intemperance were, last year, in one regiment, 10; in another only 4. This refers to Europeans; among the natives there was none. The admissions caused indirectly were in the case of one regiment 15; in the other regiment not known. No natives were admitted on account of intemperance. There are no available materials for the preparation of a statistical table showing the effect of abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station. Drunkenness is always punished as an offence. 3. Arrack, supplied by the commissariat, is sold in the canteens, and the quantity generally consumed is 1 dram per man a day; more than 2 drams is not allowed. It is of good quality. Distilled spirits of the worst description are sold in the bazaar, and may be had in almost any village. In the bazaar the sale should be repressed more stringently than it is. Spirit is not part of the soldiers' ration at the station, on the march, or in the field. None is issued from the canteen but what is paid for by the men. The quality of the spirit is good. No spirits are allowed before dinner, and no morning drams. Spirit is never given as a ration to convalescents. A convalescent is not allowed to enter the canteen. Drinks injurious to health, other than intoxicating drinks, are sold in the bazaar, but not in the canteen. 4. Opinions differ as to whether the consumption of spirits is conducive or injurious to health. Some would allow no spirits except under special circumstances, such as great fatigue: while others think them beneficial, or, at all events, not injurious, when used in moderation. If used in moderation it does not affect the discipline or efficiency of the corps. 5. It would be beneficial to restrict or abolish the use of spirits if it could be effectually done; but if there was no canteen the men would resort to the bazaar, and drink the bad liquor vended there. As matters stand, to abolish the use of spirituous liquors would be injurious. 6. Good malt liquors are preferable to spirits in this climate. Wine is better than spirits, but not so good as malt liquor, and its expense is too great to admit of its being used by the men. 7. Coffee, tea, lemonade, &c., are in use to a very considerable extent. Their influence is good in every respect; they tend to keep the soldier from drinking other liquors, and whatever diminishes drunkenness is beneficial to health and discipline. 8. We are not prepared to say that it would be beneficial to suppress the issue of spirits from the canteen, as the men would get liquor and of a bad quality elsewhere. 9. It would be beneficial to prohibit the sale of spirituous liquors in the canteen, and to substitute beer, coffee, &c., but to prohibit the sale of spirituous liquors there would not be advisable. 10. The present canteen regulations work well. There should be a good large canteen where the men could sit down and drink their liquor comfortably. A good coffee shop should be attached to all barracks; and the sale of liquors in the bazaar to soldiers should, if possible, be wholly prevented. 11. The canteen regulations are according to section x. 3rd Appendix, Jameson's Code. There are no regimental bazaars.

VI. Diet.

1. The diet for Queen's British troops and European troops of the Indian army is the same at this station, and consists of—

Bread	1 lb.	Tea	$\frac{5}{7}$ oz.
Meat	1 lb.	Sugar	$2\frac{1}{2}$ oz.
Rice	4 oz.	Salt	1 oz.
Vegetables (8 oz. of these usually potatoes)	1 lb.	Firewood	3 lb.

When tea is not supplied $1\frac{3}{4}$ oz. of coffee is issued. The vegetables are the produce of the country, and vary according to the season of the year. A responsible inspection of the ration is made by corporals of companies, and by the orderly officer daily; and an inspection of them is frequently made by the commanding officers.

2. Complete rations are supplied, including vegetables, but no fruit. The stoppage is 3 annas 4 pice per day per man. There are three meals; in one regiment breakfast at 7 o'clock, dinner at noon, and tea at 4. In the other, the hours are 8 a.m., 1 p.m., and in the evening respectively. There is one pound of vegetables in each ration.

3. An improvement in the ration would be made if the quantity of rice were reduced, and the supply of vegetables or bread increased. Spices and cocoa-nuts should be added to the ration to enable the men to have currie occasionally. Mutton should be sometimes substituted for beef, which is the meat always supplied at this station. Such a thing as a soldier selling or exchanging his ration is of very rare occurrence; but part of the rice is often given to native cooks and others. Soldiers often purchase extras at their own expense.

4. The means and apparatus for cooking are the ordinary kitchen, with camp kettles, frying and stew pans, flesh forks, meat dishes, and tins. There is no cause of complaint with reference to the cleanliness, lighting, or ventilation of the kitchen, but the water supply is not so copious as might be wished. The food is cooked as the soldier wishes; besides having it boiled or roasted he may have it stewed or made into pies. There are few complaints about the cooks; considerable variety in cooking is attainable in this country; tea is properly prepared. A soldier pays one rupee per month for cooking. The men have tea, coffee, or other refreshment generally in the middle of the morning's march.

5. Gardens for the cultivation of vegetables could not be advantageously established for soldiers, as without the assistance of a native they would be too much exposed to the sun; and much of their time in the morning and the evening is occupied by drill, rifle practice, &c. Small plots of ground near the barracks would be useful as a recreation, but the number of men that have a taste that way is small. If they were established it should be under such regulations as the commanding officer might think necessary from time to time.

VII. Dress, Accoutrements, and Duties.

1. The component parts of a soldier's dress are:—A tunic of red cloth, a red serge frock, one pair of Oxford mixture trousers, one pair light blue cloth trousers, two suits of cotton dyed cloth called khakee, a wicker helmet with khakee cover, and a blue felt forage cap with the same kind of cover. The accoutrements are a shoulder and waist belt for carrying the ammunition and bayonet.

List of necessaries for Europeans and natives, extracted from Jameson's Code, pages 32-33, section 13, Appendix.

Infantry of the Line.

Europeans.

1 forage cap with chin strap.
2 white cotton covers for ditto.
2 white cotton covers for dress cap.
4 white cotton jackets.
5 pairs white cotton trousers.
2 pairs dark blue ditto (barrack change).
4 white cotton shirts.
2 check ditto (barrack change).
3 flannel waistcoats or belts.
4 pairs cotton socks.
2 pairs worsted ditto.
4 towels.
2 pairs braces.
3 pairs shoes.
1 sleeping carpet (6 ft. by $2\frac{1}{2}$).
1 numda mattress.
2 cotton covers for mattress.
2 sheets.
1 Europe blanket or 2 kumblee blankets.
1 coir pillow.
2 cotton cases for ditto.
1 haversack.
1 jamboo, with plate and cover.
1 comb.
1 hair brush.
1 clothes brush.
2 shoe brushes.
1 razor, brush, and soap.
1 sponge.
1 button stick and brush.
1 marking stick.
1 knife, fork, and spoon.
1 holdall.
1 account book.
1 gun stopper.
1 oil rag.
Blacking and pipe clay.

Additional, when on field service, 1 water canteen.

Natives.

1 Kilmarnock forage cap with chin strap.
2 white cotton covers for ditto.
1 chin chain for ditto.
2 white linen or cotton jackets.
3 pairs white linen or cotton trousers.
2 pairs black cotton ditto.
1 great coat.
2 pairs braces.
1 canvass bag.
1 clothes brush.
1 shoe brush.
1 button stick and brush.
1 marking stick.
1 gun stopper.
1 oil rag.
Blacking and pipe clay.
2 pairs shoes.
2 meerzaies.
1 dhoputta ($2\frac{1}{2}$ yds. long by $2\frac{1}{2}$ ft. wide).
2 dhoties or paijamas.
2 chudders.
1 ruzzai.
1 sleeping carpet (6 ft. by $2\frac{1}{2}$).
1 haversack.

*Cooking utensils.**

1 brass lota (small, $5\frac{1}{2}$ inches wide, $3\frac{1}{2}$ inches deep), and cord.
1 brass lota (large size).
1 tuvwa (iron), 9 inches wide.
1 thalee (brass), 9 inches wide and 2 inches deep.
1 kuttora (brass).
1 chimcha (brass).
1 chimta (iron).

Additional, when on field service, 1 water canteen.

* Total weight not to exceed $6\frac{1}{4}$ pounds.

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*cont.*	The above equipment is sufficient and suitable. We have no improvements to suggest beyond the addition of a puggree to the Kilmarnock cap of the natives. The guard dress from sunset to 8 a.m. is a tunic and cloth trousers. By day a serge frock or khakee clothing. Guards have shelter in guard-houses, and the sentries in verandahs or sentry boxes.
Duties.	1. Recruits should be thoroughly drilled at home, and sent out direct to India without residence at an intermediate station. Some think that a recruit learns his duty best with his regiment, and that he should join it at once. 2. The usual routine of a soldier's duties are guards, roll calls, parades, and drills. Morning parades and evening drills are one hour in duration. Morning roll call at ½ past 5 a.m.; noon roll call at noon; afternoon roll call at 5 o'clock; tattoo roll call at 9 p.m. The number and duration of drills is much left to the commanding officers, who take care that they are not carried to an extent to prove injurious. Early morning is the best time for drill or march when the weather is fine. The men should be in barracks or on their encamping ground not later than an hour after sunrise. The orders are that on all ordinary occasions the marches should be "so timed as to bring them to "their ground by or soon after sunrise." The average number of nights the men have in bed during the week varies from 3 to 5 or 6, according to the strength of regiments and the amount of duty. 3. The most distant guard from the barracks is about 2 miles. All guards are for 24 hours, of which the soldier stands 8 hours on sentry, viz. 2 hours out of every 6 hours. There are day and night roll calls, but they vary very much at the discretion of the commanding officers, who avoid disturbing the men at night as much as possible. Night guards are injurious to health, and there should be as few of them as possible, and those in the most healthy position admissible. The great coat should be worn close to the body and the accoutrements outside.
VIII. Instruction and Recreation.	1. The means of instruction and recreation are as follows:—There is one ball court between the greater part of two European regiments and about two skittle grounds per company; there are also cricket bats and balls and quoits. There are schools with good schoolmasters, also a library, which is sufficiently lighted till tattoo. There is no day room or soldiers' clubs. There are some small gardens near the barracks cultivated by the soldiers, but from the want of water very little can be done in them except during the monsoon. One regiment has a tailors' and carpenters' shop, but there are no workshops properly so called; they are much wanted. There is no theatre or gymnasia. The means are not sufficient even for one regiment to keep the men occupied during the wet season and the heat of the day, and the greater part of two regiments are occupying the several buildings intended for one regiment only. One regiment is restricted from exposure when off duty during the hot weather from 8 a.m. to 4 p.m.; in the other there is no restriction but that the head be properly covered; the men are, however, discouraged from exposing themselves during the heat of the day. The rule observed by the latter regiment we think preferable. Too much confinement is bad. 2. Workshops should be built to encourage soldiers to practise their various trades; gymnasia should be attached to every range of barrack; each barrack should have a reading-room; also sheds for games in the hot and wet weather. To the above many would add theatres, but we think they lead to too much excitement, to be conducive either to health or discipline. The well behaved should be allowed to go out shooting and coursing. 3. Savings' banks have long been instituted. In one regiment (the 83rd), the deposits amount to 53,000 rs. 4. The only shade is from the barrack verandahs, which are not sufficient to enable the men to take exercise. Additional sheds, and the planting of small clumps of trees near the barracks, which could easily be done at this station, would conduce to the health of the men.
IX. Military Prison.	1. The cells are solitary, 10 feet square, well ventilated, and not prejudicial to health.
X. Field Service.	1. There are no local regulations for field medical service not included in the general presidency regulations. 2. The practical working of the powers of the medical officer, as regards the conduct of the line of march of troops, bivouacking, &c., is generally good, as his recommendations are usually attended to; but often bad, as a medical officer has no power to interfere further than the commanding officer may think proper to permit. Should the worst encamping ground be chosen, and the most injurious marches made, it may not be safe for a medical officer even to make any representation on the matter, as it subjects him to censure. 3. The practical operation of camp regulations for the preservation of the health of the troops, &c., is generally satisfactory. The medical officer has no independent power; his recommendations are usually attended to from courtesy, and a desire for the welfare of the men on the part of the commanding officers; but we think on these matters, he should always be consulted, and when his advice is disregarded, commanding officers should be bound to submit their reasons to higher authority. 4. A force on taking the field is provided with tents for field hospitals, and they are so used, when houses or other better accommodation is not available. A field surgeon is appointed to take charge, with assistants and hospital establishments on the same plan as regimental hospitals; and according to the number of the sick, field hospitals are established at the most convenient stations, when from the large number of sick it may be desirable to disencumber the force of them. In the field, according to present regulations, 5 per cent. of doolies, with 6 bearers each, and 1 per cent. of spring carts, are allowed to Europeans, and 1 per cent. of doolies, and 1 spring cart to 500 natives. The doolies and carts are procured by indent on the ordnance department, and the bearers and cattle from the commissariat. Hospital supplies are carried and provided by the commissariat department. The regulations bearing on these matters are to be found in the medical codes and general orders, separate, of which the committee have not copies to spare. (See Medical Code, sec. xi., p. 123 to 129; also General Orders, separate, section Carriage.)

By order of the Acting Principal Inspector-General, Medical Department,
W. J. Coles, Assistant Surgeon,
Secretary.

Office of the Principal Inspector-General, Medical Department,
Bombay, 10 October 1860.

BELGAUM. BOMBAY.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1. Ground plan and elevations of hospitals transmitted. 2. The distances of the hospitals from the barracks vary from about 200 yards in the fort to about 600 in the camp. The artillery stables are outside the fort, and about one third of a mile from the hospital. In camp there are no stables. The distance of the European hospital from the bazaar is about half a mile to the north-west, of the native hospitals about a quarter of a mile to the westward, and of the artillery hospital in the fort about a quarter of a mile to the eastward. The hospital in the fort is rather confined, from the walls of the fort, trees, and buildings; but in camp the hospitals have open sites and free ventilation. The sites of all the hospitals are, upon the whole, good, not being near any rivers, marshes, nullahs, &c., and should the ground be foul and there be nuisances, it will be from want of cleanliness. 3. The water supply is wholesome, but limited, it being all brought by water carriers. There are no means of increasing the supply, except by increasing the number of water carriers. 4. There are no sewers for removing refuse water. The rain water everywhere flows naturally away over the surface. The artillery hospital in the fort has a small cesspool attached to the cook room and close to it. The native hospitals have no artificial sewerage. The European infantry hospital in camp has cesspools attached to the privies and cook rooms, with which they communicate by small masonry slab drains. Sweepers are attached to each, who remove all solid matter daily, and the cesspools are emptied whenever necessary. 5. The height of the lowest wards above the ground varies from 2 to 6 or 7 feet. The floors are solid, and only in one ward, which is upper-storied, is there perflation of air underneath. The soil is generally porous, and part of the roof water is absorbed into it, but the greater portion is carried off by the natural drainage. There are open gutters round the hospital, which are sufficient for carrying off the water rapidly. The material of which the hospital is built is generally laterite and lime. The walls and roofs are high, but not double, and are sufficiently thick to keep the building cool. The hospitals are supplied with verandahs on both sides, of different breadths, varying from $8\frac{1}{4}$ to 9 feet. They are sufficient to afford shelter from the sun's rays. The verandahs are only used for the accommodation of the sick, convalescents and others in extreme cases, under great pressure for want of hospital accommodation. Of the hospitals at this station there is only one ward which is upper-storied. Table of Hospital Accommodation. Date of construction.—Hospitals of native regiments in camp, 1834. Artillery hospital in fort, 1837. Part of the European hospital in camp, wards numbered 1, 2, 3, and separate ward with the subsidiary buildings to the right of the centre dividing wall, in 1841–42. The remainder finished in 1860. Total number of wards, 12. Total regulation number of beds, 283.*a*.

a The number of beds in each ward is calculated by first excluding the doors, and then giving 6 feet from centre to centre of each bed.
b Height under the beam.
c Ventilating windows high up in the walls, half filled with wooden bars.

* N.B. Most of these calculations are according to an old scale; the rule is now to allow 1,800 cubic feet for each European and 1,100 or 1,200 for each native patient in hospital.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	The artillery hospital in the fort is too much surrounded by buildings and arboreous vegetation, and the wards of the European hospital in camp are so placed relatively to each other that the full benefit of the prevailing winds is greatly interfered with as regards one of them. The windows open to the inside by halves, and are sufficient for ventilation and coolness. It might be an improvement if the portions between them and the relieving arch above were filled with Venetians, instead of being built in. 6. Beyond the ventilation in the roof and the doors and windows there is no artificial ventilation; but the above is found sufficient to keep the hospital free from odour or closeness when not overcrowded. There are no jalousies or jhilmils. 7, 8, 9. There are no means of cooling the air in the wards or of warming them. The walls are as a rule whitewashed once a quarter, but oftener if necessary. The several privies are provided with iron pans which are removed and cleaned out at least once a day. The supply of water is very limited. The cesspools are always more or less offensive, and it is exceedingly difficult to prevent them being otherwise. 10. There are no lavatory arrangements. This is a great want. 11. There are no means of bathing the sick beyond large tubs and slipper baths, except at the European hospital in camp, to which a shower bath is attached. 12. The hospital linen is washed by washermen away from the hospital, and the work is generally done satisfactorily. 13. The storage generally is sufficient and dry. 14. The bedsteads used in hospital are iron cots with cross bars; the bedding consists of mattresses stuffed with straw, and pillows stuffed with straw or hemp. Cotton sheets and woollen country blankets. There is great room for improvement in the quality and manufacture of these articles. They are supplied by contract, and are of very inferior description. 15. The several kitchens are all conveniently situated; they are ventilated by the doors and windows as well as by the roof, and they contain the means of cooking the diets in such variety as the sick require. 16. Diet tables, &c., according to regulation. 17. The following attendance is provided for the sick. There is a hospital serjeant whose duty is merely to see to the cleanliness of the hospital and its discipline. There are ward boys for attending on the sick, and also dooly bearers, sweepers to keep it clean, a matron and assistant for the female hospital, an apothecary and assistant apothecary, a compounder of medicines and dressers, and a steward for the provision and clothing department. The attendance is sufficient. The establishment of native hospitals is the same, only that they are much smaller. All the servants are native, and there is no matron. 18. As already stated, one ward is greatly shut out from the breeze. To another the privy is somewhat a nuisance. Cases of epidemic disease have appeared in the wards, but only when prevailing at the station. Sores, especially venereal, sometimes take on an erysipelatous or sloughing action, but this is believed to be attributable to the climate rather than to anything about the hospitals. 19. Some of the wards are badly placed relatively to each other; the privies and most of the outhouses are too close to the wards, and the whole are too much crowded together. One essential improvement required is, that the ward so much closed in should be made an upper-storied one, and proper lavatories should be attached to all the wards. These remarks apply to the European hospital in camp. The artillery hospital in the fort is too low and narrow. The two hospitals for natives which are in camp are too small and have no wards for infectious diseases. 20. Convalescents can walk about the compound or hospital enclosure, and go beyond it, accompanied by an orderly, morning and evening. There is not sufficient ground suitably fenced, and there are no shaded walks or seats except in the verandahs of the hospital. 21. There is a female hospital, with a suitable establishment, in which sick women and children are treated. The arrangements are satisfactory and sufficient to meet every useful purpose. 22. There are no special local hospital regulations. Everything is done according to the rules laid down in the medical code. 23. The medical officer has an establishment, and he has the power, and it is his duty to enforce cleanliness. In repairs to buildings he has no power, but through his commanding officer or superintending surgeon, or both. Any defects it is his duty to report to them. As to changes of diet, &c., his power may be said to be unlimited, but under the control of the superintending surgeon and director-general of the medical department, to whom he must always be prepared to give an account; but they seldom if ever object if the explanation of its having been required for the benefit of the sick is satisfactory. 24. There are no convalescent wards or hospital, nor would they be of any advantage.
XIII. Burial of the Dead.	1, 2. The burial ground used for British troops is within the camp limits. The land winds pass over it to the European cantonment, but at a considerable distance, and the sea breezes pass over it to the native town and fort, the latter being a long way off. Acres. Protestant burial grounds - - 1·8 Roman Catholic - - - 1·2 3· } They are adjoining, with a wall between and a wall all round. The subsoil is principally decomposed laterite. It is carefully kept, and decomposition ought to be rather rapid as the ground is low and damp.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead—*cont.*	3. The usual dimension of a grave for an adult is 7 feet by 2½ feet. The space between graves is 2 feet. The depth depends somewhat on the soil; when it is hard or rocky, it is 6 feet; when soft, 7 or 7½ feet. Instances of re-opening graves have been very rare, and only at the special request of a near relative of the deceased. The orders of Government now forbid the same ground being used a second time. There is no specified time for interment; but it takes place within 24 hours after decease. During epidemics, if death occurs in the forenoon, interment takes place in the evening; if in the afternoon, early the following morning. As regards natives, the grave space is less, as they do not use coffins. The intervals between them are greater, as they usually bury in an open plot of ground; their depth is also less. They are not reopened, nor, as a rule, is more than one interred in the same grave. The time of interment is not compulsory, but it takes place in much the same time after death as with Europeans. 4. The grave-yard is never offensive. In cases of severe epidemics, when many bodies are interred in the same pit, it is made deeper than usual, or more earth is heaped upon it. There are no regulations with regard to the burial of British troops, but interment takes place within 24 hours after death. And under all ordinary circumstances, in the evening before sunset, or in the morning very shortly after sunrise. 5. The dead of camp followers or bazaar people are carried beyond the camp limits, and buried or burnt. 6. No injury accrues to the public from the present practice that we are aware of; but in cases of burning, the smell is sometimes unpleasant. 7. There are no objections to the present arrangements, and no improvements are suggested.

(Signed) F. T. FARRELL, Major General, Commanding Southern Division of the Army.
T. MACKENZIE, Superintending Surgeon, Southern Division of the Army.
T. WALLER, Staff and Civil Surgeon.
W. R. DICKINSON, Captain Engineers, Executive Engineer, Belgaum and Kolapore Districts.

31st July 1860.

AHMEDABAD.

Accommodation:
- British Troops: Artillery - 1st Company, 1st Battalion.
- British Troops: Infantry - Wing 4th King's Own Regiment.
- Native Troops: Artillery - 3rd Battalion.
- Native Troops: Cavalry - Part of Guzerat Irregular Horse.
- Native Troops: Infantry - 11th and 14th Regiment N. I.

References to Subjects and Queries.	Replies.
I. TOPOGRAPHY.	1. The country surrounding the station is flat and cultivated with grain and pulses, and large forest trees, but not densely planted or obstructing the wind. It is sandy and dry, when the monsoon water is drained off. There is a little wood, and a river running at the back of the camp; no jungle. 2. The elevation of the station above the sea is about 320 feet, and the adjacent country is on the same level as the camp. The nearest water is the river Saburmuttee, flowing a quarter of a mile from the camp, which is built along its left bank. There is no higher or healthier ground adjoining the station. 3. The nearest mountain is Mount Aboo, situated about 150 miles from camp, with an elevation of about 4,500 feet above the level of the sea. Powa Ghur is nearer, but is not adapted for a sanitarium. 4. The sea is about 65 miles from camp, and the river about a quarter of a mile as above stated. The district is not liable to an overflow of water, and there are no ravines or broken ground. 5. The station is open, and well exposed; there is nothing to interfere with free ventilation; and in our opinion the temperature is not raised by reflected sun heat. It is exposed to the hot and cold winds which blow from the S.W. and N.E., but they have no effect on health. 6. The surrounding country is cultivated. There are no works of irrigation that we are aware of. The cultivated grounds are irrigated, but I have not observed that health is in any way affected by it. The cultivation of rice is prohibited within two miles of camp; neither is there any cultivation of hemp, indigo, or flax. 7. The city of Ahmedabad is about 3½ miles from the station. 8. The geological structure is sandy, and the ground new. 9. Water is usually found during the dry season at a depth of about 35 feet, and in the rainy season at about 25 feet. 10. The rain-fall runs off and becomes speedily absorbed. The country being level, there is no adjacent ground, the drainage from which passes into the subsoil of the station. 11. The water supply is derived from deep wells, from which it is drawn by bullocks. There are no tanks in the immediate vicinity. The wells are kept cleared, and there is no malaria. 12. There is a sufficient supply of water, and it is wholesome, colourless, and free from smell. The river water is of sp. gr. 1·001 in the dry season, somewhat greater in the rains. The water from wells is of greater specific gravity. The water from the river is more wholesome than that from wells, which after long use is apt to induce disease of the spleen, a result unknown from the use of river water. The microscopic appearance cannot be determined as there is no instrument allowed. The water is drawn up from wells, and is then distributed

I. Topography—*cont.*	about the station by bheesties. We are not aware that better water could be obtained, nor have we any recommendations to offer. 13. We are not aware of any other topographical points bearing on the health of the station. 14. No new stations have been selected in the Bombay Presidency within the last 20 years.
II. Climate.	1. The instruments available for meteorological observations are thermometers and pluviometers. 2. The following Table gives two years of observation :—

Years of Observation.

From January 1858 to December 1859.

Months.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Winds. Direction	Winds. Force.	Remarks.
January -	71	13	78	65	N.N.E.	Moderate.	Agreeable ; occasionally cloudy.
February -	80	31	96	65	N.N.E.	Do.	Agreeable.
March - -	83	21	94	73	N.E.	Do.	Sultry.
April - -	93	22	104	82	S.W.	High.	Hot.
May - -	97	22	108	86	W.S.W.	Do.	Sultry.
June - -	89	10	94	84	S.W.	Do.	Do.
July - -	90	27	104	77	S.W.	Monsoon.	Do.
August -	84	15	92	77	S.W.	Do.	Cloudy.
September -	83	13	90	77	S.W.	Do.	Sultry.
October -	83	13	90	77	N.E.	Moderate.	Sultry ; occasionally heavy dews.
November -	78	17	87	70	E.N.E.	Do.	Cool.
December -	69	19	79	60	E.N.E.	Do.	Do.

	3. The climate is dry, except during the monsoon ; sand storms occasionally occur during the hot season, but they do not appear to have any injurious effect. The climate does not appear to affect the health of the troops. They are exposed as little as possible during the heat of the day, the regimental duties being performed morning and evening. The hot season from March to June is the healthiest. October is very unhealthy. During that month and the cold season fevers prevail, chiefly of a quotidian intermittent type. 4. There is no district that we are aware of near the station the climate of which would be more conducive to health. 5. I have served longer at this station and Deesa (both in the same province) than at any other. I have also served at Dharwar in the Deccan about three years, but judging from the hospital records, there appeared to be very little difference in the health of the troops (native). The above is the recorded opinion of the medical member. The president (Col. Lucas) has served upwards of 20 years in Guzerat, 19 of which has been at Ahmedabad. He considers it about the most healthy station in the Bombay Presidency for troops, with common care and prudence.
III. Sanitary Condition of Station.	1, 2, 3. Maps and plans. 4. The following Table shows the barrack accommodation :—

Date of Construction, June 1858.

Total number of rooms or huts, 10 chuppered and 1 tiled.

Total regulation number of non-commissioned officers and men, 50 in each chuppered hut.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms or Huts. Length.	Breadth.	Height.	Cubic Contents in Feet.	Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows. Number.	Height.	Width.
		Ft.	Ft.	Ft.	Ft.		Ft.	Ft. in.		Ft.	Ft.
2 chuppered Barracks for Artillery -	50	250	11	12	37,812	756	55	1 7	—	—	—
1 Staff Serjeant's Quarters (chupper) - -	2	56	15	12	10,080	5,040	420	1 7	—	—	—
1 tiled Barracks, 4th K.O. Regiment -	100	252	22½	14½	99,038	990	56	1 7	56	4	3
10 chuppered Barracks	50	250	11	12	37,812	756	55	1 7	22	3½	3
2 Staff Serjeants' quarters	2	56	15	12	10,080	5,040	420	1 7	8	3½	3
1 tiled Staff Serjeant's quarters - - -	2	56	15	12	10,080	5,040	420	1 7	8	3½	3
1 Guard Room 1/1 Artillery - - -	8	25	15	12	4,500	562	47	1 7	3	3½	3
1 Chupper Guard Room 4th K.O. Regiment -	8	30	15	12	6,525	815	56	1 7	3	2½	3
6 Prison Cells - -	1	10	10	21	2,250	2,250	100	1 7	—	—	—

In the chuppered temporary barracks the windows are all on the same side (the north). They consist of matting nailed over a wooden framework, hung from the lintel, and opening outwards, supported by lifting sticks. In the tiled barrack the windows are glazed, open outwards, and are on opposite sides. A verandah 6½ feet broad extends the entire length in front of the chupper barracks, and one 10½ feet broad extends all round the tiled

References to Subjects and Queries.	REPLIES.
III. Sanitary Condition of Station—*cont.*	barrack. The verandahs are not occupied as sleeping quarters by soldiers or other persons. There are no jalousies or jhilmils. 6. The bedsteads are wooden planks upon iron trestles; 1 foot 9 inches from the ground. I have no improvement to suggest. 7. The following table gives the dimension of tents:—

	Dimensions of Tents.							Men to each Tent.	Square Feet to each Man.
	Length.	Breadth.	Superficies.	Height of Wall.	Cubic Content.	Upper Part.	Whole Cubic Content.		
	Feet.	Feet.				About			
Tent Hospital, European	22	14	308	6′ 6″	2,002	2,000	4,002	12	$25\frac{8}{12}$
Tent Hospital, Native	22	15	330	6 0	1,980	1,320	3,300	15	22
Tent, European Serjeants', Single Pole	14	14	196	6 0	1,176	588	1,764	8	$24\frac{1}{2}$
Tent, Staff Serjeant's	10	10	100	6 0	600	300	900	1	100
Tent, Native Serjeants', Double Pole	22	13	286	2 0	572	1,716	2,288	30	$9\frac{5}{30}$

Ahmedabad Arsenal, June 4, 1860. E. WRAY, Major, C. Ordnance.

8. There is a continuous ventilator in the roof of the tiled barrack. Each chuppered barrack has its chupper opened and raised in four places. Each ventilator is $7\frac{1}{2}$ feet by 2 feet. The same system of ventilation obtains in the guard rooms, huts, &c. The ventilation is quite sufficient to keep the air pure at all times. There are no means used for cooling the air, the barracks being temporary.
9. The temporary chupper barracks are constructed of sun-dried brick and mud, with roofs of round teak wood and chupper. The doors and windows are of matting nailed over jungle wood frames. The walls mud, plastered and whitewashed inside and out. The floor is raised from 1 to $2\frac{1}{2}$ feet. The tiled barrack is of burnt brick and mud, with trussed roof of squared teak wood; the walls are plastered inside and out, and whitewashed. The windows are of glass, and the doors half glazed and half panel.
10. The floors are of earth and broken brick, well rammed and solidified; they are raised from 1 to $2\frac{1}{2}$ feet above the level of the ground. They have no passages for air underneath.
11. The barracks being only temporary structures, hastily erected to afford shelter to Europeans at a time of great emergency, have hitherto answered very well, but if European soldiers are permanently to be located in Ahmedabad, substantial barracks must be provided. Repairs are executed by the Public Works Department, and are performed with all reasonable dispatch. The walls and ceilings of barracks are cleansed and limewashed always once a year, but at any time on a requisition from the commanding officer the walls can be whitewashed.
12. Sketch of washhouse; 50 feet by 7. Refuse water drained into cesspools; cesspools are cleansed daily.
13. Sketch of cookhouse; it is 50 feet by 12, and the refuse water is drained into cesspools, and emptied daily. Bheestees bring the necessary supply from the neighbouring wells. Dirty linen is washed by native dhobies in the river.
14. The contents of the privies and urinals are removed every morning and evening.
15. These buildings are ventilated in the same manner as the barracks. The barracks are lighted at night with oil lamps suspended from the roof with iron rods.
16. The barracks neither have nor require any arrangement for draining or sewering. The surface water during the monsoon either flows off into a natural drain, about 150 yards to the west of the barracks, or is rapidly absorbed. The drainage from lavatories, cookhouses, privies, and urinals, being collected in cesspools, can be removed at pleasure. No part of any building is damp, the nature of the soil prevents it. There are no large cesspits nor foul ditches.
17. The refuse of the station is carried away daily by the Barrack department beyond camp limits and burnt.
18. The surface of the cantonment is kept perfectly free from vegetation. There are no old walls or thick hedges, &c., to interfere with ventilation.
19. The sanitary condition of the bazaar is good as respects ventilation, cleanliness, &c., but is rather crowded in consequence of the increased number of troops during the past year; the water supply has been sufficient in consequence of the vicinity of the river. Sweepers are kept for preserving cleanliness in the bazaar, under the supervision of the bazaar master. The native houses are small, but no dung-heaps or cesspits are allowed. There are no native buildings in the vicinity of the barracks to occasion nuisance by the wind blowing over them.
20. Animals are slaughtered at about three-quarters of a mile distant from the station. No particular regulations are in force as to the disposal of the offal; it is removed by sweepers. Were it not that the station is said to be about to be removed, we would recommend the erection of burning kilns.
21. No horses are allowed to be kept in the bazaar.
22. The are no stables at the station, and the picketing grounds for the horses of the artillery and cavalry are to the rear and to leeward of the men's barracks, at a distance of about 150 yards, and a mile from the hospital.
23. There is ample accommodation for married non-commissioned officers and men.

Officers' Quarters.

1. The temporary huts for officers' quarters are small; they are well ventilated and properly drained. Substantial houses are much required, with well-fitting doors and windows to keep out the hot winds.

IV. HEALTH OF THE TROOPS.

1. We are of opinion that the station, district, and native population are tolerably healthy.
2. The most common diseases are fevers, and occasionally cholera.
3. We attribute the healthiness of the native population to the dry sandy nature of the soil, and the absence of large bodies of stagnant water.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	4. The 4th Regiment King's Own came from the Mauritius, where they were from August 4th, 1857, to November 24th, 1858. They enjoyed good health there. The prevailing diseases were hepatic. They arrived at this station February 16th, 1859, and the diseases from which they have since chiefly suffered have been fevers. The 11th Regiment Native Infantry came from Bombay, where they were stationed two years. The health of the regiment was good. They left Bombay 2nd March 1858, and arrived here March 24th. During their residence here they have enjoyed good health. No part of the barracks is remarkable for its unhealthiness. 5. The troops (European) were under canvass from November to March during the time their huts were being repaired, but it had no perceptible effect on their health. 6. I have never been in charge of troops at hill stations. 7. I have not observed whether troops resident for some time on the hills are more or less liable to attacks of disease on returning to the plains. 8 to 16. We have had no experience in regard to the effect of hill stations on the health of troops. 17. The highest ground with which we are acquainted is Mount Aboo, 150 miles from the station. It is used as a sanitarium, and is 4,500 feet above the level of the sea; but we have no experience in regard to it. 18. We have no experience as to the class of soils most healthy for stations. 19. The best age for soldiers proceeding to India is from 20 to 25, and the cold season is the best for them to land. I cannot speak from experience as to the disposal of troops on landing, my duties having been confined to native troops. The above is the recorded opinion of the medical member. Recruits are attached to the depôts in Bombay on first landing, and sent up to Poona and Ahmednuggur as quickly as possible by rail, where all their wants are attended to. The precautions necessary are, good barrack accommodation, attention to clothing and diet, and avoidance of all unnecessary exposure to the sun. 20. It is better for troops to be sent direct from England to India, and then forwarded to well established healthy stations. 21. The mode of transport from the port to the interior is on land by marches, and on water by country boats and steamers when available. 22. The British soldier should serve in India 15 years. 23. Medical boards are always properly conducted. 24. The time of year desirable for invalids to leave India is in January and the commencement of February, from Western India.
Diseases.	1. There are no inspection parades for the discovery of disease amongst natives. We are informed that European troops are inspected weekly. 2. There has been no scorbutic disease at this station. 3. I am informed that out of 1,070 cases admitted into hospital, 4th King's Own, during the past year, 37 were from hepatic disease, but only two deaths occurred. 4. No cases of dracunculus have presented themselves. 5. Out of a daily average of sick from all causes of 28, the proportion of venereal disease would be 5. The medical officer 4th King's Own, recommends the establishment of lock hospitals, which the committee coincide in on the grounds of health; but as they were done away with some years back, being looked upon as sanctioning immorality, the committee must leave it to superior authority to decide. 6. No epidemic has shown itself during the two past years among the European or native troops. 7. There has been no appearance at this station of zymotic diseases. The hot season is the period when they usually prevail, and a sultry and cloudy condition of the atmosphere precede or accompany them. When they do occur, they are generally confined to the crowded parts of the bazaar. Insufficiency of food among the lower classes of the native population, their personal dirty habits, and the overcrowding of their dwellings, would appear to predispose them to zymotic disease. 8. No epidemic having appeared, it cannot be stated whether the duties of the soldiers would have any influence in this respect. 9. In isolated cases quinine has been used as a prophylactic against malaria, with a satisfactory result. 10. We have no recommendations to offer, with a view to the prevention of disease. The country is very open, and there is a free circulation of air throughout the camp.
V. Intemperance.	1. The soldiers at this station are generally temperate, and there are no confirmed drunkards. 2. The returns of admissions into hospital for intemperance are in the office of the superintending surgeon. The diseases directly caused by intemperance are ·08 per cent., and indirectly 3 per cent. Drunkenness is punished as an offence. 3. Spirits are sold in the regimental canteens, and under restriction in the bazaar. The arrack is 24° below London proof: the quantity allowed is one dram daily. Spirit is not part of the ration, either at the station, on march, or in the field. The canteen is never opened in quarters before noon. On the march or on service the men are sometimes allowed to receive their daily dram immediately after coming off the march. This is not good for the health when allowed. Spirits are given as a ration to convalescents at the discretion of the individual medical officer. No other drinks are sold in the canteen or bazaar which are injurious to health. 4. The consumption of spirits by troops is injurious to health. If given in moderation, it is conducive to discipline and efficiency, as it prevents troops going to the bazaar and getting country liquor, which is poison to them. 5. It would be beneficial to health to abolish the use of spirits, but impossible to be carried out. 6. Malt liquor gives an improved tone to the system, which is not imparted by wine and spirits, and the consumption of it cannot be too much encouraged. 7. We understand that there is a coffee room in the 4th Regiment King's Own and artillery, and that it is generally used. The effect of using tea, coffee, &c., is good. 8. It would be beneficial to substitute coffee for the spirit ration in the early morning, and beer in the evening and at dinner. 9. It would be beneficial to permit only beer, tea, coffee, &c., to be sold in the canteens.

AHMEDABAD. BOMBAY.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	10. I have no other recommendations on these points. 11. Canteen and bazaar regulations annexed. The following are the more important points in the canteen regulations:—Canteen open from 12 to 12¾ o'clock, to issue malt liquor only. Open from 2 to 3 p.m., and from sunset to tattoo, to issue spirits and malt liquor. No man allowed more than one dram of spirits, or one quart of malt liquor at one issue. Allowance of arrack, one dram per diem Arrack to be consumed at the place of issue. All issues to be paid for on the spot. No spirits to be issued before dinner time. Intoxicated persons or men under punishment not to enter the canteen. By the bazaar regulations no liquor can be sold to any European without the written permission of an officer.
VI. DIET.	1. The ration for British troops consists of 1 lb. bread, 1 lb. beef, 5 days, and 1 lb. mutton 2 days a week, 4 oz. rice, 1 oz. salt, 2½ oz. sugar, $\frac{1}{2}\frac{0}{1}$ oz. black tea, $\frac{5}{2}\frac{}{1}$ of green tea, 1 lb. vegetables, comprising ⅓ potatoes, ⅓ onions, ⅓ yams, 3 lb. firewood. No changes are found necessary. The rations are inspected by the orderly officer of the day. 2. A complete ration is issued, including a due proportion of vegetables. The stoppage is 3 annas 4 pice daily. The soldier has three meals a day:—Breakfast at 7 a.m.; dinner at ¼ to 1 p.m., and tea at 4 p.m. 3. We would recommend giving mutton four times a week, and beef three times, instead of as at present. The beef in this country is lean and tough, and more indigestible. The rations cannot be disposed of. 4. The cooking is done in cookhouses by native cooks. The kitchens are clean, light, and well ventilated, and water is supplied by bheesties. The meat is boiled and roasted, and is at all times properly done and cooking sufficiently varied. During a march the men are halted and provided with coffee in the early morning. 5. Gardens might be advantageously cultivated, under such regulations as the commanding officer might see fit to adopt.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldier's dress consists of 1 wicker helmet, 1 forage cup and cover, 1 cloth tunic, 1 serge frock, 2 khakee frocks, 1 pair cloth trousers, 1 pair blue ditto, 2 pairs khakee ditto, 3 pair boots (2 English). The accoutrements are 1 20-round pouch, 1 40-round ditto, 1 pouch belt, 1 waist belt, 1 waist belt plate, 1 firelock sling. The present dress, as lately altered, is suitable to the climate, and under the present system no improvements can be suggested.
Duties.	1. The men may be drilled either at home or in India. 2. Drills are not prejudicial to health as at present arranged, viz., morning and evening, which are the best hours. There are no general orders on the subject. The following are the average number of nights the men have in bed during the week.

	Sergeants.	Buglers.	Corporals.	Privates.
European Artillery, 1st Company, 1st Battalion	5	3	5	5
4th King's Own Regiment	2	2	4	6
	Havildars.	**Buglers.**	**Naigues.**	**Privates.**
Native Artillery, 3rd Battalion	5	2	5	3½
11th Regiment Native Infantry	5	6	3	4
14th Regiment Native Infantry	3	3	3¼	4

	3. Guards are mounted close to the barracks, within 20 yards. They last day and night. Picquets from sundown till gun fire in the morning. There are roll calls morning and evening and at tattoo. We have not discovered that night guards have any injurious effect on the health, and we cannot suggest any additional precautions.
VIII. INSTRUCTION AND RECREATION.	1. There are no ball courts, day-rooms, workshops, theatre, or gymnasia at the station. There is a skittle ground and gardens; the latter at present not worked owing to the hot weather. There is no school room built for the purpose, but the school is held in one end of the harness room, a very hot place, and unsuited to the purpose. There is no trained schoolmaster; one of the soldiers does the duty in the 1/1 artillery, and is not properly qualified. There is no building for the library; one of the non-commissioned officers' quarters is used for it; it has one lamp. There are no proper amusements for the men, and no place for them to go to when wet or in the heat of the day. The barracks are very narrow. There are strict orders prohibiting men from exposing themselves to the sun in the heat of the day. Without such restrictions there would be more instances of apoplexy than there are. 2. For increasing the means of recreation we would recommend a ball alley, a good school room, and a gymnasium. 3. The institution of soldiers' savings' banks would be advantageous. 4. There is sufficient shade to enable the men to take exercise from verandahs, &c.
IX. MILITARY PRISONS.	1. Six cells have just been erected; they are substantially built of burnt brick; each cell is to hold one man. They are badly arranged for ventilation.
X. FIELD SERVICE.	1. We know of no local regulations for field medical service. 2. The medical officer has full powers to recommend anything tending to the health of the troops, as to the time of marching, encamping, &c. 3. He has full power to recommend or to object in all matters of sanitary regulation, and his doing so would lead to the assembling of a committee to consider and carry out any subject he may bring forward. 4. The inquiry respecting the arrangements adopted in the Presidency for field hospitals, supplies, &c. we respectfully refer to the Inspector-General at Bombay for reply. Sick carriage consists of doolies, sick carts to hold four, and kagamas or camels for convalescents.

XII. HOSPITALS.	1. Plan of new hospital. 2. A new hospital is just completed, which is a very good one. The building at present used for a hospital by the 4th Regiment is a large bungalow in the N.I. lines, formerly the residence of a general officer. It contains eight rooms and accommodates 54 patients. The division into so many small compartments prevents that free ventilation so desirable for the sick; and in no way does this building afford the necessary accommodation for a European regiment. There are no quarters for 1st-class servants, and the offices in the rear give but ill shelter for the 2nd class. Compared with the rest of the buildings in camp belonging to regiments it is a superior place, inasmuch as it possesses chunam floors, and walls, and a ceiling. The recent erection of puckerries and officer's quarters, and the increased strength of the corps, renders it neither large enough nor fitted for its purposes, for such an essential condition as free ventilation is destroyed by the accumulation of dwelling houses in its vicinity and to windward thereof. 3. The water for hospital use is supplied from a well in the compound, and is good and abundant. 4. Refuse water and other impurities are removed by means of cesspits. 5. There are no air passages below the wards, which are raised about two feet from the level of the ground. The roof water sinks into the subsoil; there is no surface drainage. Of the permanent hospital the walls are burnt brick and lime, sufficiently thick to keep the hospital cool. The roof is double-tiled, and ventilated by iron cowls. The hospital is surrounded by a good large verandah which is frequently used for the accommodation of sick. The hospital consists of one flat only. The following table shows the accommodation in the temporary hospital. Date of construction, not known. Total number of wards, 8. Total regulation number of beds, 59.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Ft.	Ft.	Ft.			Feet.	Feet.		Feet.	Feet.
1	8	22	20	18	6,920	865	55	2	—	—	—
2	5	18	11	12	2,276	456	39	—	—	—	—
3	12	35	20	18	12,600	1,050	58	—	2	6	4
4	8	20	19	18	6,540	855	47	—	—	—	—
5	8	20	20	18	7,200	900	50	—	2	6	4
6	4	17	10	11	1,870	467	42	—	1	6	4
7	5	21	10	11	2,310	462	42	—	1	6	4
8	4	17	10	11	1,870	467	42	—	—	—	—

N.B.—The wards without windows have each 4 doors.

The permanent hospital is so placed as to receive the full benefit of the prevailing winds, that is, the hospital for the 1st company 1st battalion artillery. The windows open outwards, and their arrangement and construction are conducive to ventilation and coolness.

6. The wards are ventilated by the windows and the iron cowls on the roof. There are no jalousies or jhilmils.
7. Punkahs and tatties are used for cooling the air.
8. There are no means of warming. The walls and ceilings are cleansed and limewashed every three months.
9. A commodious latrine has been lately constructed, but at too great a distance from the main building to admit of a covered way. There are cesspits in connexion with the hospital latrines; they are satisfactorily deodorized by salt, lime, and charcoal, and the refuse is removed morning and evening daily.
10, 11. The lavatory arrangements consist of rows of basins around a small bath room, filled by hand from the well in the compound. There is also a large bathing tub, good.
12. No arrangement is required for washing linen; it is done by dhobies.
13. There are two storage rooms for medicines and clothing.
14. The bedsteads are made of iron, and the bedding is good. The mattresses are stuffed with straw and periodically renewed.
15. The kitchen is one of the outhouses in rear of the hospital, a mere make-shift. The cooking utensils are those in common use in the country, and are sufficient and good.
16. Forms transmitted.
17. The attendance on the sick consists of one hospital serjeant and one orderly, to march the sick to and from hospital. It is sufficient.
18. The sanitary condition of the hospital is good. No epidemic has occurred.
19. I have no improvements to suggest.
20. In the 4th King's Own hospital the convalescents walk in the large compound. There are no seats, but there is shade. There is the same provision for the 1st company 1st battalion artillery, with the exception of shaded walks.
21. There is a row of patcheries, but no proper hospital for the wives and children of the 4th King's Own. The women of the artillery have a commodious hospital, and the arrangements are satisfactory.
22. There are no special local hospital regulations.
23. The medical officer has full powers to suggest or object in all sanitary matters affecting the state of the hospital.
24. There are no convalescent wards; such would be an advantage.

XIII. BURIAL OF THE DEAD.

1. The burial-ground for British troops is about a quarter of a mile from the station. It is properly situated, being to the N.E.
2. It is 160 feet long by 160 broad. The soil is sandy, and the ground is carefully kept.
3. The grave space allowed is six feet by two. The interval between the graves 1½ feet. The depth of graves is from six to seven feet. They are never re-opened unless to inter another

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead—*cont.*	member of the family, or to erect a tomb. Interment takes places within 24 hours after death at ordinary times, and during epidemics as soon as possible. Arrangements for natives are left to the people themselves. Mahometans bury their dead, and Hindoos burn them. 4. The graveyard is never offensive. British troops are buried agreeably to the army regulation, in the morning and evening. 5. The dead of camp followers and bazaar people are disposed of by their own relations according to the rules of their different castes. 6, 7. No injury whatever to health accrues from the present practice, and no improvent can be suggested.

(Signed) Charles Lucas, Colonel Artillery,
Commanding the Station.
M. Thompson, Staff Surgeon, Ahmedabad.
C. T. Boddam, Captain Bombay Engineers,
Executive Engineer, Ahmedabad.

4th May 1860.

I. Topography.	1. The general aspect of the country surrounding the station is flat, sandy, and highly cultivated, and very swampy in the monsoon. There is a great deal of wood, principally trees and hedges, with little jungle, but plenty of water. 2. The elevation of the station above the level of the sea is 90 feet, but on a level with the adjacent country. A small river runs along the eastern boundary of the cantonment almost stagnant for 9 months in the year. There is also a tank 600 yards from the barrack and 300 yards from the nearest bungalow. There is no higher or healthier ground adjoining the station. 3. The hill fort of Powagurh distant 26 miles is the only high ground within sight of the station. 4. The nearest water to the station is the Wishwamuntree river, 100 yards from the hospital. The vicinity is liable to overflow near the banks in the rains, which lasts as long as the rain falls, leaving stagnant pools. There are a few nullahs near the station, and water pits all over the country, which have a very prejudicial effect on health. 5. The station is so encumbered with trees that it is not sufficiently exposed to the breeze. The temperature of the station is raised by the buildings being exposed to reflected sun heat. The breeze blows from the direction of the sea for the greater part of the year, and from November to March the land wind blows from east and north-east. The surrounding country is cultivated. There are no large works of irrigation near the station, and artificial irrigation is not observed to have any effect on the health of the station. The cultivation of rice is prohibited only within camp limits, and plenty of rice is grown close to the cantonment in every direction. The country outside the limits belongs to the Gaicowar. Indigo is not cultivated, nor the preparation of hemp or flax carried on near the station. 7. The city of Baroda to the south of the station is distant a mile and a half. 8. The geological structure of the district is alluvial deposit. The surface is admixture of black soil and sand, and the subsoil contains more clay. The station occupies new ground. 9. Water is usually found at a depth of 50 to 35 feet in different parts of the camp. 10. The rainfall, or water from surface springs, does not flow readily away. It disappears partially by sinking into a pervious subsoil; partly oozes out near the level of the station; but principally lies on the surface till evaporated. There is no higher ground, the drainage from which passes into the subsoil of the station. 11. The water supply of the station is derived from wells, and is stored in a tank of 12,000 square yards of surface; it is principally used for washing. It always has water in it. There are no plants whatever in the tank, but large quantities of fish and frogs. There is no tank used for drinking purposes that is also used for bathing. The water tank is not liable to pollution from leaves or any other matter falling into it. There is no nuisance or malaria experienced from the tank, but there is from the water holes. Draining is the only means that can be adopted for preventing this. 12. The water supply of the station is unlimited. The water is clear, and without taste or smell; it is soft, of good quality, and contains no lime salts. The chemical composition of its solid contents is, for the most part, chloride of sodium; but it also contains carbonate and bicarbonate of soda, and is alkaline; the evaporated water strongly so. It also contains a trace (faint) of lime, but no iron. There are no sulphates, phosphates, or nitrates in it. The water is raised in leather buckets by manual and bullock labour, and distributed by water carriers. 13. The villages in Guzerat, but more particularly in the Gaicowar's territory, are excessively filthy, and no means are taken for cleansing them. Water lodges in every hollow, and as the soil is very tenacious, remains stagnant till evaporated. Every road also is partly under water in the rains, there being no made roads in all Guzerat; roads are generally lower than the adjacent fields, and have very high thick hedges on each side. Filth, excessive vegetation, and stagnant pools in the surrounding country, must have an effect on the health of the station. 14. New stations are selected by order of Government, either after inquiry or trial.

BARODA. BOMBAY.

References to Subjects and Queries.	REPLIES.

II. CLIMATE.

1. There are a thermometer and pluviometer at the station, for conducting meteorological observations.

2. The Table of meteorological observations is made up from 3 years' barometrical and 12 years' thermometrical observation, and from observations for 12 years of the rain-fall, and prevailing winds.

YEARS of OBSERVATION from January 1847 to December 1853.

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Rain.	Winds. Direction.	Winds. Force.
		°		°	°	Inches.		
January - - -	30·220	71	—	84	58	00·2	E. & N.E.	Moderate
February - - -	·215	70	—	90	56	·02	E. & N.E.	Moderate
March - - -	·542	83	—	96	71	·06	N.E.,N.W.	High
April - - -	29·845	81	—	94	69	·00	W.	High
May - - -	·801	94	—	105	83	·57	W. & S.W.	High
June - - -	·755	89	—	98	80	6·26	S.W.	Calm / Variable
July - - -	·650	85	—	91	80	15·85	S.W.	Monsoon
August - - -	·730	84	—	88	76	8·10	S.W.	Monsoon
September - - -	·788	83	—	90	77	4·26	Variable.	Variable
October - - -	·671	80	—	87	73	0·37	W.	Calm
November - - -	30·222	77	—	90	64	·02	NNE., NW	Calm
December - - -	·093	73	—	89	58	·07	E. & N.E.	Moderate

3. The climate is comparatively moist, and very damp in the rains. Fogs prevail to the end of November, and during the hot season hot winds and dust prevail; it is never very cold. There are too many trees about. The influence of the climate on the troops is deleterious. Woollen clothing and good diet should be provided during the rains. Parades should be either early or late, and the men should not be exposed to the sun. The most healthy time of year at the station is from November till June, and the most unhealthy from June till November. The prevailing diseases are fevers of a very malignant type.

4. At about 18 miles from the station there is a place, Dubka, on the bank of the Mhye river, admirably adapted for the formation of a sanitarium. It is situated on the high bank of the river, on one of its bends. The soil is sandy, and cut up by numerous deep ravines, which ensures its being well drained, even during the rains. Removal to Dubka proved of the greatest advantage to a detachment of the 33rd Foot, when attacked by cholera in March of the present year.

5. The following is a list of stations, at which the Assistant Surgeon has served:—
Bombay, Mulligaum, Ahmednuggur, Ouna, Vingorla, Rajkote, Deesa, Nusseerabad, Neemuch; nine healthy stations.
Kurrachee, Dhoolia, Ahmedabad, are not injurious.
Baroda, Hydreabad, Sukkur, positively injurious.
Poona, healthy. Deesa is healthy, except in the very hot weather. Hyderabad and Mooltan, unhealthy; Belgaum, healthy; Peshawur, unhealthy; Dhoolia, average; and Baroda, unhealthy.

III. SANITARY CONDITION OF STATION.

1, 2, 3. Plan and tracings of the station, surrounding country, barracks, &c., are transmitted.

4. TABLE of barrack accommodation:—

Date of construction of barrack, 1859. Total number of rooms, 4.

Barrack Rooms or Huts.	Regulation Number of Men in each Room.	Dimensions of Rooms. Length.	Breadth.	Height.	Cubic Contents.	Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows. Number.	Height.	Width.

Guard Room -	12	66 6	16	Mean 12	12,768	1,064	88	1 8	—	—	—

5. There are windows and doors on both sides of the rooms, and doors at the end; they open inwards. There is a verandah all round each barrack 7 feet wide, and 8 feet to the eaves; used by the soldiers as sleeping quarters on hot nights. There are no jalousies or jhilmils.

6. The bedsteads used in barracks, tents, &c. are boards supported on iron trestles with a straw mattress. Coir mattress is recommended.

7. The following are the dimensions and structure of the tent:—

Description of Tent.	Dimensions.					Number of Men allotted to each Tent.		Cubic Feet to each Man.		Number allotted to each.		Cubic Feet per Man.	
	Length.	Breadth.	Height in Centre.	Height of Walls.	Contents in Feet.	European.	Native.	European.	Native.	Europeans if Sick.	Natives if Sick.	Europeans Sick.	Natives Sick.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	8. The barracks are ventilated by openings in the roof averaging 10 by 2 feet. These afford sufficient ventilation. The air is cooled by means of punkahs and tatties. 9. The barracks are made of burnt brick and mortar pillars supporting the roof and the spaces between, filled up with sun-dried brick and mud, the roof is double tiled. 10. Some of the floors of the barrack rooms are made of brick and some of chunam or lime, raised 4 feet above the ground. There is no passage for air beneath them, being all solid. 11. The materials of which the barracks, tents, &c. are constructed, are good enough and suitable for the climate. The barracks are kept in repair by the Engineer department; repairs are quickly executed. For the general cleanliness of camp the cantonment staff officer is responsible. The walls and ceilings are cleansed and lime-washed whenever they require it. 12. The water for the men's lavatories is suppled by bheesties. The water is drained out into an open ditch 7 or 8 yards from the room. A tub is used for washing. 13. The water for the barrack cook-houses is supplied by bheesties, and the refuse water is drained off into cesspools in the rear. The linen of the station is washed by dhobies, who take the things away and wash them in the river or in the tank. 14. The contents of the privies are taken away by sweepers through a trap-door in the rear. 15. The ventilation of the privies is effected by openings in the side walls under the eaves. 16. The only drainage is that which comes off the roof in the rains, when a shallow ditch is excavated all round, and the water carried off by an open drain 1ft. by 2ft. The country being so flat prevents any good system of drainage being carried out except at great expense. Neither barrack or hospital is damp. The fluid refuse of the barracks is received into cesspits, which are situated in rear of the cook-houses, and are not near the wells; they are distant from the barracks about 40 yards. There are nullahs on all sides of the station; but average 400 or 500 yards from the barracks, stagnant pools remain in them occasionally, 17. With respect to the surface cleansing of the cantonment, the dead leaves are collected and burnt once a year; the refuse, &c. is thrown into the nearest nullah. 18. No grain is allowed to be grown in the cantonment. There are no old walls, thick hedges, &c. interfering with the ventilation of the station or bazaar. 19. The bazaar is well drained, but badly ventilated and much crowded. The streets are very narrow, for want of space, but they are clean. All inhabitants of the bazaar keep their premises clean, and collect the sweepings in front of the house, whence it is removed in rubbish carts. A daily inspection is made. Four peons are allowed, which is sufficient as sanitary police. There are no native houses near the station. No nuisance is experienced in barracks from wind blowing over native dwellings. 20. The animals for the use of the troops are slaughtered within the station. The place is kept scrupulously clean, and inspected daily. The offal is removed daily. No nuisance is experienced in the station. 21. 22. There are no cavalry or artillery stables, but a shed only for sick horses, to the leeward of the barracks. The picketing grounds are arranged in lines, and surrounded by a hedge, they are too near the hospital. 23. There is plenty of accommodation for married non-commissioned officers and men. No married people occupy the barrack rooms.
Officers' Quarters.	1. The sanitary condition of officers' quarters at this station is good. There is no arrangement for drainage; as the country is so flat a very expensive general system of drainage would be required. Thinning the trees is an improvement much required, and one which is now being made.
IV. Health of the Troops.	1. The whole district, both as regards the station and the surrounding country, is decidedly unhealthy. 2. Cholera, intermittent fever, variola, leprosy, and spleen disease are prevalent among the native population. 3. The prevalence of the above diseases may be attributed to a general want of cleanliness among the population, to bad drainage, and a consequent impurity of air, in addition to which the whole country for many miles is thickly covered with trees. 4. The detachment of Her Majesty's 33rd regiment left Deesa, in September, 1859, having been there about 15 months, during which time the health of the men was tolerably good. They suffered from bad rations in the hot weather, and there were some deaths in the regiment from apoplexy. They arrived at Baroda in good health in the early part of March, 1860, and only suffered from fevers until the 28th March, when cholera appeared, and they lost 20 men out of 200. From September 1859 to March, 1860, the detachment was on field service in Okamundel, and was very healthy. There is no portion of the men's accommodation at this station more healthy than the rest. 5. The troops have always lately been marching for a great portion of the year as a detachment on field service. Europeans were camped at Dubka in April and May to avoid cholera.

IV. Health of the Troops —*cont.*	6. None of the Commissioners have been in charge of troops at hill stations. 7. None of the Commissioners have any experience of the effects of hill stations on troops. Major McGrigor has been at the Nielgherry hills for two years, and at Aboo for six months, when suffering from fever, and having got over the attack had no return of it on going back to the plains. 8, 9, 10. No experience in hill stations. 11. The best time for residence in hill stations is from April to June, and three months the shortest period of residence which would enable troops to receive full benefit to their health. 12, 13. The Commissioners have had no experience as to the injury likely to be inflicted on the health of troops on leaving hill stations for the plains, or what precautions are necessary on such occasions. I have never heard of any one finding his health impaired by prolonged residence at a hill station; but the reverse. 14. The Commissioners consider that residence at a hill station, with the shortest possible period of service in the plains, as most conducive to health. The present arrangement of changing stations about every three years on the plains seems as good as could be adopted. 15. I believe there is scarcely any barrack or hospital accommodation for troops at hill stations in this presidency. A few hills are used as sanitaria, but not as stations for troops. 16. The most suitable sites for hill stations are obtained at an elevation of between 4,000 and 8,000 feet above the level of the sea. 17. There is no higher ground near this station which could be advantageously occupied as a hill station. There is a hill fort, Powagurh, about 26 miles off, but is not sufficiently extensive. 18. Black soil, for a station, is generally considered unhealthy. 19. Soldiers should not be sent to India until over 20 years of age, and should be landed not earlier than November nor later than January. I am unable to recommend any precautions beyond the regulations at present in force. 20. Troops should be sent direct from the home depôts to India. They should be sent on arrival to hill stations. 21. The mode of transport of troops from port to the interior is dependent on the station. Sometimes it is by rail, bullock train, or steamer, if available; but generally by marches on foot. Ample regulations exist for preserving the health of the troops, if they are acted up to. 22. The number of years I consider a British soldier should serve in India is seven. 23. No answer to this question. 24. Invalids should leave India for home about the month of February.
Diseases.	1. The Europeans are inspected weekly every Saturday morning, and the native troops at irregular intervals, at the discretion of the medical officer. 2. There has been no case of scorbutus at this station within the experience of the Commissioners, which is, however, limited to three months. 3. There have been three serious cases of hepatitis occurring among the Europeans since the arrival of the troops now in Baroda. Of these one proved fatal, one was invalided, and one recovered, in addition to which some more trifling cases of congested liver have been under treatment. Under these circumstances the Commissioners (whose experience of the station, as above stated, is very limited, and who have no records to guide them) are of opinion that this disease is not prevalent in Baroda. 4. Among the Europeans no cases of dracunculus have occurred, but among the native troops it has been prevalent. 5. Within the experience of the Commissioners venereal diseases have been rare at this station. Among the Europeans there has not occurred a single case of syphilis since the arrival of the detachment at the station, and only a few of gonorrhœa. The native troops have enjoyed an equal immunity. 6. The following are the diseases from which the troops at this station have suffered:— *Fevers.*—Among the Europeans, common continued fevers, with a tendency to head symptoms, and lasting for 3 or 4 days, have been prevalent. Those of the intermittent and remittent types have been comparatively rare. *Dysentery.*—There have been very few cases, and those of a mild form. *Cholera.*—This disease has been prevalent in the station and surrounding country during the past hot season, proving fatal to 20 men of the detachment 33rd regiment (the strength of which was 200), and to many of the native troops, and to large numbers in the city, bazaar, and villages surrounding the camp. *Small-pox.*—No cases have occurred since the arrival of the troops now in Baroda. *Rheumatism.*—There have been no cases of acute rheumatism, and only a few of the chronic form. The following shows the proportion which admissions and deaths from these diseases bear to the total admissions and deaths. Detachment H.M. 33rd Regiment. Return of sickness and mortality in the above detachment from the under-mentioned diseases during the period of its station at Baroda, from 11th March to 31st July 1860.

IV. Health of the Troops —*Diseases—cont.*	7. The more frequent zymotic diseases are febrile diseases and epidemic cholera. Fever appears about October, when vegetation is decaying, and moist muggy heat prevails; cholera about the end of the hot season, when dry hot winds and dust prevail. The eating of large quantities of unripe fruit by the troops and natives seems to be the predisposing cause of these diseases. 8. Every precaution is taken to preserve the soldiers from excessive fatigue or any predisposing influence to disease. 9. Doses of quinine have not been given as a prophylactic against malarial disease at this station. 10. The cause of unhealthiness does not exist within the station, but in the surrounding country, and in its general position and want of drainage.
V. Intemperance.	1. As a rule, the men at this station are temperate, the majority of the detachment, 33rd regiment, being soldiers not brought to notice for drunkenness. There are no confirmed drunkards; and although several are hard drinkers, no court-martial for habitual drunkenness has taken place. 2. There are no admissions into hospital from diseases directly caused by intemperance; but indirectly a large amount of the fever cases are caused by the intemperance of the men. Those who are hard drinkers come into hospital time after time with fevers. Drunkenness is always punished as an offence. 3. Distilled spirits are sold at the canteen to Europeans, and in the bazaar by a contractor to natives only. One dram of arrack and 1 quart of porter can be purchased at the canteen per diem, but form no part of the ration for soldiers, either at the station, on march, or in the field. The men cannot get spirit before morning parade from the canteen, and any liquor they drink then must be obtained from improper sources. Spirit is never given as a ration to convalescents. No injurious drinks other than intoxicating ones are sold either at the canteen or bazaar. 4. Taken in moderation, spirit is not injurious to troops or convalescents. Taken moderately, it does not interfere with the efficiency or discipline of the corps; but, at the same time, most of the crime among the Europeans is attributable to this source. 5. The use of spirituous liquors is restricted, but all the surrounding villages are the Gaicowar's, not subject to our regulations, and the soldiers procure liquor by some secret means. 6. In my opinion, malt liquor is preferable to spirits. 7. Tea, coffee, lemonade, soda water, &c., are not much used at this station. 8. As above stated, there is no spirit ration, but it can be procured at the canteen on payment. 9. It would not be beneficial to prohibit the sale of spirituous liquors, because they can procure worse liquor secretly, and it is impossible to prevent this. They can purchase at the canteen a quart of porter and a dram of arrack per diem. 10. The interior of the canteen is very dull, and has no furniture except tables and benches. The addition of draught boards, chess, and backgammon would render the canteen a more pleasant lounge for the soldier; and the sale of tea and coffee might be added. 11. No liquor is allowed to be sold in the bazaar by any contractor to any European soldier, and rewards may be offered not exceeding 50 rupees for the apprehension of any person providing the men with illicit spirits, which reward shall be charged against the contractor, if it occurred through his negligence. The sale of European or other foreign spirits is prohibited in the camp bazaars without licence. All cooks, clean boys, &c., must drink their liquors at the shops; and they are on no account allowed to take any away. All liquor shops are closed at 9 p.m.
VI. Diet.	1. The composition of the ration for Queen's British troops is as follows, viz., 1 lb. of bread, 1 lb. meat, 1 lb. vegetables, 3 lbs. wood, 4 oz. rice, 1 oz. salt, $2\frac{1}{2}$ oz. of sugar, $\frac{10}{21}$ oz. of black tea, and $\frac{5}{21}$ oz. green tea. Mutton is issued twice a week, and on the remaining days beef. The vegetables consist of 12 oz. potatoes, and 4 oz. onions, or 12 oz. pumpkin and 4 oz. onions. The ration generally is very bad, the meat being of poor quality, deficient in nourishment and unpalatable. The vegetable supply is limited to potatoes (often bad), onions, and pumpkins, an innutritious watery vegetable, very cheap, and consequently substituted for potatoes by the contractor when he is not prevented. There is a daily inspection made of the ration by the Quartermaster Serjeant, and four times a week by the officers of the detachment. On any complaint being made the ration is reported on by a board, consisting of two officers and the medical officer of the detachment. 2. There is a complete ration with a due proportion of vegetables, but the latter are insufficient, and the ration generally, as above stated, is bad; there is no fruit included in it. The stoppage is 3 annas 4 pice per day per man. The men have breakfast at 7 a.m., consisting of bread and tea, dinner at 1 p.m. composed of meat and vegetables, and supper at 4 p.m. of bread and tea. The proportion of vegetables which enters into the constitution of the ration is 40 per cent., but of most inferior description. 3. In this station where the meat is so very bad, the issue of preserved meat (similar to that supplied to troops on board ship) twice a week, would be most conducive to the health of the European troops: this remark applies more especially to the hot weather. Measures should also be taken for the regular supply of wholesome vegetables. There is no special arrangement for the prevention of the disposal of any part of the ration by the troops, beyond the fact that the orderly corporals and orderly men of each company are responsible for the due supply of the ration to the men of their own company. The men show no disposition to sell their ration; on the other hand they have often to buy extra meat out of the bazaar. 4. The means for cooking available at this station consist of what are called cooking pots, copper tinned, and are similar to those used by all classes of Europeans in this country. The cooks are for the most part Indo-Portuguese. The kitchens are well ventilated; they are blackened inside by the smoke from the open fireplaces, but are otherwise clean. The food is both boiled and roasted, also stewed, curried, fried, and cooked in several other ways, at the option of the soldier. The cooking is properly done and sufficiently varied. Tea is prepared twice a day, but not coffee; the former, supplied by the commissariat, is always good. During a march there is usually a half way halt, when coffee is provided for the men on payment, but it is generally of indifferent quality. I have observed that it is apt to give the men diarrhœa on the march.

VI. Diet—*cont.*	5. Gardens for the soldiers would be an advantage most decidedly, wherever there is a permanent European station. Not only would good vegetables be thus obtained for the men, but it would also be a source of healthy amusement to them. They should be established under this regulation, that each man should have a piece of ground a quarter of an acre in extent, each company's plot of ground to be separate. This plan is calculated to excite a spirit of emulation among the men.
VII. Dress, Accoutrements, and Duties.	1. The soldiers' dress consists of a loose tunic of khakee in hot weather and red serge in cold, trousers of khakee in the hot, and the serge in cold weather for Europeans, with khakee helmet. Since the introduction of khakee in the hot months, and of san topees, the soldier's dress has been most suitable. The red serge tunic is also a great improvement on the tight shell jacket for the monsoon and cold season. The Commissioners do not suggest any improvement in the present dress, except in the bad fit of the men's boots, which is often a cause of lameness when on the march, and a consequent burthen on the sick carriage of the regiment.
Duties.	1. The men should be thoroughly drilled at home before being sent to India. 2. The men get up at daybreak, drill for an hour, and sometimes in the evening light, out at 9 p.m. in summer, and 8 p.m. in winter. The men do not suffer in health from drill. The best time for drill is early in the morning or late in the evening. There are several general orders on the subject, also limiting the duration of any parade to one hour. The average number of nights which the men have in bed is for Europeans 10 and natives 5. 3. The only permanent European guard is the quarter guard; but occasionally when there are prisoners in cells there is a cell guard. Guards mount for 24 hours; both are within 100 yards of the men's bungalows. There are four regular roll calls during the day, and in the hot weather every two hours, to ensure the presence of the men in barracks, and to prevent their exposing themselves to the sun during the day from 9 a.m. to 5 p.m.
VIII. Instruction and Recreation.	1. The following are the means of recreation and instruction at the station:—There is neither ball court, skittle ground, nor school; there is a small library and reading room, not lighted at night, but neither day room, soldiers' clubs, soldiers' gardens, workshops, theatre, nor gymnasia. The men have cricket things supplied from the head-quarters of the regiment, but Baroda not being a large European station, there is no gymnasium, the men play at cricket at the officers' gymkhana weekly. More means of recreation during the heat of the day are desirable. The commissioners would suggest an increase to the books of the library of a kind suitable for the soldier, and above all the establishment of workshops. 2. To increase the existing means of occupation, I suggest that workshops should be erected for different kinds of works, but particularly carpentry, and house joinery. Carpenters might earn 6 and 7 or 8 annas a day at this work, and be a saving to Government. 3. Soldiers' savings banks are instituted. 4. The means of amusement are not sufficient.
IX. Military Prisons.	1. The cells at the station, six in number, are very bad, all under one roof, and badly ventilated, in fact the doors cannot be closed during the day. The cells are so bad, that they are only used in extreme cases. Every cell should be separate and surrounded by tatties or mats of straw; and they should be in a prison yard, each having an iron grated door.
X. Field Service.	1. There are no local medical regulations not included in the general presidency regulations. 2. Recommendations from medical officers as regards the conduct of the line of march are invariably attended to. 3. Encampments are directed to be on high open ground, to the windward of any village or swampy ground, and near water. Any medical officer making a suggestion has been attended to, as far as our experience goes. 4. No answer to this question.
XI. Statistics of Sickness and Mortality.	The following table gives the statistics of the station.

XII. HOSPITALS.	1. A ground plan, and marginal sketch of the hospital is forwarded. 2. The hospital is to the east or to leeward of the whole station, but far removed from the bazaar. The whole surrounding country is covered with trees, hedges, and cultivation, and there are many trees in the vicinity. Its site is much too close to the river and to the horse lines. 3. The water supply of the hospital is abundant and good. 4. The refuse water is carried off by a barrel drain, and emptied into the river through a nullah, outlet 50 yards distant. 5. The wards of the hospital are raised 1½ feet above the ground; The floors are solid, and consequently there is no ventilation under them. There is no provision made for conveying away the roof water, but it flows off towards the river. The materials of which the hospital is composed are brick and mud, pointed with chunam. There are verandahs all round the building, from which sufficient shade is obtained, they being 8 feet broad. The verandahs are sometimes used for the sick to take exercise in. The hospital consists of one ground floor. TABLE of hospital accommodation :— Date of construction about 1826. Total number of wards, 4. Total regulation number of beds, 120.

Wards or Hospital Huts, Number.	Regulation Number of Sick in each Ward.	Dimensions of Wards. Length.	Breadth.	Height.	Cubic Contents.	Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows. Number.	Height.	Width.

XII. Hospitals—*cont.*	The hospital is not so placed as to receive the full benefit of prevailing winds; on the contrary it only gets the wind after it has passed over or through the whole station, which is, moreover, so crowded with trees as to render proper ventilation next to impossible. The windows open inwards, and should be much enlarged. 6. The means of ventilation in use in the wards of the hospital are the windows, doors, and ventilators in the roof. In the hot weather punkahs are pulled day and night. Altogether the means are sufficient. There are no jalousies or jhilmils. 7. The air of the wards is cooled by punkahs and kus-kus tatties. The punkahs are suspended from the ceiling, provided with a curtain loaded with shot or sand at the bottom, and pulled by a rope. Six punkahs are pulled by one rope. The tattie is applied to the windows, and kept wet with water, and the hot wind is thus cooled before entering the ward. Every window not having a tattie must be closely shut. 8. There are no means of warming the wards, nor are any required. The ceiling and walls of the wards are cleansed and whitewashed, whenever required by the medical officer. 9. The privies of the hospital are the same as those of the barracks, and are connected with the hospital by a covered way; they are properly cleansed, and are not offensive. 10. The washing arrangements of the hospital are very good, and there is a large room provided with ghindies, or copper washing basins, tinned. 11. There is a large tub in the washing room about 8 ft. by 3 ft., kept constantly full by a bheestie, for those men who are sufficiently well to avail themselves of it for bathing. 12. The washing and drying of the hospital linen is performed by dhobies; the means are quite sufficient. 13. The storage is sufficient and dry. 14. The bedsteads of the hospital are portable iron cots, with sacking lashed to them by rope, and on this a straw mattress. Coir is recommended for stuffing the mattresses in preference to straw. 15. The hospital kitchen, cooking apparatus, &c., are similar to those at the barracks, but on a smaller scale. The cooking is well done, and the means are sufficient. 16. Diet tables according to regulation. The forms forwarded are of two descriptions, those for the superintendent surgeon of the late company's service, and those for the deputy inspector-general of H.M.'s hospitals at army head quarters. 17. The provision for hospital attendance on the sick is as follows:—There is a corporal who acts as hospital serjeant to the detachment hospital, and four ward boys to attend upon the sick. In addition to this, a European orderly is provided for such men as are seriously ill, and need constant attendance, and where natives could not be trusted. In addition to these, who are termed second-class hospital servants, there is an assistant apothecary with the detachment corporal. 18. I think that the European hospital, taken as calculated to afford accommodation to the detachment, is in itself all that could be desired; but its situation in the lee of the whole station, and close to a nullah used as a necessary by the natives, and as a receptacle for the filth of the station, is most objectionable. During the cholera, which attacked the detachment in March last, the men were at once removed from it. 19. I know of no other deficiencies, but the grand defect of position just mentioned. 20. There is no stated ground in which convalescents can take exercise, nor are there any seats. Any exercise which they require they must take in the verandahs during the day, and in the evening in the hospital compound. There are a few convalescents who live in their barrack rooms, and have permission to walk about the station. 21. There is a female hospital for the soldiers' sick wives and children; but it has no matron or assistant matron. The few women and children of the detachment are therefore attended in their own houses. The present arrangements are sufficient. 22. There are no special local hospital regulations not included in the general presidency medical regulations. 23. The application of the medical officer, in all matters appertaining to the sanitary state of the hospital, is always attended to. 24. There is no ward or hospital for convalescents at the station, nor is any such required.
XIII. BURIAL OF THE DEAD.	1. The burial ground for British troops is 500 yards to windward of the station. 2. The area of the ground is 10,000 square yards; the soil is black, and decomposition takes place rapidly. The drainage is effected by a passage through the wall, made by leaving a brick out here and there; no regular drainage The ground is carefully kept. 3. Ample space is allowed as an interval between the graves, which are never on any occasion re-opened. There is no regulation depth of graves. The graveyard is not yet full. Interment is usual within 12 hours after death. There are no regulations as regards the burial grounds used by the native troops; the Jews and Mahommedans bury in their separate burial grounds, which are not offensive. 4. The graveyard is never offensive. As regards the burial of British troops, the practice is frequently to bury within 12 hours, if possible; always within 24. 5. The dead of camp followers are disposed of according to caste:—The Parsees expose to fowls of the air; Hindoos burn; and the Mussulmen bury. 6, 7. No injury from this practice accrues to the public health. There are no improvements to be suggested.

I. Topography.	1. The country surrounding the station is barren, with occasional patches here and there of vegetation and groves of trees. It is dry and undulating, and there are hills and spurs of ghats within distances of from 10 to 25 miles. There is no jungle in the vicinity, but occasional clumps of scattered bamboo and other trees. A river runs near the station, but is only visible where one is close upon it or from considerably elevated ground.
	2. The station is elevated about 1,800 feet above the level of the sea, but is on a level with the adjacent country. There is no higher ground adjoining the station which could be made available for military purposes of any moment, unless it might be the hill of Parbuttie on the other side of the city from Poona, which, as it overlooks the city, would be a valuable military point to occupy.
	3. The nearest mountain or table land is Singhur, about 13 miles distant. It forms a portion of a spur or range of hills running in an easterly direction from the Western Ghauts. Its height above the station is about 2,400 feet.
	4. The nearest water worth consideration is the river Mota Moola, about three-quarters of a mile from the camp. The vicinity is not liable to overflow, as the river keeps within its banks. The ground near the station is a flat, almost unbroken, table land of the trap formation. There is nothing in the form of ravines or waterpits productive of any ill effect on the health of the station.
	5. The station is open and freely exposed to the winds, and is not encumbered in any way with trees, hedges, gardens, &c., so as to interfere with either free external or internal ventilation. The temperature of the station is not raised by exposure to reflected sun heat, being too largely scattered for such a contingency. From November to February cold land winds prevail, with occasional sea-breezes; from March to June hot, scorching, variable winds, and for the rest of the year the prevailing winds are from the sea. The cold and rainy seasons are beneficial to the health of the troops, but in the hot season fevers and congestive visceral disease prevail.
	6. The surrounding country is chiefly uncultivated. Gardens and fields there are, but only where water is handy, and they may be said to be in patches. There are no works of irrigation near the station, and artificial irrigation being confined to garden cultivation has no appreciable effect on the health of the station. Rice is not cultivated in the neighbourhood, and the health of the station is not affected by the cultivation of indigo or the preparation of hemp or flax.
	7. The large native city of Poona, containing about 80,000 inhabitants, lies to the west and windward of the cantonment about three-quarters of a mile; in other words, the cantonment is on the wrong side of the city, which lies in a hole below the station. Besides this city there are two small villages, Wanoree and Ghorpooree, both so near the cantonment, especially the latter, that they are a nuisance. Last year the cholera first showed itself in Wanoree, which is only about 100 yards or so from the lines of the artillery officers. They should both be removed, the owners of the houses receiving ample compensation.
	8. The upper surface of the station is, generally speaking, of moorum, with patches of black soil here and there, and below trap rock. The station occupies new ground, i.e. it was first established 43 years ago, and had not been occupied before.
	9. Water is usually found in the dry season at a depth of about 33 feet below the surface, and during the rainy season at about 19 feet.
	10. The rain-fall and water from surface springs flows readily away, though some of it doubtless sinks into a pervious subsoil, whence it runs off into the river. The fact, that a few hours after heavy rain the ground is nearly dry, proves that the rain-water does not lie on the surface till it evaporates. No drainage of any consequence passes into the subsoil of the station; the natural nullahs run off the water into the river, which acts as a drain to the station.
	11. The water supply of the station is derived from one aqueduct, 51 wells, three tanks, and from the river, the water of which is forced by pumps into camp. The aqueduct has its source about a mile and a half from the south-east side of the camp; it runs through the cantonment, and terminates in one of the peits or streets of the city. In the hot weather it runs nearly dry, and is obliged to be fed by water from wells in the vicinity of the source. Some of the water is stored in open tanks. The three tanks in the cantonment have a surface area of 280,450 square feet, but the water is not drinkable. There is, besides, one tank in the civil limits, close to the camp, which contains a surface area of 69,800 square feet. The water is good for drinking at certain times of the year, but not in the hot weather. The following table shows the tank surface in camp and civil limits.

Camp tanks - - - - -	280,450	square feet.
Civil do. - - - - -	69,800	,,
Total square feet -	350,250	superficial area.

I. Topography—*cont.*	The tanks are generally full from the setting in of the rains in June till the commencement of the hot season in March, when the supply of water steadily decreases. and in May they are generally dry. The civil tank, however, never dries up. The nature of the plants and animals which the tanks contain is unknown. There are no tanks in camp containing drinking water, the civil tank is not used for bathing purposes. The tanks are not liable to pollution from leaves falling into them. There are no precautions against foul drainage or surface impurities passing into them; but the water is not used for drinking purposes. It cannot be said that either nuisance or malaria proceeds from any of the tanks within or without the station, owing to their having a natural base in the trap formation, and comparative freedom from alluvial deposit.

12. Between June and February the water supply of the station is obtained from an aqueduct, 51 wells, and three tanks, to an amount sufficient for the wants of the cantonment (the exact quantities cannot be stated), but during the hot weather, when many of the wells run dry, the water is forced up from the river by a bullock engine at the rate of 75,000 gallons per diem; but even this extra supply is insufficient to meet the demand. A better water supply for the station is absolutely necessary. The water is colourless, tasteless, and inodorous. It is soft, but its microscopic characters are unknown. The quality is good, but the present amount is insufficient.

The following table shows the chemical composition of the water.

The water in the wells is raised by common leather buckets, and taken away in leathern skins on bullocks or in skins on the backs of coolies (bheesties). Each private individual has his own bheestie, and each regiment its set of bheesties, whose duty it is to supply water daily as it is wanted. The aqueduct water is collected here and there in branch reservoirs, and is carried away as above described, but the supply is insufficient, and, excepting during the monsoon, has to be taken care of and not wasted. A detailed scheme, accompanied by plans and estimates, for bringing more water into the cantonment was framed by Colonel Hart of the Bombay Engineers, and long since submitted to Government. The amount estimated was rupees 4,49,463, four lacs, forty-nine thousand four hundred and sixty-three. The superintending engineer, Lieutenant-Colonel Munbee, states that the estimates have been sanctioned, but when the work will be actually commenced is uncertain.

13. There are no other topographical points calling for remark which bear at all on the health of the station.

14. New stations, whether on the hills or plains, are selected by a mixed committee, composed of the senior military authorities, executive engineer, and senior medical staff, who, after making inquiry into sanitary and other questions, communicate with the civil authorities, the final decision resting with the Government. Stations have hitherto been selected on the plains.

1. There is an observatory at this station under the charge of Assistant Surgeon Chapple, R.A., with two intelligent non-commissioned officers as assistants. The following are the instruments in charge:—

3. A reference to the preceding table will show the general character of the climate in every respect. There is almost a total freedom from fogs, and dampness is only observable during the rains, and mild in degree. Only garden irrigation and tree planting exist, and do not produce any perceptible influence on the climate. Dust storms are rare, only occurring just previous to the setting in of the rains, and not perceptibly affecting the purity of the atmosphere. The climate (a table land of the trap formation, elevation above the sea of about 1,800 feet) is most favourable to the health of troops. The diet, as per regulation, is found to be ample. The shelter afforded at present is partially good, but better accommodation is sanctioned and in progress. During the hot months the light khakee clothing should be worn; during the rainy and cold months woollen clothing, and always at night warm woollen covering is desirable, the latter owing to the great sensible variation of temperature between the day and night arising from atmospheric dryness. The most healthy months at this station are July, August, September, December, January, and February, and the most unhealthy, October, November, March, April, May and June. During October and November, owing to the cessation of the rainy season, with the elevated temperature, remittent and intermittent fevers, with visceral diseases, prevail; during the hot months of March, April, and May these, and also eruptive fevers, and congestive diseases of the cerebral, thoracic, and abdominal organs, and in June bowel complaints. Rheumatism prevails during the cold months.

4. There is no district near this station, the climate of which is more conducive to health than that of the station.

5. We have served in most of the stations in the Deccan, the southern Mahratta country, the Mhow division, Sinde, the Concan, and Guzerat. These stations in the Deccan being on an elevated table land of the trap formation, about 1,800 feet above the level of the sea, are the most conducive to the health of troops; next in degree those in the southern Mahratta country and the Mhow division from the same causes, next in degree those in Scinde; for though the elevation above the sea is slight, the country surrounding the stations is, for the most part, a sandy plain free from jungle vegetation. The stations in the Concan or coast border of the presidency are comparatively healthy, being situated within the full influences of the sea breezes, but are, however, subject to severe visitations of epidemic and zymotic diseases. With the exception of the Deesa station (salubrious from being situated in an open sandy plain) the stations in Guzerat are positively injurious, the elevation above the sea being very slight, and the soil alluvial, with a rich rank vegetation, and abounding in rivers with a small degree of fall, exhibiting extensive alluvial banks.

III. Sanitary Condition of Station.

1, 2, 3. General Maps of the station generally, with plans of the surrounding country and of the barracks are transmitted.

III. Sanitary Condition of Station—*cont.*	N.B.—There are six temporary chuppered buildings (barracks for the artillery) which will be pulled down when the new barracks, which have been approved, are built. There are also 14 chuppered barracks near the church (temporary buildings), erected in 1823; but they are to be pulled down on the completion of the 10 upper-storied barracks, of which six are ready.

5. The windows in the barracks are always on both sides (as are also the doors), which arrangement ensures some degree of ventilation. The windows open on hinges. In the upper-storied Wanowrie barracks there is a closed verandah, on both sides of the upper and lower rooms, 11 feet wide. The Horse Artillery upper-storied barrack has an open verandah on both sides, above and below, 8 feet wide; and the Ghorepooree barracks have open verandahs on both sides, averaging 10 feet in width (in the old barracks only 7 feet). The open verandahs are not used as sleeping quarters, and the closed verandahs of the upper-storied Wanowrie barracks only occasionally on emergency. There are jalousies in some of the barracks, and they are properly constructed.

6. The bedsteads used in the barracks are mostly boards and trestles, but there are iron bedsteads, with cross thin iron straps. The bedding for each soldier consists of 1 numda, 2 cumlie blankets, and 2 pairs of sheets, with 1 cotton coverlid, all supplied by Government. We have no improvements to suggest.

7. The following tables show the dimensions and construction of the tents used in camp.

TENT for EUROPEAN SOLDIERS, double pole.—Double poled, with fly and shed, and single set of walls.

Extreme length within	22 feet	For 14 Horse Artillery.
„ breadth „	14½ „	or 22 Foot „
Height of walls	12¼ „	or 22 Infantry.
„ to ridge	12¼ „	or 16 Cavalry.
Total area	319 square feet.	
Cubic space	2,393 cubic feet.	

TENTS for EUROPEAN SOLDIERS, single pole.—Single pole, with fly, shed, and single set of walls.

Extreme length within	14 feet	For 8 Horse Artillery.
„ breadth „	14 „	10 Cavalry.
Height of walls	6 „	or 13 Foot.
„ to cap	12′ 2″	
Area	196 square feet.	
Cubic space	1,268 cubic feet.	

EUROPEAN HOSPITAL TENT.—Double poled, with fly, shed, and double sets of walls.

Extreme length inside	22′ 9″	For 12 Europeans, or 15 Natives.
„ breadth „	16′ 4′	
Height of walls	6′ 3″	
„ to ridge	12′ 9″	
This gives about	30 sq. ft.	Per European.
And	260 cub. „	

TENTS for NATIVE SOLDIERS.—Double poled, oval shape, with fly only.

Extreme length within	26′ 8″	For 25 Cavalry.
„ breadth „	13′ 9″	or 30 Infantry.
Height to ridge	9′ 6″	
Area	383 square feet.	
Cubic space	1,030 cubic feet.	

TENTS for NATIVE SOLDIERS, single pole.—Nearly circular, with bell-shaped fly only.

Diameter	11 feet	For 12 Infantry.
Height to cap	10 „	
Area	94 square feet.	
Cubic space	180 cubic feet.	

8. In the upper-storied Wanowrie barracks continuous ventilation is obtained by raising the upper part of the roof above the lower; the lower rooms are ventilated by a range of square holes contiguous to the floor of the upper rooms. In the other barracks there are only cowl ventilators, which are objectionable, as they always leak in the rains, and their weather sides have to be dammed up during the monsoon. Tents and guard-rooms require no extra ventilation than what they ordinarily possess by doorways and windows. The ventilation in all the barrack rooms is insufficient. Arrangements should be adopted (which the soldier

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	could not interfere with) for the free ventilation of the rooms when the doors and windows are closed. There are no means in use at this station for cooling the air admitted into the barrack rooms. 9. The barracks are constructed of brick and lime plastered; the roofs are double tiled, with teak trusses and rafters. Some of the barracks have paved floors, and all should possess them. 10. The floors (most of which, as before stated, are paved) are raised, on an average, about 3 feet above the ground, but there is no passage of air underneath them. 11. The materials of which the barracks, tents, &c., are composed are good; but the Committee are unanimously of opinion that in this country barrack rooms should be elevated above the ground at least 14 feet. Such an arrangements entails at all times a clearer and more healthy atmosphere for the soldier both by day and by night. The lower portion of the buildings might be converted into dining-rooms, washing-rooms, libraries, skittle-alleys, &c. &c. Most of the subsidiary detached buildings would thus be done away with, and no extra expenditure entailed. We also would strongly advocate for all new barracks the adoption of open verandahs; the men like them, and they add to the ventilation of the barrack rooms. The barracks and cantonment are kept in repair by the executive engineer. The repairs are mostly executed by native contractors, and often times delay is experienced in consequence of the natural dilatory disposition of the native, want of sufficient supervision, and other circumstances. No officer is responsible for the general sanitary state of the cantonment. The Committee strongly recommend that it should be the sole duty of a separate medical officer to attend the sanitary state of so large a cantonment (including Poona and Kirkee). The walls and ceilings of the barrack rooms are cleansed and lime-washed at intervals of three months, oftener if necessary. We would recommend that in future barrack rooms should be lime-washed "regimentally," and that lime, brushes, &c., should always be kept in store by the quarter-master. 12. The lavatories are merely open paved verandah rooms, with tubs placed in them amply supplied with water. The refuse water runs off into tubs placed outside. We would recommend that, instead, cut stone wedge-shaped cesspools, guaranteed against leakage, should be adopted; or perhaps large iron tubs, japanned or glazed, would be better still. There are two washing-rooms generally to each barrack room. 13. The regimental cook-room is a simple rectangular building, with an opening in the roof and walls for the smoke to escape. The fireplaces are nothing but masonry platforms about 2 feet high, with iron rests, called choolas, for the cooking pots. Water is supplied by the bheesties, and the refuse water is drained into cesspools, which are cleaned out nightly by halalcores or sweepers. Large iron japanned-glazed tubs would be better still. The washing and drying of linen for the soldiers are satisfactorily effected by dhobies employed regimentally. 14. The privies for Europeans are simple buildings, and will be easily understood by the sketch transmitted. The filth falls into baskets and is carried away by sweepers, the urine draining into cesspools. The privies for native soldiers are also enclosed buildings. The sweetness or otherwise of these places depends entirely on the sweepers and a liberal supply of deodorising materials. Pans similar to those recommended for the cook-rooms would be better than cesspools. 15. The means of ventilation have been described. None of the buildings above-mentioned are lighted at night except the barrack-rooms. These latter are not sufficiently lighted, and very great difficulty has been experienced in trying to remedy the evil. We would recommend that similar lanterns to those used on board of Her Majesty's troop ships (swinging lamps and deck lamps) should be introduced as an experiment. 16. There are no arrangements at this station for draining and sewering the barracks, but all deposits, waste water, filth, &c., &c., are removed to a specified locality by the sweepers. This system of removal under the existing arrangements is found to answer. The barracks and hospitals are never damp except in the rains, when artificial means, such as pans of lighted charcoal, are placed in the rooms for as long as may be deemed advisable or necessary. There are a few small cesspools, about $3' \times 3' \times 3'$ here and there, but they are daily cleaned out. They are not in the vicinity of any wells. There are no foul ditches near the station. 17. The surface cleansing of the cantonment is well attended to. The refuse, manure, &c., is carried away in carts and burnt in a filth-burning kiln situated at the south-east end of the camp. 18. The surface of the cantonment is kept free of vegetation. There are no old walls, and the hedges in the camp are kept cut to a certain height, so as not to interfere with the ventilation of the station. We would recommend that householders should be forced to remove these hedges, and substitute low masonry or brick walls. We are also of opinion that all hedge-rows, outside but in the vicinity of the camp, and on either side of the road from Poona to Kirkee, should never be allowed to exceed 3 feet in height. 19. The bazaar is not well drained, nor can it be so until the supply of water is better than it is at present. The ventilation of the bazaar is pretty good generally speaking, but when the poorer classes, such as hamals, dooly-bearers, beggaries, &c., are congregated, better ventilation is desirable, and could be obtained by extending the bazaar. The water supply is not sufficient in the hot weather months, but this will be remedied if Colonel Hart's scheme is carried out. The bazaar is kept very tolerably clean. Latrines and privies for the use of the inhabitants of the bazaar are much needed, as at present the poorer classes are obliged to go to a considerable distance to attend to the calls of nature. The establishment to superintend the cleanliness of the bazaar consists of one havildar, one naique, and 20 peons. Under their superintendence are employed one muccadum, eight sweepers, and six carts. The duties of these are to daily collect and carry away the rubbish and filth of the bazaar to selected places. This establishment is far too small, and should be increased. The population consists of 27,000 inhabitants. Men are also employed, exclusive of the above, to keep the lanes in repair, cutting down prickly pear hedges, and cleaning drains, &c. The provost sergeant and the kotwals see that the above establishment do their duty. The houses of the merchants and shopkeepers in the bazaar are generally of a good description and roomy. The houses of the labouring classes are principally made of mud bricks dried in the sun, with grass chuppers for roofing, but these are gradually giving place to better buildings with tiles. There are no dung-heaps within them, as they are not allowed. It must be remarked, that when the bazaar was first formed in 1819 no attention was paid

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	to regularity of streets and houses, but people were allowed to retain the spots of ground where they had first squatted after the battle of Kirkee and Poona, in 1817. The Sudder bazaar is in front instead of rear of the officers' quarters and the cantonment, which is most objectionable. No nuisance is experienced in barracks from wind blowing over the native dwellings, except in the cases of the villages of Ghoreepoore and Wanowrie. Their contiguity to the station is the cause of this nuisance, and nothing but their removal will eradicate it. 20. The slaughter-house is at present within the cantonment, but it is shortly to be removed to a convenient place, about two miles from the centre of the camp. All slaughtering is ordered to take place during the night, and the offal to be removed to the filth burning kiln. The present slaughter-house is found to be a nuisance, and hence the necessity for its removal. 21. The bazaar horses for hire (saddle) are picketed in the horse lines between the centre street and Malcolm Tank road, and are to the number of about 20. The lines are kept clean and in repair by the owners of the horses, under the direction of a head man or muccadum. The manure is carted away by the surrounding gardeners, tile makers, &c., or taken to the jungle. All the manure is cleared away daily. The horses for carriages to the number of about 75 are kept in stabling in the bazaar. Horses for private purposes are kept in stabling in the compounds of the house owners. The manure is disposed of as above stated. 22. The horses of the cavalry and artillery are picketed in the open, in lines constructed for the purpose to the eastward of the men's barracks and hospitals. The manure is removed daily. In the picketing grounds the horses are eight feet apart, arranged in rows, and are about a quarter of a mile from the nearest hospital and barrack-room. 23. There are sufficient quarters provided at this station for the families of married soldiers, none of whom occupy barrack rooms with the men.
Officers' Quarters.	1. Officers live in separate private bungalows, situated in compounds, averaging 100 yards × 80 yards, and arranged conveniently with respect to the soldiers' quarters. We have no improvements to suggest further than that it would be advisable that several ill-conditioned houses in this cantonment should be pulled down and a better class be erected in their stead. We do not advocate officers' quarters in this country.
IV. Health of the Troops.	1. The station, surrounding district, and adjoining native population are healthy. 2. Spleen disease is very rare at this station. At the setting in and termination of the rainy season, bowel complaints and fevers of the remittent and intermittent types prevail; during the hot season eruptive fevers, particularly variola, varicella, and rubeola, and during the wet and cold season catarrhal and rheumatic affections. 3. I attribute the healthiness of the neighbouring native population to elevation, the trap formation of the surrounding country, freedom from alluvial deposits, the general prevalence of westerly or sea breezes, and good water. 4. The stations at which the troops at this station were located before arriving here are as follow, viz., Her Majesty's 4th troop Bombay Horse Artillery, last stations, half troop at Sholapore, and half troop at Kolapore. The troops stayed at these stations for six months, and left for this on the 4th February 1860. The state of their health there was good, and the disease from which they chiefly suffered was intermittent fever. They arrived in Poona on the 18th and 22nd of February 1860 in a good state of health, and the diseases from which they have suffered since arriving are fever and stomach and bowel complaints. Royal Artillery, No. 1. battery 13th brigade, was quartered at the Cape of Good Hope, and No. 7 battery, 13 brigade, in England. The former battery had been two years at the Cape, but the latter had been always in England. The former left the Cape in September 1858, and the latter quitted England on the 10th August 1858. The health of both batteries was very good; a few of the ordinary cases of sickness only in hospital. The date of arrival in India of No. 1 battery was 10th November 1858. It was then stationed a short time at Baroda, where the men suffered from sun stroke and fever; but since their arrival in Poona their health has been good. No. 7 battery arrived on the 8th of September 1858, and though many of the men have suffered from cholera, the health of all now is good. Her Majesty's 56th Regiment was at Belgaum two years, and left on the 21st February 1860. The health of the men there was good; the prevailing diseases were fevers, hepatic, stomach, bowel, venereal, and rheumatic affections. The regiment arrived in Poona on the 23rd March 1860, in an unhealthy state, from cholera and bowel complaints, but their health has much improved since their arrival here, the prevailing diseases now being ephemeral fever and mild bowel complaints. Her Majesty's 57th Regiment was stationed at Ahmednuggur, with detachments at Aden, Sattara, and Mulligaum. They were at Aden two years and nine months, and at the other places about 10 months. They left Aden in December 1859, where the health of the men was good, and the prevailing disease venereal affections. They arrived in Poona on the 15th March 1860. Head quarters left Ahmednuggur in January 1860, at which place their health was very indifferent from intermittent fevers, and arrived here in the same month. Since their arrival here their health has much improved, and the prevailing diseases of the united corps now are ephemeral fevers, bowel and rheumatic complaints. Her Majesty's corps of Sappers and Miners, Indian army, head quarters stationary. The health of the men of this corps is good, and the prevailing diseases are fevers and bowel complaints. Her Majesty's 15th Regiment Native Infantry were at Kolapore for about 18 months, and left it in wings, the right in October 1859, arriving in Poona in November, and the left in March, arriving in April 1860. The health of the men, both before and since their arrival here, generally good. The prevailing diseases are mild fevers and bowel complaints. Her Majesty's 25th Regiment of Native Light Infantry arriving in Poona in March 1859, after nearly two years field service in Central India. They were very unhealthy from scorbutus and general cachexia; but the health of the men has much improved since their arrival here. The prevailing diseases have been fevers and bowel complaints.

IV. Health of the Troops —*cont.*	No portion of the men's present accommodation at this station is more unhealthy than the rest, all being alike healthy. 5. Troops at this station are not camped out during any portion of the year. 6. We have never been in charge of troops at hill stations, but the following replies are founded on the opinions of C. Morehead, Esq., M.D., late acting superintending surgeon at Poona, published in the "Transactions of Bombay Medical Society." His experience and researches are favourable to the residence of troops in hill stations, provided the proper season is chosen for sending troops, and if sick or convalescent that a proper selection is made. His experience is founded on personal knowledge, and the reports of medical officers stationed at Malcolm Pait, on the Mahableshwur hills, and at Poorundhur. 7. Dr. Morehead states :—If the debilitated soldier who in the plains would recover his health and strength slowly after the removal of positive disease will, by commencing a residence on the hills in October, or during the hot months, having become fitted for duty, be less liable to fresh attacks of disease, and when attacked the disease will be of a milder type; whereas, on the other hand, the continued residence in the plains leaves him predisposed to attacks of the severer forms of disease—the ultimate effect of a freer use of hill climates must be to reduce mortality and invaliding. He disapproves of sending troops during the cold or rainy months, if sick, as liable to be injured by a return of former diseases. 8. Hill stations should most decidedly be selected for troops, but only as a change of climate. 9. Convalescents sent to the hills in the cold and rainy seasons are liable to recurrences of organic visceral disease. Again, if troops go to them exhausted by service in the field they are liable to congestive, inflammatory, and organic visceral disease, but otherwise they are only subject to mild hill diarrhœa, and the general effects of a rarefied atmosphere. 10. With respect to the precautions necessary as to diet, clothing, shelter, duties, &c., &c., no data are given by Dr. Morehead's report; but the inference is clear, that as there is liability to the formation and recurrence of visceral disease, cerebral excitement, and other complaints of the sthenic type, the diet should be of a non-stimulating nature, the clothing adapted to a climate much cooler than the plains, the shelter affording perfect protection from fogs, rains, and the direct rays of the sun, and the duties and exercises depending upon the improving health of the soldier. 11. From the reports of the medical officers of the Deccan hill stations it appears that from the commencement of the month of March to the middle of the month of November the greatest advantage to health will be gained by the debilitated or convalescent from disease at Poorundhur. The rainy portion from June to October is inapplicable to Malcolm Pait. The healthy soldier may reside with advantage at Poorundhur or Pauch Gunny at any season. As far as practicable all ailing men should be afforded one month's residence in hill stations, but the period required for complete restoration of strength will vary in different cases, and its determination should be left to the discretion of the medical officer in charge of the sanitarium. 12. Applying the question of length of residence in hill stations to the hills of the Deccan, as affecting the health of troops returning to the table land on which the military station is situated, or to other stations in this presidency, Dr. Morehead states that the hill climate, from the middle of November to the end of February, might not prove injurious. Still, it possesses no advantages over that of the Deccan, and that season is most suitable for return to all stations in the plains. 13. Proper selection of period and good ambulance are the precautions required for protecting the health of troops on leaving hill stations for the plains. 14. In answer to this query, Dr. Morehead says, the question has been often raised, Would a regiment fresh from England, located at an elevation of, say 7,000 feet, retain its European vigour? Doubtless it would, a deduction being made for a rarefied atmosphere; but this regiment would not be efficient for the contingencies of service in India. If suddenly called to the plains for service in the hot season, it would show a heavy sick-list, and a rapid loss of vigour and stamina would ensue. But an improved state of general health will accrue to the soldier in India from an improved sanitary system, including the avoidance in the hot season of the heat of the plains by a more extended resort to hill stations. The maintenance of the greatest degree of health and efficiency for the ordinary contingencies of service in a tropical country is to be attained by avoiding as much as possible unhealthy localities and seasons, such as localities with malarious characteristics, the hot season all over India, and the rainy season in many parts of it. These points attended to, frequent change of service in the plains, which is most harassing to the soldier, will be quite unnecessary, and can only be deemed even advisable when troops are located in unhealthy districts. 15. The amount of accommodation in barracks and hospital at the hill stations is quite insufficient. There are two recognised sanitaria in the Deccan, Malcolm Pait, established in 1828, and the hill fort of Poorundhur, in 1852. European troops have not been located at the former, but there are Government quarters for 16 sick officers, and 77 private bungalows. Upwards of 300 visitors resort there annually, with such a favourable result to health, that with proper barrack and hospital accommodation it might be rendered an equally favourable sanitarium for troops, except during the rains, when the fall of rain, about 240 inches, renders it uninhabitable; but a distance of 10 miles on the eastern slope Pauch Gunny, at about 500 feet less elevation, with a fall of only 80 inches, would render this circumstance avoidable. At Poorundhur there are 2 barrack rooms, affording accommodation for 100 men, and a very good hospital adapted for 40 sick. There is also a patchery for 10 families, and a small female hospital. The sanitarium may at present be considered sufficient for 130 soldiers and 10 families. 16. Experience shows that an average height of 4,000 feet above the level of the sea affords the most suitable site for a hill station. 17. Poorundhur, about 20 miles distant from the station, is the nearest higher ground. Its means of access are very indifferent. Its elevation is 4,200 feet. There is much atmospheric dryness in March, April, and May, and the rain-fall during the rainy season is 72 inches; it is then frequently enveloped in mist. Its mean temperature in the cold season is 67°5, in the hot season 75°5, in the rainy season 67°4, and in October 69°6.

IV. Health of the Troops —*cont.*	18. Surfaces of the trap formation, as in the Deccan generally, also, where sand, with the detritus of metamorphic rocks prevail, are the most healthy; where the surface is alluvial, of the peat formation, as black soils, the most unhealthy, as in Guzerat. 19. Soldiers should on no account proceed to India earlier than 20 years of age, and should land there at the commencement of the cold season, viz., November. Troops in this presidency, when landed in Bombay, are first located in barracks situated either in the centre of the fort or at the end of a spit of land "Colaba," both of which sites, and the nature of the barracks, have been repeatedly condemned as most unhealthy. Their clothing, drills, and marches are according to the season, and the duties are excessively heavy for troops on arrival in such a depressing climate as that of Bombay. If recruits arrive early in the cold season they should be at once drafted to their respective regiments as soon as they have been properly equipped, otherwise to be at once removed to the table land of the Deccan, and to remain there till the opening of the next cold season. 20. Troops should be sent direct from the home depôts, so as to arrive early in the cold season. Regiments on their arrival in Bombay should commence their tour of service on the Deccan table land as far as practicable. 21. Troops are transported from Bombay to the centre of the Deccan table land by railway and from thence to the different out stations by bullock train or marches. The precautions to preserve health are marching in the cold season; marches not exceeding 12 miles, made between 2 and 7 a.m.; halting every fourth march one day; careful selection of encamping ground as regards soil, good water, avoiding the neighbourhood of large native towns on account of the probable presence of epidemic disease; good tents, not crowded, with tarpaulins for the floors: coffee before starting; and no grog before the first meal. 22. A British soldier should not serve in India for a period exceeding 12 years. 23. The invaliding boards in this presidency are composed entirely of medical officers. There is no conflict of opinion as regards invaliding; but we would suggest that these boards assemble oftener, to afford more frequent opportunities for the sick soldier to be sent home. 24. Invalids should leave India for home in January or February, which are the most favourable months, and not later than the first week in March, so as to insure their arrival in England in June, and secure a favourable passage.
Diseases.	1. There are weekly inspections for Europeans in the morning for the discovery of incipient diseases; but none in the native army, as it would offend the prejudices of religious caste. 2. Scorbutus is almost unknown in this station, either in the European or native regiments. Her Majesty's 25th Regiment Native Light Infantry arrived here in March 1859, suffering severely from this disease, the result of privation and fatigue on field service in Central India. Its effects in about a twelvemonth almost disappeared. No special preventive measures are necessary. 3. The proportion of hepatic disease among European troops is about 1 in 17. It is caused by the climate and intemperance, and is almost always idiopathic. The prophylactic measures necessary to diminish its frequency are strict attention to the wearing of flannel next the skin, moderate exercise, and the limited use of fermented and spirituous liquors. The native portion of the army is almost entirely exempt from this disease, which is to be ascribed to their abstinence from spirituous liquors, and their simple diet. 4. The Europeans are almost free from dracunculus at this station. Among those in whom it has appeared it originated in other stations. The proportion of cases of this disease depends on locality, and may be traced to bathing in and drinking tank water subject to fluctuations in depth, and extent of water surface, and alluvial deposit. In this station the annual number of admissions in a native regiment is about 1½ per cent. 5. The proportion of constantly sick from venereal disease to the total sick in hospital from all other diseases is about 14 per cent. among the European troops, and 3·5 per cent. among the native troops. To diminish the liability of the soldier to these diseases a strict examination should be made from time to time of the prostitutes, and the removal of the diseased women from the bazaar. The establishment of lock hospitals would be highly advantageous to the health of the army. 6. The troops at this station suffer from diseases chiefly of the endemic class. The diseases named below are rarely epidemic at this station:— *Fevers* of the ephemeral and intermittent classes are the most prevalent, then those of the remittent type. Simple continued and typhoid fevers are very rare. *Dysentery* and all bowel complaints are prevalent at the commencement and during the rainy season. *Cholera*, as an epidemic, rarely occurs at this station; it prevailed as such at the latter end of May and during June 1859 among the European Troops in the barracks and lines on the southern border of the camp. Sporadic cases occur annually at the same season among the Europeans and natives. *Small-pox*, chicken-pox, and measles prevail among the native population during the hot season. Small-pox rarely appears among the troops, European or native, or their families, owing to the careful practice of vaccination. *Rheumatism* prevails among the European troops, chiefly with a venereal taint. Among the native troops lumbago, arthritis, and idiopathic rheumatism occasionally appear. The proportion which admissions and deaths from these diseases bear to the total admissions and deaths is as follows:—Europeans, total admissions, 1,478; total deaths, 20.

Diseases.	Admissions.	Deaths.
Fevers (present)	1 in $4\frac{107}{158}$	1 in 10
Dysentery	1 in 82	1 in 10
Cholera	1 in 164	1 in 5
Small Pox	1 in 739	None.
Rheumatism	1 in $14\frac{1}{3}$	None.

References to Subjects and Queries.	Replies.

IV. Health of the Troops —*Diseases—cont.*

In a native regiment of average strength, 650, total annual admissions, 350; total deaths, 5.

Diseases.	Admissions.	Deaths.
Fevers (present)	51·4	1
Dysentery	2·5	None.
Cholera	0·5	„
Small Pox	0·5	„
Rheumatism	2·8	„

7. The most frequent zymotic diseases are fevers of the ephemeral, intermittent, and remittent types, dysentery, diarrhœa, cholera, rheumatism, syphilis, and eruptive fevers. During the hot season the eruptive and other sorts of fevers prevail, and during the rainy season cholera, bowel complaints, and rheumatism. Intermittent and remittent fevers, together with rheumatism, are prevalent in the cold season. The eruptive and other forms of fever are, in the hot season, accompanied by scorching winds, with occasional thunderstorms and heavy showers of rain. For diseases of the rainy season the causes are apparent. The diseases of the cold season are accompanied by much dryness of the atmosphere and variation of temperature. These diseases do not prevail in one part of the camp more than another, except fevers of the eruptive class and bowel complaints, which prevail most in the bazaars and where natives reside, owing to the general unsatisfactory sanitary state of the bazaars, the want of ventilation in, and crowding of the native dwellings, bad drainage, and deficient water supply. The European troops at this station exhibit no particular predisposition from personal habits or condition to these diseases. The poorer natives occupying small huts or otherwise crowding together, and having a national objection to the admission of air and light into their dwellings, are, from these causes, sufficiently predisposed to the above diseases, especially among the lowest castes, owing to their filthy habits of living and eating.
8. The prevalence of epidemic disease is influenced on the march and in the field by curiosity and other causes, inducing both Europeans and natives to go into the towns and villages near the camp, where epidemic disease is generally prevalent, their careless exposure to the mid-day sun, even when exhausted after the march, and their drinking the roadside water. In cantonments there is nothing in their duties or occupations to render them liable to this class of disease, precautions being taken to prevent their appearance.
9. There is no record in the camp of the trial of small doses of quinine as a prophylactic against malarial diseases.
10. Epidemic diseases very rarely prevailing among the troops at this station; it is not apparent that any permanent measures are required for their prevention or mitigation.

V. Intemperance.

1. The soldiers at this station are temperate, the proportion of confirmed drunkards being about 1 in 200 or ½ per cent.
2. The proportion of admissions into hospital from diseases caused directly by intemperance is 1 in 113, and indirectly from such cause 1 in 28. No statistical records of the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime, being kept in European hospitals, the Committee are unable to furnish a satisfactory reply on this subject. Drunkenness is always punished as an offence.
3. Distilled spirits are sold at the canteen as furnished by the commissariat department, but are forbidden for the soldier in the bazaar. The quality is good, and the amount sanctioned is one dram per diem, of which two-thirds only is generally consumed. Spirit is no part of the soldier's ration at this station, but is so, at the option of the soldier, on the march and in the field. The quality is good, and the allowance is two drams per man per diem. It is not a habit to give a dram before morning parade. Spirit is not given to convalescents. No drinks, other than intoxicating drinks, injurious to health are sold in the canteens, and precautions are taken to prevent it in the bazaar.
4. Spirit, if taken in moderation, is not injurious to the health of the men, or injurious to the efficiency and internal discipline of the corps.
5. As regards a ration of spirits it is seldom given in cantonments; while on the march, when porter or beer are not procurable, we consider spirit advantageous. We do not recommend to abolish the sale of spirits in the canteen. In the bazaar the sale is prohibited, but it is found impossible to prevent the sale in an underhand way. We would rather wish to see the canteen system thrown more open to the soldiers after certain hours of the day, and allow them to obtain spirits, wine, or beer in moderation, to be drunk on the premises, and to do away with the present system of "calling the roll of different companies, for the men "to come to the table and swallow down at a gulp their allowance." The canteen might be conducted as in England, with tables, and forms, where a soldier might call for what he wants and sit down and drink it at his leisure. This would, we are convinced, check the demand on the unlicensed seller in the bazaar, and the disposing of his unwholesome and diabolical liquor.
6. The use of malt liquors or wines are, to a considerable degree, less likely to produce visceral congestion, the fertile source of all tropical disease, than spirits, as the latter produce the same effect on the system as the elevated temperature of the tropics.
7. Coffee, tea, lemonade, &c., are much used at this station, but there are no data in existence on which to offer a satisfactory opinion as to their influence on health, efficiency, and discipline, as compared with spirits and malt liquors.
8. The spirit ration no longer exists in cantonments; porter is given as a substitute, with benefit to the health of the troops.
9. It would not be advantageous to prohibit the sale of spirituous liquors in the canteen, but it is very desirable that good malt liquor, coffee, tea, &c. should be sold as well.
10. We have no additional recommendations to make on these points.
11. The orders and regulations for the supply of liquors in the bazaars to natives, as also the license granted to European shopkeepers, are seldom infringed, the penalties being very heavy, when any parties are convicted of having surreptitiously sold any liquor otherwise

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	than as the regulation provides. No liquor is allowed to be given or sold to any European soldier, their wives or children, in the bazaar. All classes of natives who act as soldiers' servants must drink their liquor at the shops, and for this observance the kelals are held responsible. Liquor sellers have to purchase their supplies from the liquor contractor, and no other person. No liquor is allowed to be brought into camp without a pass, nor is any allowed to be sold except between the hours of six o'clock, a.m. and 8 o'clock p.m.
VI. Diet.	1. The ration for Queen's British troops and European troops in the Indian Army is the same, and is composed as follows: 1 lb. bread, 1 lb. meat, beef, twice a week mutton; 4 oz. rice; 2½ oz. sugar; $\frac{5}{7}$ oz. tea or 1$\frac{3}{7}$ oz. coffee; 1 oz. salt; 1 lb. vegetables, according to the season, but at all times ½ lb. of potatoes; 3 lbs. of firewood. The soldier has three meals per diem. The only periodical changes are in vegetables. Prior to their issue the rations are inspected by the officers on duty agreeably to Her Majesty's Regulations, by the quarter-master, and occasionally by the commanding and medical officers. 2. A complete ration, with a due proportion of vegetables, is issued to the soldier daily, but fruit does not form any portion of it at this station. The stoppage for this ration is 3 annas 4 pie daily. The soldier has three meals per diem, viz.: breakfast, at 8 a.m., of bread and tea; dinner at 1 p.m., and composed of meat and vegetables, cooked as most agreeable to the men, as curried, stewed, or roasted, and the evening meal, at 6 p.m., of bread and tea. The proportion of vegetables which enters into the ration varies according to the season, but at present the 1 pound is made up as follows: viz., ½ lb. potatoes, ¼ lb. cabbage, and ¼ lb. onions to each man. 3. The ration being so ample we have no suggestions to offer. To prevent the troops from disposing of any part of the rations precautions are taken by a non-commissioned officer being made responsible for them until they are served out to the men at the hours appointed for meals. 4. The means for cooking available at this station are of the most simple description; large and small copper vessels, tinned twice a month, and oftener if necessary, resting on iron stands over wood fires, and a spit for roasting. Permanent brick ovens are supplied in some barracks, but are not generally used. The kitchens are not sufficiently large, and, being over-crowded by native cooks, are not so clean, light, or well ventilated as they should be. They are sufficiently supplied with water. The food is boiled, roasted, and fried according to the option of the different messes. The ration is also occasionally made into curry. The cooking is properly done and sufficiently varied. Tea and coffee are properly prepared. Coffee is prepared by a canteen man before a march, and is supplied, on payment, to any of the men who may desire it. 5. Gardens for the cultivation of vegetables by soldiers could be advantageously established near the station as a recreation for the men.
VII. Dress, Accoutrements, and Duties.	1. The soldiers' dress and accoutrements at this station are composed as follows: a wicker helmet, made in India, with a turban; a forage cap (English); a tunic, cloth, and one of serge, alternate years; black cloth trousers (English); blue size trousers; six calico shirts; six pairs socks; two suits of khakee clothing; three pairs boots (1 pair English every year); three flannel waistcoats, and two flannel belts. The accoutrements as in England. With the exception of the cloth tunic and trousers, which we consider made of too heavy a material, we think the present dress is suitable to the climate; they should be made of a light material. When the troops are on field service during the hot season they should be supplied with cumberbunds as a protection to the spine and stomach from sun heat. The guard dress from 1st October to 15th June is khakee clothing by day; but at night black or blue trousers, with red serge tunic, occasionally changing to the cloth tunic on cold nights. From 15th June to 30th September red serge tunic with black or blue trousers, both by day and night. The greatcoat is taken on guard and worn when desirable, and the men mount with packs, but do not carry them on sentry. There are permanent guard rooms with sun-shades for the sentries large enough to walk about under.
Duties.	1. Soldiers should not be sent to India under 20 years of age. They should be thoroughly drilled at home, and the more they know of their duty the better. 2. The soldier at this station rises at 4.30 a.m. in the hot weather, and goes on parade about 5 a.m., with a half to one hour's drill or inspection parade with or without arms. In the cold season he rises about 5.30 a.m., drills and parades till 7 or 8 a.m., according to circumstances. Evening parades are from 5 to 6.30 p.m. Every attention is paid to the health of the soldier, and seldom does a commanding officer distress them at drill. We do not consider their health suffers from the routine of duties or drill in the garrison. The best time for drills and parades is early in the morning, and from 5 to 6.30 p.m., and marches should generally be made during the night, so as to arrive at the halting place by about half an hour after sun-rise. Orders are invariably issued, drawing the attention of the commanding officer, that the men never be kept out in the sun. The average number of nights the men have in bed here during the week is between four and five. 3. The most distant guard from the lines is about a mile and a half. The guards mount at sun-rise for 24 hours. Roll calls are made by companies at breakfast, dinner, and tattoo. There are none at night, as a general rule, but occasionally, if required. The men do not appear to suffer from the night duty. The men always take their bedding on guard with them, and it is carried by coolies, who are paid from the canteen fund. Boards and trestles are provided in each guard room.
VIII. Instruction and Recreation.	1. The following are the means of instruction and recreation:—There is a ball court, one skittle ground, and another sanctioned; schools, with good schoolmasters, and a library and reading-room, but these latter being at this station attached to the schools are on that account objectionable. They are sufficiently lighted at night. There are neither day-rooms or soldiers' clubs, soldiers' gardens, workshops, theatre, or gymnasia at this station, but the three latter are much needed. At present the means are not sufficient to keep the men occupied during the wet season and heat of the day, but if the deficiencies were made good we hope they would prove ample. The men are not allowed to expose themselves to the sun between the hours of 8 a.m. and 4 p.m. The medical officers are of opinion that the health of the men has not been affected by unnecessary exposure to the sun and rain. 2. Every means should be taken to afford places of amusement; a room should be set apart for a theatre, and a reading-room separate from the school-room, as it is found inconvenient to

References to Subjects and Queries.	Replies.
VIII. Instruction and Recreation—*cont.*	have them combined. If the fives court were covered in it would afford amusement during the day, and also be suitable for rackets. A skittle court is highly desirable. A workshop for men to follow their trades is absolutely necessary, and every facility should be afforded to the industrious soldier to follow his trade. At present they have no means for such employment and of assisting their comrades. Gardens would prove advantageous as a recreation. 3. A savings' bank exists here, and is much approved of by the soldier who has any tendency to lay by any of his earnings. 4. There are merely open verandahs to some of the barracks, which are made available for exercise, and we would insist on the adaptation of open verandahs to all barracks and other military buildings at this station. There are no trees or shade sufficient for the purpose of taking exercise.
IX. Military Prisons.	1. There are no military prisons, and we would strongly suggest the adoption of one at this station for the troops of this division. The cells are sufficient in number, and we have no objection to offer relative to their effect on the health of prisoners; but as regards prison discipline they are very deficient in arrangements and detail. If they are retained a house is required for a provost serjeant, a wall with railing to encircle them, a guard-room at the entrance, and a shed for exercise and drill. A cook-house and privies are absolutely needed.
X. Field Service.	1. There are no local regulations for field medical service not included in the general presidency regulations. 2. According to the existing regulations in the local army, medical officers can only make recommendations; it rests with the military authorities to carry them into effect, the medical officer having no authority *per se*. By the new medical code of the royal army these duties are much better defined. 3. The selection of encamping grounds rests entirely with the Quartermaster General's department; the medical officer can only (on arrival of the force) suggest or recommend; in the same way with the general arrangements for cleanliness, &c., there being no general sanitary regulations on the subject in the local army. When troops are marching, and more than one medical officer is present, one should accompany the officer of the Quartermaster General's department to assist him in the selection of the site and general sanitary arrangements of the camp, with power (if they differ) to refer personally to the decision of the commanding officer. Instructions and rules as to choice of proper sites, water soil, sanitary regulations, &c. should be published as means of guidance. Water is supplied to the men by puckal bheesties, to the hospitals by a permanent establishment, according to strength. 4. All arrangements and regulations with respect to field hospitals, ambulances, &c., will be found on a reference to the general presidency regulations, and the medical codes of the royal and local armies, all of which must be in the office of the Secretary of State for India.
XI. Statistics of Sickness and Mortality.	The following are the statistics of the station:—

Note.—No reliable statistical information as to the diseases and mortality of native population procurable.

By order of the Principal Inspector-General, Medical Department.

Office of the Principal Inspector-General, Medical Department,
Bombay, 30th January 1860.

W. C. COLES, Assistant Surgeon
Secretary.

FOONA. BOMBA

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1, 2. Plans of the hospitals, showing position as regards barrack buldings and the bazaar, are transmitted. The sites of the hospitals are generally open, and freely ventilated, and there are no causes interfering with the ventilation. The sites are generally healthy, and no nuisances arising from drainage, malaria, river banks, marshes, nullahs, ditches, water pits or foul ground, exist. 3. Although the supply of water in camp is generally insufficient, the supply to the hospitals is abundant and wholesome. 4. There is no regular system of artificial drainage in this camp, it not being allowed by Government regulation. All refuse water and other impurities are carried away by sweepers employed for the purpose, to such a distance from the camp as to ensure perfect immunity from noxious influences. 5. The lowest wards of the hospitals are raised an average of 3 feetabove the ground, but there is no perflation of air beneath the floors. The roof water sinks into the subsoil. There is no surface drainage or guttering round the hospital; but from the porous nature of the soil and the situations of the hospitals the rain fall is rapidly carried away. The hospitals are built of brick and mortar, or brick and mud pointed with mortar. The roofs of the two native hospitals are thatched, those of the Europeans tiled; the floors of the former are made of a light description of clay, those of the latter are flagged. The roofs and walls are single, but sufficiently thick to keep the hospitals cool. Verandahs do not exist in the European hospitals, but they do in the native hospitals, and these average 10 feet wide, and afford sufficient shelter from the sun's rays. The verandahs are not used for the accommodation of sick, convalescents or others. The hospitals consist of one flat.

TABLE OF HOSPITAL ACCOMMODATION.

Wards.	Regulation No. of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area, in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.			Remarks.

Horse Artillery.												
Hospital - - -	21	$62\frac{1}{2}$	24	18	27,000	1,286	71	1 4	14	3	5	Built in 1860; additions made in 1848.

As far as practicable 1,800 cubic feet of air are allowed for each patient.

The hospitals are so placed as to receive the full benefit of prevailing winds.

The windows open outwards, and their arrangement and construction are conducive to coolness and ventilation.

6. The means of ventilation in the hospitals are the doors, windows, and cowl ventilators; but these are scarcely sufficient for the purpose. A portion of the roof should be raised a foot above the lower portion entirely round the building. There are no jalousies or jhilmils.
7. The air, during the hot season, is cooled by passing through tatties, formed of a fibrous root (the "kus-kus,") which are kept constantly watered by coolies, and by punkahs.
8. There is no necessity for warming the air admitted to the hospitals. The walls and ceilings of the wards are cleansed and whitewashed whenever they require it.
9. The privies are the same as those in use in barracks. They are washed out frequently by the sweepers, are not placed over cesspits, but a deodorising material being supplied, when properly and effectually used they are not offensive. The medical officer is held responsible for this.
10. Tubs and basins, with an ample supply of water, are alone furnished for lavatory purposes at the hospital; but permanent lavatories with shower baths are much needed.
11. There are no bathing places here for the sick; but the general means for giving them hot water and other baths are supplied.
12. The washing and drying of the hospital linen are carried out by the commissariat department outside the limits of the cantonment.
13. The storage is amply sufficient.
14. The cots or bedsteads in the hospitals consist of iron frames, with broad cotton tape bottoms. The beds of the Europeans are made of quilting stuffed with straw, but the natives use their own bedding, which is simply a small rug or carpet. Some of the cots have a moveable head and foot piece. Warm cumble blankets and sheeting are amply supplied by Government.
15. The hospital kitchens are of the usual construction, and situated conveniently to the wards, and the means and apparatus are the same as those already described, and are sufficient. The cooking is properly done and sufficiently varied.
16. The diet tables and returns used in European hospitals are forwarded; but all those in use are to be found in the General Presidency Regulations and the medical codes of the Royal and local Armies. Native troops diet themselves both in and out of hospital.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	17. The establishments of sick attendants are according to Government Regulations, to be found on reference to the General Presidency Regulations and medical codes of the local army. The attendance is found sufficient. 18. The sanitary state of all the hospitals is good; and no epidemic disease, hospital gangrene or pyœmia have appeared in the wards. 19. I would suggest the following improvements:—Verandahs all round the hospitals; separate wards for contagious and epidemic diseases, a distinct ward for obstetric cases to be attached to the female hospitals, with residences for the matrons. Good accommodation for the hospital subordinates and the hospital sergeant is wanting, besides the deficiencies already mentioned. 20. Convalescents, unable to take walking exercise are carried out in doolies. There is sufficient ground round the hospitals for general exercise; but there are no shaded walks or seats. 21. There is some accommodation at each of the European hospitals for the sick wives and children of soldiers. The arrangements in this respect are, however, very unsatisfactory, being too small, which renders it necessarily to all, and the women and children at their quarters, a source of great inconvenience and danger. 22. There are no special local hospital regulations not included in the General Presidency Medical Regulations. 23. The powers of the medical officer as to sanitary arrangements and repairs in the hospitals are confined to recommending what is desirable, to be supported by his medical superior, and eventually carried into effect by the various departments within whose province their fulfilment rests. All subjects connected with dieting the sick, medical comforts, &c., rest with the medical officer, subject to after supervision. 24. There are no wards or hospitals for convalescents at this station, but in in this country we are of opinion that such accommodation is highly desirable.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is about three quarters of a mile from the station, and is to the leeward of the prevailing winds as regards the station. Its area is 149,000 sq. feet; it has a surface of black soil, and subsoil of moorum. Drainage is not required; and the ground is carefully kept; decomposition takes place rapidly. 3. The grave space allowed is 2½ by 6½ feet, with an interval between each grave of 2½ feet, and a depth of 6 feet. The graves have not as yet been re-opened. Interment is compulsory, both at ordinary times and during epidemics, within 12 hours; and the same in native burial grounds. 4. The grave yard is sometimes a little offensive in the hot weather, but not sufficiently so to become a nuisance. British troops are buried agreeably with English customs. 5. The dead of camp followers and bazaar people are disposed of according to religious caste. Hindoos are burned; Jews and Mussulmans buried. 6. No injury accrues to the public health from the present practice. 7. No improvements, in the shape of regulations or otherwise in the burial, or disposal of the dead, are suggested.

I. Topography.	1. The country surrounding the station is barren, but with occasional patches here and there of vegetation and groves of trees. It is dry and undulating, with hills and spurs of ghat within distances of from 2 to 14 miles. There is no wood or jungle in the vicinity. The river runs round three sides of the cantonment, in some parts bordering it; but generally from half to three-quarters of a mile from those parts used as barracks. 2. The station is elevated about 1,900 feet above the sea, but is on a level with the adjacent country. There is no higher or healthier ground adjoining the station, except the minor hills mentioned above; but none of these afford the space of table land requisite for a cavalry regiment. 3. The nearest table land is distant about half a mile, and may rise about 300 or 400 feet, and the nearest mountain is Surghur, about 2,500 feet above the station, and distant 15 miles. 4. The nearest water (except wells) is the river Moola, distant half a mile. There is no lake, marsh, nullah, or canal within 4 miles, and the vicinity of the station is not liable to overflow. There is no broken ground near the station, but there are some water pits between the lines and the bazaar, which fill in the monsoon, are a receptacle for filth, and near enough to be prejudicial to health. 5. The station is open and freely exposed to winds, and is encumbered in no way by anything so as to interfere with either free external or internal ventilation. The temperature of the station is raised by exposure of the buildings to reflected sun heat, the station being too largely scattered for such a contingency. From November to February cold land winds prevail with occasional sea breezes; from March to June there are hot, scorching, variable winds, and for the rest of the year the prevailing winds are from the sea. The cold and rainy seasons are beneficial to the health of the troops, but in the hot season fever and congestive visceral disease prevail.

KIRKEE. BOMBAY.

References to Subjects and Queries.	REPLIES.
I. Topography—*cont.*	6. About one half of the land in the neighbourhood of the station is cultivated, but the remainder is barren. There are no works of irrigation near the station. No rice is grown near the cantonment as the soil is unsuitable for it. Indigo is not cultivated, nor the preparation of hemp or flax carried on near the station. 7. Poona is the nearest large city, and is distant about three and a half miles from the station, but does not affect the health of the latter. The village of Kirkee is so near the cantonment that it is a nuisance. It should be removed, the owners of the houses receiving compensation. 8. The surface of the station is, generally speaking, moorum, with patches of black soil here and there, and below it trap rock. The station occupies new ground. 9. Water is usually found at a depth of about 33 feet below the surface in the dry season, and 19 feet during the rainy season. 10. The river acting as a drain, the rain-fall and water from surface springs flow readily away; but, except where the ravines carry off the rain more directly, it oozes into a pervious soil, and so drains off. There is no drainage from higher ground passing into the subsoil of the station. 11. The water supply of the station is derived from wells, but most of these drying up in the hot season, the supply is then drawn mainly from the river. There are no tanks. 12. The water supply of the station is obtained from 7 wells, averaging 50 feet in depth, and the river. These wells are totally insufficient; they often run short (as in the present season) and Government is then put to the expense of bringing water from the river by water carriers. The bottoms of these wells are, with one or two exceptions, actually several feet above the bed of the river. To be of any permanent service they should be sunk.

The water in the wells is raised by common leather buckets, and taken away in leather skins on the backs of bheesties or bullocks. The water is soft and the quality good, but its microscopic characters are unknown. The water supply of Kirkee is quite inadequate. In the hot weather the wells run dry, and the conveyance of water from the river is an expensive and inconvenient arrangement. In the cold weather Government pays monthly 433 rupees for water carriers, and during the hot months 617 rupees. The wells and the river are at present the only sources from which water is obtained. No aqueduct exists, nor is such a thing as a pump known at Kirkee, and all the arrangements for drawing water are what they may have been some 1,000 years or more ago. The executive engineer says that a scheme was devised in 1853 by Captain Berthon, late Engineers, for bringing water from a nullah about 4 miles south-west of Kirkee, near the village of Pashan, and that his estimate for the same was 75,585 rupees; but the project was ordered not to be carried out, as it was questionable whether the station of Kirkee was to be retained. The scheme was again ordered to be taken in hand in 1857, in conjunction with the design of the new barracks, but subsequently the then executive engineer, Colonel Hart, wrote in to say that he could not possibly undertake it till an efficient assistant was afforded him; and thus the affair has remained in *statu quo* ever since. The contemplation of this scheme has invariably been the excuse from year to year for not going to the expense of deepening the wells. The committee are of opinion that a special officer should be detached to carry out Captain Berthon's scheme of bringing water from the rivulet in question, and that it will be bad economy not to set about it at once.

13. The barracks in reference to the sea breeze, are built on the wrong side of the slight slope on which the cantonment stands. This should be attended to when the new barracks are ordered to be commenced.

14. New stations, whether on hills or plains, are selected by a mixed Committee composed of the senior military authorities, executive engineer, and senior medical staff, who after making inquiry into sanitary and other questions, communicate with the civil authorities, the final decision resting with the Government. Stations have hitherto been selected in the plains.

II. CLIMATE.

1. No meteorological instruments are specially available. Kirkee presents a more favourable aspect as regards temperature, being at all seasons some degrees cooler than Poona.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	3. There is almost a total absence of fog, dampness is only observable in the rains, and then is mild in degree; only garden irrigation and tree planting exist, and do not produce any perceptible influence on the climate. Dust-storms are very rare, only occurring just previous to the setting in of the rains, and they do not affect perceptibly the purity of the atmosphere. The climate is favourable to Europeans. The diet here is good and varied; but the barracks are very indifferent with the exception of two new buildings. The precautions necessary to be observed are:—duties should be light, and drills take place early in the morning, and in the evening. Woollen clothing should be worn during the rains, and khakee clothes during the hot months. The most healthy months are July, August, September, December, January, and February, and the most unhealthy October, November, March, April, May, and June. During October and November, owing to the cessation of the rainy season, with elevated temperature, remittent and intermittent fevers, with visceral diseases prevail; during the hot months of March, April, and May, these, and also eruptive fevers and congestive diseases of the cerebral, thoracic, and abdominal organs, and in June, bowel complaints are frequent. Rheumatism prevails during the cold months. 4. There is no district near the station more conducive to health that would be available for cavalry. If the barracks are rebuilt, it would be desirable to select a better site in advance of the present position, where the ventilation would be much improved. 5. We have served in most of the stations of the Deccan, the Southern Mahratta country, the Mhow division, Sinde, the Concan and Guzerat. These stations in the Deccan being on an elevated table land of the trap formation, and about 1,800 feet above the level of the sea, are the most conducive to the health of troops. Next in degree are those of the Mahratta country, and Mhow division from similar causes, and next those in Sinde, although the elevation is slight; the country surrounding the station being for the most part a sandy plain, free from jungle vegetation. The stations in the Concan, or coast border of the presidency are comparatively healthy, being situated within the full influences of the sea breezes, but they are, however, subject to severe visitations of epidemic and zymotic diseases. With the exception of the Deesa station, (salubrious from being situated in an open sandy plain), the stations in Guzerat are positively injurious, the elevation above the sea being very slight, and the soil alluvial, with a rich rank vegetation, and abounding in rivers with a small degree of fall, exhibiting extensive alluvial banks.
III. Sanitary Condition of Station.	1, 2, 3. Map and plans of the station, and the surrounding country, and plans of the station are transmitted. 4. Table of Barrack accommodation. Date of construction—new barracks in 1843 and 1852. Old barracks in 1827 and 1837. 5. There are no properly constructed windows, but wooden shutters, which fold back on hinges, on all four sides of each barrack. There is an open verandah along the south side of each of the old barracks, about five feet wide, and in the two new barracks an open verandah about nine feet wide on the north side. There is also an enclosed verandah of same width on the south side; except on an emergency, these verandahs are never used as sleeping quarters by soldiers or other persons. There are no jalousies or jhilmils, except in the two new barracks, which are properly made. There are 14 old, and two new barracks.

6. The majority of the bedsteads used in barracks are merely boards and trestles, but there are a few iron bedsteads, with cross thin iron straps. The bedding for each soldier consists of one numda, two cumlie blankets, and two pairs of sheets, with one cotton coverlid, all supplied by Government. The Committee are of opinion, that iron cots should be generally substituted for the boards and trestles as securing greater health and cleanliness.

7. The following Tables show the structure and dimensions of the tents used in camp:—

Tent for European soldiers, double poled, with fly and shed, and single set of walls.

Extreme length within,	22 feet - -	For 14 horse artillery.
,, breadth ,,	14½ ,, - -	or 22 foot ,,
Height of walls	12¼ ,, - -	or 22 infantry.
,, to ridge	12¼ ,, - -	or 16 cavalry.
Total area	- -	319 square feet.
Cubic space	- -	2,393 cubic feet.

Tents for European soldiers, single pole with fly, shed, and single set of walls.

Extreme length within,	14 feet - -	For 8 horse artillery.
,, breadth ,,	14 ,, - -	or 10 cavalry.
Height of walls	6 ,, - -	or 13 foot.
,, to cap	12 ,, 2 inches -	
Area	- - -	196 square feet.
Cubic space	- -	1,268 cubic ,,

} For 12 Europeans, or 15 natives.

This gives about 30 square feet
And 260 cubic „
} Per European.

Hospital tents for native soldiers, double pole, oval shape, with fly only.

Extreme length within, 26 feet 8 inches
„ breadth „ 13 „ 9 „
Height to ridge, 9 „ 6 „
} For 25 cavalry, or 30 infantry.

Area - - - 383 square feet.
Cubic space - - - 1,030 cubic „

8. In the old barracks, which include all except two, there can scarcely be said to be any ventilation. Each house, however (holding half a troop), has two small pigeon-house (louvre boarded) ventilators in the roof, but the construction of these is so imperfect that during the annual rains, when ventilation is most needed, they are obliged to be covered with tarpaulin by the Engineers' Department. The ventilation of the new houses is by louvre boards on the sides, and holes (of insufficient size) in the upper part of the walls of the sides, and ventilation through the roof at the top with louvre boards. The ventilation on the whole in the new houses is good. The huts and guard-rooms have no ventilation whatever, except what they receive from doors and windows. The ventilation is not sufficient to keep the air pure by night. Some arrangements should be adopted (which the soldier could not interfere with) for the free ventilation of the rooms when the doors and windows are closed. There are no means used in the barracks for cooling the air admitted.

9. The two new barracks are of burnt brick and lime; the remainder are of burnt brick and mud. The floors of the new barracks are paved; those of the old ones are of earth. The roofs of the former are tiled, and those of the latter thatched. The huts, or married men's quarters, are constructed, some of stone and mud, and some of wattle and daub, and are mostly thatched.

10. The flooring of the 14 old barracks is of mud. They can scarcely be said to be raised above the level of the ground; and such being the case, there can of course be no passage of air underneath. The floors of the two new bungalows are of stone. They are raised three feet above the ground, but there is no passage of air beneath them.

11. The materials of which the two new barracks are constructed are good; those of the other 14 decidedly the reverse. The former would be vastly improved by a continuous ventilator in the roof, as in the new upper-storied barracks at Poona. Of the remaining barracks it can only be said that they are condemned, being merely old, worn out, thatched sheds. New barracks are sanctioned, and the sooner they are begun the better, as these present old places are hardly habitable, and not suited to the climate. In fact, they are defective *in o*. In this country, barrack rooms should be elevated above the ground at least 14 feet, as such an arrangement entails, at all times, a clearer and more healthy atmosphere for the soldier both by day and night. The lower portion of the building might be converted into dining rooms, washing rooms, libraries, skittle alleys, &c. Most of the subsidiary detached buildings would thus be done away with, and no extra expenditure entailed. We would also strongly advocate, for all new barracks, the adoption of open verandahs, as the men like them, and they add to the ventilation of the barrack rooms. Some of the lower portion of the building might be made available for saddlery, and harness for horse artillery, and cavalry respectively. The barracks and cantonment are kept in repair by the executive engineer, and the repairs are mostly executed by native contractors, and oftentimes delay is experienced in consequence of the natural dilatory disposition of the native, want of sufficient supervision, and other circumstances. No officer is responsible for the general sanitary state of the cantonment. The Committee strongly recommend that it should be the *sole* duty of a separate medical officer to attend to the sanitary state of so large a cantonment (including Poona and Kirkee). The walls and ceilings of the barracks are cleansed and limewashed at intervals of three months, and oftener, if necessary. We would recommend that in future barracks be whitewashed "Regimentally," and that lime, brushes, &c., should always be kept in store by the quarter-master.

12. The lavatories at this station are merely open, paved verandah rooms, with tubs placed in them, amply supplied with water. The waste water runs off into tubs placed outside. We would recommend that instead of these, wedge-shaped cesspools of cut stone, guaranteed against leakage, should be adopted, or, which would, perhaps, be better still, iron tubs, japanned or glazed. There are two washing-rooms generally to each barrack room.

13. The regimental cook-room here is a simple rectangular building, with an opening in the roof and walls for the escape of the smoke. The fire-places are nothing but masonry platforms, about two feet high, with iron rests, called choolas, for the cooking-pots. In all these cook-houses the ventilation is so imperfect that the escape for the smoke is insufficient. Water is provided by bheesties. The refuse water is drained into cesspools, which are cleaned out nightly by halalcores or sweepers. Large iron japanned glazed tubs would be better still. The washing and drying of linen in India are invariably done by the natives, who take the clothes away, wash them, and bring them back clean and dry, except during the rains, when the natives have no means of drying them, and necessarily bring them home wet. The Government do not provide the troops with any means of drying the linen. The captains of troops, however, provide, at their own expense, large baskets over pans of lighted charcoal, on which the clothes are placed and dried. The Committee are of opinion that captains of troops should not be put to this expense.

14. A plan of the privies, &c. is transmitted. The privies for Europeans are simple buildings, and will be easily understood by the sketch forwarded. The filth falls into baskets, and is carried away by sweepers, and the urine drains into cesspools. Pans, similar to those recommended for the cook-rooms, would be better than cesspools, and we would recommend that in lieu of the baskets the pans be adopted. The contents of the privies are

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	carried away twice a day by the natives, to a spot about half a mile distant from the barracks. When the wind sets from that quarter, the smell is sometimes complained of. A kiln in which to burn the filth is in course of construction. 15. Each barrack (holding half a troop) is lighted by four single wick oil lamps. In no case is the light given by the barrack lights sufficient for a man to read by, and those men who wish to read are obliged to purchase oil and lamps for themselves. We would recommend that similar lanterns to those used on board of Her Majesty's troop ships (swinging lamps and deck lamps) should be introduced as an experiment. 16. No arrangements for drainage exist in the barracks. All deposits, waste water, filth, &c., are removed to a specified locality by the sweepers. There is no drainage for carrying away the refuse water from the wash-houses, cook-rooms, privies, &c. In the two new barracks there are two small pits, about nine feet from the end of each building, which are cleaned daily. In the other barracks the water runs out into tubs. The urine is deposited in iron vessels, which are emptied three times a day, by sweepers, into leather bags, and these are carried away by bullocks, and emptied at a proper distance from the barracks. The buildings used as barracks and hospitals are all dry in the dry weather, which lasts nine months, but are wet and damp during the remaining three months. The primary cause of the damp is the excessive amount of moisture in the air during the wet season. Pans of lighted charcoal are placed in the rooms, for as long as may be deemed advisable, when necessary. As before mentioned, all refuse, both fluid and solid, is carried away by the sweepers. There are small cesspools, three feet by three feet by three feet; but, as above mentioned, they are daily cleaned out, and are not in the vicinity of any wells. There are no ditches near the station. 17. The surface cleansing of the cantonment is done by natives, and, so far as the defects stated above will allow, is well done. Everything solid is removed daily, or twice a day, to a spot half a mile distant, to be burnt. The manure is removed daily to a distance and sold. 18. The surface of the cantonment is kept free of vegetation. There are no old walls, and the hedges in the camp are kept cut to a certain height, so as not to interfere with the ventilation of the station. We would recommend that householders should be forced to remove these hedges, and substitute low masonry or brick walls. We are also of opinion that all hedge rows outside, but in the vicinity of the camp, and on either side of the road, leading from Poona to Kirkee, should never be allowed to exceed 3 feet in height. 19. The drainage of the bazaar in this station is less objectionable than is usually the case in most Indian bazaars, and, not being crowded, there is little fault to be found in the ventilation. The river runs within 80 yards of the base of the bazaar, so that the water supply is sufficient. The bazaar is kept clean. Latrines have been much wanted for the station. These have just been sanctioned, but an extra one is specially needed for the bazaar people. The chowdrie of the Kirkee bazaar, which belongs both to the regiment and the station, inspects it daily, to see that it is kept properly clean. The conductor also visits this bazaar four times a month. The dust is carted away to the jungle in the same way as in the Sudder bazaar in Poona, and by the same establishment. The native houses near this station are of fair average construction, and there are no dung heaps nor cesspits within them. No nuisance is experienced in barracks from wind blowing over the native houses. 20. There are no slaughter-houses at Kirkee, the meat for the soldiers being supplied from Poona. 21. The camp bazaar horses are picketed outside and to leeward of the followers lines and the bazaar, in places about half a mile distant from the station, and to leeward of the barracks. The manure is carted away by the surrounding gardeners, tile makers, &c., or taken to the jungle. It is cleared away daily. Horses for private purposes are kept in stabling in the compounds of the house owners, and the manure is disposed of as above. 22. There are no stables, except for sick and delicate horses. The horses of the regiment are picketed out in lines; but these lines are not to windward of either the mens' barracks or the hospital. The manure is removed daily by the native followers, and sold to a contractor. The horses are picketed in open columns of troops (from 30 to 40 horses in each line), distant about 80 yards from the barracks, and about double that distance from the hospital. 23. The quarters for married non-commissioned officers and men are sufficient in number, but extremely bad in construction, except a portion for the superior non-commissioned officers, for whom the accommodation is excellent. There are no married people in barrack rooms.
Officers' Quarters.	1. There are no officers' quarters at this station, but the officers rent houses built for them by speculators in the cantonment. As regards any sanitary improvements we have no suggestions to offer.
IV. Health of the Troops.	1. The station, district, and adjoining native population are healthy. 2. Spleen disease is very rare here, but at the setting in and termination of the rainy season, bowel complaints and fevers of the intermittent and remittent types prevail; during the hot season eruptive fevers, particularly variola, varicella, and rubeola, and during the wet and cold seasons catarrhal and rheumatic affections are prevalent. 3. This healthiness is attributable to the elevation and the trap formation of the surrounding country, its freedom from alluvial deposits, and the general prevalence of westerly or sea breezes, and to good water. 4. The regiment came straight from England, and landed here in October 1858; the men were healthy on disembarking. The chief diseases since have been fever and diarrhœa, and about six deaths from cholera. The married men's quarters, on the right flank, are very bad, ventilation deficient, and during the rainy season they are very damp. 5. The men at this station are not camped out. 6. We have never been in charge of troops at hill stations. The following replies are founded on the opinions of C. Moorhead, Esq., M.D., late acting superintending surgeon at Poona, and published in "Transactions of Bombay Medical Society." His experience and researches are favourable to hill stations for troops, provided a proper season is chosen for sending them; and, if sick or convalescent, a proper selection made. His experience is founded on personal knowledge, and the reports of medical officers stationed at Malcolm Pait, on the Mahableshwur hills, and at Poorundhur. 7. Dr. Morehead states, if the debilitated soldier, who in the plains would recover his health and strength slowly after the removal of positive disease, will (by commencing a residence on the hills in October, or during the hot months, having become fitted for duty) be less liable to fresh attacks of disease, and, when attacked, the disease will be of a milder type, whereas, on the other hand, the continued residence in the plains leaves him predisposed to

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops—*cont.*	attacks of the severer forms of disease. The ultimate effect of a freer use of hill climates must be to reduce mortality and invaliding. He disapproves of sending troops during the cold or rainy months, if sick, as liable to be injured by a return of former diseases. 8. Hill stations should decidedly be selected for troops, but only as a change of climate. 9. Convalescents sent to the hills in the cold and rainy seasons are liable to recurrences of organic visceral disease. Again, if troops go to them exhausted by service in the field, they are liable to congestive, inflammatory, and organic visceral diseases, otherwise they are only subject to mild hill diarrhœa, and the general effects of a rarefied atmosphere. 10. Concerning diet, clothing, shelter, exercises, &c., no data are given in Dr. Morehead's report. The inference, however, is clear that, as there is liability to the formation and recurrence of visceral disease, cerebral excitement, and other complaints of the sthenic type, the diet should be of a non-stimulating nature, the clothing adapted to a climate much cooler than that of the plains, the shelter affording perfect protection from fogs, rain, and the direct rays of the sun; the duties and exercises depending upon the improving health of the soldier. 11. From the reports of the medical officer of the Deccan hill stations, it appears that, from the commencement of the month of March to the middle of the month of November the greatest advantage to health will be gained by the debilitated or convalescent from disease at Poorundhur; the rainy portion from June to October is inapplicable to Malcolm Pait. The healthy soldier may reside with advantage at Poorundhur and Panch Gunny at any season. As far as practicable, all ailing men should be afforded one month's residence in the hills; but the period required for complete restoration will vary in different cases, and its determination should be left to the discretion of the medical officer in charge of the sanitarium. 12. Applying the question to the hill stations of the Deccan, as affecting the health of troops returning to the table land on which the military stations are situated, or to other stations in this presidency, Dr. Morehead states that the hill climate from the middle of November to the end of February might not prove injurious; still it possesses no advantages over that of the Deccan, and that season is most suitable for return to all stations in the plains. 13. Proper selection of period, and good ambulance, are the precautions necessary for protecting the health of troops on their leaving hill stations for the plains. 14. Dr. Morehead says the question has been often raised, would a regiment fresh from England, located at an elevation of, say, 7,000 feet, retain its European vigour? Doubtless it would, a deduction being made for a rarefied atmosphere. But this regiment would not be efficient for the contingencies of service in India, and if suddenly called to the plains for service in the hot season, it would show a heavy sick list and a rapid loss of vigour and stamina would ensue. But an improved state of general health will accrue to the soldier in India from an improved sanitary system, including the avoidance in the hot season of the heat of the plains by a more extended resort to hill stations. The maintenance of the greatest degree of health and efficiency for the ordinary contingencies of service in a tropical country, is to be obtained by avoiding, as much as possible, unhealthy localities and seasons, such as localities with malarious characteristics, the hot season all over India, and the rainy season in many parts of it. These points attended to, frequent change (which is most harassing to the soldier) will be quite unnecessary, and can only be deemed even advisable when troops are located in unhealthy districts. 15. The amount of barrack and hospital accommodation provided at hill stations is totally insufficient. There are two recognized sanitaria in the Deccan, viz., Malcolm Pait, established in 1828, and the hill fort of Poorundhur in 1852. European troops have not been located at the former, but there are Government quarters for 16 sick officers, and also 77 private bungalows. Upwards of 300 visitors resort there annually, with such a favourable result to health that, with proper hospital and barrack accommodation, it might be rendered an equally favourable sanitarium for troops, except during the rains, when the fall of rain, about 240 inches, renders it uninhabitable. But at a distance of 10 miles, on the eastern slope, Panch Gunny, at about 500 feet less elevation, with a fall of only 80 inches, would render this circumstance avoidable. At Poorundhur there are two barrack rooms, affording accommodation for 100 men, a very good hospital for 40 sick, a patchery for 10 families, and a small female hospital. The sanitarium may at present be considered sufficient for 130 soldiers and 10 families. 16. An average height of 4,000 feet above the sea affords the most suitable sites for hill stations. 17. The nearest ground (higher than the station) is Poorundhur, distant about 25 miles, and with an elevation of 4,200 feet. Its means of access are very indifferent. There is much atmospheric dryness in March, April, and May, and the rain-fall during the rainy season is 72 inches, when Poorundhur is frequently enveloped in mist. Its mean temperature in the cold season is 67° 5′, in the hot season 75° 5′, in the rainy season 67° 4′, and in October 69° 6′. 18. Surfaces of the trap formation as in the Deccan generally, and also where sand with the detritus of metaphoric rocks prevail, are the most healthy for stations; but where the surface is an alluvial of the peat formation, as black soils, it is most unhealthy, as in Guzerat. 19. Soldiers should on no account proceed to India before 20 years of age, and should land there at the commencement of the cold season, viz., November. In this presidency, when landed in Bombay, troops are first located in barracks situated either in the centre of the Fort or at the end of a spit of land, "Colaba," both of which sites, and the nature of the barracks, have been repeatedly condemned as most unhealthy. The clothing, drills, and marches are according to the season, and the duties are excessively heavy for troops on arrival in such a depressing climate as that of Bombay. If they arrive early in the cold season, they should be at once drafted to their respective regiments, as soon as they have been properly equipped, or to be at once removed to the table land of the Deccan, and to remain there until the opening of the next cold season. Suitable clothing should always be provided for troops immediately on their arrival in Bombay. 20. Troops should be sent to India direct from the home depôts, so as to arrive early in the cold season. Regiments on arrival in Bombay should commence their tour of service in the Deccan table land, as far as practicable. 21. The transport of troops from Bombay to the centre of the Deccan table land is by railway, and from the Deccan to the different out-stations by bullock-train, or marches. The precautions to preserve health are, to march in the cold season; that the marches do not exceed 12 miles, and are made between 2 and 7 a.m., with a halt every fourth march for one day; a

References to Subjects and Queries.	Replies.
IV. Health of the Troops—*cont.*	careful selection of encamping grounds as regards soil, good water, and avoiding neighbourhoods of large native towns on account of probable presence of epidemic disease; good tents, not crowded, and with tarpauling floors, coffee before starting, and no grog before first meal. 22. A British soldier should not serve in India for a period exceeding 12 years, but the President is of opinion that it should be limited to 10 years. 23. The invaliding boards in this presidency are composed entirely of medical officers, and there is no conflict of opinion between them. We would suggest that these boards assemble oftener to afford a more frequent opportunity for the sick soldier being sent home. 24. Invalids proceeding home should leave India in January or February as the most favourable months, and not later than the first week of March, so as to ensure their arrival in England in June, together with a fine and favourable passage, except in cases of a special nature, when they should go overland at all seasons.
Diseases.	1. Inspection parades for the discovery of incipient diseases, at this station, take place weekly, and oftener. 2. No case of scorbutus has taken place among the troops here. 3. The proportion of cases of hepatic disease usually under treatment is 1 per cent., it is generally combined with dysentery; it is to be attributed to the effects of the climate and constitutional predisposition or intemperance. 4. Dracunculus is occasionally prevalent at this station. The origin of this disease has not been determined, and its propagation is involved in obscurity. 5. The proportion of cases of venereal disease among the European troops is 14 per cent., and among the native troops about 3·5 per cent. To diminish the liability of the soldier to these diseases I would suggest the strict examination from time to time of the prostitute class, and the removal of those diseased from the bazaars. The establishment of lock hospitals would be greatly advantageous to the health of the army. 6. The troops at this station suffer from the following diseases, viz.:— *Fevers*, intermittent, of the tertian and quotidian types, and also from remittent. *Dysentery.*—Acute, the result of chills; and sometimes attributable to habits of intemperance. *Cholera.*—The different forms of Asiatic cholera. *Small-pox* is not frequent. *Rheumatism.*—Frequent. The following is the proportion which admissions and deaths from these diseases bear to the total admissions, and deaths. Total admission from all diseases during the year 884. Admissions from fever 192; 2 deaths. Proportion of admissions of all fevers to total admissions 21·7; of deaths to admissions 1·0 per cent. Cholera, admissions 7, proportion to total admissions 0·9; deaths 3. Small-pox, none. Rheumatism, admissions to total 2·0 per cent.; deaths none. 7. The nosological character of the more frequent zymotic diseases is as follows:—Intermittent fevers, generally of the tertian type. Acute dysentery, diarrhœa, carbuncle, rheumatism, continued fevers, generally mild; gonorrhœa, syphilis, and ophthalmia. These diseases mostly occur before and after the rainy season, and sometimes during the hot months. These diseases are accompanied by an atmosphere generally oppressive, muggy, and loaded with electricity; they are also frequently preceded by thunderstorms. The European troops at this station exhibit no particular predisposition, from personal habits or condition, to these diseases. The poor natives, occupying small huts or otherwise, crowding together, and having a national objection to the admission of air and light into their dwellings, sufficient causes exist to predispose them to the above diseases, especially among the lower castes, owing to their filthy habits of living and eating. 8. The prevalence of epidemic disease among the soldiers is partly due to the following causes. On the march and in the field curiosity, and other causes, inducing both Europeans and natives to go into the towns and villages near the camp, where epidemic disease is generally prevalent, their careless exposure to the mid-day sun even when exhausted after the march, and their drinking the roadside water. In cantonments there is nothing in their duties or occupations to render them liable to this class of diseases; precautions being taken to prevent their appearance. 9. Small doses of quinine have not been given as a prophylactic, at this station, against malarial diseases. 10. Epidemic disease very rarely prevailing among the troops of this station, it is not apparent that any permanent measures are required for its prevention or mitigation.
V. Intemperance.	1. The soldiers at this station are usually very temperate. The strength of the regiment is about 580, and 3 only have been tried for habitual drunkenness; but 10 others get drunk on every available opportunity, and drink hard. 2. The proportion of admissions into hospital from diseases caused directly by intemperance is 1 in 361. No statistical records are kept in European hospitals to show the effect of total abstinence, temperance, and drunkenness on the amount of sickness, mortality, and crime at the station. Drunkenness is always punished as an offence. 3. Distilled spirits are sold at the canteens as furnished by the commissariat department; but are forbidden to the soldiers in the bazaar. The quality is good, and the quantity allowed to be drawn by each man is one dram. Spirit forms no part of the soldier's ration at the station; but it does both on the march and in the field. The quality is good, and the amount two drams each man per diem; but it is not a habit to give a man a dram before morning parade. Spirit is never given as a ration to convalescents. I am not aware of any drinks, other than intoxicating drinks, being sold at the canteen or in the bazaar. 4. If taken in moderation and diluted, spirits are not injurious to the health; but the drinking of them interferes with the efficiency and discipline of any corps. 5. It would be beneficial to abolish the sale of spirits in all bazaars, but not in canteens. 6. The use of malt liquors or wines are to a considerable degree less likely to produce visceral congestion, the fertile source of all tropical diseases, than spirituous liquors; spirits producing the same effect on the system as the elevated temperature of the tropics. 7. Coffee, tea, lemonade, soda water, &c. are much used at this station; but there are no data to enable me to say what influence they have on health, efficiency, and discipline as compared with spirits and malt liquors. 8. The spirit ration no longer exists in cantonments; but porter is given as a substitute, and with benefit to the health of the troops.

References to Subjects and Queries.	REPLIES.
V. Intemperance—*cont.*	9. The prohibition of the sale of spirits in canteens in England has answered well. 10. I have no recommendations to make on these points, saving those already advanced. 11. No liquor is allowed to be sold in the bazaar to European soldiers or their wives or children, and all natives acting as soldiers' servants must drink their liquor at the shop. The kelals are responsible for the due observance of these rules. The liquor sellers must buy their supplies from the contractor, and from no other person. No spirits are allowed to be brought into the cantonment, unless covered by a pass, and no liquor is allowed to be sold, except between the hours of 6 a.m. and 8 p.m. The bazaar orders and regulations are seldom infringed, the penalties being very heavy on conviction.
VI. DIET.	1. The ration for Queen's British troops and European troops in the Indian army is the same, and is composed as follows:—1 lb. bread, 1 lb. meat, beef (mutton twice a week), 4 oz. rice, 2½ oz. of sugar, $\frac{5}{7}$ oz. of tea, or 1$\frac{3}{7}$ oz. of coffee, 1 oz. of salt, 1 lb. vegetables, according to season, but at all times ½ lb. of potatoes, 3 lbs. firewood. The soldiers have three meals per diem, and the only periodical changes are in the vegetables. A responsible inspection of the constituents of the ration is made by the orderly officer and quartermaster. 2. The daily ration is composed as above. The men have three meals a day at this station; viz., breakfast at 8 a.m., bread and tea (the men generally, however, provide themselves with meat, at their own expense, for this meal); dinner at 1 p.m., consisting of soup, meat, and vegetables; tea at 7 p.m. The stoppage per man is 3½ annas. The men have a cup of coffee and a biscuit early in the morning before going to parades, which they purchase, but it ought to form a part of their daily ration. No fruit is allowed as part of the ration. The proportion of vegetables varies according to the season, but at present the one pound is composed as follows, viz., ½ lb. potatoes, ¼ lb. cabbage, and ¼ lb. onions to each man daily. 3. The president is of opinion that a larger proportion of vegetables should be allowed in the hot season. Precautions are taken that no part of the rations is disposed of by the troops, by a non-commissioned officer being made responsible for them until they are served out to the men at the hours appointed for meals. 4. The means and apparatus for cooking available at this station are of the most simple description. Large and small copper vessels, tinned twice a month, and oftener if necessary, resting on iron stands over wood fires, and a spit for roasting. There is an oven in each cook-house, but too large to be of any use. The kitchens are not sufficiently large, and, being overcrowded by native cooks, are not so clean, light, or well ventilated as they should be, but they are amply supplied with water. The food is boiled, curried, stewed, and fried, and the cooking is good, tea and coffee included. By a regimental arrangement, the men have a cup of coffee or tea and a biscuit before a march, but the charge for this is additional to that for the regular ration. 5. Gardens are of no use in India to a cavalry soldier, as his mornings and evenings are always occupied.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The dress and accoutrements in use here in the cold season are the same as those in England. During the hot weather they consist of wicker helmets with a puggre, two khakee jackets, six pairs of white trowsers, eight calico shirts, two pairs of drawers, six pairs of socks, three flannel waistcoats, and two flannel belts. I consider the present dress as suitable to the climate; but the cloth tunic and trousers should be of a light material. When troops are on field service in the hot season, they should be supplied with cummerbunds, as a protection to the spine and stomach from sun-heat. The guard dress, from 1st October to 15th June, is khakee clothing by day; but at night black or blue trousers, with red serge tunic, occasionally changing to the cloth tunic in cold nights. From 15th June to 30th September, red serge tunic, with black or blue trousers, both by day and night, are worn. The great coat is taken on guard and worn when desirable, and the men mount with packs, but do not carry them on sentry. There are permanent guard-rooms, with sun-shades, for the sentries, large enough to walk under. We would also recommend that a quilted moveable lining be provided to button inside the khakee jacket to protect the spine and loins from the heat of the sun. The present guard dress in the hot weather is khakee, with cloth overalls at night, and wicker helmets during the rest of the year. The men are protected suitably on guard from sun and wet.
Duties.	1. As regards health, it would be advisable that the men should be thoroughly drilled at home before being sent to India. 2. There is generally a mounted drill of about an hour and a half duration about four mornings in the week; after that "stables" for about three-quarters of an hour; and a foot drill in the afternoon twice a week, about three-quarters of an hour in duration. The men do not suffer from drill or work, only from *ennui*. The best hours for drills, parades, and marches are—drills in the cold weather from daybreak till 8 a.m., in the hot weather till 7 a.m., and marches so as to arrive on the camping ground by sunrise. Orders are occasionally issued on these points in the hot weather. The average number of nights the men here have in bed during the week is six. 3. The furthest guard from the barracks is the bazaar guard, about one mile distant. All regular guards last 24 hours. There is a roll-call at 11.30 a.m., at reveille in the morning at 5.30, and names are called over in the barracks. In this part of India the nights are quite healthy, and exposure to the night air has no injurious effect on health.
VIII. INSTRUCTION AND RECREATION.	1. The following are the means of instruction and recreation available at this station:—North and South Ball Courts, schools with good schoolmasters, and a library and reading-room, by subscription among the men. None is provided by Government; but a grant of 200 old volumes was made in its aid by Government. The following do not exist here for the men, but are much required by dragoons, viz., day room, soldiers' clubs, soldiers' gardens, workshops (except for the ordinary regimental tradesmen). There is no theatre, no skittle ground, no gymnasia. If these were supplied, the means would be sufficient to keep the soldier occupied during the wet season and heat of the day. A dragoon has so much to do, morning and evening, that he is comparatively little inclined to knocking about during the day. Every endeavour, however, as far as persuasion and personal influence can effect, is used to prevent the men exposing themselves to sun and rain. A room should be set apart for a theatre; a reading-room separate from the school-room, as it is found inconvenient to have them combined. If the fives court were covered in, it

References to Subjects and Queries.	Replies.
VIII. Instruction and Recreation—*cont.*	would afford amusement during the day, and also be suitable for rackets. A skittle ground is highly desirable; a workshop for men to follow their trades is absolutely necessary. Every facility should be afforded to the industrious soldier to follow his trade. At present they have no means for such employment, and of assisting their comrades. Gardens would prove advantageous as a recreation. 2. In addition to the means mentioned above, we would recommend the adoption of a room well supplied with foils, single-sticks, masks, &c., which would be conducive to the men's health, amusement, and efficiency, as dragoons. 3. Savings' banks are instituted, and are found advantageous. 4. There is not sufficient shade afforded by trees, verandahs, &c., to enable the men to take exercise without injury to health.
IX. Military Prisons.	1. There are no military prisons, but we would strongly suggest the adoption of one at this station for the troops of this division. The cells are sufficient in number, but are deficient in arrangements and detail. If they are retained, a house is required for a provost-serjeant, with a wall and railing to encircle them; also a guard-room at the entrance, a shed for exercise and drill, and a cook-house. Privies are absolutely needed.
X. Field Service.	1. There are no local regulations for field medical service, not included in the General Presidency Regulations. 2. According to the existing regulations in the local army, medical officers can only make recommendations, and it rests with the military authorities to carry them out, the medical officer having no authority *per se*. By the new medical code of the Royal army these duties are much better defined. 3. The selection of camping grounds, and the sanitary arrangements, cleanliness, &c. of the camp, rests with the Quartermaster-General's department. Instruction and rules as to the choice of proper sites, water, soils, &c., should be published as a means of guidance. Water is supplied to the men by puckul bheesties, and to the hospital by a permanent establishment, according to strength. 4. Regulations as to field hospitals, ambulances, transport of sick, &c., will be found by a reference to the General Presidency Regulations, and the Medical Codes of the royal and local armies, in the office of the Secretary of State for India.

By order of the Principal Inspector-General, Medical Department,
W. C. Coles, Assistant Surgeon,
Secretary.

Office of the Principal Inspector-General, Medical Department,
Bombay, 30th January 1861.

KIRKEE. BOMBAY.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1, 2. A plan of the hospital is transmitted. The site is good, freely ventilated, and healthy; indeed, the most healthy in the neighbourhood. 3. Bheesties supply the hospital with water in sufficient quantities, as it may be needed. 4. There is no regular system of drainage in the camp, it not being allowed by the Government regulation; but all refuse water and other impurities are carried away by sweepers to such a distance from camp as to ensure perfect impunity from noxious influences. 5. The floors of the lowest wards are raised three feet above the ground, but there is no perflation of air underneath. The roof water sinks into the subsoil. There is no surface drainage or guttering, but from the porous nature of the soil, and the situation of the hospital, the rain fall is rapidly carried away. The hospital is built of brick and lime; the roof is double-tiled, with teak trusses; the walls are single, and the floor paved. The roofs and walls are sufficiently thick to keep the hospital cool. There are verandahs to the inside of the hospital, but they are also required on the east and west outer sides. They answer well as protection from the sun's rays, and are not used for the accommodation of sick, convalescents, and others. The hospital is on one flat.

TABLE of HOSPITAL ACCOMMODATION.

Date of construction - - - - - -	1830
Two additional wards added in - - - - -	1850
Total number of wards - - - - -	6
Total regulation number of beds - - - - -	100

		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
6	2 small Wards capable of containing 10 sick each. 2 middle Wards capable of containing 12 each. 2 Wing Wards for 28 sick each. 100 Beds - -	360	24	Mean. 16½	142,560	1,425	86⅔	Ft. in. 1 4	46	7	5

The hospital is placed so as to receive the full benefit of the prevailing winds. The windows open into the wards, and are conducive to ventilation.

6. The ventilation is effected by doors, windows, and cowl ventilators in the roof; but they are scarcely sufficient. A portion of the roof should be raised a foot above the lower part entirely round the building. There are no jalousies or jhilmils.
7. The air admitted to the wards is cooled by kuskus chicks to the windows, saturated with water during the hot season. Punkahs are also required.
8. There is no necessity to warm the air, but stoves in the monsoon might be advantageous. The walls and ceilings of the hospital wards are cleansed and lime-washed every three months, and oftener if necessary.
9. The privies are washed out frequently by the sweepers, and, a deodorizing material being used, are not offensive.
10. Tubs and basins, with an ample supply of water, are alone supplied in the hospital, and permanent lavatories, with shower-baths, are much needed.
11. There are no permanent bathing places for the sick, and are much required; hot and other baths in general use are supplied to them.
12. The Commissariat department wash and dry the hospital linen. Means for drying are much wanted.
13. The storage is sufficient and dry.
14. Iron cots are used in hospital, with a straw mattress. Cocoa-nut shreds ought to be used in place of straw; it would be much cooler and more comfortable, and could be well washed after ordinary cases.
15. The hospital kitchen is at one end of the enclosure. Brass and copper utensils are used in cooking, and these are tinned every month. Diets are properly cooked and varied.
16. The diet tables and returns used in the European hospitals are forwarded.
17. The establishment for attendance on the sick is composed as follows, viz., hospital serjeant, ditto steward, apothecary, 2nd ditto, dresser, compounder, apprentices, and ward boys. These are sufficient.
18. The sanitary condition of the hospital is good. No epidemic disease, hospital gangrene, or pyæmia have appeared in the wards.
19. I would suggest the following improvements for the hospital at this station; verandahs round the outside, distinct ward for obstetric cases to be attached to the female hospital with better accommodation for the matron and ward boys, and on account of Kirkee being such a long way from Poona, a small native hospital is much required at the station.
20. Convalescents unable to take walking exercise are carried out in doolies. There is sufficient ground round the hospital, but no shaded walks or seats.
21. There is a female hospital for soldiers' sick wives and children, with an European nurse and native assistant; but the accommodation is too small, which renders it often necessary for the medical officer to attend the women and children in their own quarters.
22. There are no special local hospital regulations not included in the general Presidency Medical Regulations.
23. The medical officer has sufficient power in all matters appertaining to the sanitary state of his hospital, repairs in buildings, change of diet, &c., &c., but in consequence of the crippled state of Indian finances, many recommendations, acknowledged to be desirable, cannot be immediately carried out, on the constant plea of want of funds.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	24. There is no convalescent ward here, but such accommodation would be desirable.
VIII. Burial of the Dead.	1, 2. The burial ground for British troops is rather more than a mile from the station and to leeward of the cantonment. Its area is 8,500 square yards; its soil black soil, and its subsoil moorum. There is no artificial drainage, but the river acts as a drain to it. The ground is hardly so well kept as it might be. 3. The grave space allowed is 7 feet by 3½ feet, and the interval between the graves is never less than 2 feet; the depth is 6 feet. Graves have never been reopened. Interment is compulsory at ordinary times within 12 hours, and during epidemics from six to 12 hours. 4. The grave yard is never offensive. British troops are buried agreeably to the orders of the home army. 5. The dead of camp followers and bazaar people are disposed of as follows, viz., Parsees are removed to towers of silence near Poona, Hindoos are burnt, and Jews and Musselmans are buried according to religious caste. A native Christian burial ground is much needed. 6, 7. No injury accrues to the public health from the present practice, nor have we any improvements to suggest in the way of regulation or otherwise in the burial or disposal of the dead.

(Signed) C. Cameron Shute, Colonel 6th Dragoons,
Commanding Poona Brigade and Station.
Wm. Deeble, Surgeon,
56th Regiment.
W. J. Stuart, Surgeon,

I. Topography.	1. The surrounding country is a large sandy plain, dotted with cultivation, dwarf trees, and numerous tanks. It is flat and dry, with a range of hills about six miles to the north-west. There is very little wood or jungle in the vicinity. 2. The elevation of the station above the sea is about 1,500 feet. It is from 50 to 60 feet above the adjacent country, and from 40 to 50 feet above the nearest water. There is no adjoining higher ground suitable for a military station. 3. There is a range of hills running north-east and south-west, about six miles from the station, from 300 to 400 feet high. 4. The nearest water is a large tank called "Bhotaya Khera," distant half a mile. There are two other large tanks close to the southern boundary of the cantonment. These tanks are liable to overflow during the rainy season, but cease almost immediately after the termination of the monsoon, the water being drawn off for the purposes of irrigation. The two latter tanks become dry in the cold season, and their beds are cultivated. There are some ravines, but they are the natural watercourses, leading into the different tanks. 5. The station is openly situated, its elevation is higher than the adjacent country, and it is freely exposed to winds. The temperature of the station is not raised to any considerable extent by the buildings being exposed to reflected sun heat. During the hot season, which prevails from the middle of March to the middle of July, the prevailing winds are from the south and south-west. These are scorching, and in order to keep the barracks cool kuskus tatties are used. During the monsoon the winds are variable and pleasant. In the cold season, from November to March, the winds are from the north and north-east. The troops are healthiest in the hot season and gain strength in the cold. 6. The surrounding country beyond the limits of the cantonment is cultivated. There are no public works of irrigation; artificial irrigation, however, has no bad effect on health. No cultivation is permitted within camp limits, but a very inconsiderable quantity of rice is grown near the Bhotya Khera tank. Indigo and hemp are grown in different parts of the province, but not in the immediate vicinity of the camp. No injury or nuisance is sustained from it. 7. Ajmere, about 15 miles distant, is the only large town near the station, but there are a number of villages at various distances from it. The station bazaar itself has a very large population, amounting to upwards of 15,000. 8. The geological structure of the district belongs chiefly to the metamorphic group of rocks. The sub-stratum consists for the most part of transition gneiss, reached at a depth of a few inches in many places, while here and there the bare rock appears. In some situations the soil is many feet in thickness; it is formed of disintegrated rock, chiefly decomposed felspar (one of its constituents), producing a clay of considerable fertility and moisture. The ground appears never to have been pre-occupied by population. 9. During the dry season water is found from 10 to 50 or 60 feet below the surface, according to situation, and as a general rule at the same depth in the rainy season.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	10. There are no surface springs, and the cantonment being situated high the rain-fall flows readily off. The drainage is from and not into the cantonment, and what little is not carried off by natural and constructed outlets sinks rapidly into the ground. No drainage from higher ground passes into the subsoil of the station.
	11. The water supply of the station is derived from wells and tanks. The extent of tank surface within the station is 46,309 square yards, and within half a mile of it 2,899,125 square yards. The tanks fill during the rainy season, and have a fresh supply from rain-falls during the end of December or beginning of January. They nearly all run dry towards the end of the hot season; and if the commencement of the monsoon is delayed, as has been the case this year, great inconvenience, and even misery, is felt by the inhabitants of the bazaar. The European troops at the station are supplied with drinking water principally from a well at a village a mile and a quarter from the barracks during the hot season. Bathing is not allowed in tanks reserved for drinking purposes. The tanks and wells are generally free from causes likely to pollute them. With regard to whether the tanks within or without the station produce malaria, there is but very little of malarial disease within the station, particularly if the cold season quickly follows the cessation of the rains.
	12. The amount of water supply for the station is upwards of 21,000,000 of gallons, exclusive of the supply in the tanks without the cantonment limits, and upwards of 4,000,000 of gallons are supplied from wells in which there are springs. The tanks contain rain water, and its use is not injurious to health. There are eight good wells in camp, and one at the village of Dilwarra, about two miles from the centre of camp, which has a most abundant spring, and it is from here that the principal supply of water for Europeans is obtained. In the other wells the water can scarcely be denominated spring water in the strict acceptation of the term, inasmuch as in many instances it contains such a large proportion of salts as to be unfit for domestic use, and might be classed under the head of mineral water. Where the wells are tolerably deep and regularly worked, the water is generally clear and free from smell, but hard and more or less of a brackish taste derived from the salts, but the flavour varies according to the quantity of salts contained, which is seldom constant, even in the same well; at one time the water from a particular well may be palatable, and at another so loaded with saline ingredients as to be useless. A quantity of water was taken on several occasions from a well in the cantonment, used and pronounced wholesome by the natives, and carefully evaporated to dryness, when saline matter, together with some vegeto-animal impurity, was found in the very large proportion of 1 in 200. The salts consist principally of chloride of sodium and probably other chlorides, with various sulphates, chiefly those of alumina and potassa. The water is raised from wells, by means of ropes and buckets, by bheesties, who fill their mussacks, and distribute it as required. It is also conveyed in water carts, and in larger mussacks carried by bullocks.
	13. No reply to this query.
	14. New stations are usually selected by committees assembled by order of the Commander-in-Chief. A medical officer, usually the superintending surgeon of the division, is one of the members.
II. CLIMATE.	1. A thermometer and rain-gauge are the only available means for conducting and registering meteorological observations.
	2. Table of meteorological observations from August 1859 to July 1860 inclusive.

Months.	Mean Temperature.	Mean Maximum.	Mean Minimum.
1859.

June - - -	93·5	99·0	88·0
July - - -	87·5	91·0	84·0

* During the present month up to the 7th September (1860) the range of the thermometer has been excessively high; the lowest range being 84°, and the highest 94° Fahrenheit.

3. During the hot and cold season the climate is dry; during the monsoon it is moist. The cold season commences in November and lasts till the middle of March; from that to the middle of July is the hot weather. The rains generally cease about the 15th September, during the remainder of which month and October the weather is warm and oppressive. Fogs are rare, and when they do occur it is generally towards the close of the monsoon. Dust storms are very frequent during the hot season and last for hours and sometimes during the whole day and night; they have the effect of cooling the air. The heat during May, June, and July is very great, ranging as high as 102° or 103° Fahrenheit in houses and barracks that are not artificially cooled. The monsoon season is more temperate and less subject to variation, the thermometer ranging from 78° to 86°. During the cold months the cold is very sensibly felt and warm clothing is worn throughout the day. Europeans may be all day in the open air without sustaining any injury from sun. The diet issued to the soldiers in India is of the best quality and can scarcely be improved. The shelter should be large, roomy, and well-

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	ventilated barracks. Light khakee clothing should be worn in the hot months, and the usual warm clothing during the monsoon and cold weather. In the cold season the troops may drill and exercise every day, if necessary, and almost at any time of the day, but during the months of March and April they should exercise early in the morning, so as to be dismissed drill by 7 a.m. Evening drill should not commence before half-past 5 p.m. and not last more than one hour. In May, June, and July there should be as little parading as possible, but during the monsoon the troops may parade as weather permits. The most healthy months are from January to August inclusive. The remainder are the unhealthy months, during which fevers, dysentery, and diarrhœa prevail. 4. The want of good drinking water is the great fault at this station; but taking all things into consideration, there is no district or situation near the station better suited for a military cantonment. 5. Lieutenant-Colonel Holmes has served at Bombay, Poona, Surat, Baroda, Rajcote, Sukkur, and Hyderabad (in Sinde), Kurrachee, Nusseerabad, and short periods at Deesa and Sattara, and is of opinion that Poona, Deesa, and Nusseerabad are the healthiest stations. Sukkur and Hyderabad are decidedly unhealthy. Surgeon-Major Durham has served at Bombay, Shikarpore, and Sukkur in Sinde, Ahmedabad, Kaira, Ahmednuggur, Neemuch, and Nusseerabad, and considers Nuggur and Nusseerabad both healthy stations. Kaira is an unhealthy place. Captain Griffith has had no experience with troops, having been in civil employ nearly the whole portion of his service.
III. Sanitary Condition of Station.	1, 2, 3. A map of the station, with plan of the station and ground plan of the barracks, are forwarded. 4. Table of barrack accommodation. Date of construction of barrack, March 1860. Total number of rooms or huts, 9. Total regulation number of non-commissioned officers and men, 786.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.

5. Doors and windows on all sides. The shutters open upwards into the verandah, and are made of canvass, painted and stretched on frame work. There are verandahs on both sides 159 feet long by 10 feet broad. When barrack accommodation is completed it is not intended that the verandahs should be used as sleeping quarters. Heretofore they have been occasionally used when barracks are under repair or new ones in the course of construction. There are no properly constructed jalousies or jhilmils.

6. The bedsteads are wooden charpoys, laced with either cotton tape or cord; some are of iron, and others of boards and trestles. The beddings are cotton mattresses about three-quarters of an inch in thickness. Each man has three cotton sheets, two blankets (country manufacture), and one cotton rug. This bedding is not adapted to the climate of Nusseerabad during the monsoon, the cotton mattress getting very damp during the rains and the blankets not being sufficiently warm during the cold season. The bedsteads, with the exception of those of iron, harbour bugs, and it would be better that iron bedsteads should be generally used. It is difficult to suggest an improvement in the description of mattresses, for if made of any other material than cotton it would be difficult to convey them on a line of march, unless the stuffing of the mattress were of straw, in which case it could be thrown away.

7. The tents used are of three kinds,—1. European soldiers' double-poled two-walled tent 2. European hospital tent; and 3. European soldiers' single-poled tent.

No. 1 are as follows :—

Inner dimensions, 22½ × 14 × 13¼. Kanauts (or walls) 6 ft. high } to hold 22 men, 100 cubic feet per
Outer do. 27½ × 19⅔ × 15¾ do. do. } man, and 15½ square feet per do.

Outer do. 27½ × 19½ × 15 do. do. } man, 15⅓ square feet per do.
4 doors - - 5¾ × 4½.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	No. 3. Dimensions - 13,5 × 13,5 × 12,5. Kanauts (or walls) 6 ft. high { to hold 13 men, 100 cubic feet per man, 14 square feet per do. 2 doors - 5¾ × 3·5. 8. The barracks are ventilated by means of doors and windows. Of the former there are 16 and of the latter 44 in each; and in addition, there are small apertures in the wall on a level with the floors between each window, and a similar aperture 5 feet above each window. The ventilation is sufficient to keep the air pure by night and day, but it is open to the objection of too many draughts during the monsoon and cold weather. The means for cooling the air in barracks and other quarters are by punkahs and kus-kus tatties. The former is used only in the married men's quarters. It consists of an iron rod about ¾ of an inch in diameter and 6 ft. 6 in. long. To this three iron rings are attached for its suspension, and beneath hangs a fringe of coarse cloth about the same length, 9 inches in depth, weighted with leaden grains about the size of shot, procured from the Ajmere mines. The tatties are made of a framing of whole and split bamboo fastened with string made of a kind of grass. The kus-kus is brought in from the neighbouring villages. 9. The new temporary barracks are constructed as follows:—The foundations and plinth and main walls of stone and lime plastered outside; the interior and partition walls of sun-dried brick plastered with mud, and colour-washed; the roofs are of thatch, supported on date post trusses. 10. The floors are of three kinds, all solid, viz., flagstone, chunam, and moorum, but the former are mostly in use. The ground is first filled in with earth to within 6 inches of the plinth level, which is generally not less than 1 ft. 6 in. above the ground, and frequently as much as 2 feet, and even 2 ft. 6 in. The earth is well rammed, and over it a layer of stone and lime about 4 inches in depth is laid. On this rest the flagstones (dimensions 1 ft. 6 in. by 1 ft., and 2 in. thick), the joints of which are set in chunam. Chunam floors are constructed thus:—Over the layer of earth, which is usually from 9 inches to 12 inches above the ground surface, a bed of dry stone chips 4 inches in depth is laid; on this, again, is a kind of concrete of large and small limestones, mixed with sand, and well pounded together; and on top of all is a layer of plaster 1 in. or 1½ in. thick, of fine lime, which, being well beaten and rubbed to a smooth surface, forms the floor. 11. The barracks being temporary, situated on high ground, the floors tolerably well elevated and well ventilated, besides being roomy, the materials may be said to answer very well. It must be borne in mind that this was not a station for European troops previous to the mutiny, with the exception of a company of European artillery. Her Majesty's 83rd Regiment was the first European infantry that occupied the station, and it was necessary to run up barrack accommodation for them as quickly as possible. On the operations against the rebels being completed, the head-quarters and three squadrons of Her Majesty's 8th Hussars were quartered here. For these also barrack accommodation had to be constructed with all expedition. The country is very deficient in good timber for building purposes, and time did not permit of its being procured from a distance; the consequence is, that the wood work is not what would be ordinarily used. Annual ordinary and extraordinary repairs of barracks and cantonments are executed by the executive engineer, and petty repairs by the barrack department. They are quickly executed. The sanitary state is superintended by the quartermaster-general's department. The walls and ceilings of barracks are always cleansed and whitewashed once a year, and oftener on special requisitions. 12. Each of the men's wash-houses is 18 ft. by 9 ft. by 8 ft. The foundation plinth and superstructure is of stone and mud plastered inside and out with lime, and the roof is of babul wood rafters and bamboo battens, with single date mat and single tiles. They have ridges, hips, and eaves, and flagstone floors set in chunam. The walls are colour-washed a blueish grey; they have one door 6 ft. 6 in. by 3 ft. 6 in., and two fixed Venetian windows 4 ft. by 1 ft. 6 in. The cost of one wash-house is about 260 rupees. Tubs are supplied to each building, and the water is brought daily by the water-carriers. 13. The interior of the old cook-rooms is divided by a centre wall into two compartments, giving accommodation for two barracks; the whole building being of stone plastered with chunam. The roof is of slab stone, and egress for smoke is provided by small apertures in the roof, and also by semicircular openings (four on each side). There are two doorways and four windows. The number of cooking places is 36. There is a fixed establishment of washermen for the European troops and for hospitals; they wash the linen, and dry it on lines fastened to poles, which, with ironing, is all that is required in this country. 14. The contents of privies are removed twice a day by sweepers. The urinals are sluiced with water, and drained into absorbing covered cesspools. 15. These buildings are ventilated by doors and circular apertures in the walls. 16. There are no constructed drains and sewers for the barracks; any water that lodges near there is carried off by surface drainage. Being situated on the highest point of the cantonment, all surface water quickly runs off, or readily permeates. During the monsoon there is always more or less dampness; but for nine months in the year the barracks and hospitals are perfectly dry. The system of drainage that obtains in England is not required in this country, the water being carried off as above described. Each wash-house, cook-house, and urinal is furnished with its own cesspit, the contents of which are removed when requisite. The distance of the hospital cesspool is 125 yards from the nearest men's quarters; but there is a latrine belonging to the quarters themselves which is not 20 yards distant from them. The cesspool is distant 97 feet from the hospital. There are no foul ditches, but there are several natural watercourses, and some constructed ones, which conduct the water to the different tanks. 17. The surface cleansing of the cantonment is performed by sweepers every morning; they collect all rubbish and filth, part of which they carry off in their baskets, and the remainder is carted away. The manure is eagerly bought by villagers and people who keep cattle, who convey it away. 18. The surface of the cantonment is kept free from vegetation. There are no old walls, thick hedges, &c., interfering with the ventilation of the station. The ventilation is very good. 19. The main and cross streets of the bazaar have covered drains on both sides, the whole of

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	which empty themselves into the nullah on the west of the bazaar. There are a few wells used for bathing which require drains; they are in the course of construction. The ventilation on the windward side of the bazaar is good, but towards the east the bazaar is much crowded, especially where the coolies and lower classes reside. There are 25 latrines, kept clean by the sweepers to whom they belong, and who are responsible for their cleanliness; they are constantly inspected by the police. There is at present only one scavenger's cart allowed by Government; it was, however, suggested by a committee that assembled in June last that 5 carts and 5 sweepers should be sanctioned. The drinking water is supplied principally from two tanks north and south of the bazaar. There are 30 wells in the bazaar and its vicinity, but only 6 contain drinkable water, which, with the tanks, generally yield a sufficient supply, except in extraordinary dry seasons, when no drinking water is procurable within a mile of it. Each individual is held responsible for the cleanliness of his premises and the portion of street in the front of his house; and each house has a basket into which the sweepings are gathered morning and evening, to be taken away when the sweeper or scavenger's cart comes round. The crowded part of the bazaar will eventually be opened out as its population decreases, which will be when the public buildings now under construction are completed, and there will be no further employment for them. There are no native houses within half a mile of cantonment limits, which are very extensive. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. Two slaughter-yards, where sheep and goats are killed, are within the present bazaar limits; and another for slaughtering bullocks just without and in rear of bazaar: they were all originally outside. The butchers are in both places held responsible for the cleanliness of the yards, and sweepers are kept by them to convey the offal as the animals are killed to a place appointed about three-quarters of a mile to the south-east of camp; from which direction the wind very seldom blows. It is contemplated to remove the slaughter-yards 250 yards in rear of the bazaar, the ground for which has already been marked out. 21. There are not more than 10 or 12 horses belonging to residents in the bazaar, and these are kept in private stables. The camp followers' and grass-cutters' ponies belonging to cavalry regiments, &c. are picketed outside their lines, and the picketing grounds are kept clear under regimental arrangement; the manure is daily taken away by the milk-men, potters, and villagers. 22. There are no stables for cavalry or artillery horses. No dung-hills are allowed to collect, the manure being sold and carried away, as before stated. The 8th Hussar horses are picketed to the rear of the barracks, and the line of pickets run perpendicular to the front of the barracks at a distance of 90 yards. The native cavalry horses are picketed in front of their lines; the line of pickets running perpendicular to the front and separated by a broad roadway from the lines. The native battery horses are picketed in the same line as the horses of the native cavalry; the lines of the company are situated on the right flank of the horses. The European infantry barracks are situate between the lines of the native cavalry and the native battery. The pickets of the 3rd Troop Horse Artillery run in front of the barracks and parallel to it. Horses are picketed in line,—a troop occupying a double line—horses facing each other. There is a low wall running in front of the horses to protect the fodder. Along the rear of the line a drain is cut, and the ground on which the horses stand is raised and slopes from the wall in front to the drain in rear; there is a space of 9 feet between each horse, and the breadth of the street is 6 yards. Each horse is picketed by one head and one heel rope. 23. The accommodation for married non-commissioned officers and men is not yet quite sufficient, but will be provided.
Officers' Quarters.	1. The officers live in a line of bungalows running north and south, and each bungalow is situate in a separate compound. The ventilation is good. Drains run along in front and rear of the compounds to carry off the water, and also along the sides, where it is necessary to make watercourses. The arrangements to keep these clear are in the superintendence of the executive engineer, and are well attended to.
IV. Health of the Troops.	1. The station, generally speaking is healthy, and the same may be said of the district. The native population are usually healthy, except during the season of fevers and when epidemics prevail. 2. The most prevalent diseases among the native population are, fevers, dracunculus, small-pox, dysentery, and diarrhœa. Diseases of the spleen are of common occurrence after fever. Cholera occasionally makes its appearance, but more rarely than in most parts of India; there has not been a case for three years. 3. The healthiness of the native population is attributable to the superiority of the climate. 4. The 3rd Troop Horse Artillery came from Persia and Kurrachee. It joined General Roberts' camp before Kotah in March 1858, and was employed on field service in Central India, and came into cantonment on the 28th April 1859. It has received many volunteers from other regiments to replace those who took their discharge. Since arrival here the principal diseases have been dysentery, fevers, and rheumatism. The 8th Hussars arrived in Bombay from England, and were sent up into Rajpootana on field service. This is the first cantonment occupied by the regiment, and one squadron is at the station of Neemuch. They arrived at Kotah on the 28th March 1858. H.M.'s 28th Regiment was quartered in Bombay for about 13 months, and left on the 24th January 1860. The general state of health of the men in Bombay from May 1859 was decidedly bad, the prevailing diseases being fever and bowel affections; asthenic and cachectic conditions of constitutions became thoroughly established, and the health of the regiment undermined. It was subsequently removed to Poona, where the head-quarters arrived on the 24th January; the left wing having been sent to Ahmednuggur some time previously. At these places some amendment took place, when the regiment was ordered to Nusseerabad. The march of the head-quarters commenced from Poona on the 17th February, and was not completed till the 12th May 1860, when the hot season was prevailing. On arrival at Nusseerabad the health of the men was very indifferent, they have since chiefly suffered from attacks of fever, and relapses have been frequent. There was one bomb-proof barrack

NUSSEERABAD. BOMBAY.

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops—*cont.*	that was occupied by the Hussars, that was considered rather unhealthy, it had been a sick horse stable, and was used as a barrack on the emergency. The floor has since been flagged, and there is not so much objection to it. There is ample accommodation for the Hussars without it. 5. Troops are not usually camped out, but during the period of the mutinies, the 3rd Troop Horse Artillery, the 8th Hussars, the 4th Co. 3rd Battery of Artillery, the 1st Lancers, H.M.'s 83rd Regiment (now at Belgaum), and the 12th Regiment Native Infantry were constantly on field service. The 12th Native Infantry were stationed at Deesa before coming to the station, and the head-quarters were there for one year and nine months. Five companies came to Nusseerabad and Neemuch six months earlier. 6. No experience of hill stations. 7. From general observation we (the committee) should say that troops would be less liable to attacks of febrile and other diseases on returning to the plains, provided they have resided on the hills a sufficient time to acquire strength and throw off the attacks in the first instance. 8. We have had but little experience on the subject, but would certainly say it would be advisable to select hill stations for troops. 9 to 13. No experience with troops at hill stations. 14. As a general rule, the longer troops can be located on hill stations the more conducive it would be to their health. Frequent change of station in the plains is beneficial. Men weary of being a long time at the same station, and long for change. 15, 16. No experience of barrack accommodation or sanitaria at hill stations, or what ranges of elevation are most suitable for such stations. 17. With regard to the question as to whether there is any higher ground near the station which could be advantageously occupied as a hill station; the hill fort of Tarra-ghur, 15 miles distant, rising 1,000 feet immediately above the city of Ajmere, and about 3,000 feet above the level of the sea, has very limited space on it, and there would not be room for more than three barracks, to contain one company each. This year it is under trial as a sanitarium, and the reports of it are very favourable. The temperature of it is much lower by day, and is usually from 8° to 10° lower than in the plains. The nights are almost invariably cool, being 17° lower. There are two pathways, one very precipitous, accessible only to men on foot; the other is more circuitous, but mules, camels, and pack bullocks can go to the summit. In case of permanent occupancy this road would have to be improved. 18. A dry gravelly surface with a percolating subsoil for stations will be found most favourable to health, but however satisfactory the condition of the surface may be, if the subsoil retains moisture and the temperature is high, malaria will be more or less abundant according to the degree of heat and amount of previous saturation of the ground. 19. The best age for soldiers proceeding to India is 22 years of age, or whenever their constitution is formed by attaining full growth and strength; and the best period for them to land there is in the months of November, December, and January. If there are barracks available at the station where troops land, they are marched into them; if not and the troops are destined to go up country, they are encamped. Their clothing must, in the first instance, be such as they have brought with them; drills and duties depending on commanding officers; or if a regiment garrisons the place it lands at, it furnishes such guards as are ordered by the commandant's authority. Troops on landing should not be detained in Bombay, but marched to some healthy station, such as Poona; they should also be furnished with light clothing suited to the climate, and a helmet and puggree to wear round it. A depôt has been established at Khandalla, where drafts for regiments are to be sent. 20. Troops should be sent direct from home to India when their health and strength is at the best. European troops should be sent to the hill districts on landing, to accustom the men to the climate, and to all the new habits of life, absolutely requisite to be acquired for preserving health in the altered circumstances in which the soldiers are placed, with regard to food, clothing, and temperature. These circumstances, on first landing in India, under the present system, become fruitful causes of disease, when predisposition has been established to a certain degree by the greatly elevated temperature. 21. The mode of transport to the interior can be more effectually explained by the quarter-master-general's department. The troops should be exposed as little as possible to the sun, and all reliefs and movements should take place during the cold weather, *i.e.*, in the months of November, December, January, and February. 22. With regard to the number of years a British soldier should serve in India, it would be advisable to have reliefs every 10 years. Strong healthy men wishing to volunteer might be allowed to do so for a further period of five years, but beyond 15 years it would not be advisable to keep British soldiers in India. 23. In reference to the mode of conducting the business of medical boards as to invaliding; medical committees or boards, both at the Presidency and out-stations, have rules and regulations for guidance, and they work perfectly satisfactorily. 24. The best time for invalids to leave India for home is during the months of January, February, March, and April.
Diseases.	1. The Europeans are inspected once a week for the detection of local affections and any ailments indicated by the countenance or skin. 2. Generally speaking there is no scorbutic disease among the troops, but cases have occurred occasionally among the native troops. It is attributable to the want of wholesome diet and good vegetables, which latter are now grown in abundance. 3. The proportion of hepatic diseases during the last 12 months has been 4 per cent. to other diseases. The principal causes are intemperance, atmospherical vicissitudes, and exposure to draughts, after being in a profuse perspiration from exercise. It is said that the transmission of pus or vitiated secretion to the liver from an ulcerated intestine is a frequent cause of hepatic abscess, but of this I am by no means certain, as I have seen frequently

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	ulceration of the intestines without abscess, and abscess without ulceration, and often both combined. The preventives are temperance, a cool atmosphere, careful diet, and the avoidance of draughts after profuse perspiration from exercise. 4. The proportion of dracunculus to other diseases has been $\frac{1}{2\,3}$ nearly; the cause is drinking water which contains the ova. Filtering or straining the water before using it would greatly diminish its frequency, if not altogether do away with it. 5. The proportion of venereal diseases to all other diseases in hospital is $\frac{5}{8}$. It would be very desirable to establish lock hospitals. 6. The troops at the station suffer from intermittent, remittent, and continued fever. *Dysentery.*—Acute and chronic. *Cholera.*—There has been no case for the last three years. *Small-pox.*—Distinct and confluent. *Rheumatism.*—Acute and chronic. In the 3rd Troop Horse Artillery, from 28th April 1859 to 27th August 1860, the total admissions were 422, and the total deaths were 34. The admissions from these diseases are in the proportion of 68 to 211 to the total admissions, and the deaths are to the total deaths as 2 to 4. In the 8th Hussars, from the 21st May 1859 to the 31st July 1860, the total admissions were 713, and the total deaths 19. Admissions from the above diseases to total were 231 to 713, and deaths to total deaths 13 to 19. In the 1st Bombay Lancers from 1st March 1857 to 31st August 1860, the total admissions were 1,776, and the deaths 11. Admissions from above diseases to total admissions were 161 to 296, deaths to total deaths 4 to 11. In Her Majesty's 28th Regiment for the quarter ending 30th June 1860, the total admissions were 482, and total deaths 5. Admissions from the above diseases are to the total admissions as 263 to 482, and the deaths are as 5 to 0. In the 12th Regiment Native Infantry, from 1st December 1857 to 27th August 1860, the total admissions were 2,561, and the total deaths 15. Admissions from diseases named above are to the total as 1,385 to 2,561, and deaths to total deaths as 6 to 15. In the depôt Company 4th Battalion Artillery, from 1st December 1857 to 27th August 1860, the total admissions were 493 and deaths 4. Admissions to total admissions were 252 to 493, and the deaths to total deaths were 1 to 4. 7. Small-pox, chicken-pox, and measles are the most frequent zymotic diseases, and they are most prevalent during the months of April, May, and June, when the heat is very great, with hot winds blowing from the south-west. The bazaar is tolerably well drained, and, in most parts, well ventilated. There are a number of wells, but of brackish water. Care is taken to keep the bazaar clean, and, considering the amount of population (upwards of 15,000), there has been very little sickness in it. There are no peculiar habits among the troops or native population which predispose to these diseases; they are incidental to the country. 8. The prevalence of epidemic disease is not influenced by the soldier's duties and occupations in barracks, but when undergoing fatigue in the field the soldier is more liable to the influence of those diseases. 9. Small doses of quinine have not been tried here as a prophylactic against malarial diseases. 10. Great precaution should be taken in keeping the cantonments clean; removing all vegetation from the vicinity of the barracks; having always an abundant supply of water for the men, for washing purposes; providing roomy accommodation for the troops, so that the barracks may not be crowded; being very particular in the inspection of the rations supplied to the men, and should the epidemic be cholera or small-pox, to allow of as little communication as possible between the bazaar and the barracks. It may be necessary in some cases to remove the troops, or a portion of them, to another encampment, where the disease is not so prevalent.
V. Intemperance.	1. The soldiers at the station are usually temperate, and there are very few drunkards. 2. The medical officers find that it is very difficult to say what is the proportion of admissions into hospital from diseases caused directly or indirectly by intemperance, as it does not prevail to any extent, and there are no absolute temperance men, that is, men who abstain totally. Drunkenness is always punished as an offence. 3. Distilled spirits, *i.e.*, arrack or rum supplied by Government, are sold at the canteen, but not in the bazaar to European soldiers, and the quality is good. A man may draw one quart of porter and one dram of arrack daily; or two drams of arrack and no porter. Spirit is no part of the ration for soldiers at the station, on march, or in the field. The men are not allowed a dram in the morning. Spirit is not, as a rule, given as a ration to convalescents; it depends upon the medical men to recommend it or otherwise. No other drinks are sold at the canteen which are injurious to health. 4. A moderate use of spirits is not injurious to men in health. Whether it should be given or not to convalescents depends upon the individuals. The use of spirit has no effect on efficiency and internal discipline, but the abuse would be detrimental. 5. The moderate use of spirits is not injurious; to abolish it altogether would be objectionable, as in so exhausting a climate as India a certain amount of stimulant is required. 6. Either malt liquors or wines may be taken with benefit or be injurious, according to the constitution of the men using them. Wines are not within the reach of soldiers; malt liquors also are expensive, and not procurable when on field service or on the line of march. There remains the spirit ration, which it is better that the men should receive of a wholesome quality from the canteen than drink such as is procurable in the villages. 7. Tea, coffee, and ginger-pop are used at the station, but lemonade and soda-water are too expensive except when supplied at the public expense in the hospitals. With regard to their effect on health, efficiency, and discipline, as compared with spirits, it is the abuse and not the use of the latter which affects the former. 8, 9, 10. It would not be beneficial to abolish the spirit ration, whether for soldiers or convalescents, and to substitute for it beer, tea, or coffee, &c., neither would it be beneficial to prohibit the sale of the former in the canteen, and permit only the latter to be sold there. No recommendations to suggest.

NUSSEERABAD, BOMBAY.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	11. The canteen and bazaar regulations is very voluminous; they are contained in Section X. of the 3rd Appendix of Jameson's Code, a copy of which the committee suggest should be forwarded to the Royal Sanitary Commission.
VI. Diet.	1. The ration for Queen's troops and European troops in the Indian army is the same, and consist of 1 lb. bread, 1 lb. meat (beef or mutton), $\frac{5}{7}$ oz. of tea, $2\frac{1}{2}$ oz. sugar, 4 oz. rice, 1 lb. vegetables, $\frac{1}{2}$ oz. salt, 1 dr. pepper, and 3 lbs. of wood daily per man. The rations are inspected every morning by the orderly officer, and quartermaster, and mess orderly and corporal of each troop or company, and if disapproved of, a committee of three officers inspect it. 2. A complete ration, including vegetables, is provided, and the troops have three meals a day; there is, however, a slight difference of time between the different regiments,— Breakfast being from 7 a.m. till 7.15 a. m. Dinner „ 12 noon „ 12.45 p.m., and Supper or tea „ 5 p.m. „ 6.15 p.m. The value of a full ration is 3 annas and 4 pice per diem, which the soldier is entitled to receive as compensation when the ration is not supplied. The proportion of vegetables in a ration is 1 lb. 3. The vegetable element, though sufficient in quantity, is too frequently, in this country, deficient in anti-scorbutic properties. The fruits and vegetables, *e.g.*, limes and oranges, cabbages and radishes, the highest in the scale as prophylactics, are not to be procured in any quantity during the hot season; or the natural families to which they belong (aurantiaceæ and cruciferæ) will not flourish at all in some localities; it therefore becomes a question whether in such stations as Nusseerabad and Deesa it would not be conducive to the general health to issue a certain proportion of lime juice as a ration during the months of April, May, June, and July, in addition to the onions, pumpkins, and bad potatoes, all of comparatively small value as preventives of scurvy. It will usually be found that the scorbutic tendency will manifest itself after the hot season, and before fresh vegetables have become sufficiently abundant to be easily procurable. 4. The means available for cooking are, cooking pots, gridirons, stew and frying pans, spits, &c. Being of copper, they are tinned regularly once a month. The kitchens cannot be said to have a very clean appearance in this country, inasmuch as there are no chimnies to the cook-houses, and the walls are generally blackened by the smoke, which makes its escape from various apertures, which also serve the purposes of windows. The apertures, together with the doors, form the means of ventilation. The kitchens to two new barracks, lately built, are of different construction, having an upper ventilating roof, with a clear space of two feet for the egress of smoke. The food is both boiled and roasted. The cooking seems to meet with very general approval, and is perhaps as varied as it is possible to be. In addition to the soup, the daily ration of meat is sufficiently ample to admit of small messes in each company, such as kabobs, chili fry, mutton pie, Irish stew, curry, and beef-steak pudding. The tea is reasonably good, and very many of the men are in the habit of taking coffee early in the morning. Tea and coffee can always be obtained by the men before a march, and advantage is almost always taken of the refreshment. 5. Gardens for the cultivation of vegetables by the soldiers are already established. The 28th Regiment and the Horse Artillery have gardens for that purpose. The men are allowed to cultivate plots on their own account, or may cultivate larger plots in partnership.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress and accoutrements in the Hussars, are a wicker helmet, full-dress tunic, cloth overalls, stable jacket, forage cap with cover, white summer tunic, white overalls, cloak, sword, and carbine, pistols for troop serjeant-major and trumpeter, pouch and sword belts, and six-revolvers for non-commissioned officers, Wellington boots and spurs, shoes, and sabretache. In the infantry, one great coat, one cloth tunic, one pair of black cloth trousers, one serge frock, one pair of blue serge trousers, one wicker helmet with padded cover and turban, one forage cap with cover, one pair of English boots, and two pair of country, waist and pouch belt, frog for bayonet, two ammunition pouches and cap pouch. In the Horse Artillery, a full-dress jacket, undress or shell jacket, metal helmet, forage cap, wicker helmet, cloth overalls, cloak, sword, pistol, pouch and sword belts, and pouch, spurs, Wellington boots and country shoes, khakee tunics and overalls. The present dress is suitable to the climate and the soldiers' duties by day and night, if varied according to the seasons. It is also suitable for stations in the hills and plains if varied as found requisite. Malaria does not exist in elevated stations; elevations of 4,000 feet and upwards are supposed to be beyond fever range. Well chosen stations are as free from malaria as the absence from marshes, jungles, and cultivation can make them. In marching, the numerous fires that are generally made around the camp are great preventives of malaria. These fires cannot well be too numerous, and camp followers should be encouraged to keep them up on all route marching; but when troops are in pursuit of an enemy, fires must be repressed.
Duties.	1. It would be of the greatest advantage if every soldier was thoroughly drilled before commencing his career of Indian service. The drill of a recruit in this country is necessarily prolonged over a considerable period from the small portion of each day which can be set aside for the purpose. Many weakly constitutions suffer from even the short daily exposure necessary, or a habit of frequently coming to hospital for trifling causes is acquired, also it may be a permanent distaste for all drill exercise. Instruction in the necessary duties at home would be a suitable service for the young soldier from 18 to $21\frac{1}{2}$ years of age, and would conduce to the development of the frame until the constitution acquired sufficient strength better to withstand the influences of climate. 2. The usual routine of a soldier's duties are—in Her Majesty's 28th Regiment, morning drill from 5 to 6 a.m., three times a week; roll calls, 5 to 5.30 a.m., twice a week; medical inspection 5 to 5.50 a.m. once a week. Divine service, one hour every Sunday. Evening roll call from 5 to 5.30 p.m., daily. Morning ditto, in barracks, at 10 a.m. daily, except

VII. Dress, Accoutrements, and Duties—*Duties—cont.*	Sunday. When the barracks are inspected and the men paid, on Wednesday evening a marching order parade. In the Horse Artillery there are field exercise parades from 1½ to 2 hours; sword drill half an hour; field piece drill 40 minutes; marching drill ¾ of an hour; heavy ordnance drill 40 minutes; equitation drill one hour; stables, morning and evening, one hour each; also duties, guards, night pickets, and day line duties. In the Hussars they have field drill, mounted, from 1½ to 2 hours; skirmishing, advance and rear guards, and posting pickets from 1½ to 2 hours; sword and carbine exercise for ¾ hour; riding drill, under riding master, one hour; also duties, guard, and night patrol. The men do not suffer from drill, provided judgment is exercised in not working them at sickly periods, or exposing them to the sun in hot weather. The best hours for drill and parades are from 4.30 a.m. to 5.30 a.m., according to the time of year, and the same hours for the evening. Marches must be regulated according to the distance. In hot weather troops should not be out later than 7 a.m. The march of cavalry may be calculated at 3¾ miles per hour, and of the infantry at 2¾ miles per hour. The Hussars have 8 nights in bed; the Horse Artillery have 5 nights; the 28th Regiment 10 nights; the 1st Lancers 1¾ nights; the 4/3 Artillery 3 nights; and the 12th Regiment Native Infantry 4½ nights in bed. 3. The 28th Regiment have three guards, at distances of 812, 1,000, 1,625 yards from the barracks; all other European guards are regimental, and within the limits of their own lines. Day guards last 24 hours; night guards or pickets mount at sunset and are relieved at daybreak, the time varying according to length of day. There are two roll calls by day and one by night. Night guards have no bad effect on health.
VIII. Instruction and Recreation.	1. The following are the means of instruction and recreation at the station. There is one ball court, but there should be two others for the 8th Hussars and 28th Regiment. There are some skittle grounds, and others will be made. Schools, with schoolmasters, exist, but school-rooms have to be built. There are also libraries, and portions of barrack accommodation are used as reading-rooms; proper accommodation is not yet provided. No day rooms or soldiers' clubs are established; but there are soldiers' gardens, worked by the men, according to their own fancy. There are no workshops, except the usual regimental ones. There is a theatre, and soldiers constantly perform in it, and there is also a gymnasium, where both officers and men meet once a week to play cricket, quoits, and skittles. Races, both pony and foot, take place, and also jumping and other gymnastic exercises. When a sufficient fall of rain has occurred, so as to cool the earth and cause vegetation, the rainy season is not usually hot, and the days being often cloudy, the men can take outdoor exercise with impunity. There are sources of amusement enough to occupy them, but it would be a great benefit if workshops of different descriptions were established, in which the men might be encouraged to work at such trades as they may have acquired, and be remunerated for their labour. There is restriction against exposure to sun and rain out of barracks when off duty, when considered necessary, and the object is to preserve health. 2. There should be two double ball courts erected, one for the European infantry and one for the cavalry regiment at the station. Avenues of trees should be so planted as to give shelter for skittle and quoit grounds, for air and exercise are absolutely necessary to many men for the preservation of health. Good reading rooms should be built. Workshops of various kinds, such as tailors', shoemakers', carpenters', joiners', and watchmakers', should be established, and as much regimental work as possible should be done in these shops. Government work should be given to them to the extent of their ability to execute without detriment to their duties as soldiers. Where the heads of trades are not nominated by Government, the different trades should be allowed to select their own master. Work must be allowed to be entirely voluntary; the men to be permitted to work for as long or as short a time as they like. No coercion should be used, and the remuneration to depend on the amount of labour. 3. Savings' banks are already established, and have proved advantageous. 4. There is not sufficient shade from trees or other means to enable the men to take exercise without injury to health during the day. This has only become a station for Europeans since the commencement of the mutinies.
IX. Military Prisons.	1. There is a new range of cells built for the European regiment of infantry, and which are at present used by the European cavalry regiment also. The range requires a verandah to its west side, that face being exposed to the heat of the sun and to the scorching hot winds during the hot season. These are solitary cells, and therefore cannot be crowded. The only other places of confinement are the prison rooms of the quarter guards of regiments. When men are sentenced to long periods of confinement and hard labour, it is requisite to send them to Bombay.
X. Field Service.	1. There are no local regulations for field medical service not included in the General Presidency Regulations, which latter are strictly enforced. 2. The medical officers on field service or the line of march have little or no power. On the line of route from station to station encamping grounds are defined by the quartermaster-general's department; they are usually the most healthy spots, affording abundant supplies. When moving after an enemy, the route, of course, depends upon the direction the enemy have taken. To this, of course, the medical officers can have nothing to say. In ordinary marching, should the men feel fatigued, the medical officer might recommend a halt whenever requisite. If troops are encamped on the same ground for any length of time, the medical officer may recommend a change of site for sanitary reasons. It is his duty to make requisitions for the carriage of the sick as such is required. 3. As before observed, encamping grounds on the line of route from station to station are laid down by the quartermaster-general's department as the most eligible in every respect. Water is brought to the tents and hospitals by the water-carriers, of whom there is an increased establishment to every regiment when on field service or on the line of march. Ventilation is always well preserved by pitching the camp, where circumstances admit of it,

X. Field Service—*cont.*	in as open and airy a position as possible. The power of the medical officer is confined to the charge of the sick, and any suggestions he may make regarding them should always meet with attention. The rules and regulations for route marching are explicit, and only require to be attended to. 4. The arrangements in the Presidency for field hospitals, transport of sick, &c., are laid down in the Presidency code of Regulations for the medical department.

By order of the Principal Inspector-General, Medical Department.

Office of the Principal Inspector-General, Medical Department, Bombay, 22nd December 1860.

W. C. COLES, Assistant Surgeon, Secretary.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1, 2. At present there are no regular hospitals for European troops, with the exception of one for the troop of Horse Artillery. Barrack buildings are occupied by Her Majesty's 8th Hussars and 28th Regiment as hospitals, and they are in every respect like the other barracks. The hospital of the Horse Artillery is situated 850 yards from the nearest point of the bazaar, and due west from it. The hospital of the 28th Regiment is 1,000 yards distant from the same point west north-west, and the hospital of the 8th Hussars is 2,500 yards north-west by north. Plans and estimates for a suitable capacious European hospital have been called for, and when sanction has been given the buildings will be commenced. The site is open and freely ventilated, and equally healthy as to elevation and freedom from malaria and other nuisances with the rest of the barracks. 3. An ample supply of good water is brought to the hospitals daily by bheesties. 4. The drainage is the same as described with respect to the rest of the barracks. 5. The floor of the hospital is raised 1 foot 6 inches above the surface of the ground. There is no perflation of air underneath the floors, which are all solidly constructed. The roof water runs off. The rain which falls on the buildings (the foundations of which are slightly raised) is carried off by the inclination of the ground on each side to small channels partly natural and partly artificial, which all tend ultimately to the western slope of the very gentle undulation, on the highest part of which the barracks are built. The materials of construction of the hospitals are the same as the barracks, and they are similarly supplied with verandahs. When the number of sick exceeds 85, the least important cases occupy the verandahs, together with any men detained in hospital in consequence of trifling ailments. The hospital consists of one flat only.

Table of hospital accommodation.

The date of construction of the present Artillery Hospital, formerly the Church bungalow, is unknown. (The church was built about 35 years ago and was adapted for hospital purposes since the mutinies).

Total number of wards, 8.
Total regulation number of beds, 41.

The whole range of barracks is admirably placed so as to receive the full benefit of the prevailing wind during the hot weather. The windows open upwards, and their arrangement and construction are conducive to ventilation.

6. The means of ventilation are ample, and consist of doors, windows, and apertures in walls. There are no jalousies or jhilmils.
7. The hospitals are cooled in the same manner as the barracks.
8. There are no means of warming the wards other than by closing the doors and windows. The walls and ceilings of the wards are cleansed and limewashed as often as the requisition is made.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	9. The ordure is removed from the privies several times a day by sweepers, and the privies are soused with water, and the cesspool into which urine falls is emptied daily. They are not offensive. 10, 11. The lavatory arrangements of the hospital are said to be insufficient, but it must be borne in mind that the barrack is only temporarily fitted as a hospital. The means of ablution for sick men are certainly inconvenient as far as the lavatories are concerned. There are four wooden tubs and four gindees to each lavatory; there are also 40 crockery basins for washing purposes in the hospital. 12. There is an establishment of three washermen to each European regiment, who wash and dry the linen; they have always been considered sufficient. 13. The storage is said to be insufficient, the hospitals to each regiment being temporary. 14. The bedsteads in use in the hospitals are chiefly wooden charpoys, laced with broad cotton tape, but there are also some iron cots. The mattresses and pillows are stuffed with straw. The sheets and coverlids are of cotton, and the blankets European and country. 15. The kitchens are the same as those to the other barracks. The fire-places are of stone and mud plastered with lime, and the means for cooking consist of cooking pots, gridirons, frying pans, and spits. They are sufficient for the purpose. The diets are properly cooked, and varied as circumstances permit; but the want of good vegetables is sometimes felt. 16. The diet rolls, tables, &c. are according to the Medical Code of the Bombay Presidency. 17. By the regulations the following establishment is allowed to a regiment of European cavalry or infantry, or a battalion of artillery complete:— 1st class servants—1 apothecary, 1 steward, 1 assistant apothecary and steward, 3 apprentices, and 1 serjeant. 2nd class hospital servants—1 matron, 1 assistant ditto, 1 native writer, 1 compounder, 1 dresser, 2 stewards' servants, 1 shop servant, 10 ward coolies, 5 bheesties, 3 dhobies, 2 tailors, 5 sweepers, 1 head cook, 2 assistant cooks, 1 leech man, 1 barber, and 10 dooly bearers. 18. No epidemics have broken out in the regimental hospitals, nor have hospital gangrene or pyæmia appeared. 19. The hospitals should be larger, better raised, and better fitted up, but as has been observed the buildings are only temporarily occupied as hospitals. 20. The convalescent system cannot be satisfactorily carried out, inasmuch as there are no wards for the purpose. When men have been discharged from hospitals, however, they are considered at convalescents in barracks, placed on barrack rations, paraded every morning for inspection at hospital, and marched out under a non-commissioned officer for morning and evening exercise. 21. In the 28th Regiment two compartments of the married men's quarters are set aside as a hospital for the sick wives and children of the men of the regiment. In the 8th Hussars they are attended at their own quarters. The hospital arrangement for this purpose is incomplete, regular hospitals not having yet been built. 22. There are no local hospital regulations which are not included in the General Presidency Medical Regulations. 23. The control of the medical officer is complete as regards change of diet and consumption of medical comforts, and whenever repairs are required to hospital or its out-offices, his requisitions are always attended to. 24. With regard to accommodation for convalescents, a proper European hospital has not yet been provided. By the regulations there should be both a convalescent and a female ward, and there will be great advantage from such accommodation.
XIII. BURIAL OF THE DEAD.	1. The graveyard is 812 yards from the nearest point of the lines, which are those of a native infantry regiment on the extreme left, 1,250 yards from the Horse Artillery lines, 1,750 yards from the nearest barrack of European infantry, and 3,000 yards from the nearest barrack of the 8th Hussars. It lies due west from the nearest point; south-west from the centre of the lines, and south-south-west from the lines on the extreme right. The prevailing winds are from the south-west. 2. The burial ground is almost a square; its area is 29,172 square yards; it is enclosed by a wall and is carefully kept. Water percolates into the subsoil or evaporates. 3. The graves are 7 feet long, 3 feet broad, and 6 feet deep, with an interval of 3 feet between each. They are never re-opened. The hours of burial are 6 a.m. and 5.30 p.m.; those dying during the night are buried the following evening, and those that die during the day on the following morning. This is a general rule, but interments frequently take place at lesser intervals, and during epidemics as quickly as arrangements can be made. The natives burn their dead in the morning after sunrise and in the evening just before sunset. Incremation takes place as soon as possible. 4. The grave yard has never as yet proved offensive, though it is to the windward of the camp. It will, however, be necessary to remove it to another position before long, as the garrison of this station has been increased by two European regiments beyond what were ever cantoned here before. British troops are buried with funeral honours. 5, 6, 7. With regard to the disposal of the dead of camp followers and bazaar people, Mahomedans bury them, and their principal burying ground is 2,000 yards from the nearest barrack, and direct eastward of it; the smaller burial ground is 820 yards from the centre of the line of barracks, and due west from it. A large proportion of the Hindoo population burn their dead; their burial ground is 1,650 yards due east from the bazaar, and 3,250 yards from the nearest point of the lines, which are on the left. No injury to the public health has as yet accrued from the present practice, and no improvement in the mode of burial is suggested.

(Signed) J. HOLMES, Lieut.-Colonel,
Commanding at Nusseerabad.
A. DURHAM, M.D., Surgeon-Major,
H.M's. 1st Bombay Lancers.
JULIUS G. T. GRIFFITH, 2nd Captain, Acting Executive Engineer, Nusseerabad and Neemuch Division.

22nd September 1860.

DEESA.

Accommodation - European Troops - Artillery, one troop, horse - 184; Infantry, one regiment - 928
Native Troops - Cavalry, one squadron - 151; Infantry, one regiment - 930

I. Topography.	1. The general aspect of the country surrounding the station is flat and sandy, gradually sloping from north southwards, sufficient only to convey the water of rivers rising in northern Rajpootana to the Gulf of Cambay. There is no wood, jungle, or water in the vicinity. 2. The station is said to be about 400 feet above the sea-level. It is on the same level as the adjacent country generally. The present cantonment not being on equal ground, the adjacent race-course presents a better spot. Its elevation is equal to that of the highest portion in cantonment, and its space is ample. 3. The nearest high land is the Jassore range, running through Rajpootana from north south-westerly, and terminating within 15 or 16 miles of Deesa. Mount Aboo is the highest point near Deesa, it is believed. The trigonometrical survey not having been published, its height is not exactly known. 4. The nearest water is the river Bunnass, which bounds the western side of the cantonment. The vicinity is not liable to overflow of water. There are many ravines but no water pits. 5. The station is open and freely exposed to the winds, but in some parts of the cantonment the arrangement of the buildings prevents the full benefit of exterior ventilation being felt. The temperature is not raised by reflected sun heat. The S.W. wind or sea breeze blows from about the middle of March to the end of June, but reaches this station as an exceedingly dry scorching wind; wet and dry bulb thermometers often showing a difference of 30° F. and upwards. Apoplexy not unfrequent at this season. Winds are more variable from the beginning of July to the end of September, but generally from the south and west. This is the wet season, and bowel complaints and fever are the most prominent ailments. Between October and March northerly winds are most frequent, and four months of this period are dry, cool, and bracing. 6. The surrounding country is uncultivated on the western side only. There are no works of irrigation near the station, and no cultivation of either rice, indigo, hemp, or flax. 7. The nearest civil population is the Sudder bazaar, which is inside the cantonment, and suburbs extend outside. The interior population is about 9,000. 8. As to geological structure, the upper soil is white friable earth. The subsoil red earth with limestone. The ground was first cleared for occupation as a cantonment. 9. Water is found at a depth of from 60 to 70 feet below the surface during the dry season, and from 50 to 60 feet from the surface in the wet season. 10. The rain-fall and surface water flows readily away, sinking into the subsoil. The drainage from higher ground on the east flows through the subsoil of the cantonment. 11. The water-supply of the station is derived from wells. There are no tanks. 12. The water is abundant, clear, agreeable, and devoid of smell. Its chemical composition has not been determined, but the saline or mineral ingredients seem to be inconsiderable, and the water would appear to be almost free from organic matter of any description. It is drawn for use in leathern bags, lowered over rollers, and pulled up by bullocks, and is distributed by bullocks and carriers. The wells might be larger in diameter and worked by machinery. Better water cannot be obtained. 13. No other topographical points besides those mentioned above. 14. Not aware of the manner in which stations are selected.
II. Climate.	1. There is a government observatory. 2. The following table gives the meteorology from January 1st, 1857, to December 31st, 1859.

Months.	Barometer Mean.	Mean Temperature.	Mean daily range.	Mean Maximum.	Mean Minimum.	Mean Dry.	Mean Wet.	Mean Sun Temperature.	Rain.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks, Clouds, Dew, Storms, &c.

II. Climate—*cont.*	3. As regards the influence of the climate on health, the extreme heat and dryness of the climate in the hot season are very exhausting, and the atmosphere is often loaded with dust, as much apparently from some electric disturbance or peculiarity as from the force of the winds. During the wet season the fall of rain is inconsiderable, and as the soil is very sandy the water rapidly disappears. There is therefore little excessive vegetation or dampness, and though fever is a frequent disease, yet it is seldom severe, while cases of dysentery are rare. The climate must be considered rather healthy, but it is nevertheless so exhausting that troops should not serve longer than two years at a time in the station. Recruits should not be sent to it till they have been seasoned in the milder climates of Poona, Khandala, or Kurrachee. There are no peculiar precautions necessary as regards clothing, diet, &c. But during the hot winds khakee is too thin a covering to protect the surface against such rapid evaporation, and coats of this material should be made with two folds in the back. From the beginning of April to the end of August the meat is necessarily of inferior quality from the want of grass for the cattle. The healthy months are November, December, January, February, March, and April. The unhealthy months are May, June, July, August, September, and October. The prevailing and fatal diseases during the latter months are apoplexy, fever, and bowel complaints, affections of the liver not being uncommon. 4. In Mount Aboo there is an elevated plain known under the name of "Ooria," near 5,000 feet above the sea, sufficiently large to accommodate at least the wing of a regiment. Ground has been selected on the same hills, about three miles from this plain, as the site of a new sanitarium for 200 men. 5. The stations at which I have served are Gazeepore, Agra, Wuzeerabad, Sealcote, Mhow, and Deesa. Gazeepore and Agra are objectionably situated on the bank of a river, and the latter possesses a very hot climate, and was not at all adequately drained. The ratio of mortality from apoplexy, dysentery, and fever is accordingly comparatively high. Sealkote has hitherto enjoyed a high character for salubrity, and Mhow, both as regards climate and salubrity, has long been a favourite station.
III. SANITARY CONDITION OF STATION.	1. 2. 3. Plans appended. Barracks constructed in 1828. Eleven rooms for 800 non-commissioned officers and men. The following table gives the details:—

Rooms.	Regulation Number of Men per Room.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in Feet per Man.	Height of Beds above Floor.	Windows.

12 - - each	1	9	9	11	891	891	81	—	—	—	—

5. The windows are on opposite sides of the rooms, and open outwards. There are verandahs on all sides; average width 10 feet, height 14 feet. They are occupied as sleeping quarters by soldiers at their own discretion. There are venetian shutters to the windows.
6. The bedsteads consist of iron trussels and boards. Bedding, one munda mattrass, with two covers for same; two cotton sheets and two country blankets. The soldier in India is well found in these particulars.
7. Structure of tents unknown. The dimensions of huts now occupied by troops in cantonment are as follows:—Soldier's tent, 14 feet square, with walls 6 feet high, poles 12¼ feet high. Cubic contents about 1,580 feet. Superficial area 196 feet. Total occupants 20 (16 men, 4 serjeants), giving 79 cubic and 9·8 superficial feet per man.
   The hospital tent is 16 × 22 feet. Pole 12 feet high. Walls 6 feet high. Cubic contents 2,818 feet, which at 25 men gives about 112 cubic feet per man. Rowties for natives are 14 × 10 × 9 feet high, with semicircular ends. Cubic contents 1,090 feet nearly. Superficial area 293 feet, giving, at 14 men, about 78 cubic and 21 superficial feet per man.
8. Ventilation of barracks is effected by punkahs, doors, and windows, and ventilators in the roof. The ventilation is scarcely sufficient for a crowded barrack.
   Punkahs and tatties are used for cooling the air. The tatties are frames of bamboo, spread over with a layer of roots of "kuskus" grass, placed in front of doors and windows, and kept continually wet by pouring water over them.
9. The barracks are constructed of burnt bricks and mortar. Roof teak wood, double tiled.
10. The floors are of concrete, raised about 2 feet above the level of the ground on the average. No passage for air beneath.
11. As regards construction, loftier barracks would be preferable, and further ventilation in the roof and walls. The floor should be of paved stone, and in no part less than 3 feet above the ground. Arrangements for privies and urinals should be entirely changed, so as to require no underground drainage.
   The barracks are kept in repair by the public works department. Ordinary repairs, or such as are necessary to maintain the buildings, are made annually. Petty repairs are made on requisition by the party in charge of the building. Repairs are executed as quickly as they can be with the labour and materials procurable. Neither are very good.
   The walls and ceilings are limewashed at no stated period. Limewashed whenever required.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	12. To each barrack is attached a washing room. There are no conveniences, however, to show in a sketch. There are two plunge baths (50 feet by 20) for the European regiment, and one smaller one for the troop of horse artillery in the cantonment. 13. (Cook-houses of the usual construction.) Natives are employed as washermen, and the work is done satisfactorily at a charge of 8 annas per month to each soldier. 14. (No description of privies or their mode of drainage, only a sketch appended.) 15. Three oil lamps allowed for each barrack room. Two kept burning all night. 16. Barracks drained by small underground drains about ½ foot square, leading to circular cesspools about 2 feet diameter and 10 feet deep. These last are emptied as found necessary. The drainage is not sufficient. No part of the barrack is damp. The fluid refuse of the barracks sinks into the subsoil. There are no foul ditches near the station. 17. As regards surface cleansing, no refuse or manure of any description is allowed to remain on the surface. Coolies and carts are employed daily to remove any filth which may be deposited between the barracks or on the officers' lines. 18. There is little or no vegetation on the surface of the cantonment, except during the rainy, season, and even then it is not excessive as in most other stations, which have a damper climate. Weeds and growth of every kind are cleared away on the recommendation of the station sanitary officer. The ventilation of the station or bazaar is not interfered with by old walls, and hedges are cut down periodically to assigned limits, as well as cleared of grass and weeds. Branches of trees are lopped off annually to a distance of six or seven feet from the ground. 19. The bazaar extends as a single street mainly along the bank of the river Bunnass, which, with the addition of open channels or surface drains, serves to carry off superfluous water. Ventilation is defective, owing to the structure of the houses, and in some places the absence of plan in their relative position to each other. The water supply is abundant and good. Cleanliness is defective, except in the main street. There are no latrines, and the natives resort to distant nullahs, and to the banks of the river. The crowding is in proportion to the poverty of the people, who are ill clad and worse fed; yet there has been no epidemic disease among them during the past year. Every precaution is taken to guard against injury to the public health, by enforcing a habit of general cleanliness throughout the bazaar, as well as by removing every sort of rubbish and filth, the presence of which might induce disease. Dungheaps are a never failing condition of native life in India, and whether there are cesspits depends on the nature of the ground and the state of the weather. Nuisance is experienced in the natives lines from wind blowing over the native dwellings. It could be obviated by taking up other ground for the native lines, which are too close to the bazaar and too confined in space. 20. Animals are slaughtered in the sudder bazaar, close to the river. The skins of the animals are cured near the ground by a rough and summary process. The dung is carried off as manure to the enclosed patches of ground under cultivation along the margin of the river, and the offal is eaten to a shred by the low caste or poorer portion of the inhabitants. 21. The horses of the bazaar people and of camp followers are either picketed in the compounds or premises of their owners, or occupy some portion of their houses set apart as shelter. The same regulations as to general cleanliness are observed, and the salubrity of these stables is preserved by causing the proprietors to remove the manure to a place beyond the limits of the cantonment, from whence it is carried away by the villagers as manure for their fields. 22. The troop horses are picketed in the open in front of the men's barracks, which are in front of the officers' lines, and these last are in front of the hospital. The manure in dry weather is sold. The stabling ground is a quadrangle about 400 feet by 300 feet. It is about 150 feet in front of the barracks, and there are about 1,400 feet in front of the hospital. 23. There are 84 married quarters for the European regiment and 14 married quarters for the troop horse artillery. Married people do not occupy barrack rooms with the men.
Officers' Quarters.	1. The sanitary condition of the officers' quarters is generally good, being kept clean by the occupants. There are no details as to drainage, none being provided. Officers should have quarters provided by the Government, a monthly rent being deducted. A suitable arrangement of officers' quarters in conjunction with the soldiers' lines would tend much to a healthier condition of cantonments; were all quarters Government property, there would be no dilapidated ruins of fallen houses, &c. as are remarkable here.
IV. Health of Troops.	1. The native community is healthy both in this station and in the district generally. 2. The prevailing diseases among the native population are diarrhœa, fever, intermittent and remittent, but spleen disease is not common. Epidemics have not hitherto occurred, but this year cholera has visited many villages in the surrounding districts, and cases of small-pox are occasionally presented. 3. The healthiness of the district is attributable to a dry climate, a sandy, rapidly absorbent soil, good water, absence of excessive vegetation, and of the sudden changes of temperature, which elsewhere, when accompanied with a moist atmosphere and other causes, produce dysentery, fever, &c. 4. The European field artillery, after two years' field service in Central India, arrived at the station in June 1859, in indifferent health, having suffered from fever and apoplexy, and since that date, fevers, boils, and guinea worm have been the most prevalent diseases. The European infantry arrived at Poona in the autumn of 1857, and enjoyed good health till November 1858, the prevailing diseases being fever and bowel complaints; arrived at Deesa in December 1858, and in the early part of 1859, and has since been in indifferent health having suffered from fever, apoplexy, diarrhœa, and cholera. No part of the men's accommodation at the station is obviously more unhealthy than the rest. 5. The troops are not camped out here. 6. I have not been in charge of troops at hill stations.

References to Subjects and Queries.	Replies.
IV. Health of Troops—*cont.*	7. In former times the health of troops resident for some time on the hills was occasionally compromised by want of variety and deficiency of vegetables in the soldiers' rations, as well as by defective conservancy arrangements and indifferent barracks. Scurvy, scorbutic dysentery, general cachexia, and anæmia were the results. Last year a company of the regiment returned to Deesa, after a year's residence in the sanitarium at Mount Aboo, and the men have since suffered from intermittent fever, which they contracted at Aboo, as a consequence of the defective nature of the barracks and their unhealthy malarious position. The only two cases, and both fatal, of heat apoplexy which occurred this year were presented in the same company, the men having been predisposed apparently to the disease by the fact of passing the previous hot season in the comparatively cool climate of the hills.
	8. I approve of hill stations for troops.
	9. There are diseases peculiar to hill stations. Some of these stations are not beyond the limits of malarious fever, while others predispose to diarrhœa, known as "hill trot." It must be added also, that most diseases of an organic nature are aggravated by hill climates.
	10. At hill stations, the precaution as regards shelter and duties must be matter of simple experience, having reference to peculiarities of climate and locality in each case. But defective diet, bad barracks, and imperfect hygienic conditions have hitherto served occasionally to cast some discredit on hill stations. The company above referred to joined the regiment from Aboo not only reduced and anæmic from the influence of the malarious poison, but somewhat scorbutic also, and it appears that mutton was the only meat issued to this company for 12 months.
	11. The best period for residence at hill stations is from the 1st April to the beginning or middle of November. The shortest period within which troops could be benefited by a hill residence would be one such season.
	12. If detained in the hills for more than two hot seasons consecutively, troops would probably arrive in the plains predisposed to apoplexy, cholera, and the more severe forms of fever; and if the conditions of life have not been favourable in regard to diet, barrack accommodation, and hygienic arrangements, they might bring with them a tendency to dysentery or diarrhœa, and a scorbutic deteriorated state of the blood.
	13. Troops should be removed from hill stations in November, and all undue exposure avoided during the ensuing hot season.
	14. The highest standard of health would be secured to troops by locating them in the hills from April to November, and in the plains from November to the end of March, alternately. On the plains frequent change of station is beneficial to the spirits, when the change is not from a good to a bad station, for on this point both officers and men are sure to entertain an opinion of some sort; beneficial to health if the march be made in cold weather, and no epidemic disease, such as cholera, prevail, but moving troops late in the season and over cholera-affected districts should be avoided, as likely to cause considerable loss.
	15. The barracks and hospitals at Kussowlie and Subathoo are considered defective in structure and plan, and inferior to those at Dugshai. At Aboo, the two barracks have been erected in a malarious gulley, surrounded on three sides by steep high hills, and communicating by a ravine into a large lake, not more than about 200 yards distant, and they are built of temporary materials, wattle and dab.
	16. No experience as to the best elevation for hill stations.
	17. The nearest hill station is Mount Aboo, 45 miles distant, approached to the foot of the hills by a level sandy road, and thence ascended by a bridle-path in about two hours. The climate has proved favourable to residents, and to the children of the Lawrence Asylum. The elevation varies from 4,000 to 5,000 feet.
	18. In India, where surface moisture is such a frequent source of disease, the more absorbent or pervious to water the subsoil for a station is, the more healthy is the station; but no locality should be selected as the site of a station in which the standing point of water is near the surface; and the banks of rivers should be avoided.
	19. The best age for a soldier proceeding to India is from 22 to 25; and the best time for landing in India is from November to January.
	20. One year's residence in the Mediterranean would be an advantage for troops intended for service in India. As regards the Bengal presidency, it would be advisable to send troops on landing to the hills and to the up-country stations; and in the Bombay presidency it is desirable to locate the troops at Poona, Kirkee, Khandala, or Kurrachee, before sending them into the hotter climates of Central India or Guzerat.
	21. No reply.
	22. British troops should serve 10 years in India. The mortality in this country is generally high during the first year's service, after which it continues less considerable for some years, while in men between 10 and 15 years' service, the death-rate becomes much increased.
	23. As regards medical boards, the opinion of the Station Invaliding Committee is very generally respected by the Presidency Board; but surgeons of regiments should be allowed to keep their invalid list open as late as possible in the year, for, if the Station Committee assemble in October, and men do not proceed to the Presidency till December, it is obvious that some cases in the meantime may present themselves which may with propriety be added to the list.
	24. Invalids should leave India for home in the end of January, if sent by the Cape; in the end of March, if sent by the overland route.
Diseases.	1. Disease inspections are held every Saturday morning, or oftener, if necessary.
	2. There is no scorbutic disease at the station.
	3. The proportion of cases of hepatic disease in the British infantry regiment last year was nearly 4 per cent. of the total admissions; and in the European artillery, not quite 3 per cent. Excessive heat and sedentary habits conduce to the disease. Young men who have not passed a previous hot season in the country, and old residents, are most subject to it.
	4. Dracunculus does not appear to be a disease of the district, except very rarely.

References to Subjects and Queries.	Replies.
IV. Health of Troops—*Diseases—cont.*	5. The proportion of cases of venereal disease in the British infantry regiment was 13 per cent. of the total admissions; and in the artillery regiment, 25 per cent. A lock hospital should be established, and put in charge of the staff surgeon of the station. 6. The epidemic diseases at the station are :— *Fever* of the intermittent and remittent types is the most prevalent disease. *Dysentery* is not a common disease at the station. *Cholera* has appeared twice in the British infantry lines since December 1859, and up to this date (August 1860) has carried off about 26 men. *Small-pox* is occasionally seen in the bazaar. *Rheumatism* is not a prevalent ailment. In the British infantry regiment the number of admissions from fever between the 1st April 1859 and the 31st March 1860 was 918, or nearly 50 per cent. of the total admissions; the number of deaths 14, or 48 per cent. of the total deaths. The number of admissions for dysentery was 34, or 1·7 per cent. of the total admissions; the number of deaths 2, or nearly 7 per cent. of the total deaths. The admissions from cholera were 5 and deaths 4, or nearly 14 per cent. of the total deaths. The admissions from rheumatism were 49, or 2·4 per cent. of the total admissions. In the European artillery the admissions for fever during the same period were 18 per cent.; for dysentery, 2 per cent.; for rheumatism, 4 per cent. of the total admissions. No deaths and no cases of cholera. 7. As regards nosological characters :—In the hot dry months of April, May, and June, fever is generally either ephemeral or continued; the latter often complicated with gastric irritation or tendency to head symptoms. In the wet season and autumn the disease assumes the intermittent and remittent forms. Diarrhœa is most frequent in wet weather, and is generally of a painless, watery character, seldom passing into dysentery. Cholera is excessively fatal, marked by early profound collapse, rather than by severe cramps or copious evacuations. These diseases have not been especially prevalent among the native population, and it has hitherto enjoyed complete immunity from cholera. It is true that the sanitary condition of the bazaars and native dwellings is at all times unsatisfactory and imperfect, yet it would appear that the exposure of all descriptions of filth—human excreta—to the free air of heaven is a great improvement to the civilization which implies the use of cesspools, sinks, urinaries, and drains, such as are exhibited at this station. Last year indifferent meat, and the bad description of vegetables, tended to impair the *physique* of the European troops, and the defective conservancy system in use, as regards cesspools, ablution rooms, sinks, urinaries, and drains, may have tended to produce zymotic disease. 8. There is nothing in the nature of the soldier's duties or occupations in the barrack to encourage epidemic disease, or to increase its prevalence on the line of march or in the field. 9. Small doses of quinine have not been tried as a prophylactic. 10. For the mitigation or prevention of epidemic disease, all liquid and solid excreta should be removed direct from the camp twice a day, the fluid from the privies, urinaries, and ablution rooms being received into iron vessels with this view. Sinks, cesspools, and drains should be entirely abandoned in the conservancy arrangements of the station; in fact, should be strictly forbidden, as dangerous to health. Placing the barracks in echellon (instead of in lines one behind another), over an extensive space of ground, would have tended to limit the prevalence of epidemic and zymotic disease in this station.
V. Intemperance.	1. The soldiers at this station are usually temperate. There are about two per cent. confirmed drunkards. 2. The proportion of admissions to hospital, directly or indirectly caused by intemperance, is not more than two per cent. A statistical table, showing the effect of intemperance on disease and crime, cannot be made out with sufficient accuracy, and in any case the result would be valueless, except in connexion with periods of service in the country, for the drunkard is most often an old resident, and long residence in India is itself an element in excessive mortality rates. Drunkenness is punished as an offence. 3. Spirits are sold in the canteens. The quality is good. In the artillery company, the consumption is scarcely one dram for each man per diem. In the infantry, during the last six months, it has amounted to two gallons eighteen drams per each man. The use of spirits is optional, and no dram is issued before morning parade. Two drams are allowed daily in the barracks and in the field. Spirits are not issued to convalescents. There are no injurious drinks other than intoxicating drinks, sold in the canteen or bazaar. 4. The consumption of spirits is injurious, if more than one dram be taken daily. It is not conducive to the internal discipline and efficiency of the corps. 5. Spirits are not given as part of the ration. Its use is entirely optional, and some men seldom or never touch it. A second dram should never be allowed in barracks, and the use of spirits should be abolished. 6. Malt liquor is essential to preserve the troops in health and vigour, but spirits are not necessary for this purpose. Of the use of wine, there is no experience. 7. Coffee, tea, lemonade, &c., are much used as drinks. Their influence is beneficial, but one material disadvantage attends the use of these drinks, as well as of spirits and malt liquor, namely, that of drawing the men into crowds in a confined space, for two or three hours in the evening, often the most oppressive part of the day, and that in which apoplexy is especially liable to occur. 8. It would be beneficial to suppress the use of spirits altogether, and to substitute beer, tea, coffee, &c. 9. It would be beneficial to prohibit the sale of spirituous liquors in the canteens and to permit only beer, tea, coffee, &c., to be sold.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	10. In regard to recommendations; if the spirit ration be allowed, it should be issued only once a day. Canteens are usually thrown open two or three hours before tattoo every evening, and, unless the accommodation is very capacious indeed, the result is overcrowding to a great extent, and fever, apoplexy, and a general increased prevalence of disease, endemic or epidemic, is the sure consequence. Moreover, as it is found practically impossible to limit the consumption of each man to the quantity of liquor he is entitled to draw, or to ascertain that he drinks the liquor he procures, it is obvious that if spirits be issued at night, drunkenness must be in many cases the necessary result. 11. As regards canteen and bazaar regulations, the orders laid down in Jameson's code and appendices are carried out at the station.
VI. Diet.	1. The ration for European troops consists of 1 lb. bread, 1 lb. meat (mutton twice a week), 1 lb. vegetables, 4 oz. rice, $\frac{5}{7}$ oz. tea (one-third green, two-thirds black), $2\frac{1}{2}$ oz. sugar, 1 oz. salt. Last autumn it was found necessary to substitute 4 oz. dhol twice a week for 4 oz. of rice, in order to add variety to the vegetable elements of the soldiers' diet, and to make up the amount of nitrogen deficient in the meat of the season. The rations are inspected by the orderly officer. 2. There is a complete ration given, but the meat is indifferent from April to the end of August. The soldier has three meals a day; breakfast, at 8 a.m.; dinner, at 1 p.m.; supper, at 5 p.m.; a portion of the meat is grilled, curried, &c., for breakfast. The remainder is cooked for dinner. The stoppage amounts to fivepence per diem. 3. The ration is susceptible of improvement. Meat of improved quality is required in the summer and autumn months, and during the latter vegetables of a proper description (which are sometimes wanting) are desirable. The rations are inspected at meal times by the orderly officers. 4. There are cookhouses well ventilated through the roofs, each having a structure of masonry extending along the centre of the room, and provided on each side with numerous cells for cooking utensils, the latter being of copper, and tinned inside twice a month, or oftener when deemed necessary. There is one master cook and 4 or 5 assistant cooks for each company. Most of them are Portuguese. Their cooking is good, and the dishes embrace curries, stews, grills, puddings and pies, &c. in great variety, and according to the taste of the men themselves. Tea and coffee are well prepared. The men have coffee on the march. 5. Soldiers' gardens for the cultivation of vegetables could be advantageously established near the station. The land assigned for this purpose should be allotted by companies; a free supply of water and tools should be available. The assistance of native labour should be provided in all the rougher operations, and sheds built to shelter the men at times from the sun and rain. Prizes might be offered with advantage for the best show of vegetables, and an equivalent for the amount of vegetables supplied might be deducted from the daily stoppage, to enable the soldier to purchase for himself eggs, butter, milk, &c.
VII. Dress, Accoutrements, and Duties.	1. In the European infantry each soldier has one forage cap, one wicker helmet with turban, six cotton shirts, two flannel shirts, or two belts, two pairs of woollen socks, four pairs of cotton socks, cloth tunic, serge tunic, cloth and serge trousers, two coats and two pairs of trousers of khakee, three pairs of boots, and one great coat. The European artillery are equally well provided. The present dress is suitable for the climate and duties. The wicker helmet with turban, the serge frock, and trousers supply deficiencies which formerly existed; but the khakee coat is too thin to protect the spinal column from the excessive heat of the sun, and should have two folds of the cloth in the back. Waterproof capes and English boots should be available for men exposed to the wet during the monsoon months, whether in the plains or in the hills. The guard dress is determined by season. Serge coats and trousers are now generally worn during the rains, and great coats when necessary. Khakee clothing is worn in the hot dry months, and warm clothing in the cold season.
Duties.	1. It would be advisable as regards health that the men should be thoroughly drilled before being sent to India. 2. In the infantry the usual duties consist of morning and evening parades, one hour after sunrise and one hour before sunset. The artillery are generally occupied in the morning for $2\frac{1}{2}$ hours on parade and stable duties, and in the evening for one hour at stables. The guards night and day are light and the duties in no way injurious to health. The infantry have from 7 to 10 and the artillery from 4 to 5 successive nights in bed. 3. The most distant guard is not more than one mile from the barracks. The day guards last for 24 hours, and each sentry is on duty four hours by day and four by night at two different periods of two hours each. There are roll calls at meals, at morning and evening parades, and at tattoo. The night guards are light and not manifestly injurious to health.
VIII. Instruction and Recreation.	1. The means of instruction and recreation consist of ball court, schools, libraries, workshops, soldiers' gardens. The last two are not kept up, however. There are no skittle grounds, day rooms, or soldiers' clubs, theatre, or gymnasia. Were all these provided perhaps it would tend to give occupation. At present not. The men are not allowed to leave their barracks during the heat of the day from the beginning of April to the commencement of the rains. The results, all things considered, are doubtful. There are advantages and disadvantages. 2. It would be advisable, by way of improving the means of recreation, to make up the deficiencies in the above list. Sheds should be constructed to protect the troops in the skittle grounds and gymnasium. A day room, provided with refreshments, would prove most useful, and divert the men from the canteen, about which they are so much addicted to crowd in the evenings. 3. The institution of soldiers' savings' banks is advantageous. 4. There is not sufficient shade from trees, sheds, verandahs, &c., for men taking exercise.

References to Subjects and Queries.	Replies.
IX. Military Prisons.	1. The solitary prison cells are ranged in two lines within a square, surrounded by a wall about 10 feet high. These buildings stand upon elevated foundations, are lofty, and are ventilated by iron bars in the doors, and by holes in the walls near the roofs. They have proved (and it is a fact worth noting) remarkably healthy, though quite unprotected from the sun and hot winds.
X. Field Service.	1. There are no local regulations for field service. 2. Camping grounds for troops on the line of march are laid down on ordinary occasions in "routes," furnished by the quartermaster-general's department; and representations from medical officers with regard to pitching the camps, halting, changing ground, &c., would, except in cases of military emergency, receive due consideration. 3. The senior medical officer is *ex officio* sanitary officer of the station, and his recommendations as to encamping any portion of the troops, as well as his sanitary suggestions generally, have hitherto been, as far as practicable, attended to. 4. No reply.
XI. Statistics of Sickness and Mortality.	1. The following form gives the statistics of sickness and mortality:—

Deesa.—European Troops.

Years.	Corps.	Strength.	Fevers.		Eruptive Fevers.		Diseases of the Lungs.		Diseases of the Liver.		Diseases of the Stomach and Bowels.		Diseases of the Brain.		Epidemic Cholera.		All other Diseases.		Total.		Ratio per Cent. to Strength.

By order of the Principal Inspector-General, Medical Department,
W. C. COLES, Assistant Surgeon,
Secretary.

Office of the Principal Inspector-General Medical Department,
Bombay, 22nd December 1860.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1. Plans, &c., of hospital.

2. The European regimental hospital is about 1,600 feet north-east of the barracks, and immediately in rear of the officers' lines. The troop hospital is 1,400 feet north-east of the horse artillery barracks, and also in rear of the officers' lines. The bazaar occupies the S.W. extremity of the cantonment. The site of the European hospital is the highest and best in the cantonment. The officers' lines are too close, and obstruct the breeze. The artillery hospital is on lower ground, and at a similar disadvantage as regards the breeze. There are no nuisances, malaria, &c., in the vicinity.
3. The water supply is abundant and wholesome.
4. The drainage is similar to that described for the barracks.
5. The ward floors are raised about 1½ feet above the ground. No ventilation underneath.

The roof water sinks into the subsoil. There is no surface drainage or guttering round the hospitals.

The hospitals are built of similar materials to the barracks. The walls are single. No complaint has been made as to heat from the roofs; were the walls higher, however, it would tend to coolness. There are verandahs 10 feet wide all round, sufficient to afford shelter from the sun's rays. The front or closed verandah of the British infantry hospital has, under circumstances of great pressure, been partially occupied, but platforms were erected on the recommendation of the medical officer, on which tents are constantly pitched for the accommodation of convalescents. The hospitals consist of one floor. They were constructed in 1827–28, and contain 12 wards and 505 beds.

The following table gives the details of the accommodation :—

Wards.	Regulation Number of Sick per Ward.	Dimensions of Ward. Length.	Breadth.	Height.	Cubic Contents.	Cubic Feet per Bed.	Superficial Feet per Bed.	Height of Beds above Floor.	Windows. Number.	Height.	Width.
		Ft.	Ft.	Ft.	Feet.			Ft. In.		Feet.	Feet.
No. 1	6	25	25	17½	10,937½	1,822 9/10	104 2/10	1 7	—	—	—

No. 2	7	20	23	22	10,120	1,445 7/10	65 7/10	1 7	4	5¾	3¾
Female ward 3	6	20	19	17¼	6,555	1,092½	63⅕	1 7	4	5¾	3¾

The hospitals are not so placed as to receive the full benefit of prevailing winds. The windows open outwards; they are of Venetian construction.

6. The hospitals are ventilated by ventilators in the roof, punkahs, doors and windows. The ventilation is generally sufficient, but not superior to that obtained by better construction.
7. Punkahs are used for cooling the air.
8. No means of warming are required.

Limewashing of wards is used whenever required; there is no stated interval for doing this.

9. The privies are detached from the hospital, and are adjacent to cesspits similar [to those of the barracks.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	10. In the artillery hospital, the lavatory arrangements are insufficient. In the infantry hospital, they consist of sheds projected from the rear verandah, fitted up with tables, basins, chatties and towels. The water supply is abundant, and the arrangements are sufficient, but not satisfactory, as the sheds interfere with the ventilation of the wards. 11. The means of bathing consist of chatties, tin baths, and basins, not sufficient nor convenient. 12. Native washermen employed by the month take away the hospital linen, and wash it at the river side, or at rain water pools. 13. The hospital storage is sufficient and dry. 14. The hospital bedsteads are made of iron, bottomed with iron plates or strong cotton tape, and are excellent. The bedding consists of counterpanes, blankets, sheets, mattresses, stuffed with rice straw, or cotton; but hair or cocoa-nut fibre would be preferable materials. 15. The means of cooking are like those described for the barracks,—cells in masonry, copper pans, pots, kettles, &c. The cooks are Portuguese or natives, and do their work tolerably well, varying the cooking as required, and acting under the superintendence of the hospital steward, and an orderly from the regiment. 16. Diet tables, &c., the same as in all other hospitals in the Presidency. 17. The attendance on the sick is ample and sufficient. In the European regiment it consists of an apothecary, steward, assistant apothecary, medical apprentices, compounder, matron, assistant matron, hospital serjeant, and the second class hospital servants, as detailed in the monthly returns of sick; orderlies from regiments being employed during epidemic disease, or in particular cases of importance. The artillery hospital is equally well provided for. 18. The sanitary condition of the hospitals is excellent. No epidemic has originated in the wards. No instance of pyæmia or hospital gangrene; ulcers and wounds heal rapidly. 19. All sanitary defects have been corrected on the representation of the medical officer; thus, ventilators have been constructed in the roofs of the privies; a dead wall in each of the wings forming the subsidiary buildings has been removed, and new ablution rooms have been constructed. But the hospital accommodation is too limited. Two small wards are required for cases of contagious disease, and for insane or drunken men, and one ward is required capable of accommodating 20 convalescents. 20. The hospitals stand in large spaces enclosed by hedges in which convalescents exercise morning and evening along walks shaded by trees. Horse exercise is allowed in the artillery when deemed necessary. 21. There is a separate hospital for women and children. The present arrangements in this respect are satisfactory. 22. There are no local hospital regulations. 23. Representations on all subjects connected with the hospital, sick, &c., have been made from time to time, as occasion required, and they have invariably received prompt attention. 24. There are no convalescent wards or hospital, but as the hospitals are too small, accommodation for convalescents, both artillery and European infantry, is necessary. It may be mentioned that the artillery hospital has no apothecary's quarters, no dead house, and no guard house, and that the men on guard occupy a corner of the front verandah of the hospital, where they eat, drink, and smoke at their discretion.
XIII. Burial of the Dead.	1. The British burial ground is inside the cantonment, and is well open to every breeze. 2. The area is about 2¼ acres. Soil, white earth; subsoil, red earth with limestone. Drainage, surface and rapidly sinking into the subsoil. 3. Grave space 3 feet wide; same distance between the graves. In ordinary cases the depth of graves is 6 feet. During epidemics it is 7 to 8 feet. Graves have never been re-opened in late experience, and the re-opening of them is only admissible for the remains of relatives of parties previously interred. Burial takes place within 24 hours after death at ordinary times. During epidemics, 16 hours after death, or 12 hours after, if practicable. 4. No graveyard is now offensive. When a soldier dies, a casualty report is forwarded by the medical officer to the officer commanding and the chaplain, in which the hour for burial is named. At that time the deceased is removed in a hearse (closed), and accompanied to the graveyard by his company and former friends. 5. The Mussulmans bury their dead in an appointed spot on the western extremity of the bazaar, near the bank of the river. The Hindoos burn their dead near the bed of the river, and the ashes being afterwards collected, are thrown into the water and washed away. 6, 7. No injury to the public health from the present practice of burial, and no improvements to suggest.

(Signed) T. Williams, Brigadier,
Commanding Deesa Field Brigade.
W. Hanbury, Surgeon, H.M. 33rd Regiment.
John R. Maunsell, Captain Engineers,
Executive Engineer, Deesa and Aboo.

Deesa, 4th September 1860.

ASSEERGHUR.

Accommodation { Queen's Troops—Infantry { H.M. 95th Regiment. The new barracks will hold 100 men when finished.
Native Troops—Infantry. Nine pendalls, about 50 men each.

References to Subjects and Queries.	Replies.
I. TOPOGRAPHY.	1. The general aspect of the country surrounding the station is wild, and cut up by ravines. To the west, and at a greater distance to the S. and S.E., it is mountainous; the rest is hilly. The surface is generally dry, but water lies for many months in the ravines. The station is in the centre of a belt of jungle, 20 miles in breadth. 2. The station is about 800 feet above the level of the sea. The nearest water is in the tanks of the fortress, which are kept filled. The river Taptee flows past at about 8 miles' distance. There is no higher or healthier ground adjoining the station. 3. The nearest hills are about 3 miles from the fortress; their summits are, however lower than the station. 4. There is no liability of the water overflowing in the vicinity. There is much broken ground, but this has no effect upon the health of the troops. 5. The station is very open, and much exposed to winds. The temperature of the station is raised by the reflected sun-heat from the rock formation universally prevalent in the fort. The winds are very variable; both the east and west winds being violent, the latter most prevalent. 6. Very little of the surrounding country is cultivated within a radius of 6 miles. There are no works of irrigation near the station. Neither rice, indigo, hemp, or flax are cultivated near the station. 7. Burhampore is at a distance of 13 miles. 8. The geological structure of the district consists chiefly of trap rock; there is very little soil, the surface is morum. The station does not occupy new ground. 9. From the nature of the surface, water cannot be dug for. There are many rocky caverns winding through the village, as well as in the station; these are nearly dry in the hot season, but are full of water in the rains. 10. The rain-fall partly flows away into the principal nullahs, and the remainder evaporates in pools. There is no adjacent higher ground the drainage from which passes into the subsoil of the station. 11. The water supply of the station is derived from tanks and rain-fall; these tanks being open, and generally well filled. The tank surface is 163,000 square feet in the fort, and about 7,000 square feet in the lower fort and village. The tanks contain *datura stramonium*, *hyoscyamus niger*, the nim tree, or *melia azadirachta*, a valuable febrifuge, &c., &c.; and all along the banks of the Taptee and close to the station may be found every kind of game, a large species of antelope, the *tigris felis*, the bear, the somber, the bison, &c. One tank is used for drinking and bathing; for the former the natives slightly clear away the surface. The water near the N. I. pendalls "15 to 20," emits effluvium during the rains; if the tanks were drained and the water cleared out this might be prevented. From the amount of minute vegetable matter in the open tanks, malaria must emanate, especially before the rains; yet this is a healthy station, and generally free from fever. 12. The water supply is sufficient for 3,500 inhabitants, inclusive of the water in the fort. There are not sufficient means at the station for analyzing the water; it is moderately hard; there is no microscope. The water in the sweet well reserved for Europeans is good, but that in the tanks is very bad, though not considered so by the natives when filtered, and the tanks are preserved for the use of the garrison, and used only for drinking. The water is raised and distributed by the mussacks of water carriers. There is no better supply to be had. Probably the supply of good water might be increased by making fresh wells in the rock. 13. The ruined walls of old native edifices might be pulled down, as they only serve as screens for an accumulation of native filth. 14. New stations should be selected by engineers and medical officers; elevated ground, with geological facilities for drainage and the formation of wells and tanks, and the cultivation of gardens should be selected; and all jungle should be destroyed within a circumference of half a mile on all sides of any new station.
II. CLIMATE.	1. The only instruments at the station for conducting or registering meteorological observations are a thermometer, pluviometer, and a rain gauge. 2. No observations or meteorological tables have been kept. 3. The climate is excellent, moderately dry, and not very variable; it is not affected by tree planting or canal irrigation. It has an excellent influence on the health of the troops, who require in this station no diet, shelter, or clothing beyond that which they receive at other stations in India. The precautions to be used with respect to drill, duties, &c. are the same which common sense dictates, and is practised in other parts of the country. The first quarter of the year is the most healthy season, and the third quarter the most unhealthy, although the difference is hardly appreciable; fever of a remittent type is prevalent in the third quarter. 4. There is no other district adjacent to the station which would offer a superior position, or be more conducive to health. 5. Assistant-Surgeon Irwin, of H.M. 28th regiment of Foot, has served in Bombay, Nussick, and Asseerghur; the first he considers quite unfit for the British soldier; the second, a much healthier station, but much visited by epidemics of cholera; the third, salubrious and conducive to health. Col. H. James, commanding Asseerghur, states, he was attached and did duty with the 1st battalion of 10th N. I. at Poona, from April to September 1821; in October he joined the 2nd battalion 9th regiment N. I. at Severndroog,

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	and followed the fortunes of that regiment (which, on the reorganization of the army on the 1st May 1824, became the 18th regiment N. I.) until February 1845; it was then at Sinde, when he left on medical certificate for England, and rejoined his regiment in 1847, and commanded it for 8 consecutive years until December 1855, when he was sent home from Aden on medical certificate. He served at most stations in the Bombay Presidency. The men were at all times healthy, except when attacked with cholera *en route* from Kulladgee to Belgaum in 1837; the regiment went to Baroda, and remained six years, during which time it was very healthy. At Aden the men suffered from scurvy the first year (1855-6); 14 officers were on sick certificate in England; 8 officers and 2 medical men left it for Aden. Sinde and Aden are the only 2 insalubrious stations; none are positively injurious.
III. Sanitary Condition of Station.	1 to 4. Plans of the station and surrounding country are transmitted. Very few drains. All refuse is thrown over the fort wall. The barracks are in course of construction for 100 men. The detachment of H.M. regiment since their arrival have occupied a fine old mosque, which will accommodate about 50 men; at present it is very crowded, with 73 men; the remainder of the detachment (20) reside in a house formerly the staff-serjeants' quarters, which is in a dilapidated state. Had the one barrack been completed, with its conveniences, the cost of which would have been about 300 rupees, the Europeans would have been supplied with splendid quarters. The right half barrack is finished, with the exception of the glass, and will accommodate about 50 men when completed; but the work of all public buildings is stopped by order of the Government. 5. The windows in the new barracks are on opposite and adjacent sides, all round the verandah; to these there are glass window shutters; and the walls of the main room are pierced with arches, without frames, and have walls built in them to the height of 4 feet. The verandah is carried round the building, and is 10 feet wide; it is not yet occupied. There are neither jalousies or jhilmils. 6, 7. There are no tents used in the garrison. 8. In the new barracks there is a ventilator, open on four sides, on the summit of the roof; all other ventilation is effected by having the walls of the sleeping apartments furnished with numerous arches which open into the verandah. The means of ventilation is decidedly sufficient to keep the air pure by night as well as by day. There are no other means adopted for the purpose of cooling the air. 9, 10. The new barracks are built chiefly of brick, partly of stone and lime. The floors are intended to be of stone; their surface will average 5 feet above the ground level; there is no passage of air beneath. 11. The walls of the barracks should be made of brick, 3 feet thick; the verandahs 4 yards in width; a double roof to the barracks, the outer roof being elevated 1 foot from the inner one, and of a smaller area; thus allowing a free current of air from below upwards, and *vice versâ*. It is the duty of the engineer officer, should he be at the station, or in his absence the fort adjutant, to keep the barracks and cantonments in repair. The work is performed by contract, and the medical officer is responsible for the general sanitary state of the cantonment. The walls and ceilings of the barracks are cleansed and lime-washed inside every 6 months; outside every 12. 12. A marginal sketch of the men's lavatories is appended to the plan transmitted. The water is supplied by hand, and drained into a cesspool near the building. 13. A marginal sketch of the cookhouses in the barracks is transmitted. The means of drainage is by removing the refuse water by hand from a reservoir outside. There are no conveniences for washing or drying linen. 14. A marginal sketch of the privies and urinals is attached and transmitted. 15. The only means of ventilation adopted for outbuildings is by the windows and doors being open; the former being upon vertical hinges in the usual way. The barracks are lighted by oil in earthen lamps. 16. The construction of sewers and drains has not been considered as yet in the new barracks; but the sewerage will be probably removed by hand. One of the tanks on the west side of the fort is unsavory at certain seasons of the year. No part of the buildings used as barracks or hospitals is in the least damp. The refuse is in all cases thrown over the fort wall. There are no foul ditches near the station. 17. There is one open space of ground near the main guard and parade ground, where all the native women of the station defæcate; this is cleaned by the mehter once a day, but the smell which arises is always offensive, and would nurture epidemic diseases, especially cholera, should it break out. The refuse, as is usual in all cases, is thrown over the fort wall. No case of cholera has as yet occurred, although it is prevalent in the Pettah below, and in the adjoining villages. 18. The surface of the cantonment is kept free from vegetation. The ruins of the old palace on the west side might with great advantage be pulled down and removed, as it only serves as a screen for filth, and would improve the health of the station. 19. The sanitary condition of the bazaar is satisfactory; it is well drained and ventilated, well supplied with water, and kept clean. The sweepers carry away all the dirt, dry leaves, &c. collected. A policeman ought to be entertained to enforce the regulations in the fortress bazaar. The native houses near the station are built in all shapes and of all sizes in the Pettah, and are irregular, like all old villages; there are neither dungheaps or cesspools within them; but no nuisance is experienced from them at the barracks. 20. Bullocks are slaughtered in the Pettah, about a mile below the fort; one sheep occasionally slaughtered in the fortress for the use of the European residents. No nuisance is experienced in the station from the condition of the slaughter-houses. 21. There are no arrangements for the stabling or picketing of bazaar horses, or those of camp followers. 22, 23. There are neither picketing grounds or stables for the artillery or cavalry horses at the station. There is no accommodation whatever for married non-commissioned officers or men; and there were two of H.M. 28th regiment who occupied barrack rooms with the men, and one of H.M. 95th regiment who does so now.
Officers' Quarters.	1. The sanitary condition of the officers' quarters is good and airy; being on a slope, the rain runs off immediately. All houses should be tiled; all grass roofs positively prohibited.

ASSEERGHUR. BOMBAY.

References to Subjects and Queries.	Replies.
IV. HEALTH OF TROOPS.	1 to 3. The surrounding district and native population are essentially unhealthy. Cholera and fever are prevalent. This may be attributed to the excessive filthiness of the habits of the native population, and the total absence of all sanitary enforcement.
	4. H. M. 28th detachment were at Bombay previous to arriving at this station, at which they remained 1 year, leaving that place on December 10th, 1859. They suffered from fever and dysentery, and arrived January 10th, 1860. Their health was good on arrival at this station. They have chiefly suffered from fever since.
	5. The troops are not camped out.
	6, 7, 8. Hill stations always to be preferred; they are more healthy for the troops.
	9 to 11. Not aware of any diseases peculiar to hill stations which the troops are liable to be attacked with on going to them. The hot seasons are best adapted for residence in hill stations. The shortest period of residence to enable troops to receive the full benefit of the hill stations would be 4 months.
	12. No injury to the troops by a longer residence.
	13. There are no special precautions required for the protection of the health of the troops on leaving hill stations for the plains.
	14. Hill stations are the best for the troops, their periods of service on the plains being brief and well-timed as to season, &c. Frequent change of station would be beneficial, respective of season.
	15. The barrack and hospital accommodation is sufficient for the troops at hill stations I have had experience of.
	16, 17. There is no higher ground near the station which could be advantageously occupied as a hill station.
	18, 19. The British soldier should land in India under 22 years of age, and during the months November, December, and January. Precautions should be taken to clothe them suitably upon landing, giving them abundance of vegetable diet, prohibiting dram drinking almost to interdiction, and promoting healthy and interesting exercise.
	20. Troops should be sent direct from the home depôts to India. If they land in the hot weather they should be gradually acclimatised by a preliminary residence in hill stations.
	21, 22. A British soldier should not serve more than 5 years at a time in India.
	23, 24. Invalids should leave India for home during the cold season.
Diseases.	1. There is a regular weekly inspection parade for the discovery of incipient diseases.
	2. There has been a tendency to the development of scorbutus in H. M. 28th detachment, owing to deficiency of the vegetable element and the rations; this might be remedied by allowing the men to cultivate gardens.
	3. The proportion of cases of hepatic disease is about 4 per cent. It is attributable to the climate, and may be considered as a primary affection; not aware of any prophylactic measures.
	4. No case of dracunculus has occurred at the station.
	5. Cases of venereal disease are few and far between.
	6. The troops at this station suffer from endemic diseases, such as remittent, intermittent, and common fevers, acute and chronic dysentery, and acute rheumatism. No case of cholera or small pox has occurred; neither has there been a death.
	7. Zymotic diseases have been so rare that no distinct axiom can be drawn as to their general nosological character.
	8. The prevalence and extent of epidemic disease in this country is influenced considerably by the absence of healthy occupation for both mind and body, as also by the long and tedious marches which the troops are subjected to.
	9. Small doses of quinine have not been administered at the station as a prophylactic against malarial diseases.
	10. Thorough and efficient surface cleansing of the station and its vicinity, good drainage, the occasional cleansing of tanks from superabundance of vegetable matter, and the strictest attention (and this is often disregarded) to avoiding overcrowding the men in barracks would be the best means of preventing or mitigating epidemic disease at the station.
V. INTEMPERANCE.	1. The soldiers at this station are generally temperate; there are only between two or three confirmed drunkards.
	2. The proportion of admissions into hospitals caused by diseases the direct result of intemperance is 1 per cent.; there are none caused indirectly. Having arrived only four months since at the station there are no statistics prepared of the amount of sickness, mortality, or crime at the station caused by intemperance, total abstinence, or temperance; besides the number of men is only 79 Europeans. Drunkenness is punished as an offence.
	3. Distilled spirits are sold in the bazaar, but European soldiers are not allowed to buy them. The quality is: arrack, $\frac{1}{2}\frac{9}{5}$ths; water, $\frac{6}{2}\frac{}{5}$ths. Spirits form part of the soldier's rations at the station, on the march, and in the field. No spirits are issued on the march before sunset; one dram is allowed in the morning before breakfast. This practice is not detrimental to their health in the cold season, but good strong hot coffee would be a good substitute in the hot season. One dram is given at the discretion of the medical officer.
	4. Malt liquor is decidedly preferable to spirits for troops and covalescents; spirits are not generally issued or allowed by the medical officer to convalescents. The consumption of spirits throughout India is not conducive to the efficiency and internal discipline of the corps; yet the 95th detachment here has not been materially affected by it.
	5. Decidedly agree in abolishing the issue of spirits, except on the march, substituting an equivalent of beer or porter for the dram.
	6. Malt liquors, to the extent of one quart per day, are decidedly beneficial to the soldier in the habit of drinking fermented liquors, and are far superior to spirituous liquors in conserving health.
	7. No coffee is issued at the station; tea is used in moderation; ginger beer is the only effervescing drink used, and that very moderately. Their use is much more conducive to health, efficiency, and discipline than the use of spirits, or excessive consumption of malt liquors.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	8. It would be most decidedly beneficial to the health of the troops on the station if the spirit ration was abolished. Let beer and coffee be substituted. 9. It would be emphatically beneficial to prohibit the sale of spirituous liquors in the canteens to the troops. 10. No further recommendations on these points.
VI. Diet.	1. The ration for Queen's British troops and European troops in the Indian army is exactly the same, consisting of:—1 lb. bread, 1 lb. beef or mutton, 1 lb. mixed vegetables, 4 oz. rice, 1 oz. salt, $\frac{5}{7}$ oz. tea (mixed), $2\frac{1}{2}$ oz. sugar. The ration is inspected by the officer of the day, and the quarter-master sergeant. 2. A complete ration is provided; stoppage 1 rupee 4 pice per month; 3 meals per diem. One pound of mixed vegetables enters into the constitution of the ration. 3. It would be a considerable improvement in the ration if 1 cup of coffee and a hard biscuit were given to each man in the early part of the morning, before parade; the men having to rise very early in tropical climates, and at present have to go through fatiguing drills, &c. on an empty stomach, having to wait until 8 p.m. for breakfast. 4. The rations are cooked on an open fire-place by native cooks. The kitchens are at present dirty, and not well ventilated. They are, however, undergoing alterations, and will be white-washed when finished. They are well supplied with water. The food is roasted. The cooking is properly carried out, and tea and coffee properly prepared by the native cooks. When practicable the men on march have coffee issued to them after the first halt, 1 hour after leaving the old camp ground. 5. Gardens for the cultivation of vegetables by soldiers would have to be 3 miles away, each time descending and ascending the hill, the ground being also stony all around, and very little water obtainable 2 months after the monsoon.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress and accoutrements at this station consist of khakee clothing by day and large clothing by night, during the summer months, from 1st April to the middle of the monsoon in August. Cloth clothing is worn during the winter months or cold season, from September to April. The soldier's clothing is sufficient and suitable to the climate. The wearing of flannel next the skin should be enforced; the helmet should be made of wicker-work, and covered with pith 1 inch in thickness. The guard dress consists of khakee clothing, and the wicker-work helmet and cotton turban. English cloaks are the only protection from wet.
Duties.	1. Owing to the enervating, relaxing effects of the climate on Europeans, drill would be better and more readily learnt at home, and the figure better set up, than in India. 2. The usual routine is drill 1 hour after sunrise, which is beneficial to the men's health; it is the best time for drill. Marches should be performed so as to reach the new camp ground as soon as possible after sunrise. The men have on the average 4 or 5 nights in bed during the week. 3. Guards are mounted between 200 and 300 yards from barracks, and are relieved every morning. The roll is called after revéillée and before each meal. No additional precautions are requisite at this station for the performance of this duty.
VIII. Instruction and Recreation.	1. The means of recreation and instruction at this station consist of a ball-court, which is out of repair, a company library, and a theatre in a private house. There are no skittle-grounds, day-room, or soldiers' clubs, workshops, or gymnasia, consequently the men are not sufficiently occupied during the wet season or during the heat of the day. Restrictions are placed on the men as to exposure to the sun and rain when off duty, which, when carried out effectively, conduce to their health. 2. I would suggest the putting of the ball-court in working order, allowing fishing in the tanks, providing skittles and a skittle-ground, and encouraging quoits, leap-frog, &c. 3. Soldiers' savings' banks advantageous. 4. There is no shade from trees or sheds. In the new barracks, the verandahs are ample and well adapted for walking exercise.
IX. Military Prisons.	1. There is no military prison; the cells are good in a sanitary point of view.
X. Field Service.	No information under this head.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1, 2. The hospital is situated in the most elevated locality in the station, near the barracks. There are no stables. It is remote from the bazaar of the fort, which is very small. The civil houses are very few. The site is open and airy, and the ventilation is not obstructed by any buildings; the site of the hospital is in all respects healthy. 3. The water from 1 well only is good, but as this is reserved for Europeans only there is an abundance for them. Filtration of the water through charcoal and sand is a cheap and easy method of purifying it; and the practice should be instituted and enforced. 4. There is no drainage, but refuse matters and sewage are removed by the native sweepers. 5. The height of the lowest wards in the hospital above the ground is 4 yds. 1 ft. $9\frac{3}{4}$ in. There is no perflation of air beneath the floors. The roof water sinks into the subsoil. The hospitals being situated on elevated ground, the slope carries off the water rapidly and sufficiently. There are no drains or gutters around it. The hospital is built of brick, mud, and timber, and brick tiles. The roofs and walls are single but sufficiently thick to keep the hospital cool. There are verandahs on three sides, the length of which is 35 yds. 1 ft. 10 in., the breadth 2 yds. 2 ft. $\frac{1}{2}$ in., and the height 3 yds. 5 inches; these are used by sick patients during morning and evening, when able to take such exercise. The hospital

ASSEERGHUR. BOMBAY.

6. The ventilation in use in the wards is by means of doors and windows, which are sufficient; no punkahs are used here. There are neither jalousies or jhilmils.
7. There are no means of cooling the air in the wards.
8. There is no necessity for warming the hospital wards. The walls and ceilings are cleansed and lime-washed twice a year interiorly, and once a year exteriorly.
9. There is 1 privy closely adjacent to the hospital; it is made of brick, and quite sufficient. There is no system of drainage; the mehter cleans them twice daily; they are not offensive.
10. There is 1 ample bath room for bathing and washing; this is sufficient for the requirements of the sick that the hospital can contain.
11. There is a large tub which is used for bathing by the sick, also a mussack bath, convenient and sufficient.
12. The washerman cleanses and dries the hospital linen, and performs this duty satisfactorily.
13. The storage is sufficient.
14. The bedsteads are constructed of iron with tapes (which are washed once a month) for supporting the mattresses.
15. The hospital kitchen is commodious, being adjacent to the hospital. The means and apparatus are abundant, tinned copper ghindies being the vessels employed the cooking of diets is properly done and sufficiently varied.
16. A copy of the diet table and diet roll is transmitted; all the other forms, &c. are those prescribed by the new hospital regulations for Queen's troops.
17. The attendance upon the sick is provided by a plentiful supply of ward coolies, dressers, &c., but a European soldier, when requiring it, can have the attendance of a comrade by permission of the medical officer. There is an acting hospital serjeant resident in the hospital.
18. During my experience (4 months) the sanitary condition of the hospital has been very good; no epidemic disease, hospital gangrene, or pyœmia have appeared in the wards.
19. There are no deficiencies or sanitary defects, excepting the very dirty and unwhitewashed condition of the hospital out-houses.
20. There is no special provision for the exercising of convalescents. The hospital dhoolie is occasionally used in the evening by convalescents. There are no shaded walks or seats for the sick. When able the sick take exercise in the hospital compound in the evening.
21. The soldiers' sick wives and children are treated in their own quarters; the present arrangement is sufficient as only 1 woman 1 child are present with the detachment.
22. There are no special local hospital regulations.
23. Practically speaking the medical officer has no power in matters connected with the sanitary state of his hospital, for although he may make suggestions he cannot enable them to be carried out with that energy and speed which the vital subject of preserving the health of the British troops demands. As regards diet, medical comforts, &c. at this station, his powers are ample.
24. There are no convalescent wards in the hospital. The number of British troops being so small (only 100 here) there is no necessity for them.

XIII. BURIAL OF THE DEAD.

1. The station is very limited and the burial ground is within the station and about 200 yards from the main guard. The prevailing winds, especially at night, blow from this ground over the main guard and native prison and the present barracks.
2. The area of the burial ground is 11,400 square feet, its soil is morum; and it is carefully kept.
3. The burial ground in the station is on the west side, but is not a nuisance. A space of 6 feet by 3 feet is allowed for each grave and an interval of about 3 feet between them. The graves are about 3 feet deep, and are never reopened excepting to erect a tomb of masonry. Only 1 corpse is buried in a grave. Interment takes place generally 24 hours after death, as the body decomposes quickly, at ordinary times; in cases of cholera immediately. There is no burial ground for native troops.

XIII. Burial of the Dead —*cont.*	4. I have not detected any offensiveness arising from the graveyard. 5. The dead belonging to camp followers and bazaar people are buried or burnt according to caste, outside the fortress. 6. I have not detected any injury to the public health arising from the practice. 7. I should suggest a burial ground being established below the fort, at a distance of half a mile from the pettah, since within such a very circumscribed space as the fort occcupies, a great accumulation of interred corpses must eventually tell on the health of the residents, especially in a tropical climate.

(Signed) H. James, Colonel, commanding Asseerghur.
John S. Allanby, M.D., Assistant Surgeon, H.M. 82nd Regt.

I. Topography.	1. The country surrounding the station is completely open and gently undulating; in some parts the undulations being very slight. The soil of the station is gravelly, with an underlying rock of sandstone; while that of the adjacent country consists of black, or what is termed cotton soil. There is no wood or jungle whatever, and the supply of water in the vicinity is very limited. 2, 3. The elevation of the station above the sea is 1,821 feet, but it is on much the same level as that of the adjacent country. The nearest water is a large tank, to the north of the artillery lines, the surface of which is 48 feet below barracks, and 44½ feet below the hospital floor level. Within 30 miles of this station there is no higher ground than the camp of Sholapore, and we are unable to state whether an extra elevation of 200 feet, which is obtainable at that distance, would be attended with any corresponding advantages to health and situation. The higher ground referred to is a tract of table land. 4. With the exception of a nullah which overflows its banks during the rainy season, and forms a marsh 3½ miles from camp to the north-east, the nearest water is the Seena river, which bends in such a form as to be within 13 miles of the camp to the east and eight to the south. The overflow from the nullah generally takes place in September and renders the road impassable for three or four days, but probably the adjacant country remains flooded for ten days or a fortnight. There is some slightly broken ground, some small ravines, and one or two water pits in the vicinity of the cantonment, but they have never been found injurious or in any perceptible manner to affect the health of the station. 5. The station is completely open and exposed to the prevailing winds, and none of the buildings exposed to reflected sun heat. The sea breeze is not felt at Sholapore, and the only wind which may be said to be disagreeable is that from the east. It is during the prevalence of this wind that fevers, ague, &c., usually occur. 6. The surrounding country is cultivated principally with dry crops, such as jowarree, bajree, grain, linseed, and cotton. There are no works of irrigation near the station, and no sensible effect has been found from the very slight artificial irrigation that is carried on in the vegetable gardens in the vicinity of the station. There is no ground suitable for rice cultivation within six miles of camp, at which distance there are only a few acres under cultivation. Indigo is not grown, nor is the preparation of hemp or flax carried on near the station. 7. The town of Sholapore, containing nearly 60,000 inhabitants, is within a mile of the station to the north. 8. The geological structure of the district consists of trap rock, generally speaking, covered by a bed of reddish kunkur, on which rests the regur or black cotton soil. There are also to the south, small ranges of low flat-topped hills, composed of laterite, remarkable as rising above the low trap formations amid which they are situated. We have no reason to believe that the ground which the station occupies has ever previously been occupied by population. 9. During the dry season the wells are dry, and water would not probably be met with in any quantity at a less depth than 80 feet below the surface, but during the rainy season water may be found at a depth of from 20 to 30 feet, varying in quantity according to the rainfall. 10. We believe that water from superficial springs flows readily away. A portion sinks into the pervious subsoil, and is so drained off; it does not ooze out after once being absorbed, and except in tanks, there is no spot where it can lie on the surface and evaporate. There is some slightly higher ground in the vicinity, but owing to the nature of the surface of the ground about the camp, the surface drainage is very effective. 11. The water supply is derived from wells fed for the most part by the percolation of the water stored in tanks on a higher level. Water for other than drinking purposes is stored in open tanks, and the surface of those within the station, when full, covers 152,736 square yards. Unless there is heavy rain in the months of April or May these tanks are liable to dry up, but it is five or six years since either of those at Sholapore were quite dry, still there is a great difference in the quantity of water stored immediately after the monsoon and the quantity in the tanks just before its commencement. Besides the grasses of different descriptions, and rushes, which line the banks of the tank to the north of the station adjoining the fort, the water contains flos aqua, and the infusoria which accompany them viz. the encapsuled amabæ, also oscillatoria and œdogonium. The water in the tank near the artillery lines may contain some organic matter, but it is free from plants, owing to its basin being of rock. Arrangements are made to guard against the water in any tank used for drinking purposes being also used for bathing, and these arrangements are, as far as practicable, enforced. The only well which would be liable to pollution from leaves or other matter falling into it, is protected by a roof, constructed of durable materials; and precau-

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	tions are taken to prevent any foul drainage or surface impurities draining into the tanks containing drinking water. If there should have been a scarcity of rain, and the water of the tank near the town fall so as to expose the ground and admit of the decomposition of the flos aqua, the houses on its bank have proved most unhealthy, and it is difficult to suggest means for preventing such nuisance. 12. The amount of really good water available for the station is limited, and in 1853 there was a scarcity of it. The drinking water is very good and soft. Its specific gravity, when filtered, is 1000·4, and the approximate number of grains of solid matter in a gallon is 30. It is altogether colourless; and with regard to its microscopical character, a bottle of water that was sent to Bombay to be tested was reported to contain nothing but a little shiny film of organic matter. It may, therefore, be inferred that it is very pure. The quality of the water is considered to be very good, and in no way injurious to health, but, as previously stated, the supply is limited. The water is raised from wells, generally speaking, by leathern vessels used by bheesties. It is not improbable that a better supply of water might, at a large expenditure, be obtained, but the means to be adopted for securing such must in a great measure be experimental. 13. We have no other topographical points to offer bearing on the health of the station. 14. It is, we believe, customary for the Government to decide who shall be appointed for the duty of selecting new stations. We think that considerable care is bestowed on the subject, and all possible means to guard against failure resorted to; still we are of opinion that it is a matter of very serious difficulty to decide whether a spot which is in every way found to be favourable for a native population should be equally so for the European constitution, and for this reason consider that in every case there should be a temporary before a permanent location.
II. CLIMATE.	1. The only instruments at present available for meteorological observations are the thermometer and pluviometer. 2. The following meteorological table is the result of 10 years' observations, from January 1850 to December 1860, as far as the instruments available have admitted of their being taken :—

Months.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Rain, Inches.	Winds.	
						Direction.	Force.
	°	°	°	°			
January -	74·5	10·2	79·6	69·4	·08	E.	Moderate.
February -	77·9	11·6	83·7	72·1	·46	Variable.	Calm.
March -	84·5	12·3	90·7	78·4	·333	W.	Gales.
April - -	88·7	8·5	93·0	84·5	1·92	N.	
May - -	87·9	10·8	93·3	82·6	2·273	N.W.	Stormy.
June - -	83·3	8·5	87·6	79·1	3·680	W.	High winds.
July - -	80·5	5·9	83·5	77·6	4·255	W.	do.
August -	80·2	6·6	83·5	76·9	6·223	W.	Moderate.
September -	80·5	7·6	84·3	76·7	6·770	W.	Monsoon.
October -	79·7	7·1	83·3	76·2	4·715	N.E.	Calm.
November -	77·1	7·5	80·9	73·4	1·411	N.E.	Calm.
December -	71·8	11·9	77·8	65·9	·496	N.E.	Calm.

3. The climate of Sholapore is warm and dry during the greater part of the year, the average temperature for the year being about 80°, and the lowest not under 65°, and the mean maximum 93°, thus showing a considerable range. The mercury obtains its highest elevation in the month of May, and its lowest in December. The greatest variability of temperature occurs in March, when the mean is 12° during the 24 hours, and the least variability is observed in October, the mean then being 7°; the mean daily range for the whole year being 9°. The greatest rain-fall has been 40 inches, and the least 13. Fogs occasionally occur during the months of February and March, towards evening. Tree-planting has been carried out to so small an extent that its effect can scarcely be appreciated. The atmosphere is pure, and during the greater part of the year highly rarefied. The high winds that prevail at certain seasons tend in a great degree to purify the air, and remove noxious vapours and effluvia; the absence of the conditions which are necessary to the production of malaria conduces also to this result. Hitherto the station has ranked high in the scale of localities at which European troops have retained their health; we are not aware that any particular kind of diet is necessary. Shelter, of course, should be of a superior description; but as regards clothing, we do not consider any change or addition requisite. The early morning and evening parades at the regulated hours, decreasing the amount of drill during the hot weather, are matters which have been duly considered, and the regulations in force under this head for the guidance of commanding officers are most judicious. The most healthy months are February, March, and April, and the most unhealthy are July, August, December, and January. The prevailing diseases during the months of July and August are intermittent fevers of the quotidian and tertian types, and diseases of the stomach and bowels (chiefly diarrhœa and dysentery). The prevailing diseases in the months of December and January are intermittent fever, congestion of the internal organs, and functional hepatic disorders.

4. We have no reliable data to base an opinion as to the advantages of any district near the station which might prove more conducive to health than that of the station.

5. The president, during a service of 41 years, has served at every military station in the Bombay Presidency, except Mhow and Deesa. He believes Baroda and Ahmedabad to be the most unhealthy, and Poona the most healthy. The senior medical member of the Committee, during a service of 28 years, has served at most of the stations of the Bombay army, and considers Ahmedabad and Baroda the most unhealthy, and Neemuch the most healthy station. The junior medical member has served longest at Deesa, Mhow, and Sholapore, and considers Deesa and Mhow decidedly the most healthy. The engineer officer has served at Poona, Belgaum, and Sholapore only, during a service of seven years. The stations above named stand high in the scale of salubrity.

Prison cells -	1	12 6	12¼	13¼	2,028	2,028	153	Are ventilated by means of air holes in the walls and by ventilators in the roof.			

5. The windows are ordinary plank shutters, three in number, two of which open horizontally for the lower half, and one vertically for the upper half. They are on opposite sides of the rooms. The barracks have a verandah on one side, but it is never used as sleeping quarters. There are no jalousies or jhilmils.
6. The bedsteads used in barracks are either planks on iron trestles or wholly of iron. In the tents, straw is served out. The bedding consists of a felt cushion, blankets, sheets, pillow stuffed with coir, and a carpet to tie up the whole in.
7. The following table gives the dimensions, &c. of the tents used in camp:—

Description of Tents.	Dimensions.		Space allotted to each Man.			Materials of which compose
	Superficial Area.	Cubical Space.	Number of Men to each Tent.	Superficial Area.	Cubical Space.	
	Sq. ft. in.	Cub. ft. in.		Sq. ft. in.	Cub. ft. in.	
Tent, hospital, European soldiers' double-walled - - - - - - -	330 0	2,655 0	12	27 72	221 432	Cloth dungaree, double, outer white; lining either blue, red, or yellow. Poles, some of bamboo, some of teak.

Do. do. hospital - - - -	330 0	2,655 0	12	27 72	221 432	

8. In barracks, ventilation is effected by means of ventilators of different descriptions, fixed to the ridge of the roof. No measures are taken for ventilating tents beyond the doors, and taking precautions against crowding within them. The ventilation of the sepoys' huts is left entirely to themselves; but the ventilation of the guard-room is secured in the same manner as the barracks. Considerable attention is paid to the subject of ventilation, and all Government buildings are periodically inspected by responsible officers. The air in barrack rooms is cooled by "kuskus tatties," which are kept continually wet. A tatty 7 feet by 4 feet would cost 4 rupees, and a bheestie at 7 rupees per mensem, and one coolie at 3 rupees 8 annas, would be able to keep watered the windows and doors of a barrack for 100 men.
9. The barracks are constructed of burnt bricks and lime, with thatched roofs. The principal material made use of in the construction of tents is a description of cotton cloth called "dungaree," of which there are 4, 5, or more folds in the top and walls. Huts are constructed by the sepoys themselves out of an allowance made them by the Government, and are of the poorest description, being mud walls, averaging 10 feet square, and 5½ in height, with a thatched roof.
10. Floors are invariably raised above the ground level, but there is no passage of air beneath. If not paved with stone they are made of clean gravel and sand well watered and rammed; the surface being plastered once a week, or oftener, with cowdung.
11. Regarding the material of which the barracks at this station are constructed, we have no objection to raise, believing it to be an established fact that thatched roofs are cooler than those that are tiled. As to the construction it would be quite possible to improve the design, as the present buildings were erected some 30 years ago; but whether such alterations and improvements would increase their salubrity very materially we cannot pretend to say, the hospital reports being most favourable. Still, we are of opinion, that if additional accommodation for lavatories was available, the comfort of the men would be very materially increased. All repairs to barracks and buildings in the cantonment, and the repairs of all roads, &c. are executed by the executive engineer; the responsibility of the general sanitary state of the cantonment resting with the barrack-master under the orders of the brigadier commanding. The walls and ceilings of barracks are cleansed and limewashed once every six months.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	12. There are properly speaking no lavatories, the men washing themselves in one end of the verandah of the barrack; but at a short distance from the barrack there is an excellent plunge bath 30 by 20, and 4½ feet deep at one end and 8 feet deep at the other. This bath is well supplied with water from a reservoir, and constantly changed, the bath being emptied by a drain leading to the bed of a nullah about 100 yards off. 13. The cook-houses are of the ordinary description made use of in this country, merely a cooking range with iron tripods for camp kettles; the ingenuity of the cooks supplying all deficiencies of apparatus. Water is supplied by bheesties, and the refuse water is drained away into sinks at the corners outside, which, when full, are emptied by sweepers and others retained for the purpose, and the contents removed to a distance. All arrangements for washing and drying linen are left to the regimental dhobies, and the present system is unobjectionable. 14. The contents of the privies are immediately removed, and the urinals frequently cleansed with lime, and the buildings themselves are all that could be desired. We believe it to have been established that it would not do to allow either cesspits or urinals to remain unemptied for any length of time, and the actual design of a privy in the absence of such pits and urine basins is immaterial. 15. These buildings are sufficiently ventilated by honeycomb tiling in the walls, but are not lighted at night. 16. There are no sewers or drains whatever in the vicinity of the barracks; all refuse water, &c. being removed as before mentioned. There is no part of any of the buildings in any locality damp. The drainage is sufficient; the only fluid refuse of the barracks is from the men's lavatories, which is thrown out on the surface and evaporates; all other fluid refuse, as before stated, being removed. No cesspits exist, the litter heaps being the only things of the sort near the men's quarters and hospital, but as the manure is removed daily, they can scarcely be designated a nuisance; no smell being perceptible even in the immediate vicinity. There are no foul ditches. 17. The surface cleansing within the cantonment and its vicinity is efficiently done, an establishment being kept up for the purpose, and the work at some part or other of the camp carried on daily. The refuse manure, &c. is carted to different distant localities, and burnt or buried. 18. The surface of the cantonment is kept free of vegetation; no old walls, thick hedges, &c., or other obstructions to the ventilation of the station, exist. 19. The bazaar is clean, well drained, and ventilated. The water supply is derived from wells which, though not affording a very ample supply in the immediate neighbourhood, still no scarcity is complained of except during seasons of drought. Existing regulations secure cleanliness and efficiency in all sanitary arrangements, and though no paid establishment exists for this purpose (owing to the military bazaars here not being very extensive), the sanitary condition appears to be all that is desirable. In large bazaars not removed to any great distance from native towns, probably improvements in the sanitary police would be necessary, but none in our opinion is called for at Sholapore. A superintending officer looks after the native houses in the Sudder bazaar; no other native houses exist near the station, nor any dung-heaps or cesspits. None of the native houses are to the windward of the barracks. 20. There are two slaughter-houses within the bazaars of the cantonments, which are kept clean by means of a fund created for that purpose, called the slaughter-house fund. Each butcher slaughtering an animal pays a small fee, which is devoted to the above purpose, and to the carrying away out of camp all offal and refuse. Strict supervision is exercised over all slaughter-houses; and a peon is constantly in attendance to prevent nuisance, either in them or the adjoining meat markets. No nuisance from these places has been complained of. 21. No person is allowed to picket an animal of any description in or near a road, except in places devoted to the purpose, which last are visited daily to see that there is no accumulation of litter. The manure is, generally speaking, made into fuel, which is done in open and uninhabited places far from any houses. This fuel is valuable, from the scarcity and consequent high price of wood. 22. At this station the artillery and cavalry horses are (with the exception of those that are sick) picketed in the open and appear very healthy. The dung-heaps are, together with the litter, quickly removed by the buffalo keepers, to whom it is sold, and we have reason to believe that they give it to the buffaloes as a portion of their food. The picketing grounds are clean and remarkably well kept. 23. No married people occupy barrack rooms, but such quarters as do exist at this station for married soldiers are not creditable to the Government. Suitable buildings have been estimated for, but no steps appear likely to be taken for securing the erection of the buildings.
Officers' Quarters.	1. The officers' quarters at this station consist of detached bungalows. The drainage and ventilation of these buildings, we believe, are suited to the wants of the officers. We have no improvements to suggest, as the regulations provide for the removal of any unhealthy or dilapidated quarters situated within the cantonment limits.
IV. HEALTH OF THE TROOPS.	1. The station, district, and adjoining native population are generally healthy, excepting epidemics. 2. The civil surgeon at Sholapore (a resident of nine years) states that the most prevalent are quotidian, intermittent fever, diarrhœa, dysentery, and guinea worm. Cholera and small-pox occur epidemically at certain seasons, but seldom to a great extent; and less among the inhabitants of the cantonment and town of Sholapore than amongst those resident in certain parts of the districts. Diseases of the spleen are not of very common occurrence. 3. The causes to which the diseases prevailing among the native population may be attributed are, principally, exposure to alternations of temperature without proper covering, improper or insufficient food, neglect of ordinary sanitary precautions in the arrangements of their dwellings, abuse of intoxicating drugs, and the impurity of the water during the hot season. Their immunity from many diseases is referable to the character of the soil, freedom from jungle and other sources of malaria, and the general equability of the climate. 4. The artillery came from Poona, where they had been for six months, and which they left on the 7th January 1858. Their state of health there was good, the regiment having chiefly suffered from fever. On arriving at Sholapore they were in good health, and since then intermittent fevers have been the cause of the greater number of admissions into hospital.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	The cavalry came from field service at Jhansi, where they had been for 18 months, and which they left on 2nd December 1859 in good health. Fever was the most prevalent disease there as here, but their health since arrival has been generally good. The native infantry came from Dharwar, where they had been for two years and eleven months. The state of their health there was good, the regiment having chiefly suffered from intermittent fevers and diarrhœa. The prevailing diseases since arrival at this station have been fever and dracunculus. No portion of the men's present accommodation is more unhealthy than the rest. 5. The troops are never camped out. 6 to 13. No experience with troops at hill stations. 14. Frequent change of station we consider would be decidedly beneficial to troops. 15, 16. No experience of hill stations. 17. We are not aware that there is any high ground near the station which could be advantageously occupied as a hill station. 18. Cannot say which is the healthiest or unhealthiest class of surface and subsoil for stations. 19. Soldiers should not proceed to India before they are 20 years old, but as soon after that age as possible. Troops should land in India between the months of November and January, and recruits should be sent at once to the Deccan, in order to preserve their health. 20. Troops intended for the Bombay Presidency, if they were sent immediately to the Deccan, might, without any evil consequences, come direct from home to India. It would be advisable that new troops on landing should be sent to a station where there is another regiment that has served some time in India, whether it be in the plains or on the hills, but the latter would be preferable. 21. The usual mode of transport into the interior is by marching early in the mornings at the rate of 10 miles a day, with occasional halts, the men invariably passing the day under canvass. We cannot recommend any additional precautions, and, provided the season of the year is favourable, the health of troops on the march is, we may say, proverbially good. 22. No experience to say what is the number of years a British soldier should serve in India. 23. We think that medical boards should assemble in every division with the deputy inspector-general as president, when practicable, whose decision shall be final. In the event of the deputy inspector-general not being president of the divisional committee, the opinion of such committee should in no case be final. 24. The end of December or the beginning of January is the time of year for invalids to leave India for home, if proceeding by the Cape of Good Hope route.
Diseases.	1. There are no inspection parades at the station for the discovery of incipient diseases. 2. There have been cases of scorbutus in the European artillery and native cavalry and infantry, but were attributable to service in Persia, Central India, and previous disease. They have all recovered. 3. Hepatic disease does not exist at this station. 4. The proportion of cases admitted of dracunculus for the last year is 6·75 per cent. It is attributed to the men drinking and bathing in impure water, but we cannot suggest any prophylactic measures. 5. The proportion of admissions from venereal disease to the total admissions for last year has been 2·25 per cent., and the proportions of constantly sick from venereal disease to the total sick has been 1·04 per cent. for the past year. The establishment of lock hospitals would not prove disadvantageous. 6. We have not had any epidemic at this station for some time. The prevailing diseases are fevers of the intermittent quotidian type in a mild form. There have been but few cases of rheumatism. The want of correct data prevents our giving the proportion which admissions and deaths from fevers, dysentery, cholera, small-pox, and rheumatism, bear to the total admissions and deaths. 7. The principal zymotic diseases met with amongst the native population of Sholapore are, of endemics, intermittent fever, which generally assumes the quotidian type; of epidemics, cholera in its spasmodic form, and choleraic diarrhœa. Of contagious diseases, small-pox and measles are the most frequent. Intermittent fever prevails more or less in the months of November, December, and January, which are characterized by hot days and cold nights, a strong drying easterly wind, and hot sun. The months of May, June, July, and August, during which cholera prevails, are for the most part hot, cloudy, and oppressive, with occasional showers of rain, and a highly electrical condition of atmosphere. When small-pox and measles prevail, which is in the months of March and April, there is nothing observable in the state of the air, the temperature being equable and warm, and the atmosphere clear. We are not aware, however, that the diseases above enumerated are more prevalent in one locality than another. Imperfect ventilation of their dwellings, scanty unnutritious diet, and neglect of the ordinary sanitary precautions, are the causes which predispose the native population to the attacks of the above-mentioned diseases, and conduce to a larger rate of mortality than would otherwise obtain here. 8. No reply to this question. 9. Quinine has not been tried at the station as a prophylactic against malarial disease. 10. The measure to be taken for the prevention or mitigation of epidemic disease is removal from the spot where the disease is prevalent.
V. Intemperance.	1. The soldiers at the station are temperate, only two men out of the 76 forming the artillery company being confirmed drunkards. 2. The medical officers cannot prepare the statistical table of the effect of total abstinence temperance, and drunkenness on the amount of sickness, mortality, and crime at the station having been generally in charge of native troops, with an occasional temporary charge of detachments of Europeans. Drunkenness is always punished as an offence. 3. Spirits, supplied by the commissariat department 24 degrees below proof, are sold in the canteen, also brandy and gin under certain regulations. It is strictly against orders for a bazaar shopkeeper to sell liquor of any sort to a soldier. A man may have either two drams of spirits or two quarts of malt liquor, or one dram of spirits and one quart of malt liquor; but he cannot have two drams of spirits and one quart of malt liquor, or two quarts of malt liquor and one dram of spirits, without permission. Spirit is no part of the soldier's ration at the station, on march, or in the field; he pays for it on all occasions, and has one quart of porter and one dram of spirits on payment. The commissariat department, however, cannot always supply porter; and when such is the case, two drams of spirit per diem are

SHOLAPORE. BOMBAY.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	supplied on payment. The canteens are not opened for spirits until evening, in quarters. On the march the grog is generally served out as soon as possible after arrival on the new ground, say 8 a.m., the men usually preferring it at this hour. No ill effects are attributed to this practice, particularly as the men do not go out much in the sun after morning's march. Spirit is never given as a ration to convalescents. No injurious drinks other than intoxicating drinks are sold in the canteen; but in the bazaar, where soldiers manage to get drink notwithstanding all endeavours to prevent it, all manner of compounds are sold, which, if not decidedly poisonous, must be injurious to health. 4. The consumption of spirits is, we think, injurious to health, and cannot conduce to the efficiency and internal discipline of the corps. 5. It would be beneficial to abolish the spirit ration. If this were not advisable, it might with advantage be restricted considerably. 6. The influence of malt liquor on health is more beneficial than spirits. 7. Soda water, lemonade, and ginger beer (a very objectionable drink, in our opinion, being made with toddy, or the date-tree juice, to insure the "pop,") are sold by a few shopkeepers in the bazaars, but, owing to similar articles being attainable in the coffee-shops, no large sales are made, and, except during the hot months, the quantity consumed is not large. We would recommend that the soldier should be supplied with malt liquor in moderate quantities, and the oftener in the day the better. 8, 9. It is difficult to say whether it would be beneficial or otherwise to suppress altogether the spirit ration, and to substitute for it beer, tea, or coffee, &c. There are some men in every company who cannot do without spirit; and if the ration of wholesome spirit from the canteen was withheld, they would procure most poisonous compounds from the bazaar, which are there sold so cheap that a man may become intoxicated for a couple of pice (one penny). 10. No recommendations are made on any of these points besides such as are contained in the foregoing replies. 11. The canteen and bazaar regulations are those contained in Section X. 3rd Appendix, Jameson's Code, which are in general use in the Bombay Presidency.
VI. DIET.	1. The composition of the daily ration for Queen's British troops and European troops in the Indian army is as follows:— 1 lb. bread, 1 lb. meat, 4 oz. rice, 1 oz. salt, 2½ oz. sugar, $\frac{10}{21}$ oz. black tea, $\frac{5}{21}$ oz. green tea, 3 lbs. wood, and 1 lb. vegetables. No periodical changes are made that we are aware of. The commissariat officer is directly responsible for the quality of the rations issued to the troops, but they are also inspected by the orderly men, told off for the duty by the quartermaster-serjeant, and by the orderly officer of the day. The inspection is made early in the morning, when the provisions are brought. 2. Vegetables are provided as above, but no fruit. The men breakfast at a quarter to 8 o'clock a.m., dine at a quarter to 1 p.m., and have supper at sundown. At breakfast they have tea, bread, and meat; at dinner, meat, vegetables, and bread, if they choose; and at supper, bread and tea. The stoppage for the ration is 3 annas 4 pice daily, in addition to which 6 pice, or half an anna, are stopped daily for providing them with extra vegetables. 3. The addition of milk to the ration would be beneficial in our opinion. The rations are given in charge to the orderly men after being inspected, and it is the duty of the orderly men to make over the same to the cooks, and look after their work in preparing the same for the men. 4. The cook-rooms are Government buildings, the cooks being paid by the men, as soldiers do not cook for themselves, generally speaking, in this country. The copper camp kettles, supplied by Government, are the only means of cooking available. The kitchens are kept clean, well lighted, well ventilated, and sufficiently supplied with water. The food, as a rule, is boiled or stewed, the cooks dressing each man's dinner, as far as practicable, according to his wish; for instance, one man may like a curry, and two or three a pie, which are thus prepared by the cooks. The cooking is properly done, and sufficiently varied; tea and coffee are efficiently prepared; but the men who wish for it carry the latter from the coffee-shop. We believe that if the men wish for tea, coffee, or other refreshment before a march, they have to make their arrangements for it. The coffee-shop keeper at this station sends round the coffee for the barracks at 4 o'clock a.m., so that the men may have it before parade, if they wish; probably similar arrangements would be made on the march. 5. Soldiers' gardens could be advantageously established, if the men would take the trouble of working in them; some of the men have them already. Gardens for the cultivation of vegetables could be only advantageously established under Government control, and the soldiers be paid for working in them.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The European soldier wears a cloth jacket or tunic, and serge or cloth trousers, as warm clothing, and a rusty drab coloured loose khakee (jacket and trousers) as light clothing, with a wicker helmet, having a padded cover of khakee and a forage cap as head-dresses. The only belt they wear is a waist-belt, from which is suspended the sword. The present dress, having been suggested and adopted by urgent necessity, is suitable to the climate, especially the khakee clothing. The wicker helmet is an admirable head-dress. It would be impossible to have one particular suit of clothes which would be adapted to day and night duties and the cold and hot seasons. As a general rule, we consider that if cotton shirts were done away with as regimental necessaries, and flannel shirts substituted, it would be an improvement, and the advisability of obliging each man to wear a flannel belly-band cannot be questioned. At present the men mount guard in khakee, and put on cloth shell jacket and serge trousers at picket mounting. The only sentry by day has a verandah to pace up and down in.
Duties.	1. Being of opinion that it is very desirable for the European constitution, that the soldier should arrive in this country as soon after attaining the age of 20 as possible, we consider that the health of the recruit would subsequently be beneficially affected by his being drilled after arrival in India. 2. The routine of a soldier's duties is as follows:—A man who has finished his drill attends morning parades (which last an hour) on five days in the week; his tour of guard comes round once in four, five, or six days, according to the number of men present; when not on guard, he cleans his arms and accoutrements if they require it; makes up his kit on the cot and shelf, according to regulation, has to attend afternoon roll call and answer to his name

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*cont.*	in barracks at tattoo roll call. The men do not suffer in any way from drill. The best time for drills and parades is early in the morning, all the year round; for marches, in the cold weather, early in the morning; and in the hot weather at sunset. At present the men have four nights in bed during the week to one on guard or picket. 3. The only European guard is mounted not 50 yards from barracks. The guard stays on for 24 hours, the picket for less than 12 hours. There are roll calls by day, but none later than tattoo at night. Night guards at this station are not at any time of the year injurious to health, and we are unable to suggest any additional precautions in performing this duty.
VIII. Instruction and Recreation.	1. The following are the means of instruction and recreation at the station:—There is a ball court, also a skittle ground, which in our opinion ought to be roofed. There is a library, which is lighted at night, and a school, but no trained schoolmaster. No day rooms or soldiers clubs exist; there are however plots of ground which the soldiers can cultivate; but there are no workshops, theatres, or gymnasia, and the means are not sufficient to keep the men occupied during the wet season and the heat of the day. The men are restricted from exposing themselves to the sun and rain when off duty, and the restriction is attended with considerable benefit to health. 2. Workshops for all common trades, which are a great desideratum, should be established, and also gymnasia; one large and lofty open shed might be constructed and so arranged as to afford the extra accommodation required. 3. Soldiers' savings' banks would be decidedly advantageous, provided workshops were established, in which the men might carry on a profitable business in trades in which they might be skilled, such as tailors, shoemakers, carpenters, &c. We consider that such an arrangement might have a good effect in inducing many to be industrious and keep out of the canteen. 4. There are no trees or sheds to enable the men to take exercise without injury to health during the day, and the verandah space is too limited to be of any use.
IX. Military Prisons.	1. Considering the climate of this station, we consider the prison cells small and badly ventilated.
X. Field Service.	1. There are no local regulations for field medical service. 2. The medical officers have no power whatever as regards the line of march of troops, bivouacking, camping, &c. 3. We would recommend that the senior medical officer should accompany the assistant quartermaster-general to select the site of the camp. The medical officer at present has no power in these matters. 4. The arrangements adopted in the Presidency for field hospitals, ambulances, transport of sick, and hospital supplies are according to the Presidency Medical Regulations.

By order of the Principal Inspector-General, Medical Department.

W. C. COLES, Assistant Surgeon, Secretary.

Office of the Principal Inspector-General, Medical Department, Bombay, 30th January 1861.

XII. HOSPITALS.

1, 2. The site of the European artillery hospital is open and freely ventilated, and everything that could be desired. The native infantry and cavalry hospitals are, we think, sufficiently commodious and well ventilated.

3. The hospital is supplied with excellent water from a well distant half a mile. It is conveyed to the building by puckal bheesties, and there does not seem to be any necessity for improving it in this respect.

4. All fluid refuse is removed from the vicinity of the hospital by an establishment of sweepers and others, kept up for the purpose. There are no drains or sewers whatever.

5. The lowest wards are raised one foot above the ground and are solid. There is no contrivance for the free perflation of air underneath the floors, and taking into consideration the site, the committee is of opinion that no such contrivance is called for. Owing to there being a gentle slope on all sides of the hospital, the roof water is quickly got rid of, and obviates the necessity for any provision for conveying it away. The surface drainage about the hospital is sufficient to carry away the rain-fall rapidly. The walls of the hospital are constructed of burnt bricks and chunam, with a double-tiled roof having ventilators. Neither the walls or roof are double, but the verandahs all round the building are well shaded, and the hospital kept sufficiently cool. The verandahs are eight feet broad, and with the addition of bamboo matting weather frames afford sufficient shelter from the sun's rays. Being shut in, they afford accommodation for the exercise of convalescents, and are, from want of room, made use of for other purposes. This objectionable practice will cease as soon as the extra ward, sanctioned by Government, is erected. The hospital accommodation is on the ground floor only.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	Table of Hospital Accommodation. Date of construction, 1830. Total number of wards - - - - 3 Total regulation number of beds - - - 28

Wards.	Regulation Number of Sick in each Ward	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Feet. In.	Feet. In.	Feet. In.	Feet.			Inches.		Feet. In.	Feet. In.
2 - - -	10	31 6	24 0	14 9	11,150·5	1,115·05	75·6	18	4	5 4	3 10
1 for women -	8	30 2	21 10	17 0	11,196·43	1,399·5	82·3	18	6	7 6	4 5

The hospital is placed so as to receive the full benefit of the prevailing winds. The windows are of the ordinary construction, and might be altered so as to open vertically (for the top half) as well as horizontally with great advantage.

6. Iron revolving cowl ventilators are fixed to the ridge of the roof, and appear to secure efficient ventilation. There are no jalousies or jhilmils, but the glare is kept out by the bamboo matting weather frames, or sun shades.

7. The air admitted into the wards during the months of April and May is cooled by means of kuskus tatties.

8. There are no means of warming the wards. The wards and ceilings are whitewashed and cleansed every three months, and whenever found necessary.

9. The privies are properly cleansed, and all that is offensive daily removed by sweepers. They are not more offensive than the best of such places usually are in this country.

10. The lavatory arrangements might be greatly improved, and the health and comfort of the sick would be greatly enhanced thereby. The present arrangements appear to be a make shift.

11. There is a bath room to the hospital, but all apparatus is entirely wanting, to the great discomfort of the soldier.

12. The washing and drying of hospital linen is left to the regimental dhobies, and no inconvenience apparently results therefrom.

13. The hospital was erected 30 years ago, and the accommodation of course is in every way susceptible of improvement; but with regard to the storage, looking to the generality of such buildings in this country, we have nothing to condemn strongly in the European artillery hospital here.

14. The cots in the hospital are generally of iron, with straw mattresses laid on them. No improvements in these are suggested.

15. The means and apparatus for cooking are primitive, but such as have been found best adapted for the Indian cook.

16. Diet tables, diet rolls, &c. are according to regulation.

17. The provision for attendance on the sick is good and sufficient.

18, 19. The sanitary condition of the hospital is good, no epidemic diseases of any kind have appeared. No improvements are suggested.

20. The accommodation for exercising the convalescents is limited to the verandahs adjoining the hospital ward.

21. Although there is a ward for women in the compound they prefer remaining in their own huts, and with their children are usually attended there by the medical officer. No resident matron is allowed for the hospital, but considering the small number of women and children, and provided suitable quarters for the married people were erected (which the committee believes is in contemplation) the present arrangement is conducive to comfort, and in no way objectionable.

22. There are no special local hospital regulations enforced at the station, not included in the General Presidency Medical Regulations.

23. All recommendations made by the medical officers with reference to the sanitary state of the hospital, &c. are immediately attended to.

24. There are no convalescent wards or hospital at this station, nor would they be of any advantage, considering the small number of Europeans present.

XIII. Burial of the Dead.

1. The British burial ground is situated in the station, but it does not appear to be badly placed as regards the prevailing wind.

2. Its area is 14,000 square yards, and its soil is alluvial, lying on rock. The drainage is efficient, owing to the ground being placed on the sloping bank of a nullah. The ground is well kept.

3. The grave space allowed is 7ft. by 3ft., and the interval between graves 6 feet; the depth is 5 feet. Graves are scarcely ever re-opened, and no more than one body is buried in the same spot. Interment is compulsory at ordinary times, and during epidemics within 12 hours after death. The conditions of interment and cremation of native troops are the same. The native burial and burning grounds are looked after by the barrack department under the orders of the brigadier.

4. The graveyard has never been offensive. The regulations with regard to the burial of British troops are strictly enforced.

SHOLAPORE. BOMBAY.

XIII. Burial of the Dead—*cont.*	5. The dead of camp followers or bazaar people are burnt or buried at localities set apart for the purpose in the vicinity of the camp. 6, 7. No injury appears to have accrued to the public health from the present practice, and no improvements are suggested in the burial or disposal of the dead, as the existing arrangements provide for all requirements under this head.

I. TOPOGRAPHY.	1. The general aspect of the country surrounding the station is open and flat, dry during the cold and hot seasons, swampy during the monsoon. There is but little wood or jungle in the neighbourhood, but an abundance of water. 2. The elevation of the station is 33 feet above the level of the sea, but is on a level with the adjacent country. It is 18 feet above the level of the Taptee river. There is no higher ground adjoining the station. 3. The low hills of Rajpeepla commence at Vusranee, 29 miles to the north-east and by east of Surat. The nearest mountain is Songhur, about 42 miles east of Surat, and the nearest table-land is 40 miles in the same direction beyond Songhur and at the top of the Rondabarree Ghaut. The height is the average of that of the Western Ghaut. 4. The nearest water to the station is the Taptee river, which forms the north-west boundary of the camp, and sometimes overflows, and the camp is then completely under water from one to ten feet in depth. There is neither broken ground, ravines, nor water-pits near the station. 5. With the exception of the eastern boundary, which is framed by the town, the camp is open and well ventilated. The temperature of the station is not raised by the buildings being exposed to reflected sun heat. From March to October the sea breeze prevails, and during the remainder of the year the land wind is predominant. The effects produced upon different individuals by these two winds vary considerably, but generally speaking fever is most prevalent during the appearance of the land winds. 6. The country surrounding the station is cultivated. There is no artificial irrigation, but a few gardens which are watered from wells, nothing more. Rice is not cultivated nearer than four miles from the camp. No indigo is cultivated near the station, but hemp is prepared about four miles off on the other side of the town; no nuisance is experienced from it in the camp. 7. The large and populous city of Surat forms the north-east boundary of the camp. 8. The geological structure of the surface of the station is a black soil, varying in depth. Beneath is a thick clay, in which a large quantity of lime-stone gravel is found (morum), and beneath that again, at the depth of 18 or 20 feet, basalt. 9. Water is found at a depth varying from 20 to 30 feet in the dry season, and the wells have about five or six feet more water in them during the monsoon. 10. A small portion of the rain-fall is absorbed into the soil; more runs off by artificial and natural drainage, but some quantity lies on the surface till it evaporates. There is no higher ground adjacent. 11. The water supply of the station for drinking purposes is derived from wells, the river is also occasionally used by the natives for bathing. There are no tanks either in the station or near it. The wells are not liable to pollution from leaves or other matter falling into them; no foul drainage or surface impurities are allowed to drain into them; no nuisance or malaria proceeds from the wells. 12. There is not a well containing good drinking water in the station, every one being more or less impregnated with salt. Some of the water is very foul and appears to be impregnated with sulphureted hydrogen gas; but there are two wells beyond the limits of the camp from which tolerably good water can be obtained. There is no record of its chemical analysis, but it may be said to be decidedly brackish: its microscopic characters are unknown, nor can they be ascertained by any instrument at the station. The water within camp limits is so bad that no one thinks of drinking it; it is raised by hand in leather buckets. Fresh and good water might be obtained in abundance by means of pipes laid from a point about 10 miles up the river from the station; this might also be made available for the inhabitants of the city. 13. It would be advisable to remove the native lines, which are very old and in a hollow, and have long been condemned by competent authorities, to a spot a little to the left of the Domus road, which is a few feet higher than the present situation. It may be observed, that if the slightest inundation occurs the lines are the first flooded. 14. New stations are selected by a mixed committee composed of officers from the quartermaster-general's department, and also engineer and medical officers, but what weight is attached to the opinions of the various departments is unknown.

References to Subjects and Queries. | Replies.

II. Climate.

1. The only meteorological instruments at the station are a thermometer, rain gauge, and weather cock.

2. Table of meteorological observations from 1st January 1850 to 1st January 1860.

Months.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.
1850–60.				
January - -	72·9	28·2	87·3	59·1
February - -	76·9	22·1	91·3	69·2
March - - -	84·1	27·6	97·7	70·1
April - - -	88·0	24·6	100·5	75·9
May - - -	89·4	20·4	100·4	80·0
June - - -	87·1	14·2	94·3	80·1
July - - -	84·0	12·0	89·9	77·9
August - -	82·5	8·4	87·0	78 6
September - -	83·3	12·8	89·9	77·1
October - -	82·6	19·9	92·8	72·9
November - -	78·1	23·6	90·5	66·9
December - -	74·3	25·0	87·5	62·5

3. For about nine months in the year the climate may be said to be decidedly moist, the wind coming from the direction of the sea, which is only about 10 miles distant. It is never very cold, and the temperature rises considerably as elsewhere during the months of April and May. There is but little, if any, fog in the camp, though it is sometimes observed on the other side of the river, which is somewhat on a lower level. There is no irrigation to speak of, therefore the climate is not perceptibly influenced by it. There are occasional dust storms, but generally speaking the atmosphere is free from dust, as the wind blows from the sea chiefly over cultivated lands. No medical officer present having been in Surat more than a few months, no trustworthy information can be afforded as to the effect produced on the health of the troops by the above climatic characteristics. From the end of the monsoon, that is to say, from the beginning of October to the middle of December, is the most unhealthy period of the year, when intermittent fever is the prevailing disease.

4. Domus, on the sea shore about 10 miles west of Surat, possesses the following advantages over this station:—The air is cooler and purer, and there is an abundance of good water in tanks, which if proper care is taken would contain water all the year round.

5. The following is a list of stations in India at which I have served, viz.:—Poona, Ahmednuggur, Dharwar, Belgaum, Kurrachee, Vingorla, Asseerghur, Nassick, Sattara, Bombay, Surat, Broach, Ahmedabad, Sholapore, Rajcote, Bhoog, Hyderabad (Sinde), Jacobabad, Sukkur, Shikarpore, Neemuch, Nusseerabad, Mhow, Dhoolia, Mulligaum, and Tanna. Of these the first 10 may be said to be salubrious climates, and Neemuch and Mhow, the next best adapted to health. The most injurious to European constitutions are probably Jacobabad, Suckur, Shikarpore, and Nusseerabad.

III. Sanitary Condition of Station.

1, 2, 3. Map and general plans of the station and surrounding country, with plan of the barracks, are transmitted.

4. Table of barrack accommodation. Date of construction of barrack unknown, the barrack being part of the Castle buildings, which were constructed before the English took possession of Surat. But they were adapted for the residence of the European troops in 1857, by providing for light and ventilation. Ten pendalls for Native Infantry were constructed in 1824, and the other four in 1840.

Total number of rooms or huts:—Barrack rooms for European troops, 4. Pendalls for Native Infantry, 14.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms. Length.	Breadth.	Height.	Cubic Contents.	Cubic Feet per Man.	Superficial Area in feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows. Number.	Height.	Width.	Remarks.

References to Subjects and Queries.	REPLIES.
III. Sanitary Condition of Station—*cont.*	5. The windows are on opposite sides, opening from below, being attached above by hinges to the window frames. There are neither verandahs, jalousies, or jhilmils. 6. The cots used in barracks are of wood, with country bedding, cotton cloth, stuffed with straw, serge blankets, and country counterpanes and sheets. In the tents the beddings are on the ground. 7. This question having reference to the structure and dimensions of tents used in camp will be answered by the quartermaster-general's department at the army and division head-quarters. 8. Ventilation is effected in the barracks through the door and windows. These barracks are in the Castle, about 14 feet above the ground. The tents are ventilated by opening doors and walls; the huts through the doors, and the guard-rooms by doors and windows. The ventilation is quite sufficient. Punkahs are used for cooling the air in the barrack rooms, at a cost of about 12 rupees each, but as the allowance for pulling them is only 25 rupees a month, the full number allowed cannot be worked. 9. The barracks are composed of stone or brick masonry, the tents of Dungary cloth, and the huts of split bamboo walls and daubed with mud, &c. For further particulars see the plan transmitted. 10. Half the floor of the barracks on the south side of the Castle and the floor of the barracks in the south-east tower, as well as that of the barrack room, No. 12, are of chunam, and the floors of the remaining barracks are of teak planks. The floors of the native huts are of mud and are nine inches above the ground. All the barracks but one, No. 12 (now used as a school room, and whose floor is three feet above the ground) are on the first story, and from 13 to 20 feet above the general level of the ground. There is a free passage of air beneath the latter; but no ventilation through them. 11. There are no regular barracks for Europeans at this station. The room allowed for each man in the pendalls is not sufficient. The barracks are kept in repair by the engineer department, and the works are quickly executed. The fort adjutant, under the orders of the commanding officer, is responsible for the general sanitary condition of the camp. The walls and ceilings of the barracks are cleansed and limewashed twice a year generally, on requisition from the commanding officer of the station. 12. There are no regular washing places built for the men, but the eastern corner (ground floor) of the barracks on the south side of the Castle is used for that purpose. There are five tubs, and they are supplied daily with fresh water by bheesties. The drainage is carried out through the walls into the river. 13. A plan of the barrack cookhouses is transmitted. There are provided one set of copper cooking utensils for every 10 men, and they are tinned monthly. Water is supplied by bheesties. All the clothes are sent to the washermen. 14. A plan of the privies is transmitted. They are provided with iron pans, which are emptied by sweepers into the river; the urinals have a drain which discharges into the river direct. 15. Two lights burn in these buildings all night and two till tattoo. The ventilation is effected by several ventilators at the top of the roofs. 16. There are separate drains and sewers in each of the barracks to carry off to the river the dirty water, &c. The dimensions of these vary from 4 in. diameter (drains of round tiles) to 8 in. by 8 in. (brick and chunam sewers). The distance between the barracks and the river is from 100 to 350 feet. The drainage is sufficient, and no part of any building used as a barrack or hospital is damp. There are no cesspits or foul ditches. 17. All refuse matter is removed from the surface of the cantonment daily, and thrown into the river. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls or thick hedges, &c., interfering with the ventilation of the station or bazaar. 19. The drainage and ventilation of the bazaar are as good as possible. The water supply is obtained from wells about the camp. The bazaar is kept clean, and, to preserve this, is subject to the regulations as laid down in general orders. It is very small. No alterations to suggest. There are very few native houses near the station, and there are no dung-heaps or cesspits within them to cause any nuisance to the camp. When the wind blows over the native town it is considered unhealthy; when it blows from the north, it passes over a bank, which is laid bare at low water, and from which noxious vapours arise. The only quarter from which it blows, and is considered to be healthy, is from the south-west. 20. The animals for the use of the troops are slaughtered in the town about half a mile from the Castle, and no nuisance is experienced. 21. The bazaar is very small, and no horses are allowed in it. 22. There are no stables constructed at this station for artillery or cavalry horses, nor any picketing grounds arranged. 23. There are quarters at the station sufficient only for three married non-commissioned officers or men; married people do not occupy the barrack rooms with the men.
Officers' Quarters.	1. The officers' quarters in the Castle are very salubrious, but officers' lines in the camp are quite the reverse. The situation of the latter being bad, no improvement could be effected, except by building better houses, which nobody could afford. All the above questions under the head of Sanitary Conditions, unless otherwise specified, relate to the troops in the Castle.
IV. HEALTH OF THE TROOPS.	1. The station, surrounding district, and the adjoining native population, are generally unhealthy. 2. The diseases most prevalent among the native population are spleen disease, small-pox, and cholera. 3. The unhealthiness of the native population may be attributed to want of cleanliness, from the ruinous state of the town and the filthy habits of the natives, imperfect drainage, and the bank referred to before. 4. Detachment 4th Foot arrived here from Ahmedabad on the 28th December 1859. There were at that station 17 men for one year and eight months, and 38 men for ten months; they left it on the 21st December 1859. State of their health there very good, and on their arrival here they were healthy; but since then fever has been a

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	prevalent disease. The 16th Regiment Bombay Native Infantry were at Shikarpore for 13 months, and left that station on 20th January 1858, having suffered there from intermittent fever. Their state of health on their arrival here (26th February 1858) was very weakly, and they have suffered since their arrival from intermittent fever, diseases of the bowels, &c., &c. There is no part of the men's present accommodation at this station more unhealthy than another. 5. The troops are occasionally out in tents during an epidemic, and this is found to be very beneficial. 6. No medical officer here has been in charge of a hill station. 7. Troops at hill stations are less liable to fever and other diseases on return to the plains, which result is to be attributed to the improved state of their constitutions from residing on the hills. 8, 9. Hill stations are approved of for troops. Mount Aboo is the only one with which we are acquainted, and weak men on arrival there are liable to attacks of fever and diarrhœa. 10. Warm dry clothing, wholesome diet, regular exercise, and good shelter, are indispensable precautions to be observed for the men resident in hill stations. 11, 12. The period best adapted for a residence in the hills is from the beginning of March to the middle of July, or the first fall of rain. No experience to prove what period of residence would be injurious or beneficial to troops. 13. The ordinary protection from the sun must be observed for protecting the health of troops on leaving hill stations for the plains. 14. As a general rule it would be better to locate the troops in the hills with short service on the plains. Frequent change of station also would be decidedly beneficial. 15. No answer to this question. 16, 17. The elevation above the sea most suitable as a site for a hill station is about 4,000 feet. There is no higher ground near this station which could be advantageously occupied as a hill station. 18. Red sandy soil, with scant vegetation, is the best adapted for stations. The soil here is black loam, with a subsoil of clay, and is very unhealthy. 19. I consider the best age for soldiers to proceed to India to be from 19 to 27, and they should land here from about the middle of November to the beginning of January. I would recommend recruits on first landing in India to avoid intemperance and exposure to the sun. 20. With reference to Bombay, troops on landing should be immediately despatched to the high table land of the Deccan. 21. No experience as to the mode of transport of troops from the port to the interior. 22. The number of years a British soldier should serve in India is 10. 23, 24. No experience as to the manner of conducting medical boards, as regards invaliding. Invalids should leave India for home during the months of January and February.
Diseases.	1. There are regular inspection parades every Saturday morning for the discovery of incipient diseases at this station. 2, 3, 4, 5. There has been no case of scorbutic disease among the troops of this station, nor any of hepatitis amongst the Europeans, and only one with the natives, since the arrival of the regiment. Dracunculus is of rare occurrence here. The proportion of the constantly sick from venereal diseases to the total sick in hospital from all other diseases, is very small, both with Europeans and natives; but the establishment of lock hospitals would be beneficial. 6. The following are the diseases from which the troops, European and native, suffer, viz.— Fever.—Intermittent and common; remittent occasionally occur. Admissions - Europeans 70 - Natives 815 Deaths - ,, none - ,, 5 Dysentery.—No cases have occurred with Europeans, and with natives it is rare. Admissions - Europeans 1 - Natives 29 Deaths - ,, none - ,, 1 Cholera.—Only 1 case among the Europeans. Admissions - Europeans 1 - Natives 11 Deaths - ,, 1 - ,, 4 Small-pox.—Epidemic affections are rare. Admissions - Europeans none - Natives 5 Deaths - ,, ,, - ,, none. Rheumatism.—Is common among the natives; rare among Europeans. Admissions - Europeans 2 - Natives 70 Deaths - ,, none - ,, none. The proportion which admissions and deaths from these diseases bear to the total admissions and deaths is as follows:— Admissions - Europeans 74 - Natives 930 Deaths - ,, 1 - ,, 10 7. No answer can be returned to this query from want of experience. 8. Occupation and amusement are the most likely preventives of epidemic disease. 9. No doses of quinine have been given at this station as a prophylactic against malarial disease. 10. With regard to the preceding points, I would recommend a better system of drainage; but on account of the absence of good water, the station is not suitable for a camp.
V. Intemperance.	1, 2. The soldiers at this station are temperate, and there are no confirmed drunkards. There are no admissions into hospital from diseases occasioned either directly or indirectly from intemperance. There are no cases of drunkenness; but it would always be punished as an offence.

SURAT. BOMBAY.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	3. Soldiers are allowed to buy 2 drams of arrack, or 1 dram and 1 quart of porter at the canteen; there is no proper restriction in the bazaar. The spirits are good; they do not form any part of the soldier's ration, either at the station or on the march, it is not known if they do in the field. The men do not take a dram before morning parade. Malt liquor is given as a ration to convalescents in quantities varying from half a pint to a quart daily; but spirits are not. Nothing is allowed to be sold in the bazaar to Europeans, and nothing but arrack, porter, and beer are sold in the canteen. 4. The consumption of spirits is decidedly injurious to health; not so that of coffee and malt liquor. A moderate use of the former (spirit), however, is not injurious to Europeans. 5, 6. It would be advisable to abolish spirits as a ration, and substitute malt liquor in its stead. The same in respect to canteens. Malt liquor is recommended as being beneficial. 7. Coffee, tea, lemonade, soda water, &c., are not much used here. These articles are decidedly superior to spirits, but malt liquor in conjunction with them would be beneficial. 8, 9, 10. Beer, porter, tea, and coffee should be substituted for the spirit ration, and it would be beneficial to prohibit the sale of spirituous liquors in the canteens, and permit only beer, coffee, tea, lemonade, &c., to be sold to the troops. I have no other recommendations to make on these points. 11. The detachment here has no regular canteen.
VI. DIET.	1. The composition of the ration for Queen's British troops, and European troops in the Indian army, is as follows, viz.:—bread 1 lb., beef or mutton 1 lb., wood 3 lbs., onions 4 oz., potatoes or other vegetables $\frac{3}{4}$ lb., rice $\frac{1}{4}$ lb., salt 1 oz., tea (green) $\frac{5}{21}$ oz., and black $\frac{10}{21}$ oz., sugar $2\frac{1}{2}$ oz., 1 quart of porter, 1 dram of arrack, or 2 drams of arrack liquor paid for by the soldiers. There is an inspection of the constituents of this ration made every morning by an officer. 2. The rations provided for the troops are free of expense. The soldier has 3 meals a day, breakfast, dinner, and tea; nothing after that. 1 lb. of vegetables, which are varied according to the season, enters into the daily composition of the ration. 3. I have no improvement to suggest in the composition of the soldier's ration. An orderly corporal attends the issue, hands it over to the cooks, and sees it is not disposed of. 4. The usual copper cooking utensils are supplied to the detachment, and are found quite sufficient for the purpose. The kitchens are clean, well lighted, and well supplied with water; the food is cooked as the men wish it, is properly done, and sufficiently varied. No coffee is supplied to the men except on a march, when they have tea, coffee, or other refreshment half way. 5. Gardens could not be established at the station in consequence of the water being bad.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldier's dress and accoutrements consist of 1 cloth tunic, 1 pair cloth trousers, 3 pairs boots, 1 serge tunic, 1 pair serge trousers, 4 white and 2 blue shirts, 1 pair white trousers, 2 pairs blue trousers, 6 pairs socks, 2 khakee tunics, 2 pairs khakee trousers, 1 helmet, 1 forage cap, 2 flannel belts, 2 towels, 2 blacking brushes, and clothes brush, 1 small book, a comb, spoon, knife, fork, razor, soap brush, button brush, button stick, 1 piece of soap, 1 of pipe clay, 1 of sponge, a mess kettle with cover, knapsack and straps, 1 pair knee caps, 1 pair braces, 1 blacking box, 1 neck tie, 1 cotton bed, a blanket, a sheet, a rug, and 2 cap covers. I consider the present dress as suitable to the climate, and a great improvement on the old dress. For the hot weather a helmet and khakee are worn; for rainy weather, serge tunic and barrack change pantaloons and forage cap with covers; for cold weather full dress tunics and cloth pantaloons. The guard room is very badly ventilated, but the best available position for the guard is the Castle.
Duties.	1. No answer from want of experience. 2. The soldiers at this station parade every morning for an hour with arms and accoutrements, and in the evening for half an hour three days in the week setting up drill, roll call for the remainder. The men do not suffer in health from this. The times for parades, &c. should be so regulated as to avoid the sun as much as possible, and in the rains the men should not be exposed to the damp ground; the same rules should be observed in marching. The troops at this station average six nights in bed out of the week. 3. Each sentry is on duty eight hours out of the 24, and he is relieved every two hours, both day and night. The sentries are in the barracks. There are 7 roll calls day and night. 1st morning parade, 2nd breakfast, 3rd dinner, 4th evening meal, 5th parade, 6th half-past 7 o'clock, 7th tattoo. The men do not suffer from night guards.
VIII. INSTRUCTION AND RECREATION.	1, 2. The following are the means of instruction and recreation at the station. There is no ball court, but there is a skittle ground, and a school. There are neither library or reading room, day room, soldiers' clubs, soldiers' gardens, workshops, theatre, or gymnasia; in fact the means to keep the men occupied during the wet season or heat of the day are insufficient. In the hot weather the men are not allowed to go out after 8 o'clock in the morning till 5 in the afternoon, and in the cold weather till 4 in the afternoon. Establishing the above places for recreation, instruction, and amusement, I would suggest as a great desideratum. 3. Soldiers' savings' banks exist here, and are found advantageous. 4. There is not sufficient shade from trees, sheds, verandahs, or other means to enable the men to take exercise without injury to health during the day.
IX. MILITARY PRISONS.	1. The cells in the Castle have been condemned, and there are none in the camp.
X. FIELD SERVICE.	No information under this head, as the questions do not seem to apply to Surat.

By order of the Principal Inspector-General, Medical Department.

Office of the Principal Inspector-General, Medical Department, Bombay, 22nd December 1860.

W. C. Coles, Assistant-Surgeon, Secretary.

XII. Hospitals.

1. Plan of the hospital is transmitted.
2. The barracks and hospital are in the Castle and close to one another, and the native infantry hospital is a house formerly a private building. There are no stables. The Castle hospital is surrounded on three sides by the native town; but the native hospital is isolated from any building. Both hospitals are well ventilated, and there are no high walls or trees to interfere with the ventilation. The European hospital is not in a healthy position; the native is healthy enough, and free from nuisances.
3. The water supply is abundant, and as good as can be got in the neighbourhood.
4. There are several drains, and they are all cleansed daily by the sweepers, and in the native hospital the impurities are removed by sweepers. The river, which is the outlet for the sewage, is situated 30 yards from the Castle hospital and 130 yards from the native infantry hospital.

SURAT.
BOMBAY.

References to Subjects and Queries.	REPLIES.
XII Hospitals—*cont.*	5. The wards of the hospital in the Castle are 21 feet above the level of the ground, and they have a free perflation of air underneath the floors. The down-stair ward of the hospital for native infantry is two feet above the ground, and as it has a mud floor there is no free passage of air beneath it. The two upper wards are 14 feet above the ground, and they have a free perflation of air beneath. The roof water of the Castle hospital falls on a chunam terrace beneath, whence it is at once drained off into the river, and that of the hospital for native infantry falls on the ground around it; but most of it makes its way to the river, without sinking into the ground. There is no obstruction to the free surface drainage round both hospitals, the ground of the Castle hospital rain-fall having a natural slope, and a gutter is kept open during the monsoon for the proper drainage of the native infantry hospital. The walls of the Castle hospital are of brick and chunam masonry, the floors of chunam, and the windows are provided with Venetian and glass shutters, &c. See plans of this and the native infantry hospital transmitted. Verandahs are used in the native hospital, but there are none in the European; those in the former are used for the sick when required. The European hospital has an upper story, and the native infantry hospital has one also, but it cannot be used.

Table of hospital accommodation.

Date of construction unknown, as the European hospital is part of the Castle, which, as before mentioned, was constructed before the English took possession of Surat, and the native infantry hospital was formerly a private building.

Total number of wards, for Europeans, 2; for native infantry, 3.

Total regulation number of beds, for Europeans, 18; for native infantry, 24.

Wards or Hospital Huts. No.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Feet.	Feet.	Feet.			Feet.	Feet.		Feet.	Feet.
In the Castle. For European Troops - No. 15, 1	10	38	20	10	7,600	760	76	1½	8	6	4
	8	29	20	12	6,960	870	72½	1½	4	6	3·5
on the Cantonment. For Natives. Down-stair ward	12	46·25	21·5	13	12,926·87	1,077·24	82·86	1½	8	4·5	5, mud floor.
Ward on upper story.	6	23	21·5	12	5,934	989	82·42	1½	6	6·25	4·25

Both hospitals are placed so as to receive the full benefit of prevailing winds. The buildings at present occupied as hospitals were not constructed as such, but have been selected as the most suitable.

6. The ventilation is good in both hospitals. There are no jalousies or jhilmils.

7, 8. There are no means of cooling the air admitted into the wards, and none are required for warming it, it being hot enough already. The walls and ceilings of the hospital wards are cleansed and whitewashed every three months by Government general order.

9. There are no regular privies or urinals in the European hospital; night-stools are used and emptied by the sweepers. The native hospital has a range of privies near it, which are daily cleaned out. There are no cesspools, but the privies are highly offensive in consequence of imperfect cleansing.

10, 11. The lavatory arrangements in the hospitals consist of bath tubs in sufficient quantities, and the means of bathing the sick are convenient and sufficient.

12, 13. The washing and drying of the hospital linen are done by native washermen. The storage is sufficient and dry.

14. The bedsteads and bedding used in the hospital are the same as those in use in barracks.

15. The place used as a kitchen is a small dark apartment, insufficient for the object intended, but the best place that could be selected. The cooking pots are regularly tinned once a month, and the cooking of the diet is properly done.

16. The returns of the diet tables, diet rolls, &c. cannot be furnished by the European detachment, and the diet table is the same as will be furnished by the head-quarters of the regiment, as well as all other forms. The native hospital returns are transmitted. There are no diet tables in the native hospital.

17. For the European hospital a serjeant is allowed; and in all the other establishments are natives, as allowed by Government, consisting of two ward boys and a dresser for a detachment of that strength. For the native hospital an orderly is allowed, and men are selected to attend on the sick when required.

18. The sanitary condition of both hospitals is good, and there has been no outbreak of any epidemic disease.

19. The building of the European hospital is unfit for the accommodation of European patients. The native hospital is not sufficient for the accommodation of the regiment, and new hospitals should be erected in suitable situations.

20. There are no provisions made for the exercise of convalescents, either European or native; but the former may walk on the ramparts and the latter in front of the hospital.

21. There are no female wards, but the women are attended by the medical officers at their own quarters, which latter are badly ventilated. The buildings in the Castle do not admit of any improvement.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	22. There are no special local hospital regulations in force at this station, not included in the general presidency medical regulations. 23. As regards the sanitary state of his hospital, repairs in buildings, change of diet, &c. the medical officer's suggestions are always attended to. 24. There are no wards or hospital for convalescents, but such accommodation would be advantageous.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is two miles from the Castle, and about four miles from the camp, and cannot affect the sanitary condition of either. 3, 4. The grave space allowed is according to the size of the deceased. Graves are six feet deep, and have a six feet interval between each. [It is presumed that no answers are required to queries 2, relating to the area, subsoil, and drainage of burial ground, or 4, which relates to the state of the graveyard, and precautions to prevent nuisances.] 5. The dead of camp followers and bazaar people are buried or burnt, according to caste. 6, 7. No injury accrues to the public health from the present practice, and no improvements are suggested.

(Signed) Keith Jopp, Major,
Commanding the Garrison of Surat.
S. M. Pelly, Surgeon,
H. M. 16th Regiment, Bombay Native Infantry,
Senior Surgeon at Surat.
H. F. Hancock, Captain,
Acting Executive Engineer, Surat.

14th November 1860.

I. Topography.	1. The country surrounding the station is undulating, sandy, and dry. There is a little wood on all sides. 2. The station is elevated 99·35 feet above the sea, and 40½ feet above the adjacent country. The nearest water is the river Indus, about three miles from cantonment, and some small nullahs, which are filled by the annual inundation of the river. There is no higher or healthier ground near the station. 3. The nearest mountain is about 20 miles from cantonment on the opposite side of the river Indus; it is elevated about 800 feet above the station. 4. Immediately below the plateau on which the cantonment of Hyderabad is, and close to the native infantry lines and officers' quarters, there is a sheet of water, but this only exists during the inundation. The vicinity is only liable to overflow during the inundation of the river Indus, which lasts about four months. There is some broken ground near the station, but it does not affect the health of the troops. 5. The station is freely exposed to the winds: the temperature is raised by the buildings being exposed to reflected sun-heat. Cold and variable winds affect the health of the station more or less. 6. The surrounding country is cultivated during the inundation. There are works of irrigation near the station, but not within cantonment limits. They have no effect on health. Indigo is not cultivated, nor the cultivation of hemp or flax carried on near the station; in fact all cultivation is prohibited within certain limits. 7. The native town of Hyderabad lies on the eastern side of the station, and adjoining it. 8. The district has a range of low calcareous hills running parallel to the river Indus at a distance of about three miles. On the northerly point of these hills stands the station of Hyderabad, having an elevation of about 40 feet above the adjacent country; with this exception the district consists of sandy plains and alluvial deposits from the river Indus. The soil is generally of extreme fertility if well watered, but if left uncared-for the surface soon turns to firm and drift sand. In many places the water is brackish, and throughout Sinde wells are maintained by very feeble springs. Most wells can be exhausted in 12 hours by a well-worked Persian wheel. The ground on which the camp stands was not previously occupied by population before the present station was formed on the plateau. 9. Water is usually found below the plateau at about 20 feet in the low season, and 15 feet in the high season. 10. The small annual fall of rain in Sinde does not affect the wells, but the rise and subsidence of the Indus does. There is no drainage from higher ground passing into the subsoil of the station. 11. The water supply of the station is derived principally from wells which are filled by the river Indus during the inundation. The water is stored in an open tank, the surface of which is about 80,000 square feet. The tank is full during the inundation, but almost dry during the months of May and June. There are neither plants nor animals in the tank, the water of which is not used for bathing purposes. The tank is not liable to pollution by leaves or other matter falling into it, neither does any nuisance or malaria proceed from it.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	12. Some of the wells are brackish, but in the majority good water is found. A few during the hot weather become dirty and offensive from not being properly attended to; but in others, less used, purer water is at all seasons obtainable. The chemical composition of the water I do not know, but that in common use is soft in character, dissolving soap readily. Although I have never examined it microscopally, I have no doubt it swarms with animal life. The quality is undoubtedly good and wholesome, and the supply abundant. 13. Hydrabad is situated on the most northerly of a chain of low calcareous hills running north by east, between the rivers Indus and Fullailee; on a bare plateau of small extent at the foot of the hill on which the town is built, and to the westward of it are cantonments, and between this plateau and the river Indus, and on a lower level, there extends a thinly-wooded plain of an average breadth of three miles, part of which is flooded at certain seasons of the year by water from the river to the east of the town. Eastward of the town, between the elevation of the hill on which it is built and the banks of the Fullailee, there is a plain of nearly one mile average breadth, which has a greater elevation than that existing between the main river Indus and the hill. At a certain season of the year the water of the Fullailee is dammed and made available for the purposes of irrigation, at which time the bed of the river is almost dry, but at other times there is a large body of water, and it is then that the western plain between the cantonments and the Indus becomes flooded. I have not observed in one year's experience that malarious fever is more common among the troops of the station during the one period than the other; nor do I know whether the inhabitants of the houses in the town, which are situated near the river Fullailee, are more subject to fever and other diseases when the river becomes dry than at another time, or than those occupying houses at a greater distance; but the houses in the cantonments on the edge of the plateau overlooking the westward plain extending to the Indus, and which is periodically flooded, are considered unhealthy. 14. I am not aware what amount or kind of inquiry is gone through before new stations are selected.
II. CLIMATE.	1. Beyond a Fahrenheit's thermometer in use in every hospital, I am not aware of any meteorological instruments available at the station; an instrument to determine the amount of rain is easily made when required. 2. Table of Meteorological Observations for two years, from 1st Jan. 1856 to 31st Dec. 1857.

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain, Inches	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks as to Cloud, Dew, Wind, Storms, &c.
Jan. -	—	64·2	12·5	70·5	58·	64·2	56·	—	·55	N.E. & N.W.	Variable & Moderate.	—	Generally cloudy, rain on two occasions.
Feb. -	—	71·2	15·8	77·8	62·	71·2	60·	102	·46	S.W., N.E. & N.	Moderate.	—	Cloudy in the early part, heavy with dews in morning, several dust storms, rain on occasions.
March	—	80·7	17·	89·	71·8	80·7	66·5	115	—	S.W. & W.	High.	—	Cloudy on 10 days, hot winds prevalent, dust storms prevail, and sometimes last three or four days.
April	—	86·5	16·7	93·9	77·6	86·5	72·	117	·62	S.W. 25.	High.	—	Two or three cloudy days with lightning in the evening, hot and sultry, several dust storms, on one occasion violent sandsquall, followed by thunder, lightning, and rain with hailstones.
May -	—	91·	16·	99·	83·	91·	76·3	122	—	S.W.	High.	—	One or two cloudy days, hot winds blowing, with plenty of dust. Mornings and evenings cool.
June -	—	92·2	14·1	99·3	85·2	92·2	79·	123	—	S.W.	Calms, High.	—	Several hot and sultry days in early part. Windy nights, dust storms frequent.
July -	—	90·6	10·5	94·5	84·	90·6	81·	114	1·87	S.W. & W.	High.	—	Generally cloudy. One dust storm followed by thunder and heavy rain. Rain fell on 4 occasions.
Aug. -	—	88·	10·4	92·6	82·2	88·	80·	108	14·79	S.W. & W.	More moderate.	—	Cloudy. Rain fell on 13 days in 1856.
Sept. -	—	85·	9·3	89·5	80·2	85·	78·	104	2·07	S.W., W.N.W.	Moderate.	—	A few cloudy days before rain-fall. Violent sand squall followed by rain. Calm, sultry, cloudy weather common during this month.
Oct. -	—	82·4	14·	89·5	75·5	82·4	73·	113	—	S.W. 23 N.E. 8.	Calm.	—	Dew in the nights and mornings common during this month. Days clear, and sun's rays scorching.
Nov. -	—	72·5	15·	80·1	65·	72·5	61·2	103	—	N.E., N.W. & S.W.	Moderate.	-	Fine weather. Mornings and evenings cold.
Dec. -	—	65·5	15·	73·	58·	65·5	57·	92	—	N.E.	Variable.	—	Early part clear fine weather, latter part cloudy accompanied by several slight dust storms.

II. Climate—*cont.*

3. The atmosphere is exceedingly dry, even when heavy showers of rain fall about July and August. There is little moisture in the air, and evaporation goes on rapidly for seven months of the year, from the middle of March to the middle of October. The heat is extreme in these months, and during the day a hot breeze blows from the westward, and dust storms are frequent; but the nights and mornings are clear, cool, and refreshing, except in September and October, when all the 24 hours are disagreeably oppressive. In December and January, the weather is pleasant and bracing. In the cold season, morning fogs in the neighbourhood of the Indus are frequent; but they are altogether confined to the banks of the river. With regard to irrigation, the alternate flooding and drying of the land, which is its result, must, according to the ordinary theory, be a fertile source in the production of malaria; but I have no means of knowing whether malarious fever prevails to a greater extent in the district now than formerly. Dust storms, which are very frequent during the hot months, are local. I am not aware of any impure admixtures affecting the atmosphere over large areas of country; but I should imagine that at times malaria was pretty widely diffused. The depressing and exhausting tendency of the hot season has a decided influence in predisposing Europeans to disease, although I scarcely think that of itself it proves an exciting cause. Animal food cannot be procured of first-rate quality in the hottest weather, and from the short space of time in which it becomes bad, it is frequently eaten in a tough indigestible state. Bread, too, of good quality is made with great difficulty in the hot season; and the first description speedily gets sour. Protection from the sun is at all times necessary for the health of the troops, and sun-shades ought to be substantial and effective. The men on duty should not wear the same clothing at night as during the day, and the night clothing ought to be of woollen material. The most unhealthy months are at the changes of the seasons. On the approach of the hot weather, malarious fevers, with lassitude, debility, and chronic affections of the abdominal viscera prevail; while at the change from the hot to the cold, the same diseases of a more inflammatory type are common.

4. There is no district near this station, the climate of which is more conducive to health than that of Hydrabad.

5. Colonel Hough has served at the following stations: Mhow, Poona, Sholapore, Kuladgee, Belgaum, Bombay, Kirkee, Ahmedabad, Kurrachee, Gharra, Hyderabad, Sinde, Shikapore, Sukkur, and Dera Ghazee Khan. He considers that all are healthy, but that Mhow agrees best with his constitution. Captain Houghton has served in Rajcote, Kurrachee, Hyderabad, Sinde, Kolapore, Poona, Sattara, Belgaum, Sholapore, and Bombay, and considers them all healthy. Belgaum agrees best with his constitution.

III. Sanitary Condition of Station.

1, 2, 3. Plans of the station, surrounding country, and barracks are transmitted.

4. Table of barrack accommodation.

Date of construction, 1854–55.

Total number of rooms or huts, 10 blocks compose the European barracks.

Total regulation number of non-commissioned officers and men, 1,000.

Barrack Rooms.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
10	96	172	24 + 12 + 12 48	Mean. 21½	177,504	1,849	86	About 1½ ft.	38	2	4
Guard Room -	6	26½	18½	20	9,805	1,634⅙	81¾	1½	4	3½	6½
Prison Cells -	1	10	10	16	1,600	1,600	100	—	2 1	2½ 2	2½ 1

5. The windows are on all sides. There are verandahs on four sides of the barracks 8½ feet wide; but they are never used as sleeping quarters for soldiers or others. There are also properly constructed jalousies.

6. The bedsteads and bedding, &c., are of the usual description used in all barracks.

7. The following are the dimensions of the tents for European soldiers, viz.:—

Double-poled tents - -	23	15	12	5⅔.
Single-poled tents - -	15⅔	15	11¼	5⅔.

The cubic space per man in the double-poled tents is 125 feet, and the superficial area is 14 feet.

8. The barracks, guard-room, &c., are ventilated by means of ventilators in the roof of the buildings. These are quite sufficient to keep the air pure by night as well as by day. The air admitted into the barrack-rooms is cooled by means of punkahs and tatties, well watered during two months.

9. The barracks are constructed of pucka brick and lime, with a roof of queen-post trusses, and tiled.

10. The floors are partly of pucka brick, and partly of stone, of an average height of 2½ feet above the ground; but with no ventilation at the bottom.

11. The barracks at this station are large and comfortably built of brick, with tile roofs. Though more durable, this material is far inferior to mud, as it is more easily heated, and retains the heat much longer. A great improvement, too, doubtless would be in having all the barracks upper-storied, or built on arches, in which case there would never be any inducement for the occupants to sleep in the open air, and from the well-known habit of malaria in keeping towards the surface of the earth, I have no doubt the cases of fever would be greatly diminished. The huts for the native troops are much too small, especially as regards the height of the walls. The tents are all that could be desired, consistent with portability. The barracks are generally cleansed and limewashed twice a year, or whenever they seem to

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	require it; the hospital every quarter, or oftener if necessary. The drainage in the European lines is in every respect satisfactory, and the surface water, &c., is received into cesspits. Dampness is unknown in any house in the station. The cesspits are situated in the rear of each barrack, there being one to each. The dimensions are about 5 feet deep, by 4 feet 6 inches in diameter. They are so constructed of solid workmanship, that they can be thoroughly cleaned, which is done every night, the contents being carried in skins on bullock backs to a distance. The privies are cleansed twice a day by sweepers, and deodorising substances are occasionally used. There is no well within half a mile of them. In the native lines the cesspits are smaller, but more numerous, and in more convenient places close to the huts. They too are regularly cleaned twice a day, and the contents thrown about in the close vicinity of the cesspits; but as the cleaning is daily attended to, anything edible is immediately picked up by birds or dogs, and as evaporation is rapid, there is no nuisance. There is great room for reform in the privies attached to the lines of one of the native regiments. They are regularly cleaned by sweepers; but as all matter is deposited on the ground, the cleaning process cannot be efficiently performed, and the liquid substances are allowed to sink into the subsoil, so that the earth is thoroughly saturated, and a noisome odour constantly pervades the surrounding atmosphere. The other refuse of European and native lines is collected into heaps, and removed every morning by scavengers' carts, which carry it to some distance, where it is burnt. On the whole, the sanitary condition of the station is satisfactory. 12, 13, 14. Plans of the lavatories, the barrack cook-room, and the privies are transmitted. The linen is washed by native washermen, who are sufficient for the wants of the station. 15. The buildings are ventilated by openings in the roof of each block, and lighted by oil lamps. 16. The barracks are principally drained naturally with small gutters to carry off all water, &c. about five yards from the buildings. These means are sufficient. Neither the barrack or hospital is damp. The fluid refuse of the barracks is received into cesspits, which are about 500 yards from the nearest tank. There are no foul ditches near the station. 17. The surface cleansing of the cantonment is performed by men kept for the purpose by Government, under the superintendence of the staff officer. The filth is carried away in carts, and burnt in kilns kept for that purpose. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c. interfering with the ventilation of the station, bazaar, &c. 19. The drainage of the bazaar is principally natural. Water is bought by residents for their own use. There is no crowding in the bazaar, and it is always kept clean by sweepers, employed by Government for that purpose. The condition of the native houses near the station is good. There are no dung-heaps, &c. permitted within them. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. Animals for the use of the troops are slaughtered in the Sudder bazaar, about a mile from barracks. 21, 22. Horses are not picketed near the station, but those of the artillery occupy a picketing ground about 200 yards from the men's barracks in the open air, and about one mile from the hospital. 23. The married quarters for non-commissioned officers and men are quite sufficient. Married people do not occupy barrack-rooms with the men.
Officers' Quarters.	1. There are no public quarters for officers at the station, they are all private.
IV. HEALTH OF THE TROOPS.	1. The station and district are not by any means unhealthy, but when disease does occur a change is generally necessary for recovery. The adjoining native population too is healthy, but they are said to suffer severely from fever and vesical calculus, which latter disease is very common among them. 2. Small-pox and measles are epidemic occasionally here. Malarious fevers often associated with spleen disease prevail at all seasons, but chiefly in the autumn. Poverty and filth are the sources of many and varied diseases. 3. The alternate inundation and drying of the soil must be a fertile source of malaria. The simple habits of the people tend to preserve them in health, but total disregard for ventilation in their dwellings and poverty make a scorbutic tendency prevalent. 4. The men of the 3rd Company 1st Battalion Artillery have joined from Belgaum, Deesa, and Ahmednuggur. They were about five years at Belgaum, where they enjoyed excellent health. They left on 18th October 1858, and arrived here on 30th November 1858, in good health. Soon after arrival a number of cases of Guinea-worm occurred; but the men have been and are healthy, though cases of malarious fever, thermatic and hepatic affections do occasionally occur. The 1st Belooch Battalion Native Infantry had been on field service in Hindoostan for more than two years previous to their arrival at this station on 21st May 1859. During that period thermatic diseases and fevers prevailed, the latter less frequent than since their arrival here, but the cases more severe. A great number of men were then always returned as sick from being foot sore, which is not to be wondered at, as they march in ammunition boots, without stockings. But, strictly speaking, the regiment was healthy. Since arrival here, cases of malarious fever have predominated, and rheumatic affections, chiefly of a syphilitic origin, while cases of dysentery and intractable ulcers are common. Were the habits of Belooches less debauched and more cleanly, the health of the regiment would be perfect. There is no portion of the barracks nor of the native lines more unhealthy than another. 5. The artillery are camped out once a year for a month or so for practice, without detriment to their health. 6, 7. No experience of hill-stations. 8. I approve of hill stations for troops. The higher the situation of any station in India, within a certain range, undoubtedly the healthier and more agreeable it is. 9. There are no diseases peculiar to hill stations with which troops are liable to be attacked on going to them. 10. Wholesome diet, with a moderate allowance of stimulants, woollen clothing next the skin (especially at night), shelter from the sun's rays, light duties, and active inspiriting exercises are conducive to health in hill and all other stations.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	11. The seasons best adapted for a residence in the hills depends on the locality, and the period of residence required in order to receive benefit, on the nature and stage of the disease. 12. The longer an invalid resides in a climate adapted to the cure of his disease and favourable to his constitution, the more robust he will become, and the better able to serve in the plains. Acclimatation is a myth, as generally understood. Habits and customs suitable to the place of residence only require to be adopted. 13. Every possible precaution to prevent excesses of any kind, and more particularly exposure to the sun, is required to protect the health of troops on leaving hill stations for the plains. 14. European troops generally are fond of change of station. It is certainly not advisable to keep them long in unhealthy districts; and for these I should strongly advocate frequent reliefs. But, unless an epidemic be raging, the stations of native troops ought to be changed as seldom as possible. 15. No reply to this query. 16. The elevation above the sea most suitable for hill stations is about 5,000 feet. 17. Some of the hills surrounding the station have been proposed as sites for sanitaria, but difficulty of access and want of water render the carrying out of such a project impracticable, except at an enormous expense. 18. No experience of hill stations. 19. The best age for a soldier to proceed to India is from 20 to 22 years, when growth and development of the system have well advanced, and they should land here early in November. On landing they should be moved to a healthy district near the port of disembarkation and out of the way of all temptations. No fatiguing duties or drill should be imposed on them, nor should a long march be entered upon. Good sun hats and suitable clothing of woollen texture should be supplied at home and served out for use as soon as the troops come into a warm latitude. Cloth clothing of every description should be entirely abolished in the plains of India. 20. Troops should be sent direct from the home depôts to India. The mortality of the first years of service could, I think, be considerably diminished by a more careful selection of the men at home, by sending no man to India until he has learned obedience, and been fully initiated into all the duties of a soldier, by visiting with severe punishment any transgression of rules on first arrival here, and favouring all sorts of amusement and recreation to keep the men contented and happy. On march the distance should not exceed 10 or 12 miles a day. Coffee before the march should never be omitted. 21. No transport of troops takes place from this station. 22. A British soldier may serve as long in India as in any other part of the world. Two-thirds of Indian stations are as healthy as any in Europe, provided the habits be adapted to the country. 23. Medical boards are absurdities. Every medical man, if imbued with a kindly feeling, considers it necessary if at all consistent with his views to uphold the opinion of a brother in the profession. The opinion of one honourable, upright, and well-qualified medical officer is of more value than those of a thousand boards. 24. Invalids proceeding home should leave India about March, or so as to arrive in England at a genial season of the year.
Diseases.	1. There are no inspection parades here for the discovery of incipient diseases, nor are they necessary. 2. The European troops at this station have no tendency to scorbutic disease, nor will they have so long as they are so well dieted as at present. Among the native troops it does not prevail to a great extent, but cases frequently occur, generally in men who have large families, or in those who waste their money and live poorly. Among the rural population the disease is common, but the cases are not extreme. 3. In a company of European artillerymen (average strength 74), there have been only seven admissions from hepatic disease during late years, but I know that other cases have occurred associated with other diseases under which they have been classed. In most cases there is no doubt that free living and indolent habits induce the disease, but in others it is difficult to assign any origin. Everything that contributes to sobriety and activity, both of body and mind, must have a good effect in diminishing this disease. Among natives acute affections of the liver are not common, whereas chronic enlargement is not rare. 4. Just after arrival here a number of cases of dracunculus occurred in the men of the 3d Company 1st Battalion of Artillery, but since then not a man has suffered from it, nor have I ever seen a case here in a native. No precautions to suggest. 5. Among the artillerymen a very small proportion of venereal disease is ever under treatment, frequently not a case; but among the natives more than half the sickness of the regiment is more or less attributable to this disease. So far as European troops are concerned it is scarcely necessary to establish a lock hospital, and I am doubtful if one would have much effect in diminishing the frequency of this disease among the sepoys. 6. The troops at this station suffer from diseases chiefly of the endemic class; quotidian, intermittent, and remittent fevers are the most common; and the tertian and quartan types are not rare. Among the troops during the last twelve months there occurred the following diseases and deaths :— Europeans, Strength, 74. { Dysentery, 5 cases. No deaths. / Fevers, 17 cases. 1 death. / Rheumatism, 16 cases. No death. / No case of small-pox. / Ditto cholera. Natives, Average Strength, 887. { Fevers, 159 cases. No death. / Dysentery, 21 cases. 2 deaths. / Rheumatism, 65 cases. No death. / Small-pox, 1 case. No cholera.

HYDERABAD, SINDE. BOMBAY.

References to Subjects and Queries.	Replies.
IV. Health of Troops—*Diseases—cont.*	7. Cases of zymotic diseases have not prevailed here for a long time. There are always sporadic cases of small-pox, &c. in the town. These diseases are most prevalent in the autumn, when a muggy heavy atmosphere prevails, and breezes are less frequent than at other times. No particular locality has been distinguished as prolific of zymotic diseases. A native of India is a most extraordinary animal, who builds walls and partitions in his habitation and obstructs ventilation, while at the same time he makes receptacles for filth, and these habits greatly foster the above diseases.
	8. No epidemic disease has prevailed here for some time.
	9. Small doses of quinine have not been given on a large scale as a prophylactic against malarious diseases here.
	10. Strict attention to all sanitary matters should be paid in order to prevent or mitigate epidemic disease. No overcrowding of barracks. Making more commodious and extended the accommodation of native troops, more especially as regards the height of the walls of tents; and above all, removing dilapidated houses and putting a stop to the overcrowding of buildings, characteristic of every native town.
V. INTEMPERANCE.	1. The soldiers at this station are temperate, and there are very few confirmed drunkards in the artillery.
	2. Drunkenness is always punished as an offence.
	3. Distilled spirits are sold both at the canteen and bazaar, and are good in the former but very bad in the latter. A cunning man may procure any amount. Spirit is supplied on payment at the station, on the march, and in the field. The dram before morning parade depends upon the will of the commanding officer. As regards the health of the men it is quite unnecessary. The smallest or largest quantities imaginable of spirits may be given to convalescents, at the discretion of the medical officer. Filthy lemonade, &c., not tending to promote digestion, are sold in the bazaar.
	4. The consumption of spirits by troops can be done without, and certainly is not conducive to internal discipline.
	5. I would recommend Government to abolish the spirit ration, restrict the sale in the canteens, and prohibit it altogether in the bazaar.
	6. Malt liquors and wines are not so deleterious as spirits.
	7. Coffee, tea, lemonade, &c. are used at this station, and are not nearly so detrimental as spirits or malt liquor.
	8, 9. It would be beneficial to suppress the spirit ration altogether, except in the case of convalescents, at the discretion of the medical officer.
	10. I would punish severely every case of drunkenness, and give every inducement to the men to abstain, by providing them with varied sources of amusement and recreation.
	11. No reply to this query.
VI. DIET.	1. The soldier's ration at this station is as follows:—Beef or mutton, first sort, 1 lb.; fine white wheaten bread, first sort, 1 lb.; vegetables of sorts, half of which are potatoes, 1 lb.; rice, 4 oz.; tea, $\frac{10}{21}$ oz. black, and $\frac{5}{21}$ oz. green; (or coffee, $\frac{1}{7}$ oz.); salt, 1 oz.; sugar, $2\frac{1}{2}$ oz.; and wood, given free, 3 lbs. Beef is the usual meat ration, but where good mutton is procurable it is given twice a week. Potatoes sometimes cannot be had. The rations are inspected by the orderly officer every day before issue, and by the commanding officer once a week, or oftener.
	2. A complete ration is provided for the troops, and the stoppage, or rather the money a man gets if he does not draw his ration, as in the case of a married man, is 3 annas 4 pice daily. When the ration does not cost Government this amount, the surplus is given to the soldier. The soldier has three meals a day; viz., breakfast at 8 a.m., of meat, bread, and tea or coffee; dinner at 1 p.m., meat, vegetables, bread, and a pint of porter to those who choose to purchase and bring it from the canteen; and tea, a little before 5 p.m., consisting of bread and tea. Such men as choose to do so can purchase a meat supper and coffee in the coffee shop.
	3. I do not think the men make away with any part of their ration, excepting the rice, which is sometimes changed for milk, butter, eggs, and pepper. The rations are excellent.
	4. The cooking is done by hired cooks, generally Portuguese. There are three to a company; a master-cook and two mates. The cooking utensils are of copper, tinned once a month, and consist of stewpans, fryingpans, large tea kettles, and camp kettles. The cook-houses are detached from the main buildings, and are well suited to natives but not to Europeans. The floors are of stone; and everything about the kitchens is inspected daily by the orderly officer. The cooking is very good; and tea and coffee are properly prepared. The variety in the cooking is according to the fancy of the mess, and is very considerable. On the line of march the men can always have a cup of coffee from the coffee shop on payment.
	5. It would be impossible to establish gardens for soldiers here, there being no water near the barracks.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldiers' dress and accoutrements at this station are of the description usual in India, and suitable to the climate. Khakee cotton clothing is the most excellent dress ever devised for hot weather in India. The guard dress here is, from March to November, khakee cotton clothing and wicker helmet in the day time; forage cap at night; and from November to March, cloth shell jacket, serge trousers, and forage cap, without cover. The sentries are protected from sun and wet by a broad verandah.
Duties.	1. As far as the health of the men is concerned, I think it is advisable they should be drilled in India; for by the way in which he lives during the first year of a man's life in India, his habits in the country are in a great measure formed. It is remarkable how much more healthy a recruit is at drill than an old soldier who has come out instructed. The recruit's time is fully occupied, and by the time he has passed his drill he has had sufficient experience of the climate to make him careful.

References to Subjects and Queries.	Replies.

VII. Dress, Accoutrements and Duties— *Duties—cont.*

2. An artillery soldier has to turn out at daylight, and five times a week attend drill, which lasts one hour, three-quarters of an hour, or half an hour, according to the drill, and the season. I have never known a man suffer in health from this. Guards come round to a man once in seven days. The men have usually six nights in bed in the week, when we are up to our full strength.
3. All our guards mount within 100 yards of the barracks, and last for 24 hours. A picquet lasts from sunset till daylight next morning, and each sentry mounts for two hours. There is a morning roll call at parade hour, and one half an hour after daylight, a tattoo roll call, and the last roll call at night. There are also short roll calls, as they are termed, for men without good-conduct badges. Night guard is the most trying part of a soldier's duty in cantonment; but I think all the precautions that can be taken to make it as little detrimental to health as possible are already taken.

VIII. Instruction and Recreation.

1. The following are the means of instruction and recreation as this station:—A ball court, a skittle ground, a school, with a good schoolmaster, a library, and reading-room, much too small, and insufficiently lighted, the lights being paid for by the men. We have a cricket club, and the men also play a good deal at a game called long bullets. The men have in the hot weather (save those who can read) positively nothing to do. There is no restriction to exposure to the sun, and I have always found the men less anxious to expose themselves when there is no such restriction.
2. I would recommend the establishment of large airy workshops at the station, and am confident they would prove a boon to the soldier. Were arsenal, commissariat, and engineering officers instructed to give as much work to the men as they would undertake, I think they would get the work better, and as cheaply done as at present, while it would be a great boon to the soldier, by occupying his time and by enabling him to feel he was doing good. A good reading room, well lighted at night, is a great want, and a more suitable supply of books. A money allowance to be made for this. All manly games should also be encouraged.
3. We have savings' banks for soldiers already established here. They answer admirably.
4. There are no trees near barracks, but the men can walk about in the north verandahs, without exposure, if that can be called exercise.

IX. Military Prisons.

There is no crowding in the military prisons at this station, and the ventilation is good.

X. Field Service.

1. There are no special local regulations for field medical service not included in the General Presidency Regulations.
2. The practical working of medical officers on the line of march consists in attendance on the sick, and in procuring a sufficient supply of carriage. Medical officers are at liberty to offer an opinion on the salubrity or otherwise of the ground selected for bivouacking or encamping; but it depends altogether on the officer commanding, whether the medical officer's suggestions are attended to.
3. The selection of encamping grounds, and general camp regulations, rests with the commanding officer and his staff, the medical officer exercising a careful supervision over the salubrity of the situation, effects of the water, &c.
4. The selection for field hospitals depends on the country or locality in which operations are being conducted. The transport of sick generally consists of doolies, spring carts, and stretchers; the latter formed of two bamboo poles, with strong canvas in the centre. Regulations bearing on these matters are to be found in the Medical Code.

By order of the Principal Inspector-General Medical Department,

Office of the Principal Inspector-General, Medical Department,
Bombay, 30th January 1861.

W. C. COLES,
Assistant Surgeon, Secretary.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1. A plan of the hospital is transmitted. 2. Its distance from the barracks is 600 yards in rear, and its position as regards the Sudder bazaar is north-west, as also of the native town. The site is open, healthy, and in no way obstructed. 3. The water is wholesome, and the supply abundant. 4. Refuse water and other impurities are carried away by open drains, discharging into cesspools, which are regularly cleaned out. 5. The wards are raised three feet above the ground, but there is no perflation of air beneath them. Provision is made for carrying away the roof water; the whole of it does not sink into the subsoil. There is an open drain all round the hospital, which carries away the rain-fall rapidly. The hospital is built of pucka brick and lime, with a tiled roof, having a false verandah, which is intended to keep the wards cool. The hospital is supplied with double verandahs in front and rear, and single ones on the sides. They afford sufficient shelter from the sun's rays, but are not used for the accommodation of sick, convalescents, or others.

References to Subjects and Queries.	Replies.

XII. Hospitals—*cont.*

Table of Hospital Accommodation.
Date of construction, 1854–55.
Total number of wards, 5.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards.			
		Length.	Breadth.	Height.	Cubic Contents.
		Feet.	Feet.	Mean.	
No. 1	—	222	24	28	149,184
,, 2	—	43	24	28	28,896
,, 3	—	77	24	28	57,744
,, 4	—	97	24	28	65,184
,, 5	—	45	16	18	12,960

The hospital is so placed as to receive the full benefit of prevailing winds. There are no windows to the hospital, but doors, the construction of which is conducive to ventilation and coolness.

6. There are sufficient ventilators, with Venetian shutters, to keep the wards cool and free of odour.
7. During the hot season the air is cooled by passing through kus-kus tatties, placed opposite the doors and kept constantly wet with water. The wards are well supplied with punkahs.
8. There are no means for warming the air admitted to the hospital. The walls and ceilings of the wards are cleansed and limewashed yearly, or oftener if thought desirable by the medical officer.
9. The privies are situated on the northern and southern extremities of the hospital, and constructed of pucka brick and lime, with flat roofs. They are placed on cesspools, which are carefully cleansed, and deodorizing substances are made use of. They are not offensive.
10, 11. There are no lavatory arrangements for the sick in hospital other than a tub or hip bath, which is neither sufficient nor convenient.
12. The linen of the hospital is washed, and dried by being exposed to the sun, which is quite sufficient.
13. The storage is sufficient and dry.
14. The cots are made of wood, standing about 2½ feet high. The part on which the bedding rests consists of broad tape lashed from the side and end pieces of wood, and is occasionally undone and washed. The beds are stuffed with chopped straw, which is from time to time renewed.
15. The position of the kitchen is east of the ward. The cooking utensils are of copper, tinned over, and the means are sufficient.
16. Diet tables, rolls, and other returns are given in the Medical Code of Regulations since January 1861.
17. Ward boys are allowed by Government for attendance on the sick, and a comrade can always be procured, or a nurse on the requisition of the medical officer. This establishment differs according to the strength of the corps or detachment.
18. The sanitary condition of the European hospital is good, and no epidemic, as far as I know, has prevailed in it.
19. The storehouses and apothecary's quarters are situated too near to and in wrong position as regards the hospital.
20. There is no ground or walk for convalescents. An unweildy and uncomfortable cart is allowed by Government to each corps or detachment of the sick for the exercise of convalescents, but it is taken little advantage of by the men.
21. There is a small female hospital, and a matron for each corps or detachment; but in an unhealthy season the accommodation would be deficient.
22. There are no special local hospital regulations not included in the General Presidency Medical Regulations.
23. The medical officer can of course prescribe diet and medical comforts as he thinks fit, but any extraordinary expenditure is subject to the sanction of the Deputy Inspector General; and the same with regard to repairs or alterations.
24. There is no hospital or ward for convalescents, nor is any such required.

XIII. Burial of the Dead.

1. The burial ground for British troops is about one mile from and to the north-east of the station. The prevailing wind, with regard to the station, is generally from south-west or north-east.
2. The area of the ground is about 200 square yards, and its soil is sandy. There is no drainage, and decomposition takes place rapidly. The ground is surrounded by high walls so as to render it perfectly secure.
3. There is no specified grave space, but there is usually an interval of 3 or 4 yards allowed between the graves, which are usually about 7 or 8 feet deep, and are never re-opened. Interment, as a general rule, takes place 12 hours after death.
4. The graveyard is never offensive. Whenever a man dies, if it be any time before 2 or 3 in the day, the funeral takes place next morning, with all the usual ceremonies.
5. The dead of bazaar people are buried or burnt, according to caste.
6, 7. No injury accrues to the public health from the present practice, nor are any improvements to be suggested.

(Signed) L. S. Hough, Lieut.-Col., Commanding Hyderabad.
W. R. Houghton, Captain,
Staff Officer, and Officiating Executive Engineer.
C. Gordon Asher, M.D., Assistant Surgeon,
Civil Surgeon, Hyderabad.

20th February 1861.

Examined by A. F. Cunynghame, Major-General,
Commanding in Sinde.

KURRACHEE.

Accommodation
- Queen's Troops
  - Artillery, 1 Troop, Horse, complete.
  - Infantry, 1 Regiment of Her Majesty's Service, complete.
  - Infantry Barracks, (Queen's Depôt) for 423 men.
- Native Troops
  - Artillery, 1 Company, Golundaze (Native Artillery).
  - Infantry, 2 Regiments.
  - Infantry, Sappers and Miners, Lines for 1½ Companies.

References to Subjects and Queries.	Replies.
I. Topography.	1. The country surrounding the station consists of a sandy valley, the dry bed of a river being in the lowest part, with belt of trees and cultivation; the ground is sloping, and, in the distance, sandy hills. An inland salt-water swamp 5½ miles square approaches within a quarter of a mile of the cantonments, and lies between them and the sea, which is 3 or 4 miles distant on the south-west margin of the valley. This point is the inlet of the swamp, which is here about a quarter of a mile broad. In the lowest part of the valley there is the belt of trees, which is, however, not very extensive, and also some cultivation.
	2. The elevation of the station above the sea is about 27 feet, but somewhat lower than the adjacent country, except towards the river Lyaree and the sea. The dry bed of the former, which is about half a mile distant, is 16 feet below the station, and the salt-water swamp is about 20 feet below the level. Clifton and Manora point, at the entrance of the harbour, are higher and probably healthier than the station. The former is 2½ miles and the latter 6 miles from the cantonments, and their elevation above the sea is about 100 feet, and 70 feet above the station. Both are occupied, but are too limited for military purposes.
	3. A low mountain chain, running westward to the sea and rising to an elevation of about 800 feet, is situated about 6 miles distant from the station on the north and north-west aspect.
	4. The sea is distant about 3 miles. The bed of the river Lyaree, which is usually dry, is about half a mile from the station. When rain falls the bed is then filled with water, but this is very seldom. Wells are, however, pretty numerous in the lower part of the valley: There are also a few open tanks, but these are often dry. The vicinity of the station is not liable to overflow. No broken ground, ravines, or water pits exist near worthy of notice.
	5. The station is open and well ventilated, and from the usually strong winds that blow any elevation of temperature by the exposure of the buildings to reflected sun heat must be inconsiderable. The station is not exposed to cold and variable winds. Land and sea breezes prevail in spring and autumn, but with no particularly marked effects on health.
	6. The surrounding country is uncultivated except on the eastern bank of the river Lyaree. No works of irrigation exist. There is no cultivation of rice or indigo, nor is the preparation of hemp or flax carried on near the station.
	7. The town of Kurrachee is distant 2½ miles from the station, and contains a population of 22,000.
	8. The ridges of the amphitheatre are mostly limestone, abounding in fossils, the lower hills being composed some of sandstone and some conglomerate. Below is blue clay, resting on the sand and conglomerate of the miocene period. The surface on the more level parts is alluvial, clayey, and in some parts gravelly, the subsoil being clay, sand, and gravel. The station occupies new ground.
	9. Water is found at about 12 to 20 feet below the surface during the dry season, and in the bed of the river at 2 feet. Rain feldom falls, and when it does it soon flows off.
	10. There are no surface springs, and the drainage from higher ground mostly runs off, and the surface dries immediately.
	11. The water supply is derived from wells. There are 2 or 3 tanks, but their extent of surface is inconsiderable. Being dependent on the rain-fall they are seldom full, generally being quite dry. There is nothing conspicuous in the nature of the plants or animals they contain. No tank used for drinking purposes is also used for bathing, nor are they liable to pollution from any source. No nuisance or malaria proceeds from any tank within or without the station.
	12. There is no lack of water in the wells, the supply never having been known to fail, and some wells would yield a larger quantity. The water is rather dull in colour, and has an earthy taste, but is without smell. It contains chloride of sodium, sulphate of soda, sulphate of lime, sulphate of magnesia, carbonate of lime, and carbonate of magnesia, and the best wells contain nearly one two-thousandth part of saline matter. The quality is not good, and it is injurious to health; the quantity, however, as before stated, is not defective. It is raised by Persian wheels and hand buckets, and distributed by water carriers in skins and by casks in carts. Water should be brought from the Mulleer river, about 11 miles distant, or from the Indus.
	13. In the salt swamp adjacent, which covers an area of 5 square miles, all the conditions necessary to the production of mephitism exist.
	14. With regard to the selection of sites for stations, it is believed that no particular rule exists, but there is a rule in reference to the selection of sites for new buildings, especially barracks, pendalls, and hospitals. The committee of selection, consisting generally of the officer commanding the station, an engineer officer, assistant quartermaster-general, and a medical officer appointed for the latter purpose might also determine the sites for stations.
II. Climate.	1. The means and instruments available at the station for conducting and registering meteorological observations are 1 anemometer, 1 pluviometer, 1 mountain barometer, 1 Daniell's dew point hygrometer, 1 Regnault's ditto, 1 standard dry bulb thermometer, 1 standard wet bulb thermometer, 1 heat thermometer, 1 minimum in grass thermometer, 1 maximum in air thermometer, 1 minimum in air thermometer, 1 maximum wet thermometer, 1 minimum wet ditto.

November - -	30·044	73·19	86·75	57·61	78·88	62·81	106·55	—	N.	0·38	—	Do. do. mornings moist.
December - -	30·155	65·16	78·52	57·76	71·39	59·27	94·30	0·20	N.E.	0·59	—	Dews, dust storms, cold nights.

3. The climate is good. The month of November is characterized by dryness, July and August by humidity. The maximum of heat, about 86° to 94°, occurs in May and June, the intermediate spring and autumn months, viz., March, April, October, and November, being variable; December, January, and February, being the cold months. Fogs appear at times during the variable seasons, especially when they touch the extremes of the cold season. From May till September is the hot season, during which time strong westerly monsoon winds prevail. Damp cannot be said to exist at any time. Tree planting is but little attended to, less perhaps than it ought to be. There is but little irrigation, and what exists has no influence on climate, but the place is very often obnoxious to dust. Mephitism may also extend in a diluted form from the delta of the Indus to the station. Intermittent fevers show the noxious quality of the climate, and to these may be added hepatitis and diarrhœa as resulting from its influence. Cholera of late years has not existed. Scurvy is often severer amongst natives. The best diet, with the free use of vegetables, ample accommodation in space, clothing of a light texture in the hot season and warmer in the cold, should be provided. Drills, duties, and exercises ought to be more moderate in the hot season. The comparison of a good many years gives, as the result, the greatest mortality to the months of May, June, and December, but the sickness prevails rather at the changes of the season than when fairly set in. The deaths, mostly of chronic cases, are not coincident with the greatest sickness. The prevailing diseases are fevers and affections of the bowels.

4. There is no district in Sinde more conducive to health than that of the station. Ghizree is a mere experimental sanitary station, and owes its superiority to elevation and proximity to the sea. Manora, the promontory that forms the western boundary of the harbour, is perhaps the most healthy spot in Sinde, but it is too small for troops and inconvenient for supplies. It is also without water, like Ghizree.

5. I have served at Bombay, Tanna, Poona, Mulligaum, Surat, Baroda, Sukkur, Hyderabad, and Kurrachee. Of these stations, Baroda is the worst; Tanna, Sukkur, Hyderabad, and Bombay are bad; Poona and Mulligaum good; and Kurrachee the best. This last owes much to improved sanitary arrangements generally and in some of the barracks and hospitals.

III. Sanitary Condition of Station.

1, 2, 3. A map of the adjacent country, and plans of the stations and barracks, are transmitted.

III. Sanitary Condition of Station—*cont.*	5. The windows are on opposite sides. There is a verandah 10 feet wide on both sides of the barracks, but it is never used as sleeping quarters by soldiers or other persons. There are no jalousies or jhilmils. 6. The bedsteads in use are boards on iron trestles. 7. The tents are made of strong Dungaree cloth. 8. The barracks, &c., are ventilated by openings in the roof, by fixed venetians in the walls, high up on both sides, by badgheers (windshafts), and by keeping the doors and windows open as much as possible. The ventilation is sufficient to keep the air pure night and day. No means are resorted to in order to cool the air of barrack-rooms, the sea-breeze being generally ample. 9. The barracks are constructed of stone and lime, the tents of canvass, and the huts of sun-dried mud bricks. 10. The floors are constructed of cut stone in the permanent barracks, and chunam and earth in others. They are raised 3 feet above the level of the ground in the former, and vary in the latter from 3 feet to 6 inches. There is no passage of air beneath. 11. The materials and construction of barracks, tents, and huts are suitable for the climate. The barracks are kept in repair by the Public Works Department, and the cantonment by the station staff officer, and in bazaar limits by the cantonment magistrate. The repairs are quickly executed. The commanding officer of the station is responsible for general sanitary state of the cantonments. Walls and ceilings of barracks are cleansed and lime-washed every six months. 12, 13, 14. Plans of the cook-houses, privies, and lavatories are transmitted. The washing and drying of linen is performed by washermen, and these means are sufficient. 15. The privies are ventilated by doors and openings in the roof. The barracks are lighted at night by oil lamps. 16. There are no main drains and sewers to the barracks; the system pursued is that of immediate removal. The surface and other drainage is conveyed into cesspools close to the buildings, which are emptied as soon as filled. No part of the barracks or hospitals is damp. The cesspits are about 2 feet in diameter by 3 feet deep, and their distance from the wells varies according to the position of the barracks, but none are sufficiently large to taint any well or tank. These cesspits are close in the rear of the men's quarters and hospital, and, as before stated, are emptied as soon as filled. There are no foul ditches. 17. The surface cleansing of the roads, waste ground, and the outsides of compounds is performed by sweepers under the barrack department, and is efficiently done. Owners of houses are responsible for cleanliness inside their own compounds. 18. There is no vegetation in the station, nor any old walls, &c., to interfere with the proper ventilation of the station, bazaar, &c. 19. There is no drainage in the bazaar, all filth being removed daily, and the bazaar kept as clean as the limited number of sweepers will allow. It is very crowded. The sweepers carry away the filth in carts to the kilns, where it is burnt. An increased number of sweepers

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	is required. The sanitary condition of the native houses near the station is for the most part good. They have cesspits, but the contents are emptied daily. No nuisance is experienced in barracks from the wind blowing over the native houses. 20. Animals for the use of soldiers are slaughtered about a mile from the station, and the offal is used as manure. No nuisance is experienced from the slaughter-houses. 21. Horses of parties authorized to let carriages on hire are located in stables and compounds attached to houses in cantonment. Care is taken that these places are kept in a state of cleanliness; if found otherwise a fine is inflicted. The manure is carried out of camp, like all other refuse. 22. All the horses, with the exception of the sick, are picketed in the open air. The sick stable consists of a quadrangle of sheds open to the inside, with an uncovered court-yard in the centre. The lines are immediately in the rear of the men's barracks, and a hundred yards to the north of the hospital, but to windward of it, and immediately in front of the married men's quarters. There are no dung-heaps, and the litter is removed daily to a distance of 500 yards by the troop-carts; the dung is carried off as it drops. The horses are picketed at intervals of four yards, with streets between them. 23. There are sufficient quarters for married people, and none occupy barrack-rooms with the men.
Officers' Quarters.	1. There are no public officers' quarters. The houses belong to private individuals, from whom the officers are obliged to rent them, according to proximity to the lines. The officers' houses at the north end of the camp are too small and very close together. Owners should be encouraged to improve their property, and some of the worst structures should be cleared away to admit of a freer circulation of air in that neighbourhood.
IV. Health of the Troops.	1. The station, district, and adjoining population are healthy, but sickness occasionally shows itself at the great changes of the year; that is, towards the beginning and close of the hot season. 2. Fevers, accompanied and followed by spleen disease and bowel affections, as also scurvy and ulcers, are the most prevalent diseases among the native population. 3. The healthiness of the natives is attributable to the salubrious situation, soil, proximity to the sea, and the monsoon winds; their unhealthiness to the swampy margin of the sea, and perhaps also to the Indus. The drinking water is the cause of the scurvy and diarrhœa. 4. The 64th Regiment and Troop Horse Artillery arrived about two years ago from field service. One Foot battery arrived about two years ago, and the other about a year since, from Bhooj. The native regiment came from Bombay about 1½ years ago. In the depôt recruits pass from England to the Punjab, and invalids and time-expired men from the latter to England. There is no precise information as to any striking peculiarities of disease before or since arrival at the station. A portion of the men's present accommodation is more unhealthy than the rest, the unhealthy portion being the old barracks, which are far too small. 5. The troops at the station are never camped out. 6, 7, 8. I have no experience of hill stations except personal, but approve of their selection for troops. The hill-station is to the plain as the open air to the hot-house. 9. No reply. 10. Ample accommodation, good food and water, with absolute cleanliness, would probably render many evils in hill stations. 11 to 16. No experience with the troops at hill stations. 17. There is no higher ground near the station which could be advantageously occupied as a hill station. 18. The surface and subsoil of this station are healthy. 19. Soldiers proceeding to India should be 20 years of age, and land there in November. On landing detachments proceed to the depôt barracks and regiments to their own barracks. Clothing adapted to the season is provided, and drill, &c., carried out, as in other regiments. Recruits, on landing, should be provided with good accommodation, suitable clothing, good food and water, and have moderate drill only, especially if not drilled before. Amusements should be provided, and they should be discouraged from drinking habits. 20. Troops should proceed direct from the home depôts to India, where, if they land in November, they might remain with their regiments, going to the hills for the hot season. 21. The mode of transport from port to the interior by water, embarking at Keemara or Ghizree (according to season) in steamers and flats; but sometimes men march to Tatta on the Indus, 60 miles, and embark there. About 11,000 men have passed up in the last six years, and it does not appear that any loss has been sustained. 22. A British soldier should serve 20 years in India. 23. There is no conflict of opinion at medical boards as regards invaliding. Medical officers compose the board. 24. Invalids leaving India for home should depart in January, February, or March.
Diseases.	1. There are weekly inspection parades at the station for the discovery of incipient diseases. 2. Scorbutus has existed, but is rare in European troops; among natives it is more prevalent, and has at times proved fatal; it exists also in recruits landed from England, about 10 per cent. being infected; it is attributed principally to the water, inferior accommodation, and bad food, such as putrescent fish. Good water and good food are the remedies. 3. Hepatic disease affects Europeans at the rate of 3 per cent., but scarcely 1 per cent. of natives are affected by it. It is originated by heat and the use of spirits, and also accompanies the severer fevers and dysentery. Pure air and disuse of spirits, modified clothing and exercise, such as drills, but not so as to fatigue, are the prophylactic measures for diminishing its frequency. 4. Dracunculus does not exist here unless imported. 5. In European regiments about 20 per cent. of the total sick are affected with venereal disease. In the artillery 10 per cent., and in native regiments 3 per cent. only are affected. The expulsion of prostitutes from bazaars, the removal of the restriction on marriage, and the education and religion of the soldier, are the safeguards against the disease. Lock hospitals have advocates, but were put down at the instance of the highest ecclesiastical authority.

IV. Health of the Troops —*Diseases—cont.*	6. The troops at the station suffer from the following diseases of the epidemic and endemic class :— Fevers.—Intermittent, remittent, and continued. Dysentery.—Occasionally. Cholera.—But not since 1852. Rheumatism.—Occasionally. The proportion of admissions from the above diseases to total admissions is about 45 per cent. in Europeans, and 50 per cent in natives. The deaths to total deaths are about equal in Europeans and natives ; viz., 33 per cent. 7. Small-pox is usually of a mild form in natives. Measles has been severe in its attacks. Croup is rare, but sometimes fatal. Diarrhœa is mild, and dysentery little known, except in children. Cholera, except sporadically, has not appeared since 1852. Scurvy affects the gums with ulceration, and the legs with hard and painful swellings, sometimes with cold, and sometimes with a hot sensation, and generally pain in the limbs; when fatal there are anœmia, præcordial pains, and syncope, death being often sudden. Fevers are mostly intermittent, the lighter cases being of the tertian type; the severer cases quotidian; remittent, or continued, generally of a milder form. Erysipelas is rare, and mostly very slight, but it has proved fatal. Syphilis is not generally untractable. Phagedœna has been seen at times. Zymotic diseases are not prevalent at any particular seasons, but vicissitudes of weather, such as the changes in spring and autumn, seem to influence fevers. The most prominent phenomena which precede or accompany their appearance are the variation in the force and direction of the winds, and humidity and increased range of temperature. Wherever ventilation in the bazaars is most interrupted fever prevails to the greatest extent. The smallest barracks are found similarly obnoxious to this disease. Bad food and bad dwellings with the natives, and fatigue with the troops, predispose them to fever. 8. There is nothing prejudicial in the nature of the soldier's duties or occupations in barracks, or habits on the march and in the field. Occasionally duties may be hard and too little sleep allowed. In habitual fever, hepatic, or visceral disease, spirit drinking must be fatal. 9. Quinine has not been tried at this station as a prophylactic against malarial disease. 10. To mitigate epidemic disease here the swamp should be extirpated, and the vegetation thinned ; this latter, however, does not affect the troops. Strict attention should be paid to the kilns which are used for consuming refuse and all waste matter which collects in the cantonment. Better barracks should also be built in lieu of the old and small barracks.
V. INTEMPERANCE.	1. The soldiers at the station are generally temperate, confirmed drunkards being only about 1 per cent. 2. There is no information to be procured from the records of the hospital to enable us to say what is the proportion of diseases caused by intemperance, except as regards delirium tremens, which varies, but may be stated at about 1 per cent. Drunkenness is punished as an offence. 3. Distilled spirits are sold at the canteen and in the bazaar, but there is a prohibitory order against the sale of them to European soldiers in the latter place. Spirit is no part of the ration for soldiers either at the station, on march, or in the field. Morning drams are not allowed. Spirit is not given to convalescents except when prescribed. No drinks injurious to health, other than intoxicating drinks, are sold in the canteen or bazaar. 4. There is no reason to suppose that spirit is conducive to health, and it certainly often proves injurious. It is not conducive to efficiency and internal discipline. 5. With regard to the question whether it would be beneficial to the health of troops to restrict or abolish the use of spirituous liquors and their sale in the canteens or bazaars, so long ago as 1836 the Government gave this announcement,—" We attach great importance to " the measure recommended by the medical board for preserving the health of the European " troops under our Government, viz.,—the substitution, as far as practicable, of tea, coffee, " &c., for ardent spirits, and the establishment of temperance societies." Beer and porter have been imported and sold in the canteens in order to beat spirits out of the field. 6. There is only one degree of difference as to the influence on health in the use of malt liquor or wines as compared with spirituous liquors. 7. Coffee, tea, lemonade, and similar drinks are much used at the station; these are not injurious, but spirits and malt liquors are. 8. There is no spirit ration, and the use of other beverage is encouraged. 9. It might be beneficial to prohibit the sale of spirituous liquors in the canteen, and to permit only beer, coffee, tea, lemonade, &c., to be sold to the troops ; but the prohibition should not be too suddenly introduced, lest confirmed drinkers of spirits should be driven to purchase clandestinely a more deleterious kind of liquor elsewhere. 10. We would recommend that the prohibition should not be made applicable to soldiers now in the service, but commence with recruits on first landing in India. 11. The canteen regulations of the 3rd European regiment prohibits the admission of any liquor, except that furnished by the commissariat, and the issue of any spirituous liquor, wine, or beer, directly or indirectly, to any native or follower of the regiment, nor can any liquor be taken away from the canteen except under an order from the commanding officer. No man on duty, drunk, or undergoing punishment, is permitted to enter the canteen, nor are any women or children admitted. The canteen is open from 12 to 1 o'clock for the issue of porter only, and from sunset until the quarter bugle for the issue of spirits and malt liquor. A supply of cool filtered water to be kept for the use of the men. Crowding is forbidden in the canteen. Every man is allowed one dram of spirits and a quart of porter daily. No spirits are issued on any occasion before the usual dinner hour, nor is a man allowed more than one dram of arrack, or one quart of malt liquor at one issue, which must be paid for with ready money. The canteen of Her Majesty's 64th regiment is open from half-past 11 till 12 o'clock, a.m., for the supply of malt liquor, and from 12 till a quarter to 10 o'clock p.m. for men of the regiment off duty. It is open from half-past two p.m. for the issue of spirits to those men who did not receive malt liquor before dinner, and from sunset to quarter to the first post for issue of one dram of spirits to each man. The quantity issued to each man is one quart of malt and one dram of spirits daily. All liquors are paid for. No water to be brought into the canteen for mixing with the arrack, except in presence of the officer on duty. The bazaar regulations prohibit the sale of liquors there without a licence. No liquor can be sold to European soldiers, or any person amenable to the articles of war under the rank of warrant officer, without a licence.

References to Subjects and Queries.	Replies.
VI. Diet.	1. The ration for Queen's troops and European troops in the Indian army is the same, and consists of meat 1 lb., bread 1 lb., rice 4 oz., salt 1 oz., tea $\frac{5}{7}$th lb., vegetables 1 lb., firewood 3 lbs. Mutton is given twice a week, and beef five times, and the vegetables as the products of the station may be. An inspection of the ration is made by the commissariat agent, regimental quartermaster, quartermaster-serjeant, orderly officer, and occasionally by the officer commanding the regiment or corps. 2. A complete ration, including vegetables, is provided for the troops, but no fruit. The stoppage is 3 annas 4 pie, or 5*d.* per diem. A soldier has three meals a day, viz.,—breakfast at 8 a.m., consisting of tea or coffee and bread, with part, perhaps, of the meat ration. Dinner at 1 p.m., consisting of meat, vegetables, and bread, and a supper of tea and bread. The proportion of vegetable which enters into the constitution of the ration is about one-third its weight. 3. The ration is ample for ordinary times; but fruits or other vegetables may be requisite in excess when scurvy prevails. There are no particular arrangements taken to prevent the disposal of the ration. 4. The means and apparatus for cooking are detached kitchens, one camp kettle containing seven gallons, one baking dish, and a three-gallon tea kettle for every 10 men. The cooks are Portuguese. The kitchens are clean, light, well ventilated, and sufficiently supplied with water. The food is boiled for dinner, and the cooking is properly done, and sufficiently varied. In some regiments the men have tea or coffee before a march, but there is no general rule for this, nor could any hold good. 5. Soldiers' gardens could not be established here.
VII. Dress, Accoutrements, and Duties.	1. The soldiers' dress and accoutrements are as follows:—

Return of the Arms, Accoutrements, and Regimental Necessaries of Foot Artillery, European Soldier, Gun Lascar, and Driver.

Camp Kurrachee, 7th October 1860.

—	Arms and Accoutrements.									Regimental Necessaries.

VII. Dress, Accoutrements, and Duties—*cont.*

List of Clothing for a European Infantry Soldier.

	No.	Articles.	
Furnished by the State.	1	knapsack and slings	Agreeably to pattterns furnished by Government.
	1	dress cap	
	1	red coatee (dress)	
	1	shell jacket (undress)	
	1	pair trousers (woollen cloth)	
	1	great coat	
	1	canvass bag	
Furnished by the soldier.	2	khakee tunics	Agreeably to sealed patterns approved of by the Commander-in-Chief.
	2	pairs khakee trowsers	
	4	white shirts	
	2	check ditto	
	3	banyans (flannel)	
	4	pairs socks (cotton)	
	2	ditto (worsted)	
	2	pairs braces	
	4	towels	
	2	khakee covers for dress cap	
	1	forage cap and strap	
	2	khakee covers for ditto	
	3	pairs of shoes	
	1	clothes brush	
	2	shoe brushes	
	1	hair brush	
	1	comb	
	1	razor, brush, and soap	
	1	button stick and brush	
	1	marking stick	
	1	sponge	
	1	holdall	
	1	knife, fork, and spoon	
	1	account book	
	1	mess tin, with cover	
	1	gun stopper	
	1	oil rag	
	1	sleeping carpet (6 feet by 2½)	
	1	numda mattress	
	2	cotton covers for ditto	
	2	sheets	
	2	kumblee blankets	
	1	coir pillow	
	2	cotton cases for ditto	
	2	pairs of small brass or iron hooks, 1 inch long, to be sewn on the right and left sides of the coatee and shell jacket, to sustain the waist-belt.	

Native Infantry Soldier.

	No.	Articles.	
Furnished by the State.	1	knapsack and slings	Agreeably to sealed patterns approved of by the Commander-in-Chief.
	1	red jacket (dress)	
	1	red jacket (undress)	
	1	pair trousers (woollen cloth)	
Furnished by the soldier.	1	great coat	
	3	pairs trousers (white linen)	
	2	ditto (black cotton)	
	1	epaulettes or wings for dress coat	
	1	Kilmarnock forage cap	
	1	chin chain and chin strap	
	2	white cotton covers for forage cap	
	2	pairs shoes	
	2	pairs braces	
	1	clothes brush	
	1	shoe brush	
	1	button stick and brush	
Found by the soldier.	1	oil rag	
	1	ruzzai	
	2	meerazeis	
	1	dhoputta (2½ yards long by 2½ feet in width)	
	2	chudders	
	2	dhoties or paijamas	
	1	sleeping carpet (6 feet by 2½ feet)	
	1	brass lota (small, 5½ inches wide, 3½ deep, and cord)	
	1	brass lota (larger size)	
	1	tuvwa (iron, 9 inches wide)	
	1	thaler (brass, 9 inches wide)	
	1	kuttora (brass)	
	1	chimcha (brass)	
	1	chimta (iron)	
	1	canvass bag, agreeably to pattern	
	2	pairs small brass or iron hooks, 1 inch long, to be sewn on the right and left sides of the jacket, to sustain the waist-belt.	

Horse Artillery Gunner.

No.	Articles.	No.	Articles.	No.	Articles.
1	forage cap and chin strap.	2	pairs braces.	1	clothes brush.
2	khakee covers.	2	pairs boots.	2	shoe brushes.
2	white helmet covers.	1	pair of shoes with clasps.	1	razor, brush, and strop.
1	pair of cloth overalls, leathered.	1	pair of chain straps.	1	sponge.
3	pair of khakee overalls.	1	numbda.	1	button stick and brush.
3	khakee coats.	2	cotton covers for ditto.	1	marking stick.
4	white shirts.	1	coir pillow.	1	knife, fork, and spoon.
2	barrack change ditto.	2	pillow cases, cotton.	1	holdall.
3	stomachers.	1	saddle bag, lined.	1	account book.
4	pair white cotton socks.	1	haversack.	1	khakee cover and turban for wicker helmet.
2	ditto, worsted ditto.	1	jamboo, plate, and cover.	1	wicker helmet.
4	towels.	1	hair brush and comb.		

Accoutrements.

1 pouch belt and pouch. | 1 sword belt.

Horse Artillery Gun Lascars.

1 undress jacket, cloth.	2 ditto cap covers.	2 brushes.
1 ditto overalls.	2 pair of shoes.	1 lota.
2 khakee jackets.	1 button stick.	1 cooking pan.
2 ditto overalls.	1 sponge.	2 talees.

Accoutrements.

1 sword belt. | 1 pouch belt.

The present dress is suitable to the climate, and for the soldiers' duties by day and night, and no improvements are suggested. The dress for the guard in the hot season is drill dyed earth colour (khakee), and for the cold season, woollen. There are sun shades and boxes for the sentries, and well built guard houses for protection from sun and wet.

Duties.

1. A man should be thoroughly drilled at home before being sent to India.
2. The usual routine of a soldier's duties is,—morning parade for half an hour in the hot weather, and an hour in cold, Sundays and holidays once a week excepted; guard happens every 6 days. The duties do not affect the men's health. The best time for drills, parades, and marches is in the morning and evening, varied a little in time, according to season. The men have 6 nights in bed during the week.

References to Subjects and Queries.	Replies.
VII. Dress, Accoutrements, and Duties—*Duties—cont.*	3. Guards are mounted in the barrack square or within 100 yards of the barracks. Night guards last 12 hours; day and night guards 24 hours. There are roll-calls thrice daily, and occasionally others. The men do not suffer in health from night guards.
VIII. Instruction and Recreation.	1. The following are the means of instruction and recreation at the station:—There are ball courts, skittle grounds, schools with schoolmasters, library, and reading room. There are workshops and a theatre, but the former are not efficient, and the latter receives no aid from Government. There are no day rooms, soldiers' clubs, gardens, or gymnasia. The above means are not sufficient to keep all the men occupied during the wet season and heat of the day. A restriction is placed on the men when off duty as to exposure to sun and rain, when such is thought necessary, and with beneficial results. 2. Soldiers should be encouraged to work at their original trades or to acquire some useful occupation. Gymnastic exercises, under qualified instructors, should be available. Were restriction on marriage removed, and the standing of the soldier raised, many would find the best employment and recreation in the care, instruction, and amusement of their families. 3. The institution of soldiers' savings' banks would be advantageous. 4. There is no shade from trees at the station, but there are good verandahs, though little fit for exercise.
XI. Military Prisons.	1. The cells for prisoners are well built and ventilated. The space is ample for one man in each cell, but not for more without crowding.
X. Field Service.	1. There are no special local regulations for field medical service not included in the General Presidency Regulations. 2. The medical officer has no positive power as regards the conduct of the line of march, camping, &c., but if consulted he would give his advice. If he thought an error was committed he would point it out; or, if he believed that health suffers from existing arrangements, he would seek to have them altered. 3. The arrangements for preserving the health of troops, in the selection of camping ground, and general sanitary regulations, are all provided for in the general regulations of the service. The senior medical officer is looked to for advice in sanitary matters. Something more positive, some initiatory power, should be vested in the medical officer of each corps or civil or military station. The medical officers, in fact, should be the eyes, and the quartermaster-general's department the hands of the army, empowered to maintain, and ever busy in maintaining a perfect military sanitary police. 4. Field hospital arrangements (see Appendix).
XI. Statistics of Sickness and Mortality.	The following tables give the required information under this head.

By order of the Principal Inspector-General, Medical Department,

W. C. COLES, Assistant Surgeon,
Secretary.

Office of the Principal Inspector-General, Medical Department,
Bombay, 30th January 1861.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1, 2. The hospital for the permanent infantry is well removed from the barracks, but all the others are near to them. There are no stables, but the artillery hospital is very close to where the horses are picketed. The general hospital is nearest to the bazaar, which is 200 yards distant. The others are remote from it, and, with the exception of one native hospital, from the residents' houses also. The sites are pretty open and freely ventilated, with the exception of the hospital above named, and generally healthy as to elevation, drainage, &c. 3. There is an abundance of water, though not of good quality; but a project for a permanent supply of good water for Kurrachee is under consideration. 4. There is no drainage, all refuse, solid or otherwise, being removed daily by sweepers.

XII. Hospitals—*cont.*	5. The wards of the hospitals (with the exception of one native hospital) are raised about 3 feet above the ground, but there is no perflation of air beneath. No provision is made for carrying away the roof water, some of which sinks into the subsoil, the rest flowing away. There is no surface drainage or guttering round the hospital. The rainfall at Kurrachee is small. The older hospitals are constructed of sun-dried bricks, and the new one of stone. The general hospital and one native hospital have double roofs and walls, but the others are single. They are all mostly as cool as private dwellings. The hospitals are provided with verandahs from 8 to 12 feet in breadth, which are a sufficient protection except from the morning and evening sun. In the general and native hospitals, which have double roofs and walls, the verandahs are inside. The closed verandahs are only used for the accommodation of sick, &c., when the wards are crowded. The open ones are never used for that purpose. With the exception of the last built hospital for the infantry barracks, all the hospitals consist of one flat only. The hospitals are so placed as to receive the full benefit of the prevailing winds. The windows open vertically in halves, and their arrangements and construction are conducive to ventilation and coolness. 6. The wards are ventilated by doors, windows, and openings in the roofs. These means in the new hospitals are adequate, but are not so in the old. There are no jalousies or jhilmils. 7, 8. No apparatus for cooling or warming the air in wards exists. The walls and ceilings of the wards are cleansed and lime-washed once every three months. 9. The privies are immediately in rear of the hospitals, and are provided with cesspools, which are cleansed daily, and quick-lime put into them. They are not offensive if carefully kept, but they admit of improvement. 10, 11. Sheds supplied with tubs are provided for the men to wash in. Slipper baths are used as required for bathing the sick, but are neither sufficient or convenient for the purpose. 12. Washermen wash and dry the hospital linen apart from the hospital, and are sufficient. 13. The storage is sufficient and dry. 14. Iron bedsteads, which were long since recommended, are in use, but not universally. They are 6 ft. 5 in. by 2 ft. 8 in. by 1 ft. 6 in. Wooden cots are also used in the European hospital, and entirely in the native hospitals. They are 6 ft. 4 in. by 2 ft. 10 in. by 1 ft. 2 in., and are made of squared timber laced with cotton tape. The bedding is suitable, and consists of straw in bed-cases, with pillows of the same; sheets, blankets, and quilts according to season. Every bedstead should be of iron, the wooden ones harbouring vermin. 15. The kitchens which are near the hospital are open and well-aired rooms. The cooks are Portuguese, and the apparatus like that used in the regiments. In this respect the hospitals resemble private families, but the younger and inferior cooks, from being paid less, are found in hospitals. 16. Diet tables, diet rolls, &c., are transmitted. 17. A hospital serjeant is attached to every hospital for European troops, under orders of the medical officer; a matron and assistant matron being provided for the female hospital. There are 10 native ward boys, and when the sick exceed 80 in number one additional boy for every 8 patients, and one also, at the discretion of the surgeon, for every bedridden patient, and frequently a comrade in extreme cases. The attendance is sufficient in number but often inferior in kind, and embarrassment arises whenever there are fresh regiments or fresh ward boys; difficulty also from ignorance of the language. In native hospitals there is a hospital orderly, usually a havildar (serjeant), and the bedridden are attended by comrades, who obtain leave from duty for the purpose. 18. The new hospital is the only one which is adequate. The depôt hospital is not large enough, and one native hospital has been condemned more than once. The artillery hospital is good, but requires an upper story, and the general hospital is in want of many improvements. Phagedœna and gangrene have been witnessed, for which occasional crowding may perhaps account. Phlegmasia dolens has occurred, but not in hospital, and no case of pyœmia nor any epidemic originating in hospital have been seen. 19. Want of space is the great defect. Better adaptation of privies and baths, more open space in the walls for ventilation, and an experienced matron to superintend the cooking and distribution of diets in the wards would be most desirable. 20. There is no fenced ground with shaded walks and seats for the exercise of convalescents. They walk in the vicinity of the hospital or verandah, or go out in an ambulance cart in the evenings. 21. Separate hospitals for women and children are built near to the hospitals in European regiments, and are provided with matrons and assistant matrons and ward women. No such arrangements exist for native corps. The present arrangements are satisfactory for the Europeans. In every station for native troops a hospital for females with a maternity hospital ought to be established. 22. There are no local hospital regulations not included in the General Presidency Medical Regulations. 23. Matters appertaining to the sanitary state of hospitals, &c., are all presented in the regulations, and there is little latitude of action for the medical officer. His suggestions may be acted upon or not by higher authority. 24. There are no convalescent wards or hospitals, but when there are several wards one may be used for convalescents, but hospital rules in their integrity should be uniformly administered.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is one mile from and to leeward of the station. Its area is 600 square feet, the soil and subsoil are of clay, sand, gravel, and argillaceous earth. There is no drainage, but decomposition takes place quickly, and the ground is carefully kept. 3. The grave space allowed is, for adults 7 feet by 2 feet; for children 4 feet by 1 foot 6 inches, and the interval between each grave is 3 feet. Graves are 5 feet deep; they are never re-opened. Interment takes place at ordinary times from 12 to 24 hours after death, and during epidemics within 6 hours after decease. Mussulmans and the poorer classes and the lower castes of Hindoos bury their dead. Other classes of Hindoos burn them. Cremation and burial grounds are about 2 miles from the camp. The graves, which are never re-opened or used for more than one corpse, are deep but pretty close. The dead are quickly disposed of. There are no regulations on these points but the customs of the people.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead —*cont.*	4. The new burial ground has never been offensive, but in the old burial ground, now seldom used, quick-lime was occasionally resorted to. 5. The dead of camp followers and bazaar people are disposed of in the same manner as native soldiers. 6, 7. No injury accrues to the public health from the present practice, and no suggestions for improvement can be offered.

(Signed) H. Stiles, Colonel and President,

A. F. Cunynghame, Major-General, Commanding Sinde Division.

4th January 1861.

Appendix 1.

Field General Hospitals.

1. Whenever it may become necessary, in consequence of the increased number of sick and wounded men during war or distant campaigns, to have recourse to field general hospitals in fixed situations, one or more such hospitals are to be established accordingly, upon the general principles, in regard to supplies of medicines, diet, and necessaries, prescribed for regimental hospitals.

2. As soon as the officer commanding the troops shall have determined, in communication with the deputy inspector-general, on the place at which a field hospital is to be established, and the number of patients to be transferred to it from the regimental hospitals in camp, or for whom it might be advisable to prepare hospital accommodation and necessaries, instructions are to be forthwith issued to the commissariat for the immediate preparation and supply of all articles, including cots, for the sick and wounded, with the requisite establishment of hospital servants furnished by that department, according to the statements to be prepared by the inspector-general of hospitals, and sanctioned by the officer commanding the troops.

3. As the hospital establishments of European regiments, of which the sick and wounded are sent to field hospitals, may admit of being for a time diminished, as many servants and as much clothing and bedding shall accompany sick and wounded men sent from the hospitals as can, in the judgment of the deputy inspector-general, be spared, with reference to the present exigencies or prospective wants of such regimental hospitals.

4. The commander-in-chief, when with the army, will, in the same orders which direct the formation of one or more field hospitals, authorize the provision by the proper departments of all articles necessary for the purpose, and the entertaining of the requisite establishments. When the commander-in-chief is not present with the army, or a division of it, the officer commanding will issue orders to the above effect, under discretional authority, to be previously consigned to him.

5. Medicine indents are to be prepared by the surgeon or medical staff officer, who may be selected for the charge of a field hospital, under the instructions of the deputy inspector-general, by whom they are to be countersigned, for such supplies of those articles as may be deemed necessary, and can be spared from stores in camp in the first instance, until further supplies can be drawn from the stationary depôts, or the indents shall be made on the stationary depôts, in the event of its being practicable, in consequence of previous arrangement, for the first demands to be thence supplied in proper time.

6. Whenever the probable time and place at which it may become necessary to establish one or more general hospitals, for the reception of the sick and wounded during war, can be anticipated by the commander-in-chief, or the officer commanding the troops, the earliest intimation will be given to the commissariat and the nearest medical depôts, in order that the attention of officers in charge of those departments may be directed to the probable demands that will be made upon them, or according to the nature and probable duration of the service in prospect. Adequate supplies for one or more general hospitals will accompany the army in the first instance, or be intermediately brought forward to such advanced situations as may be found convenient.

7. The expense that may be incurred in furnishing petty stores, necessaries, &c., by the hospital storekeeper is to be charged in a contingent bill monthly, liable to be attested upon oath when required. These bills are to be countersigned by the surgeon or senior medical staff officer in charge of the hospitals in which the articles charged for shall have been expended (or for which they may have been provided, in the case of any remaining on hand at the end of each month), and also by the inspector-general of the division in testimony of their correctness, to the best of the knowledge and belief of these officers; statements, in the form of indents, which are to accompany the bills for payment, are also to be signed by the surgeon of the hospital, setting forth the several articles which have been required from time to time for the use of the sick and wounded.

8. An advance of cash will be made on this account, in the first instance, on the application of the surgeon or medical staff officer, who may be appointed to the charge of the hospital, to be made through the deputy inspector-general, and a sum equal to the amount required for the monthly disbursements is to be advanced by the paymaster, or the collector, where there may be no pay officer at hand, upon timely application being made by the hospital storekeeper, through the surgeon in charge of the hospital. The amount to be adjusted as usual in other cases of moneys being advanced by collectors on account of military disbursements.

9. A medical staff, consisting of a surgeon for the general charge and superintendence of the field general hospital, with a salary of Bombay rupees 600 per month, exclusive of the usual pay, batta, and tent allowance of his rank, with as many surgeons or assistant surgeons for the duties thereof as may be necessary, and can be spared, together with an assistant surgeon for the appointment of hospital storekeeper to the general hospital, will be appointed by the commander-in-chief, to whom a list of those most available shall be submitted by the medical board or by the deputy inspector-general, if those appointments be made immediately in the field; care being taken in all such cases not to remove from the charge or duties of regimental hospitals either the surgeon or assistants, to the prejudice of the management and requisite duties of those hospitals respectively; and to provide for this eventual arrangement and other calls for medical aid during war, a sufficient medical staff will always be appointed in the first instance, when practicable, to do duty with every considerable division of the army that may be ordered to take the field.

10. The assistant surgeon who may be appointed to act as hospital storekeeper to a general hospital shall invariably, in addition to that charge, afford such personal medical attendance to the sick as may be required of him by the surgeon in charge of the hospital.

11. An officer or other agent of the commissariat department will attend every field general hospital that may be thus established during war, as well for the purpose of furnishing and maintaining the requisite hospital equipments and diet for the sick, as for supplying provisions to the men who may be discharged from the hospital fit for duty until they shall rejoin their corps.

12. An apothecary and steward, with such other first-class servants as may be necessary, are to be appointed, on the recommendation of the deputy inspector-general, to each field general hospital that may be established during war; and such a number of second-class servants as he may deem proper shall be drawn from the commissariat for the same purpose.

13. The establishments that may be allowed for field general hospitals, as well as the establishments fixed for the medical depôts in the field, are to be mustered on the first of each month by deputy inspector-generals or the commanding officers on the spot, or officers properly authorized,

as the case may be, and regular muster rolls are to be prepared for all those establishments, and to be attested in the usual manner by the mustering officer, whoever he may be.

14. The pay of hospital servants employed in field general hospitals is to be drawn from the commissariat, and paid according to the rules prescribed on the subject for regimental hospitals.

15. An officer from each corps is always to be sent in charge of the sick, when they amount to 20 men, who may be sent from regiments or corps of Europeans to field general hospitals, and a sufficient number shall remain on that duty until it may be necessary to accompany the men when ordered to rejoin their corps.

16. Whenever men may be discharged from field general hospitals as no longer requiring medical attendance, yet in the opinion of the surgeon requiring some modification of their ordinary diet, rations of provisions, if Europeans, will be supplied to them by the commissariat, on provision rolls framed on this principle, to be presented daily by the commissioned or non-commissioned officers under whose charge they may be placed; and the provisions to be thus supplied may be made to vary from the articles usually issued to troops in health, according to the state of convalescence of men thus circumstanced, and for whom certificates are to be furnished by the medical staff who may have attended them in the field general hospital, describing the diet, &c. most proper for the men whilst in progress for their corps, according to which the provision rolls are to be prepared, and the certificates above mentioned are to be countersigned by the officer in charge of the men, and delivered as vouchers to the commissariat department, stoppages being made from the men on this account, agreeably to the regulations on this subject, when rations or messes are furnished for men not in hospital, or under such further regulations as circumstances may render expedient.

17. The regulations respecting hospital stoppages from Europeans, as detailed in section 5, are applicable to and are to be particularly attended to by the medical officers in charge of field general hospitals, and when men are discharged from them they are, as in regimental hospitals, to be furnished by them with the regulated certificates.

Arrangements in the Field before and after Action.

18. When the force to which a medical officer is attached is placed under circumstances rendering it likely that in the course of service it may be engaged with an enemy, the medical officer will arrange with the adjutant, or staff officer of his charge, for the attendance at the hospital or his own quarters of the band men, to the end that they may be by him instructed in the application of field tourniquets.

19. He will explain to them their use, mode of application, &c., and will satisfy himself that they are in so much fitted for the duties they may soon be employed in.

20. While the troops are moving on, medical officers will follow their respective corps with all the empty sick carriage, &c., but as soon as they deploy, or form for action, all, excepting one medical officer for each brigade or body of equal strength, will move a short distance in the rear, out of the range of musketry, and will there make their preparations for succouring the wounded, and performing any operations that may be then necessary; cordials, &c. should be at hand, and all instruments and dressings, &c. ready to be used.

21. In the rear of each brigade and within range of musketry, one medical officer (in general, an assistant surgeon and the junior present) will, as above stated, be stationed for the purpose of checking any alarming hemorrhage, and expediting the removal of wounded men to the stations in the rear.

22. For this purpose the doolies and other sick carriage will be placed under his orders, and the band men and others will assist the wounded from the ranks to the place where the medical officer is stationed, and from thence into the doolies.

23. To all the band men and others employed in this duty field tourniquets should, previous to the action, have been issued. No men are to be allowed to go into doolies who can possibly walk to the rear.

24. The surgeons or medical officers of regiments are, as has been stated, to be stationed at a short distance in the rear, but out of the range of musketry, and there the wounded will be dressed, and all cases requiring immediate operations be attended to; at these posts bheesties with water will be placed, and from thence all men sent to field general hospitals will be despatched.

25. These posts are to be in as sheltered situations as possible, and if not very easily seen, to be distinguished by some flag or other conspicuous object.

26. If any town or village be situated in the rear not far from the scene of action, in which there are houses or buildings calculated to receive wounded men, straw, &c. for bedding, and abundance of water, &c., should be provided and kept in readiness for them, and to this at least all those severely wounded ought to be removed.

Removing Sick or Wounded to the Rear or to Field General Hospitals.

27. The quantity of carriage rendered disposable by the consumption of stores of every kind is invariably to be notified to the deputy inspector-general, or medical officer performing his duty with the force, or in their absence to the medical officers with corps, to the end that it may be taken advantage of in the transport of sick or weakly men; and in the same manner when carriage so rendered disposable is sent to the rear, it ought to be employed in the conveyance of men to field general hospitals.

28. By taking advantage of these opportunities the force can be easily disencumbered of its chronic cases.

29. To enable deputy inspectors-general and medical officers to perform this part of their duty without inconvenience, the place of destination, with notice of the exact day and hour when such carriage is to proceed to the rear, ought to be intimated to medical officers.

30. In addition to those means of moving sick to the rear, or at times when these do not exist, advantage must be taken,—

1st. Of the doolies and sick carriage belonging to their charge.

2nd. Of transport belonging to the country.

31. When it can possibly be avoided, the first ought never to be detached, unless for short distances, or excepting when stores of some description, such as medicines, instruments, &c., are to be brought up from the rear; and in both these cases the most positive directions should be given for its immediate return.

32. The transport of the country should be divided into classes, as doolies, cots, &c., for those unable to ride or go in carts, &c., and carts, bullocks, &c., for the slighter classes.

33. Medical officers must always, in person, class off their sick, and apportion the different modes of conveyance for individuals.

34. When water carriage is to be had, it is incumbent on the medical officers to ascertain whether the boats are decked, open, or capable of being protected by awnings, and the cases should be allotted to them according to their condition.

35. Regimental surgeons should be directed to take advantage of every opportunity which offers for sending to the rear their chronic cases. Acute cases should be kept as long as possible with their regiments, or at least so long as there remain any symptoms to subdue.

36. No case should be sent to the rear for reception into field general hospitals which can be conveniently treated in the regimental hospital, with the probability of the soldier soon being made effective.

37. All convoys of sick sent to the rear should, according to their magnitude and the importance of the cases sent, be accompanied either by a medical officer or subordinate medical servant.

38. They ought to move at proper hours and by such routes as may have been laid down for them.

39. Care should be taken that every sick soldier sent to the rear has his blanket, watch cloak, warm clothing, and knapsack with him.

40. In case a subordinate medical servant only be attached to the convoy, he is to report himself to any medical officer that may pass him on the march, and in any case of difficulty is to request the assistance and advice of any medical officer who may be within reach.

41. The medical officer into whose charge the subordinate medical servant will deliver the men is to report the state in which they were received, with any casualties that may have occurred on the way.

42. During any halt of the convoy the clothes and bandages, &c. of the men ought to be well washed and aired, &c., and the persons of the men themselves should be made as clean as circumstances will permit.

First Assistant		1
Second Assistant		1
Apprentices		2
2nd Class.		
Sweepers		2
Bheesties		2
Goorgah		1
Cook		1
Dhobie		1
Dooly bearers		5
One Dooly to	20	100
One Spring Cart to	100	500

Doolies are intended for the worst cases, spring carts for those not so seriously ill or wounded.

An additional dooley and spring cart are allowed when the strength exceeds by more than one-half that entitling to one of each.

Doolies and spring carts are supplied by the ordnance department on indent; dooly bearers, all other sick carriage, and carriage for hospital stores are furnished by the commissariat department on indent.

Separate indents are required for carriage for the sick, as dooley bearers, &c., and for carriage for hospital stores, &c.

Commanding officers can indent on the commissariat for extra sick carriage to the extent of five per cent. of strength, without special sanction of the commander-in-chief. Indents in duplicate must specify the nature of the sick carriage, its necessity under certificate of medical officer, period for which required, &c., countersigned by the deputy inspector-general; and if no commissariat at hand, by obtaining the necessary carriage otherwise and charging for the same by contingent bill.

Appendix 2.

From D. Grierson, M.D., Surgeon Major, Staff Surgeon to the President of Committee on Questions of Royal Sanitary Commission.

Sir,

I have the honour to request of you the favour to transmit along with the information furnished by the Committee the following observations, made on my part in accordance with the permission granted in the last paragraph of the instructions issued for the guidance of the Committee.

2. Were this the first time I had turned my mind to the considerations about to be entered on, I should think it presumption to submit them now. The case is different; and as with me the subjects have both a history and a special character, I shall proceed to deal with them in a chronological order, as well as in an expository method.

3. The subjects I wish to speak of are intemperance, prostitution, accommodation for troops, and medical police.

4. From October 1832 till July 1835 I served in the Indian Navy, and observed facts connected with the issue of spirits to the men which led me to submit a statement on that and other subjects to the Superintendent of the Indian Navy, then Sir Charles Malcolm, and to urge a diminished supply. The reply was, "In every part of your "arrangement regarding the allowance of spirits, the super- "intendent fully concurs, and it is very satisfactory to him "to have so many proofs adduced as you have done in "favour of a reduced quantity." In the year 1838, in connexion with a detachment of Her Majesty's 40th regiment, the subject was again forced on my notice, but without practical result. In regard, however, to the canteen system, and especially that part of it which provides for the accumulation of profits by the sale of spirits, and the expenditure of these profits for what were called charitable objects, the note I made of it was, "Thus, by a most sin- "gular arrangement, the very vice of the soldier is made to "provide for him in the day of his misfortune, and he is "tempted, under the delusion that what he spends is not "all lost, or at least benefits others, to part with his money, "ruin his health, and acquire those habits which may ren- "der him a torment to others or effect his own destruc- "tion." Since those days indirect ways have been taken to diminish the taste for spirits and the use of them. It was, indeed, before that time, namely, in the year 1830, that spirits, as part of the soldier's ration, had been abolished; but in 1847 the introduction of porter and beer was intended to promote the same object. Coffee shops are strictly enjoined by the canteen regulations, and regimental libraries have been established, and have been justly thought to conduce to the same result; and to these means, and in the same category, are to be added ball alleys, skittle courts, and work shops. While these indirect methods have been tried, it would seem as if it were not generally known, to judge by one of the questions put by the Commissioners, that the more direct voluntary plan of temperance societies had been discouraged and suppressed in the army. This was done many years ago, and in consequence no means at present exist to enable any one to supply a comparison of the ratio of sickness in abstainers and among those who use spirits. But comparisons of this kind were made in former years, and it may be well to produce one of them. The following statement is taken from the *British and Foreign Medical Review*:—"A temperance society was established "in the Cameronian regiment in 1837 at Fort William. "The surgeon, Mr. Bell, reports most favourably of the "results. The admissions into the hospital were, of the "society, 1 in 25, of the rest of the regiment 1 in 11. The "deaths in the regimental hospital were, in 1837, 26, and "in 1838, 22; whereas for 14 years previously the mortality "had been nearly 72 per annum. The consumption of "spirits has diminished from 14,000 gallons (which was "the amount consumed on the arrival of the regiment in "India) to 2,516 gallons. Liver complaint has diminished "from 111, 140, and 135, as in 1832, 1833, and 1834, to 82 "and 50 in 1837 and 1838. It also appears that by tem- "perance two-thirds of the sickness has been removed."—Ed. *M. Jour. of Med. Science*, No. VI., June 1, 1841.

To this exhibition of facts, the result of abstinence, it is impossible to add force; neither can one forbear to deplore that so promising a movement was nipped in the bud. This is not the place to offer many remarks; yet it is desirable to allude to other changes. It was thought a very great and beneficial advance when in 1830 Lord Hardinge, then Sir H. Hardinge, abolished the spirit ration; and this merited the commendations it received when spoken of as an act of wisdom and courage. Perhaps but for this other measures would have followed more slowly. Be this as it may, in 1837 good-conduct pay became an institution; in 1844 savings' banks; in the year 1846 flogging was limited to 50 lashes as a maximum; and in the following year the sale of spirits, as distinguished from the issue, was put a stop to in canteens; service on enlistment was limited to 10 years; and regimental schools were introduced.

A century and a half ago, that soldiers were a body of men distinct from the body of the people, governed by different laws, whose only principle was blind obedience, and that they could not be made obedient to the allurements of rewards, as coercion, generally speaking, is the surest principle of all vulgar obedience, were approved maxims; and at a much later period it was publicly stated that "the "worst men were the best soldiers." The changes above alluded to are evidences that the ancient prejudices and practices of an evil day are gone for ever; but the question is, what effect have these changes had on the habits of the soldiers as regards drinking? It may be conceded at once that they have been beneficial; that they have not gone far

KURRACHEE. BOMBAY.

enough there is reason to believe. I take up a medical journal published last year, and I find that in one regiment three canteen serjeants perished of *delirium tremens* in 18 months. The surgeon remarks, "The canteen serjeantcy "seems to be allotted as a kind of reward to the steadiest "and best men of the longest service, whose previous good "conduct, however, seems literally unequal to the great "temptation of a free access to liquor." This reminds one of the maxim, *Nemo mortalium unquam fuit repente turpissimus.* I have seen within three years one soldier brought to hospital a corpse who, drunk, a prisoner, and being taken to the guard-room, tried to escape, and was killed on the spot by one of the guard, who threw his bayonet at him; and I saw another who had just been killed by a drunken antagonist, with whom he had retired from the barracks to end a brawl by fighting. Within the same time, in one year, I treated for *delirium tremens* 10 men in a company of artillery of about 100 strong. The staff hospital receives the warrant officers of the arsenal, commissariat, and brigade-major's establishment, the men of which departments, it is believed, may be considered the picked men of the service; yet from amongst them, a small class, in the last four years there have been 9 admissions for *delirium tremens*, and one of these members of this class perished in this horrible disease. In mentioning these men, I have chosen, as a proof of drunkenness, extreme cases; but this procedure, the only tangible one, is open to no objection, for every case of *delirium tremens* represents, besides a deplorable individual instance, an undefined but certain amount of drunkenness—it may be 10, 50, or 100 to 1. Proofs, however, are scarcely needed, for I suppose no one conversant with the subject will deny that the great majority of military crimes owe their origin to the love of drink or the consequences of indulgence in it.

It remains to inquire if anything can be done to lessen intemperance. The preceding narrative points out temperance societies as an efficient beneficial agency, and these ought to be encouraged. Men are influenced by example. Example derives force from numbers. A society developes this force and displays it, and is a quiet antagonist of drunkenness and a protest against it; it is a rallying point, and will always attract some to support the cause it represents, from amongst those who esteem it more noble to overcome evil with good than to be overcome by it, and better to assume an attitude of opposition to this special evil than to be indifferent. Instruction, amusement, and occupations are all subsidiary means of raising the character of the men, and enabling them to despise debasing pleasures and resist seductive habits; and it ought to be be received as a maxim that when any one is addicted to vice, unless a feeling of opposition to it be raised in the man's own mind, prevention will only stimulate ingenuity, and punishment suggest greater caution in the means and measure of indulgence; but the eradication of drunkenness from the army depends not on desultory indirect efforts. It must be the result of a system; such a system, it is conceived, is possible, and has nothing of an active or aggressive character about it; it has rather a negative character. Its chief feature is to let the men alone, and if evils arise from this inaction, then it would be required to deal with them as evils. The present system is erroneous and inconsistent, to say nothing of lacs of rupees lost in condemned porter, or of the 5,000*l.* per annum paid simply for coverings of mat to protect the transport boats on the Indus, to say nothing of the impracticable nature of the present plan in time of war, or the huge monopoly. Spirits were at first allowed to soldiers on the wrong principle, that the addition of spirits improves the quality of the water when bad, or makes it innoxious when hurtful, and what was granted at first as a bounty was soon claimed as a right. There is neither room now for the illusion nor ground for the claim of right, and what is wanted is that the State cease to be a great hotel keeper, and abandon all those allurements to their customers, such as charitable donations out of the canteen fund, the provision of balls, quoits, and other necessaries for games and amusements, supplied from the same source, which throw a covering over the nakedness of the system, and impart to it an interest not rightly belonging to it. Until this is done there is an inevitable inconsistency in the fact that Government supply, as every one must allow, daily opportunities and means of drinking to the soldier, and, as most think, really train him in many instances to become a drunkard, and then punish him when his passions, habits, and infirmities lay him open to faults and negligences, or stimulate him to more active crimes. Let Government abolish the canteen, and stand aloof from the provision and sale of liquor, and then the officers of Government can come in contact with offenders, not only without embarrassment, but deal with them strengthened by the awe inspired by a just and venerable authority. In this case in all its functions Government would be in direct opposition to drinking habits, as well as the evils they lead to. The contrary is exemplified now. Liquor paid for by the soldiers is provided by Government, and though paid for by the soldier, yet access to it is a privilege, the privation of access a punishment; and by restrictions and indulgencies, multifarious interferences, minute and misspent care, a fictitious interest is created in what ought to be left to stand simply in its own nakedness and ill desert. Not only in dealing with crime does the present system lead to embarrassment, a prior charge lies against it, as it affects moral responsibility. When drink is provided by Government, when peculiar advantages are procured to the soldiers by the profits of drink, human nature were no more human nature if drinking, accompanied with so many adventitious recommendations, were not the rule in a regiment, and if example, so highly commended and sanctioned, did not beget an imperious fashion, and lead young and old, with exceptions no doubt, captive at her will. In this state of things young soldiers are scarcely left free, especially after the punishment like privation of liquor, while at drill, and surrounded by influences, all of which appeal to them in behalf of the practice, it is no wonder if the soldier soon learns to drink, and falls a prey to a habit which soon gets beyond control. To redress evils of this kind once fostered is impossible; to prevent them for the future demands, and is worthy of, the greatest solicitude, and the means to accomplish this end, as before stated, seems to me to be that the Government stand aloof, that no dazzling halo be cast around drinking practices, and no sanction be lent to what is too often a commencement of moral delinquency, and what must be often dealt with in its results as a crime; besides, when the soldier has neither sanction nor facility for drinking provided, he is fairly and honourably cast on his own responsibilty, his interests are in his own keeping, he is dealt with as a man, not a pupil; his noble instincts are appealed to, he yields to the appeal, and instead of a descent of progressive debasement, he enters on a course of progressive amelioration. The result of this negative action on the part of the Government will immeasurably benefit the soldier, add strength to the army, shed lustre on a wise administration, and remove a national reproach.

As there is always a presumption in favour of established usages, so no innovation upon them can be proposed that is not met by objections. Possibly some may yet urge that alcohol gives strength and adds to productive energy; some less probably may say that alcohol protects from diseases to which soldiers are exposed, especially fevers. These were once favourite arguments, but if pressed by the fact of ill consequences resulting from drinking, the advocate of alcohol would profess to obviate them by proposing the dilution of spirits, or substitution of beer and porter for spirits. But as these measures have been tried and drunkenness yet exists, the great, if not only argument, now is that the canteen secures good liquor, and if done away with the men would resort to shops or taverns where bad liquor would be procured and the health of the men injured. The reply to this is the difference implied in the terms good and bad, when used in respect to liquor, is not what the words themselves signify. It is a difference not of contrast but comparison, not of kind but degree. Whatever change would follow, therefore, in regard to liquor, is one not absolute but limited, both in the quantity of liquor and in the effects produced by it. It may next be observed that soldiers do not use bad liquor rather than good as a matter of taste. They use what is cheap and easily procured. A monopoly, if it secures a good commodity, compels unscrupulous men to seek hazardous and precarious gain by illicit and spurious substitutes. Competition, by bringing the good commodity to a lower level, cuts up the root of the illicit traffic, and the measure proposed, therefore, contains, in itself, the remedy for the evils alleged as likely to follow it, or rather will prevent the occurrence of them. But again, the objection has no force, for this reason, crimes and disease exist already in the regiments; either, therefore, these evils originate in the canteen or they do not; if they do, it is a reason to abolish them; if they do not, they arise from sources beyond the limits of the regiments, and if so, and this will hardly be denied by any one, then the very evil dreaded exists already. Illicit liquor is procured by illicit means, and the health of the men injured by spirits used beyond the prescribed degree. The objector then must show, not that men would get bad liquor, but that they would get it worse or in greater quantity than they do now, but this he cannot show; on the contrary, it has been rendered evident that were the canteen abolished, the evil would be diminished or cease.

The conclusion come to then is, that the canteen should be abolished, men left free to drink or not as they choose, the military crime of drunkenness discouraged, and, if need be, punished, and drunkards, if they be found under the new system, weeded out of the army.

Prostitution.

In the letter before alluded to, addressed to Sir Charles Malcolm, attention was directed to a practice which had long existed in the Indian navy. What I mean is the countenance of prostitution. When a ship was in harbour boats might be seen in the evening lying near full of prostitutes, when, at a given signal, permission being granted to come alongside, the sailors might then be seen rushing to the boats, each to select his partner for the night, as a butcher might be imagined to select fat lambs from a flock. This fact is valuable as an indication of public opinion, but I mention it to the credit of Sir Charles Malcolm, that a system so abhorrent to right feeling, and so prejudicial in many ways, was no sooner thus officially brought under his notice than it was abolished.

Again, about the year 1840–41, being then a regimental assistant surgeon, I pointed out the evils resulting from the residence of prostitutes in bazaars, the suffering to individuals induced by it, the loss to the State, and the advantages that would result from their expulsion. My representations, I believe, never reached head-quarters, but were met by the military authority, and resented as an interference with what did not concern me, and by the medical, as being a matter with which it was not felt there was any call to meddle. It was but three or four years before this that the lock hospitals, so called, had been abolished by order of Government, at the instance urgently repeated of the Bishop of Bombay, and supported by the strong arguments of the then Metropolitan of India. Regret was very generally felt and often expressed at this abolition; hence the indifference or hostility with which any further step was encountered.

It was not till lately, about two and a half years ago, that I felt again disposed to take up or justified in referring to this matter in an official manner. In an evil hour, and in ignorance apparently of what had been done in former times, in the extinction of *Lal Bazaars*, and of the late orders of Lord F. Fitzclarence, it was resolved to institute what was called a venereal dispensary at Kurrachee. I will not relate the history of this short-lived institution. It is my object rather briefly to show the objections I entertained and urged against it. It was pointed out that for 500 years at least the law of England regarded the prostitute as a criminal, that this was also the law of India, by the enactments of its Supreme Council, and that it was the law of the military bazaars of the Bombay Presidency; that the object of legislation has uniformly been not the regulation of an admitted evil, or the protection in any way of those who favour or commit it, but the punishment of the offenders and the suppression of the crime. It was shown that Christianity condemned prostitution, and the remonstrances of Bishop Carr and of Bishop Wilson were quoted which they urged against lock hospitals. It was then added, what is rooted in religion and embodied in law must also be seated in human nature, unless indeed the first be fictitious, and the second usurp a power and an office where neither are rightfully due. But this conclusion cannot be drawn in this instance; for so long as modesty, integrity, self-restraint, honour, chastity, are reputable qualities of the individual, commendable and excellent, so long must it of necessity be that the dissolute, those abandoned to the sway of one of the basest passions, the sexual appetite, shall be held as evil-doers, corrupt and corrupters by practice and example, enemies to social well-being, fallen or who ought to fall from the privileges, protection, and enjoyments of society. It is the voice of reason and of nature, that if we would cherish whatever is loveliest and dearest in our estimate of human character, we must set the stamp of reprobation on all that tends to diminish its production, to render precarious its continuance, to impair its lustre, or to annihilate its existence. Nature, religion, and law, then, all concur in visiting the prostitute with their peculiar penalties—moral, spiritual, and legal, and heavy is the responsibility of those who lightly set them aside. To do so, in truth, is to take the opposite view altogether, for if we once depart from the wholesome principle of viewing the prostitute as a criminal and as a violater of moral law, what little soever notice we bestow, it is countenance bestowed; and how little soever we regulate her affairs, it is protection and reward.

But it might be objected,—it is not reasonable to deny the woman aid in her distress, any more than to forbid assistance to be given in any case where the imprudence of the sufferer has been the occasion of his malady. To this it is replied, all sufferers from disease, though themselves the cause of it, address an irresistible claim to the sympathy and aid of the physician. On this there is, there can be, no dispute. Patients suffering from *delirium tremens* are cared for with the greatest solicitude; and so are women labouring under venereal disease, nor is less done for the greatest of all criminals, the man who with sacrilegious hands has violated in his own person the sanctuary of life. But no rational man can fail to have some respect to the consequences of his acts, and in the instances advanced, or any other of the like kind, when a comparison is instituted, it is easy to see that a special peculiarity attaches to the case of the unfortunate female. In other instances, the victims of self-inflicted disease, when restored to health, are thrown upon their own responsibility. The health and improved condition they have gained form no necessary preparation for the unavoidable issue of renewed vicious indulgence. The lesson which teaches the connexion of vice and suffering has been brought home to personal experience; on this may be grounded an exhortation and appeal to a mind consciously awakened to see the nearness and magnitude of a danger hitherto little appreciated; and the conviction which springs from these truths is happily found to be not always unavailing. But the restoration to health of the female is the very condition of the resumption of her nefarious occupation, and, qualified again as she is to this resumption, her necessities impel her. She may feel the sense of responsibility keenly, may weep over the past experience of her sorrows, may shudder at the prospect the future offers to her; but we have qualified her to tread the path she trod before, taken from her the provision she got before, and that thorny path she must tread again. Now to warn, exhort, dissuade from evil in such circumstances, if that be all we do, is little better than hypocrisy, and means little else than reproach. And we see ourselves reduced to this extremity, that either we must act in a way outrageous to humane feeling, or, by our silence, though accompanied with inexpressible pain, seem to countenance a course which we abhor.

It may be worth while to illustrate this point by way of analogy. Those who suffer injuries in following occupations and trades are humanely cared for, and treated at public expense or by private bounty. When the endeavour fails to restore a useful member of society to his place and functions, a debt is paid to the unfortunate, and compassionate feeling is satisfied. If the result be more fortunate, a benefit is conferred in the restoration of a useful member to society. Suppose, however, a society of mistaken philanthropists followed an army to cure the wounded of the enemy, and restore them to their friends again, to fight against the country of their benefactors, this conduct would be absurd, and the humanity of it would be lost sight of, in the contempt and scorn, or direct opposition which would be turned against so unwise and unpatriotic a procedure. Or again, imagine a state of civil disorganization where thieves and burglars should often meet in conflict a feeble police, and where wounds and severe injuries were frequent. Imagine, further, that a benevolent society were constituted to shelter, provide for, and cure these lawless combatants, and when cured to dismiss them to pursue their disorderly life, would not the act of humanity be forgotten in the indignation felt against those who evaded the law, harboured, aided, and encouraged the disturbers of the peace, the enemies of the public safety? But these fictitious cases are similar in principle to the institution which should simply take charge of the prostitute when unable to follow her unlawful occupation, feed, clothe, shelter, cure her, and then, as soon as fit to resume them, dismiss her to fall again upon her evil practices. Hence the conclusion seems just and reasonable, let there be simply a dispensary or hospital opened, provided with necessaries and the requisite attendants for the reception and cure of women who live by prostitution, and become diseased by following this mode of life, where shelter, care, and cure are all gratuitous, and the condition of obtaining the advantage of them is the attendance or residence of the applicant; let the plan be as remote from the continental system of Europe, registration, domiciliary visits, compulsory inspection, and medication, as possible, and as consistent with the liberty of the subject and the protection afforded by law as can be desired; still there attaches to the modified scheme a character, the vices of which exclude it from the category of legal institutions, and bid away from it the cold approval the moralist and philanthropist would feel disposed at first sight to bestow upon it.

But it is not alone by an appeal to fictitious analogies, or by the assertion of undeniable principles, that we reach this conclusion. Tried by practical application, the institution and the associations it provokes challenges only reprobation. This point was put forward in reference to the establishment set on foot at this place, and I desire it should be pointedly mentioned, that nothing has appeared in public to tend to the belief that, though the establishment at Kurrachee was abolished, yet similar establishments do not exist at Poona and Belgaum to this hour. The remarks to be repeated here, therefore, have a living interest at this moment. Were it otherwise, yet their repetition

is desirable, for it seems as if most minds never contemplated any other means of abating the evils of the venereal disease amongst troops except the establishment of lock hospitals, and the proposal is continually coming to view, put forward, it is believed, by men who not only know nothing better, but have never heard of any other plan or possibility of dealing with an admitted evil, a detriment, and reproach. Speaking in regard to the establishment of a venereal dispensary at this place, it was said, these things are done, not in accordance with any known law, but in opposition to it. Women of disreputable character the law enjoins should be expelled from cantonments; but this is not done. They are countenanced and permitted to remain. When sick, they are lodged, fed, and receive care and medicine at the public expense, as if they were valuable members of the community, or servants of the State. And what a contrast do the industrious and decent inhabitants, as respects their treatment or the neglect of their necessities, afford! It was proposed to take their school from them for the accommodation of their vicious neighbours. When sick, what care do they receive? A few applicants and an occasional inmate, of the female sex, are seen at the general hospital; but let returns of all the hospitals in Sinde be called for, excepting at the same time the patients in jail, and perhaps not half-a-dozen will be found. Again, I have attended, in the dwellings of the native poor, women in child-birth, some of whom I am certain, as one can be in such matters, but for help must have died, and some of whom earlier relief would have saved from death; but who ever heard in the provinces, and only lately at the presidency, of a maternity hospital, an institution than which few could be more desirable, and none bear a higher stamp of Christian philanthropy? In plain terms, and this statement in its general extent cannot be denied, the vicious, whom law, religion, and morality condemn, receive indulgence, protection, and support in their necessities from the public money, while the honest, industrious, respectable, however necessitous, are not thought of, or viewed with unconcern, apathy, or contempt.

If we inquire what effects such a practice is likely to have on the minds of others, we shall find it far from salutary. The woman is encouraged and confirmed in her evil courses. The soldiers are countenanced in crime; and if they contract disease will be apt enough to reproach the Government which has held out a false hope of immunity. Decent inhabitants cannot but be perplexed, when they think that a Government, which in principle approves of honesty and industry, should yet make its especial favourites the impure, the corrupt, the disorderly; and in their bewilderment they will probably lose what little hold on their confidence and affection, as nature and duty teach them, the rulers of the country are entitled to and enjoy. Nor is it impossible that the parents of Christian youth in the cantonments look with dread on an establishment where the modesty of tender years may be endangered and vicious habits contracted under sanction of authority.

But as respects the soldier, who rejoices not in his improved condition of late years? Who is there who sympathizes not with every regulation directed to his elevation and well-being as a man and as a Christian? And not a little has been done, and with no little effect in late years. The schools in regiments, the Ten Years' Enlistment Bill, good-conduct badges and pay, all indicate the same purport, and tend to realize the same desirable result. All address themselves to his capabilities of improvement and moral elevation, and all are intended, by bettering the condition of the soldier, to raise the character of the service, facilitate the supply of men to constitute an armed force, and to make that force when constituted more valuable and efficient. Now the institution under review is not in harmony with these regulations and usages. It does not facilitate their action, but is opposed to them and detrimental. The dissolute soldier, the man under the tyranny of lust, is the discontented, needy, dishonest, drunken, untruthful, quarrelsome, disobedient, and negligent soldier; and this institution is designed for men like these, or will make men like these. The good can have no benefit by it. Their concern with it is to deplore its existence, and regard it with alarm and abborrence. It is therefore the antagonist of the school, the church, the reading room, the playground, and every thing which is brought into use or may be brought into use to make the soldier an instructed, a contented, and a happier man. I can conceive the incredulity with which those who best love the soldier, and most earnestly, consistently, and successfully seek his amelioration, would hear of an institution like this being organized in these times (May 1858), and at this time of day; but I cannot conceive the horror with which many would receive the evidences of its existence.

If it should be asked, how then deal with the offenders in the bazaars of this class? The answer is, as the law directs. Expulsion is that law. If it be objected that this is cruel, that evils will follow it, as well might it in any case be said that justice is cruel, or the law tyranny. Execution of the law occasions distress, gives rise to evils; but execution is not a daily office, and it is enforced that greater distress and greater evils may be anticipated. And as for evils to come, the fallacy is easily exposed. We must not do evil that good may come is an admitted truth; as we must not do good lest evil may arise is an oft-enacted fallacy. The good in the latter case is positive, the evil only contingent, and if the evil comes, for every wrong and for every evil there is a remedy. The course therefore is plainly marked, and if we believe in a moral governor of this world who delights in goodness, we cannot refuse to acknowledge that in this very faith he has given us ample encouragement to prosecute what is good, and just reason to think that he will favour the good and set his face against all that is evil.

It has been already shown how repugnant this establishment is to law, religion, and morals, and it is not meant to recur to that view of the subject. But to cut off all objections, if there must be an institution for the care of prostitutes, it is desirable to indicate the principles on which it might be legally founded and honourably conducted. Examples of institutions of this kind are seen in Great Britain and Ireland, and the great Scott, the commentator, was chaplain of the London Lock Hospital. These institutions are signalized by the aspect of reform of character as much as by that of punishment. The law does not forego its claim to deal with prostitutes as criminals, but religion steps in and deals with them, and tries to make them penitents. By the various names of Magdalene asylums, lock hospitals, penitentiaries, and such like, these houses of correction are known, and the objects common to all are by sobriety, cleanliness, and medical assistance, by a regular series of labour, by solitary confinement during the intervals of work, and by religious instruction, to preserve and amend the health of the offenders, to inure them to habits of industry, to guard them from pernicious company, to accustom them to reflection, and to teach them the principles and practice of moral and social duty. Institutions like these are within the bounds of law, are approved by reason, and sanctioned by religion. Institutions with attributes like these are schools or churches, as well as jails. But to aggregate prostitutes in a public building and give them public support where no such attributes hallow the scene, is to constitute neither a church nor a school nor a jail, but a brothel.

Another letter by way of supplement was afterwards forwarded. In this I took occasion to quote the recorded opinions, or, in one instance, oral testimony, of Lord F. Fitzclarence, Sir Bartle Frere, General Jacob, Colonel Edwardes, and Sir John Lawrence on the subject in question, and this weight of authority was thrown into the scale which bore the condemnation of the lock hospital system. Lord F. Fitzclarence, through the Adjutant-General, announces his views thus:—"I am directed to intimate that after "giving the whole subject his best attention, his Excellency "concurs with his predecessors in command of the army, "that police measures for preventing the infection of the "soldiers with the venereal disease cannot be carried further "than therein ordered (this alludes to orders for expulsion) "without involving the certain degradation and oppression "of many women of respectable character, and occasioning "other evils which in his Lordship's opinion would be "much greater than that which it is the object to remedy." General Jacob, amongst other remarks, makes the following:—"I would not interfere with these women in any way, "and although it might be good policy to provide dispen-"saries or hospitals, to which such persons might resort if "they chose, there should be none specially set apart for "them. The proper and only wise method of reducing "this disease is to improve the condition, the state of moral "being of those who resort to these women. Coercion of "every kind always increases these evils. Moral forces "alone are of any value." He adds, speaking of the Sinde horsemen, the elder, graver, and better part of the soldiers, seven-eighths of the whole number probably have their families here, and do not resort to public women, except when they employ them at nauches, &c. &c. Colonel Edwardes and Sir John Lawrence both concur in the propriety of expulsion of prostitutes, and signalize the restriction on marriage amongst the English troops as a great evil and hardship, and assert that married men are the better soldiers, and women and children no impediment in time of service, as they are left in cantonments.

To this weight of authority, it was said, I would add one or two facts. The 4th company of reserve artillery at present stationed here (1858) I have had charge of for 14 months, and the strength, inclusive of men attached from other companies at Hydrabad and Shikarpoor, has been the

average of 107 men per mensem. Of primary cases of venereal affection there have been treated 13, which by calculation gives for 1,000 men per mensem for one year 111 cases. I have had charge also of the depôt 1st Fusiliers for nearly 19 months. Of these months I omit the first, as it represents the whole regiment not the depôt. The strength for these months is 95, as in that time about 150 recruits passed through. The primary venereal affections in these 18 months are 20, which by calculation would give per 1,000 per mensem in the year, cases, 140. The mean of the Artillery and Fusiliers is 125, which divided by 12 for 12 months gives an average of admissions per mensem in a European regiment 1,000 strong of $10\frac{1}{2}$ nearly. I served for five years with a native regiment, the 1st Grenadiers, an abstract of the return of which I have now before me. The strength was 781 per annum, the number of primary venereal affections amongst the privates (there was not one amongst the native regimental officers) was 77, the annual average was therefore 15. This by calculation for 1,000 gives admissions 19 per annum, and per mensem $1\frac{7}{12}$. When we compare, therefore, the condition of a European regiment and of a native regiment in this matter of venereal infection, the native regiment appears to a greater advantage, by five times over, than the European. And it will be extremely difficult to find any satisfactory explanation of this deplorable fact, other than that in the European regiment marriage is restricted and widows unkindly used; whereas in the native regiment marriage is free, and the native soldier's family generously treated.

It was already stated that these representations were followed by the destruction of the ill-featured institution which was set up here. But whether its congeners at Poona and Belgaum shared the same fate has never, I believe, been made public. If these exist the reasons urged are as applicable to them as they were in the instance which gave rise to them. But the subject would be imperfect indeed if we stopped here. The system is called for, it is not said wisely called for, because of the deep pervading power of the sexual passion, and the evils which arise from its promiscuous indulgence. Now the wisest law that ever was promulgated on this subject, the only one which deals a deadly blow at the heart of the vicious and debasing crime in question, is the simple one, "Let every man have his "own wife, and every woman her own husband." How complex, how difficult, how unavailing all other legislation on the subject except this, and this how plain, how obvious, how admirable! This law, however, has been set aside; there has been wailing in families, and immorality in public places, because this law has been set aside. The British public though late, has recognized the fact, and sympathises with those who are sufferers by it. The Government will not overstep public feeling, but concentrate its action, and gain merited applause if it lends ear to a law which should never have been violated. But the marriage of the soldier will entail additional expense on the public. If it be so, and this may on a comprehensive view be doubted, let the public know why, and it will not complain. Besides, does any one think that the pay of the soldier is ever to continue at the venerable 13 pence a day? Sir Archibald Alison has publicly stated his opinion that the soldier's pay ought to be 20 pence a day. With changed times, is everything to change but the soldier, his pay, his prospects, his happiness? I conclude then that these two principles of the repression not recognition of prostitution, and of the permission not restriction of marriage amongst the European soldiers in India, indicate clearly what is needed in the way of Christian and public duty, and what is best for the elevation of the soldier, as respects morality, health, happiness, and efficiency for the public service. And I add my conviction that this, the true remedy, bounty to soldier, not the prostitute, will, whenever applied, declare itself in its simplicity, perfect propriety, efficiency for the end desired, and the many priceless advantages it will bring in its train.

Accommodation.

In the year 1851 it occurred to me to be engaged in conjunction with others, one of them the Superintending Engineer of the province, in devising the plan of a lunatic asylum for Kurrachee. It then appeared how vague were existing opinions on the subject of space in buildings, and how little information was available from any source to satisfy the inquirer. The subject occupied attention. Sir Charles Napier had wisely insisted on having hospitals and barracks greatly larger than those heretofore in use; but the principle, or rate, to guide to the determination of what the actual space should be, was not to be found. Sir Charles particularly desired height, and had no better reason to assign for the preference than that the doctors would no longer be able to stuff their patients into the corners of the hospitals. This was sometimes jocularly, or perhaps seriously, met by the statement, that we had a tall column of air in dead wells, yet the air sometimes was fatal to those who descended into them. Dr. D. B. Reid had recommended 1,500 cubic feet per man, but this, almost by common consent, was declared an extravagance. In April 1852 it became my duty to make a special report on the jail at this place. The space allowed for patients was very small, and seemed to have been really productive of very bad effects. It was remarked,—"It has not been "hitherto sufficiently considered that a man in 24 hours "must breathe 300 cubic feet of fresh air or sicken. "Were he confined in a space of this extent, without the "access of new air, the process of vitiation must commence "with the first respiration, and the man could not live "in health and vigour for 24 hours. Hence the necessity "of spacious accommodation, and of free ventilation, with-"out due observance of which health cannot be maintained, "disease will be aggravated, and life itself destroyed. In "Europe, a space from three to five times exceeding that "mentioned, or from 1,000 to 1,500 cubic feet, together "with good ventilation, is judged suitable as an allowance "for each individual in any establishment permanently "occupied and the air of which is liable to constant vitia-"tion. And it might be easily shown that the conditions "obtaining in hot climates render desirable an increase and "not a diminution of this allowance." This, however, did not escape without what was meant, perhaps as correction, but looked like animadversion. It was observed, "In re-"ference to Dr. Grierson's special report on the Kurrachee "jail the Board direct me to remark that though the "number of cubic feet of air necessary to be respired in "24 hours by a single individual be stated at a moderate "amount, they are of opinion that that officer rather "exceeds when he talks of 1,000 or 1,500 cubic feet, "together with good ventilation, being considered suitable "as an allowance for each individual in any establishment "permanently occupied, and the air of which is liable to "constant vitiation," at least in practice it is not so, "for "even in the metropolitan hospitals of London, Dublin, "and Edinburgh, in the provincial hospitals of all England, "and in the general hospitals, naval and military, of the "British Government, the allowance is under 1,000 feet; "while to British soldiers in barracks at home and in tem-"perate climates, the allowance is 450 to 500 cubic feet, "increased in tropical countries, in hospitals, to 650 or 700 "feet, 1,000 feet in barracks, and 1,500 in hospitals is as "much as could be desired for each European even in the "tropics." The force of the concluding sentence here, it is presumed, depends on the assumption that the want of the native in respect of air is less than that of the European. Natives generally want less, as pay, for instance, and possibly they may want less atmospheric air; but the fact, I think, has not yet been determined by experiment. This recusancy on the part of the Medical Board is not to be wondered at. Opinions grew very slowly on this subject, and perhaps have not yet reached their maturity. Lavoisier, whose merits are so well known, in the end of last century, pronounced the air required in respiration for one man in 24 hours to be 120 cubic feet. Sir G. Blane, in the beginning of the present century, named 600 cubic feet in hospitals as a minimum, and thought 1,000 not too much. Dr. Bostock, in 1826, quotes with approbation this conclusion, the former had embraced. In the year 1833, Begin in the *Dictionnaire de Medecine et de Chirurgie Pratiques*, under the Article *Hôpital*, assigns 20 cubic *mètres* as the volume of air calculated for fever cases in hospital, and the equivalent of this in English cubic feet is a space of 700 cubic feet; but when he gives the dimensions which should characterize the hospital he approves of, he seems to raise to 1,000 cubic feet this amount of space. About 1844 Dr. D. B. Reid recommended 1,500 cubic feet, and there opinion in England seems at present to halt. However, the authorities of King's College, London, did not adopt that standard, but allow for each patient a minimum of 1,800 cubic feet, and a maximum of 2,400 cubic feet. Besides this diversity and gradual development of views, confusion of thought was occasioned by the connexion subsisting between space and ventilation. In the progress of knowledge events lag behind. Principles always precede their practical application, and even when more enlarged notions of the necessity of increased space began to prevail, there were very strong objections entertained to pulling down small, and then erecting new and suitable buildings. The intention of this increase, it was allowed, was to give fresh air, and this intention it was sought to accomplish, not by increase of space within, but by means of better ventilation from without. Yet no attempt was made to determine in what relation space and ventilation stood to each other. Again, in India, it was often said, rules like these apply in Europe, where buildings are shut up on account of climate, but with us buildings are almost always

KURRACHEE. BOMBAY.

open, are thus ventilated at all times, and the increase of space demanded in Europe is not requisite. To this argument no effectual answer was forthcoming.

It was in the same year, 1852, that I was under the necessity of considering the question again. The occasion was this, I was called on by the Medical Board to report my experience and opinion of the station of Colaba as affecting health, and especially the health of European troops. The subject of space in barracks and accommodation fell thus to be specially adverted to, and it was sought to attain some definite notion, which should assign a just limit to precepts hitherto apparently arbitrary.

In my reply, therefore, in October 1852, I wrote thus :—

" Accommodation is highly important for troops. Besides " protection from the various changes of the weather, space " and ventilation demand more attention than they have " hitherto usually received. The amount of space allowed " to troops on Colaba is not known; but, though recently " enlarged, it may be presumed, if one judges by the views " very prevalent, to be defective still. It cannot be in- " opportune, at any rate, to say a few words on the subject. " Pneumatic chemistry seems to have been long cultivated " before chemists saw the relation it bore to space in dwell- " ings and ventilation, and the mode of estimating these " which is perhaps the best, is of very late introduction. " Dr. Bostock, who criticises with great care the experi- " ments on respiration made before he published, was aware " of the relation alluded to, but contented himself too " easily by giving an approval of Sir G. Blane's estimate " of 600 cubic feet of space for every man. This allowance " is about twice the amount of air a man respires in 24 " hours. Dr. Reid, when he published about eight years " ago, recommended from three to five times the amount in " cubic feet of the air respired, that is from 1,000 to 1,500 " cubic feet; and it has been very lately announced that " the Hospital of King's College, London, is to have wards " to contain 14 beds, with a minimum of space of 1,800 " and a maximum of 2,400 cubic feet for each patient. " These numbers represent nine times and twelve times re- " spectively the amount of air respired in 24 hours. It will " give, perhaps, a clearer conception of these differences to " state, that a space $8\frac{1}{2}$ feet in length, breadth, and height, " contains a little more than 600 cubic feet. Ten feet in " the dimensions mentioned contain 1,000 cubic feet. " Twelve and one-sixth, in the same way, give 1,800 cubic " feet. For 2,400 cubic feet the space must measure, in " the three dimensions, nearly $13\frac{1}{3}$ feet, and for 3,000, " almost $14\frac{1}{2}$ feet. Two modes have been adopted for " estimating the space required for each individual. Find- " ing the amount of air respired, it has been multiplied a " given number of times, and the product according to the " multiplier assumed as the space required. Thus a late " writer states (*Tomlinson on Warming and Ventilation, Lon- " don*, 1850,) as follows :—' In the process of respiration a " ' full grown man draws into his chest about 20 cubic " ' inches of air, only one-fifth of this is oxygen, and nearly " ' one-half of this oxygen is converted into carbonic acid. " ' Now, allowing fifteen inspirations per minute for a man, " ' he will vitiate about 300 cubic inches, or nearly one-sixth " ' of a cubic foot of atmospheric air, and this by mingling " ' as it escapes with several times as much, renders at least " ' two cubic feet of air unfit for respiration.' This esti- " mate gives air respired in 24 hours 250 cubic feet, and this " multiplied by 12, the number stated, viz., $\frac{1}{6} \times \frac{12}{1} = 2$, is " 3,000 cubic feet. The other mode is to find the amount of " carbon expired in 24 hours, to calculate the oxygen this " requires to convert it into carbonic acid, and to determine " from this the quantity of pure air necessary to be respired " in order to supply the requisite amount. Thus the same " writer says,—' From a comparison made by Professor " ' Miller, of King's College, of the result of numerous " ' experiments, it appears that a man of ordinary stature " ' consumes in the course of 24 hours 9 oz. troy of carbon; " ' that the heat generated is sufficient to boil away 8 lbs. of " ' water; that the consumption of oxygen on this process " ' is equal to 24 oz., or 19·4 cubic feet, that the quantity " ' of air vitiated amounts to 97·2 cubic feet, and the pro- " ' duct in carbonic acid to 33 oz.' By the quantity of air " vitiated here is meant the amount from which the oxygen " is wholly withdrawn, which is just five times the oxygen " consumed. But the quantity of air respired is twice as " much; for only one-half the oxygen inspired is consumed " during each respiration. The air respired, therefore, by " this mode of calculation is nearly 200 cubic feet in 24 " hours. Now, nine times this amount is 1,800 cubic feet, " and twelve times the same amount is 2,400 cubic feet; and " these are precisely the results, as they were most probably " the data, used in determining the construction of the " new hospital of King's College, and they approximate " pretty closely to those found by the other method before " explained."

" These are the rules for guidance on a subject scarcely " yet fixed on settled principles, and which, when better " understood, will create a demand for yet greater space in " buildings. It remains, however, to inquire how far they " are consistent with propriety and suitable to the end in " view. The carbonic acid being the most abundant of the " noxious products thrown off in respiration, and most " easily measured, is taken as the basis of the calculations " regarding space and ventilation. The mean amount of " carbonic acid in ordinary atmospheric air is about $\frac{1}{2000}$, or " ·0005. The amount in air expired is about $\frac{1}{12}$, or ·083; " and in air vitiated to this degree combustion ceases, and " plants and animals cannot live long. Practically, then, it " may be assumed, that respired air contains $\frac{1}{10}$, or ·1, of " carbonic acid, and this must be diluted 10 times to make " the air safe. Thus $\frac{1}{10} \div \frac{10}{1} = \frac{1}{100}$, or ·01, and this again " divided by 10, or $\frac{1}{100} \div \frac{10}{1} = \frac{1}{1000}$, or ·001, gives the " amount of ventilation needed to reduce the air to that state " of purity that only $\frac{1}{1000}$ more of carbonic acid should be " added to the air, when it would be represented by ·0015 " instead of ·0005. Observing this rule, and taking 300 " cubic feet to represent the quantity of air respired in 24 " hours, to dilute it 10 times it must be mixed with 10 times " the same bulk, or converted into 3,000 cubic feet, the space " to be allowed for one individual. But if it is wished to keep " up a pure air, it must be mixed with 10 times this bulk " again, or 30,000 cubic feet, which shows the ventilation " needed to maintain an atmosphere nearly pure. In other " words, there must be admitted into the space of 3,000 cubic " feet nearly 21 cubic feet per minute of fresh air by ventila- " tion, if the individual confined in it is to breathe an atmos- " phere which shall contain only three times more of carbonic " acid than the air he breathes originally contained. Or " again, 300 cubic feet, 3,000 cubic feet, and 30,000 cubic " feet, mark the requirements of one individual in 24 " hours for respiration, space, and ventilation respectively."

" These are the conditions necessary to maintain a pure " air according to the data made use of. There are, how- " ever, other facts to be adverted to which, wherever they " exist, and some of them always exist, render still more " imperative the claims put forth for space and ventilation. " These it is not needful to illustrate at length; the enu- " meration of them will suffice. They are a humid air, " high temperature, the privation of oxygen in respired air " as well as and nearly equivalent to the vitiation by car- " bonic acid gas, and lastly, the watery vapour, laden with " offensive animal matter, exhaled from the skin and lungs " during respiration. The last of these is especially impor- " tant. It has been stated that ' the odour of the air at " ' the top of the ventilator of a crowded room is of so " ' noxious a character that it is dangerous to be exposed " ' to it, even for a short time. If the air be passed through " ' pure water, the water soon exhibits all the phenomena " ' of putrefactive fermentation.' To the same cause, also, " is due much of the effect described in the following " quotation :—' In the houses of the poorer classes in " ' Russia, where the windows are single, and a number of " ' persons occupy a small stove-heated room, a thick icy " ' crust forms on the inside of the windows during frosty " ' weather, arising from the condensation of the breath, " ' perspiration, and the aqueous fumes of candles and " ' of the stove, &c. When a thaw comes on, the icy crust " ' is converted into water, and a deleterious principle is " ' disengaged which produces effects similar to those " ' arising from fumes of charcoal. Persons so affected " ' are immediately carried into the open air and placed in " ' the snow, with very little clothing; the temples and the " ' region of the stomach are well rubbed with snow, and " ' cold water is poured down their throats, and the friction " ' is continued until the livid hue of the skin disappears, " ' and the natural colour is restored.' With these effects " we may contrast those of a purer air. For instance, a " manufacturer puts a ventilating fan in his factory to " remedy the evils of a highly vitiated air. The result is, " the people apply for higher wages, because their appetites " are keener, and they require more food. The veterinary " surgeons recommend ventilation for stables, and the " annual saving to the British Government is 10,000*l.* per " annum. The effects of condensed air are very similar, and " perhaps for the same reason, that more oxygen is breathed, " under circumstances favourable in other respects to the " healthy functions of the body. There is felt a pleasant " sensation in the chest; there is increased vigour of body " and of mind, with improved condition of some diseased " states, and more effective performance of some healthy " actions."

" These considerations, with others which need not be " adduced, occasion reasonable apprehension that many " evils in barracks and hospitals accrue to the men from " want of space and ventilation; and in any place, as in " Colaba, where other injurious influences are also at work,

" the respective effects of each separate cause are aggravated " by reciprocal reaction."

Passing on now in the progress of events and the history of opinion, I extract from a public document, namely, *Budget of Public Works of the Presidency of Bombay*, 1857–58, dated April 15, 1857, the following:—" The desirable- " ness of establishing some general rule for fixing the " amount of space to be set apart for each man in the " hospitals of European troops of this presidency was in " the beginning of 1853 brought under the consideration " of Government by the late Lord F. Fitzclarence. His " Lordship considered it of great importance that a fixed " rule on this subject should be adopted and enforced, in " order to prevent overcrowding in hospitals, and also to " enable the medical authorities to know at all times with " correctness the amount of suitable accommodation avail- " able for troops."

" After consulting the Medical Board on the subject, " this Government, in accordance with the Board's recom- " mendation, decided that 1,800 cubic feet per man should " be made the standard in the hospitals of the Bombay " presidency.

" Subsequent to the adoption of the above standard, the " Commander-in-Chief pointed out that nearly every Euro- " pean and military hospital in this presidency was deficient " in accommodation, and required to be considerably " enlarged. In this opinion, which was supported by the " Medical Board, the local Government fully concurred."

With the affirmation of this rule, if it may so be called, which indicates a slight advance in the opinion of the Medical Board upon that before alluded to, the matter rests. Lord F. Fitzclarence died in 1854, and in 1857 the public works were suspended; and in this breathing time it is important to inquire whether the decision come to by Government be adequate to the necessity of the case. In the first place, no mention is made of barracks, and it is presumed the space of 1,800 cubic feet was not meant to be allowed in barracks. If, then, this amount of space be barely sufficient for hospitals, and less be allowed in barracks, then, to say nothing of ordinary occasions, whenever the weather or other cause constrains men to occupy the barracks more than usual, or a greater number of men than usual is put into barracks, the space is too little, and health must suffer. But for hospitals even the space is insufficient. Did this opinion rest simply on my own decision of the question, however firmly and in good faith I might hold it, still I might hesitate to give it prominence; but it happens that I can adduce authority which will command respect. It was shown before that space and ventilation are inseparably connected, and it would not be possible to give dimensions to a building, as a habitation for living beings, which should obviate the necessity of ventilation; in other words, renewal of the air of the interior which supplies the inmates with air for respiration. It is evident also, that for health in buildings, just in proportion as space is small, so is the need of ventilation greater. Now, when 1,800 cubic feet is decided on as the space in hospitals, there is no provision for ventilation, and no one is in condition to say that ventilation is duly performed. It is left to the operation of doors, windows, and some few apertures in the roof or elsewhere, and to the action of the outer air, which of course daily, perhaps hourly, varies, as the temperature, force, and direction of the winds vary. It cannot be denied, then, that where ventilation is so uncertain, and may altogether fail, as in calm weather it must, the greatest limits of space are very necessary; and it will appear yet more evident when the matter is put in another light. In the *British and Foreign Medico-Chirurgical Review* for April 1860, in the article on the site and construction of hospitals, when the reviewer treats of ventilation, he says, "The French hospitals " contracted for a supply of 2,220 cubic feet of air per bed " per hour." But "to give," says Dr. Sutherland, "the " air of a ward the highest degree of freshness, the amount " of air passing through it should be at least double the " amount required by the French hospital contracts, or " about 4,000 cubic feet per bed per hour."

We shall suppose, then, as we have reason to do, that the wards here spoken of allow 1,000 cubic feet per man. Let us next convert the hourly supply into that of 24 hours, which conversion gives for the French hospitals 53,280 cubic feet per diem, and for the proper amount, nearly double as Dr. Sutherland says, 96,600 cubic feet per diem. These sums bear to 1,000, the cubic space per man, the proportion of 1 to 53 and of 1 to 96, that is, in the former case the air must be renewed 53 times, and in the latter 96 times per diem. But what it is important to observe is this, that were the space in the French hospitals doubled, or made 2,000 cubic feet instead of 1,000 cubic feet, then, though the renewal of the air be half the number of times only, yet the purity of the air in either case would be the same. And the reason is not obscure, for the air of the smaller hospital is contaminated twice as much, and requires twice as much ventilation, that is renewal, to maintain the same degree of purity. Observe, again, for confirmation of this fact, that it is the same amount of air in either case which is needed for ventilation. The difference consists only in the rapidity or number of times with which air equal in amount to the contained air is transmitted through the hospitals. Now, if the hospital with the space of 1,000 cubic feet per man requires 96,000 cubic feet of new air per diem per man, or necessitates the renewal or change of the air 96 times, the hospital with space per man of 1,800 cubic feet requires only 53,333; for as 1,000 : 96,000 :: 1 : 96, and as 1,800 : 96,000 :: 1 : 53,333; and what immediately concerns the result of this investigation, as 3,000 : 96,000 :: 1 : 32. It follows, therefore, that the hospital with space of 1,000 cubic feet per man must have new air 96 times a day; that whose space is 1,800 cubic feet 53 times a day; and that whose space is 3,000 cubic feet, only 32 times a day. The first is possible only by the aid of strong mechanical means; the second would require, probably, less expenditure of force, and would not be independent of it; and the third only approaches the conditions which would probably make natural spontaneous ventilation effective to maintain the purity of the interior air. The conclusion is, that for Indian barracks and hospitals, if they must be built, and the latter, it is presumed, must be built, 1,800 cubic feet, unless in conjunction with artificial ventilation, is greatly too little; and that two alternatives offer themselves to remedy the defect—either to enlarge the space or to employ artificial ventilation.

It has been, perhaps, noticed, but may with propriety be pointedly referred to, that provided, as is probable, Dr. Sutherland's calculation proceeds on the *datum* of a space of 1,000 cubic feet per man, the conclusion he comes to agrees well with that which was stated in the foregoing part of this paper, for 1,000 × 96,000 = 96,000,000 differs but little in such a calculation from 3,000 × 30,000 = 90,000,000. Add but 2,000 cubic feet to the ventilation in the latter case, that is, make the 30,000 32,000, and the result is precisely the same. This is the more satisfactory, as the aim of both calculations was identical. This design he announced to be " to give the air of a ward the highest degree of " freshness," and in the foregoing pages it was said, "There " must be admitted into the space of 3,000 cubic feet nearly " 21 cubic feet per minute of fresh air by ventilation, if the " individual confined in it is to breathe an atmosphere " which shall contain only three times more of carbonic " acid than the air he breathes originally contained." The only sound principle in this question is the maintenance of a pure air. Data may differ. Calculations may reach the same result by different ways, but if the ultimate end be not a pure air, nothing is right, nothing thoroughly effective. And it is to be borne in mind, when the means to accomplish this end are considered, that space and ventilation bear an inverse ratio to each other, that as space increases ventilation becomes less, and that they may reciprocally bear that relation to each other, when ventilation shall become easy, or, perhaps, natural and spontaneous.

One who reflects carefully on these things, who sees the direction they point to, and would wish to realize the facts of speculations like these, would be wholly destitute of foresight, if he did not anticipate an objection, which will be immediately raised. It will be said, the increase of space you require is enormous, the expense would double that of the erection of the present hospitals and barracks. This view of the question may be admitted. Probably, indeed, the truth of it cannot be disputed. But it may be urged that this view presents but one side of the account. There is another, which it is the duty of professional men to try to exhibit. Against the expenditure in money we have to show the removal of lessened vigour and vital energy, of languor, lassitude, and discontent, of impaired health, vitiated moral tone, of disease often, and deaths not seldom, the results not obvious to sense, undeniable in reason, of the contaminated air of barracks and hospitals. But who shall estimate in money value the difference between an army moral and effective at all points, and one debased in character, and deteriorated and inefficient in physical condition? There is yet another side of this question, which appeals to the sensibilities of men. We demand for men every where, we judge imperative for those whom we would maintain in health, good and pure water, good and clean food, and we are sympathized with, and it is considered a great evil when matters are otherwise, and would be regarded a monstrous, an intolerable grievance to insist that impure and bad water, bad and impure food, should be made use of: here where matters are more patent to observation and better understood, the state of feeling corresponds at least in some degree to the necessity, and it provides against or exposes where they exist, and removes evils of

this description. But air is more necessary to man than even food and water; and pure and good air is as imperatively wanted as pure and good food, or pure and good water, nor is it in reason in any degree less unseemly that men should content themselves with, or be constrained to submit to, impurities of the one kind any more than to those of the other. If besides the injury be taken into account, it is, perhaps, just as great or greater in the instance of impurities of the air than in those of food and water. The harmony of the being and constitution of man with the physical conditions of the world which surrounds him is so perfect that nature cannot be violated by ignorance or artificial arrangements, without injury, loss, and embarrassment; and we may safely repose that confidence in that harmony which shall enable us to observe it as a rule of duty; and if, in following it out in this instance, the soldier receives the benefit of what best promotes his well-being as a man and as a moral and religious being, and amongst other things of the purest air, the result it cannot be affirmed will be inexpensive. The expenditure, however, will be the most profitable, the only suitable, well laid out in performance of a solemn duty, and in maintenance of the efficiency of that force which gives security to the common interest, upholds the throne, maintains the administration of justice in mercy, and repels, if that evil day should come, foreign invasion.

Medical Police.

In the year 1843 I served in a committee at this station, the object of which was to report on the conditions prejudicial to health existing in cantonments, and to point out remedies. The analogy of this climate to that of the Persian coast was pointed out, the existence of fever inferred as probable, the peculiarity of this place in the limited quantity of rain was dwelt on, and the necessity of peculiar care and assiduity in sanitary matters enforced from this consideration. The reason of appointing this committee was the prevalence of sickness at the time. A year of very great sickness and mortality followed elsewhere in Sinde, and the sickness which existed here was, perhaps, on that account less observed, and little or nothing was effected for cleansing the cantonment. When first occupied, Kurrachee was esteemed and reported by Dr. Cahill, an intelligent observer, as peculiarly healthy. My own note of the place, when I first landed here, in November 1839, was, "Kurrachee has now been occupied for upwards of 12 "months, and has acquired, though I think hardly with "justice in so short a time, a reputation of peculiar "salubrity." It was occupied in the year 1838. It lost this character, as is evident from the formation of the committee before alluded to; but it was not till 1846 that it was signalized by an outbreak of cholera, sudden and terrible, which gave it a bad eminence, never to be forgotten. Out of a force of 6,626 men bearing arms, almost in equal numbers Europeans and natives, including women, children, and native followers, the deaths in different hospitals were 915 out of 1,841 attacked by the disease between June the 14th, when it made its appearance, and July the 11th, when it ceased. In four days, from 15th to 18th inclusive, there were admitted on an average 203, of whom on an average 110 died daily. Two regiments suffered in an especial manner. In Her Majesty's 86th regiment, out of 434 seized, of whom were 18 women, five children, and one native follower, 258 died, of whom 15 were women, four children, and one native follower. In the 1st European regiment Fusiliers, there were 252 admissions, of whom six were women, six children, 19 native followers, and of these died 103, being men 83, women five, children three, and native followers 12. Cholera had prevailed sporadically for about 12 months previous, but before that time also had prevailed, but never with such dread severity. Now, passing all other circumstances without notice, and some of them are not unimportant, such as the dearth and scarcity of provisions at the time, it is very desirable that it should be distinctly known, as Dr. Arnott informs us, that the state of camp and neighbourhood at that time was most obnoxious, and as much neglected as if medical police had never been heard of. In No. II. New Series of *Transactions of the Medical and Physical Society of Bombay*, page 182, published in 1853, Dr. Arnott mentions sources of disease common to all regiments then at the station, and then he says:—"But "there were others peculiar to the position of the camp of "Her Majesty's 86th regiment and the Bombay Fusileers. "They lay still further to the eastward or leeward of the "other lines, and of the suddur bazaar. Between the "latter and these camps . . . was a large piece of "bare waste ground, where all dead animals, the cleanings "of necessaries, the sweepings of streets, and where in fact "most of the filth and offal of the camp was deposited. "The accumulation of putrid animal and vegetable matters "was enormous." He states that the Fusileers had been too long encamped on the same ground, that the tents were crowded, and the ventilation little attended to, and then adds,—"Under these circumstances there was "certainly enough, if not to engender disease, at least "to encourage its propagation and extension. And "I have always viewed them as accounting for the "intensity of the attack in these two regiments." Had this fact been known to Dr. Carpenter, *Human Physiology, Ed.* IV., 1853, pp. 549–50, he would have found in it, it is presumed, a more efficient cause of this disaster than even previous fatigue and overcrowding, which, no doubt, the latter especially, were very prejudicial. His analysis of the features of the case omits this scandalous impropriety, and is somewhat inaccurate in other particulars; but his conclusion that corrupted air gave intensity to the malignant scourge is only more confirmed by the fact, judiciously recorded by Dr. Arnott. Kurrachee, in 1839, was healthy. In 1843 fever prevailed severely. A peculiarity, elsewhere observed by others in situations where corrupted air infested the locality or the antecedents which generate it, abounded, was very frequent in Kurrachee in 1843. It was experienced amongst others by myself. At meals principally, or immediately after, without much warning, uncontrollable nausea and vomiting suddenly appeared and quickly subsided, without other obvious derangement of health, previous or subsequent. In 1846 the unhealthiness of the place culminated as has been related; but frequent sickness and cholera in milder forms prevailed afterwards, especially in the years 1851 and 1852. In the former year, in April, by the foresight and energy of Sir Bartle Frere, then Commissioner in Sinde, a committee of conservancy was formed, and of this committee, in November of the same year, I became secretary. The appointment of this committee was the first step to sanitary improvements in Kurrachee. In less than one month from its formation, the resolution for the erection of furnaces was passed, at first only experimentally; but the existence of many of these erections now gives a feature peculiar to itself to Kurrachee as respects the outskirts both of the town and cantonment. In 1852 the practice of the inhumation of the waste and filth of the jail was carried out by the committee, a practice which to this day beneficially continues. The operations of the committee were limited and embarrassed by want of funds; for available resources were yet small, and all the suggestions of the committee could not be immediately embodied in the material accomplishment of their designs. It was therefore reserved to Sir John Hall, on his visit to this place as Deputy Inspector-General in the early part of the year 1853, to point out, as he did most forcibly, the unreformed nuisance which had existed since 1846 and shed its baneful influence ever since, though not with such awful virulence as marked the calamitous cholera of that year. By his report the interest of Lord F. Fitzclarence was roused, and thus a new and happy impulse was given to sanitary improvements at Kurrachee. By additional furnaces, by increased establishment of those employed in the cleaning department, and by better supervision, the most prominent evils were completely removed and a system set agoing which rendered the recurrence of them impossible. It cannot be said that all is even now as it ought to be; but there is a readiness to recognize defects,—a great contrast to former times,—which consist principally in the yet too limited establishment, and which there is reason to hope will be removed.

But little interest, it may be thought, attaches to a narrative like this. Perhaps even it may be judged by a severer censor that, through partiality and an overruling estimate of local concerns, it is sought to give undue prominence to what does not merit deliberate consideration. Let us then revert to the facts already noticed: at first Kurrachee was healthy; gradually the health of the place deteriorated, and the year 1846 makes it memorable as the theatre of one of the most calamitous epidemics recorded in the annals of medicine or of history. Nor was it till after the year 1852 that the place enjoyed an immunity from yearly attacks of fever and often of cholera. But this is exactly the era of the sanitary reforms, and the removal of obnoxious practices and nuisances is precisely simultaneous with the cessation of epidemic disease. No one can consider the history and connexion of these facts with due care and avoid the inferences that neglect of sanitary police and the presence of disease, and, on the other hand, attention to police and the cessation of disease, which they fully establish, stand in this case in the relation of cause and effect, that it is not hopeless to set limits to the most virulent diseases, and that were due precautions, such as science indicates and experience confirms, had recourse to, life would be saved, much misery averted, and climates, without changing character, would lose the terrors and the dangers which environ them, which impair the enjoyment of life, often curtail it, and add incalculably to the expense of the government of the country. It must be

admitted that this year, contrary to expectation, cholera visited the place. It advanced from the eastward, invaded several villages, appeared at the harbour, at Keeamaree, in the town and jail, and, lastly, in the cantonment. The incursion, however, was brief, the numbers attacked limited, and the deaths few absolutely, and even more so relatively to the actual amount of the developed disease. There have been then seven years of exemption from the disease with diminished sickness in other respects, and, in the eighth year, an attack which one cannot but characterize as mild, and this, though it qualifies yet cannot set aside, and scarcely, when we make allowances for other circumstances, invalidates the general result.

This result certainly merits attention as an instance of the effect of sanitary measures, and the good which ensues when they are pursued on an adequate scale; and, as before hinted, this result, confirmed by experience, is indicated also by science. The geologists in some of their sketches picture to us the naked crust of the earth, then the disintegrated mountains, next the decomposition of the fragments thus freely exposed by the agencies which operate on them. Plants spring up after this, and the mixture of organized products with the inorganic transforms the sandy soil into fertile mould, increase of vegetation goes on, and, lastly, animals appear upon the scene. Now in the earlier stages of this process, and in all that we recognize then in the inorganic constituents of the earth and air, there is found nothing noxious to the life and health of animals. Organization afterwards gives rise to new compounds and new products, and when these, as waste refuse material, are accumulated in neglected masses, in the process of reduction to simpler combinations, the result of ordinary chemical affinities when the cessation of vitality has left the organized structures an easy prey to them, gaseous compounds are formed prejudicial to health, and which are capable, some of them, of a power passively or more actively to extinguish life. Connected with this subject, in the report on Colaba, I had occasion to observe "earth, air, " and water, though viewed very differently in ancient and " modern times, are still the great elements which influence " man's condition and development, and the health he " enjoys. They are simple, harmless, beneficial in themselves. The necessities of vegetable and animal life, the " action of living properties, and the affinities of organized " products resolve them into new combinations, and some " of these are highly injurious. It is the object of science " to disclose and unveil all evils of this kind, and of " science, practically applied, to obviate and remove them, " and a generous confidence in the harmony of man's condition with his duties and enjoyments ought to make us " slow to believe that any natural evil is beyond the control " of science rightly directed or without a remedy of which " only lack of industry or of sagacity may obstruct the discovery and the application. Nor when we pass from the " more tangible objects comprised under these divisions " to the consideration of the imponderables,—heat, light, " and electricity,—is there found any fact which renders " the judgment of nature and of science which has been " announced visionary or untrue." Man received commandment to increase, multiply, and fill the earth and subdue it, and more especially in regard to that portion where his lot was cast to dress and keep it, and it is evident that his success in compliance with the former part of his obligation is dependent on his diligence in the execution of the latter part of his office. Nor is this true simply as respects subsistence, but as respects health and well-being also. He dresses the earth for food, but if he neglects to keep it, to return to it what he takes from it, the accumulated waste materials will accuse him and punish him for neglect, and the earth itself will fail to yield its increase. Thus uncultivated marshes generate ague, torment and kill men, but, drained and cultivated, they are beautiful, healthful, and produce food for man and beast. The waste of animal matters, recrementitious products of the arts, or decaying products of organization left to diffuse the noxious gases that arise from them into the air, contaminate it, and affect the health, longevity, and productiveness of man, teach him, if he will hear, how he has neglected his duty to the earth and himself, and warn him to dress the earth and keep it. Towns and camps, where medical police has failed to remove noxious matter, have often afforded proofs and illustrations of this hurtful ignorance and prejudicial neglect of duty. Kurrachee was an instance of this kind, and though at this place the condition of agriculture and the prejudices of the people in great measure rendered it impossible to return immediately to the earth for fertilizing purposes the waste products of busy industry and civilization, yet the partial compliance with the great primitive commandment carried out by the inhumation of noxious substances and their assimilation with the soil and the dissipation of their elements by incremation and their transmission through the air to feed the vegetation they should come in contact with. Even these imperfect modes of freeing the station from impurities have been attended with results most evident, efficient, and satisfactory.

The chemist takes a small piece of rock, submits it to his refined analysis, and ascertains with precision the ultimate components of it, and their respective proportions. He knows then, without further research, that he can affirm correctly what are the ingredients of the mountain from which the fragment was taken, of the chain of mountains to which the first belongs, of other chains, possibly, which stretch into other countries, or even of those, perhaps, which exist in countries divided by the ocean from that which afforded the specimen subjected to his analysis. And, however this may be, he is at least certainly in condition to declare, whenever a substance which possesses the same sensible and physical properties as that examined by him offers itself to his notice, that the components of it are identical with those of the portion of rock the constituents of which he had determined. Universally in nature the same results are yielded by homogeneous substances when chemically analysed. The same universality belongs to experiments in physical science. When Pascal found that the column of mercury varied in height, when measured at the bottom, middle, and top of the Puy de Dome, he felt quite sure that the same result would be found on any other mountain by any other philosopher who should make the experiment. Uniformity of antecedents produces uniformity of consequences also. In medical and in sanitary matters the same principle eminently applies. How many thousands of important decisions are made daily by the application of analysis, and how fruitful is this procedure in good results. But how few comparatively are guided by the results of actual and immediate experiments. The few labour, and the many enter into their labours. Experimental philosophers and discoverers are rare, but innumerable are those who, by the knowledge of their discoveries and the use of analogy, reap the fruits of their sublime achievements, and confer untold benefits on the world. This principle, though constantly operative, is no doubt obscurely recognized; and the reason of this is, that it is often prejudiced by misapplication. Were it possible, by due discrimination, to secure identity of circumstances in the matter dealt with, compared with that to which by analogy we liken it, there would be no disappointment in results. The event would answer expectation, and the principle would be as familiar and well known as its effects would be evident and beneficial. In inquiries in science this precision is attainable, and the progress in knowledge corresponds; but in the vast multitude of the world's mixed affairs discrimination is often at fault, perfect adaptation and similitude neither can be effected nor offers itself, the conclusions we desire and anticipate come not into view, or come denuded of their splendour or mutilated in their fair proportions, and then doubt, mistrust, and suspicion attach to the principle and procedure, which ought rather to be attributed to him who has made a wrong application of them. In applied science, therefore, the obstructions are formidable, the world is incredulous, and progress is slow; yet sure it is, though slow. And just in proportion as care and discrimination are used in the application of principles in practical science, established by experiment or example, to cases in actual life, just in the degree there is attained a conformity of conditions or circumstances between these original examples or experiments and the analogous cases which present themselves, just in that same degree and proportion shall results conform to expectation, effects to principles, and then shall the application of them, by analogy, stand vindicated to all the world. Practical ability consists in the perception of these analogous conditions, and he only profits by experience who learns readily to apprehend and rightly to use them. The sanitary measures resorted to at Kurrachee may be regarded as bearing a double relation. When it is considered that examples innumerable have established the principle, just as if it had been ascertained by so many experiments, that impurities caused by waste and excrementitious vegetable and animal matter contaminate the air, which, being respired in this state, originates disease in the human frame, that the removal of these impurities where they exist, or the prevention of them, removes or prevents disease, and when by analogy use is made of this principle, and the cleanliness it demands is realized in Kurrachee, and the exemption from disease which was expected is experienced, the measures adopted here are in that case neither an original experiment nor a deduction from numerous observations, but the application of a precept or principle by analogy; there is no novelty and no uncertainty in the matter; on the contrary, the precept receives additional illustration and confirmation from the new example. Again, if we look at the measures put in use here, not in reference to the principle that guides

them or the end proposed, but in respect to the means by which this is effected, these, it is seen, are peculiar, and perhaps merit some separate consideration. It might almost seem, indeed, that in this view what has been done here may claim the rank of an original experiment; original only, however, it is in the means employed and in urging the necessity of the strictest sanitary police for the health of troops in camps or cantonments; and in holding up Kurrachee as an example pregnant with instruction, it is to be observed that what is demonstrated and enforced by it is cleanliness. If it be thought and said that the means used here, the burning in furnaces and the burying in trenches of the waste matter of the town and cantonment, are simple, easily worked, and admirable in their effects, and therefore worthy of imitation elsewhere, this is quite a secondary affair. What is really insisted on is an absolutely perfect system of sanitary police. The means by which it is carried out may vary indefinitely, but that method only is the best which, without damage done to any other private or public interest, combines cheapness in cost, ease in working, and efficiency in result. It is the object, then, of these remarks strongly to insist on the benefits of sanitary police at Kurrachee, to urge the adoption of similar measures in every standing camp or cantonment or town in India, and if no better means suggest themselves, to recommend the use of those which have been employed at Kurrachee.

It remains to present in brief form the conclusions established and measures recommended. Drunkenness, the parent of crime, disease and death, is an obtrusive, obnoxious habit in the army. All endeavours yet made to eradicate the evil have failed. The great step to be made in order to extirpate drunkenness, that without which other means will prove abortive, is the abolition of the canteen. Prostitution, which produces five times a greater amount of venereal disease in European regiments than what exists in native regiments, ought not in any way to be sanctioned, nor ought any regulations except those which are repressive to exist on the subject of prostitution. Marriage, on the other hand, the only effective remedy for immorality and for venereal disease amongst the troops, ought not to be restricted, but free, and the additional cost which might follow, if any follow, should be asked for from the nation, which must have troops, and would choose rather to have moral, healthy, effective troops, and would willingly pay for them. As respects accommodation, that hitherto supplied to troops has been extremely defective, nor has the nature of the structures in barracks and hospitals remedied the defect. Two alternatives exist if a remedy be sought. These are enlarged structures or ventilation. Space in buildings and ventilation bear an inverse ratio to each other, and as in India artificial ventilation does not exist, ample space is all the more requisite. This space must always be required in hospitals, but if the expense for barracks be too great, another course, not before indicated, may be adopted in lieu of barracks. Following the example of native troops, let the men marry and live in cottages. These aggregated and constituting villages, would resemble the lines of a native regiment. Perfect cleanliness in every town, station, camp, cantonment in India should be observed. Waste matter of every kind should be with the greatest care and promptitude reduced to innoxious forms, and if not applied to agriculture or other useful purposes, disposed of as at Kurrachee, by incremation or inhumation. If we suppose the troops have good water, good food, good clothing, and good medical attendance, the measures enumerated above seem to be those which make the complement of what is needed to constitute a perfect sanitary system for the army. They are not less important, though less obvious and appreciable, than those advantages which we assume the troops to enjoy. Their importance is such that no greater benefits, when we except divine grace, which no act of man can convey, can be conferred on the troops. The want of them vitiates much good. The attainment of them therefore is a double benefit. In the removal of evil, in imparting good, in the emancipation from pernicious influences, and restrictions, and in bestowing those privileges and advantages on the troops, the ravages of immorality, disease, and death will be checked, many valuable qualities will be brought into being, the soldier will rise in new splendour and dignity, become an example to the nations, and adorn the religious character of his country, to which he has too long and too often been a blot and a reproach.

It remains to make one remark. It has been said by a high authority, European soldiers cannot maintain health or vigour in the plains. Without disputing the statement, the fact, it is averred, has not been proved. The statement it may be said, rests on experience. But the experiment has never been made, nor experience gained in circumstances which command respect. If the foregoing remarks prove anything, they show that the conditions of the experiment have never yet been pure and simple, that the accessory conditions have produced disturbing effects, and vitiated the results. What is called experience, therefore, in this case is fallacious. We may not affirm that the assertion is wrong. We affirm that the conclusion is premature. This point is to be decided only when the conditions of the experiment have been purged. Then only shall we attain a conclusion, as derived from the unmixed conditions of the case, on which reliance may be placed. This remark applies to the plains generally, as also specially to many stations, pronounced unhealthy, when the experience which decided the question was both far too limited and obtained under circumstances which, as they vitiated it, should have robbed it of the confidence hastily reposed in it. Again it is repeated, purge the conditions of the experiment of all accessories that complicate and vitiate it, then begin anew, note what happens, and adopt it as conclusive, for then only are we following the rules of philosophy, then only reaping facts which as the fruit of genuine experience are entitled to confidence and respect.

I have the honour to be,
Sir,
Your most obedient servant,
D. GRIERSON, M.D.,
Surgeon Major, Staff Surgeon.

Kurrachee, 31st December 1860.

NEEMUCH.

I. TOPOGRAPHY.	1. The country within five miles of this station is flat, undulating, rocky, and dry. There is no wood or jungle in the vicinity, and no water of any considerable extent. 2. The station is elevated about 1,476 feet above the sea; but is on the same level as the adjacent country. It is from 10 to 12 feet above the nearest water. There is no higher or healthier ground adjoining the station. 3. The nearest mountains are at a distance of about 70 miles from the station. 4. There are two nullahs within camp limits, which contain running water for about nine months in the year. There are several nullahs and small rivers within five miles of the station. The vicinity is not liable to inundations. The ground is slightly broken and irregular along the banks of the nullahs, which almost encircle the station, and is doubtless a source of malaria during and after the rains. 5. The western side of the camp is well exposed to the prevailing winds, and is not encumbered with trees, &c., nor sheltered by higher ground. The eastern portion is shut out from the prevailing winds by the bazaar. The temperature of the station is not raised by exposure to reflected sun heat. For four months of the year cold north and north-east winds prevail, and for the remainder of the year west and south-west winds. The station is

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	too far inland to derive any benefit from the sea breeze. The dry north-east wind appears to predispose to hepatic affections and rheumatism. 6. The country surrounding the station is cultivated; but there are no works of irrigation near it. There is no cultivation of rice or indigo, neither is the preparation of hemp or flax carried on near it. 7. The town of Neemuch is within half a mile of the station. The population varies from 8,000 to 10,000. 8. The ground on which most of the buildings in camp stand is a red soil with a substratum of trap, and indenting and encircling the camp is a belt of black soil. The ground has not been occupied previous to the erection of the station. 9. On the lower ground water is to be obtained at a depth of 19 feet during the dry season; whereas on the higher ground the wells run dry. During the rainy season water is to be found at a depth of from three to five feet below the surface. 10. The natural drainage of the station is good, and there is no lodgment of water even after a heavy fall of rain. The subsoil being impervious, the drainage is entirely on the surface, the water finding its way to, and being carried off by the nullahs. No drainage from higher ground passes into the subsoil of the station. 11. The water supply of the station is derived from wells; but is not stored in tanks. There is a tank within a short distance of camp, containing water for about 10 months in the year; but it is not used for the purpose of supplying the station with water. It does not contain either plants or animals. The wells which contain drinking water are not liable to pollution from leaves or other impurities falling into them. No surface impurities can drain into them. No nuisance or malaria proceeds from either the tank or wells. 12. There are 39 wells in camp, which give a sufficient supply of water. The water is hard, but good, and there are no marked peculiarities in its colour, taste, or smell. The water is raised and distributed by water-carriers specially employed for that purpose. Any further supply can be obtained, when desirable, by sinking other wells. 13. There are no other topographical points on which to remark. 14. All stations are selected by a military committee composed as follows:—One officer of the quartermaster-general's department, one medical officer of superior rank, and an officer of rank and standing, together with a civil officer in charge of the district. No improvements can be suggested.
II. Climate.	1. The only instrument available at the station for conducting and registering meteorological observations, is a common thermometer. 2. Table of meteorological observations from 1st January 1860 to 31st December 1860.

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain, Inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks as to Clouds, Dew, Winds, Storms, &c.
		°	°	°	°			°					
January -	—	55	18	62	49	—	—	75	0·00	N.E.	Moderate.	—	Cloudy. A light shower of rain fell on the 22nd.
February -	—	60	21	71	50	—	—	84	0·34	Variable.	Calm.	—	Cloudy on the 20th.
March -	—	70	23	80	60	—	—	97	0·00	W. & S.W.	Moderate.	—	
April -	—	81	22	92	70	—	—	97	0·00	W. & S.W.	High Winds.	—	
May -	—	84	20	94	75	—	—	94	0·31	W. & S.W.	High Winds.	—	Cloudy on the 16th.
June -	—	80	17	82	78	—	—	82	1·65	W. & S.W.	Monsoon from about the 20th, occasional storms.	—	Cloudy on the 12th, 13th, and 30th.
July -	—	74	11	76	73	—	—	—	11·79	W. & S.W.	Monsoon.	—	Cloudy and thundering from the 1st to 6th, and again from 11th to 22nd, and from 26th to 30th.
August -	—	74	9	75	73	—	—	—	15·68	W. & S.W.	Moderate.	—	Clouds and thunder from 1st to 20th.
September	—	75	12	79	71	—	—	82	3·83	W. & S.W.	Calm.	—	
October -	—	71	19	77	66	—	—	—	0·23	N.E. & W.	Calm.	—	Cloudy. Light showers of rain fell on the 3rd and 16th.
November	—	67	22	78	56	—	—	89	0·00	N.E. & W.	Moderate.	—	
December	—	65	21	76	55	—	—	87	0·33	E. & N.E.	Moderate.	—	Light showers fell on the 19th and 20th.

3. The climate varies with the season of the year. From the 15th November to the 15th February it is cold, dry, and bracing, and from the middle of February to the middle of June the heat gradually increases, the maximum being attained during the month of May, when fierce hot winds prevail. During the monsoon the climate is mild and pleasant. In October the heat again increases, decreasing at the latter end of the month. The diurnal variation of the temperature is great, the nights being generally cool and pleasant, owing to the elevation. The atmosphere contains but little moisture, even during the monsoon, and the air is free from dust and other impurities. The surrounding country is but thinly covered with trees of any size. With proper precautions the climate would not be very prejudicial to the health of the troops. The diet should embrace a liberal supply of vegetables, and beer in moderation. The barracks should be spacious, well raised from the ground, and sheltered from the sun's influence by broad verandahs. The clothing at present in use appears to be well adapted to the climate, as it is sufficiently loose and allows the free movements of the body and unimpeded circulation. The khakee clothing is admirably suited for the hot weather, as is also the serge tunic during

NEEMUCH. BOMBAY.

References to Subjects and Queries. | REPLIES.

II. Climate—*cont.*

the damp and variable weather of the monsoon. The wicker helmet is an insufficient protection and requires a thicker covering of cotton to protect the head from the powerful influence of the sun's rays during the hot season. A moderate amount of exercise is required for the preservation of health in India, and therefore drill, if carried out with a due regard to the season of the year, cannot but prove beneficial. In the hot months soldiers should not be exposed on parade later than half an hour after sunrise, or before sunset. Soldiers on duty should have sufficient accommodation to shelter them from the sun and weather, and sentries should always mount guard under cover. December, January, and February are the most healthy months, and May, June, October, and November the most unhealthy at this station. Fevers are the prevailing diseases at all seasons.

4. There is no district near the station with a climate more conducive to health than that of Neemuch.

5. The experience of the Committee has been extended over nearly the whole of the Bombay Presidency. It is of opinion that the stations in the South Mahratta country and the Deccan possess climates the most conducive to the health of the troops.

III. SANITARY CONDITION OF THE STATION.

1, 2, 3. Plans of the station, district, and barracks are transmitted.

4. Table of barrack accommodation :—

Date of construction, 1858. Total number of rooms, 9.

Total regulation number of non-commissioned officers and men, 109.

Barrack Rooms.	Regulation Number of Men in each Room.	Dimensions of Rooms. Length.	Breadth.	Height.	Cubic Contents in Feet.	Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows. Number.	Height.	Width.
		ft. in.	ft. in.	ft. in.				ft. in.		ft.	ft.
1 Main Room - -	100	200 0	24 0	21 0* Mean.	100,800	1,008	48	1 9	28	5	4
4 Non-commissioned Officers' Rooms.	1	18 0	10 0	11 9	2,115	2,115	180	1 9	2	5	4
4 Ditto - - -	1	10 0	10 0	9 10½	987·5	987·5	100	1 9	2	5	4
Guard Room - -	1 Serjeant 12 Privates	35 0	17 0	9 6	5,652·5	434·8	45·77	1 9	2	4½	3
									2 Doors	6½	3½
Prison Cells - -	1 or 3	19 3	11 6	14 0	3,099·18	3,099·18	221·37	1 9	1 Door	6	2
						1,033·06	73·79				

* Mean, including Roof.

The solitary cells are only 8 in number, and therefore, should occasion require it, as many as 3 men may be put into one cell. Each cell has a door, 6 × 2 feet, and 2 ventilators in the roof, which is flat.

5. The windows of the main room are on opposite sides; of the small non-commissioned officers' rooms, on adjacent sides; and of the larger non-commissioned officers' rooms, on the same side. They are French windows, and open inside. There is a verandah on both sides extending the whole length of the building, the end portions forming the non-commissioned officers' rooms. The extent of the verandah is 161 ft. 6 in. by 10 ft. wide, measuring from the wall to verandah pillars. Neither the men nor anyone else are allowed to sleep in the verandah at night. There are no jalousies or jhilmils, but there are weather screens called "jhamps," which keep out both sun and rain.

6. The bedsteads consist of 2 planks supported by trestles, and the bedding is as follows :— 1 pillow, 2 pillow covers, 2 sheets, 2 camolines, and 1 carpet.

7. The tents used at this station are of the usual square form, 14 ft. square, 5½ ft. to the tops of the "kanats" or sides, and 14½ ft. high at the apex (interior dimensions), which gives a cubic content of 1,666 ft. The number of men in a cavalry or artillery tent is 8, and they have therefore 208¼ cubic feet, and 24½ superficial feet per man. In an infantry tent there are 10 men, which gives 166·6 cubic, and 19·6 superficial feet per man.

8. The barracks are ventilated by means of ventilators in the side walls, just under the wall plate. The guard rooms have flat slab stone roofs, through which are open ventilators protected by a slab on the top. The tents have doorways on opposite sides, which afford ventilation. In the barrack rooms, when all the doors and windows are kept shut, the ventilation is insufficient. The ventilators at the top allow the foul air to escape, but do not admit the fresh. No ventilation for tents is required in addition to that derived from the doorways. The air is cooled by means of tatties made of "kuskus." The kuskus is placed on a wooden frame made to fit the doorways. Water is constantly thrown on the tatty from the outside by a man kept for that purpose, and the hot wind playing through this apparatus is rendered cool and pleasant inside the room. The tatties cost 3 annas 6 pice per square foot. A tattie for a barrack doorway of the usual dimensions, 7½ × 4½ ft., costs 7 rupees 4 annas and 2 pice, or 14*s.* 6¼*d.*

9. The present infantry barracks at this station were run up in a short space of time, when cover was urgently required for the European troops after the mutiny of 1857. These, therefore, are not permanent. The plinth and foundation are of stone and lime work, but the superstructure of the main building is of sun-dried brick and mud, the verandah pillars (which are exposed to the rain) being of kiln-burnt bricks and mud. The tents are constructed of three thicknesses of canvass, with a lining of red or blue serge inside. There are no huts.

10. The floors of the barracks are filled up to the level of the plinth (an average height of 1 foot at this station), with earth well watered and rammed, upon which is placed a layer of stone flagging. There is no passage of air beneath the floor.

11. The materials used in the construction of the barracks are good, but the barracks themselves are merely semi-temporary ones. There are no huts for Europeans. The materials used in tents are also good. No improvements are suggested. The repairs are executed quickly by the executive engineer. The senior medical officer is responsible for the general sanitary state of the camp, but his suggestions can only be carried out through the military authorities. The walls and ceilings of the barracks are cleansed and limewashed once in six months.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of the Station—*cont.*	12. The lavatories, as shown in the sketch transmitted, are small flat-roofed buildings, one being attached to each barrack. There are two baths, one for the artillery, and the other for the infantry. The bath is built entirely of brick and lime masonry, with a single tiled roof. The depth of water therein is five feet at the deepest, and four and a half feet at the shallowest part. The water is supplied by a duct leading from a well outside the building, and is carried off by a pipe passing from the bottom of the lower end of the bath through the outer wall, and thence through an open watercourse, the ground having a natural slope towards a nullah. 13. A sketch of the barrack cook-house is attached. The means of cooking are the usual Indian fire-places, and the vessels are of copper tinned monthly. The water is supplied as usual by water carriers. The drainage is insufficient, and is about to be improved. The washing of the linen is performed in the usual manner by native washermen. 14. Sketch of the privies is transmitted. The privies are built of stone, with flat slab stone roof. The night soil and urine is carried away daily by sweepers appointed for that purpose. 15. The privies have open ventilators on opposite sides; but they are not lighted at night. The barracks are lighted by means of brass lamps, suspended from the tie-beams, which burn oil. There are also oil lights placed on small niches along the walls. 16. The drainage is quite insufficient, and of the very worst description. The drainage of the privies and urinals is only on the surface, which is not suitable for buildings of this description. Closed drains and cesspools are required. In the lavatories there are "percolating cesspools;" but the soil does not admit of free percolation. In the cook-houses there is only surface drainage. The barracks and hospital are dry. The fluid refuse of the barracks is daily carried away by sweepers, a regular staff of these men being kept up for the purpose. The water of the lavatories only is received into cesspits. These cesspits are within 16 yards of the barracks; but only in one instance is there a well near to a cesspit; and this is not at all affected by its proximity. The lavatory cesspits are within 15 yards of the men's quarters, from which the hospital stands at a distance of upwards of one mile. There are no foul ditches near the station. 17. The surface of the cantonment is kept properly cleansed. The refuse, and manure, &c., are carted away to a distance, that it may be burnt. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c., interfering with the ventilation of the station, bazaar, &c. 19. The sanitary condition of the bazaar is tolerably good; but the ventilation and drainage are imperfect. The water, supplied from four wells, is good and sufficient. The latrines are too close to the houses, and are not used at present for lack of a proper establishment to keep them clean. The people are obliged to resort to the surrounding country for the purposes of nature. The inhabitants of the bazaar pay sweepers to keep their premises clean. The superintendent of bazaars maintains a strict supervision, and punishes the inhabitants by fines or otherwise, if they do not attend to this matter. It would be advisable to have the latrines moved to a distance, to keep up a proper establishment for keeping them clean, and sufficient force of sanitary police to enforce the latrines being used. The native houses near the station are more or less dirty, as is usually the case. There are dung-heaps close to them; but they are not sufficiently near the station to produce any ill effects from malaria, &c. The barracks, at the eastern end of the camp, are exposed to the disagreeable emanations from the bazaar at certain seasons. This nuisance could be prevented by the removal of the bazaar, or by building new barracks at the western extremity of the camp. 20. The slaughter-house is well situated with regard to the station, being at a sufficient distance from the barracks, hospital, and bungalows. No nuisance is experienced therefrom. 21. There is a regulation in force against picketing horses in the bazaar. They are removed to a village at a distance of half a mile from the station. There are no particular regulations in force with regard to these picketing grounds, as they are sufficiently removed from the station to obviate any nuisance being experienced therein. The manure is removed for the purposes of cultivation by the people round about. 22. There are no stables for artillery or cavalry horses. The manure is carried away to a distance and burned. The picketing ground for the European artillery is within 100 yards of the nearest artillery barrack, and that of the native cavalry is within 15 yards of the nearest huts occupied by the men. The native hospital is within 400 yards of the picketing grounds; but the European hospital is fully half a mile distant. 23. The quarters for married non-commissioned officers and men are sufficient for the present requirements of the station. Married people do not occupy barrack-rooms with the men.
Officers' Quarters.	1. The officers at this station occupy private houses. These quarters are good, and I have no improvements to suggest in regard to them.
IV. Health of the Troops.	1. The station, surrounding district, and adjoining native population, are generally healthy. 2. Fevers prevail to a considerable extent; but the mortality is not great. 3. The healthiness of the population is to be attributed to the district, being on high table-land, without swamps or marshes, and to the absence of rank vegetation. 4. All the troops at present in this station were on field service in Central India before coming here—the greater part of them for a period of nearly two years. A portion of the infantry barracks on the right of the line is less healthy than the remaining portion. The ground is rather low, the floors are not sufficiently raised, and the prevailing winds are partly excluded by higher ground to the south-west. 5. The troops at this station are not camped out. 6 to 13. No experience in hill stations. 14. Frequent change of station on the plains is not desirable for the troops. A residence of at least three or four years at a healthy station is requisite to restore the tone of a sickly regiment. 15, 16. No experience of hill stations. 17. There is no higher ground near the station which could be advantageously occupied as a hill station. 18. A red ferruginous soil resting on a subsoil of slate or trap, or a dry sandy soil provided there be sufficient slope for thorough natural drainage, is best suited for military stations. 19. The best age for a soldier to proceed to India is at about 20 years, and the period of the year for him to land there, in November and December, in order to reach his station before the hot weather sets in. The troops on landing are sent to their regiments if near at hand, if at a distance they are sent to Khandalla on their first arrival, where they remain until a

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops—*cont.*	sufficient number of them be collected to be sent off to the regiment. They then go through their usual course of drill, and take their share of duty with the remainder of the regiment. I would recommend, for preserving the health of recruits on first landing in India, moderate exercise without undue exposure to the sun, and a careful avoidance of liquor in excess, unripe fruit, &c. The diet should embrace a sufficient supply of vegetables with a moderate amount of animal food. 20. Troops should be sent direct from the home depôts to India. With due precautions a regiment's earlier years of service in the plains would not be attended with greater danger than after a more protracted residence in the country. 21. Troops are conveyed from the port to the interior in the following manners: by water when they are transported in steamers (if available) or country crafts; by land they proceed by railroad or by bullock train, when available; otherwise they proceed by ordinary marches. The regulations in force on the subject of transport are sufficient for the due preservation of the health of the troops. 22. from my experience I consider that the number of years a British soldier should serve in India ought not to exceed 12. 23. The present system of conducting medical boards, with respect to invaliding, works satisfactorily. 24. Invalids leaving India for home should embark in January or February so as to arrive at the beginning of the English summer.
Diseases.	1. There are regular inspection parades, for the discovery of incipient diseases, once a week at this station. 2. There has been scorbutic disease among the men of the 95th regiment, but as the head quarters of the regiment has left the station, there are no records to refer to by which means the proportion could be ascertained. The disease is attributable to the bad state of the health of the regiment at the time of its arrival here, and not to any peculiarity of the climate of Neemuch. 3. There are no records of the cases of hepatic disease available for Europeans, as the European regiment has lately left the station. Among the native troops hepatitis is a rare disease, only one case having occurred during the year 1860. 4. Dracunculus is not a common disease amongst the troops at this station. Amongst the native troops the admissions during the year 1860 has amounted to 1·4 per cent. 5. The proportion of venereal disease amongst the native troops is 3·3 per cent.; but the establishment of lock hospitals is a doubtful measure. 6. The troops at this station suffer from the following diseases, viz.:— *Fevers*, intermittent, remittent, and continued. *Dysentery*, acute and chronic. *Cholera*, Asiatic. *Small-pox*, and *Rheumatism*, acute and chronic. The following return shows the proportion which admissions and deaths from the above diseases bear to total admissions and deaths amongst the native troops, from January 1860 to December 1860:—

Total Admissions - - - 1,194 Total Deaths - - - - 5	Admissions.	Deaths.	Proportion of Admissions.	Proportion of Deaths.
Fever - - - - - - - -	626	1	52·4	20·0
Dysentery - - - - - -	6	—	0·5	—
Cholera - - - - - -	—	—	—	—
Small-pox - - - - - -	6	1	0·5	20·0
Rheumatism - - - - - -	78	—	6·5	—

There are no records on this head available for European troops.

7. Intermittent and remittent fevers are the most frequent zymotic diseases, and are most prevalent during the hot weather and rains. No unusual atmospheric conditions have been observed to precede or accompany these diseases. These diseases are not limited to any particular spot in the bazaar. The sanitary condition is pretty equal over the whole extent of the bazaar. The personal habits and conditions of the European troops are not such as to predispose to these diseases; but the natives, being more or less dirty in their habits, are more liable to them.
8. The duties and amusements of the troops at this station are conducive to their general state of health, provided that long exposure to the sun be avoided. They are consequently not such as to predispose to these diseases.
9. The medical officer of Her Majesty's 95th regiment has tried small doses of quinine as a prophylactic against malarious disease with advantage.
10. The removal of the troops to the high and open ground to the left of the present line is to be recommended. A more ample provision for the occupation and amusement of the men would also be advisable.

V. INTEMPERANCE.	1. The soldiers at this station are on an average temperate. There are very few confirmed drunkards amongst them, and no records exist from which the proportion of these could be obtained. 2. Drunkenness is always punished as an offence. 3. Distilled spirits are sold at the canteen, but are not permitted in the bazaar. The spirit, which is arrack, is of good quality. Each man is allowed one dram per diem. Spirit does not form part of the ration, either at the station, on the march, or in the field. The men are not allowed to get a dram from the canteen before parade. Spirit is never given as a ration to convalescents. No drinks, other than intoxicating drinks, injurious to health, are sold at the canteen or in the bazaar. 4. The consumption of spirits is injurious to the health of the troops, and is not conducive to the efficiency and internal discipline of the corps.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	5. Spirituous liquors are not supplied as part of the ration, but each man is allowed to purchase one dram from the canteen. The abolition of the sale in the canteen might prove injurious to habitual dram-drinkers, but it would be advisable to induce all the men, if possible, to take some substitute for the spirit, either beer or porter. 6. Both wines and malt liquors would prove beneficial to health as compared with spirits, but preference is given to malt liquors. 7. Coffee, tea, lemonade, soda water, and similar drinks are used at this station. Their influence on the health is beneficial, but a certain amount of stimulant is required in a tropical climate. 8, 9. It would be beneficial to prohibit the sale of spirits in the canteen, and permit only beer, coffee, tea, lemonade, &c., to be sold to the troops. 10. A reading room with a coffee shop attached is to be recommended; the coffee shop to be distinct from the canteen. 11. The bazaar regulations are such as are laid down in Jameson's Code, which apply equally to all stations. They are effectually carried out. European soldiers cannot purchase liquor in the bazaar on any consideration; natives may do so, provided it be drunk on the spot, but he may not remove it from the bazaar.
VI. Diet.	1. The ration for all European troops in the Presidency is as follows:—1 lb. of beef or mutton, 1 lb. bread, 1 lb. mixed vegetables, 4 oz. rice, 1 oz. of salt, $2\frac{1}{2}$ oz. sugar, $\frac{5}{7}$ oz. of black and green tea mixed, in proportions of $\frac{2}{3}$ to $\frac{1}{3}$ respectively, and 3 lbs. of firewood. The rations are inspected daily by the officer on duty, and the quarter-master, and sometimes by the commanding officer and surgeon. 2. The ration is in general complete, but fruit is not included in it. The vegetables are not always in due proportion. The stoppage is 3 annas and 4 pies (5*d.*) daily. The soldier has three meals per diem. Breakfast at 8 a.m. of bread and tea; dinner at 1 p.m. of meat, vegetables, and rice, made into various messes and stews; and supper at 4.30 or 4 p.m. (according to the season) consisting of bread and tea. The proportion of vegetables in this ration is 1 lb. for about seven months in the year, and $\frac{1}{2}$ lb. for the remaining five months, which include the hot season. 3. A liberal supply of potatoes at all seasons would be conducive to health, as many of the country vegetables at present supplied are not relished by the men. At present only $\frac{1}{2}$ lb. potatoes is supplied from about November until June. The rations are under the supervision of a non-commissioned officer, who superintends the cooks. There is no opportunity for the men to dispose of their rations. 4. Cooking houses, with the usual Indian fire places, are provided at this station, and are furnished with copper vessels, tinned monthly, large boilers, frying pans, dishes for baking, and tea kettles. The kitchens are clean, light, and well ventilated, and sufficiently supplied with water. The food is boiled, stewed, and baked; the cooking is properly done, and sufficiently varied. The tea is prepared in the large boiler as at home, and is not first rate. The men do not have tea, coffee, or other refreshment before a march. 5. Gardens for the cultivation of vegetables by soldiers could be advantageously established near this station, under regulations to be decided by a local committee.
VII. Dress, Accoutrements, and Duties.	1. In addition to the usual clothing worn in England, the troops at this station have for the warm weather a suit of "khakee," and serge for the monsoon. Wicker helmets, with covers, and "pugrees," are worn at all seasons. In the hot weather a waist belt and small pouch are worn, and in the cold weather an additional pouch and shoulder belt, with 20 rounds of ammunition at all times. The clothing as issued at present to the troops is suitable for the different seasons in all respects, with the exception of the head dress, which does not afford sufficient protection from the sun. A lighter and stronger description of helmet of felt instead of wicker might be substituted with advantage. The upper leather of the boots should be properly blocked, so as to fit the feet more naturally. The men on guard wear "khakee" clothing during the day, and cloth clothing from sunset to sunrise, according to the season of the year. The sentries are generally planted under cover.
Duties.	1. It would be advisable to drill the men at home and not in India, as here they have but an hour's drill in the morning and evening. 2. The men drill for an hour morning and evening four days in the week, weather permitting. They are on guard one day in seven, excepting during the period of musketry instruction. The musketry drill necessitates the men being kept out during the day exposed to the sun. The time occupied in firing 90 rounds is too great, and the number might in India be reduced to 60 rounds with advantage, as the climate does not permit of an equal amount of drill or an equal number of days as at home. From ordinary drills the men do not suffer in health. The best time for drills and parades in the hot weather is early in the morning; and we do not recommend drill in the evening at all at that season. Troops on the march should arrive at their camping ground by sunrise. The men at this station have on an average six nights in bed during the week. 3. The furthest guard is mounted at a distance of one mile from the barracks. The guards last 24 hours. There are roll calls at meals and at tattoo beatings, and on the days when there are no parades there are roll calls morning and evening. There is no doubt that night duties are trying to the men, but they are necessary to be performed. No additional precaution for preserving the health of the troops can be suggested.
VIII. Instruction and Recreation.	1. The following are the means of recreation and instruction at this station,—skittle grounds, schools with good schoolmasters, a library and reading-room, the former well lighted at night, a day-room and soldiers' gardens under the management of the men. There are neither work-shops, ball courts, theatre, or gymnasia, but the first will be shortly erected. These means are sufficient to keep the men occupied in the wet season and during the heat of the day, but a theatre and gymnasia would be a great addition, and conduce much to the pleasure and health of the men. During the hot months the men are not allowed to leave the barracks, except for necessary purposes, from 8 a.m. to 4 p.m. The result is beneficial to health. 2. Suitable buildings should be erected for workshops, theatre, and gymnasium. Should the regiment here at present be raised to its full strength, an additional building would be required as a library. 3. Soldiers' savings' banks are in existence here, and are found to be most advantageous. 4. There is no shade from trees, sheds, or verandahs, &c., to enable the men to take exercise during the day, without injury to health.

NEEMUCH, BOMBAY.

References to Subjects and Queries.	REPLIES.
IX. MILITARY PRISONS.	1. The cells at this station are objectionable in every respect. They are old gun-sheds inside the fortified square; and from their situation, immediately in contact with the outer wall, it is impossible to keep them cool or well ventilated. It is most desirable that large well-ventilated cells should be erected in a healthy situation, as a protracted residence in the present cells cannot but prove prejudicial to the health of the prisoners.
X. FIELD SERVICE.	1. There are no special local regulations for field medical service, not included in the general presidency regulations. 2. The medical officer can make any suggestions as regards the conduct of a line of march, bivouacking, camping, billeting, &c., and they are generally attended to. 3. Camping grounds are selected by the quartermaster-general's department; the main object being a supply of good water and high open ground. Should there be any objections in a sanitary point of view, the medical officer can make suggestions, which are invariably attended to whenever it is possible to do so. The regulations now in force appear to have worked satisfactorily throughout the Central Indian campaign, and no improvements can be suggested. 4. No reply to this query.
XI. STATISTICS OF SICKNESS AND MORTALITY.	No information under this head.
XII. HOSPITALS.	1. Plan of the hospital is transmitted. 2. The hospital is 1,100 yards distant from the nearest barrack, 850 yards from the nearest stable, and 450 yards from the bazaar. The hospital has an open site, and stands on high ground, which slopes away from it on all sides. There are no buildings, &c. which interfere with the ventilation. The site is generally healthy with reference to elevation, drainage, absence of malaria, &c. 3. The water supply is sufficient and wholesome. 4. The refuse water and other impurities are collected in cesspools and carried away at night. The night soil is removed in the usual way by sweepers. 5. The average height of the plinth is 3 feet above the ground. The floors are solid, and there is no perflation of air underneath; in fact, a passage of air beneath floors (in other stations) has been found not to succeed. The roof water is carried off by small channels projecting over the walls of the building. It does not sink into the subsoil, but is carried off by the natural slope of the ground. No guttering is required round the hospital for the rain-fall, as it runs off rapidly. The hospital is built principally of stone and lime masonry, the pillars and partition walls of brick. The walls and roofs are single, but the former are of a good thickness and keeps the hospital tolerably cool. There are no verandahs. The hospital consists of two flats. It was originally built as a residency, and has only been used as a hospital since the year 1857. The rooms are of various dimensions. Those on the upper story are seldom required for use as wards, as there is more than sufficient accommodation for the ordinary number of sick in the lower story. In the following table the dimensions of one room (the largest on the ground floor) are given, as that is always used.

TABLE of Accommodation.
Date of construction, 1821.

Wards.	Regulation Number of Sick in each Ward.	Dimensions of Wards. Length.	Height.	Breadth.	Cubic Contents.	Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows. Number.	Height.	Width.
		Ft.	Ft.	Ft. In.				Ft. In.			
No. 1	30, or if occasion require it 35	79	27½	25 10	56,115·67	1,870·52 1,603·3	72·4 62	1 9	11 Doors*	9½	5

* There are no windows on the lower story. The doors are double, the outer ones being Venetians, the inner glazed from top to bottom.

The hospital is so placed as to receive the full benefit of prevailing winds. The windows are French, and open inwards; they are of ample dimensions, and cannot be improved in any way.

6. None of the lower wards, with one exception, have any ventilation except by the doors and windows. The smaller of the two large rooms has 8 ventilators at the top of the room. The upper wards have ventilators in the slab stone roof. There are Venetian shutters, painted green, attached to all the doors and windows.
7. The wards are cooled during the hot months, when the hot winds prevail, by "tatties" made of "kuskus," the same being constantly watered by men employed for that purpose.
8. There are no means for warming the wards. The walls and ceilings of the wards are cleansed and limewashed once every 3 months, or as often as is required.
9. There is a privy and urinal to the N.N.E. of the hospital. Its construction is much the same as that of the barracks. It is properly drained into a cesspool, which is emptied out daily by the sweepers The cesspool is at a little distance from the privy, and is not offensive.
10. There are two wash-houses for the hospital close to the building. They are similar to the barrack wash-houses, and are sufficient for the sick.
11. There are no bath rooms, but there are ten flat baths, which are used when required, and are sufficient.
12. The native dhobies do the washing of the hospital linen in the usual manner.
13. The storage is sufficient, and dry.
14. The bedsteads in use are the common country wooden bedsteads, laced with tape, and the bedding a mattress and pillow stuffed with straw, two sheets, a blanket, and a coverlid. Iron bedsteads should be substituted as cleaner, and less likely to be infested with vermin.
15. There is one kitchen on the north side of the hospital, and another larger one on the opposite side. They are both too close to the building, and are not large enough. There is no

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	apparatus beside the usual Indian fire-places, and copper pots tinned. The cooking is properly done, and sufficiently varied. 16. The diet tables, rolls, &c., are in strict accordance with the medical regulations of the Presidency. 17. Ten ward coolies are allowed to a regiment for attendance on the sick. They are generally very attentive, and make good nurses. Besides these, every severe case is allowed a comrade to wait upon him. Such attendance is considered sufficient. 18. The sanitary condition of the hospital and the present accommodation are as good as can be expected in a private house; but should any great increase of sickness take place, the accommodation would not be sufficient. 19. Suitable buildings for cells, for insane patients, and for hot and shower baths, are required. It is also recommended that proper quarters for warrant medical officers and for the 2nd class hospital servants be erected. The room occupied as a female hospital is too small, and not sufficiently ventilated, being low in the roof and otherwise unsuitable. 20. There are sick carts drawn by bullocks and elephants, which carry about the convalescents. There is no provision for shaded walks, &c. 21. A small detached house to the south of the building is used as a hospital for the women and children, but only a temporary measure. No improvements can be made. 22. There are no special local hospital regulations not included in the General Presidency Medical Regulations. 23. With regard to change of diet and medical comforts, the medical officer has power to order whatever may be requisite under the supervision of the Deputy Inspector-General of Hospitals. The repairs to buildings are carried out by the Public Works Department. The sanitary arrangements are partly under the supervision of the medical officer and partly under the Conservancy Department. 24. There are no wards or hospital for convalescents. Such accommodation would, of course, be advantageous, but it would be attended with enormous expense.
XIII. Burial of the Dead.	1. The burial ground used for British troops is fully quarter of a mile from the nearest building. It is to leeward of the station, with reference to the prevailing wind. 2. Its area is 9,157 square yards. Its soil is the black cotton soil, and the subsoil trap rock. Surface drainage. The ground has a good slope towards the nullah. Decomposition takes place very rapidly, and the ground is carefully kept. 3. The space allowed for each grave is 7 ft. × 3 ft. wide, with an interval of 3 ft. between each. They are dug 6 ft. deep, and are never re-opened, only one body being interred in each grave. Interment takes place about 12 hours after death. There is no burial ground set apart for Native troops; they are buried in the same place as other natives. 4. The grave-yard is never offensive. The British troops are buried in the usual manner with military honours. 5. The Mussulmans dead are buried in a burial ground at a distance of 900 yards in rear of the bazaar. The Hindoo dead are burned at about the same distance. 6, 7. No injury accrues to the public health from the present practice, nor are any improvements suggested in the modes of disposal of the dead.

I. Topography.	1. The station of Ahmednuggur, distant about a mile from the town, is situated near the head of the Seena valley, about six miles from the source, and is surrounded on three sides by hills, having slight elevation above the plain, on which the station is built. The features of the ground hence admit of the water draining off freely, and little opportunity is offered for its being retained in pools and swamps. There is no wood or jungle, and little water, beyond that contained in a few pools in the bed of the Seena river, to be found in the vicinity of the station. 2. The station is about 1,900 feet above the sea level, and, being at the head of the valley, and partially surrounded by hills, it has in different places a greater or less elevation above the adjacent country. The nearest water is 52 feet distant. The station occupies the highest ground available in the neighbourhood for a cantonment.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	3. At a distance of six miles from camp is an isolated hill, on which a capacious building was constructed about 400 years ago. This place having been found to be well adapted for a sanitarium, has been occupied recently for that purpose. Its elevation above the station is 617 feet. 4. The only water in the vicinity of the station is in the bed of the Seena river, three miles from camp. The bed is usually dry for eight months in the year, and the water only appears at the surface at a few spots where pools have been formed. There is also a large nullah, a tributary to the above, which passes through camp, at some distance from the public buildings, but the quantity of water retained in the bed is very small. In heavy floods during the rainy season the water is liable to overflow the banks of both streams, but quickly subsides, and has no tendency to settle or soak into the adjacent land. There are no large pits or excavations in which the water accumulates. It is readily drained off by the natural watercourses. 5. The station, generally speaking, has an open aspect, and is well exposed to the prevailing winds. There is garden ground within the cantonment, but care is taken to prevent excessive vegetation, and hedges and trees are constantly cut and kept in order. The close proximity of the suburb or native town of Bhingar is liable to have a prejudicial effect on the health of the troops. The place contains about 3,000 inhabitants, and is kept generally in a dirty state. The streets and lanes are narrow, and badly ventilated, and the sanitary arrangements generally defective. It is desirable to extend to it the regulations in force in the cantonment, or to institute the same measures which have effected such great improvement in the state of the town of Ahmednuggur. The buildings of the station occupy a commanding position, and are not in the slightest degree liable to be affected by reflected sun-heat. The station is singularly exempt from variable winds, which have a prejudicial effect on health. It is freely exposed to the sea breeze, which diminishes the temperature, and renders the place more congenial for Europeans. 6. Generally speaking, the surrounding country is uncultivated. Towards the bank of the Seena crops are grown, but at a distance from camp. Works of irrigation are restricted to a few patches of land, watered by the surplus water from the aqueduct which supplies the camp, and by wells sunk along the river bank. It is, however, little adopted. No injurious effect has ever been known to arise from irrigation. Its extent is too limited to allow of an opinion being formed on the subject. The cultivation of rice is not prohibited, but there is not, I believe, a rice field within ten miles of Nuggur, and very few fields in the Talooka. No indigo is grown, to my knowledge, in the Nuggur Talooka, neither are hemp nor flax grown within many miles of the cantonment. A solitary and detached plot of ground may be cultivated occasionally with either of these crops, but the quantity grown is so small as not to affect health in the slightest degree. 7. The town of Ahmednuggur, containing a population of 36,000, is situated on the outskirts of camp. The suburb of Bhingar, occupied by 3,000 people, is built in continuation of the cantonment on the north-east side, and in immediate proximity to the European lines. 8. The geological structure of the district around the station comprises a trap formation, which is extensively met with in the long spurs jutting out in an easterly direction from the western range of the Ghauts. This rock is covered by a layer of black soil, which increases in thickness as the hills gradually submerge into the vallies, at the lowest points of which, and towards the banks of the principal watercourses, its depth becomes considerable, and in numerous localities the understratum of trap is found to have given place to a layer of limestone (commonly termed kunkur), which is largely employed to produce mortar for building purposes. The site on which the station stands was not in former days occupied for the purposes of habitation. 9. During the dry season water stands at a level of 18 feet below the surface. During the wet season it is only 8 feet below the surface. 10. The porous nature of the subsoil, where it consists of trap rock, which in great measure is of a soft and friable nature, affords ample means for complete under drainage of the country. The black soil, being a retentive stratum, the water which falls thereon lies on the surface till it evaporates, but the nature of the ground in the vicinity of camp does not admit of such taking place to any great extent. The rapid fall of the high ground adjacent to the station, and the defined character of the natural watercourses, preclude, in great measure, the accumulation of moisture in the subsoil of the station, beyond what is advantageous to an efficient supply of water in the wells. 11. Water is obtained from aqueducts, which have their source in large wells or reservoirs near the foot of the hills, the supply of which is further increased by percolation through the stratum, along which the excavation for the galleries or channels extend. There are numerous aqueducts and branches for the use of the town, but only one in use leads to the European lines. There is no storage of water in open tanks. The wells at the source are in many instances covered in with masonry domes. The head reservoir contains always a sufficient supply of water. These reservoirs contain no animals nor plants, and they are never used for bathing. There can be no impurities from foul drainage, &c., and no malaria can arise from any tank. 12. There are four distinct aqueducts, with numerous branches which supply the town and station. It would be difficult to arrive at an estimate of the total amount of the supply. The quality is good and wholesome, and the amount sufficient. No means of ascertaining the chemical composition. The water is discharged into distribution wells and reservoirs, and raised thence by Bheesties, who distribute the water for watering cattle and horses. Troughs are built in convenient localities in which water is maintained at a constant level. The system of supply by aqueducts has been in use for many years, and generally with satisfactory results.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	There are faults in the details of the system which demand attention, and regarding which references have often been made, but, as a whole, the arrangement is good, and adequate for the requirements of the station.
	14. The authorities appointed to determine upon and select sites for stations usually comprise members of the medical, quartermaster-general, and engineer departments, together with officers of any other service who may be considered to have a local knowledge of the subject. The system scarcely admits of improvement.
II. Climate.	The meteorological instruments at this station consist of barometer, thermometers, and rain gauge, kept at the artillery hospital, Ahmednuggur.

3. The climate of Ahmednuggur is healthy and dry like that of the Deccan generally, which is attributable to the elevation, 1,900 feet above the sea level. Except in the immediate neighbourhood of the cantonments, there are few trees. No canal, and but little irrigation. Occasional dust storms during the hot months, March, April, and early part of May. During the monsoon and cold months warm woollen clothing is necessary for the troops, lighter clothing during the hot months, March, April, and May. Morning and evening are the best hours for drills, parades, and exercises. The most unhealthy period is the hot months and immediately after the rains. In the former fevers and affections of the head and liver prevail. It is also the time when cholera and small pox have in general appeared. After the rains diarrhœa and dysentery are most prevalent.

4. There is no district near the station, that I am aware of, more conducive to health than the station itself.

5. I have served at Bombay, Cutch, Kurrachee, Poona, Deesa, Rajcote, and Ahmednuggur.

I regard the climate of Bombay as the worst for Europeans I have seen. I have known the health and efficiency of more than one regiment suffer to a very great extent from it. I may instance Her Majesty's 17th Foot and Her Majesty's 57th regiment, which contracted fever there, and from which the latter still suffers. The climate of Cutch is not considered good for Europeans. The 2d European Bombay light infantry suffered so severely there some years since that they had to be removed in a lamentable state. There was no European regiment there when I was there, but the European officers of native regiments, as well as the regiments themselves quartered at Bhooj, enjoyed good health. The climate of Kurrachee, now that good barracks have been built, is, I imagine, as good as any on the Bombay side of India. Kurrachee is subject to epidemics, such as cholera, dreadfully severe; but at the time of cholera, there were a great many more troops than there was proper accommodation for, as the barracks were low and small. They have been since replaced by the finest and best constructed barracks I have seen in India.

Near Kurrachee is the sanitarium of Gizree on the seaside, the pure air of which and the sea bathing are of great use to weakly men.

The climate of Deesa is exceedingly hot during some months, with hot winds like the blast of a furnace. They are not unhealthy, if Europeans avoid exposure to them. The outdoor heat is so great that healthy men have been struck down dead as if shot. The cold months are very pleasant, being bracing, with occasional frost. Within 50 miles there is a beautiful and salubrious station, Mount Aboo, now a regular sanitarium, but the climate is exceedingly damp and the rains very heavy. During the rainy months Mount Aboo is, on account of damp, unfit for many diseases, especially these of the chest and bowels. Fevers also are prevalent at that period. At other seasons the climate is delightful, almost European, sharp hoar frost and clear bright weather having a most exhilarating effect on the system. A somewhat lengthened experience leads me to consider the climate of Deesa, although hot, decidedly good, and one suitable to Europeans with certain precautions.

AHMEDNUGGUR. BOMBAY.

References to Subjects and Queries.	REPLIES.
II. Climate—*cont.*	The climate of Poona and Ahmednuggur are very similar, except that the latter is further from the sea, and has little sea breeze. The climate is very good, the hot months few, with cool nights, and during the rains, delightful, somewhat like that of Italy. Cold weather agreeable. During hot months, March, April, and first part of May, a hot dry wind prevails, particularly felt by those liable to liver derangement, and interfering with the action of the skin. Refreshing showers fall at the end of May, and the monsoon begins in June. October is sometimes a hot and disagreeable month. At Rajcote European officers and their families enjoyed good health. The seaside is within easy reach from it. The great want on this side of India are good sanitaria along the coast. There are no fine hills like those in the other presidencies on which to locate troops, but there are places on our coasts where sanitaria could be built, and which for certain diseases would be preferable to hill stations, such as Porebunder, Dhin, and other places on the Kattiwai coast. Dapoolie and Naree, in the neighbourhood of Vingola, on the southern coast might be named, from which one or more sites for sanitaria might be selected, the use of which might obviate the necessity for sending a great many men to England, while the quickness and facility with which men might be sent to them, would save many valuable lives, besides economizing public money.
III. SANITARY CONDITION OF STATION.	1, 2, 3. (Maps and plans.)

4. The following are the details of barrack accommodation at the station.

Date of Construction.	Permanent Barracks 1831.	Temporary Barracks 1859.
Total number of rooms or huts.	- Ditto 12.	- Ditto 12.
Total regulation number of non-commissioned officers and men	- Ditto 600.	- Ditto 600.

Barrack Rooms or Huts.	Regulation Number of Men per Room.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in Feet per Man.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		Feet.	Feet.	Feet.	Feet.			Feet.			
Permanent Barracks :											
Artillery 12 -	50	107·5	24	22	56,760	1135·2	51·60	1·5	22	4	3
Temporary Barracks :											
Infantry 12 -	50	131	22	14	40,348	806·96	57·64	1·5	12	4	3
Guard-rooms :											
Artillery - -	9	24	18	14	6,048	672	48	1·5	2	5	3·5
Infantry - -	8	22	22	14	6,776	844·5	60·5	1·5	2	4	3
Eight Prison Cells -	1	10	10	15·5	1,550	1,550	100	1·5	Ventilating apertures instead of windows.	—	—

5. The majority of the buildings are provided with windows on opposite sides of the rooms. The windows are usually fixed in folding frames opening from the inside. Verandahs are invariably provided, in some instances enclosed at the extreme ends to form quarters for non-commissioned officers and other similar purposes. The average width is 10 to 13 feet.
   In the broader verandahs the space is enclosed to add to the interior capacity of the buildings, and to furnish an additional apartment for the men to take their meals in.
6. The beds consist of iron trestles with boards. The bedding supplied by Government, good and sufficient, no improvements to suggest.
7. The tent accommodation is as follows :—European double poled for 22 men consists of fly, shell and six feet walls of three thicknesses of cloth. Interior dimensions 22 feet by 15 feet. Cubical contents 2,826 feet. Superficial area per man, $15\frac{2}{3}$ feet. European, single pole for 13 men, as above, 14 feet square, cubic contents 1,601 feet. Superficial area per man 15 feet. European hospital tent for 20 men consists of fly shell and double walls, six feet and five feet, forming a verandah. Interior dimensions 24 feet by 14 feet, cubic contents 2,821 feet, superficial area per man $16\frac{4}{5}$ feet. Tent, native double poled, for 30 men consists of single fly of two thicknesses of cotton cloth. Interior dimensions 22 feet by 14 feet. Cubic contents 903 feet. Superficial area per man $8\frac{6}{15}$ feet.
8. Ventilation in permanent barracks is effected by giving the rooms a sufficient height, with clerestory windows in the height of the walls. There are metal and wooden ventilators in the ridges of the more temporary buildings. Where the walls are low, ridge ventilation is generally employed.
   The arrangements suffice to ventilate the buildings equally well by night and day.
   No artificial means of cooling the air are required in this climate.
9. The permanent barracks are built of brick. The temporary barracks of wood framing and wattle and dab walls.
10. Floors generally are made of moorum well beaten down and consolidated with water. Their surface is raised from one to two feet above the level of the ground, but there is no arrangement for a current of air passing under the buildings.
11. The materials used for building are generally well adapted to the climate, but in temporary buildings it would be desirable to substitute kutcha brick for wattle and dab.
    Repairs are executed by the executive engineer and (by recent arrangements) partly by the barrack master, immediately on representations being made by the officers in charge of the buildings.
    The brigadier, or chief military authority here, is responsible for the sanitary state of the station.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	Barrack walls are whitewashed at intervals usually of six months, but oftener if the medical officer considers the work essential.
	12. There is a separate lavatory to each barrack, and the water after flowing off the washing bench is made to pass through a urinal, which it cleans in its passage, and thence into a cesspool.
	13. The cooking apparatus is simply a raised masonry bench with projections on which the cooking utensils are supported. The water is supplied by bheesties, and the refuse liquid is collected in cesspools which are cleansed daily. No linen is washed at the barracks; it is taken away by washermen and brought back when ready.
	14. The privies are built in the immediate vicinity of the barrack buildings. Their contents are removed daily by sweepers, and the refuse liquid of privies and urinals is collected in cesspots and removed daily.
	15. The ventilation of the privy buildings is given by a large cubic space and numerous openings.
	16. There is no drainage by sewers. Night soil is daily removed from the cesspits of privies and urinals. The ground in the vicinity of the barracks slopes sufficiently to admit of all surface and other drainage being readily carried off. No part of the buildings is damp. All the fluid refuse, as already stated, is collected in cesspits and removed daily. These cesspits are three feet by three. They are at the end of each barrack, built at the surface of the ground, distant from the wells, which cannot be injured by them. The spot of ground adjacent to the station behind Bhingor is made very offensive by the native population of the latter using it as a receptacle for dirt and refuse.
	17. Surface cleansing is done daily by the conservancy carts, and is as efficiently done as the limited establishment will admit. An increase is required and strongly recommended. Refuse and manure are removed to a considerable distance; that from stables, &c., is disposed of and carried away by purchasers.
	18. The cantonment is kept free of vegetation, except the officers' compounds. There are no old walls, hedges, &c., interfering with the general ventilation.
	19. With regard to the bazaar the surface drainage is good, and water is rapidly carried off. The water supply is abundant, and cleanliness strictly enforced. There are no latrines. No crowding permitted. Two carts and two pairs of bullocks carry away the refuse daily. Every one is obliged to collect it in a basket, and throw it into the cart as it passes the house, and constant supervision of the premises, with fine, if found offensive and dirty. The system works well and the bazaar is clean. No improvements suggest themselves. The inhabitants of Ahmednuggur and Bhingar are permitted to answer the calls of nature on the very boundary of camp. The effluvia from this cause, while objectionable, is unavoidable. When the wind blows from the north, over the native dwellings to the cantonment, the smell of ordure is very perceptible. This arises from the fact that the residents of places not under military control are allowed to have their privies near their houses, and the removal of the filth not being duly attended to, the atmosphere must become tainted. This as regards Bhinghar is repeatedly felt. The remedy is simply that the places, if permitted to remain, be daily cleansed.
	20. Animals are slaughtered on the limits of camp. No regulation relative to slaughter places, save as regards time and cleanliness. Cattle are killed morning and evening. Birds of prey and dogs devour the offal. No nuisance experienced from slaughtering places.
	21. The bazaar horses, where there are no stables, are picketed on a piece of ground behind the bazaar. The place is swept every morning, and the dung either removed or made into fuel.
	22. There are no stables belonging to the station. Artillery and cavalry horses are picketed in an open space in front of the artillery barracks, at a distance of 200 yards. Dung is removed daily, and disposed of to brick manufacturers as fuel.
	23. There are 80 separate permanent quarters for married artillery soldiers; enough for the barracks. There are none for the infantry in the temporary barracks, and it is not yet decided if any will be required.
	Officers' Quarters.—1. Officers live in bungalows, the property of private individuals. They are advantageously arranged as regards position and other sanitary respects.
IV. Health of the Troops.	1. The station of Ahmednuggur, the district, and the native population are healthy.
	2. The disease most prevalent among the native population at certain seasons is fever of the intermittent type. They have had occasional invasions of epidemic cholera and small-pox; the latter is, however, becoming more rare as the benefits of vaccination are becoming better known and more permitted among the native population, who here, as elsewhere in India, have been exceedingly averse to it. Affections of the spleen are not common.
	3. I consider the absence of jungle and rank vegetation as the great cause of healthiness in the surrounding district; also that there are no swamps or other sources of malaria.
	4. The artillery who form my medical charge are principally recruits fresh from England. No. 18, light field battery, arrived here from active service in Central India on the 16th of September 1859; generally speaking the men were in good health on arrival, and have continued so since; some have had rheumatism and some fever, but not to any great extent. Three of the barrack rooms are not so good as the others, on account of some mistake in the estimates for improvements.

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops —*cont.*	5. The troops are not, as a general rule, camped out. A portion of Her Majesty's 57th Regiment have been lately camped out for rifle practice in the cold season; their health was very good.
	6. I have not been in charge of troops at hill stations.
	7. So far as my limited experience goes, I cannot say that troops who have been at hill stations have suffered more on returning to the plains than their comrades who had not gone.
	8. My experience of hill stations has been very limited, but under certain conditions I should think that hill stations would be beneficial to the health of European troops.
	9, 10. No experience.
	11, 12. The best months for residence at hill stations would be March, April, May, and October, the hot months. There should be 12 months' residence.
	13. Troops on leaving hill stations for plains require no special precautions beyond being kept from unnecessary exposure.
	14. With regard to change of stations; I do not think troops should be moved too frequently on the plains, except the station be a decidedly unhealthy one, in which case it ought not to be occupied by European troops at all. I think a move every three years often enough. More frequent moves are distasteful to married men, besides being unnecessary.
	15, 16. No experience.
	17. About 5 miles from the cantonment there is a hill on which accommodation for about 100 men has lately been provided. It is 617 feet higher than the station; it is cooler and the nights delightful. It is useful where a short change is required, but being on the top of a lonely and barren hill, there would be a total want of occupation, and men would suffer from ennui. Water has to be brought from a considerable distance, and baths would be very expensive. Supplies have to be brought from the cantonment. The place is only fit for a few men at a time.
	18. From my experience, I should say that dry and sandy soils are most healthy for stations.
	19. I do not think that soldiers should be sent to India before 18, between which age and 24 is, I think, the best age for soldiers proceeding to India. They should land in the cold season. The barrack accommodation at Bombay, where troops are landed, is very bad. It is, I believe, in contemplation to send troops when landed at once by rail to Khundala, on the line of the Ghauts, separating the Deccan from the Concan. This, for various reasons, would be attended with many advantages. Artillery recruits are sent off without delay to Poona and Ahmednuggur.
	20, 21. I do not think it would be found convenient, nor would any benefit be derived from locating troops, intended for India, at any intermediate station, and therefore that they should be sent direct from the depôts. I would strongly advise that troops on landing should not, if possible, be delayed at Bombay, but marched direct to the railway. Those whose regiments were at a distance, to be located for a time at Khundala. Those for Poona and Ahmednuggur to proceed there at once; those for Sinde or the North-west Provinces could be sent to Kurrachee without landing at Bombay. Troops proceed direct to the interior by rail or macadamized roads.
	22. With regard to the length of a man's service in India, my own opinion inclines to 12 or 15 years, or even more, provided he takes rational care to avoid unnecessary exposure and intemperance. A man who has served some years in India, and whose constitution is good, as will generally be the case if it is allowed fair play, has become acclimatized, and therefore is worth half a dozen raw unacclimatized lads, especially where the duty entails fatigue and exposure. Were short services adopted the State would lose the services of hardy, acclimatized, and useful men, to be replaced by raw lads, useless in India until they had served three or four years, which is nearly as long as the advocates of short service think a man should serve within the tropics.
	23. As regards medical boards, it would be unbecoming in me to pass strictures on my seniors; I may, however, observe that I think the medical officer, under whose charge proposed invalids have been, is the person best qualified to judge as to what should be done with them, and that in all cases his opinion should have great weight, and not be set aside unless in certain rare instances, in which he was clearly in error. I have seen an instance of lamentable results attending the disregard of the regimental medical officer's opinion, and men returned to their regiments who had been recommended to be sent to Europe.
	24. Invalids should leave India so as to arrive in England towards the end of spring or beginning of summer.
Diseases.	1. Health parades are discontinued in the artillery, on account of being exceedingly obnoxious to the men's feelings. Men are warned in all cases to present themselves in hospital at once. Nearly 20 years' experience has proved to me that health parades are needless. They should be abolished throughout the army. Failing immediate application, the men should have "with delay" marked against their names in the report book, and they should be obliged to make good all guards and other duties missed while in hospital. This or similar punishment would be found quite sufficient to prevent delay in application.
	2. Only three cases of scorbutus have occurred among the European artillery at this station in ten years, and they were recruits from England.
	3. The admissions from hepatic disease in the same arm here have been 2·3 per cent. of the total admissions from all diseases, or 1 in 44. The deaths, 8 per cent. of the total deaths from all diseases, or 1 in 13. This disease has decreased of late years.
	4. Only 11 cases of dracunculus have occurred in 16 years in the artillery, among men who had arrived from stations where the disease prevailed.
	5. The admissions from venereal diseases have been 12·5 per cent. of the total admissions from all diseases, or 1 in 8. Next to fevers and diarrhœa, this has been the most prevalent disease at the station. It is difficult to suggest any means of diminishing this liability

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	The only method would be inspection of the women. I think it would be highly advantageous to establish lock hospitals, but to be of use they must have suitable establishments attached to them. 6. *Fever* has been the most prevalent disease in the European artillery. The proportion of fever admissions to admissions from all diseases has been as 1 to 4, and the deaths from fever as 1 to 22 of the total deaths. Ephemeral, remittent, and continued fevers prevail in the hot months, and intermittents after the termination of the monsoon. The admissions from ephemeral fever 9·2 per cent., and from intermittents 14·5 per cent., of the total admissions. During the last 10 years, 29 cases of remittent, and 20 cases of continued fevers have been admitted. There were no deaths from ephemeral fever and intermittents. Four deaths took place from remittent, 4·6 per cent. of all deaths from disease. No deaths occurred from continued fever. *Dysentery.*—The admissions from dysentery have been 2·1 per cent. of the total admissions from disease. The deaths 21·8 per cent. of the deaths from disease. In some years it has prevailed very much, as, for instance, in 1854 and 1859, at the termination of cholera, when the greatest number of casualties occurred from it. *Cholera.*—The cholera admissions have been 1 to 132 of the total admissions, and the deaths from cholera 1 in 3 of the total deaths from disease. In 1854-1859, nearly two-thirds of those attacked died *Small-pox.*—Only 5 cases, and 1 death among the artillery in 10 years. *Rheumatism* has supplied 1 in 16 of the total admissions from disease. 7. The above, with diarrhœa, are the more common diseases at the station. Catarrh and throat affections are also common. Fevers are most prevalent in the hot months and after the rains. Hepatic affections during the hot months. Catarrh and throat affections at the conclusion of the cold and commencement of the hot months. As influencing disease at the station, the proximity of the village of Bhingar, already mentioned, is to be regretted. It is a refuge for bad characters from the camp; liquor is sold in it to the soldier. It is not under camp regulations, and is crowded, ill-ventilated, and dirty. The stations of the cantonment show that almost every epidemic has its origin in Bhingar. I believe that more than one ineffectual attempt has been made by the local military authorities to have the village removed, which would be an immense advantage if it could be carried out. 8. As regards the effect of habits and duties in predisposing to disease, the great bane of the soldier's life in India is want of occupation. It is that which leads him to drink, and so lays the seeds of disease. On entering a barrack room, for one man employed six will be found doing nothing. I have the most profound opinion that too great exertions cannot be used to furnish legitimate amusement and occupation for the men. Much has been done of late years, but a great deal remains to be done. The men, as a class, are not given to literary pursuits, although this is daily mending. For one man in the ranks who could read and write in former times, ten can do so now. It is well known that in the field in India, even during the hot weather, while there is excitement among the men, there is little sickness and epidemic disease. But if the exposure is kept up without excitement, the men are almost certain to be attacked by an epidemic. Hence Europeans should only be moved during the cold months, unless on unforeseen emergency. 9, 10. Quinine is not needed as a prophylactic. No recommendations to make as to precautions to prevent epidemic disease other than those in use.
V. Intemperance.	1, 2. The soldiers on the station are temperate. No confirmed drunkards. No record kept as to diseases occasioned by intemperance. Drunkenness, *per se*, is punished as an offence. 3. There is an exclusive privilege of sale of spirits in the bazaar, which fetched by auction 19,560 rupees for the current year. It is for natives. Mowra is chiefly sold. Spirits are not a component part of the soldier's ration at the station, it being optional to purchase liquor or not. The quality is $\frac{12}{25}$ spirits, and $\frac{6}{25}$ water; not more than two drams a day allowed to each man under any circumstances. It is not a habit among the men to take a dram before parade. On march spirits are a part of the ration, and invariably so in the field. Spirits are not given as rations to convalescents. No liquors injurious to health are sold by authority in the bazaars. 4. I do not consider the consumption of spirits by troops and convalescents conducive to health; on the contrary, I consider ardent spirits injurious to health. The quantity allowed (1 dram in quarters and 2 in the field) cannot be detrimental to efficiency and discipline. 5. I would abolish the use of spirituous liquors as part of the soldier's rations. The old soldier might feel the loss, but the young soldier would derive benefit from not acquiring the taste for ardent spirits, which, were it not part of the ration, he might never taste. 6. Beyond all comparison, I am of opinion that the use of malt liquor is preferable to that of spirits or wines. I consider the introduction of malt liquor for the use of the soldier as the greatest benefit that could have been conferred on him. And I am of opinion that the more the use of malt liquor is brought into play, and the less that of ardent spirits, the better it will be for the men. 7. I do not think that tea, coffee, lemonade, and soda water, and similar drinks, are much used at this station. I am in favour of abstinence altogether from spirits, but think that malt liquor in moderation is far preferable to the slops (ginger beer, lemonade, sherbets) which men are apt to drink when thirsty, and which are apt to induce diseases of the stomach and bowels. 8. I am of opinion that it would be beneficial to suppress altogether the spirit ration, and to substitute beer in its place. 9, 10. I would permit spirituous liquors to be sold in canteens only on particular occasions, and under the special and express sanction of the commanding officer. On such occasions, the spirit should be *the best of its kind* without regard to price. 11. The bazaar regulations for the sale of liquor are as follow. They are generally speaking obeyed.

AHMEDNUGGUR. BOMBAY.

V. Intemperance—*cont.*	"No licensed liquor seller residing in the cantonment shall on any pretence whatever give or sell liquor to any European soldiers, their wives or children. All cooks, cleaning boys, madrassis, and that class of natives who act as soldiers' servants, shall drink their liquor at the shops, and on no account shall they be permitted to take any away. For the observance of this rule the kilals shall be held responsible. The liquor sellers shall purchase their supplies from the liquor contractor, and from no other person. "All liquor shops shall be closed at 9 o'clock P.M., and not opened before gun-fire in the morning." (True extract.) W. V. JONES, Captain, Superintendent of Bazaar. The canteen regulations in Jameson's code are strictly acted up to.
VI. DIET.	1. The composition of the ration in both European services is as follows:— 1 lb. bread - - - $\frac{5}{7}$ oz. of tea 1 lb. meat - - - $2\frac{1}{2}$ oz. sugar 4 oz. rice - - - 3 lbs. wood } per man. 1 oz. salt - - - 1 lb. vegetables No changes are made in this. Fresh vegetables are always given when in season. The constituents of the rations are inspected, first, by the European supervisors of the commissariat department, and then, previous to issue, by the regimental authorities. 2. A complete ration, including vegetables (no fruit) is allowed to every soldier. Non-commissioned officers and married men can each draw compensation in lieu, at the rate of three annas four pice a day, in which case they make their own arrangements for rations. Soldiers living in barracks take three meals a day; breakfast at 7 A.M.; dinner at 1 P.M., and tea at $4\frac{1}{2}$ P.M. 3. I think that the ration both as regards quantity and quality is good. There ought, however, to be a greater variety in cooking it. At present the vegetables and meat are served in the men's jamboos, and form a greasy indigestible soup-like mess. It would be better if the several messes had their meat roasted or boiled together in joints, and that the meat and vegetables should be separately served, when in cantonment. The rations cannot be sold by the men. 4. Food is cooked without any apparatus, by means of large copper cooking pots and pans. The kitchens are clean. The meat is boiled or baked, according to the wish of the men. 5. There are soldiers' gardens at this station. They are under regimental arrangement.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. In cold weather and rains the dress is cloth clothing. In hot seasons and on fatigue duties khakee and white clothing. The usual accoutrements. The serge tunic and trousers with great coat are sufficient for cold weather; the khakee, everything that could be desired for the hot. The dress on guard is according to season, and there are good guard rooms and sentry boxes. No improvement can be suggested. The late alterations in dress,—the helmet—doing away with the stiff stock, and making the clothing loose, the trousers narrower below than above, are great improvements as regards health and comfort. Every man should wear a flannel belt next the skin. To prevent foot sore is a most important object. To this end the boot should *fit well;* too great stress cannot be laid on this. The present practice of serving out boots of similar shape to men with differently shaped feet cannot be too much reprehended. Big ill-shaped boots chafe the feet after a march of a couple of miles. Small boots, if the man can march at all, will cover his feet with sores and corns, and the man's efficiency is compromised. It would require more trouble and somewhat more cost to introduce a better system, but both would be amply repaid by increased efficiency. The uppers and soles, both separate, but otherwise made, should be sent out to India, all of the largest size, and fitted and made up for each man on the spot. European shoemakers should be attached to each company for the purpose. The stocking should fit well, otherwise foot-sore will be occasioned. For a march soft woollen is best; for other duties cotton. When both boot and sock fit, the soldier should be taught to rub a little common brown soap on each heel and instep each morning before march, and with this trifling precaution (and taking off boots and socks before crossing streams) a soldier may march from the Himalayas to Cape Comorin without getting a sore foot. At present, the wonder is that every man who marches a dozen miles is not laid up with foot-sore.
Duties.	1. I do not think, as far as health is concerned, that any object would be gained by having the men thoroughly drilled before coming out to India. But I am of opinion that it would be highly advisable that the first year of a recruit's life in India should be passed in as good a climate as possible. 2. I do not think men suffer from drills or parades, provided they are not of too long duration and are at proper hours. 3. Morning is the proper time for drills and parades. They should be concluded before the sun has any power, especially in the mounted branches of the service, the men having stables afterwards. In marches the men should arrive at their camping ground as soon after sunrise as possible. This is the usual custom. The reliefs are as follows:—*European:* cavalry, 15; artillery, 10; infantry, 8. *Native:* cavalry, none; artillery, $3\frac{1}{2}$; infantry, 9. 3. Guards mount from private parade grounds and are relieved daily. Night roll calls are only resorted to when circumstances require them. Night guards are not detrimental to health, and no additional precautions are required than those usually adopted under existing regulations.
VIII. INSTRUCTION AND RECREATION.	1. The station is supplied with ball courts, skittle ground, schools, library and reading room. There are also regimental soldiers gardens, besides workshops and a theatre. There are no day rooms, and no gymnasium. There are soldiers' savings' banks. The recreations are sufficient, but should be more extensive for the station. There are restrictions on exposure during the heat of the day in hot seasons, but not during the rains or in cold weather. 3, 4. There is sufficient shade to enable the men to take exercise, without injury to health.

References to Subjects and Questions.	Replies.
IX. Military Prisons.	1. The cells are 10 feet by 10 feet. I would suggest their being considerably increased in size.
X. Field Service.	1. There are no local regulations for field service. 2. The recommendations of the medical officer on a march are invariably weighed and considered. 3. The medical officer can remonstrate, which I consider sufficient. 4. Arrangements as to field hospitals, &c., are conducted under the superintendence of the Principal Inspector General, Medical Department.
XI. Statistics of Sickness and Mortality.	1. The following are the statistics of the station:—

By order of the Acting Principal Inspector-General, Medical Department,

Office of the Principal Inspector-General, Medical Department, Bombay, 27th July 1860.

W. C. COLES, Assistant-Surgeon, Secretary.

References to Subjects and Queries.	REPLIES.
XII. HOSPITALS.	1, 2. The hospital is situated to the south-west of the barracks and is adjacent to them. The horse lines are in front or west side of the hospital, and distant about 200 yards. The hospital is at a considerable distance from the bazaar, and the only houses near it are those of the officers at the rear of the building. The site is open and freely ventilated. There are no houses, walls, &c., to interfere with this. It is healthy as to elevation, drainage, absence of malaria from river banks, nullahs, ditches, or any other nuisance. 3. The water supply is abundant and wholesome. 4. The refuse water is carried away by means of drains which lead to cesspools outside the hospital, from which it is removed and taken to a distance from camp. 5. All the ward floors are raised four feet above the surface of the ground. They are of stone. There is no perflation of air below the floors. There is no provision made for conveying away the roof water which sinks into the subsoil. There are superficial gutters for carrying away surface water. The hospital is built of brick with a tiled roof; both walls and roof are single, but sufficiently thick to keep the hospital cool. There is a verandah, eight feet wide, on both sides, which with *chicks* afford sufficient shelter from the sun's rays. The verandahs have on occasions of emergency been used as accommodation for sick, for which they are not well adapted. Parts of the verandahs are used as places (they cannot be designated as rooms) for eating meals in, there being no rooms for that purpose. There are three wards, all on the ground floor, and 60 beds. The following are the particulars of the accommodation:— Date of construction, 1831; raised and otherwise improved, 1856; wards, 3; beds, 60.

Wards.	Regulation Number of Sick per Ward.	Dimensions of Wards. Length.	Breadth.	Height, Mean.	Cubic Contents.	Cubic Feet per Bed.	Superficial Area per Bed in Feet.	Height of Bed above the Floor.	Windows. Number.	Height.	Width.
										Ft. In.	Ft. In.
1	20	70	24	24	40,320	2,016	84	1½	Top - 18 Bottom 10	4 0 6 7	3 0 3 0
2	20	64	24	24	36,864	1,843	76·9	1½	Top - 19 Bottom 11	4 0 6 7	3 0 3 0
3	20	64	24	24	36,864	1,843	76·9	1½	Top - 19 Bottom 11	4 0 6 7	3 0 3 0

The hospital is so placed as to receive the full benefit of prevailing winds. There are two sets of windows in each ward, one below and the second six feet higher up. The lower windows open in the centre, having a fan above, which can be opened or shut independently of the rest of the window. The upper windows are on a pivot in the centre, and are opened and shut by means of a rope. This double set of windows is most conducive to ventilation and coolness.

6. The windows are used for ventilation and are sufficient to keep the wards free from odour or closeness. The upper windows have jalousies, opened and shut by a rope. The lower windows have none.

7. There are no means of cooling the air. Shutting the wards up by day in the hot weather being sufficient, while the nights are always cool and pleasant.

8. No means of warming are necessary.

The walls of the wards, &c., are whitewashed every three months or oftener if necessary.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	9. Privies and urinals are at a short distance from the hospital, and connected by covered passages. The drainage is good, leading to cesspools outside, from whence the contents are removed by hospital sweepers, and taken to a distance by night carts. Water is freely used in the urinals, by which, and the use of deodorizing agents, both privies and urinals are kept quite free from noxious or offensive exhalation. 10. The bathing apparatus in India is in general very simple; copper handbasins and wooden tubs with slipper baths for those requiring hot baths near their bed side. The artillery hospital has also shower baths, and the lavatories are being enlarged. 11. The bathing rooms, when enlarged, will be sufficient for sick. 12. Hospital clothing is washed at a distance by native washermen and returned fit for use. 13. The storage is sufficient and dry. 14. The hospital cots are of iron painted, some having iron, some tape bottoming. The mattress is made of straw, bed-clothes according to season. Sheets, blanket, and counterpane in cold weather. No blanket in the warm season. Iron cots all that could be desired. 15. The cook room is convenient, and contains everything necessary for cooking diets. 17. The hospital attendance consists of the hospital serjeant and ward boys, in numbers proportioned to the sick. Patients who wish it may have a comrade as orderly to attend on him. The attendance is sufficient. 18. The sanitary condition of the artillery hospital at this station is very good. No gangrene or pyæmia. Cholera has appeared in it as elsewhere. 19. The only deficiency in the hospital is a convalescent's dining room. They dine in the verandah at present, but anything is better than dining in the wards; among other reasons, because flies, which are a pest of the first magnitude in India, are attracted by it. Such dining rooms are required for all hospitals. 20. There are grounds but no shaded walks where convalescents can take exercise. 21. There is a female hospital, with matron and assistant matron, for the wives and children of the artillery. The accommodation is not sufficient. Alterations have been recommended, but deferred. 22. There are no special hospital regulations for this station. 23. The hospital is under the direct control of the medical officer. He can suggest and make requisitions for repairs, change the diets and prescribe comforts, subject to the supervision of the superintending surgeon of the division. 24. There is no convalescent ward.
XIII. Burial of the Dead	1, 2. The burial ground is within camp limits, but at the outskirts. Its position as regards prevailing winds is favourable. Area, 300 feet by 200 feet. Soil, morum (schist); subsoil, white clay. Decomposition takes place very readily; the grounds are carefully kept. 3. Grave space 7 feet by 2 feet. Two feet between the graves. Depth of graves, 5 feet. Not re-opened except vaults, which are hermetically closed over each coffin. Interment takes place within 12 hours, always within 24 hours after death; in cases of cholera or epidemics, as soon as possible. 4. The grave yard is never offensive. 5. The dead of camp followers and bazaar people are either burnt or buried according to the customs of their caste. The burial ground and place of cremation are on the outskirts of camp. 6. No injury to health accrues from the present practice of burial, and 7. No improvement in the regulations can be suggested.

21st June 1860.

J. Hobson, Brigadier.
W. L. Cameron, Surgeon, 1st Batt. H.M.B. Artillery.
A. U. H. Finch, Capt. Engineers.

ADEN.

Accommodation:
- Queen's Troops: Artillery - 140. This is to be doubled—sanction obtained.
- Queen's Troops: Infantry - 350. To be increased to 500—sanction obtained.
- Native Troops: Artillery - 100.
- Native Troops: Infantry - 1,100.

References to Subjects and Queries.	Replies.
I. Topography.	1. Aden is a peninsula connected by a narrow neck of land with the sandy plains of the interior of Arabia. The country is nearly flat for miles, but there are high and lofty hills in the distance. There is no wood or jungle in the vicinity. 2. The cantonment at the upper end of the crater is 123 feet above the level of the sea at high tide, but the adjacent country is almost on the level of the sea for miles. The only high and healthy ground adjoining the station is Mur Shag hill, about 300 feet above high tide, which juts out into the sea a considerable distance in an easterly direction, and is therefore under the influence of both monsoons, the prevailing winds thus passing freely over it fresh from the sea without being raised in temperature by coming over any land. The difficulty of access and transport for water and provisions throw great obstacles in the way of its being used for military purposes. 3. There is no mountain or table land at all available as a military site. 4. The nearest water is at Shaik Othman, about five miles in the interior. The vicinity is not generally liable to an overflow of water; but when the violent thunder storms occur, which is usually about once every three years, the crater of Aden, on which the camp and town are situated, is overflowed for a few hours; the water, however, is soon carried off into the sea, or sinks into the subsoil, which is of a very absorbent nature. There are no water pits, but two or three ravines exist, formed by the Shum Shum range of hills. They are not prejudicial to health.

ADEN.
BOMBAY.

I. Topography—*cont.*

5. The station is free and open to the winds in an easterly direction, and although surrounded towards the west by very high hills, the winds when blowing from that quarter are too high to be much impeded by them. There are no trees, hedges, walls, or houses that can interfere with free ventilation. In the part of the cantonment occupied by the native troops the temperature is raised several degrees by reflected heat. The station is exposed to no cold winds. The wind varies but little in its direction, blowing, when the periodical monsoons set in, from the S.W. for five months, viz., from May to September, and from the E. and N.E. for the remaining period of the year; the force of it, however, varies considerably. When the S.W. monsoon sets in, the camp itself becomes exceedingly hot, from the temperature of the air being greatly raised by the wind blowing over the high hills surrounding the cantonment. At the other season a fresh cool sea breeze blows constantly into camp.
6. The surrounding country is not cultivated, there being no works of irrigation or any water in the vicinity of the station.
7. The town of Aden is situated close to military limits, and contains 25,000 inhabitants.
8. The district is of volcanic formation, the soil and subsoil of the station being formed of the disintegration and washing down of the surrounding rocks, combined with that thrown up by the sea. The town, &c. is built upon the *débris* of former buildings.
9. The average depth at which water is found in the dry season is 140 feet below the surface. There is no rainy season.
10. The rain-fall sinks into the subsoil, which is of a very absorbent nature, or is soon carried off into the sea. There are no surface springs. The drainage from the Shum Shum range of hills and Munsoorie heights passes into the subsoil of the station.
11. The water supply of the station is derived from wells. Tanks to contain about 10 or 12 million gallons, collected from the drainage of the Shum Shum hills, are in progress, called "Taweela Valley Tanks;" and one condenser at the Isthmus, and two at Steamer Point, are nearly ready for use, and they will yield, it is believed, between them 500 gallons the hour. The tanks contain, at a rough estimate, 30,000 feet square, but are at present empty. There are three reservoirs at the Isthmus, covered in, which are full, and contain one million gallons between them; they were filled by hand, but they will in future be made use of to store condensed water in as soon as the engine is working. No tanks for drinking purposes are also used for bathing. The wells are not liable to pollution from any source.
12. The amount of drinking water is limited, but will, it is expected, be much increased shortly, when the Taweela tanks are completed and the condensers in full working order. The composition of the water of wells, which form the chief source of supply to the inhabitants for drinking purposes, is—

Specific Gravity, at 60° F.	Banian, 1007·2.	Parsee, 1006·2.	Turkish Well, 1005·1.	Taweela.
Chloride of sodium - - -	32·93	29·80	30·88	19·63
„ magnesium - - -	10·11	11·50	10·97	6·35
„ calcium - - -	14·75	13·29	11·05	15·96
Sulphate of soda - - - -	13·69	7·62	8·40	5·63
Nitrate of lime - - - -	14·09	5·23	4·50	—
Carbonate of magnesia - - -	·35	·31	·45	—

The water supplied to the troops for drinking purposes, first sort, is on the whole good, but the supply is very limited. The water is raised by bullock power, and distributed through camp on donkeys and camels. In the event of our present prospects of obtaining a good supply of water failing, it can always be obtained in any quantity at Shaik Othman, and brought in on camels; or, as formerly, an aqueduct might be constructed, the ancient one not being repairable.
13. There are no other topographical points bearing on the health of the station, not included in these queries.
14. All stations are selected by a committee of experienced officers, two of whom are the medical officer and engineer. There is no improvement in this to be suggested.

II. CLIMATE.

1. There are no instruments for meteorological observations at this station, except the thermometer supplied to the hospital.
2. TABLE of Meteorological Observation prepared on the only available data, being One Year's Observation from January 1859 to December 1859.

Month.	Mean Temperature.	Month.	Mean Temperature.
January - - -	76	July - - -	93
February - -	78	August - - -	93
March - - -	83	September - -	89
April - - -	87	October - - -	81
May - - -	90	November - -	82
June - - -	94	December - -	76

3. The climate is equable throughout the year from its vicinity to the sea; and for the same reason there is in general a good deal of moisture in the atmosphere. The temperature is pretty high, and the effects of the sun's rays are always powerful. There is no cultivation. At times, especially in the hot months, clouds of dust envelop the camp, but beyond the temporary annoyance, there are no bad effects to the health of the troops, excepting some slight cases of ophthalmia at times. The troops are generally pretty healthy; the diet and clothing require to be light, and the shelter the best procurable from the sun's rays. Every precaution is taken as to the amount, nature, and times for drills, duties, and exercise. In general the most

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	healthy months at the station are those of the cold season, from November to March. May and September may be considered as the most unhealthy months. The most prevalent diseases then are fevers, diarrhœa, and scurvy. 4. Beyond a removal from the camp to Steamer Point, a distance of about six miles, or to Mur Shag hill, about a mile off, there are no other places where an invalid can be sent without taking a long sea voyage, either to Bombay or by the homeward route. 5. Captain Fuller has served at Poona, in the Poona districts, and Concan. He prefers the Concan to the Deccan, although most people prefer the latter. The climate of the former is moist, that of the latter dry; but, in his opinion, the climate of Aden is generally more salubrious and healthy than either of the above. Major Lynch has served at almost every station in the Bombay Presidency, and has found but little, if any, difference as regards salubrity. Belgaum and Poona are generally considered the most healthy stations. Dr. Davidson has served chiefly in Sinde and Guzerat, Rajpootana, and Aden. His stay at other places was too short to form an opinion. Sinde was decidedly the most unhealthy. The others, for India, were comparatively salubrious.
III. Sanitary Condition of Station.	1, 2, 3. A map of the adjacent country and plans of the station and barracks are transmitted. 4. Table of Barrack Accommodation. Date of construction:— Isthmus barracks, 1853–58. Infantry barracks, front bay, 1857–60. Old artillery barracks, unknown. Native infantry regiment barracks, 1857–58. Sappers and Miners barracks, 1858. Total number of rooms or huts, 106. Total regulation number of non-commissioned officers and men, 1,980.

N.B.—Barracks with subsidiary buildings for one company of artillery in camp at Front Bay, and ditto ditto for one company of artillery on Ras Tarshyne, and ditto ditto for two companies of infantry on Ras Tarshyne have been sanctioned, and will be built in due course.

5. The windows are on opposite sides in barrack rooms, and open towards the outside in the Front Bay barracks, and towards the inside in the Isthmus barracks. There is a verandah on both sides. In the infantry barracks at Front Bay the verandahs are double, the interior verandah being 10 ft. in width, and the exterior one being 7½ ft. wide. The Isthmus barracks have single verandahs on both sides, 12½ ft. in width. The verandahs are used as sleeping quarters at present, on account of the limited

References to Subjects and Queries.	REPLIES.
III. Sanitary Condition of Station—*cont.*	accommodation, a wing being accommodated in the barracks for three companies. There are no properly constructed jalousies or jhilmils. 6. Planks on iron trestles are used for bedsteads in barracks, and the bedding is of carpets. No improvements are suggested. 7. The tents are made of good Dungaree, of three folds of cloth, white outside and blue inside. The following Table shows their dimensions, cubic space, &c. :—

8. The barracks are ventilated by teak wood trellis work in the walls over each door and window 2 ft. high, and the same breadth as the door and window, and are within about 2 ft. of the top of the room. There are also openings in the roof formed by decreasing the slope in places. The ventilation is sufficient to keep the air pure night and day. No cooling apparatus is necessary in the barrack rooms, as the barracks are well open to the breeze at all seasons. Punkahs have been recently erected on account of the excessive sickness among the 4th King's, recently arrived from unhealthy Indian stations.

9. The Isthmus barrack walls are built of rubble and chunam. The roof is a framing of teak with a covering of jawlies. The doors and windows are of teak. The Front Bay barrack walls are of wattle and daub nine inches thick (that is, timber framing covered and plastered with mud). The roof is of jawlies, and the doors and windows of teak. The sepoys' huts are a framing of Zanzibars, with Aden rafters, the walls and roof being covered with mats and jowlies.

10. The floors are paved, and in the Isthmus barracks are over an arched ground floor. In the Front Bay barracks the space between the plinth walls under the stone paving is filled in with dry rubble. The height of the floors above the ground is 2 ft. 9 in.; there is no passage of air beneath them.

11. The materials and construction of the barracks, huts, and tents are suitable for the climate; but the Front Bay barracks would have been more durable if the walls had

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	been built of rubble and chunam, instead of wattle and daub. In future all barracks and public buildings will be built of rubble and chunam, as approved by Government. The slope of the jowlie roofs in the above barracks is too little to let the rain run off freely, being only 30°. This slope ought to be 45°; and all roofs will be hereafter built to that angle, which will heighten the walls, and make the barracks cooler. The walls of Isthmus barracks are of rubble masonry, and similar to the above in other respects. The barracks and cantonment are kept in repair by the executive engineer and barrack-master; the latter has charge of all military buildings, and he is responsible for their sanitary state. Repairs are executed immediately their necessity is brought to notice. There are no ceilings to barracks. The walls are generally coloured and whitewashed once every two years. 12. There are no baths; the men bathe in the sea. 13. The barrack cook-houses are supplied with water by bheesties or water-carriers. The refuse water is allowed to soak into the subsoil. There are plenty of native washermen for washing and drying the linen. 14. The privies are cleaned by sweepers night and morning, and the contents burnt in furnaces built for the purpose. The urinals are flushed by the drainage of the wash-houses, and the contents flow into cesspools. 15. These buildings are ventilated by an open trellis work of Aden bamboos. The barracks are lighted by common lanterns, in which oil is burnt. 16. All drainage from barracks is allowed to sink into the subsoil, which is of a very absorbent character. The contents of urinals and wash-houses are received into cesspits. These cesspits are not in the vicinity of any wells. The cesspits at Isthmus barracks are 72 feet from the urinals in the barracks; they are 10 feet in diameter, and 6 feet deep. Those at Front Bay barracks are 20 feet from the urinals, are 10 feet in diameter, and 7 feet deep, and 40 feet from the nearest barracks. No cesspools are near the hospital. The subsoil absorbs the contents of the cesspools. There are no foul ditches. 17. Refuse and manure are conveyed away daily in carts, under the direction of the barrack-master, and burnt in furnaces in Halkut Bay. The cantonment is kept clean. 18. The surface of the cantonment is naturally free from vegetation. There are no old walls, thick hedges, &c. interfering with the ventilation. 19. The Sudder bazaar is situated at the north-west end of the cantonment, and is in close proximity to the lines of the 29th native infantry, and sappers and miners. A few officers' houses are also in the vicinity. With respect to drainage, there are no regular drains near to the Sudder bazaar, but they are not required, the ground on which the shops are built being elevated and dry. The ventilation is good, and water is supplied from the Government wells in the Khusaf valley. In regard to cleanliness, care is taken that no nuisances are committed in or near the bazaar; in the rear of the shops a privy has been constructed, resorted to by the residents, and the men and followers of the native regiments. The houses are in no way crowded, and to preserve cleanliness the bazaar peons are stationed in different parts of the camp to see that nuisances are not committed in unauthorized places. We do not think that any improvement can be effected in the sanitary condition of the bazaar. The general condition of the native houses is good, and there are no dungheaps or cesspits within them. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. The distance from the place where animals are slaughtered to the station is about a mile. It is situated in the civil limits, and the entrails of the animals are buried in a spot set apart for the purpose. No inconvenience is experienced, and we can suggest no improvement in the present arrangements. 21, 22. The bazaar followers do not possess horses; all animals are stabled in the civil limits. There are no cavalry or artillery stables, nor any picketing grounds. 23. At present there are quarters for 12 married men of the infantry in Front Bay; eventually there will be quarters for 24 more, equal to the full allowance of married men to three companies located in Front Bay and the Isthmus. No barrack rooms are occupied by married men. Quarters for 12 married men of a company of artillery are sanctioned in Front Bay, and for 12 for a company of artillery at Ras Tarshyne, and for 24 married men for two companies of infantry at the same place.
Officers' Quarters.	1. There are no public quarters for officers.
IV. Health of the Troops.	1. The station may be regarded as healthy both for the troops and inhabitants. 2. Among the native population ulcers, small-pox, and fever seem to be the general diseases; spleen disease is not of common occurrence. 3. The native population may be considered generally as healthy, from there being little malarious influence and the attention paid to the general cleanliness of the place. 4. A wing of Her Majesty's 4th, or Queen's Own, arrived about six months ago from Ahmedabad, where they had been stationed for 18 months, and where they enjoyed good health on the whole, fever being the chief complaint. About 100 men of the 13th brigade, royal artillery, arrived in October 1858 from Surat, where they had been stationed about five months, and suffered a good deal from fever and dysentery. They did not enjoy good health on their arrival, but are now healthy. During their stay here the chief diseases have been fever and bowel complaints. Their accommodation is very good, and all equally healthy. 5. The troops cannot be camped out unless on emergencies. 6 to 16. No experience of hill stations. Frequent change of station in the plains is beneficial to the troops. 17. There is no higher ground near the station which could be advantageously occupied as a hill station.

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops —*cont.*	18. A dry, sandy, or gravelly soil is to be preferred for stations.
	19. Soldiers proceeding to India should be from 17 to 25 years of age, and they should land there from November to April. Troops on landing are at once marched to barracks. Recruits on first landing in India, if in Bombay, should be sent to Poona immediately, to remain there until acclimatized.
	20. Troops should be sent direct from the home depôts to India.
	21. At Aden troops land at Steamer Point, and march up to the camp, the luggage being conveyed on carts. No additional precaution is required for the preservation of the health of the troops on the route.
	22. The period of a British soldier's service in India should be from 14 to 20 years, dependent on the station they are likely to serve at.
	23. The manner of conducting medical boards at out-stations, as existing in the Bombay army, seems to prove satisfactory as to invaliding.
	24. Invalids should leave India for home at any time, so as not to arrive either in the early spring or in the winter. Their time of departure must be regulated by the route chosen.
Diseases.	1. A medical inspection of the European troops takes place weekly. Such is not required, nor would it prove serviceable for native troops.
	2. The European troops for the last two years may be said to have been exempt from scorbutic complaints, but scurvy has been rather frequent among the native troops, the proportion being 10·6 of other diseases. It is attributable to the limited supply of good fresh drinking water; the better sort of vegetables are also dear and scarce. Tanks on a large scale are now being constructed to retain the little rain water that falls, and Government condensing apparatus are now also being erected.
	3. The following Table shows the proportion of hepatic diseases and scorbutus under treatment, to the total admissions and deaths from all diseases for the years ending 31st March 1858 and 1859:—

	1858.		1859.		Total.	
	Admissions.	Deaths.	Admissions	Deaths.	Admissions.	Deaths.
Total admissions and deaths from all diseases in the European troops -	186	3	645	15	831	18

Total admissions from hepatitis in the Native troops - - - -	2	—	—	—	2	—

4. No well authenticated case of dracunculus, having its origin in Aden, is known.

5. The proportion of sick from venereal diseases to that of others bears no constant ratio. At times the hospitals will be completely free from any venereal complaints, whilst at others numerous admissions will take place. The most obvious precaution is increased encouragement to marriage; and it is certainly advisable that some sort of surveillance should be kept over the public women.

TABLE of Admissions from these Diseases for the Years 1858 and 1859, showing the Per-centage upon the Total of Admissions from all other Diseases:—

6. The troops, both European and native, suffer but little from epidemic or endemic disease. A very severe outbreak of cholera amongst the native troops took place in October 1858; it had been unknown at the station for 10 years previous. This complaint at that particular time, and for some months afterwards, committed graet ravages amongst the population on both sides of the Red Sea; it lasted among the troops only for a week.

The following Tables show the total admissions and deaths among the European and native troops for the years ending 31st March 1858 and 1859:—

7. None of the diseases enumerated in the four orders of the zymotic class show any marked change in their nosological character from what is exhibited in other places. Fevers, diarrhœa, and dysentery are most prevalent in September, and rheumatism in the cold weather. Small-pox prevails at all seasons. No particular climatic or atmospheric conditions precede or accompany their appearance. In the bazaars disease is most prevalent, but great attention is paid to the cleanliness, ventilation, and, as far as possible, the overcrowding of the dwellings is prevented. The personal habits of the troops do not predispose to these diseases, but the predisposition to them among the native population cannot be entirely removed.
8. A soldier's duties and occupations in barracks do not influence the prevalence of disease.
9. In a station such as Aden, prophylactic doses of quinine are not required.
10. For the prevention of epidemic diseases in Aden great attention is paid to cleanliness, as well as the establishment of a native village outside the fortifications, and certain quarantine regulations; but in a migratory population like this, it is impossible to prevent the ingress of persons affected with small-pox and such like diseases.

V. INTEMPERANCE.

1. The soldiers at the station are temperate; there are no confirmed drunkards.
2. There have been no admissions into hospital from diseases directly or indirectly caused by intemperance. In the royal artillery, during the half year ending 31st March 1860, the following entries have been made in the defaulters' book:—

Regimental entry - - - -	1
Battery „ - - -	12

Of these, the regimental entry and five of the battery ones were for acts of simple drunkenness, the remainder were for very slight offences. There has been one court-martial at the station since the battery first arrived at Aden in October 1858, and that was for being drunk and fighting; the man had just joined the battery. There is no record kept of abstainers, and men are often prevented joining such a thing on account of its getting known. The men who have been invalided from or died at this station have mostly arrived here with weakened constitutions. Drunkenness is always punished as an offence.
3. Arrack is sold at the canteen and bazaar, and in the latter place other descriptions of spirits also. Twenty-four parts of water are mixed with 76 of arrack. Each man consumes about three-quarters of a dram daily. Spirit, although issued by the commissariat, is paid for by the men; it forms no part of the ration at the station, on march, or in the field. The men do not take a dram before morning parade. Spirit is never given as a ration to convalescents. No drinks injurious to health, other than intoxicating drinks, are sold at the canteens; but most probably they are in the bazaar.
4. Spirits may be taken in moderation without obvious mischief; convalescents never require any, but are given beer and wine by prescription. The limited amount of spirit allowed at the canteens cannot affect the efficiency or the internal discipline of the regiment.
5. The quality of arrack allowed from the canteen cannot be injurious to health, but that sold in the bazaar is very indifferent and decidedly injurious; to abolish the sale of spirits in the bazaar would be, consequently, advantageous.
6. Malt liquor in moderation is conducive to health in this country, and it is not often the soldiers suffer from its abuse.
7. Tea is drunk at the morning and evening meals. Good lemonade and soda water are very expensive; but ginger beer is cheap, and consequently a good deal drunk. Their influence on health, efficiency, and discipline is beneficial, and far better than intoxicating drink.
8. It would not be beneficial to suppress the spirit ration, and to substitute for it beer, tea, &c., because then the soldier would purchase an inferior article in the bazaar.
9, 10. It would not be beneficial to prohibit the sale of spirituous liquors in the canteens, and to permit only beer, tea, coffee, &c., to be sold to the troops. No recommendations to suggest on these points.
11. The canteen and bazaar rules are those laid down in Jameson's code, and they are properly obeyed. The canteen is under the management of a committee, and is provided with all necessaries. No spirits, wine, or beer are allowed to be sold to a native, nor are any of those articles allowed to be taken away from the canteen, except under special authority. The canteen is accessible to the men from daybreak to tattoo beating, but is open for the issue of liquors only during such periods of the day as may be ordered by the Commander-in-Chief. The men must drink their arrack on all occasions at the place of issue, but they may take away the mid-day issue of malt for consumption with their dinner. No spirits are issued on any occasion before the usual dinner hour. Not more than one dram of arrack or one quart of malt liquor is issued at one time. Men on guard and recruits who have not finished their drill are not

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	allowed spirits. No intoxicated person or man under punishment is allowed to enter the canteen. In the bazaars no spirit is allowed to be made or vended without special permission, under a penalty of 50 rupees for the first offence, or one month's imprisonment, and for each subsequent offence the punishment of 24 lashes, or a fine of 100 rupees. No spirituous liquors are allowed to be sold to any European soldier or woman belonging to the detachment, or to any one for their use, within the limits of the cantonment.
VI. Diet.	1. The composition of a soldier's ration is as follows:—1 lb. beef or mutton, or both, in the proportion of five to two; bread, 1 lb.; vegetables, 1 lb. (but no potatoes), composed of onions, sweet potatoes, brinjalls, and bheudy; rice, 4 oz.; salt, 1 oz.; black or green tea, $\frac{5}{7}$ oz., in the proportion of two to one; sugar, 2 oz.; sweet water, 3 gallons; and brackish water, 2 gallons. No change in the diet, except that of providing potatoes. A responsible inspection of the ration is made daily by the orderly officer and quarter master. 2. A complete ration, including vegetables, is provided; but the vegetables are not good, and the beef is inferior. A soldier takes three meals a day, viz., breakfast at 8 a.m., dinner at 1 p.m., and supper at half-past 4 p.m, The proportion of vegetables entering into the constitution of the ration is $\frac{1}{3}$th dry onions, $\frac{1}{3}$th green onions, $\frac{1}{5}$th white radishes, $\frac{1}{10}$th bheudies, $\frac{1}{5}$th pumpkin, and $\frac{1}{10}$th sweet potatoes. 3. We would strongly recommend that potatoes be imported from Bombay, and issued to the European troops, the same as is now done to native troops. The Europeans do not dispose of their rations. 4. The means and apparatus available for cooking at the station are one set of copper utensils, which are tinned once a month, to every 10 men. They consist of one cooking kettle and cover, which answers as a frying-pan, and a large meat dish. The kitchens are kept clean. The water supply is from the men's allowance of three gallons sweet and two gallons brackish water per man. About three-quarters of the meat is boiled, and one quarter fried. There are no means for roasting. The cooking is generally properly done. Sometimes the meat is cooked up with the vegetables into a soup; at others, stewed; and occasionally made into pies. Tea is properly prepared morning and evening. The great want is the potato. On the march, one pint of coffee per man is issued at the half-way halting place, one cook per company being sent on overnight to prepare it. 5. Soldiers' gardens could not be established at Aden, or near it.
VII. Dress, Accoutrements, and Duties.	1. A soldier's dress and accoutrements consist of cloth tunic, cloth trousers, helmets, regulation accoutrements, serge tunics, trousers, and helmet, khakee tunics, khakee trousers, helmet, or forage cap, a forage cap with white covers according to the season. The dress and accoutrements are suitable to the climate; the Khakee clothing especially, both by day and night in the hot weather, and serge tunics and cloth trousers by night only in the cold season. There are no improvements to suggest in the dress worn at this station. In the hot weather the guard dress is Khakee; in the cold, serge tunics and cloth trousers. The men on guard are protected from sun and wet by means of sheds or verandahs.
Duties.	1. It would decidedly be advisable that all men should be drilled at home before being sent to India. 2. At Aden there are very few parades in the hot weather. Duration of drill varies according to taste of commanding officers; but half an hour is quite sufficient. The men do not suffer in health from drill. The best time for drills, parades, or marches is either early in the morning, or late in the evening. With regard to the number of nights the men have in bed during the week, the 4th Queen's have 11 nights in bed in camp, and $3\frac{1}{2}$ nights at Isthmus. The royal artillery have 4 nights in bed. 3. Guards are mounted in the immediate vicinity of the barracks, and last 12 hours by day and 12 hours by night. There are roll calls morning, noon, and evening, when there are no parades. No ill effects arise from night guards, and no additional precautions are required.
VIII. Instruction and Recreation.	1. The means of instruction and recreation at the station are as follow:—There is one ball court, two skittle grounds, two schools, with good schoolmasters, one for European and one for native regiments, and a library and reading-room sufficiently lighted at night. There are no day-rooms or soldiers' clubs, or soldiers' gardens, neither are there any workshops, theatre, or gymnasia. The means are sufficient to keep the soldiers occupied during the wet season and the heat of the day; but the men will be better off in this respect when the whole of the barracks and buildings which have been sanctioned are completed. Europeans are not allowed out during the heat of the day. 2. To improve the existing means of recreation more skittle grounds, with sheds, should be provided; also workshops, supplied with tools, and a theatre. 3. Soldiers' savings' banks have been already instituted; many men, however, remit their money to their friends. 4. There are no trees to shelter the men during the day; the men, however, can take exercise in the hot weather in the verandah of their barracks, but the addition of a gymnasium, under cover, would prove beneficial.
IX. Military Prisons.	1. There are four cells under one roof, in an open situation on the spur of a hill. There are also two cells attached to the quarter guard of the infantry regiment, Front Bay; their ventilation and sanitary state is good. Other cells are sanctioned, and will be built in due course.
X. Field Service.	1. There are no local regulations for field medical service, not included in the general presidency regulations. 2. Medical officers are always consulted as regards the conduct of the line of march of troops, bivouacking, camping, &c., and with the greatest benefit. 3, 4. Troops are never encamped out except on an emergency. Rules and regulations for field hospitals, &c. are sent. *See* Appendix.

XII. HOSPITALS.	1. Ground plans of the hospital are transmitted. 2. The hospital of the infantry in Front Bay is separated from the barracks by a wide watercourse. The position of buildings for an hospital for artillery is quite away from the barracks and on the sea shore, in a slightly elevated position; it is also quite away from the bazaar and town. Nothing interferes with the free ventilation of these buildings, and the site in every respect is quite healthy. 3. The water supply of the hospital, which is from wells, is principally brackish, and there are but few sweet wells in Aden. Tanks in the Taweela Valley, now under construction, will be finished in about 18 months, and will contain between 10 and 12 million gallons of rain water. A condenser is erected at the Isthmus, capable of supplying 5,000 gallons a day, and two small ones, at Steamer Point, capable of supplying between them 3,000 gallons per diem at present. Extra boilers and condensers are, however, to be added. 4. There is no drainage. The refuse water from the hospital is absorbed by the soil. 5. The wards in the hospital for infantry are on the ground floor, and three feet above the surrounding ground. In the artillery hospital the wards are four feet above the ground. The floors are filled in with dry rubble, and paved with cut stone. There is no perflation of air under the floor. The roof water sinks into the subsoil. There is no drainage or guttering round the hospital, it not being necessary, as the rain-fall is exceedingly limited. The foundation plinth of the hospital for infantry is constructed of rubble and chunam masonry. The walls are of wattle and daub, and the roof is covered with jawlies. The doors, windows, and ventilators are of teak. The foundation and plinth of the walls of the artillery hospital are of rubble and chunam masonry; the roof covering is of jawlies; and doors, windows, and ventilators are of teak. The walls and roof are single, but sufficiently thick to keep the hospital cool. The hospitals are supplied with verandahs on both sides, which are used for the accommodation of the sick when the hospital becomes crowded. The buildings consist of one flat. Table of Hospital Accommodation. Date of construction:—Infantry hospital, Front Bay, 1857-8; Artillery ditto, 1860. Total number of wards, 4; European General Hospital at Point unknown. Total regulation number of beds, 54.

XII. Hospitals—*cont.*	The hospital is so placed as to receive the full benefit of the prevailing winds. The windows open outwards, and their arrangement and construction is conducive to ventilation. 6. The means of ventilation are teak wood trellis work in the walls over each door and window, and an open ventilator in the roof. The means are sufficient to keep the wards at all times free from odour and closeness. There are no jalousies or jhilmils. 7. The air of the wards is cooled by punkahs. 8. No means of warming are necessary. The walls of the wards are cleansed and lime-washed about once every quarter. 9. The privies and urinals are about 40 or 50 feet off from the hospital. They are drained by hand, and are not offensive. There are no cesspits. 10, 11. There is a bath-room attached to the hospital for lavatory purposes, and for bathing the sick. It is sufficient for the purpose, and convenient. 12. The hospital linen is washed and dried by washermen. The means are amply sufficient for the purpose. 13. The storage is sufficient and dry. 14. The bedsteads used in hospital are planks on iron trestles, the same as used in barracks. 15. The kitchen is about 30 or 40 feet from the hospital. The cooking apparatus is the same as that used in barracks already described. The means are sufficient, and the cooking of diets is properly done and varied as much as possible. Potatoes are recommended. 16. As one system of diet tables and diet rolls exists under the Bombay presidency, and the returns required for working the internal economy of the hospital, and the present forms in use for keeping statistics of mortality and invaliding are the same in all corps, varying only regarding natives and Europeans, this question will have been fully answered in the report from the presidency. 17. With regard to attendance on the sick, there is an European hospital serjeant, but no nurses. Native ward coolies to attend on the sick are in constant attendance. 18. The sanitary state of the European hospitals is good. No epidemic disease has prevailed for the last two years, neither has gangrene nor pyœmia appeared. 19. There are no deficiencies or sanitary defects to notice, nor any improvements to suggest. 20. There is no special provision made for convalescents taking exercise. 21. Soldiers' sick wives and children are treated by the medical officers of the regiment. There is at present no hospital in camp especially set apart for them; but a sanitarium for females exists at Steamer Point. A female hospital is required in camp. 22. There are no special local hospital regulations which are not included in the general presidency medical regulations. 23. The medical officer's opinion is generally attended to in all matters relating to the hospitals. He has full control as to medical comforts. 24. There is no convalescent hospital at the station, nor is one required.
XIII. BURIAL OF THE DEAD.	1. The burial ground of British troops is in a direct line to the sea breeze at all seasons. 2. Its soil is gravelly. Drainage is not necessary. Cannot say whether decomposition takes place readily. The ground is carefully kept. The camp burial ground contains 74,240 square feet, the old cemetery at Steamer Point 27,000 square feet, and the new one, at the same place, 28,350 square feet. 3. The graves are seven feet long and four feet wide, with a three feet interval between each grave. The depth for an adult is six feet, and for a child five feet. Graves are only re-opened to admit the remains of relations; two or three of the same family may be interred in one grave, but seldom more. Interment is compulsory at ordinary times within 12 hours after death, and during epidemics as early as possible. The Europeans, Jews, and Mahomedans are the only nations who bury their dead, and they bury them in fresh graves about five feet deep. 4. The grave yards are never offensive. British troops are buried in the early morning or cool of the evening, according to the hour of death. 5. Camp followers or bazaar people are buried according to caste. Mussulmen and Jews bury their dead. Hindoos and Maharattas dispose of them by cremation. 6, 7. No injury to the public health accrues from the present practice. No improvements are suggested.

(Signed) E. P. LYNCH, Major, Commanding at Aden.
ROBERT H. DAVIDSON, Surgeon Superintendent Medical Department, Aden.
JOHN A. FULLER, Captain Executive Engineer.

17th July 1860.

APPENDIX TO REPORT ON ADEN.

FIELD GENERAL HOSPITAL REGULATIONS.

1. Whenever it may become necessary, in consequence of the increased number of sick and wounded men, during war or distant campaigns, to have recourse to field general hospitals in fixed situations, one or more such hospitals are to be established accordingly upon the general principles in regard to supplies of medicines, diet, and necessaries prescribed for regimental hospitals.

2. As soon as the officer commanding the troops shall have determined, in communication with the superintending surgeon, on the place at which a field hospital is to be established, and the number of patients to be transferred to it from the regimental hospitals in camp, or for whom it might be advisable to prepare hospital accommodation and necessaries, instructions are to be forthwith issued to the commissariat for the immediate preparation and supply of all articles, including cots for the sick and wounded, with the requisite establishment of hospital servants furnished by that department, according to statements to be prepared by the superintending surgeon, and sanctioned by the officer commanding the troops.

3. As the hospital establishments of European regi-

ments, of which the sick and wounded are sent to field hospitals, may admit of being for a time diminished, as many servants and as much clothing and bedding shall accompany sick and wounded men sent from these hospitals as can, in the judgment of the superintending surgeon, be spared, with reference to the present exigencies or prospective wants of such regimental hospitals.

4. The commander-in-chief, when with the army, will, in the same orders which direct the formation of one or more field hospitals, authorize the provision by the proper departments of all articles necessary for the purpose, and the entertaining of the requisite establishments. When the commander-in-chief is not present with the army, or a division of it, the officer commanding will issue orders to the above effect under discretional authority to be previously consigned to him.

5. Medicine indents are to be prepared by the surgeon or medical staff officer, who may be selected for the charge of a field hospital, under the instructions of the superintending surgeon, by whom they are to be countersigned, for such supplies of those articles as may be deemed necessary and can be spared from stores in camp in the first instance; further supplies can be drawn from the stationary depôts; or the indents shall be made on the stationary depôts, in the event of its being practicable, in consequence of previous arrangement, for the first demands, to be thence supplied in proper time.

6. Whenever the probable time and place at which it may become necessary to establish one or more general hospitals, for the reception of the sick and wounded during war, can be anticipated by the commander-in-chief, or the officer commanding the troops, the earliest intimation will be given to the commissariat and the nearest medical depôt, in order that the attention of officers in charge of those departments may be directed to the probable demands that will be made upon them, or according to the nature and probable duration of the service in prospect. Adequate supplies for one or more general hospitals will accompany the army in the first instance, or be intermediately brought forward to such advanced situation as may be found convenient.

7. The expense that may be incurred in furnishing petty stores, necessaries, &c. by the hospital storekeeper is to be charged in a contingent bill monthly, liable to be attested upon oath when required. These bills are to be countersigned by the surgeon or senior medical staff officer in charge of the hospitals in which the articles charged for shall have been expended (or for which they may have been provided in the case of any remaining on hand at the end of each month), and also by the superintending surgeon of the division, in testimony of their correctness, to the best of the knowledge and belief of these officers; statements in the form of indents, which are to be signed by the surgeon of the hospital, setting forth the several articles which have been required from time to time, for the use of the sick and wounded (?).

An advance of cash will be made on this account in the first instance, on the application of the surgeon or medical staff officer who may be appointed to the charge of the hospital, to be made through the superintending surgeon; and a sum equal to the amount required for the monthly disbursements is to be advanced by the paymaster or the collector, where there may be no pay-office at hand, upon timely application being made by the hospital storekeeper through the surgeon in charge of the hospital. The amount to be adjusted as usual in other cases of money being advanced by collectors on account of military disbursements.

9. A medical staff, consisting of a surgeon for the general charge and superintendence of the field general hospital, with a salary of Bombay rupees 600 per month, exclusive of the usual pay, batta, and tent allowance of his rank, with as many surgeons or assistant-surgeons for the duties thereof as may be necessary and can be spared, together with an assistant-surgeon for the appointment of hospital storekeeper to the general hospital, will be appointed by the commander-in-chief, to whom a list of those most available shall be submitted by the medical board or by the superintending surgeon, if those appointments be made immediately in the field, care being taken in all such cases not to remove from the charge or duties of regimental hospitals either the surgeon or assistants, to the prejudice of the management and requisite duties of those hospitals respectively; and to provide for this eventual arrangement and other calls for medical aid during war a sufficient medical staff will always be appointed in the first instance, when practicable, to do duty with every considerable division of the army that may be ordered to take the field.

10. The assistant surgeon who may be appointed to act as hospital storekeeper to general hospitals shall invariably, in addition to that charge, afford such personal medical attendance to the sick as may be required of him by the surgeon in charge of the hospital.

11. An officer or other agent of the commissariat department will attend every field general hospital that may be thus established during war, as well for the purpose of furnishing and maintaining the requisite hospital equipments and diet for the sick, as for supplying provisions to the men who may be discharged from the hospital fit for duty until they shall rejoin their corps.

12. An apothecary and steward, with such other first-class servants as may be necessary, are to be appointed, on the recommendation of the superintending surgeon, to each field general hospital that may be established during war, and such a number of second-class servants as he may deem proper shall be drawn from the commissariat for the same purpose.

13. The establishments that may be allowed for field general hospitals, as well as the establishments fixed for medical depôts in the field, are to be mustered on the 1st of each month by superintending surgeons, or the commanding officer on the spot, or officers properly authorized, as the case may be; and regular muster rolls are to be prepared for all those establishments, and to be attested in the usual manner by the mustering officer whoever he may be.

14. The pay of hospital servants employed in field general hospitals is to be drawn from the commissariat, and paid according to the rules prescribed on this subject for regimental hospitals.

15. An officer from each corps is always to be sent in charge of the sick, when they amount to 20 men, who may be sent from regiments or corps of Europeans, to field general hospitals, and a sufficient number shall remain on that duty until it may be necessary to accompany the men when ordered to rejoin their corps.

16. Whenever men may be discharged from field general hospitals as no longer requiring medical attendance, yet in the opinion of the surgeon requiring some modification of their ordinary diet, rations of provisions, if Europeans, will be supplied to them by the commissariat, or a provision roll framed on this principle, to be presented daily by the commissioned or non-commissioned officers under whose charge they may be placed, and the provisions to be thus supplied may be made to vary from articles usually issued to troops in health, according to the state of convalescence of men thus circumstanced, and for whom certificates are to be furnished by the medical staff who may have attended them in the field general hospital, describing the diet, &c., most proper for the men whilst in progress to their corps, according to which the provision rolls are to be countersigned by the officer in charge of the men, and delivered as vouchers to the commissariat department, stoppages being made from the men on this account, agreeably to the regulations on this subject, when rations or messes are furnished for men not in hospital or under such further regulations as circumstances may render expedient.

17. The regulations respecting hospital stoppages from Europeans, as detailed in Section V., are applicable to and are to be particularly attended to by medical officers in charge of field general hospitals; and when they are discharged from them, they are, as in regimental hospitals, to be furnished by them with the regular certificates.

Arrangements in the Field before and after Action.

18. When the force to which a medical officer is attached is placed under circumstances rendering it likely that in the course of service it may be engaged with an enemy, the medical officer will arrange with the adjutant or staff officer of his charge for the attendance at the hospital or his own quarters of the bandmen, to the end that they may be by him instructed in the application of field tourniquets.

19. He will explain to them their use, mode of application, &c., and will satisfy himself that they are in so much fitted for the duties they may soon be employed in.

20. While the troops are moving on, medical officers will follow their respective corps with all the empty sick carriage, &c.; but as soon as they deploy, or form for action, all, excepting one medical officer for each brigade or body of equal strength, will move to a short

distance in the rear, out of the range of musketry, and will there make their preparations for succouring the wounded and performing any operations that may then be necessary. Cordials, &c., should be at hand, and all instruments and dressings, &c., ready to be used.

21. In the rear of each brigade, and within range of musketry, one medical officer (in general, an assistant surgeon, and the junior present) will, as above stated, be stationed for the purpose of checking any alarming hemorrhage, and expediting the removal of wounded men to the stations in the rear.

22. For this purpose the doolies and other sick carriage will be placed under his orders, and the bandmen and others will assist the wounded from the ranks to the place where the medical officer is stationed, and from thence into the doolies.

23. To all of the bandmen and others employed in this duty field tourniquets should, previous to the action, have been issued. No men are to be allowed to go into doolies who can possibly walk to the rear.

24. The surgeons or medical officers of regiments are, as has been stated, to be stationed at a short distance in the rear, but out of the range of musketry, and there the wounded will be dressed, and all cases requiring immediate operation be attended to; at these posts bheesties with water will be placed, and from thence all men sent to field general hospitals will be despatched.

25. These posts are to be in as sheltered situations as possible, and if not very easily seen, to be distinguished by some flag or other conspicuous object.

26. If any town or village be situated in the rear, not far from the scene of action, in which there are houses or buildings calculated to receive wounded men, straw, &c., for bedding and abundance of water, &c., should be provided and kept in readiness for them, and to this at least all those severely wounded ought to be removed.

Removing Sick or Wounded to the rear or to Field General Hospitals.

27. The quantity of carriage rendered disposable by the consumption of stores of every kind is invariably to be notified to the superintending surgeon or medical officer performing his duty with the force, or in their absence, to the medical officers with corps, to the end that it may be taken advantage of in the transport of sick or weakly men; and in the same manner, when carriage so rendered disposable is sent to the rear, it ought to be employed in the conveyance of men to field general hospital.

28. By taking advantage of these opportunities the force can be easily disencumbered of its chronic cases.

29. To enable superintending surgeons and medical officers to perform this part of their duty without inconvenience, the place of destination, with notice of the exact day and hour when such carriage is to proceed to the rear, ought to be intimated to medical officers.

30. In addition to those means of moving sick to the rear, or at times when these do not exist, advantage must be taken, first, of the doolies and sick carriage belonging to their charge; second, of transport belonging to the country.

31. When it can possibly be avoided, the first ought never to be detached, unless for short distances, or excepting when stores of some description, such as medicines, instruments, &c., are to be brought up from the rear; and in both these cases the most positive directions should be given for its immediate return.

32. The transport of the country should be divided into classes, as doolies, cots, &c., for those unable to ride or go in carts, &c.; and carts, bullocks, tattoos, &c., for the slighter cases.

33. Medical officers must always, in person, class off their sick, and apportion the different modes of conveyance for individuals.

34. When water carriage is to be had, it is incumbent on medical officers to ascertain whether the boats are decked, open, or capable of being protected by awnings, and the cases should be allotted to them according to their condition.

35. Regimental surgeons should be directed to take advantage of every opportunity which offers for sending to the rear their chronic cases; acute cases should be kept as long as possible with their regiments, or at least so long as there remain any symptoms to subdue.

36. No case should be sent to the rear for reception into field general hospitals which can be conveniently treated in the regimental hospital with the probability of the soldier soon being made effective.

37. All convoys of sick sent to the rear should, according to their magnitude and the importance of the cases sent, be accompanied either by a medical officer or subordinate medical servant.

38. They ought to move at proper hours and by such routes as may have been laid down for them.

39. Care should be taken that every sick soldier sent to the rear have his blanket, watch cloak, warm clothing, and knapsack with him.

40. In case a subordinate medical servant only be attached to the convoy, he is to report himself to any medical officer that may pass him on the march, and, in any case of difficulty, is to request the assistance and advice of any medical officer who may be within reach.

41. The medical officer into whose charge the subordinate medical servant will deliver the men is to report the state in which they were received, with any casualties that may have occurred on the way.

42. During any halt of the convoy, the clothes and bandages, &c. of the men ought to be well washed and aired, &c., and the persons of the men themselves should be made as clean as circumstances will permit.

JACOBABAD.

Accommodation. Native Troops { Cavalry, 2,400. Infantry, 1,600.

References to Subjects and Queries.	Replies.
I. Topography.	1. The surrounding country is a desert, and is flat, sandy, and dry; there is no wood, jungle or water in the vicinity. 2. The elevation of the station is about 220 feet above the level of the sea, but it is on the same level as the adjacent country. There is no higher or healthier ground adjoining the station. 3. The nearest mountain is 60 miles distant and about 3,500 feet above the plain. 4. There are several small canals, bringing Indus water from a distance of 52 miles, which pass through or near the station; the vicinity is not, however, liable to overflow. There are artificial tanks made on purpose to retain the Indus water; but these have no prejudicial effect on health. 5. The station is perfectly open and freely ventilated; the temperature, however, is raised by the buildings being exposed to reflected sun heat. It is exposed to fresh dry cold winds in the winter months, and in the summer to fiery hot winds. 6. The surrounding country is cultivated in some parts during the autumn. All the cultivation is by irrigation, and is all round the station. Artificial irrigation has no effect on the health of the station. Fever prevails more or less in the end of autumn, when the Indus waters are drying up in the province generally. The prevailing winds then being S.S.E. or S.E., they pass over nearly 400 miles of swampy lands, and must necessarily come charged with malaria. Directly the northerly winds set in, in November, the fever disappears. There is no cultivation of rice. A little indigo was cultivated last year 2½ miles off; but no injury to public health occurred from it. 7. A large town, containing 10,000 inhabitants, immediately adjoins the station.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	8. The general nature of the soil of the district is alluvial deposit, brought down by the canals from the Indus, occasionally covered with a layer of drift sand from the desert, which lies along the north. The station occupies new ground.
	9. Water is found at a depth of 37 feet below the surface. In 1847 it was 45 feet; but from the larger quantity of Indus water brought down, and its freely percolating into the surrounding soil by means of the tanks, there has been a permanent rise of 8 feet. The wells are kept filled with Indus water during the time of its presence, which sweetens the soil by adding to the soaking supply. Wells, previously as salt as brine, have been made perfectly sweet this way.
	10. The rain-fall, which is very trifling, 8½ inches being the largest annual fall, rapidly evaporates or soaks into the ground. No drainage from higher ground passes into the subsoil of the station.
	11. The water-supply is derived from the Indus during the inundation months, and from wells at other times. There are two open tanks, one having a surface 62,600 square feet and a depth of 20 feet, the surface of the other being about 69,750 square feet and 7 feet deep. They are full from April to September. The shallow one is dry by December, the other holds a little water, when the Indus supply returns in April. The plants and animals they contain are the same as in all Indian tanks. No tank used for drinking purposes is also used for bathing, neither are the tanks or wells liable to pollution from any cause. No nuisance or malaria proceeds from any tanks within or without the station.
	12. There are the two tanks already mentioned and some 20 wells for the water-supply of the station. The Indus water, as it first comes up, is yellow and muddy from the silt in suspension, but on this being precipitated the water becomes clear, and is most delicious to drink. There are no means of giving its chemical composition; but it will be well known to chemists. The quality of the water is very good, and not injurious to health, and the amount is sufficient. It is raised either by hand in leather buckets, or by the Persian wheel. No better supply could be obtained.
	13. The climate is totally unfitted for Europeans.
	14. Hitherto stations have generally been selected more with an eye to their military importance than for their sanitary advantages. I am decidedly of opinion that all Europeans should be located as much as possible on hill stations, or at such healthy ones on the plains as can be selected to mass troops at. It is a waste of men's lives, scattering them over the country in bad climates, and where there are no means of giving them wholesome employment for mind or body during the summer months.
II. Climate.	1. The only instruments for conducting meteorological observations are the ordinary hospital thermometers.
	2. A meteorological table is prepared, but the information is very meagre, there being no instruments. The observations on rain are obtained from the political superintendent's register.

Table of Meteorological Observations, from 1st January 1848 to 31st December 1859, the year 1857 being omitted, the regiment having gone on service to Persia:—

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Rain. Inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks.
January -	—	60	—	77	43½	Have only an Annual Record from 1851 upwards. The lowest fall of rain in one year was 2½ inches, the highest 8 inches.	N.E. & N.W.W.	Moderate commonly.	—	Cloudy, often light rain and showers. An earthquake in 1855 and thunderstorms. Wind variable, occasionally high.
February -	—	65	—	82	56		N.N.E., E., & S.	Variable, light, and moderate.	—	Showers and light rains for a few days, and an occasional dust storm.
March -	—	74	—	92½	48		E.N.E. to S.W.S.	Often high, with dust.	—	Dust storms; one or two very heavy. Light showers once or twice.
April -	—	85	—	100	70		N.W. to S.E.	Variable hot and dry winds.	—	Dust storms regularly, 7 in one month, 1851. Rain very little.
May -	—	95	—	107½	83		S. & S.E. most, occasionally N.W. to S.	—	—	Dust storms six days in 1851.
June -	—	99	—	108½	89½		S.E., variable and calms.	Simoon at times.	—	Calms and variable.
July -	—	97½	—	108	87		S.E.	—	—	Showers, occasionally heavy rain. Dust storms. 4 inches and upwards of rain fell in July 1855, 16 days.
August -	—	92½	—	102½	82½		S.W. & S.E.	Very light	—	Rain hardly noticeable generally; in 1856, 14 days' rain.
September	—	91	—	101½	80½		S.E. to E. & N.E.	Light -	—	Dews at night.
October -	—	80	—	93½	69		E. to N., S.E. to W.	Light -	—	35° of change of thermometer between morning and noon observed in 1849.
November	—	70	—	87½	52½		S.E. to E.N.E.	Variable	—	Cloudy often; dry weather as a general rule throughout the year.
December	—	62½	—	79	46		N.	Moderate	—	Ditto.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	3. The climate, during the greater part of the year, is the driest in the world, the heat in summer being excessive, rendering the station totally unfit for European soldiers. The variation of temperature is sometimes very great. The cold winter months are most agreeable to Europeans, when ice and frost at night are common: this, however, lasts only for about three months, and during this period the natives of Hindoostan and the Deccan suffer much from chest complaints. Many thousands of trees have been planted in and around the station, and they sensibly diminish the heat in summer; but they have not had much effect in producing more or regular rain. On the canals drying up in the autumn, malaria is produced, and intermittent fevers prevail sometimes prostrating the majority of the troops and the inhabitants of the country. The wind at that time is generally from the S.S.E., and passes over some 350 miles of drying swamp; but the moment the northerly winds set in here, in November, the fever decreases rapidly. September and October are the most unhealthy months. The best precautions are wholesome generous diet, avoiding exposure to the sudden changes from heat to cold during the night, turning the troops out properly clad in the mornings. Drills and exercises should be much the same as at any other time during the year, guided by common sense, that is sufficient to keep the men's interest and attention alive, but not so much as to disgust or weary them; the latter will predispose to disease at any time. 4. There is no district more conducive to health nearer to the station than Kurrachee, the seaport of Scinde, which will be fully described by the authorities there. It is one of the best localities for European soldiers in India. 5. I have served for 18 years in Sinde, at the stations of Hyderabad and Jacobabad principally, 13 of which have been at the latter. Hyderabad is almost as cool as Kurrachee, being within the influence of the S.W. monsoon; but is often most unhealthy in the autumn and winter. I have served one year in the Punjab, at Peshawur, which was very unhealthy, as it is now. This might, I believe, be remedied by extensive planting of trees, the valley being almost surrounded by hills, and after rains noxious gases are evolved, which can neither escape nor be absorbed, the trees being very scarce.
III. SANITARY CONDITION OF STATION.	1, 2, 3. Plans of the station, adjacent country, and barracks are forwarded. The large canals are on an average 10 feet deep and 20 feet broad; the smaller ones are 4 feet deep and 8 feet broad. There are no drains, sewers, dung-heaps, or cesspits. 4. Table of barrack accomodation. Date of construction of lines of - - { 1st Regiment, 1859. 2nd „ 1847. 3rd „ 1844. Total number of pendalls and non-commissioned officers' quarters, 21 double and 6 single pendalls; 87 N. O. quarters. Total regulation number of non-commissioned officers and men - 2,421.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
Pendalls -	100 men in each double pendall.	450	2 × 8	Average. 8′ 5″	61,200	612	72	1½		None.	
	50 in each single.	450	8	8′ 5″	30,600	612	72	1½		None.	
N. O. Quarters	One centre room.	18	11	10′ 0″	3,171	3,171	324	1½	6	2	Semi-circular.
	Two verandahs	18	7	9′ 5″							
Guard Room: Three quarter guards, each containing - -		2 rooms 30′	15	16½	—	—	—	—	7	2	—
		1 room 15′	16								

There are no windows, but doors to each man in front. There are no verandahs to pendalls; the soldiers sleep outside altogether in hot weather and within in the cold; there are no jalousies or jhilmils.

6. The men generally use the common charpoy of the country for sleeping on, which is an oblong framework with four legs, having coarse string stretched across it; they answer very well.
7. The men provide their own tents, which vary in form from the very humblest kind of rowtee for the sowar to a small single-poled tent for a native officer.
8. No particular means exist for the ventilation of the pendalls; no means are in use for cooling the air of barrack rooms.
9. The troops at this station live in what are termed pendalls, the foundation and plinth of which are built of burnt brick and mud, the walls of sun-dried brick and mud, and the roof of beams tatties, two mats, and rafters plastered with mud. On the rifle lines now in construction the roof is supported on light burnt brick arches.
10. Floors are usually constructed of earth, well rammed, raised one foot above the general level of the ground. In the hospitals the floor is paved with burnt brick. There is no passage of air beneath.
11. The materials and construction are suitable to the climate; and we are not aware that any improvement would increase the salubrity of the pendalls, &c. &c. Barracks and cantonments are kept in repair by the engineers' department; the commanding officer of the station being responsible for the general sanitary state. All buildings except the hospital are unwhitewashed.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	12. There are no lavatories for the men; they are not required for natives, as they perform their ablutions in the open air, with the aid of bheesties or water-carriers. 13. There are no cook-houses; each man making his own cooking arrangements. The dhobies or washermen wash and dry the clothes outside of camp, either at wells or water-courses. 14, 15. There are no privies or urinals. 16. No means of sewering or draining are required in the barracks, any water thrown about quickly disappearing by absorption or evaporation. There is no fluid refuse. No part of any building used as a barrack or hospital is damp. There are no foul ditches near the station. 17. Sweepers are employed to clear up all dirt or filth in the camp, which is then conveyed to one spot on the leeward side of the cantonment, and there burnt. This is done daily, and efficiently performed. The refuse from the horse lines is spread out over the road in camp. 18. Gardens are encouraged as much as possible in the cantonment. There are no old walls, thick hedges, &c., to interfere with the ventilation of the station or bazaar. 19. Drainage is unnecessary in the bazaar. The roads are broad, and a canal, full of water for seven or eight months, runs by it; wells are also close by. It is kept scrupulously clean, is planted with trees, and well lighted with oil lamps. Bazaar sweepers are employed to keep it clean, and offenders against regulations for preserving cleanliness are severely punished. The ordinary houses of the country are made of mud, or sun-dried or kiln-burnt bricks. No dunghills or cesspits are allowed within them for a moment. No nuisance is experienced in barracks from wind blowing over the native houses. 20. The slaughter places are at one side of the town, to leeward, about a mile from the barracks, and they are only allowed in one place. The offal is buried. No nuisance is experienced from them; if there were, those causing it would be punished under the local rules. 21. The owners of bazaar horses are allowed to keep them in their own places where they like, and are held responsible that no dirt collects or nuisances are created. 22. The cavalry stables are between the lines of pendalls, each man living immediately behind his horse. They are simply sheds, or a long connected roof covering 50 horses in each row. The stalls are open, so that there is a free passage of air. The line refuse is removed daily, and spread out on the camp roads. 23. The married men all live with their families, in houses built by themselves, well in rear of the lines. None are allowed to remain in the lines.
Officers' Quarters.	1. The officers' houses are surrounded with nice well-kept gardens and trees. No particular measures for drainage are required. The trees are kept well cropped, to ensure ventilation. No improvements are suggested.
IV. Health of the Troops.	1. The seasons at Jacobabad vary extremely, and there is a corresponding amount of sickness or otherwise. From May to September the weather is intensely trying; the daily amount of sick is then from 1½ to 2 or 3 per cent. The annual number of deaths is low in the regimental hospital. It is highest in the civil hospital, numbering 12 last year, which is about an average. The district consists of a desert, here and there cultivated, and but scantily populated. With the exception of the usual fever of the country, and from which few escape, the native inhabitants appear generally speaking healthy; but for an unlimited period of residence the same cannot be said of the European inhabitants of the station, the climate being so extraordinarily trying. 2. Intermittent, quotidian, and tertian fevers are most frequent among the natives, particularly in the autumn; which diseases are in the winter and spring complicated with chest diseases, and not unfrequently with diarrhœa and dysentery. These are the most frequent causes of death. Eye disease, which has mostly assumed the chronic form at the time of application for relief, also occurs. Spleen disease is common, but less so than might be expected, and chronic rheumatism is also frequent. 3. I cannot say how miasma is generated, but all azotized matter serves as a nidus of infection. As Faraday found with what facility organic matter clings to an earthy pulverulent substance, and showed that sand was rich in ammonia, the habitat of this noxious agent is co-existent and as extensive as the desert we inhabit. Add to this the terrific heat and the deadly simoom, and an idea can be formed of the climate of Upper Sinde. In December, January, and February the cold is greatly felt, particularly by the poorer classes, the thermometer having been as low as 29° outside at 6 a.m., with occasional heavy falls of rain, and a bleak north and north-east wind. As a natural consequence the natives suffer from chest disease, rheumatism, and disease of the bowels. To those who are able to provide suitable clothing and comforts this cold season proves restorative after the debilitating effects of the hot weather. 4, 5. The troops now at Jacobabad are all natives, and have been there for the last 13 years. No portion of the men's present accommodation is more unhealthy than the rest. The troops are always moved about in the cold weather, and kept in camp as much as possible with advantage to health. 6, 7. No experience of hill stations. 8, 9. I am of opinion that for preserving health well-selected hill stations are most suitable for troops. The European troops should be massed as much as possible at such stations, and moved about in camp in the plains in the cold weather for military exercise. To restore health hill stations are almost useless. European soldiers should be sent to England for change, as it would be cheaper in the end. 10 to 13. No experience of hill stations. 14. I should say that the course most conducive to the health of troops serving in India would be to locate them as much as possible in well-selected hill or other healthy stations, such as Kurrachee, Poona, and Belgaum in the Bombay Presidency, and only send them to the plains when absolutely necessary or for exercise in the cold weather. Fixed head-quarters, with comfortable quarters for married people, having garden plots, &c., good work-shops for men, baths, ball courts, &c., would make residence in one spot preferable to change. Marching exercise in the cold country should always be practised. 15, 16. No experience of hill stations. 17. There is no higher ground near the station, that I am aware of, which could be advantageously occupied as a hill station. 18. No experience.

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops—*cont.*	19. Soldiers proceeding to India should be 20 years of age, and should land there in November. It would be highly advantageous if recruits could always be marched by easy marches in in the cold season, under good commissioned and non-commissioned officers, from the place of disembarkation to their future station, as it would greatly aid their training, physically and morally. 20. If not sent till 20 years of age troops might be sent direct from home to India, and on landing should be sent, if possible, at once to their regiments. 21. The mode of transport through Sinde has hitherto been by the Indus by steamers. Arriving early in November, they might be marched to any part of the Punjab or North-western provinces; and this would, I think, be preferable. The confinement on board the steamers is particularly irksome and bad. 22. If barrack accommodation were better, if means of employment for the soldier were more supplied, and the Indian life made more endurable to them, I believe all soldiers of the local army would gladly enlist after their first term has expired. Regiments of the line should be relieved every 10 years, those men who liked being allowed to exchange and remain. 23. I have no suggestions to make as to the mode of conducting medical boards in regard to invaliding. 24. Invalids should leave India in the cold weather, so as to arrive in England in the spring.
Diseases.	1. There are no regular inspections for the discovery of incipient diseases at the station. 2. Scorbutus has only appeared once or twice in the regiment in six years, one case being at an outpost, when probably vegetables were scarce. In the jail, however, there are always a few cases, but seldom more than six. An extra is then allowed for vegetables, with lime juice, &c. The preventive measures are, the use of anti-scorbutics and other general means. 3. Few, if any, cases of hepatic disease, uncomplicated with other diseases, are met with, but I have seen two or three cases of abscess of the liver. In one case there was original disease of the lung, in another there was no clear history; a dispensary case. Jaundice is occasionally treated, and congestion of the liver, and other derangements, both functional and organic, are not rare. 4. Dracunculus is rarely met with in Upper Sinde, but a case now and then presents itself, once or twice perhaps in a year, among the dispensary patients. In the regiment also three or four cases may be treated, but in one or two of the latter instances the patients had lately arrived from the Deccan. 5. The proportion of constantly sick from venereal disease to the total sick admitted in the hospital was,—

			Total all other Diseases.
In 1856, syphilis, primary	6		
„ secondary	6		
	—	12	1,155
In 1857, syphilis, primary	13		
„ secondary	8		
	—	21	717
In 1858, syphilis, primary	8		
„ secondary	5		
	—	13	993

6. The troops suffer from—

Fever of the endemic intermittent form.

Dysentery.—Not very frequent in the regimental hospital, the men usually applying before the complaint has got so far, and consequently a diarrhœa is cured which might be called dysenteric; but at the dispensary, from neglect, cold, and other adverse circumstances, the case is different, and there are often cases under treatment, and these serious and long continued.

Cholera is unknown, I believe; at least I have not seen or heard of a case beyond one resembling a sporadic case six years ago.

Small-pox.—One case in an adult and two or three among children in the course of seven years. These occurred in 1854 or 1855. I heard of one case in a child this spring.

Rheumatism.—Chronic rheumatism and neuralgia is extremely common, and unfortunately often slow in recovery. Acuté rheumatism with heart disease is seldom met with; indeed I do not recollect a case occurring here.

The proportion of admissions and deaths from rheumatism to the total admissions and deaths from all diseases is—

	Diseases.	Admissions.	Deaths.	Total Admissions from all Diseases.	Total Deaths.
1856.	Rheumatism, acute	25	1	1,128	3
	„ chronic	14			
1857.	„ acute	15	1	700	10
	„ chronic	23			
1858.	„ acute	2	None	971	7
	„ chronic	33			

7, 8. I do not remember any instance of zymotic disease. The bazaar has a good supply of water from wells, two large tanks, and numerous nullahs. Cleanliness has been particularly attended to, and the lines have been recently built and improved, and extremely good and capacious, allowing of free ventilation. There are no habits among the troops which predispose them to zymotic diseases.

9, 10. Men attacked with malarial disease go into hospital and undergo a regular course of treatment. Officers and men, however, when they find that fever is about them, take quinine, which wards off or cures an incipient attack in a day or two. This occurs once or twice a month, on the changes of the moon.

References to Subjects and Queries.	Replies.
V. Intemperance.	1, 2. The questions under this head evidently refer to European regiments only. The troops at Jacobabad are all natives: two-thirds Mussulmans to one-third Hindoos. All, more or less, drink ardent spirits, but instances of drunkenness among them are rarely seen. Drunkenness is punished as an offence when it causes either neglect of duty or interference with the comfort or convenience of others. 3. Distilled spirits are sold in the bazaar by a contractor who has the sole licence to open shops for the sale of liquor, but I cannot say what is the probable amount consumed by each man per diem. Spirit is only given to convalescents in very rare cases of excessive weakness. No other drinks injurious to health, besides intoxicating drinks, are sold in the bazaar. 4. It depends entirely on the soldier and his habits whether spirit is conducive or injurious to health; but the excessive consumption of it must be detrimental to efficiency and discipline. 5. With regard to the question as to whether it would be beneficial or otherwise to restrict or abolish the use of spirituous liquors in the canteen or bazaar, if the men had better means of recreation when not on duty, they would not feel so wearied by an Indian life and would not seek forgetfulness, or in some cases necessary support, in stimulants. 6. I should say malt liquors are decidedly preferable to spirits. Lord Dalhousie ordered the experiment to be tried largely. Officers with European corps can say how it succeeded. 7 to 10. These queries do not apply to this station. 11. No bazaar regulations exist. People buy as they like from the shops opened by the liquor contractor.
VI. Diet.	Not applicable to native troops.
VII. Dress, Accoutrements, and Duties.	1. The cavalry wear a dark green alkaley and pantaloons, and in cold weather a sheepskin jacket over-all, the wool inside. The infantry wear a brown double cloth tunic, with pantaloons to match. In summer all wear cotton clothing, that of the cavalry being white and that of the infantry dyed brown. The clothing is very suitable to the climate and for the soldiers' duties at all times. The head-dress lately introduced in the Bombay army—a light wicker-work helmet, with cover and puggree—is a very good one.
Duties.	1. Recruits should be drilled at home before being sent to India; his bodily strength would thus improve, and his first impressions of the country would not be mixed up with the wearying task of the drill ground. 2. All the year round there is brigade parade once a week, and each regiment parades over separately; besides awkward men are sent to the drill squads. Parade and drills last about an hour and a half. The best time for drills, parades, and marches is early morning, except in the cold weather, when none should be attempted, unless otherwise necessary, before the sun has well risen. The men have six nights in bed during the week. 3. No guards are mounted at a greater distance than a mile from barracks; guards last 24 hours. There are roll calls every evening at sunset, Sundays excepted. Night guards have no ill effect on health.
VIII. Instruction and Recreation.	1. There is a good fives court, which has the best effect of maintaining the health of the European officers. No other means of recreation exist. 2, 4. Do not apply at this station.
IX. Military Prisons.	1. There are no cells or military prison at the station.
X. Field Service.	1. There are no local regulations for field medical service not included in the general presidency medical regulations. 2. The commanding officer is responsible for the conduct of the line of march, bivouacking, &c., and when he is in doubt would take advantage of any information the medical officer could supply him with. 3. Strict cleanliness is always enforced in camp; and any suggestions by the medical officer always receive prompt and full consideration. 4. The arrangements for field hospitals, ambulances, transport of the sick, &c. are the same throughout the presidency.
XI. Statistics of Sickness and Mortality.	The following table gives the required information under this head.

Native Troops.

Years.	Corps.	Strength.	Fevers.		Eruptive Fever.		Diseases of the Lungs.		Diseases of the Liver.		Diseases of the Stomach and Bowels		Diseases of the Brain.		Epidemic Cholera.		All other Diseases.		Total.		Ratio per cent. to Strength.

By order of the Acting Principal Inspector-General, Medical Department,

Office of the Principal Inspector-General, Medical Department,
Bombay, 9th November 1860.

W. C. Coles, Assistant Surgeon,
Secretary.

References to Subjects and Queries.	Replies.
XII. HOSPITALS.	1. Plan. 2. The hospital is in rear of the centre of the lines of each regiment. 3. The water-supply is abundant and wholesome. 4. Refuse water and other impurities are removed from the hospital by sweepers, there being no sewage to the building. 5. The hospital has only one floor, raised 2½ feet above the surface of the ground. Whenever rain falls, which is not often, it soon soaks into the soil or runs off into the trenches cut to water the trees. The foundation and plinth of the hospital is constructed of burnt brick and mud, the walls of sun-dried bricks and mud, and the roof of beams, tatties, mats, and rafters plastered with mud, and supported on light brick arches. The walls are single, but sufficiently thick to keep it cool for natives. There is a ten feet verandah all round, which affords good shelter. The hospital is used more as a dispensary; only the worst cases, requiring constant attendance, being kept in it; these are placed wherever it is coolest. The building consists of one flat, and is so placed as to receive the full benefit of the prevailing winds. The windows can be opened completely so as freely to admit the air. 6. The ventilation of the wards is good. There are no jalousies or jhilmils. 7, 8. There are no means of cooling or warming the wards. The hospital is cleansed and whitewashed about once a year, or whenever necessary. 9 to 13. There are no privies. The men make their own arrangements for cooking, washing, &c. 14. The men supply their own bedsteads and bedding. The bedsteads are made of common wood, with string stretched across. 15. There is no hospital kitchen. 16. There are no diet tables or diet rolls, &c. 17. When there are very bad cases in the hospital the patient is allowed to have a comrade to attend on him. 18. The sanitary condition of the hospital is good; and no pyæmia, epidemic disease, or gangrene have appeared in the wards. 19. There are no sanitary defects to remark upon or improvements to suggest. 20. This query does not apply to this station. 21. Soldiers' sick wives and children are treated by the medical attendants at their own houses. The present arrangements are satisfactory. 22. There are no special local hospital regulations not included in the general presidency medical regulations. 23. The hospital arrangements are left to the medical officer; and any requisition or suggestion of his is promptly listened to and complied with if expedient. 24. There are no wards or hospital for convalescents at this station.
XIII. BURIAL OF THE DEAD.	1. The Mussulman burial ground is about half a mile to the west of the station, and on the opposite side from that from which the prevailing wind blows. 2. Its area is about 1,200 square yards, the soil is alluvial and sandy, and decomposition rapidly takes place. The ground is carefully kept. 3. There are no regulations with regard to graves; but they are never less than 8 feet in depth. They are never reopened. Interment generally takes place within 24 hours, but in hot weather bodies sometimes interred within 12 hours. 4. The grave yard is never allowed to be offensive. These remarks apply to the Mussulmen, only two Europeans (officers) have ever been buried at the station. 5, 6, 7. The dead of bazaar people are disposed of according to caste—the Mussulmen are buried in burial ground, and Hindoos are burnt at a spot south-west of the station. No injury to the public health accrues from the present practice; no improvements in the manner of disposing of the dead are necessary.

References to Subjects and Queries.	Replies.
I. TOPOGRAPHY.	1. There are undulating and somewhat barren hills in the country surrounding the station, on the north, south, and west sides. On the east a black cotton plain, not perfectly flat, but in gentle swells and valleys. The general aspect of the country is hilly and dry. There is no wood or jungle in the vicinity, and no large sheet of water; but a few small tanks in the environs. 2. The elevation of the station above the sea is 2,482 feet. It cannot well be said to be above the adjacent country, which is all much of the same character; but the ground occupied is thoroughly well drained. A very small nullah runs through the station which dries up almost immediately after the rain has ceased falling. There is no marsh nor anything of the sort; and the nearest tank is 2 miles off, and is not larger than the Serpentine. The best ground appears to be that on which the station is built, and there is none higher or healthier in its vicinity. 3. There is no mountain or table land near the station. Dharwar is situated on a number of little hills, and similar features of ground are met with to the west until the Ghauts are reached. Dharwar is on the spot where the water shed divides, and consequently on the highest ground generally; though some isolated hills 30 to 40 miles away from the station, between it and the Ghauts are higher by about 500 feet. Dharwar is generally higher than the crest of the Ghaut; but 2 similar isolated hills are about 4 or 500 feet higher than Dharwar; all such hills are from 30 to 40 miles distant. To the east the ground falls away to the Madras coast many hundred miles distant. 4. With the exception of wells and drinking water reservoirs, there is no water near the station; and there is no overflow of water in the vicinity. There is a little broken ground towards the north between the jail and the fort, but well to leeward, and has no effect on the health of the station.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	5. The roads through the station have trees planted along their sides, and there are gardens and hedges, but the ventilation (owing to the high situation and size of the enclosures, which, with the exception of the hedges, are generally quite clear of vegetation) is perfect. The temperature of the station is not raised by exposure to reflected sun heat. The station is exposed to the sea breeze, which in the hot weather begins to blow late in the day, and to prevent a chill, very thin clothing should not be worn in the evening, otherwise its effect is refreshing and healthy. The land or east wind also blows particularly in December, January, and February, and is apt to cause rheumatism, &c. 6. The surrounding country is cultivated where the land is good, but owing to its barren hilly nature on the south, west, and north, there is a good deal of open land bearing a poor crop of grass, and which is used for grazing cattle only. The land in the valleys on the outskirts of the station in places is formed into terraces for the cultivation of rice; but beyond these terraces, which collect the rain water a little, there are no works of irrigation. This has not been observed to have any ill effect on the health of the station. There is no prohibition to the cultivation of rice, which is but trifling at the bottom of the neighbouring valleys. Neither the cultivation of indigo, nor the preparation of hemp or flax is carried on near the station. 7. To the east of the station and joining it there is a large native town with suburbs. 8. The geological structure of the station is metamorphic clays, and mica schists, &c. The fort has been occupied by the natives for many years, but the surrounding hillocks on which the station is built, were probably not occupied by dwellings before. 9. The depth of water below the surface, owing to the undulating character of the ground, necessarily varies; in some cases, the wells are but 20 feet deep, in others from 90 to 100 feet. The rise in the wells in the rainy season is but a few feet, and many become perfectly dry in the summer. As a rule no water is injuriously near the surface at any part of the station. 10. The rain fall flows readily away from the surface, and no drainage from higher ground passes into the subsoil of the station. 11. The water supply of the station is derived from wells and tanks. There are no tanks in the station; but immediately contiguous to it there are one or two which supply the inhabitants of the town, the extent of the surface of which is in all about 30 acres; there are also two tanks within the fort. The former of these tanks are generally dry in the hot weather; but those in the fort have a good supply of water all the year round. They contain neither plants nor animals. No bathing is allowed in a tank used for drinking purposes, and in no case is there pollution from leaves or other matter falling into them. No nuisance or malaria is experienced from the tanks. 12. The water is very good and wholesome, and there is always plenty for drinking; but for washing, &c. the supply is rather scanty in hot weather. The means are not available to give its chemical composition or microscopic characters. The water is good and not injurious to health, with the exception of its being supposed to give rise to Guinea worm among the natives. The amount is generally sufficient for drinking and cooking purposes. It is of a tolerably soft quality, and is raised from the wells by a simple bucket and string. No better supply is necessary. 13. No other topographical points occur. The station is one of the healthiest in the Bombay Presidency. 14. I am unable to say what amount or kind of enquiry is gone through as to topography, climate, sanitary condition, &c. before a new station is selected, as during my experience a new one has not been chosen.
II. Climate.	1. There are no instruments available at this station for conducting and registering meteorological observation, with the exception of a common thermometer and rain gauge. 2. Table of Meteorological Observations from 1st January 1859 to 30th April 1860.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	3. The climate is very good. November, December, January, and February, especially the first three months, are dry and cool. There is a good deal of moisture in the air in March, April, and May up to June, when the rains commence. From February to June the climate is hot in the day time, but generally cool at nights. The climate is never very cold, but occasionally foggy in the hot weather in the mornings; the temperature, also, is pretty equable. The effects of tree planting in the station are beneficial. There is no irrigation in camp, nor any impurity of air. The health of the troops (natives) is very good. No particular kind of diet, shelter, or clothing is necessary, neither is any particular precaution required (beyond what is usually adopted in all cases) as to the amount of duties, &c. I may state that the Europeans, when stationed here for a short time (two years), enjoyed very good health. During the stay of the regiment here (about 16 months) July, August, September, and October have been the most healthy, and November, December, and January, when fevers and rheumatism were the most prevalent diseases, the most unhealthy months. 4. There is no district near the station, the climate of which is more conducive to health than that of the station. 5. The following is a list of stations at which I have served, with my observations on their comparative salubrity, viz.,—Upper Sinde, unhealthy; Mhow, healthy; Deesa, healthy; Bombay, unhealthy; Asseerghur, healthy; Sholapore, healthy; Belgaum, healthy; and Dharwar, healthy. The last two-named stations are the most healthy for Europeans, but I can scarcely say which is the most healthy for natives.
III. SANITARY CONDITION OF STATION.	1 to 15. No answers to these queries, there being no barracks at Dharwar. 16. There are no foul ditches near the station. 17. The surface cleansing of the cantonment is performed by sweepers, and the rubbish is buried at a distance or burnt; the cleaning is efficiently done. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c. interfering with the ventilation of the station or bazaar, &c. 19. The bazaar is crowded and narrow, and the ventilation very imperfect. There is no supply of water, but the drainage is good, and cleanliness is ensured by frequent inspections. The filth is carted away. There are no regulations for preserving cleanliness in the bazaar further than that each householder is responsible that no filth is allowed to accumulate in front or rear of his house, and that all rubbish is cleared away by a certain hour morning and evening. The condition of the houses in the town is generally good, and there are no dungheaps or cesspits within them. No nuisance is experienced in the station from wind blowing over the native buildings. 20. The slaughter-houses are of a considerable distance from military limits. The offal is buried, and no nuisance is experienced. 21. No horses are allowed to be picketed in the bazaar, but they are kept always in the town, and no inconvenience is experienced. 22. There are no cavalry or artillery at Dharwar. 23. There are no quarters for married non-commissioned officers or men at this station.
Officers' Quarters.	1. The sanitary condition of the officers' quarters is very good; the bungalows are well ventilated, and the grounds well drained. No improvements to suggest.
IV. HEALTH OF THE TROOPS.	1. The station, district, and adjoining population are healthy. 2. The diseases most prevalent among the natives are fevers, bowel complaints, rheumatism, and guinea worm; cholera every now and then makes its appearance epidemically, but there is scarcely any spleen disease. 3. I attribute the healthiness of the native population to the following facts;—the country is generally speaking, open, well cultivated, and free from malaria; in the town of Dharwar sanitary measures are tolerably well carried out for a native town; the heat is never very great, the nights generally cool, and the natives generally in this part of the country are well-to-do, and contented. 4. The troops at this station were at Belgaum about four and a half years, with the exception of about 13 months, when the greater part of the regiment was in Persia. They left Belgaum on the 22nd December 1848, and were then in a good state of health. The principal diseases there were fevers, bowel complaints, and rheumatism. They arrived here on the 25th December 1848 in a good state of health. Fevers, bowel complaints, rheumatism, an outbreak of epidemic cholera, and latterly, guinea worm, have been the principal diseases since coming here. No portion of the accommodation here, as regards the sepoy lines, is more unhealthy than the rest. 5. The troops at the station are not camped out. 6 to 13. I am unable to answer these queries from a want of experience of hill stations. 14. Frequent change of stations in the plains is beneficial to the health and spirits of troops, if the stations be healthy, and the men march in cold weather. 15. I have no knowledge regarding the barrack and hospital accommodation at hill stations. 16. I cannot say, from inexperience, what ranges of elevation above the sea, are most suitable as sites for hill stations. 17. There is a hill on the Ghauts at Kerowlee which has been recommended as a sanitarium. It has good water on the top and table land convenient for building and exercise. Its distance from the station is about 45 miles, and to reach it about 3 miles of road on the plain (to connect with an existing road) would have to be made, and a road up the hill itself. Its elevation is about 3,000 feet above the sea. 18. I have had no experience to enable me to say what classes of surface and sub-soil are the most healthy or unhealthy. 19. I should say that from 20 to 25 years of age is the best age for a British soldier to proceed to India, and he should land here in the cold weather. In my opinion, strict enjoinment of temperance in eating and drinking, clothing suitable to the climate and season (especially as regards head-dress), exercise short of fatigue, as little exposure to the heat of the sun as possible, together with an approved system of barrack accommodation with all its appliances, moral and physical, would be the best means to resort to, to preserve the health of the recruit.

IV. Health of the Troops —*cont.*	20. My experience with European troops has not been great; but I am much inclined to think that sending them out to India direct would, on the whole, be the best plan. European troops on landing should always, if possible, be sent to cool and elevated stations, such as those on the table lands in this Presidency, Poona, Kirkee, Belgaum, &c. 21. There is no water transport from the port to the interior in this Presidency for troops, but they must either march, or are conveyed by bullock dawk, or railway carriages. I have never seen either of these modes of transport in operation, and am unable to give any opinion as to their fitness for preserving the health of the soldier en route. 22. As far as my experience goes, I think that from 12 to 15 years should be the extreme period of service in India for an European soldier. I mean for the soldiers generally in a Queen's regiment (line). 23. In my experience the manner of conducting medical boards, as regards invaliding, has always been such as to avoid conflict of opinion. 24. Invalids proceeding from India home should leave so as to arrive about the beginning of summer.
Diseases.	1. There are no inspection parades for the discovery of incipient diseases at this station. 2. There has been no scorbutic disease at this station. I have never seen this disease affecting any of the troops in this country, except during the Persian campaign, when it made its appearance to some extent amongst the natives, arising from bad water, and a deficiency of vegetables. When the causes were removed the disease soon disappeared. 3. Hepatic disease has been very rare in the regiment since its arrival here. There has been only one case, and that a slight one. 4. The proportion of cases of dracunculus usually under treatment, since the arrival of the regiment here, has been about eight per cent. The disease is supposed to arise from the use of water, but whether it is the external or internal use of it, or from its being used in both ways, that gives rise to the disease, is a point not yet cleared up. I know of no preventive, though perhaps boiling the water before use might act as such. 5. The proportion of venereal diseases, since the arrival of the regiment here, has been about eight per cent. I have not had very much experience with Europeans; but from all I have seen and heard, I certainly think it would be advantageous to establish lock hospitals. 6. The troops at this station have suffered from the following diseases :— *Fevers.*—Intermittent fever is the most prevalent disease here amongst the sepoys, but they do not suffer much from it, as it is generally of a mild uncomplicated nature. A few cases of remittents have also occurred, but most of them of a mild description. *Dysentery.*—Only four cases of this disease have been admitted at this station, and, with one exception, were of a very mild and simple kind. *Cholera.*—An outbreak of this disease in the epidemic form occurred in the months of last May, June, and July. The great proportion of cases taking place in May. It appeared in the most virulent form. *Rheumatism.*—This disease generally occurs in the chronic form, and is often very long and tedious in its cure.

The following table shows the proportion which admissions and deaths from the above diseases bear to the total admissions and deaths :—

Diseases.	Admissions to Total Admissions.	Deaths to Total Deaths.
Intermittent Fever	23 per Cent.	No deaths.
Remittent ditto	1·5 ,,	Ditto.
Dysentery	0·6 ,,	4·5 per Cent.
Cholera	4·7 ,,	77·2 ,,
Rheumatism	3·0 ,,	No deaths.

	7. The more frequent zymotic diseases belong to the miasmatic class; but the enthetic and parasitic orders also comprise a considerable number of the prevailing diseases. These diseases are mostly prevalent in the hot and cold weather. The means are not available at this station to test and record any atmospheric or climatic conditions and changes that might precede or accompany such diseases; but no such conditions or changes have been observed. In the station itself, these diseases have been most prevalent in the sepoys' lines. Their sanitary condition, with the exception that they adjoin the town of Dharwar, at their eastern extremity, is very fair. I am not aware that any particular part of the town of Dharwar is more liable to the above diseases than another. For a native town, sanitary measures are tolerably carried out in Dharwar, I believe. The personal habits and conditions of the natives, such as regard their general want of cleanliness, not only with respect to themselves personally, but in and around their houses; their close and badly-ventilated dwellings; their often poor and scanty food and clothing, with many other causes, will always predispose them (the natives) to zymotic diseases. 8. This question refers to European troops. 9. Small doses of quinine have not been tried as a prophylactic against malarial disease at this station. 10. Beyond a strict enforcement of all sanitary measures I have no recommendations to make on any of the preceding points, except it be, that when epidemic disease, such as cholera, makes its appearance amongst the troops of a station, they ought, if possible, to be marched out of camp some little distance, and there located for a time.
X. Field Service.	1. There are no local regulations for field medical service not included in the general Presidency regulations. 2. As far as my experience goes, medical officers are rarely if ever consulted as to the conduct of a line of march, billeting, &c.; but at the same time I am of opinion that good practical suggestions from medical officers, would generally be attended to. 3. As far as my experience goes, which has been limited as regards field service, camp regulations for the preservation of health were good, camping grounds well selected, and general sanitary regulations well carried out. The water supply generally abundant; but the water not always to be had of the best quality; in fact, often bad. I am of opinion that tents on field service are generally too much crowded, and field hospitals also. I cannot say what

References to Subjects and Queries. | REPLIES.

X. Field Service—*cont.*

powers other medical officers may have had in these matters, but any suggestions I have ever thought it advisable to make regarding those under my own care, were always to the best of my recollection followed.

4. The arrangements for field hospitals, ambulances, &c., &c., are detailed in the medical code of regulations of the Presidency.

By order of the Acting Principal Inspector-General, Medical Department,

Office of the Principal Inspector-General Medical Department,
Bombay, 17th August 1860.

W. C. COLES,
Assistant Surgeon, Secretary.

XII. HOSPITALS.

1, 2. There is a permanent hospital at this station for natives, but it was used by the European troops whilst they were located here. There is also a temporary hospital erected for the use of the native regiment. Both are well away from the bazaar. The permanent hospital is very much confined, being contiguous to out-buildings, &c., which obstruct the ventilation. The temporary hospital, on the contrary, is perfectly open, and thoroughly ventilated. Both sites appear to be perfectly healthy.

3. The water is brought to the hospital by bheesties, and is good.

4. There is no artificial drainage to either hospital, but refuse matter is carried away by sweepers.

5. These native hospitals are simple buildings on one floor. The floors are well raised off the ground by solid filling up, but there is no perflation of air beneath them. In the permanent hospital the roof water is received in open masonry drains laid in the ground below the eaves, and conducted away to a distance; in the temporary hospital it simply falls on the ground, which is on a slope, and is carried away immediately. The permanent hospital has brick and lime walls, with a double tiled roof, and is moderately cool. The walls of the temporary hospital are of lath and mud plaster, very thin, but still quite sufficient to keep the building cool. Each building has a verandah on each of its long sides 10 feet wide, which affords excellent shelter from the sun; they are not used for the accommodation of sick or convalescents. The temporary hospital is placed so as to receive the full benefit of the prevailing winds, but the permanent one faces too much to the south. The windows open perpendicularly in the centre, and are fitted in the permanent hospital with glass, and with venetians outside, and are perfectly well arranged for coolness and ventilation. The temporary one is simply fitted with plank shutters.

6. The ventilation of the permanent hospital is not good; it depends entirely on the doors and windows, and what little foul air can escape through the tiles. The temporary hospital has the roof at the ridge raised all along above the main roof, and overlapping it. The part of the main roof lying below it not being tiled, any foul air that collects must pass out at once. This arrangement has answered admirably. Neither jalousies nor jhilmils are required or used in the hospital.

7, 8. There is no apparatus either for cooling or warming the air admitted into the hospital wards. The walls and ceilings of the wards are limewashed four times a year.

9. The privies and urinals are simple sheds, with a passage for the sweeper at the back, who removes everything daily; no cesspits are consequently required. They are not supplied with water, but they are never offensive.

10 to 17. These queries refer to European hospitals alone.

18. The general sanitary state of my hospital (a temporary one) is very good. The only drawback to it in this respect is that were much sickness to prevail in the regiment, the accommodation would be too limited, but as yet it has not been found so. No epidemic disease, hospital gangrene, or pyæmia have appeared in the wards.

19. The hospitals with which I am acquainted are generally deficient in ventilation; their sites often not well chosen, and a bad arrangement as regards their wards. There is generally, if not always, a great deficiency of accommodation for the medical subordinates, and hospital servants.

20, 21, 22. No replies to these queries.

23. The powers of the medical officer are ample, I imagine, as regards repairs, changes of diet, medical comforts, and general arrangements of the hospital; but in any matter involving

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	much expense his suggestions to improve its sanitary state would probably, if carried out at all, only be so after considerable delay and trouble. 24. No reply to this question.
XIII. Burial of the Dead.	1. The European burial ground is about half a mile from the nearest occupied bungalow and is well to leeward. 2. It is about an acre in area, and its soil is a species of gravel formed by the decomposition of primary rocks, trap, or granite. It is kept moderately clean, and in pretty good order. 3. Being a burial ground for a small station, where interments do not often take place, there is plenty of room between the graves, none of which are ever reopened. Interment takes place within 24 hours after death, with natives within 12 hours. The native troops are buried or burned about three-quarters of a mile from camp. 4. The graveyard is never offensive in the slightest degree. British troops are buried as soon after death as convenient. 5. The dead of camp followers and bazaar people are disposed of in the same way and place as those of the native troops and townsmen. 6, 7. No injury accrues to the public health from the present practice, nor are any improvements to be suggested.

(Signed) Edward Baynes, Major,
Commanding at Dharwar.
W. Neilson, Surgeon,
H.M. 20th Regiment, Native Infantry.

12th July 1860.

I. Topography.	1. The general aspect of the country surrounding the station is that of a vast, undulating, flat, and stony plain, with cultivation in the vicinity of the town and cantonment. There is not much wood or jungle near the station, but a river which runs past the town of Rajcote is only half a mile distant from the station. 2. The station is 450 feet above the level of the sea, 100 feet above the adjacent country, and 100 feet above the river. There is no higher or healthier ground in the vicinity of the station. 3. The nearest mountain is the "Girnar," which is about 56 miles to the south-west of Rajcote, and is nearly 3,700 feet above the sea level; therefore, about 3,250 feet above the cantonments of Rajcote. 4. The nearest water is the river Ajee, which flows past the town of Rajcote at a distance of about half a mile from the cantonments. The vicinity of the station is not liable to overflow, as the water during the rains runs off into the river. There is no broken ground near the station, but a slight ravine, which runs through a portion of the camp, and which, during the rains, is usually full of water. It has not been observed to have a prejudicial effect on the health of the troops. 5. The station is thoroughly open to the sea-breeze, which blows steadily during eight months in the year. It is not encumbered with trees, hedges, or gardens, and there is nothing to obstruct its free ventilation. The temperature of the station is not raised to an appreciable degree by being exposed to reflected sun heat. During the months of November, December, January, and February the winds are northerly and north-easterly; but they have very little prejudice on health. The immediate surrounding country is cultivated. There are no works of irrigation near the station, and the cultivation of rice is prohibited within cantonment limits; none is grown in the surrounding country. Indigo is not cultivated, nor the preparation of hemp or flax carried on near the station. 7. The town of Rajcote is the largest in the vicinity of the station, and is about half a mile distant from it. Its population is 7,000 souls. 8. The geological structure of the station is as follows:—Sandstone and trap; surface, black soil and subsoil stony. The ground on which it stands was never before populated. 9. Water is usually found during the dry season at a depth of from 25 to 30 feet below the surface, and during the rainy season at from 12 to 15 feet. 10. The rain-fall flows on the hard and rocky ground into the river; but in some places, where there is black soil, it does not flow away so readily. There is no adjacent higher ground. 11. The water supply of the station is derived partly from the river, but chiefly from wells in the cantonment; there are no tanks within three miles of the station. The wells are not liable to pollution from leaves falling into them; but if not constantly used, they become very foul from the accumulation of pigeons' excrement and rubbish from their nests. 12, 13. The supply of water is abundant, both from the river and wells; it is colourless, inodorous, and well-tasted. It has not been analysed, nor its microscopic characters observed, but it is of moderate softness, and its quality appears to be good, and not in any way injurious to health. It is raised from the wells by means of a leathern bucket and rope, with which the watermen fill their water-bags, or "puckalls," and is distributed through the camp by means of bullocks. There are no other topographical points bearing on the health of the station to be remarked on. 14. No reply to this question.

RAJCOTE. BOMBAY.

References to Subjects and Queries. | REPLIES.

II. CLIMATE.

1. The following are the meteorological instruments available at the station :—One wet bulb thermometer, two common ditto, one mountain barometer made by Newnham of Regent Street, and a rain gauge, which latter consists of a copper funnel leading into a bottle, whence the water is daily removed and measured in a glass cylindrical vessel graduated to $\frac{1}{100}$ of an inch.

2. The following meteorological table contains the mean of four daily observations, viz., sunrise, 10 a.m., 4 p.m., and 10 p.m. The mean sun temperature contains the mean of observations taken only at 4 o'clock p.m., daily.

Table of Meteorological Observations from 1st January 1857 to 31st May 1860.

3. The climate of the station, on the whole, appears to be healthy. Variable monsoon weather from June to September, but the remaining eight months are dry; fogs are not frequent, mostly occurring in November and December. The climate of the station does not appear to be influenced by irrigation or tree planting, and the purity of the air is not much affected by admixture with dust or other impurity. Only native troops are at the station, and on these the influence of the climate appears to be favourable. A more substantial diet than what they usually allow themselves, as well as more spacious and better ventilated huts, would be desirable. The only precautions as to exercise, &c., at all necessary are the avoidance of long parades in April, May, and October, and too early parades in December and January. All the months appear to be healthy, except, perhaps, May, September, and October, the month preceding and the months following the rains, when fever is prevalent.

4. There does not appear to be any more healthy district near the station.

5. I served in Sinde for a few months, at detached periods, in 1856 and 1857; but at that time had no opportunity of making observations on its salubrity. The remainder of my service was spent on field service in Persia, and in the Indian navy.

III. SANITARY CONDITION OF STATION.

1, 2, 3. Maps and tracings of the station, barracks, and surrounding country forwarded.

4. TABLE of Barrack Accommodation.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms or Huts. Length.	Breadth.	Height.	Cubic Contents.	Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows. Number.	Height.	Width.

*Ventilating.

5, 6, 7. There are no windows, verandahs, jalousies, or jhilmils at this station, nor any bedsteads, cots being used.

8. In huts the door is the only ventilator; in guard-rooms the ventilation is effected by means of the doors and windows, and in the tents any one side can be thrown open. The ventilation in the native huts is utterly insufficient; there are no means for cooling the air admitted to the barrack-rooms.

9, 10. Huts for sepoys are constructed of unburnt bricks and mud, and roofed with tiles. The floors are made of earth, slightly raised, and cow-dunged over occasionally.

11. The materials and construction of huts and tents are no doubt suitable for the climate, but the huts in the native lines might be much better ventilated. The barracks and cantonments are kept in repair by the barrack serjeant, and the staff officer is responsible for the general sanitary state of the cantonment.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	12, 13, 14, 15. Negative answers to all these queries.
	16. All nuisances are removed daily by sweepers from the station; there are no cesspits or foul ditches.
	17. An establishment of two sweepers is kept up for the removal of the refuse manure, &c. within the cantonment and its vicinity.
	18. The surface of the cantonment is kept as free as possible from vegetation, and there are no old walls or thick hedges, &c. to interfere with the ventilation of the station or bazaar.
	19. The bazaar is pretty well drained by one deep nullah, but there is no artificial drainage; the ventilation is indifferent, the water supply good, but there is a great want of cleanliness. There are no latrines, and the bazaar is overcrowded in parts. No rubbish is allowed to be burnt or to accumulate, nor are holes permitted to be dug for making bricks, &c. Each householder is held responsible for the cleanliness of his own house, and the adjoining street gutters, and no house is allowed to be built or repaired without the inspection and permission of the bazaar master. There are some dungheaps, &c. near the town, but beyond the limits of the cantonments. No nuisance is experienced by the troops from wind blowing over the native dwellings.
	20. There are no slaughter places at this station.
	21. There are very few horses in the bazaar, and these are kept in private stables, the rubbish from which is removed daily, and the manure carried off and sold at regulated times.
	22. There are no stables for artillery or cavalry horses, but they are picketed in the open air in front of the men's lines, and at a considerable distance from the hospital. There are no dungheaps, the manure being carried away and sold daily. Cavalry horses are picketed by troops, front and rear ranks facing inwards, about 60 paces in front of the men's lines, but at a considerable distance from the hospital.
	23. There are no quarters for married non-commissioned officers or men at this station.
Officers' Quarters.	1. The quarters for officers at this station appear generally to be clean and well ventilated; but the addition of upper stories would be very desirable,
IV. Health of the Troops.	1. The station and the district in which it is situated appear to be generally healthy, and the population of the neighbouring native town is perhaps more healthy than such populations usually are.
	2. Intermittent fever appears to be the only epidemic at all extensively prevalent here, and spleen disease, although frequent in other parts of the province, is not so in Rajcote. Cutaneous affections, however, are not uncommon, but small-pox has not prevailed for some years. Cholera existed, though not extensively, in July 1851, and in May and June 1854, and some cases have occurred this season.
	3. The healthiness of the neighbouring native population is attributable to the dryness and fineness of the climate; and sickness, when prevalent, to the filth of the houses and streets, and the entire absence of ventilation. The rapid evaporation also of the water from the surface covered with vegetation during the rains in September and October renders fevers then more prevalent.
	4. The left wing of the troops at this station arrived at Rajcote in June 1858 from Deesa, where it had been one year. The right wing arrived in January 1857 from Bhoog, where it had been 15 months; the state of their health on arrival was pretty good. At Bhoog intermittent fevers, scorbutus, and rheumatism were prevalent, from which latter diseases the men never suffered, chiefly since arrival here. There is no difference as to the healthiness of one part of the men's present accommodation over another.
	5. The troops at this station are never camped out.
	6 to 13. No reply to these queries, having had no experience of hill stations.
	14. I should think it would be more conducive to the health of troops serving in India to locate them on hill stations, with short periods of service in the plains; and I am also of opinion that troops should not remain longer than two years at any station.
	15, 16. No experience of hill stations.
	17, 18. There is no higher ground near this station which could be advantageously occupied as a hill station. My limited experience does not enable me to point out any particular class of surface and subsoil more healthy than another for stations.
	19, 20. British soldiers should not leave home for India before the age of 21 years, and should land here at the end of November or beginning of December. Recruits on first landing in India should be kept within barracks during the day, when they might be provided with indoor amusement, allowed to engage in any trade or art they may have acquired, furnished with suitable books, kept from the bazaar at night, and not allowed to indulge in excess of any kind. If these precautions were adopted, it would be scarcely necessary to send troops to intermediate stations, nor would it be necessary to send them at once to hill stations, and the dangers of the earlier years would thus be best diminished.
	21. I have had no opportunity of observing the mode of transport of troops from the port to the interior.
	22. I am of opinion that 10 years ought to be the maximum length of continued service in India.
	23. The manner of conducting medical boards here does not appear to tend to any conflict of opinion as regards invaliding of native soldiers.
	24. I consider the best period of the year for invalids to leave India for home to be in January and the beginning of February.

RAJCOTE.
BOMBAY.

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops —*cont.*—*Diseases.*	1. There are weekly inspections of the troops at this station by a medical officer for the discovery of incipient diseases. 2. During two years, terminating March 31st, there were five cases of scorbutus in the regimental hospital, or 0·25 per cent. of all other diseases. I have not myself seen a case of it, and it is of such unfrequent occurrence at this station as to render preventive measures unnecessary. 3. No case of hepatic disease is recorded at this station for the last two years; but recently I found an abscess in the liver of a sepoy who died of intermittent fever of long continuance, hepatic symptoms having been developed in the course of the other disease. 4. Only six cases of dracunculus, or 0·3 per cent. of all diseases, have been treated in the regimental hospital during the last two years. The medical subordinate attached to the civil hospital, and who has been resident for more than 15 years, states that during that time he has not seen more than five or six cases. 5. Venereal diseases during the last two years only formed 2·9 per cent. of all admissions to hospital, and they do not appear to be prevalent in native regiments, of which only I have any experience, and when they occur are usually of a mild and tractable character. Lock hospitals in large European stations would doubtless be advantageous. 6. The following are the diseases from which troops at this station suffer :— *Fevers.*—Ephemeral and intermittent fevers, chiefly quotidian. *Dysentery.*—They scarcely ever suffer from this disease. *Cholera.*—Not at all from this disease. *Small-pox.*—This also is unknown at this station. *Rheumatism.*—They suffer to some extent from this complaint. The following are the proportions which admissions and deaths from these diseases bear to the total admissions and deaths :— Ephemeral fevers - Admissions - - 291 or 24·4 per cent. Intermittent fevers ,, - - 868 or 43·2 per cent. Ditto do. Deaths - - 4 or 26·6 per cent. of total deaths. Dysentery - - Admissions - - 14 or 0·19 per cent.; no deaths. Rheumatism - - ,, - - 150 or 7·46 per cent. Ditto do. Deaths - - 1 or 6·6 of all deaths. These are the admissions for 1858–9 and 1859–60. There was no case of cholera or of small-pox during that time. 7. Intermittent fever is the only zymotic disease at all frequent here, and it is remarkable only for its mild character and the facility with which it yields to treatment. It occurs throughout the year, but is especially prevalent in September and October. The transition from wet to dry weather, and the rapid evaporation from the surface, which during the rains is covered with vegetation, are the climatic conditions which accompany this fever. Disease does not appear to be confined to any particular portion of bazaar or native dwellings, which are defective as regards cleanliness, drainage, and ventilation, with a crowding of dwellings. The water supply is, however, abundant. There have not been observed any particular habits or conditions of the troops or among the native population to predispose to the diseases in question. 8. So far as I have observed epidemic disease does not appear to be influenced by the sepoy's duties or occupations. 9. Prophylactic doses of quinine against malarial diseases have not been tried at this station. 10. From my experience I think that epidemic disease among native troops might be much mitigated were rations to be issued to them by the Government, inasmuch as from the smallness of their pay, and their great passion of hoarding up money, they will not expend enough to procure sufficient food. An improvement too is required in the native huts, which are much too small and entirely without ventilation.
V. INTEMPERANCE.	1. The soldiers at this station are usually temperate, and there are no confirmed drunkards among them. 2. There are no admissions into hospital for diseases caused directly or indirectly by intemperance, and drunkenness does not occur. 3. Distilled spirits are sold at one shop in the bazaar. That consumed by the troops is arrack, distilled from the flowers of the maura tree, and is not unlike inferior whisky in taste; its strength is variable. Spirits form no part of the ration for troops at this station, neither is it given as a ration to convalescents; but in hospital, brandy is given in some cases at the discretion of the medical officer. No drinks injurious to health other than intoxicating drinks are sold in the bazaar. 4. We do not deem the consumption of spirit, except in very limited quantity, conducive to health or to the efficiency and discipline of the corps. 5. We think it would be beneficial to the health of European troops to restrict the use of spirituous liquors and to abolish the sale of them in canteens and bazaars. 6. We are of opinion that the use of malt liquor or wines would have a more beneficial influence on health than that of spirits. 7. Coffee, tea, lemonade, soda water, &c. are not much used at this station, being confined exclusively to officers. 8, 9. It would be better to substitute beer, tea, &c. for spirits for the use of the troops, and to permit only beer, coffee, tea, &c. to be sold to them in the bazaar. 10, 11. No recommendations in addition to the above to make. There are no bazaar regulations on the above subjects at this station.
VII. DRESS, ACCOUTREMENTS, AND DUTIES. *Duties.*	1. We think it advisable that European troops should be drilled at home before being sent to India. 2, 3, No answer to these questions.

References to Subjects and Queries.	Replies.
VIII. Instruction and Recreation.	Rajcote has never been a station for European troops. A station library and gymkhana are established here, supported by the European officers.
IX. Military Prisons.	1. There are four cells in one building at this station, and these appear to be in a very satisfactory state as regards structure, ventilation, and sanitary arrangements.
X. Field Service.	1. There are no local regulations for field medical service not included in the General Presidency Regulations. 2. So far as regards native troops, of which only we have experience, the practical working of the powers of the medical officer appears satisfactory. 3. In my experience of native troops, the practical operation of regulations, sanitary or otherwise, has not been attended with difficulty or inconvenience. 4. On field service native troops are allowed one dooly and six bearers to every 100 men, and coolies for the carriage of medical stores, &c. Any carriage in excess of these is supplied by the commissariat upon the requisition of the medical officer, and for which indents are subsequently furnished. Sick extra carriage usually consists of native carts drawn by bullocks.
XI. Statistics of Sickness and Mortality.	The following return gives the required information :—

By order of the Acting Principal Inspector-General, Medical Department,
W. C. Coles, Assistant Surgeon,
Secretary.

Office of the Principal Inspector-General, Medical Department,
Bombay 29th September 1860.

XII. Hospitals.	1. There are two hospitals in camp, one used by the cavalry, and the other by the infantry; they are precisely similar, having been built on the same plan. 2. The two hospitals, which adjoin each other, are situated about 400 yards to the west of the lines, and to windward of them, and are about half a mile to the north-west of the bazaar. The site is open and nothing interferes with the ventilation, it is the healthiest site in every respect that the camp affords. 3, 4. The water supply is abundant and wholesome, but there are no means of drainage for the removal of refuse water and other impurities from the hospitals. 5. There is only one ward in each hospital, elevated about 18 inches above the ground; but there is no perflation of air beneath the floor. The roof water sinks into the subsoil, but there is an open drain by both hospitals, which carries away the rain-fall in wet weather with tolerable rapidity. The hospitals are built of sandstone and chunam, the roofs and walls are single, without ventilation between the roofs, they are not sufficiently thick to keep the hospitals cool. The hospitals are supplied with verandahs on both sides, 6 feet 5 inches

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	on one side, and 13½ feet on the other or west side. These verandahs are only used for the accommodation of the sick when the hospitals are overcrowded. The hospitals consist each of only one story.

TABLE of Hospital Accommodation.
Total number of wards in each hospital, 1.

Wards or Hospital Huts. No.	Regulation Number of Sick in each Ward.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
1	No regulated number.	Ft. in. 98 3	Ft. in. 22 9	Ft. in. 12 6 to the slope of the roof.	Not ascertained.	Variable.	Variable.	Ft. in. 1 4	16	Ft. in 4 10	Ft. in. 3 4

The hospitals receive the full benefit of the prevailing winds. The windows open outwards and their arrangement is conducive to ventilation.

6. The windows and doors of the wards are on opposite sides, and are the only means of ventilation; they keep the hospitals free of odour and closeness when not overcrowded. There are no jalousies or jhilmils.

7, 8. There are no means either for cooling or warming the air admitted into the wards of the hospitals. The ceilings and walls of the wards are cleaned and lime-washed four times a year.

9. There is one privy, distant 17 yards from the hospital, but no cesspits. The filth is removed and the place cleaned morning and evening by sweepers. The privy is not offensive.

10, 11. There are no lavatory arrangements for the hospitals; but tepid baths are available when required for the sick.

12. There is a washerman attached to the hospital, whose services are usually sufficient for washing and drying the hospital linen, &c.

13. The storage is sufficient for a native hospital.

14. The cots used in the hospitals are made of squared wood, laced with cotton tape, 6 feet 4 inches long, 2 feet 10 inches broad, and 16 inches high; the natives bring their own bedding. The substitution of iron for wooden cots is very desirable.

15, 16. There are no kitchens attached to the hospitals, nor any diet tables in force for native troops.

17. There is one hospital orderly for attendance on the sick, and in addition to the regulated number of second-class servants, sepoys are allowed, on the recommendation of the medical officer, to watch such cases as require constant attendance.

18. Occasionally the hospital is found too small for the number of the sick; but it does not appear that epidemic disease, hospital gangrene, or pyœmia has ever originated in it.

19. No other deficiencies or sanitary defects to notice, nor any improvements to suggest besides those already remarked upon.

20. In wet weather convalescents can only take exercise in the verandahs, at other times in the vicinity of the hospitals. There are no fenced grounds, shaded walks, or seats set apart for their use.

21. There is no arrangement for the treatment of soldiers' sick wives, as native women could scarcely be induced to submit to any; but children are frequently brought to the hospital to be seen and prescribed for by the medical officer.

22. There are no special local hospital regulations which are not included in the General Presidency Medical Regulations.

23. The only control over the medical officer as regards the sanitary state of his hospital, &c., is that exercised by the deputy inspector general of hospitals, whose sanction is, in most cases, necessary.

24. There are no wards for convalescents here, and for native troops such accommodation is hardly necessary.

XIII. BURIAL OF THE DEAD.

1. The European burial ground is situated within the station, but to the leeward of the lines and officers' houses.

2. The burial ground measures 243 by 226 feet, and is carefully kept. The rate at which decomposition takes place is unknown.

3. There is no regulated space for graves, but their depth is usually about eight feet; it is never found necessary to re-open them. There is no fixed or compulsory time for interment, but it always takes place in from 12 to 24 hours after death. The native troops, with very few exceptions, are Hindoos, and burn their dead; on an average not more than one sepoy being buried yearly.

4. The grave-yard has never been found offensive.

5. The Mussulman burial ground in camp adjoins the European one, but is not much used; the dead of camp followers and bazaar people being mostly burned.

6, 7. No injury has been observed to accrue to the public health from the present practice, nor have any improvements hitherto been found necessary.

(Signed) T. TOLFREY CHRISTIE, Lieut.-Col.,
Commanding at Rajcote.

References to Subjects and Queries. | Replies.

I. Topography.

1. The country surrounding the station is level, intersected by low hills, covered with stunted brushwood. It is scantily wooded, and there is but little jungle. There is an abundance of water in the vicinity of the camp.
2. The station is elevated above the level of the sea 1,750 feet; but is almost on the same level as the surrounding country. The nearest water is the Gutpurbah, a river of importance, in which there is running water all the year round. It flows within a few hundred yards of camp. There is no higher or healthier ground adjoining the station.
3. The nearest mountain or table land is 50 or 60 miles distant from the station.
4. The vicinity of the station is not liable to overflow. There is broken ground, but no place wherein stagnant water accumulates.
5. The station is open, and freely exposed to winds, and there is no obstruction to free ventilation. The temperature of the buildings is not raised by exposure to reflected sun heat. The influence of the periodical winds (N.E. and S.W. monsoon) is regularly experienced, as also the sea breeze, which is undoubtedly beneficial to health.
6. The country surrounding the station is cultivated to a considerable extent; but there are no works of irrigation. Rice is not cultivated in the neighbourhood, nor is the cultivation of indigo, nor the preparation of hemp or flax carried on near the station.
7. The town of Kulladghee, having a population of about 2,000 souls, lies about 250 yards to the N.E. of camp, and immediately outside its limits.
8. The site of the camp is upon new ground, with a red gravelly subsoil, resting on quartz and primitive limestone.
9. Water is found in the dry season at a depth of about 70 feet below the surface; and in the rainy season at about 60 feet.
10. The rain fall or water from surface springs flows readily away, and is rapidly carried off by nullahs towards the river. There is no drainage from higher ground passing into the subsoil of the station.
11. The water supply of the station is derived from the river and from wells. There are no tanks.
12. There is an abundant supply of water always available from the river and wells. Its quality is generally good, and by no means injurious to health. It is raised by the usual method of drawing from wells and rivers.
13. The natural drainage of the camp, and the consequent absence of those causes likely to generate malaria, combine to give the native troops a comparative immunity from diseases usually caused thereby.
14. The selection of sites for new stations is conducted by mixed committees detailed for the purpose.

II. Climate.

1. The only meteorological instruments available at this station are thermometers and pluviometers.
2. Table of meteorological observation from 1st January 1855 to 31st December 1859.

Months.	Mean Temperature.	Mean Maximum.	Mean Minimum.	Rain, Inches.	Winds.		Remarks.
					Direction.	Force.	
	°	°	°				
January -	76	89	60	0·05	Easterly.	Moderate	Days clear and cool, nights cold, no dew.
February -	79	92	66	—	Ditto.	Ditto.	Ditto, ditto.
March -	88	101	74	0·05	Ditto.	Ditto.	Day sensibly warm, nights cool.
April -	89	104	74	1·45	Ditto.	Calm.	Ditto, ditto, evening sea breeze.
May -	87	101	74	3·80	Variable.	Moderate	Days hot, nights cold, evening sea breeze.
June -	84	96	72	1·62	Westerly.	High winds.	Weather cool, cloudy, and occasional showers.
July -	82	91	73	2·94	S. Westerly	Ditto.	Monsoon weather.
August -	83	93	73	2·53	Ditto.	Ditto.	Ditto, ditto.
September	82	91	73	4·1	Ditto.	Moderate	Monsoon subsiding, weather hot and unsettled.
October -	79	91	68	6·67	Variable.	Ditto.	Cloudy days.
November	76	88	63	0·64	Easterly.	Calm.	Clear and cool, cold nights.
December	72	85	60	0·4	Ditto.	Ditto.	Ditto, ditto.

N.B. The above is an average condition of the season for the period under report.

3. The climate throughout the year may be considered tolerably good. It is dry, with the exception of the monsoon months, and is uninfluenced by artificial causes of any kind likely to be injurious to the health of the troops. No suggestions seem requisite with regard to dress, drill, and exercise. The most unhealthy months are those of May and June, when cholera, fever, and bowel affections prevail.
4. The only climate near more conducive to health than this is that of Belgaum, the head quarter station of the southern division of the army, and distant 75 miles.
5. The services of the members of the committee having been distributed over very many stations in the Bengal, as well as in the Bombay Presidency, little more than opinion approximating to their comparative healthiness or otherwise can be given. As a few of the healthiest, the following may be mentioned in Bombay, Ahmednuggur, Mulligaum, Asseerghur, Kurrachee, Belgaum. The following are generally considered unhealthy, Dhoolia, Baroda, Hyderabad (Sinde), and Aden, in all of which some of the members of the committee have had experience.

III. Sanitary Condition of Station.

1, 2, 3. Map of the station with plans of the station, lines, and pendalls, &c., are transmitted.
4. No permanent accommodation for European troops.
5 to 16. These questions having reference exclusively to European troops; the committee pass to the consideration of No. 17.

KULLADGHEE. BOMBAY.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	17. The immediate neighbourhood of dwellings in cantonment is kept clean by the owners thereof, while all refuse matter in the vicinity of the bazaars and public roads is removed by scavenging carts, and deposited at a considerable distance to leeward of camp. 18. The surface of the cantonment is kept sufficiently free of vegetation, and there are no old walls, thick hedges, &c., interfering with its free ventilation. 19. The health of the permanent residents in the bazaar is generally good, and the site being high, water drains quickly off. Cleanliness is enforced by the bazaar authorities. The bazaar is under the immediate supervision of the staff officer, staff surgeon, and kotwall, who require the occupants of the various houses to keep them and their vicinity clean. The town of Kulladghee excepted, there are no native dwellings, dung heaps, or cesspits, in the neighbourhood of camp. 20. No answer to this question. 21. So few of the permanent residents of the bazaar or the camp followers living therein possess horses, that no defined limit for the purpose of picketing seems to be assigned, the beasts for the most part being allowed to forage for themselves, in the jungle by day, and at night are secured close to the dwellings of their owners. 22, 23. No European troops at this station.
Officers' Quarters.	1. The quarters occupied by officers are not public; they are invariably kept in a state of cleanliness.
IV. HEALTH OF THE TROOPS.	1. The average state of the public health in the station is good, as is also that of the adjoining native population. 2. Cholera, fever (for the most part of a mild type), and small-pox are the prevailing diseases; spleen disease occurs but rarely. 3. The neighbouring native population being almost entirely rural, in tolerably easy circumstances, and the necessaries of life being within the reach of all, and abundant, are the chief causes to which their average state of health may be attributed. 4. The troops at the station are local, with the exception of the 7th regiment native infantry, lately arrived from Bombay, where they suffered considerably from scurvy, and from which they are steadily improving. In point of accommodation sufficient difference does not exist likely to influence health to an appreciable extent. 5. Troops at this station are cantoned. 6. No member of the committee has ever held charge of troops at hill stations. 7 to 18. These questions having reference solely to hill stations, and there being no European troops here, the committee pass to the consideration of No. 19. 19. Soldiers should proceed to India from the age of 18 to 24 years, and land there from November to February. For preserving the health of recruits on first landing in India, I would recommend the following precautions:—Temperance, avoid undue exposure to the sun, wear flannel constantly next the skin, and let the duties as regard drill, &c., be as light as possible during the first four months. 20. It is the opinion of the committee that advantage would accrue in point of health by troops being sent to intermediate stations, whereby acclimation might become gradual. Troops on landing should be sent to hill districts if practicable, but in all instances they should be removed from the coast. 21. Troops are transported from the port to the interior usually for some distance by rail, then by bullock cart, and marching, and by steamers, from port to port. 22. A British soldier should not serve in India longer than 10 years consecutively. 23. It is the opinion that great benefit would arise were medical invaliding boards or committees (whose opinion would be final) appointed in each division. 24. Invalids leaving India for home by the Cape route should do so in November, December, or January.
Diseases.	1. The frequency of parade inspections for the discovery of incipient diseases is regulated by the appearance of scurvy and other ailments. 2. There has been no case of scorbutus at this station. 3. The proportion of hepatic disease usually under treatment among the native troops, is small, for the most part simply congestive and amenable to treatment, though cases do occasionally occur complicated with dysentery and other affections of the bowels. Beyond the means known to advance and preserve the standard of health, there is none which the committee is prepared to recommend for native troops. 4. As the occurrence of dracunculus is usually ascribed to the nature of the water consumed by the men, it would be difficult for the committee to suggest any prophylactic, the adoption of which would not necessarily entail what is beyond the men's reach, *i.e.*, change of water. 5. The proportion of the constantly sick from venereal diseases to the total sick is not more than two per cent. among the native troops. The establishment of lock hospitals would in the opinion of the committee be highly advantageous to the health of the European troops of the army. 6. The following are the diseases from which the troops at this station suffer:— Fevers—Of an intermittent type are prevalent at this station at certain seasons. Dysentery—But rare. Cholera—Is frequently sporadic in the camp. Small-pox—But rarely prevails to a serious extent, the benefits of vaccination being regularly promulgated. Rheumatism—Is not a prevalent disease. The following is the average proportion, taken for five years, which admissions and deaths from the above diseases bear to the total admissions and deaths.

From 1st January 1855 to 31st December 1859.

Diseases.	Total for five Years.		Average of five Years.		Remarks.
	Admitted.	Died.	Admitted.	Died.	
Dysentery - - -	38	—	7·6	—	These returns refer to the 1st Regiment Southern Mahratta Irregular Horse. Average strength at head quarters, 325.
Cholera - - - -	16	9	3·2	1·8	
Small-pox - - -	—	—	—	—	
Rheumatism - - -	59	1	11·8	0·2	

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	7. Great prostration of the vital powers is the nosological character of the more frequent zymotic diseases. These diseases are most prevalent in May and June, and are preceded by deranged electric condition of the atmosphere with frequent suspension of the usual winds. There is no particular prevalence of any of those diseases in certain parts of the bazaar. With regard to the habits of the troops, little can be said, but want of cleanliness and ill-constructed buildings predispose, to some extent, the native population to those diseases. 8. No answer to this question. 9. Small doses of quinine have not been given as a prophylactic against malarial disease at this station. 10. Epidemic diseases being rare here, the committee have nothing to recommend.
X. Field Service.	1. There are no local medical regulations not included in the general presidency regulations. 2. When any doubt exists as to healthiness of position as regards the line of march, bivouacking, camping, &c., the question is disposed of by consultation with the medical officer. 3. There do not exist any peculiar regulations for the preservation of the health of the troops, which are located in permanent and well-ventilated buildings with an abundant supply of water. All suggestions by the medical officer receive ready attention, and he is invariably consulted on the above subjects. 4. It is not in the power of the committee to afford information as to the arrangements adopted in the presidency for field hospitals, ambulances, transport for sick, and hospital supplies, &c.
XI. Statistics of Sickness and Mortality.	1. Kulladghee has been occupied by Madras as well as Bombay troops.

By order of the Acting Principal Inspector-General, Medical Department,

Office of the Principal Inspector-General, Medical Department,
Bombay, November 9, 1860.

W. C. Coles, Assistant Surgeon,
Secretary.

XII. Hospitals.	There is no general hospital at Kulladghee.
XIII. Burial of the Dead.	1, 2. There is a small burial-ground situate about a quarter of a mile to the south-east of the station, and to the leeward of it, for the interment of the European dead. 3, 4. Refers solely to European troops. There is no native burial-ground within camp limits. 5. The dead of camp followers or bazaar people are disposed of by burning or interment beyond camp limits. 6, 7. No injury occurs to the public health from the present practice, nor are any improvements, in the way of regulation or otherwise in the burial or disposal of the dead, to be suggested.

(Signed) John T. Sanderson, M.D., Assistant-Surgeon,
2nd Regiment of Southern Mahratta Horse.
H. Wilson, M.D., M.R.I.A., Assistant-Surgeon,
1st Regiment Southern Mahratta Horse.

July 1, 1860.

Tanna.
Bombay.

TANNA.

Accommodation—Native Troops, Infantry, 315.

References to Subjects and Queries.	Replies.
I. Topography.	1. The general aspect of the country surrounding the station is hilly, but in the neighbourhood of the camp it is flat; two miles to the east and west there are ranges of hills. It is well wooded, the hills on the west being covered with jungle, and there is abundance of water. The sea separates the station from the main land.
	2. The elevation of the station above the sea is about 10 feet, but is generally lower than the adjacent country. There is higher and healthier ground adjacent, but no plateau sufficiently large to be occupied by troops.
	3. The nearest mountain or table-land is two miles distant. It is 700 or 800 feet above level of station.
	4. The water nearest the station is a creek or arm of the sea which separates the station from main land. The vicinity is liable to overflow during the heavy falls of rain in the monsoon There is a nullah or ravine behind the civil lines, which contains putrid salt water and is detrimental to health in the hot season. During the monsoon the salt water is washed into the sea by rain water, the nullah being the bed of a mountain torrent.
	5. The station is shut out entirely from westerly breezes by a range of hills on the west. It is surrounded immediately on north-west and south by the suburbs of Tannah, which interfere with free ventilation and the temperature is raised by the buildings being exposed to reflected sun heat. The station is almost shut out from all breezes.
	6. The surrounding country is partially cultivated. Artificial irrigation is observed to have an effect on the health of the station, when evaporation is going on, which is injurious to health. Rice is cultivated close up to the station on all sides. Indigo is not cultivated, neither is the preparation of flax or hemp carried on near the station.
	7. The town of Tannah immediately surrounds the station, and has a population of 12,000 souls.
	8. The geological formation of the hills consists of trap with subsoil of gravel and decomposed trap. The station occupies old ground.
	9. Water is usually found about 15 feet below the surface during the dry season, and during the rainy season almost on the surface.
	10. The rain-fall or the water from surface springs in the immediate station flows readily away but in the vicinity, which is lower ground, it lies till evaporation takes place. There is higher ground adjacent, the drainage from which passes through the subsoil of the station into the sea.
	11. The water supply of the station is derived from wells and tanks. The tanks are open, and contain in surface about 17,000 square yards, they are more or less full, but nearly dry up during the hot season. They contain rank grass and lotus, amphibious animals, and numerous insects. The tank used for drinking purposes is also used for bathing, although there are rules against the same existing, which are not carried out. The tank and wells are liable to pollution by vegetable matter falling into them, but they receive no foul drainage; nuisance and malaria decidedly proceeds from the tanks both within and without the station, the best means of preventing which is to deepen and clean them out of leaves and lotuses.
	12. There is one tank and several wells for supplying the station with water. The well water is very good, but the tank water is bad, and altogether the supply is insufficient. If the rain does not fall by the 18th June, there is a great scarcity of water. The water is raised by lotas attached to ropes. A better supply could be obtained by deepening the wells and tanks.
	12. There are no other topographical points bearing on the health of the station, except that we consider the station very badly situated, being surrounded with hills on every side, which shut out the sea breeze, and the native town and bazaar being in close proximity to the station.
	14. New stations are selected generally by the Quartermaster-General in conjunction with Superintending Surgeon and an engineer: no improvements can be suggested.
II. Climate.	1. The means and instruments available at the station for conducting and registering meteorological observations are a thermometer and rain gauge.
	3. The character of the climate is excessively moist, but not variable, the temperature being generally high throughout the year. A moderate number of trees have been planted here and there about the station. There are no canals, the only irrigation influencing the climate are the numerous rice-fields which bound the station on all sides; the atmosphere is not impregnated with dust. The troops being well clothed and sheltered, and living well, the climate has not much influence on their health. The men are drilled for one hour at the time, morning and evening, during the cold weather, and once a day during the hot weather. January, February, and December are healthy months, and April, May, June, and September are unhealthy. The prevailing diseases are cholera, diarrhœa, and fever.
	4. There is no district near the station, the climate of which is more conducive to health.
	5. With regard to the comparative salubrity of stations at which we have served, Kolapore, Sattara, Poona, Bombay, Kurrachee, Sukkur, Shikarpore, Baroda, Ahmedabad, Deesa Aden, Hyderabad, Belgaum, and Dharwar are good, Kurrachee being the most healthy; Kolapore, Sattara, and Poona the climate is good, Kurrachee very good. Ahmedabad fair, Deesa very good, Aden healthy, Belgaum and Dharwar pleasant, but not healthy, while at Bombay, Sukkur, Shikarpore, Baroda, and Hyderabad the climate is positively injurious.
III. Sanitary Condition of Station.	1, 2, 3. Plans of the station, surrounding country, &c. are transmitted. All drains are open unless where an obstacle intervenes, when they are passed under. There are no sewers.
	4. The following is a table of particulars regarding barrack accommodation, &c. Date of construction of barrack, 3 erected in 1852–53, 1 in 1840–41, 3 in 1857–58. Total number of pendalls, 7. Total regulation number of non-commissioned officers and men, 315.

References to Subjects and Queries.

7 - -	82	237	31				
			Mean.				
Total - -	315	966	31	5 to 12	254,541	808	95
Guard Room -	—	$32\frac{1}{2}$	$46\frac{1}{3}$	9	—	—	—
Prison Cells -	None.	—	—	—	—	—	—

The men sleep on the ground. There are no windows.

5. There are no windows at all to the barracks. There is a verandah all round the buildings about 4 feet wide, but it is not occupied as sleeping quarters by soldiers or other persons. There are no jalousies or jhilmils.
6. The men sleep on the ground.
7. The tents used in camp are double-poled rowties, $29\frac{11}{13}$ superficial feet, and $117\frac{1}{4}$ cubic feet per man, and capable of containing 13 men in each tent.
8. The barracks require no ventilation, the door being nearly always open, and the partitions being nothing but wattle and daub. The ventilation is sufficient to keep the air pure by night as well as by day. There are no means used for cooling the air for barrack rooms.
9. The pendals are raised on wooden posts, between which are wattle and daub partitions. Tents are composed of three-fold dungaree.
10. The floors of the barracks are earthen, raised 1 to $1\frac{1}{2}$ feet above the ground, and admitting of no passage of air beneath.
11. The materials used in the construction of barrcks, &c. are suitable to the climate, and require no improvement. The hospitals and pendals are kept in repair by the executive engineer, and all necessary repairs are generally executed immediately on the requisition being received by him. We suppose the collector is responsible for the general sanitary condition of the station.
12, 13. There are no lavatories, washing-places, or baths for the men, neither are there any cook-houses. The conveniences for washing and drying linen are simply a good tank, a good stone, and a hot sun, the sepoys and dhobies going to whatever tank they prefer.
14, 15. There are no privies or urinals.
16. The natural slope of the ground carries off the water, and there is no artificial drainage. The natural drainage is sufficient for all purposes. No part of the buildings is damp. There are no cesspits, but there is a foul nullah 20 yards behind the quarters occupied by the military.
17. The general state of the surface cleansing within the cantonment and its vicinity is very good; refuse is thrown into the creek, and carried away by the tide.
18. The surface of the cantonment is kept free of vegetation. The town and suburbs interfere with the ventilation of the station.
19. The native bazaar (which is the only one) is managed very well, and is under the regulation of the police, who enforce cleanliness, and perform their duty well. The condition of the native houses near the station is good, but there are dung-heaps within them. A nuisance is experienced in barracks from wind blowing over the native dwellings, which is caused by the close proximity of the town, but there is no method of preventing this.
20. There being no European soldiers at the station, there is no cause for slaughtering animals.
21, 22. There are no stables or picketing grounds at the station.
23. No quarters are provided at the station for married non-commissioned officers or men.

Officers' Quarters.

1. There are no officers' quarters at Tanna.

IV. Health of the Troops.

1. The station, district, and adjoining native population are healthy.
2. The most prevalent diseases among the natives are fevers, chiefly of the quotidian intermittent type, splenic enlargement, and diarrhœa.
3. We attribute the healthiness of the natives to their living well, the town not being overcrowded, the streets broad, and the sanitary state of the station being well looked after by the police.
4. The troops at the station arrived from Bombay on the 14th November 1859. While there they suffered from scurvy, but with the exception of a few cases of scorbutus the men were healthy on their arrival. They have since suffered from quotidian intermittent fever. No one portion of the men's present accommodation is more unhealthy than another.
5. The troops are never camped out at this station.
6, 7. No experience of hill stations.
8. From the great benefit which European troops derive from a residence at hill stations we highly approve of their selection for Europeans.
9 to 16. No experience of hill stations.
17. There is no higher ground near the station which could be advantageously occupied as a hill station.
18. We cannot say wha class of soil is more healthy or unhealthy than others for stations.
19. Soldiers proceeding to India should be from 19 to 20 years of age. They should land there during the months of November, December, January, and February. Cannot say how troops are disposed of on first landing as regards barrack accommodation, clothing, &c., or what precautions are taken for preserving the health of recruits on their arrival in India.

References to Subjects and Queries	REPLIES.
IV. Health of the Troops —*cont.*	20. Troops proceeding to India should first be stationed at the Mediterranean or the Cape, and on first landing in this country they should be sent to the hill districts, and gradually accustomed to the climate. 21. The mode of transport of soldiers to the interior is chiefly by land. 22. The number of years a British soldier should serve in India is 20. 23. We have no experience as to the manner of conducting the business of medical boards. 24. Invalids should leave India in February or March so as to arrive home in June.
Diseases.	1. Occasional inspections are made for the discovery of incipient diseases at this station. 2. When the men of the detachment arrived at the station a number of them were suffering from scorbutus, but they have much improved in health since they came here, and are now free from this disease. 3. The sepoys at this station have not suffered from any hepatic affections. 4. Guinea worm is very prevalent amongst the native population, but only one case has been admitted into the military hospital. 5. There have been no cases of venereal diseases under treatment, and sepoys seldom suffer from this affection, so that there is no necessity for the establishment of a lock hospital at this station. 6. The troops at this station suffer from fever of the quotidian intermittent type, of a mild character, which is readily amenable to treatment. Some very severe cases of dysentery have occured amongst the native troops, but most of them yield to local depletion, ipecacuanha, and opium. Tanna and the whole of the surrounding country was visited by a very severe form of cholera in May and June 1860, and a large number of the inhabitants and prisoners in the gaol fell victims to the scourge, but there were no admissions into the detachment hospital, and there are no records in the hospital that would show that the sepoys had ever suffered much from the disease. Small-pox broke out amongst the camp followers in February 1855, but no casualty occurred; the disease has not made its appearance in the lines since. Both the acute and chronic forms of rheumatism came under our observation, and this disease principally occurred with men who had frequently been under treatment with fever. With regard to the proportion which the admissions and deaths from these diseases bear to the total admissions and deaths we can say that during the 7½ months, the present detachment has been stationed here no casualty has occurred, but we are unable to give further information for want of records. 7. There is no peculiar nosological characters of zymotic diseases to be noticed. During the months of April, May, and June cholera and diarrhœa prevail, and a large number of cases of fever are admitted in May, June, September, and October, and their appearance is always accompanied with excessive heat. The sanitary state of the whole town is well looked after by the police, the drainage, water-supply, and ventilation is good, and disease is not more prevalent in one part than another. If the natives would discontinue their filthy habits of bathing, washing clothes, and drinking the water out of the same tank, in my opinion they would suffer less from diseases of this kind. 8. The occupations and duties of the sepoys have but little influence on their health. 9. Quinine has not been tried at the station as a prophylactic against malarious diseases. 10. We have no recommendations to make towards the prevention or mitigation of epidemic disease at the station.
V. INTEMPERANCE.	1. The soldiers at the station are very temperate, and there are no confirmed drunkards. 2. There are no admissions into hospital from disease caused by intemperance. Drunkenness is punishable as an offence. 3 to 11. No answers given to these queries, there being no European soldiers at the station.
VI. DIET.	No information under this head.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The ordinary regulation dress and accoutrements of the Bombay army are worn by the soldiers at this station, and we consider it suitable to the climate here, and cannot suggest any improvements. The present guard dress is a red coat and black linen pantaloons. There are sentry boxes and great coats to protect the men from the rain or sun.
Duties.	1. We have no experience, to suggest as to whether the men should be thoroughly drilled at home, or at some intermediate station before being sent to India. 2. The usual routine of the soldiers' duty is to mount guard every third day, and be drilled about four days in the week, for one hour in the evening (weather permitting) during the monsoon, and if the drill be short a soldier does not suffer from it. The best hours for drills, parades, and marches are in the morning before sunrise, and there are general orders on the subject. The men have upwards of four nights in bed during the week. 3. The guards are mounted at about 250 yards distance from the barracks. There are roll calls morning and evening. Night guards are always injurious to health, and European soldiers ought to have at least four reliefs and native troops three.
VIII. INSTRUCTION AND RECREATION.	No information under this head, the queries applying to Europeans; it is suggested, however, that a talim khana should be provided for the sepoys.
IX. MILITARY PRISONS.	1. There are no military prisons at this station.
X. FIELD SERVICE.	1. There are no local regulations for field medical service. 2. The practical working of the powers of the medical officers as regards the conduct of the line of march of troops, bivouacking, camping, billeting, &c., is very good. 3. The practical operations of the regulations, for encamping the men are very good; on this subject we beg to refer you to page 143, Dep. General Orders, under the head of "Encampment." The medical officer has always the power of suggesting for the information of the commanding officer, and we can recommend no improvements in this respect. 4. Every regiment has its hospital establishment and carriage, the latter consisting of doolies kajavas, and spring carts. The hospital supplies are transported according to the means of carriage the country affords.
XI. STATISTICS OF SICKNESS AND MORTALITY.	No information under this head.

References to Subjects and Queries.	Replies.
XII. Hospitals.	1. A ground plan and a rough marginal sketch of the elevation of the hospital is forwarded with the report. 2. The position of the hospital is within 100 yards or so of the pendalls, and lies N.N.W. of the town and to the west of the civil population. Its site is rather open, and there are no buildings which particularly interfere with the ventilation. The site is generally very healthy there being an absence of malaria from river banks, marshes, nullahs, ditches, water pits, foul ground, or other nuisances. 3. The hospital is well and abundantly supplied with good water. 4. The hospital has no refuse or sewage water and the sweepers remove all impurities. 5. The hospital buildings are constructed 1½ feet above the ground with no passage for air underneath the floors. The roof water sinks into the subsoil, and gradually drains off to the outer drain (mentioned hereafter) the position being slightly elevated. There is no guttering round about the hospital, but it is railed in, and outside the railing enclosures there is a drain, which carries off the rain-fall. The hospital is built of stone and lime, with single roof and walls, which are sufficiently thick to keep it cool, as cool as any building in Tannah can be. There are verandahs on both sides which afford shelter from the sun, their breadth is 8 feet. They are used for the accommodation of the sick when the hospital is crowded. The hospital consists of one ground floor. The following is a table of hospital accommodation :— Date of construction, 14th October 1848. Total number of wards - - 1 Total regulation number of beds - 12

Wards.	Regulation No. of Sick in each Wardr.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patients' Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				No.	Height.	Width.
1 Ward - -	12	Ft. 56	Ft. 18½	Ft. 15 in centre 21	Ft. 18,648	1,554	86⅓	Ft. 1½	8	Ft. 4½	Ft. 3½

The hospital is so placed as to receive the full benefit of the prevailing winds. The windows (as shown on plan) open outwards, and the other arrangements are good. The windows are divided into an upper and lower portion, either of which can be open or shut at pleasure.

6. There is no means of ventilation in the wards whatever, except by keeping the doors and windows open, which is quite sufficient for the purpose. There are jalousies or jhilmils attached to the outer verandah weather boards, which can be pulled up or let down at pleasure.
7. There are no artificial means in use for cooling or warming the air admitted into the wards of the hospital.
8. The walls and ceilings of hospital wards are cleansed and lime-washed about once every three months.
9. The privy is to the south-east of the hospital and within 48 feet of it; it is built of stone and lime, with cesspool attached. The night soil is removed by sweepers three or four times a day, and no water is required, each man taking his own lotah.
10. There are no lavatory arrangements for the hospital.
11. The means of bathing for the sick is left for the native troops to arrange themselves.
12. There are no means provided for washing and drying hospital linen.
13. The dispensary is used as a store room, and found to be sufficient.
14. The bedsteads, cots, and bedding in use at the hospital is the common charpoy of the regulation pattern, with four wooden legs, and sides of square wood filled in with tape, but we suggest bedsteads ought to be made of iron, as the wooden ones harbour vermin.
15. The hospital kitchen is to the south of the sick wards. There is no system of dieting, and the natives make their own arrangements.
16. No reply to this query.
17. Each sick man is provided with an attendant when it is found necessary, and there is one orderly attached to the hospital, which we think is quite sufficient.
18. The hospital is a good substantial building, and is well raised from the ground. All the arrangements are good. Epidemic disease, such as hospital gangrene, or pyæmia, have never been known to occur at this hospital.
19. There are no deficiencies or sanitary defects at this hospital, which have come under our notice.
20. A strong fence surrounds the hospital, the enclosure within which is found sufficiently large for the sick and convalescent to take exercise; there are no shaded walks or seats set apart for their use, and they are not found necessary.
21. The wives and children of the sepoys who may be sick are treated in their lines, and no other arrangement could be recommended, neither is it necessary.
22. There are no local hospital regulations enforced at the station.
23. The medical officer has the whole power vested in him in matters appertaining to the sanitary state of the hospital, and when repairs are required he reports to the proper authorities.
24. There are no convalescent wards or hospitals for convalescents, nor would they be of any advantage at this station.

XIII. Burial of the Dead.

1. The burial-ground is in the churchyard, and is situated about the centre of the station, immediately to the north of the native infantry lines.
2. The area of the burial-ground is 1,000 square feet; the subsoil is moorum (gravelly, and of trap detritus); the drainage is efficient, and the ground is carefully kept.
3. The burials at this station are so few that the graves are dug according to convenience, or as the friends of deceased may desire. The depth of a grave is generally from 5 to 8 feet, and the graves are not reopened for second interments. Interments for both European and

References to Subjects and Queries.	REPLIES.
XIII. Burial of the Dead —*cont.*	native troops take place as soon as all the necessary arrangements can be made which is generally from 20 to 24 hours after death. 4. The graveyard is never offensive, neither can it be, as burials at this station are so few. There are no British troops at the station. 5. With respect to the disposal of the dead of the camp followers or bazaar people, if Hindoos, they are burned; and if Mahomedans, they are buried. 6. No injury to the public health accrues from the present practice. 7. We cannot suggest any improvements in the way of regulation or otherwise in the burial of the dead.

I. TOPOGRAPHY.	1. The station of Dapoolee lies in one of the numerous valleys of the Concan, on the first succession of terraces from the coast to the Western Ghauts, and around it the country bristles with hills of varying height, of rounded outline, and intersected with river or nullah courses. The surrounding country is essentially hilly, always dry after the monsoon, but during the rains in the broader valleys it is swampy. There is but little wood, jungle, or water in the vicinity, but in the Bunn Valley, lying in a north-west direction, and distant about five miles, there is some jungle. 2. The elevation of the camp of Dapoolee is about 600 feet above the level of the sea, and the mean elevation of the Concan is said to be about 100 feet. The immediately adjacent country is of the same elevation as the camp itself. The "Jog" nullah and the "Peera" river or nullah are the nearest water to the station; but these, although called rivers, are only monsoon torrents, and are dry beds in the hot season. At a distance of about two miles west a stream exists all the year, becoming very thready as the monsoon approaches. There are no lakes or marshes in the vicinity. Many of the hills are higher than the site of this station, without having any possible advantage for permanent military purposes. 3. The nearest table land is that of the Deccan; the next is Mahableshwur (considering it as an isolated position). The distance of the Deccan by a circuitous made road, and the ghaut at Koombarlee, is about 38 miles, and its elevation 1,800 to 2,000 feet above the sea. Mahableshwur, a celebrated sanitary hot-weather station, is distant about 40 miles, and stands at an elevation of 3,400 feet above this station. 4. The sea is the nearest large water, being nine miles distant in a course almost due west. The vicinity is not liable to overflow. A deep ravine runs through the station from the south-east to the north-west, and is the bed of the so-called river Peera, dry in the hot season. It can only affect the health in so far that it is the common necessary of the inhabitants and sepoys; but in this respect it is not prejudicial from experience. 5. The station, though surrounded by hills, is open to the winds, which easily pass over them, the south-east end of the station being the most freely exposed. Trees, houses, or walls do not in any material way interfere with the ventilation. The temperature of the station is raised in consequence of the proximity of dry uncovered hills. The station is not exposed to cold or variable winds, nor freely to land winds, but fully to sea breezes. These latter make the climate bearable, but are likely in debilitated constitutions to cause or prolong rheumatism; they do not possess any tonic effect on the constitution. 6. The surrounding country is cultivated in the monsoon. There are no works of irrigation near the station. The cultivation of rice is carried on immediately outside the camp limits, but there is no cultivation of indigo, nor preparation of hemp or flax in the district. 7. There is no large city or town near the station, but a large village named Jalgaon lies close on the south boundary of the camp. Its population is stated at between 3,000 and 4,000. 8. The geological structure of the district is volcanic; trap, with laterite overlying, the laterite hills having generally a rounded outline. The surface is composed of the broken-down laterite or decomposed trap; but laterite enters into all the surface and subsoil. The station occupies new ground and takes its name from a village half a coss to the north. 9. The depth below the surface at which water is found varies according to the locality; in the dry season at from three to 60 feet, and during the rainy season from one foot to 30 or 40 feet. 10. All water, from rain-fall and other sources, flows readily off, and is likewise in the rainy season quickly absorbed by the porous laterite soil. Only in parts does it lie on the surface and evaporate, and this may be easily remedied by drainage. After absorption it does not ooze out at the level of the station. The drainage from the higher ground finds its way by the gradual slopes and furrows to small watercourses, from these to larger ones, and from these again into "karrees" or creeks, and from thence to the sea. 11. The water supply of the station is derived from wells; but there are no tanks within half a mile of the station. The wells are generally so situated as not to be liable to pollution, but the situation of a few of them is such that leaves from overhanging trees may fall in. No foul drainage or other impurities run into them. No nuisance is experienced from the wells. 12. The amount of the water supply of the station varies with the season of the year; it is plentiful to the month of March, up to which time supplies are obtainable from river beds. It is afterwards nearly confined to wells, and these as the hot season draws to a conclusion gradually fail; small springs then afford a meagre supply. The number of wells in use is 77, and the population, excluding the regiment, is estimated at 3,425.

References to Subjects and Queries.	Replies.

I. Topography—*cont.*

With respect to the chemical composition of the water, it is slightly ferruginous, but its microscopic characters have not been observed. Its quality is good and by no means injurious to health, and in amount it is sufficient for the wants of the present population. For domestic purposes it is raised simply by a rope and vessel in wells near the surface, and in those deeper by a rope and wheel; for garden purposes it is raised by the Persian wheel. Better water supply might be obtained, but only at great expense, and by the formation of large tanks.

13. A portion of the camp is situated on the north-east side of the ravine (Peera river), and this place is freely used as a public necessary. There are parts of the station which from their position obtain less ventilation by wind than others, but I do not learn that the health of the people inhabiting them is thereby affected.

14. New sites for buildings are selected by committees of commanding engineer, and medical officers. The present committee does not possess the requisite amount of information with regard to the formation of new stations to enable it to suggest improvements.

II. Climate.

1. The instruments in use here for conducting meteorological observations are marine barometer, max. and min. regn. thermometer, air thermometer, wet bulb do., dry do., for sun's rays, and rain gauge; but instruments for sunshine, force of wind, &c., are not available. The observations are made four times a day, viz., at sunrise, 10 a.m., 4 p.m., and 10 p.m. There is also a vane for direction of wind.

II. Climate—*cont.*	3. The climate is divided into three seasons; 1st, the cold season, from December to end of February; 2nd, the hot season, from March till June, increasing in heat; and the 3rd or rainy season, from June till October. October and November are close hot months. The moisture and dryness vary with the season; even during the rains, there is great variation as to the hygrometric state of the atmosphere. After the rains, for several months morning mists are frequent. Irrigation does not influence the climate, and there is no amount of dust or other atmospheric admixture affecting the climate. The troops at this station are native invalids, and no kind of diet is prescribed for them. They dress always in the red jacket or tunic on duty, but use themselves light clothing in hot weather, and as warm clothing as they can obtain in the cold and rainy seasons. The cold season is the only one suited to exercise and drills, which should take place in the morning. The clothing should be light in the hot and exhausting season, with thin flannel chest and loin clothing. December, January, February, March, and April are the healthiest months. Part of April, May, October, and November, from their close heat, are enervating. June, July, August, and September are the rainy months, and predispose in the already relaxed constitution to rheumatism and chest affections, where the usual precautions are not taken. 4. There is no healthier district near the station. 5. I have served at the following stations; Poona, Deesa, Mount Aboo, Kaira, Broach, Bhooj, Surat, Kurrachee, Hyderabad, Sukkur, Shikapore, Frontier of Sinde, Jacobabad (Khangur), Larkhana, throughout Northern and Southern Concan, Sattara, Southern Deccan country, and Neemuch. As far as I have been enabled to observe (never having been in charge of British troops), the following have appeared to me healthy stations:—Poona, Deesa, Mount Aboo, Kurrachee, Sattara, and Neemuch. Sukkur and Upper Sinde, Broach, Kaira, and Lower Guzerat, were in general injurious.
III. SANITARY CONDITION OF STATION.	1, 2, 3. Map of the adjacent country, with a plan of the station, &c. are transmitted. 4. Table of hut accommodation. Date of construction of huts, 1848, and some in 1859 and 1860. Total number of huts, 358. There are no troops at present at the station.

Huts.	Regulation Number of Men in each Hut.	Dimensions of Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Feet Contents.				Number.	Height.	Width.
		Feet.	Feet.	Feet.						Feet.	Feet.
358 - - -	1	18	8	10 to ridge.	1,110	1,110	144	None.	1	1	1
Guard Room - -	24	63½	22	10	19,558	814	58	—	5	4½	3
Prison Cells - -	4	15	22	10	5,280	1,320	82½	—	1	4½	3

5. Each hut or small house used by the sepoys has one opening opposite the door; no verandahs exist.

6. No reply to this query.

7. There are no tents.

8, 9. No means of ventilation are used beyond doors and windows, which are however sufficient for natives. Huts are constructed of sun-dried bricks, covered with tiles.

10. The floors are constructed of beaten earth, raised about one foot from the ground; but there is no passage for air beneath.

11. For native troops the huts are very well adapted, but a little more room and less crowding of families would increase their salubrity. The cantonment public buildings are kept in repair. Native soldiers' huts are not limewashed.

12. There are no lavatories for the men.

13, 14, 15. No reply to these queries.

16. There are no sewers, the natural drainage with open ducts being sufficient. Dampness pervades every building during the monsoon. There are no foul ditches.

17. The general state of surface cleansing is tolerable within the cantonment. It is performed by hand labour, and requires more labour expended on it than is allowed. The refuse manure, &c. is as much as possible carried away to leeward of camp, and in the dry season is always burnt.

18. The surface of the cantonment is kept free of vegetation; there are no old walls, thick hedges, &c. to interfere with the general ventilation.

19. The drainage of the bazaar is like the rest of the station, only required during the rains, and then it is well effected by the sloping character of the place, and the various nullahs. The water supply is tolerably plentiful, and cleanliness attended to as far as possible, but there are few latrines. The crowding is, I am sorry to say, considerable, and unavoidable, but good natural ventilation exists. Five labourers are constantly employed in the cleansing of the streets and lanes, a number quite insufficient. An ample registration is required, and also the numbering and naming of streets, lanes, houses, &c. Vaccination is very imperfectly carried on in consequence of a want of registration. The native houses near the station are of the better class of huts. Dung or dirt heaps are common; and these accumulations are used at the approach of the monsoon for burning in the fields. There are no cesspits, and no nuisance is experienced in the lines from wind blowing over the native dwellings.

20. The only slaughtering that is carried on is that of one or two sheep, and one or two goats daily.

21, 22, 23. No reply to these queries.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.* *Officers' Quarters.*	1. The condition of the officers' houses is good, and there is sufficient accommodation. Natural drainage alone exists; ventilation is simple, and requires no details. No improvements are suggested.
IV. Health of the Troops.	1. The station, district, and adjoining native population are generally healthy. 2. During the hot and cold seasons few diseases are observed, but in the rainy season diarrhœa, dysentery, and chest complaints are not uncommon. Spleen disease is not often observed; cholera, choleraic diarrhœa, measles, and occasionally small-pox, occur at intervals. 3. The sea breeze tempers the great heat, and to its healthy action is attributable the immunity from general disease among the native population. Such diseases as fever may be attributed to insufficient food, exposure, and hard labour; cholera, measles, and small-pox to unripe fruit, contagion, and unknown causes, chiefly atmospheric. 4. The native veterans of this station come from all the regiments of the line, and from every station in which Bombay troops have been quartered. No portion of the men's present accommodation is more unhealthy than the rest. 5. Troops are not camped out. 6, 7. No experience of hill stations. 8. Hill stations should, whenever available, be used for the location of European troops. 9. I am not aware that healthy troops sent to hill stations contract any disease, nor am I aware that in Indian hill stations there are diseases peculiar to them. 10. No experience of hill stations. 11. The hot season is best adapted for residence in hill stations. 12. No reply to this question. 13. The avoidance of the exposure allowed with impunity at hill stations; a careful attention to dress, bathing, diet, and canteen, are the precautions necessary to protect the health of troops on leaving hill stations for the plains. 14. Short services on the plains with location at hill stations would be most conducive to the health of troops serving in India; occasional change of station in the plains is very requisite for the health and spirits of troops. 15, 16. Cannot say what barrack or hospital accommodation is provided at hill stations, or what range of elevation is most suitable for hill stations. 17. There is no higher ground near this station that could be advantageously occupied as a hill station. 18. I have not observed what particular class of surface and sub-soil is more healthy than others for stations. 19. Soldiers proceeding to India should be about 19 years of age, and should land there in the cold season. Not having served regularly with European troops, the committee cannot say how they are disposed of on first landing; but the precaution of the greatest moment to the recruits on arriving, is the placing them at once at some depôt or spot where the minimum of temptation to dissipation exists, and by giving them, wherever they may be, inducements either of employment or pleasure to remain at their quarters. 20. Troops should be sent direct from the home depôts to India. If hill districts are available it would be as well to send troops to them at once. The constitutions of the men, somewhat deteriorated by the voyage, are soon affected, if occupying hot or vitiated atmospheres, *e.g.*, town barracks. If hill stations are not available they should be sent to stations of well reputed healthiness, especially those at a distance from presidency cities or large towns. 21. In the Bombay presidency troops are conveyed by sea on steamers, or on land by rail, marching, or bullock train. The committee cannot from experience say what additional precautions may be required *en route*. 22. From 15 to 20 years is the length of time a British soldier should serve in India. 23. At stations, conflict of opinion at medical boards as regards invaliding of native troops has not been noticed. 24. Invalids should leave India so as to arrive in England during the earlier summer months.
Diseases.	1. There are no inspection parades for the discovery of incipient diseases at this station. 2. There has been no scorbutus among the troops at this station. 3. Hepatic diseases are not usually under treatment at this station. It is peculiarly free from them. 4. Dracunculus is not noticed much at this station. It occurs in the district, and is there universally attributed to the impure drinking water. No prophylactic is known. Asafœtida is looked upon by the natives and wainds, with favour in the treatment. 5. Syphilis is a disease not observed in the hospital at this station. At European stations, registers of the females of this class, with weekly examinations of their persons, and a lock hospital, seem precautions necessary for diminishing the growing evil of this disease among soldiers. 6. The troops suffer from quotidian intermittent fever and chronic rheumatism. Mortality does not take place from the above diseases. In 1858, the admissions from fever were 62, and from rheumatism 25. The proportion of admissions from the former disease to the total admissions was 28·18, and from the latter disease 11·36. 7. Intermittent fever consists of a paroxysm divided into three stages, the cold, hot, and sweating, following in regular succession, and terminating in a complete subsidence of symptoms, and, save a certain languor, return to health. After an interval in the quotidian form of about 24 hours, unless prevented, the fever returns, and runs the course of stages over again. It is generally here uncomplicated, and quickly amenable only to quinine. It occurs chiefly in the cold and hot seasons, strong sea winds acting on the enervated constitutions, especially when the person is profusely sweating. It is chiefly observed directly on the sea coast, not so much so inland. This disease does not frequently show itself in the bazaar or station. The sepoys generally contract fever on their outposts, and come to the station for treatment. The natives confine themselves much in their small close dwellings, which are generally

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	insufficiently ventilated. Sleeping in the open air, thin clothing, hard toil, and insufficient food, are predisposing causes amongst the natives to the reception of malarious poison. Intermittent fever is very little observed among the European inhabitants.
	8. The soldiers on the march, and in the field, when exposed to the action of malaria, must necessarily be liable to intermittent fever.
	9. Quinine is decidedly prophylactic against malarial diseases, though not tried in that character at this station.
	10. Ague does not appear to take its rise at this station, or at least, rarely. Bancote or Fort Victoria ought to be abandoned as a station, as hardly a civil native servant, policeman, or soldier ever escapes without ague, even after a short residence. It is about 15 miles from this station, situated on the sea, at the mouth of a creek, and is the station of a native magistrate and his court.
V. INTEMPERANCE.	1. The sepoys are temperate as a class, and no confirmed drunkards are known.
	2. There have been no admissions into hospital from diseases caused either directly or indirectly by intemperance. Drunkenness is punished as an offence.
	3. Distilled spirits are sold at the bazaar; but the quality, and amount consumed by each man per diem, cannot be ascertained.
	4. The consumption of spirits by troops is injurious to health, except when rendered requisite as a stimulant after fatigue or during toilsome work. They are not conducive to efficiency or discipline.
	5. It would be beneficial to restrict the use of spirituous liquors as part of the ration, and certainly some restrictive measures ought to be adopted concerning the sale of liquors in bazaars.
	6. Good malt liquor used dietetically is shown by all experience to be superior in its action to wine and spirituous liquors.
	7. The influence of coffee, tea, lemonade, soda water, and similar drinks, on health, efficiency, and discipline, as compared with the use of ardent and malt liquors, must be good. This answer is given on the supposition that a free use is implied.
	8. As a general rule, restriction, instead of suppression of spirit, would appear to be sufficient. Were beer of a good quality supplied, the habit of spirit drinking would fall quickly into disuse.
	9, 10. It would be very beneficial in prohibiting the sale of spirituous liquors in the canteens to permit only tea, coffee, beer, &c., to be sold to the troops. No recommendations to make on these points.
	11. There are no bazaar regulations with respect to European troops at this station.
VI. DIET.	1 to 4. No reply to these queries.
	5. At this station vegetable gardens could be easily established, and they would be healthful and advantageous.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldier's dress consists of red tunic, red shell, black cloth trousers, black drill trousers, Kilmarnock cap with white cover, highlow shoes, overcoat, and white trousers. The accoutrements are—musket bayonet, ammunition pouch, cross belt, waist belt, percussion pouch, knapsack, and sling belt. The dress used by the men at this station appears all that could be desired. We cannot suggest improvement in the present style and composition of dress used. Every necessary precaution seems to be taken to ward off the effects of sun heat, night air, and wet. At this station there are sentry boxes. The protection on guard consists of the overcoat, and the sentry ground is the verandah of the guard-house during the heat of the day and in heavy rain.
Duties.	1. The men should be thoroughly drilled at home before being sent to India.
	2. The old sepoys are not drilled. The routine of duties is, guard mounting, guards inspection parades weekly, muster parades monthly, occasional parades, anniversaries, to hear certain orders read, &c., occasional treasure guards, and the outposts supplied by the veteran battalion guarding the local treasuries. In this climate the mornings in the cold season are the best for drills, parades, and marches. The average number of nights the men had in bed during the week for the month of May 1860, was six.
	3. Guards are mounted close to the lines, and last for 24 hours. Sentries perform their guard for two hours; there are three reliefs. There are roll call parades twice in the 24 hours. The night guards are not observed to be detrimental.
VIII. INSTRUCTION AND RECREATION.	1, 2, 3. There is a native regimental school, but there are no other means of instruction and recreation.
	4. There is not sufficient shade from trees and other means to enable the men to take exercise without injury to health during the day.
IX. MILITARY PRISONS.	1. There are no military prisons or cells at this station.
X. FIELD SERVICE.	1. There are no local regulations for field medical service.
	2. The powers of medical officers on the line of march are, I believe, confined to suggesting to officers commanding what they may consider necessary as affecting or likely to affect the health of the soldiers, their comfort, &c.
	3. Dapoolee being a small out of the way station, and never visited by troops, the regulations in force for preserving the health of troops, as to the selection of camping grounds, &c., are simply confined to attention to cleanliness, cutting down exuberant or rank vegetation, &c. Whenever the medical officer suggests any necessary change or work, as far as the means are at hand, such change or work is always carried out.

References to Subjects and Queries.	Replies.
X. Field Service—*cont.*	4. The regulations for field hospitals, &c. in force, are those of the Medical Code and those in Jameson's Code. Sites for field hospitals are selected by the commanding officer and senior medical officer. Medicine, diet, and comforts are provided by the commissariat. Doolies, and sick carriages of other kinds, are used to convey the wounded. In action advantage is taken of the close vicinity of villages to form shelter for the wounded.

By order of the Acting Principal Inspector-General, Medical Department,

Office of the Principal Inspector-General, Medical Department,
Bombay, 29th September 1860.

W. C. Coles,
Assistant Surgeon, Secretary.

XII. Hospitals.

1, 2. The hospital is situated with reference to the lines of the sepoys to the north, and a little west. The Jog river runs between them and is crossed by a large bridge now broken and dangerous. The building is to the north of the bazaar, which is divided into two sections by the Jog. To the north of the hospital is a small hill, which excludes winds from that quarter. There are high trees about, but not close; affording a grateful shade, and not impeding access of winds. The site might be better and more elevated, as the hospital lies almost at the base of one of the hills, just sufficiently however on its rise to allow free running off of water. There is no foul ground near, but there is a large water pit to the north-west, filled in the rainy season, but not productive of malaria. This water-pit cannot be dignified by the name of a tank.

3. There are two wells in the compound or hospital enclosure, the water of which is good and plentiful, until the close of the hot season. There is a plentiful spring supply near the hospital; there are no present means for improving the same.

4. There is no artificial drainage for removing refuse water and impurities.

5. The hospital is raised from the adjacent ground; it has no upper story or wards. There is no perflation of air underneath the floor, which is composed of hard beaten earth, cow-dunged every week. The roof water runs off, the position of the hospital being on an incline, and some of the water sinks into the subsoil. The guttering is made annually just before the rains, and is sufficient for every purpose. The hospital is built of laterite stone, with lime plaster over it. The walls are thick and single; the roof is of tiles and double, and both are sufficiently thick to keep the hospital cool. The single ward, of which each building of the hospital consists, is surrounded by a verandah eight feet wide. It is closed by glass windows to the west, and by jhaps to the east, affording perfect shelter from the sun's rays. The northern end of each verandah is set apart for a dispensary. They are occasionally used for the accommodation of sick, convalescents, and others. The hospital consists of one flat only.

Date of construction not ascertained. One ward in each wing.

Total regulation number of beds, 5 per cent. to strength.

Wards or Hospital Huts.	Regulation Number of Sick in each Ward or Hut.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.

The hospital does not receive the full benefit of the prevailing wind, but by a valley between the two hills facing the north-west it is enabled to receive the wind from that quarter to a certain extent. To the south-west a portion of the bazaar interferes, but notwithstanding these defects of locality it is well ventilated. The windows are casements, and well adapted for ventilation, and with the doors, are the only means for that purpose. There are no jalousies.

7, 8. There are no means for cooling or warming the hospital. The wards are cleansed and lime-washed once a quarter.

DAPOOLEE. BOMBAY.

References to Subjects and Queries.	REPLIES.
XII. Hospitals—*cont.*	9. The privies are situated to the right rear or north-east of the hospital ward, and are 75 feet distant, but connected by a roofed passage, which is entirely open on both sides to admit a current of air. They consist of seats or openings on the usual native plan. The filth is received in an open trough or drain, which is constantly cleaned from the outside by sweepers. The sweepers obtain access to the drain by means of small doors or openings in the wall, under and corresponding to each seat. The privies are not drained or supplied with water; all cleansing is done by sweepers. There are no cesspits; the surface below the privies is level, and by care they are never allowed to be offensive. 10. There are no lavatory arrangements. An apparatus is built for heating water, and a bath room is attached to each ward; they are never used by native sick. 11. The native sick, when their diseases do not preclude their doing so, bathe by throwing the water, hot or cold, over their nude persons. Except in cases requiring it their custom is not interfered with. 12. Hospital linen is washed, &c. by a dhobie or washerman, forming one of the hospital establishment. The means are quite sufficient. 13. There is no storage, the clothing is kept in a clothing chest. 14. The bedsteads consist of a wooden framework, laced with broad cotton tape, taken off and washed after each patient is discharged. It appears to me, as bugs infest these wooden cots, that iron-framed ones would be an improvement. Native sick use their own bedding. 15. There are two cook-rooms for native sick (for castes) to each wing. They are simple, and have no apparatus. The native sick either cook for themselves or the Brahmin cook, one of the hospital establishment, cooks for them. 16. There are no diet tables for native sick. Since writing the above the corps, "native veteran battalion," has been disbanded; no forms are consequently forwarded. 17. An orderly selected from the corps is always in attendance at the hospital, and any sick sepoy, if extremely ill, is always permitted to have a comrade to be with him, and attend to all his minor wants. 18. I consider the sanitary state of the hospital as good; no epidemic disease, hospital gangrene, or pyæmia have appeared in its wards. 19. I would suggest the fixing in of windows or casements, glazed, throughout the hospital, and the building of a separate ward for serious cases. This latter appears to me to be a great want in all regimental hospitals. 20. There is a large sized enclosure, or compound, which might easily be made comfortable for the exercise of convalescents. Native sick, however, seldom desire to be seen outside. The compound is well shaded. 21. The sepoys' wives and families are attended to when they visit hospital, and are attended at their houses, if willing, which they seldom are. The present arrangements are satisfactory. 22. There are no special hospital regulations not included in the General Presidency Medical Regulations. 23. With reference to peculiar repairs of hospital, these are carried out under the sanction of the superintending surgeon, at his or the medical officer's suggestion. With regard to medical comforts within the hospital, stations, camps, and on the march, the medical officer directs the supply of whatever may be required, subject to the pre or past sanction of the superintending surgeon. General repairs are carried on annually by the officer in charge of public buildings. 24. There are no convalescent wards or hospital, nor does there seem for native soldiers any necessity for such.
XIII. BURIAL OF THE DEAD.	1, 2. The burial ground for European residents is within the station, and is situated on the northern side of the camp and to the west of the hospital. The prevailing winds do not blow fairly over it toward the station. It is well situated on a slope, enclosed by a high wall, and its area is 9,600. The soil and subsoil is decomposed laterite, and all water runs off quickly. It is not known, however, what effect the soil has on decomposition. The ground is not particularly attended to. 3. At present space is not apparently an object, the interval between each grave being from 6 to 10 and 12 feet, and the depth from 6 to 7 feet and more. Graves are never reopened. Interment is compulsory at ordinary times from 12 to 16 hours after death. Native troops bury their dead or burn the bodies. The Mussulman burial ground is to the north of the European one; the Mahratta and other castes are situated to the east of the camp. Natives are buried in a more superficial manner, as a general rule, though many good tombs are erected by them. 4. The graveyard is never offensive. 5, 6, 7. The dead of camp followers or bazaar people are buried in the burial ground of their castes. No injury accrues to the public health from the present practice of disposal of the dead, and no improvements are suggested.

(Signed) ALBANY TROWARD, Lieut.-Col. Commanding at Dapoolee.

References to Subjects and Queries.	Replies.
I. Topography.	1. The surrounding country is partially cultivated. It is a valley 9 miles in width and 20 in length, divided by the Panjur river in two unequal portions. It is flat, with a low range of hills on the north and south-west. The river Panjur rises from west to east, skirting the northern side of the station. The land not under cultivation is covered with low jungle. 2. The elevation of the station above the sea is about 1,000 feet, but is on a level with the adjacent country. It is about 30 feet above the nearest water. There is no higher or healthier ground adjoining the station. 3. The nearest high land is the hill fort of Galna, which is 24 miles distant; its height above the station is about 700 feet. The table mountain of Torum Mal is situated 90 miles north of Dhoolia. Its height above the sea is 4,304 feet. The following is a copy of a report on this mountain :— " To Alexander Elphinstone, Esq., Collector and Magistrate, Khandeish. " Sir, " With reference to your endorsement, No. 334 of 1849, dated the 23d ultimo, forwarding the copy of a correspondence relating to a settlement of the feud between the Bheels of the Burwanee state, and Koshia, Naig of Sinde, in the Akraum Purgunnah, and desiring me, with reference to Lieutenant Evans' remarks on Torum Mal, contained in the above correspondence, to avail myself of every opportunity that may present itself of acquiring information of the climate and salubrity of that place, I have the honour to state that I have since visited Torum Mal, and that the result of my observations is as follows :— " 2. Torum Mal is situated in the heart of the Suthpoora mountains, and forms the most elevated plateau of the whole range. It is in the Akraum Purgunnah, about 40 miles north-east from Shada, the chief town in the Sultanpoor talooka, and the nearest place from which supplies are procurable. Its distance from Mhow, *viâ* Chikulder, is about 140 miles. As far as Chikulder, the road is very good; but from the latter place to Torum Mal, a distance of about 60 miles, it is a mere footpath, through dense jungle, and a very mountainous country. The distance from Baroda, *viâ* Sagbarra and Shada, is about 150 miles; from Surat, *viâ* Nowapoor, Nundoorbar, and Shada, about 160 miles; from Dhoolia, 90 miles; and from Mulligaum, *viâ* Dhoolia, 120 miles. All these roads are very good and practicable for wheeled carriages to within about 20 miles of the summit of Torum Mal. " 3. The table land of Torum Mal forms an irregular plateau, about 20 miles in circumference. Its surface, however, is much broken by deep wooded ravines, and by irregular-shaped hills, rising from 300 to 600 feet above the general level. Towards the north-east end of this table land are two lakes, the upper one of which is between 2 and 3 miles in circumference. Its water is perfectly clear, the bottom being composed of sand and loose stones. I ascertained the depth of the water in the centre to be 36 feet; on the east side, a few yards from the bank, 31 feet; and on the west side, 27 feet. It contains no alligators nor fish, and the inhabitants say that fish put into it invariably die; but it contains a great quantity of a small species of shrimp, of which the Bheels take considerable quantities for sale to the neighbouring towns in the west of Khandeish; its surface is covered with different species of wild fowl. " 4. This upper lake is partly artificial, the east side being formed by a vellard extending across the valley at its gorge. The natives, considering this vellard beyond the power of human beings, ascribe its construction to Goorucknath, the presiding deity of the place; and from its immense solidity and extent it would certainly be considered an extraordinary work in any age and country. I ascertained by measurement its length to be 440 yards, its breadth at the base 98 feet, ditto at the surface 28 feet, and height 18 feet. A passage has been left at the south end of this vellard for the discharge of the superfluous water of the lake, and a channel cut to conduct it to the lower one, which is much smaller than the upper, and is said to sometimes dry up in the hot season. From this lower lake a broad channel has been cut for a considerable distance, which conducts the water over a perpendicular fall between 500 and 600 feet high into the valley below. " 5. The sides of the vellard of the upper lake are thickly shaded by wide-spreading trees of the ficus Indica, ficus religiosa, calyptranthes jambolana, &c., which also shade a great part of its upper surface, which being, as before stated, 28 feet broad, affords ample space for tents or small bungalows, and as a westerly wind prevails almost without change during the hot months, tents on this vellard receiving the breeze directly across the lake are kept very cool the whole day. " 6. The surface of the lake is about 400 feet below the groups of hills which border it on the south and south-west sides. The hills and plains being thickly studded with groups of large spreading carunda bushes, the toorum (a tall shrub bearing a sweet berry, peculiar to these hills), the wild mango, the ficus religiosa, the calyptranthes jambolana, and many others, give the landscape, at the dryest season, a picturesque verdant appearance, although from the habit the Bheels have of setting fire to the grass every season, the green jungle is not so continuous as on the Mahableshwur hills. " 7. I regret that I was unprovided with a barometer to enable me to fix the altitude of this plateau correctly; the boiling point of water with thermometer immersed gives an altitude of 4,304 feet above the sea level to the lake, and 5,434 feet to the hills, about a mile and a half to the south-east of the lake, and this I think will be found to be nearly the correct altitude. " 8. I noted the variation of the thermometer eight times daily during my stay, and although this was during the hottest period of the year, and I was living in a small rowtee open to

References to Subjects and Queries.	REPLIES.
I. Topography—*cont.*	the S.W. and N.E., its greatest range was 89° and least range 66°, the mean temperature being 77°, and the daily range of variation being about 16°. During this time the thermometer in a tent under shade, with wet kus tatties, in the plains ranged from 88° to 105° daily. "9. There are about 40 Bheel families dwelling on the hill. They are scattered about in hamlets of five or six huts each, and rear a great number of cattle in the rich pastures of the lower table land. They also cultivate small patches of wheat, Indian corn, grain, tor mor (a species of rice), bhurtee, &c. Each family only cultivates enough to suffice for its own wants, and therefore a great portion of the richest land is left uncultivated. The soil above the upper lake is a rich black alluvial deposit, and on the higher plateaux it is a rich ferruginous clay, which would doubtless produce good crops of potatoes and wheat. The huts of the Bheel inhabitants are strongly constructed of interlaced bamboos, thatched with a species of coarse grass, about 10 feet in height, which grows in profusion on the sides of the hills. They are in the habit of descending to the markets of Tulloda and Shada, situated in the Sultanpoor talooka, and they carry down gums, lac, honey, bees-wax, dye-woods, charolee (a species of sweet nut), &c., which they exchange for salt, spices, cloths, iron, &c. They are a very quiet, inoffensive, timid people, very different from the Bheels in the plains. Their head man is Goorkhia Naik, a fine old man, who has often rendered good service in assisting in the apprehension of desperate characters who have taken refuge in these remote fastnesses. "10. A juttra takes place annually at Torum Mal, in the month of January, in honour of Gooruknath; it had been discontinued until within the last few years, owing to the number of robbers who infested the jungles below; it is now attended by between 200 and 300 persons chiefly from the west of Khandeish. "11. Remains of stone and brick buildings are found scattered all over the hills, and a substantial stone wall varying from 10 to 15 feet in thickness has also been carried round the hills for many miles. It has been defended by round towers of most solid construction, and each of the three passes leading up to the table land has been fortified by extensive works. All these are ascribed by the natives to the period of the Gowlee Raj, or Shepherd kings, to whom are also ascribed all the works in the west of Khandeish considered beyond the powers of the present race of inhabitants. These walls and fortifications are composed of blocks of stone, piled up without any mortar or chunam being used. The outward front is perfectly smooth, and this peculiarity of construction will be found in all works attributed to the period of the Gowlee Raj, as it also distinguishes all Etruscan walls in the ancient cities of Italy. There is also a second or inner wall which appears to have been constructed at a later date, probably after the ruin of the original fortification, and was intended to prevent the ingress of wild beasts, and to keep cattle from straying. All these ruins tend to show that at some early period a very considerable population was located here. "12. There are three approaches to Torum Mal, one leading from Khandeish, one from Burwan, and the third from Sinde and the Nurbudda. There is also a difficult footpath to Dhergaum on the Khandesh side, The road is very good for the first 20 miles from Shada, but for the last 20, from the Bheel village of Chirlee, it consists of a succession of steep ascents and descents. Tattoos with light loads can ascend, and the Banians from Shada bring up their supplies on donkeys; the road might be made much easier at a small expense. The pass leading to Sinde and the Nurbudda, which would be the road for people coming from Mhow and Mundlassir, is also very steep and difficult for about three coss. The ascent by the Hiwassea gate from the direction of Burwan is the most easily surmounted by laden cattle. "13. The Bheels of Torum Mal appear very healthy. They state that there is no prevalent sickness during the rainy season, but that a large species of fly with which these hills abound is very troublesome to both men and cattle. Tigers are seldom heard of above the passes, although they are numerous in the plains below, and during my stay I did not observe a single noxious reptile or insect of any sort. "14. Game is plentiful in the hills, and peacocks, jungle fowl, the grey partridge, quails, wild ducks, hares, wild cats, jackals, foxes, and bears are pretty numerous. The latter appear to ascend the table land during the night to feed off the wild fruits and descend to the valley in the morning. The bison or Bos Ganem, which abounds in hills further west towards Dhergaum, is said by the Bheels to ascend to the table lands during the rains, but never remains during the dry season. Antelopes and the civet cat are also found in the hills, and the Meelgae and genus Cervus (the Sambee) in the valleys around. "15. The geological formation of the hills is composed of hard red sandstone, iron-stone, and masses of trap rock. On the east side scarped masses of bare basaltic rocks of a red colour rise perpendicularly to a height varying from 400 to 600 feet. The deep valleys below are concealed with thick jungle, and abound in peacocks and jungle fowl. From the lofty scarped projections, which on this side jut far out into the ravines, most extensive and romantic views are obtained over a vast extent of mountainous country towards the Nurbudda. "16. A great many trees and shrubs unknown to the plains are found on these hills; several produce edible fruits and berries, which form a considerable part of the food of the Bheels inhabitants, and several produce red and yellow dyes, which they carry to the neighbouring markets for sale. A variety of creeping plants entwine the branches of the largest trees, whilst mosses and lichens, the parasitic orchis, and viscum apontiacies strongly resembling the misletoe of Europe, tend to show the temperate climate compared with that of the low country. "17. Most of the inhabitants of this part of the Suthpoora range are a peculiar class of people called 'Panria.' Although commonly supposed to be Bheels, and classed as such, they deny all affinity with the latter, and will neither eat nor associate with them. They worship 'Waghdeo,' or the tiger demon; they do not eat the flesh of swine or cows, and their manners and customs are quite different from those of the Bheels tribes; they speak a peculiar language, are very quiet and inoffensive, robbery and plunder being almost unheard of amongst them. Most of them have settled in these hills during the last few years, having immigrated from native states bordering the Nurbudda. In the Akranee Purgunna the number of these settlers now amounts to 11,268 souls; five years ago the number was 2,570 souls; they pay to Government for the land they cultivate a sum of about 2,769 rupees annually. "18. There can, I imagine, be no question as to the salubrity of Torum Mal during the hot season, and that its invigorating climate would be a most beneficial change from the depressing heats of the plains, although the thermometer during this season averages

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	about 20° lower than it does in the plains, yet the elasticity of the atmosphere at this height, and the vicinity of a fine sheet of water, cause the climate to be still more agreeable to the feelings than the degree of temperature would indicate; the only question therefore is, whether people would consider it worth the trouble to traverse the wild mountainous country by which Torum Mal is on every side surrounded, for the purpose of enjoying a temporary sojourn on its summit. (Signed) "C. P. Rigby, Lieutenant "Camp at Shada, 28th April, 1849. Western Bheel Agent."

Register of Thermometer at Torum Mal noted in a small Rowtee open to the South-west and North-east.

„ 17 -	69	83	89	89	86	81	78	67	80	22	Cloudy weather and calm, no wind all day.
„ 18 -	74	82	87	89	84	80	79	78	81	15	Cloudy weather, with light breeze at intervals. Heavy clouds at night, and slight rain.
„ 19 -	74	75	84	84	82	80	78	77	79	10	Clear sky, with fresh breeze from N.W. at intervals, at night cloudy.
„ 20 -	70	74	82	85	83	80	79	73	78	15	Cloudy; no wind; a slight shower of rain about 8 a.m.
„ 21 -	72	80	83	88	84	82	80	70	79	18	Still cloudy morning; occasional breezes from the west after midday.
„ 22 -	69	82	85	86	83	78	80	70	79	17	Cloudy sky, with cool breeze after midday from the west.
„ 23 -	72	80	84	86	80	78	70	74	78	16	Cool breeze blowing from the S.W. all day; cloudy sky.
„ 24 -	68	72	81	82	80	75	70	70	74	14	Cold westerly wind blowing day and night; clear sky.
„ 25 -	67	70	80	82	79	74	70	68	74	15	Cold westerly wind all day and night; clear sky.

(Signed) C. P. Rigby, Lieut., W. B. Agent.

List of the principal Trees and Plants found in Torum Mal and the neighbouring Hills.

Names of Trees and Plants.	Uses to which applied.
1. Ficus Indica - - - -	——
2. Ficus religiosa - - -	Produces gum and the coccus lacca.
3. Mimosa chanda - - -	Yields a resinous gum.
4. Butra frondosa (Sans. Pullus) -	Its flowers used as a yellow dye, and its fruit as a purgative; yields gum.
5. Zizyphus Albens (Sans. Tourn) -	Its fruit is greatly prized by the Bheels; it is peculiar to Torum Mal.
6. Carissa carondas - - -	Its fruit is used as a pickle.
7. Ficus glomerata - - -	Its fruit is used as food; its wood affords good timber.
8. Tamarindus Indica - - -	Ditto Ditto.
9. Bassia latifolia (Sans. Madbura) -	Liquor is distilled from its flowers, which are also eaten when dried.
10. Zyzyphus jujuba - - -	Its fruit eaten as food; good hard wood.
11. Dispyrs glutinosa - - -	Ditto Ditto.
12. Teroura Elephantum - - -	Yields a gum.
13. Butra superba - - -	A yellow dye and gum.
14. Teeton grandis - - -	——
15. Khakur (native name) - -	Its fruit used as a pickle.
16. Calyptranthes jambolana - -	Timber and fruit tree.
17. Terminalia tomentosa - -	Its fruits used medicinally.
18. Zizyphus napica - - -	An edible berry.
19. Cordia latifolia - - -	A fruit tree.
20. Mimosa catechu - - -	Yields a gum which is used in dyes, and in making cheenand.
21. Grislea tomentosa - - -	Used as a dye.
22. Chirongia sapida - - -	Its nuts are much prized; used in confectionery, emulsions, &c.
23. Mangifera Indica - - -	——
24. Spondeas mangifera - - -	——
25. Dalbergia oojernsis - - -	Bark used in tanning.
26. Phyllanthus emblica - - -	Medicinal; its fruit used as a pickle.
27. Erytherua fulgens - - -	——
28. Dhamun (native name) - -	Good timber; its fruit is eaten.
29. Koosum (ditto) - - -	Yields a red dye.
30. Sapindus emarginatus (Soap tree) -	Its fruit used as a substitute for a soap, &c.
31. Ginlandina moringa - - -	Its flower is used as a vegetable, its bark as a medicine.
32. Hibiscus canambus - - -	Ropes made from its fibrous integuments, and oil expressed from its seeds.
33. Mimosa Sirisha - - -	Timber tree.

References to Subjects and Queries.	Replies.

I. Topography—*cont.*

"True copy.—Original sent to Government on the 9th May 1859."
(Signed) R. R. Powell, Major, Commanding at Dhoolia.

"Note from Dr. Knapp to Mr. Elphinstone.

"I heard from Rigby the other day; he sent me the observations which he had made on the boiling point of water at Toorum Mal for me to work out the height from Colonel Sykes' table; from which it appears that the level of the lake is 4,304 feet above that of the sea, and that of the summit of a hill about 1½ mile to the southward of the lake, 5,434 feet. This is higher than any part of the Mahableshwur hills, the general level of which is said to be 4,500 feet, and the highest point 4,700. I very much regret not having visited Toorum Mal, particularly as I now find that I could have had even a month's leave from the Brigadier. However, I must look forward to another opportunity, which perhaps may occur, when I may have the pleasure of visiting it with you."

"True extract.
(Signed) "A. ELPHINSTONE,
"Collector and Magistrate."

"True copies.—(Signed) R. R. Powell, Major commanding at Dhoolia."

4. The river Panjar skirts the north of the station, running east and west, but the vicinity is not liable to overflow of water. There is no broken ground to any serious extent.
5. The station is open, and would be freely exposed to winds, if not so encumbered with trees, hedges, and gardens. The temperature of the station is not raised by reflected sun heat. It is exposed to north-west and occasionally to north and north-east winds in December, January, and February, veering to west in March and south-west with monsoon.
6. The surrounding country is partially cultivated. A small aqueduct passes through the station, running parallel to the river; irrigation, however, is too insignificant, and the fields too distant to have any effect on health. There is no restriction as to rice cultivation, but it is cultivated at a distance, and cannot affect the station. Neither indigo nor flax is cultivated near the station.
7. The town of Dhoolia adjoins the station.
8. The surface of the district is black soil, with a subsoil of moorum. The station occupies new ground.
9. Water is found during the dry season at about 30 feet below the surface, and during the wet season at a depth of 23 feet.
10. The rain-fall sinks through the surface into the moorum subsoil, and so speedily drains off. No drainage from higher ground passes into the subsoil of the station.
11. The water supply is obtained from rivers and wells: there are no tanks. The wells, if not in constant use, are liable to pollution.
12. The water supply is abundant at all times. Its colour is rather blue, but its taste is agreeable, and it has no smell. It is soft and of good quality, and its amount is sufficient. There are no special means for raising and distributing it in use. No better supply could be obtained.
13. Dhoolia is situated on a plain screened by ranges of surrounding hills, and is consequently exceedingly hot.
14. New stations are selected by the quartermaster-general's department, in consultation with the medical authorities. No improvement in the mode of selection is suggested.

II. CLIMATE.

1. The only instruments for registering meteorological observations are a thermometer and a pluviometer, which are in charge of the civil surgeon.
2. Table of observations from September 1853 to March 1858.

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature at 4 P.M.	Rain, Inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks as to Clouds, &c.
January	No barometer at the station.	70·38	18·59	80·25	61·66	Not registered.	63·25	102·98	None.	N.N.W.	No data to go by.	No data.	No data.
February		75·55	20·6	85·74	65·14		64·71	105·91	·21	N.N.W.			
March		82·52	20·26	91·95	71·69		68·17	113·04	·64	N.W.			
April		87·88	19·6	98·11	78·51		73·56	114·98	·50	N.W.			
May		91·26	18·15	101·39	83·24		76·96	115·14	2·30	W.S.W.			
June		87·29	12·34	93·72	81·38		78·67	102·84	15·27	S.W.			
July		81·66	5·96	84·59	78·63		76·69	88·65	21·21	S.W.			
August		79·88	6·65	83·82	77·17		76·99	85·60	9·52	S.W.			
September		80·01	7·42	83·45	76·03		76·78	90·8	20·97	S.W.			
October		79·97	13·54	86·2	72·66		73·56	97·95	13·28	W.N.W.			
November		75·91	17·9	83·22	65·32		67·2	100·39	None.	N.W.			
December		71·8	19·82	80·52	60·7		63·44	95·88	·3	N.N.W.			

Total fall in 5½ years.

3. The climate is hot and muggy; it is not influenced by irrigation, and there are but few dust storms. It seems beneficial to the health of the troops (native). During the extremity of the hot weather the drills and exercises are of limited duration; the duties of course remaining the same. March, April, and May, and the early portion of June, are the most healthy months, and October and November the most unhealthy. Fevers, with liver and spleen complications, prevail during the latter months.
4. The Mulligaum districts, south of the Arnee range of hills, are more healthy than the present station. The station of Malligaum is 34 miles distant, is 300 feet more elevated than Dhoolia, is perfectly drained, amply supplied with water, quite open to the breeze, more free from fever during the months of October and November, and has a climate in every way more suitable to the European constitution. The only reason which can be urged against its adoption is that costly public buildings have already been erected at Dhoolia.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	5. The stations at which I have served, with their comparative salubrity, are given as follows:— 1. Poona.—Healthy. 2. Bombay.—Unhealthy. 3. Ahmedabad.—Unhealthy. 4. Kurrachee.—Healthy. 5. Hyderabad.—Variable. 6. Shikapore.—Variable. 7. Mhow.—Healthy. 8. Rajcote.—Healthy. 9. Mulligaum.—Healthy. 10. Aden.—Unhealthy. 11. Deesa.—Healthy. 12. Nusseerabad.—Unhealthy. 13. Neemuch.—Unhealthy.
III. Sanitary Condition of Station.	1, 2, 3. Plans of the country and station are forwarded. 4. Table of barrack accommodation.

Date of construction of barrack, 1858.

Total of rooms or huts - - - - 372
Total regulation number of non-commissioned officers and men - - - - - - 372 — Native infantry troops.

Barrack Rooms or Huts.	Regulation Number of Men in each Room or Hut.	Dimensions of Rooms or Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
		Feet.	Feet.	Feet.							
Of native officers:											
Subadars - - -	1	20	10	11	2,200	2,200	200		The pendalls are open sheds without doors or windows.		
Jemidars - - -	1	12	12	11	1,584	1,584	144				
Non-commissioned officers	1	15	10	7	1,050	1,050	150				
Rank and file - -	1	7½	10	7	525	525	75				
Quarter guard-room, composed of three rooms, one of which is used as a prison cell - -	15	15	12	11	1,980	237					
		12	12	11	1,584						
		12	12	11	1,584	1,584	144				

5. There are no windows, doors, verandahs, or jalousies or jhilmils to the barracks.
6. Native troops do not use bedsteads or cots, but always provide their own bedding, which they spread on the floor. No improvements are suggested.
7. The tents used are regulation double-poled rowties for native cavalry, the cubic contents of which are 1,200 feet, breadth 14 feet, height 10 feet, extreme length 25 feet, and length between the poles 9 feet. The area per man 11·7 feet, and the number of men in each 30.
8. No special means of ventilation are provided in barracks, huts, tents, or guard rooms. Sufficient ventilation is obtained by opening the tents, &c. In pendalls for native troops no means of cooling the air are provided.
9. The barracks or pendalls are constructed of fire-burnt brick pillars and walls, the roofs are double-tiled, and the posts are of cut teak-wood. The tents are of cotton wove cloth, and the huts are constructed of mud.
10. The floors are of moorum, rammed and watered, and are raised 1½ feet above the ground. There is no passage of air beneath.
11. The materials and construction of the pendalls are good. The huts are merely temporary buildings, and the tents are well adapted for the purpose. It would be an improvement if the pendalls were provided with ventilators in the roof. The barracks and cantonments are kept in repair by the executive engineer, and the repairs are quickly executed. The staff officer is responsible for the general sanitary state of the cantonment. There are no stated intervals for cleansing and limewashing pendalls, but it is done when required, as the commanding officer may direct.
12 to 15. There are no lavatories or cook-houses, neither is there any convenience for washing and drying linen. There are no privies or urinals. There are no means of lighting at night.
16. The natural drainage is sufficient for conveying away readily and efficiently all surface water. No part of any building used as barrack or hospital is damp. The drainage is sufficient for all purposes. There are no cesspits or foul ditches. There are no means of drainage or sewerage.
17. The cleanliness of the sepoy lines is maintained by sweepers; this cleansing is efficiently and duly performed, and the refuse is disposed of to the tile and brickmakers.
18. The surface of the station is kept free of vegetation. There are no old walls, thick hedges, &c. interfering with the ventilation of the station or bazaar.
19. The bazaar is well drained and open to the breeze; it is amply supplied with water; maintained in a state of cleanliness; and not crowded. The inhabitants of it maintain a sweeper. No improvements are required. The native houses near the station are generally in a good condition; no dung-heaps or cesspits are permitted within them. No nuisance is experienced in barracks from wind blowing over the native dwellings.
20. There being no European troops, this query as to slaughtering places does not apply to the station.
21, 22, 23. There are no stables for horses or picketing grounds. No quarters for married men exist at the station.

Officers' Quarters.	1. The officers' quarters are decidedly bad. If Dhoolia is to be the permanent head-quarters of a regiment, additional accommodation for officers is absolutely requisite.
IV. Health of the Troops.	1. The station, district, and adjoining native population are healthy, but the climate is not adapted to European soldiers. 2. The most prevalent diseases are fevers and spleen disease.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	3. The healthiness of the native population is attributable to the air and water being good. 4. The head-quarters H.M.'s 26th were at Sattara from 3rd January 1855 to 26th December 1856. Their general health there was good, the prevailing diseases being fevers and rheumatism. They were in Persia from 1st February 1857 to 4th September 1857, and while there their general health was good. The prevailing diseases were fever and bowel complaints. They were at Dhoolia from 30th November 1857 to 22nd November 1858, and on field service and outpost duty at Khandeish from 22nd November 1858 to 15th June 1860. Their general health is very good. The prevailing diseases have been fevers. No portion of the men's present accommodation is more unhealthy than the rest. 5. The troops are not camped out. 6 to 13. No experience of troops at hill stations. 14. Frequent change of station is not beneficial to the health, and damps the spirits of the troops. 15, 16. No experience with troops at hill stations. 17. Galna might be advantageously used as a hill station for a small number of convalescents, not exceeding 100. The distance from the station is 24 miles, and access is obtained to it by means of a country cart road. Its elevation is 700 feet above the plains, and it possesses a temperate climate. 18. Moorum is the most healthy class of surface for stations. 19. Soldiers proceeding to India should be from 20 to 23 years of age, and they should land there in November. I cannot say how troops are disposed of on their arrival, but recruits, on first landing in India, should be kept from liquor, and given abundant occupation for mind and body. 20. Troops should be sent direct from the home depôts to India, and on landing should, if practicable, be sent to hill districts to gradually accustom them to the climate. 21. Troops march on foot to the interior, or are conveyed by bullock transport trains, if their route lies along any of the great trunk roads. I am not aware of any additional precautions that are required. 22. About 12 years is the length of time a British soldier should serve in India. 23. I have no suggestions to make as to the mode of conducting the business of medical boards in regard to invaliding. 24. Invalids should leave India for home in January.
Diseases.	1. There are no regular inspection parades for the discovery of incipient diseases at the station. 2. There has been no scorbutus among the troops. 3. The proportion of hepatic disease among the native troops at the station is very insignificant, and generally is in the form of functional derangement. 4. Dracunculus is not (as far as my experience leads me) endemic to Dhoolia or its neighbourhood. I suspect the animal, in an early stage of existence, is taken into the stomach with the water drank. The prophylactic measures are, to be careful of the water in places notorious for Guinea worm; and if obliged still to drink it, to have it boiled. 5. One in 40 has been the proportion during the past 12 months of the constantly sick from venereal disease to the total sick in H.M.'s 26th Regiment N.I. Lock hospitals would be advantageous to the health of the population generally, and of the army particularly. 6. The following diseases, of the endemic or epidemic form, are those from which the troops suffer:— *Fevers.*—Intermittent, especially of the quotidian type, are more or less prevalent throughout the year, but not to any serious extent, and generally severest in November and December. Fatal cases in natives are generally complicated with some internal inflammation or congestion. *Dysentery.*—Not particularly. *Cholera* is more or less prevalent every hot season. No cases occurred in the regiment during the past official year. *Small-pox* very rare indeed, vaccination being imperative. *Rheumatism* is not prevalent to any serious extent, and very rarely with acute symptoms.

The following is the proportion of admissions and deaths from these diseases to total admissions and deaths:—

Diseases.	Per-centage of Admissions to Total Admissions.	Per-centage of Deaths to Total Deaths.
Fever	54·97	None.
Dysentery	·55	,,
Cholera	—	—
Small-pox	·27	,,
Rheumatism	6·96	,,

7. I am unaware of any diseases of the zymotic class being endemic to Dhoolia or its neighbourhood. Cholera, in its epidemic form, is the most frequent and regular in its occurrence, cases occurring sporadically at any season. In the cold season measles and mumps generally appear and small-pox and epidemic cholera throughout the hot season. Before an outbreak of the latter the air is very commonly close, hot, and sultry. The sanitary condition of the station is very good, and that of the town very superior to native towns generally. Epidemic cholera appears to have very few caste prejudices, attacking alike the rich and poor, the strong and the more delicate of both sexes.

8. This query is applicable only to European troops.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —Diseases—*cont.*	9. Small doses of quinine have not been tried at the station as a prophylactic against malarial diseases. 10. No suggestions to offer on any of the preceding points.
V. Intemperance.	1. The soldiers at the station are temperate; there are no confirmed drunkards. 2. This query does not apply to native troops. 3. Distilled spirits are sold in the bazaar of infamous quality; the amount consumed by each man is not known, but is thought to be small. Spirit is no part of the ration for native soldiers, either at the station, on march, or in the field. It is given to convalescents under medical treatment. Arrack, brandy, or wines are given medicinally. No drinks other than intoxicating drinks are sold in the bazaar. Drunkenness *per se* is not punished as an offence. 4. The consumption of spirits by troops is injurious to health, and not conducive to the efficiency or internal discipline of the corps. 5. It would be decidedly beneficial to abolish the issue of spirituous liquors altogether. 6. Malt liquors are far more beneficial to health than spirits or wine. 7. Coffee, tea, lemonade, and sherbets and water are much used here, more especially the latter, and are preferable to both spirits and malt liquors. 8. It would be beneficial to the health of troops to suppress altogether the spirit ration, and to substitute for it beer, tea, and coffee. 9. It would be beneficial to prohibit the sale of spirituous liquors in canteens, and to permit only beer, coffee, tea, &c., to be sold to the troops, provided the soldier could not purchase inferior spirits elsewhere. 10. I have no recommendations to make on these points, unless the introduction of light wines of France in wood be considered advisable. 11. There are no bazaar regulations.
VI. Diet.	No replies to queries under this head, the subject being only applicable to European troops.
VII. Dress, Accoutrements, and Duties.	1. The soldiers' dress at the station consists of a scarlet tunic of cloth, black cloth pantaloons, and black and also white cotton pants. The accoutrements are a pouch and bayonet belt, with knapsack. They have also a Kilmarnock forage cap, with white cover, ancle boots, and grey great coats for native troops. The present dress is suitable, but a khakee tunic and dhotee might be added to the above kit for field service, on march, and on guard mounting during the hot weather, and the black and white cotton pantaloons abolished. I have no suggestions to offer, except that woollen clothing (tunic) should always be worn on night duty. The present guard dress in the hot weather is scarlet tunic and black cotton pantaloons, and in cold weather and rains scarlet tunic and cloth pantaloons. The men on guard are protected by a verandah from the sun and wet.
Duties.	1. The men should be drilled at home before being sent to India, as they would be better able to defend themselves if attacked on board ship, and would be more useful if their services were required at any place en route. 2. The usual routine of a soldier's duties at the station are: a parade in the morning commencing about half an hour after reveillee, lasting one hour to one hour and a half; also a parade in the evening during the drill season,—usually the cold weather, of about three-quarters of an hour in duration, three times a week. The men do not suffer in health, but on the contrary, drills are found conducive to health. The best hours for drills are those immediately after day-break, same for parades. Marches in the hot season should invariably be commenced about half an hour before sunset; in the cold season about 3 or 4 o'clock in the morning. There are general orders on the subject. The men have two and a half nights in bed during the week. 3. Guards are mounted about 21 yards from the barracks, they last for 24 hours. There are roll calls morning and evening. Night guards render men on them liable to fevers and rheumatism, but no additional precautions in performing this duty can be taken.
VIII. Instruction and Recreation.	1. The only means of instruction at the station is a regimental school with a good schoolmaster. No means of recreation are provided, as the natives amuse themselves in their own particular fashion, and are not interfered with during their hours of relaxation. They have both quoits and skittles. There is no restriction on the men as to exposure to the sun and rain out of barracks when off duty. 2. The native troops should be instructed in field-works and in road-making; they should be taught to be self-supporting, *i.e.*, to make their own clothes, boots, shoes, &c., to build their own huts, making bricks, tiles, doors, and windows. For recreation they should have lectures on the mechanical arts, and on electricity, galvanism, and chemistry, illustrated by experiments. 3. The institution of savings' banks would be advantageous. 4. Does not apply to native troops.
IX. Military Prisons.	1. There are neither prison nor cells at the station.
X. Field Service.	1. I am not aware of any local regulations for medical field service, not included in the General Presidency Regulations. 2. The medical officer on the march is bound to offer any suggestions which he may think conducive to the health of the troops, and this course is found to be attended with advantage. 3. The practical operation of the regulations for preserving the health of troops in the selection of camping grounds, &c., as laid down in the separate general orders of the Bombay army is admirable. The medical officer represents to the military authority his opinion on the subject whenever he may consider that the ground selected is unhealthy. 4. The arrangements for field hospitals, ambulances, &c. are laid down in the Medical Regulations, Section XI. p. 123 to 134, of 1849.

By order of the Principal Inspector-General, Medical Department,
W. C. Coles, Assistant Surgeon,
Secretary.

Office of the Principal Inspector-General, Medical Department,
Bombay, 22nd December 1860.

XII. Hospitals.

1, 2. The hospital is about a quarter of a mile from the barracks in a north-west direction, and about a quarter of a mile west of the bazaar and town of Dhoolia. The site is not open or freely ventilated, for the out-buildings are to windward of the hospital and interfere with the ventilation; it is however healthy, but might with advantage, be more elevated.

3. The water supply is abundant and wholesome.

4. There is no refuse water, and the other impurities of the hospital are removed by sweepers.

5. The wards are raised about 3 feet from the ground. There is perflation of air underneath the floors. The roof water sinks into the subsoil and speedily passes away. There is a ditch which runs round the exterior of the building and rapidly carries off the rain-fall. The hospital is built of brick and chunam; the roof and walls are not double, with ventilation between, but are sufficiently thick to keep the building cool. The hospital is surrounded by a verandah nine feet wide, which affords sufficient shelter from the sun's rays. The verandahs are interior. The building being too small for its present purpose, constituted as it was for a detachment of four companies only, the verandahs are necessarily used for the accommodation of the sick. The hospital consists of one room only on the ground floor.

XII. Hospitals—*cont.*	The hospital is not so placed as to receive the full benefit of the prevailing winds. The windows open inwards, and are conducive to ventilation and coolness. 6. No means of ventilation beyond doors and windows are adopted, but the ward can thus be kept free of odour or closeness. There are no jalousies or jhilmils. 7, 8. No artificial means of cooling or warming the air of wards are employed. The walls of wards are whitewashed and cleansed every three months. 9. The privy is on the south-east corner of the hospital enclosure; it is built of stone and chunam, and tiled. The contents are removed daily by sweepers; no cesspits or drains are therefore required. 10, 11. There are no lavatories or means of bathing the sick. 12. There are no means of washing the hospital linen beyond the native washermen employed. 13. The storage is sufficient and dry. 14. Common wooden bedsteads laced with tape are used in hospital. The sepoys bring their own bedding, each being required to bring two clean sheets. No improvements are suggested. 15. The sepoys' food is cooked in an open shed in the south-west corner of the hospital enclosure. 16. No reply to this query. 17. The hospital orderly is always in attendance, and the sick, as may be necessary, are nursed by a comrade. 18. The hospital is too small for the number of troops now at the station, but no epidemic disease is known to have appeared within it. 19. The compound of the hospital should be enlarged; the out-houses should be placed further off and to leeward. The walls of the hospital are not high enough; an additional ward is required, and the whole building should be properly ventilated and sheltered from the sun by external verandahs. 20. This question does not apply to native troops. 21. The sick wives and children of sepoys, equally with themselves, receive medical attendance. No improvement is suggested in the present arrangement. 22. There are no special local hospital regulations not included in the General Presidency Medical Regulations. 23. The medical officer has unlimited power with respect to the sanitary state of his hospital; change of diet and medical comforts rest entirely with himself. All requisite repairs are executed immediately. 24. There are no wards or hospital accommodation at this station for convalescents, nor are any thought requisite.
XIII. Burial of the Dead.	1, 2. There is a small burial ground for Europeans within the station to the leeward of the prevailing winds. Its area is 100 feet by 46 feet, and is surrounded by a six-feet wall. The soil is black, and the subsoil is moorum. A drain runs along the south side. 3, 4. These queries apply only to European troops, of whom there are none at the station. 5. The dead of camp followers and bazaar people are disposed of according to caste. The Mahomedans are buried, and the Hindoos burnt. 6, 7. No injury accrues to the public health from the present practice, and no improvement is suggested.

(Signed) R. R. Powell, Major,
H.M.'s 26th Regiment, Bombay N.I.
J. M. Greig, Captain Engineers.
Henry Pitman, Assistant Surgeon.

31st October 1860.

SEROOR.

Accommodation.—Native Troops. { Cavalry, irregular, 25 for native commissioned, 32 for non-commissioned officers, and for 400 rank and file.

References to Subjects and Queries.	Replies.
I. Topography.	1. The station of Seroor is situated nearly midway between Poona and Ahmednuggur, on the trunk line of road which connects those two places. It occupies an elevated open position with regard to the country around, which has the character of being hilly, and for the most part uncultivated. On the north side of the Goar river there is a succession of hills rising in ranges one above another, and extending for a considerable distance along the bank; but on the south side, on which the station is situated, the features of the country are more regular, and the hills are only to be seen at intervals. There is no wood or jungle to be met with in the vicinity of the station, and only the small quantity of water which flows in the bed of the Goar river. 2. The elevation of the station above the sea is 1,752 feet, but has scarcely any elevation above the adjacent country, in some places being higher and in others lower than the surrounding ground. The nearest water is the Goar river, above which the station stands at a height of 45 feet. There is no ground adjoining the station which would afford a better or healthier site than that which it at present occupies. The position has been found advantageous both for European and native troops for a period of 50 years and upwards. 3. The nearest mountain or table land which presents opportunities for establishing a sanitarium is at the hill fort of Poorundhur, near Poona. There is no elevated ground adapted for the purpose in the vicinity of the station.

SEROOR. BOMBAY.

References to Subjects and Queries.	REPLIES.
I. Topography—*cont.*	4. The river Goar flows close by the station, but with this exception there is no other body of water in the neighbourhood. During the four months of the year which constitute the rainy season, the bed of the river is generally full, and in extraordinary freshes the water sometimes overflows the banks, but not to an extent sufficient to cause injury to the buildings in the town or station. The period during which such an overflow lasts is confined to a few hours. There are no pits or broken ground in which water lodges in or around the station. 5. The station generally is remarkably open and exposed to the prevailing winds. The hedge rows and gardens are kept in good order, and strict rules are enforced by the station authorities for the prevention of an undue growth of vegetation. The buildings are not exposed to the disadvantage of reflected sun heat. The sea breeze is the wind most commonly prevalent in the station; land winds also frequently blow, but no injurious effect is known to arise from their occurrence. 6. To the south of the station the country assumes a cultivated appearance, but in other directions it is singularly bleak and barren. Irrigation is not carried on in the vicinity of the station, except watering a patch of ground here and there from wells. It is not, therefore, possible to judge of the effect artificial irrigation exercises upon health. The cultivation of rice is prohibited within camp limits, but is carried on about half a mile outside. Indigo is not cultivated, nor the preparation of hemp or flax carried on near the station. 7. The town of Seroor, containing a population of 7,000 inhabitants, is contiguous to the cavalry lines, which occupy a position on the north of the station. 8. In its geological structure the district is chiefly composed of traprock, the general formation of the ranges of hills which traverse this part of the Deccan. In the valleys and the more level tracts of ground this stratum is covered with a surface layer of black soil, which, however, has no very considerable depth. 9. Water is usually found during the dry season at a depth of 30 feet from the surface, and during the rainy season at a depth of 20 feet. 10. The water from surface drainage is freely carried off, most of it by the rapid inclination the ground possesses, and partially by drainage in the porous subsoil; none of it is retained on the surface. The high ground adjoining the station is of limited extent, and has little influence in adding to the supply of drainage water which passes through the station. 11. The native portion of the community, both of the town and station, derive their supply of water from the stream which perpetually flows in the bed of the Goar. The Europeans, who are very limited in number, obtain their drinking water from wells, sunk within the compound enclosures. The system of storing water in tanks is not adopted in the station. 12. The water supply of the station is unlimited. The Goar river for four months in the year flows with a full rapid stream, and for the remainder of the season there is always copious and constant flow of water in the bed. The water contains a small portion of lime, is hard, of very good quality, not at all injurious to health, and abundant in quantity. It is obtained directly from the river, and no better supply can be had. 13. There are no other topographical points to remark on, as the station is very healthy. 14. The selection of sites for hill or plain stations is conducted by a committee appointed by Government, and constituted of officers of the engineers, medical, and quartermaster-general's departments, and a better arrangement cannot be suggested.
II. CLIMATE.	1. The only instruments available at the station for meteorological purposes are an ordinary thermometer, a minimum self-registering ditto, and a rain gauge or pluviometer. Up to two years back there were also a barometer and a wet bulb thermometer, but these instruments are no longer in existence here. The temperature both inside and outside is noted and registered four times a day, as is also the direction of the wind. The amount of rain, when any falls, is measured and noted every day. Besides these observations the maximum temperature in the sun's rays and the minimum temperature are also daily observed and noted.

2. Table of meteorological observations from the 1st January 1854 to the 31st October 1858:—

3. The character of the climate of Seroor resembles in its main points those of the Deccan generally. It is, on the whole, and with the exception of the monsoon months, dry, but not excessively so, being within the influence of the sea breeze, which generally blows pretty strongly towards the evening. The variations of cold and heat, dryness and moisture, are very moderate, and not generally sudden. There is no tree planting or irrigation carried on to such an extent as to influence the climate generally. The air is usually free from dust and other impurities, with the exception of the dust storms, which occasionally occur during the hot season, but which are not frequent. The climate of Seroor seems to exercise a very favourable influence on the health of the native troops now stationed here, amongst whom there is a very small amount of sickness, and its influence was, I believe, equally favourable

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	on that of the European troops that were formerly stationed here. I am not aware of any particular precautions being rendered necessary by the climate, other than those usually observed at all stations during the height of the hot season. There are no marked distinctions as to healthiness or unhealthiness during the different months of the year. The prevailing diseases vary only according to the different seasons; bowel complaints being frequent during the monsoon, and during the cold season rheumatism and affections of the air passages. 4. There is no district within many miles the climate of which is more conducive to health than that of the station. 5. The stations at which I have served are Ahmednuggur, Kirkee, Poona, Poorundhur, Kurrachee, and Seroor; but in all these stations my residence has been of short duration, and the present station is the only one in which I have resided throughout the year. I should say, as far as my limited experience enables me to form an opinion, that all these stations are more or less conducive to health; but I do not feel myself capable of giving a decided opinion on the comparative salubrity of these different stations; certainly not one of them can be considered as positively injurious to health.
III. Sanitary Condition of Station.	1, 2, 3. Plans of the station, adjacent country, and barracks are forwarded. 4, 5, 6. These queries and table of barrack accommodation apply solely to European barracks, none of which of a permanent kind are at Seroor, the station being exclusively occupied by native irregular cavalry who reside in huts. 7. No tents are issued to the troops in the irregular service, they being expected to furnish themselves with these articles. 8. This question is applicable to Europeans only. 9. The materials employed in the construction of barrack buildings are generally of a permanent kind; viz., burnt brick and lime walls, and single-tiled roofs. 10. The floors are, on an average, one foot above the ground, and are constructed of moorum beaten down, and consolidated with water. 11. The buildings, both in the nature of the materials of which they are constructed, and the arrangement in which they are designed, are well suited for the shelter of the troops who occupy them. Repairs are executed, whenever considered necessary, on instructions issued by the officer commanding the station, who is also responsible for the general sanitary state of the cantonment. The walls are limewashed periodically at the discretion of the commanding officer, and usually when a change of occupants of the huts takes place. 12 to 16. These questions apply solely to European barracks. There are no pools or foul ditches within the limits of the station. 17. The surface cleansing of the cantonment is performed by sweepers, of whom an adequate number is entertained for the use of the regiment Poona horse; the refuse is burnt. 18. The surface of the cantonment is entirely kept free from vegetation. There are no old walls, thick hedges, &c., to interfere with the proper ventilation of the station, bazaar, &c. 19. Regulations are enforced to have the principal streets in the bazaar always kept clean, and the inhabitants have been compelled to make efficient arrangements for the proper drainage of the place, and to remove all water which may lodge opposite their dwellings. The water supply is derived from the stream of the Goar river, which flows close by the town. All regulations and arrangements for the sanitary state of the bazaars are under the civil authorities, and have always been found satisfactory. The native houses, like those in most native towns, are built of mud-walls, and covered with tiled roofs. Their condition generally exhibits carelessness and negligence on the part of their owners to keep them in proper repair; but cleanliness is as much as possible enforced by the authorities. No nuisance is experienced from wind blowing over the native houses. 20. All arrangements for the slaughter of animals are under the civil authorities, and the Mussulmen of the corps supply themselves, according to their wants, from the bazaar. No inconvenience from the present arrangement has been experienced. 21. The arrangements for stabling or picketing the bazaar horses, and those of the camp followers generally, are all under the civil authorities. 22. There are no cavalry stables; the manure is removed to the rear morning and evening, and periodically sold. The horses are picketed in front of their owners' houses, at a long distance from the hospital. 23. No reply to this query.
Officers' Quarters.	1. The officers' quarters are all very open, well ventilated, and drained, and remarkably healthy. No improvements are suggested.
IV. Health of the Troops.	1. The station, district surrounding it, and the native population adjoining, are, as far as I am aware, generally very healthy. 2. Fever usually prevails to some extent amongst the native population, after the termination of the monsoon, but the cases are generally of a mild type, and very amenable to treatment. I am not aware of cases of spleen disease being prevalent. The epidemics which most frequently prevail are cholera and small-pox. The former is usually present in greater or less extent during the hot season, previous to the setting in of the monsoon; but it occurs generally in a mild form, and its duration is not protracted. Small-pox occurs but very rarely, and then only in particular parts, when the sanitary condition is very defective. 3. I consider that the healthiness of the station of Seroor and the neighbouring native population is due to the open situation, its exposure to prevailing winds, the almost total absence of all causes likely to engender malaria or noxious exhalations, and the dry character of the soil generally. There is also a constant supply all the year round of good wholesome river water, which may be looked upon as an important element in conducing to the healthiness, generally speaking, of the inhabitants of the neighbourhood. 4. This station is the permanent head-quarters of the Poona irregular horse, who have been stationed here for many years, during the whole of which period they have enjoyed the most excellent health. I am not aware of any portion of the men's accommodation being more unhealthy than the rest. 5. No system of camping out is carried on, but a large portion of the regiment is always away from the station on outpost duty in the surrounding districts, and the result as to the health of the men varies according to the salubrity or otherwise of the different posts,

References to Subjects and Queries.	REPLIES.
IV. Health of the Troops —*cont.*	though not sufficiently so to make any appreciable difference in the general health of the regiment. 6. I was in medical charge for rather more than three months, during the monsoon of 1857, of the hill station Poorundhur, near Poona. This station is a sanitarium for the reception of convalescents from the different European regiments serving in the Deccan and other parts of the Bombay presidency; but is not used as a hill station for healthy troops. With regard to the purpose for which it is used, the result of my limited experience is that in well selected cases, and after taking into consideration the season of the year during which the convalescents from different diseases are to be stationed there, the patients derive very considerable benefit from a more or less prolonged residence at a hill station. During my short residence at Poorundhur, however, it was in two or three cases painfully evident that, in order to gain the full benefit of a hill climate for convalescents, the greatest care is required to be taken in selecting the cases to be sent to these stations. 7. My experience is too limited to give an opinion as to whether troops resident for some time in hill stations are more or less liable to attacks of febrile or other diseases on returning to the plains, the greater portion of my service having been passed in charge of native troops; but I am of opinion that from the generally improved state of health and increase of stamina engendered by residence in a hill climate, and absence for a time from the debilitating influence of the plains, the predisposition to attacks of those diseases would be decidedly lessened, and this opinion, I think, is borne out by the experience of those European officers and their families who are able to get away from the plains and reside at one of the hill stations during the hot season. 8. I am of opinion that well-selected hill stations would exert a most favourable influence on the health of the troops residing in them. 9. I am not aware of any diseases peculiar to hill stations with which healthy troops are liable to be attacked on going to them, provided the season chosen be a favourable one. For weakly soldiers who have a predisposition to particular diseases, such as cardiac disease, rheumatism, or lung affections, I am of opinion that the hill climate is anything but beneficial, unless the hill selected be of low altitude, and it would therefore be desirable that the selection of men to be sent to hill stations should be left to the discretion of medical officers instead of their being taken indiscriminately. 10. I would recommend that men be provided with liberal means of healthful recreation and amusement, and that, as far as practicable, they should be exempted from duties of all kinds, in fact that the period of their sojourn in the hill should be a kind of holiday, spent in such a manner as to invigorate them, and put them in such a state of health as would enable them to bear with comparative immunity the heat of the plains on their return to them. I would send the third or fourth part of a regiment every year, so that every man might have the benefit of a hill climate once in every three or four years. 11. My experience of hill stations is confined to the rainy months, and with reference only to convalescents. For healthy troops I should say that the season during which the hill climate is most required, and is of the greatest service, is the hot season embracing the months of February, March, April, May, and perhaps part of June. I do not think that a residence of shorter duration than that mentioned would enable troops to obtain the full benefit to their health of such residence; but I do not think that any longer residence would, as a general rule, be required. 12. I do not think there is any period of residence beyond which injury is likely to be inflicted on the health of troops on returning to service in the plains, provided the hill station be a well-selected and suitable one. 13. I am not aware of any special precautions being required for protecting the health of troops on leaving hill stations for the plains. 14. The experiment of locating healthy troops serving in this country on hill stations for a more or less prolonged period, has not, as far as I am aware, been carried out hitherto on anything like an extended scale. My own impression, however, is that short periods of change to hill stations during the very hot months, and service on the plains during the remaining portion of the year, would be equally if not more conducive to health than their location on hill stations, with short periods of service on the plains. Frequent change of station on the plains, except where the change is from a healthy to a notoriously unhealthy one, and provided the precaution is taken of effecting the change during the most favourable season, is, I believe, undoubtedly beneficial to the health and spirits of the troops and convalescents. 15. In all the hill stations with which I am acquainted the barrack and hospital accommodation is very limited, these stations having hitherto been intended solely for the reception of convalescents, and there is not, as far as my knowledge goes, accommodation on any of the hill stations in the Bombay presidency for any considerable number of troops. At Poorundhur there is barrack accommodation for 100 men, and a hospital adapted for about 40 sick. There is also a patcherry capable of accommodating ten families, and a small female hospital in course of erection, which must be by this time approaching completion. 16. Cannot say what elevation above the sea is most suitable for hill stations. 17. There is no higher ground in the neighbourhood of this station, nearer than Poorundhur, which could be advantageously occupied as a hill station. 18. The soils for stations both as regards surface and subsoil, should be light, tolerably dry, and porous so as to allow any excess of moisture to drain away freely. 19. I consider that the best age for soldiers to proceed to India ranges between 25 and 30, and they should land there at the commencement of the cold season, which begins in the middle of November. 20. No reply to this query. 21. The transport of troops from the port to the interior is effected, if by water, in Government or private steamers or native vessels; if on land, by the railway or bullock train where available, or else by easy marches to their destination. I have no experience to enable me to state, whether any additional precautions are required for preserving the health of troops during their transport to the interior. 22. Cannot say what number of years a British soldier should serve in India. 23. As far as I am aware, the manner of conducting medical boards in the Bombay presidency is not liable to cause any conflict of opinion as regards invaliding. No suggestion to offer on this subject.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	24. I am of opinion that the best time of the year for invalids to leave India for home is from the end of December to the end of February following, so as to reach England at the commencement of the spring, but after the time during which easterly or north-easterly winds prevail.
Diseases.	1. No regular inspection parades are carried out in this station, but the men have strict orders to visit the hospital on the first symptom of approaching illness.
	2. During the year which I have been in charge of troops at this station, I have not met with a single case of scorbutus or scorbutic disease, and on referring to the regimental records I find but one case noted during many years, and that occurred whilst the regiment was on field service in Persia in 1857.
	3. No case of hepatitis has occurred during the last year.
	4. Cases of dracunculus are very frequently under treatment, but they do not usually originate here. It occurs in men who have joined head quarters from out-post duty. There is so much difference of opinion concerning the exact species of the troublesome worm and its mode of entering the body, that I cannot offer any satisfactory explanation as to the cause of the attack. I would suggest, as a prophylactic measure, the necessity of very carefully drying the body after bathing, especially in tanks or other still waters, as the balance of opinion seems to favour the view of the guinea worm entering the body from the external surface.
	5. With respect to the proportion which the constantly sick from venereal diseases bear to the total sick in hospital from all other diseases, it is impossible to estimate it, as we have no constantly sick from this disease. The cases do not average more than six or eight during the year, which is to be accounted for by the fact of the majority of the men in irregular cavalry regiments being married.
	6. The troops at the station suffer from the following diseases of the endemic and epidemic class :—

Fevers.—The fever most prevalent at the station is the intermittent quotidian type, which generally occurs during the months immediately succeeding the monsoon; and to some extent during the hot season. Other forms of fevers are rare.

Dysentery of a mild type generally prevails to a small extent during the monsoon, and isolated cases are met with occasionally throughout the year, but are generally very amenable to treatment.

Cholera occurs epidemically during the hot season, and in varying degrees of intensity in different years, but the troops rarely suffer to any great extent from this scourge.

Small-pox is very rare indeed amongst the troops. The prophylactic measure of vaccination is assiduously carried on both amongst the troops, their families, and followers.

Rheumatism of a chronic character is the chief cause of admission into hospitals during the cold months. It occurs, however, chiefly among the aged and debilitated men of the corps, and is not serious in its effects.

The proportions which admissions and deaths from these diseases bear to the total admissions and deaths are as follows :—

Diseases.	Proportion of Admissions to total Admissions.	Proportion of Deaths to total Deaths.
Fever - - -	27 per cent.	18 per cent.
Dysentery - - -	·65 „ (6 cases only having been treated in 5 years.)	0 „
Cholera - - -	4 per cent. (4 cases admitted in the same period.)	20 „
Small-pox - - -	0 per cent.	0 „
Rheumatism - - -	6 „	2 „

An average deduced from the returns of a greater number of years would probably modify these figures in some measure.

7. Purely zymotic diseases are of rare occurrence at this station, and I am not aware of their having presented any special nosological character when they have occurred. They have not so far as I am aware prevailed more at one season than at another, and I cannot say what are the climatic or atmospheric conditions which precede or accompany their appearance. They have occurred almost without an exception among the native population residing in the lowest and most densely populated parts of the town, in which almost every element conducive to a defective sanitary condition is in force. These cases however, except when in great excess, do not come under my immediate observation. There is nothing in the personal habits or conditions of the troops likely to predispose to these diseases, but amongst the poorer native inhabitants causes predisposing to these, and in fact, to all kinds of disease, are rife. Amongst these cases I may enumerate exposure to weather at all seasons, insufficient clothing, uncleanly habits, and deficient and in many cases extremely unwholesome food.

8. I consider that the duties and occupations of soldiers in barrack, when not carried to excess, are conducive to health and adverse to the prevalence of epidemic disease. The same remark may be applied to their habits, when these are not of a hurtful or debilitating character.

9. Fever has never to my knowledge prevailed to such an extent as to lead to the experiment of trying small doses of quinine as a prophylactic.

10. Epidemic disease may be considered to be at a minimum at this station, and I have no recommendations to offer with regard to its prevention or mitigation.

SEROOR. BOMBAY.

References to Subjects and Queries.	REPLIES.
V. INTEMPERANCE.	1. No body of men could be more temperate than the Poona horse, and there are no confirmed drunkards among them. 2. There are no admissions into hospital from diseases caused directly or indirectly by intemperance. No case of drunkenness is on record among the troops. 3. Arrack or native liquor is sold in the bazaar, and the sale being chiefly confined to the camp followers and persons residing out of camp limits, no average can be given of the amount consumed. No drinks injurious to health other than intoxicating drinks are sold in the bazaar. 4. The consumption of spirits by troops and convalescents is injurious to health, and not conducive to efficiency or discipline. 5. No reply to this query. 6. Malt liquor in moderation is most conducive to the health of Europeans in the relaxing climate of the plain, but wine and spirits are not at all requisite except medicinally. 7. Coffee, tea, lemonade, soda water, &c., are a good deal used at the station. No comparison as to their influence on health, efficiency, and discipline, in opposition to spirits, can be made, as the Poona horse do not drink the latter. 8, 9, 10. These queries are applicable only to European troops. 11. There are no canteen or bazaar regulations in force at this station.
VI. DIET.	The queries under this head refer solely to European troops, of whom there are none here.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldiers' dress and accoutrements at this station consist of a turban, waistband, coat, trousers, jack boots and spurs, carbine or pistol, sword, pouch, carbine, and sword belts. The present dress is suitable to the climate and the soldiers' duties by day and night, but lighter clothing might more generally be adopted in the plains. The present guard dress in the Poona horse varies according to the season of the year. All guards and sentries at the station are under cover.
Duties.	1. No reply to this query. 2. The following is the routine of the soldiers' duties :—Parade twice or three times a week, and drill five days a week for an hour in the morning and evening. These do not in any way interfere with the men's health. The cool of the mornings and evenings are the best hours for drills, parades, and marches, and, if the march is a long one, during the entire night. Full instructions are published in Bombay Separate General Orders, page 80. The men have five nights in bed during the week. 3. Guards are mounted within a circle of 300 yards, and are relieved daily; sentries are relieved every two hours. There are no roll calls in the Poona horse. No bad effect has ever been caused by night guards at Seroor, which is a particularly healthy station.
VIII. INSTRUCTION AND RECREATION.	Queries under this head refer solely to Europeans, of whom there are none at Seroor.
IX. MILITARY PRISONS.	1. The standard guard of the Poona horse is the only place used for military confinement. It is open to the winds, well ventilated, and amply sufficient for the requirements of the station.
X. FIELD SERVICE.	1. There are no local regulations for field medical service, not included in the General Presidency Regulations. 2. On the line of march the medical officer has the power of offering suggestions as to the time of march, salubrity or otherwise of proposed sites for encamping ground, and other points of a similar nature. 3. The practical operation of the rules laid down for the preservation of the health of troops in camp, in page 145 of the Bombay Separate General Orders, seems to be all that is desirable. The power of the medical officer in this matter is described in the preceding answer. 4. The arrangements adopted in the presidency with reference to field hospitals, ambulances, &c., are detailed in the Medical Code of Regulations, and at page 161 of Bombay Separate General Orders.
XI. STATISTICS OF SICKNESS AND MORTALITY.	1. The following table gives the statistics of this station :—

SEROOR.—NATIVE TROOPS.

Years.	CORPS.	Strength.	Fevers.		Eruptive Fevers.		Diseases of the Lungs.		Diseases of the Liver.		Diseases of the Stomach and Bowels.		Diseases of the Brain.		Epidemic Cholera.		All other Diseases.		Total.		Ratio per cent. to Strength.

By order of the Acting Principal Inspector-General, Medical Department,
W. C. COLES, Assistant Surgeon,
Secretary.

Office of the Principal Inspector-General, Medical Department,
Bombay, 27th July 1860.

References to Subjects and Queries.	Replies.
XII. Hospitals.	1, 2. No building has been specially erected as an hospital. The building used for this purpose is a detached bungalow in the centre of the camp, about 400 yards from the horse lines, and about 600 yards from the bazaar and houses of the civil population. The site is open and freely ventilated. There are buildings near, but which are not so situated as to interfere with a free current of air to the hospital. The site is generally healthy as to elevation and drainage, and quite free from malaria from river banks, &c., or other nuisances. 3. There is an abundant supply of good and wholesome water from two wells situated in the enclosure. 4. All impurities from the hospital are removed by sweepers as often as necessary. 5. The hospital contains only one ward, which is raised about 18 inches above the ground. No special provision is made for carrying off the roof water, but the greater portion is carried away by the natural slope of the ground, which also admits of the surface drainage being carried away without obstruction. The building is constructed of kiln-burnt bricks, and has single walls and thatched roof, which is sufficient to keep the hospital cool under ordinary circumstances. A verandah six feet in breadth runs all round, which affords sufficient shelter from the sun's rays, and the enclosed portions of which are occasionally used for the accommodation of sick or convalescents. The hospital consists of one flat only. It receives the full benefit of the prevailing winds. The windows open inwards from the centre, and their arrangement and construction is quite conducive to ventilation and coolness. 6. The ventilation of the wards is effected by means of open doors, windows, and jhilmils, which keep them cool at all times and free of odour or closeness. The jhilmils are those commonly used in India. 7, 8. There is no apparatus for cooling or warming the wards. The walls and ceilings are cleansed and limewashed whenever necessary. 9. There is one privy, of the simplest construction, situated to the rear of and detached from the hospital. It is not supplied with water, but is never offensive, being cleaned by sweepers as often as used. 10, 11, 12. There are no lavatories or means of bathing the sick; neither are there any means for washing and drying the hospital linen. 13. The storage is sufficient and dry. 14. The bedsteads used in the hospital are common wooden charpoys, laced with broad tape. The bedding, &c. is supplied by the patients themselves. 15, 16, 17. No reply to these queries, as they refer to European hospitals only. 18. The sanitary condition of the hospital is good. No hospital gangrene or pyæmia have, so far as I am aware, ever occurred. 19. I am not aware of any deficiencies or sanitary defects which call for improvement. 20, 21. Apply to Europeans only. 22. There are no special local hospital regulations not included in the General Presidency Medical Regulations. 23. The medical officer has entire control over all matters connected with the hospital arrangements, subject to the approval of the superintending surgeon of the division. 24. There is no convalescent hospital nor any wards for that purpose into which a soldier can pass until he is fit for duty.
XIII. Burial of the Dead.	1. The burial ground is about 400 yards from the camp boundary, and to leeward of the station. 2. It is about an acre in extent, with a hard and rocky soil. There is a hedge and deep drain all round it, and the enclosure is carefully kept. 3. There are no regulations as to grave space, depth of graves, reopening them, and times of burial, no British troops being now quartered at the station. The native burial grounds are outside the camp limits, and are under the civil authorities. 4. The graveyard is never offensive. 5. The dead of camp followers and bazaar people are disposed of according to the customs of the country and under civil regulations. 6, 7. No injury accrues to the public health from the present practice, and no improvement could be suggested without interfering with the native prejudices.

(Signed) R. M. Westropp, Captain commanding at Seroor, and President.

Members.
- A. V. H. Finch, Captain Engineers.
- William E. Cates, Assistant-Surgeon, Poona Irregular Horse.
- R. Thorpe Tragett, Lieutenant, Acting Adjutant, Poona Irregular Horse.

30th June 1860.

VINGORLA.

Accommodation—Native Troops—Infantry—Sawunt-Warree Local Corps 180, of all ranks.

Reference to Subjects and Queries.	Replies.
I. Topography.	1. The general aspect of the surrounding country is very picturesque from the Wharf. A chain of low hills range in a N.N.E. direction, and extend within 500 yards of the town, and outside of camp as far as "Ruree," a fortress about 9 miles in a W.S.W. direction. The country is hilly and dry, with lofty fruit trees indigenous to the country, such as jack, cashew, cocoa-nut, and mangoe. There is no jungle, but several springs in the vicinity of the station. 2. The elevation of the station above the sea is about 20 feet, about 5 feet above the adjacent

VINGORLA. BOMBAY.

References to Subjects and Queries.	REPLIES.
I. Topography—*cont.*	country. There is a chain of low hills running in a N.N.E. direction from the Wharf to within about 500 yards from the town and a mile of the cantonment; with the exception of these hills there is no ground higher or healthier adjoining the station. 3. The nearest table land is 5 miles off, but it possesses no advantages either in a military or sanitary point of view. 4. With regard to the nearest water, the river Sawkoo is about ½ a mile distant, and the sea about 2½ miles from the station. The water in the rainy season runs off very rapidly. There is no broken ground within some distance of the station. 5. The station is well exposed to the sea breeze, which is highly salubrious, and no impediment exists to its free circulation. The temperature of the station is not raised by reflected sun heat. The sea breeze which is diurnal and salubrious is the prevailing wind in the year. The land wind from the E.N.E. is usually of short duration and not prejudicial at the station. 6. The cultivation of rice is constantly in progress in the vicinity of the town, fresh water being always procurable; no other cultivation seems so desirable as this for the inhabitants. It does not seem to have any injurious effect upon the health of the station. There are no works of irrigation. Rice is cultivated within 500 yards of camp duing the monsoon, but at no other period of the year so close. Indigo is not cultivated. Hemp is prepared in the native town, but not to any great extent. No injury to health appears to arise therefrom. 7. The town of Vingorla is situated about 1½ miles from the station. 8. The geological structure of the hilly range, which commences from the wharf, is of moorum and rocky; the subsoil and surface is feruginous sand; the station has always occupied the same ground. 9. The depth below the surface at which water is found depends upon the elevation of the ground. The depth of the hospital well is 45 feet, and the well near the native lines only 35 feet. 10. The rain-fall flows off very rapidly into a rivulet which empties itself into the sea. The station being surrounded by hills, the drainage from them necessarily passes into the subsoil of the station. 11. The water supply of the station is derived from wells. There are no tanks within half a mile of it. The river near the town is used for bathing and washing linen. When the water of the river is low and stored up in small pools nuisance occasionally proceeds from it, but does not affect the health of the station, as it only exists for about two months of the year before the setting in of the monsoon. 12. The water supply is abundant for all purposes except drinking. Excellent drinking water, however, is procurable from a spring near the Wharf. The water from wells is hard, and from its being impregnated with iron cannot be unwholesome, although not so agreeable to the taste as that procurable from the Wharf. The amount is sufficient; it is raised by leather buckets, which appears to be the best for all purposes. 13. There are no other topographical points bearing on the health of the station not included in the above replies. 14. I cannot suggest any improvements in the mode of selecting new stations.
II. CLIMATE.	1. The only means and instruments available for conducting and registering meteorological observations at the station are a thermometer and a pluviometer. 2. The following table gives the result of the observations for one year.

Year's Observations from 1st January to 31st December 1857, at the Station of Vingorla.

3. There is no considerable variation in the climate. It is never very cold, and the heat is moderate, but from heavy dews it is occasionally damp at night. The air is never rendered impure by any extraneous matter, owing doubtless to the daily setting in of the sea breeze. The health of the troops is generally excellent. Morning and evening exercise is very desirable for them, except during the hot months, when once a day is sufficient. The station is considered healthy at all times of the year.

4. There is no district near the station more healthy than the camp.

5. I have served at Poona, Nusseerabad, Neemuch, Kurrachee, Mulligaum, and Sawunt Warree, and found them all conducive to health, with the exception of the last named.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of the Station.	1, 2. A sketch of the camp is forwarded. 3, 4, 5, 6. There are no barracks at the station. The hospital, which is a large commodious building, has on several occasions been used as a barrack, and for the accommodation of convalescent European soldiers from up-country stations, during which time a temporary building, constructed near the hospital, has been used for the sick. 7. No tents are used in camp. 8. The new lines are ventilated by an aperture of about 1 foot left between the top of the walls and the roof of the huts, which is sufficient for the natives. There are no means of cooling the air. 9, 10. The huts are built of mud with jungle wood roofs single tiled. The doors are of mangoe wood; they have no windows. The floors are raised about 1½ feet above the ground, and are constructed of moorum, watered and well rammed. 11. The materials of which the lines are constructed are most suitable for the climate, and they are usually kept in repair by the engineers' department. There is no cantonment at Vingorla; it is at present a civil station. 12, 13. No lavatories required for natives. All linen is usually washed at the river near the native lines. 14, 15, 16. The contents of the privies are removed by the sweepers. There are no cess-pits or foul ditches. 17. The station being a very small one there is little or no refuse, but what there is is usually burnt. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls or thick hedges, &c. interfering with the ventilation of the station or bazaar. 19. The station bazaar consists of a few shops, and the occupant of each house is required to look after the cleanliness of that part of the bazaar adjacent to his dwelling. There are few native houses within ½ a mile of the station, and their average condition is good. There are no dung heaps or cess pits; no nuisance is experienced from wind blowing over the native dwellings. 20. Animals are seldom slaughtered in the camp, and the slaughtering places are in the town, consequently too far distant to cause any nuisance. 21. Horses are very rarely picketed in camp. 22. There are no stables or picketing grounds for artillery or cavalry horses. 23. There are only two non-commissioned officers, and they do not live in camp. One of them has quarters in the depôt arsenal, and the other has a small house close by.
Officers' Quarters.	There are five bungalows for officers, two only of which are occupied by residents. They are situated in a healthy locality, and most of them being built on the side of the hill the water runs off easily. No improvements are suggested.
IV. Health of the Troops.	1. The station, district, and adjoining native population are generally very healthy. 2. Epidemics seldom prevail among the natives; spleen disease never. A few cases of cholera have occurred, but it is a very rare occurrence. 3. The healthiness of the native population is attributable to the diurnal change of the wind to west-south-west or west-north-west, which is open to the sea. 4. The detachment of the local corps at this station arrived here in February 1859 from Sawunt Warree. All accommodation for the men at this station is in a healthy locality. 5. The men remain in their lines all the year round. 6. I have never been in charge of troops at a hill station, but I have spent a hot season at the Mahableshwur hills, which I found highly beneficial to my health. 7, 8. I approve of hill stations for troops during the hot months. 9. I have known instances of hill stations proving fatal to people subject to liver disease. 10. I am not aware of any precautions as to diet, &c., which would guard men from attacks of disease, and enable them to obtain greater benefit from residence in hill stations. 11. The period best adapted for residence in hill stations is from 1st March to 31st May, which is the shortest period to obtain benefit from such residence. 12. If troops reside at hill stations during the cold season, and then return during the hot months to the plains, it is likely to prove injurious to their health. 13. The special precaution necessary on leaving hill stations for the plains is to avoid exposure to the sun as much as possible. 14. Service in the plains during the rainy and cold seasons, and change to the hills during the hot months, would be equally conducive to the health of Europeans as to locate them for lengthened periods on hill stations. This latter plan renders them less able to resist the effects of the heat when necessity obliges them to bear it. Change of station on the plains every three or four years is beneficial to the health and spirits of troops and convalescents. 15. I am not aware of any deficiencies in the accommodation for troops at hill stations. 16. No experience. 17. Although the range of hills from the Wharf is a very desirable place for health, yet the plains now occupied are exposed freely to the same salutary influences. 18. No experience. 19. Soldiers proceeding to India should be about 16 or 17 years of age, and should land there in November or December. Recruits should be provided with good solar hats and kept as much as possible out of the sun. 20. It would be very desirable to send troops for India to an intermediate station for a certain time, and on landing in India they should be gradually accustomed to the climate by being sent to the best stations. 21. Troops usually arrive at this station by sea, the Europeans in steamers and the natives in country boats. Troops ought never to march in the hot weather except in cases of the greatest emergency. 22. About 20 years is the period a British soldier should serve in India, with an intermediate furlough after ten. 23. I have no suggestions to make in regard to invaliding by medical boards. 24. Invalids should leave India for home about December or January.
Diseases.	1. Regular inspection parades are made of all the men at the station whenever any syphilitic cases are admitted into hospital. 2. I have never known any case of scorbutic disease among the troops at this station. 3, 4. No cases of hepatic disease or dracunculus have occurred.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	5. The proportion of constantly sick from venereal diseases is annually 0·58 to total admissions of 101 from all other diseases. 6. The troops at the station suffer from the following diseases: *Fevers.*—Ephemeral, continued, and remittent fevers, usually of a mild description. *Cholera.*—As an epidemic very rare. A few cases have occurred during the rainy season. *Smallpox.*—A case seldom occurs except as an epidemic. *Rheumatism* is a very rare disease at this station. The proportion of admissions from cholera for the past year was 2·97, and two deaths to one cured of this disease. No casualty from all other diseases occurred. 7. Diseases of a zymotic character have not shown themselves at this station. The sanitary condition generally of the native dwellings is remarkably good, cleanliness and ventilation in the men's lines being strictly attended to. I am not aware of any habits or conditions among the troops or population which predispose to diseases. 8. Native soldiers exposed on duty are not rendered more liable to contract epidemic disease. 9. Quinine has not been tried as a prophylactic, as there is no malarial disease prevalent at the station. 10. I have no recommendations to make on any of the preceding points.
V. INTEMPERANCE.	1. There are no European soldiers at the station, and the natives are usually very temperate. There are no confirmed drunkards. 2. There have been no admissions into hospital from diseases caused directly or indirectly by intemperance. A case of drunkenness rarely occurs, but when it does the offender is punished. 3. Spirits are not procurable except at the European shops, and there is an order against selling distilled spirits to soldiers. When recommended by the medical officer arrack is occasionally administered to convalescents. Toddy and arrack are procurable in the native town. 4. There is no consumption of spirits by troops, and that consumed by convalescents is at the recommendation of the medical officer. 5, 6. There is no occasion for abolishing the use of spirits at this station. 7, 8, 9, 10. Coffee, tea, lemonade, &c. are not used by native soldiers. 11. There are no bazaar regulations.
VI. DIET.	1 to 4. There queries do not apply to native troops. 5. Soldiers' gardens could be advantageously established near the station, as there is plenty of ground in the cantonment available for the purpose. They should be under the order of the officer commanding and the sanction of the civil authority.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldiers' dress here consists of a dark-green cloth coat, dark blue turban, and black accoutrements. They are very suitable for natives. I could not suggest any improvement in the dress for natives. The men are supplied each with a cumlie or blanket of dark colour which they make use of in wet weather.
Duties.	1. I should consider it very advisable to drill men before sending them out to this country. 2, 3. No reply to these queries.
VIII. INSTRUCTION AND RECREATION.	No means of instruction or recreation exist at this station.
IX. MILITARY PRISONS.	There are no military prisons.
X. FIELD SERVICE.	No information under this head.

XI. STATISTICS OF SICKNESS AND MORTALITY.

By order of the Acting Principal Inspector-General, Medical Department.

Office of the Principal Inspector-General, Medical Department, Bombay, 9th November 1860.

W. C. COLES, Assistant Surgeon, Secretary.

References to Subjects and Queries.	Replies.

XII. Hospitals.

1, 2. The hospital is situate about 500 yards from the men's lines, and on the east side of the camp. It is near the officers' bungalows, and about 600 yards from the bazaar. The site is on an elevation, and the building is freely ventilated, nothing being near enough to interfere with ventilation. It is very good in every respect.

3. The water is wholesome, but the hospital well is at present being deepened, which will greatly improve the water-supply.

4. The refuse water about the hospital is very limited. All impurities are carefully removed by the sweeper daily, and thrown into a ditch about 300 yards distant.

5. The height of the lowest ward above the ground is about 4 feet. There is no perflation of air underneath the floors. The hospital being on a slope, the roof water runs off rapidly into the nullahs. A small drain is dug round it which is found quite sufficient for drainage. The roof of the hospital is double tiled, and the walls, which are 2 feet in thickness, are built of stone and lime, but have no ventilation between them. There are verandahs on both sides 10 feet in breadth, which afford sufficient shelter from the sun's rays. These have never yet been used for the accommodation of sick, convalescents, or others.

Table of Hospital Accommodation.

Total No. of wards - - - - 2
Total regulation No. of beds - - - 18

Wards, Number.	Regulation Number of Sick in each Ward or Hut.	Dimensions of Wards.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width
		Ft.	Ft. in.	Ft.			Feet.			Ft.	Ft.
No. 1. -	6	32	22 6	18	10,440	1,740	120	1 6	6	6	4
No. 2. -	12	60½	22 6	18	19,738	1,644⅚	113⅚	1 6	12	6	4

The hospital is so placed as to receive the full benefit of the prevailing winds. The glass windows are so placed as to admit wind from all quarters, and perfect ventilation is thereby preserved, together with coolness.

6. The means of ventilation are by large windows and doors, which are quite sufficient to keep the wards cool and free of odour at all times. There are no jalousies or jhilmils.

7, 8. There are no artificial means of cooling or warming the wards. The walls and ceilings of the wards are cleansed and limewashed annually, and oftener if necessary.

9. The contents of the privies being removed by the sweeper, they are not offensive.

10, 11. There are no lavatories at the hospital. The natives usually bathe by throwing a small quantity of water over themselves.

12. Natives wash their own linen, and when sick a comrade does it for them.

13. The storage is sufficient and dry.

14. Wooden cots laced with cotton tapes are used in the hospital. No improvement upon this can be suggested.

15. The hospital kitchen is chiefly used by natives, and they supply their own apparatus for cooking.

16. No hospital diet is as a rule adopted for native sick by Government.

17. The attendance for native sick consists of a goorgah, bheestie and sweeper, which is found ample.

18. The sanitary condition of the hospital is generally excellent. No epidemic diseases have been known to appear in any of the wards.

19. No improvements are suggested.

20. The convalescents are permitted to take exercise morning and evening round the hospital.

21. No special provision is required at this station for the treatment of soldier's sick wives and children, as the present arrangements are perfectly ample for any emergency.

22. No special local hospital regulations exist which are not included in the general presidency medical regulations.

23. The medical officer is free to prescribe any medical comforts for the sick under his care, but repairs to the building, or any sanitary improvement requiring an outlay, must be submitted for sanction to a higher authority.

24. There are no wards or hospitals for convalescents, nor are any required at this station.

XIII. Burial of the Dead.

1, 2. The burial-ground is well sheltered from the station by an high hill which intervenes. The ground is small, being about 100 yards by 80, much neglected, and contains less than a dozen graves. The soil is of moorum and rock.

3. There are no regulations with regard to the grave space allowed or the interval between each: they are about 8 feet in depth. I have never heard of one being reopened. Interment takes place at ordinary times, about 24 hours after death, but during epidemics with as little delay as possible. There are no burial-grounds used by natives within 500 yards of the camp.

4. The grave-yard is never offensive.

5, 6. The dead of Mahomedans are buried near the native towns. The Hindoos mostly burn their dead. No injury occurs from the above practice.

7. The only improvement I can suggest is, that the present burial-ground used by British troops be walled in, and the tombs repaired annually.

(Signed) G. R. C. Westropp, Lieutenant
Commanding at Vingorla.
Lewis George, Apothecary
in medical charge of Vingorla.
Robert Moore, Sub. Cond.,
Assistant Supervisor,
D. P. Works.

26th May 1860.

RUTNAGHERRY.

Accommodation.—Native Infantry, 3 full companies.

References to Subjects and Queries.	Replies.
I. Topography.	1. The general aspect of the country surrounding the station is as follows: A sea-coast line of low hills with flat summits, with bare open rocky country inland. It is hilly, consisting of irregular rocky plateaux, broken into ravines and valleys; these hills are thinly covered with scrub. There is a scarcity of fresh water, but numerous springs. 2. The elevation of the station is 150 feet above the sea, but it is on a level with the adjacent country. The nearest water to the station is the sea and the salt water creeks N. and S. There is no higher nor healthier ground adjoining the station. 3. The nearest mountains are the Syndree range of Ghauts, at a distance of 30 miles, which are about 3,000 feet above this level. 4. The nearest water is on the sea-coast; the salt water creeks become muddy swamps at low tide. The vicinity is not liable to overflow. Ravines are numerous in the vicinity of the station, but health is not affected by them. 5. The station is very open, and there is nothing to interfere with free ventilation. The buildings are so few in number that no increase of temperature results from reflected sun-heat. The station is open to all winds. The land winds during the cold season are apt to cause rheumatism; the sea breezes in the hot season are healthy, but the damp winds in the monsoon produce bowel complaints. 6. The surrounding country is generally uncultivated, and works of irrigation are not in existence near the station. Rice is grown in quantities in the low ground near the coast, but indigo is not cultivated, nor the preparation of hemp or flax carried on near the station. 7. The town of Rutnagherry contains about 10,000 inhabitants, and adjoins the station. 8. The geological structure is of laterite, resting on trap. The station is on new ground. 9. Water is usually found, both in the dry and rainy season, at a depth of from 30 to 40 feet below the surface. 10. The rainfall in the district flows readily away,—it does not lie on the surface till evaporated. There is no higher ground near. 11. The water supply of the station is derived from wells and springs. There are no tanks. The wells are generally covered over, and no nuisance or malaria is experienced from them. 12. The wells and springs are sufficient for the demand. The water is free from taste and smell, is soft like rain water, and very good. It is raised by buckets and "lotas." None better could be had. 13. There are no other topographical points bearing on the health of the station not included in the above queries. 14. With reference to the selection of new stations the chief considerations seem to have been of a political nature, without reference to sanitary arrangements, and we would suggest that some regard be paid to these before erecting permanent barracks for troops.
II. Climate.	1. The only instruments for conducting meteorological observations at this station are the thermometer and rain-gauge. 3. The heat of the hotter months is moderated by fresh northerly sea-breezes. The climate is damp during the monsoon, and dry in the forenoon during the prevalence of land winds, from November to February. The climate may be described as generally moist, warm, and relaxing, with an annual range of about 20°, and diurnal not exceeding 12°. It is not affected by tree planting nor irrigation, nor by dust and other admixtures affecting the atmosphere. Protracted residence here would induce enervation, and render Europeans liable to sickness on transfer to other parts, where the climate is more variable. Europeans are not more affected in one month than in another; but natives suffer from fever and rheumatism in the cold season. 4. There is no district near the station the climate of which would be more conducive to health than that of the station. 5. The districts of which the Committee is able to speak from experienceare, Guzerat, Deccan, the Concan and Southern Mahratta country. Of these Goozerat is certainly the most injurious to the health of Europeans, and the Deccan the most favourable.
III. Sanitary Condition of Station.	1, 2, 3. Plans of the station and surrounding country, &c., are transmitted. 4. Table of Hut Accommodation. Date of construction of huts, 1859–60. Total number of huts - - - - - - 222 Total regulation number of non-commissioned officers and men - 235

Huts.	Regulation Number of Men in each Hut.	Dimensions of Huts.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of the Station—*cont.*	5 to 8. No barracks at this station. 9, 10. The huts are constructed of stone and mud with tiled roofs. The floors are level with the ground. 11. The materials and construction of the huts are in every respect suitable for the climate. Rutnagherry is a civil station. The public buildings are kept in repair by the executive engineer of the district. 12 to 15. No replies. 16. There are no foul ditches near the station. 17. No answer to this question. 18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c., interfering with the ventilation of the station. 19. There is no military bazaar here. The native houses in the town are under the surveillance of the Civil Department. 20 to 23. There are no European soldiers at Rutnagherry.
Officers' Quarters.	1. No reply.
IV. Health of the Troops.	1. The population in the adjoining town is very healthy. 2. The town and station of Rutnagherry is remarkably free from cholera; but it is frequent in the districts adjoining. Lumbricus is an endemic disease, accounted for by the absence of lime in the water, and the vegetable diet. 3. The healthiness of the native population is attributable to the purity of air and water as regards the town and station, and in the districts disease is produced by the close confined localities of villages, added to insufficient diet. 4. Troops have been permanently located at Kolapore and suffered chiefly from guinea worm, which has gradually disappeared since their arrival here in December 1858. No part of the men's present accommodation is, I believe, more unhealthy than the rest. 5, 6. Troops are never camped out. I have never been in charge of troops at hill stations. 7 to 13. No experience of hill stations. 14. Frequent change of station on the plains is beneficial to the health of troops. 15, 16. No experience to enable me to answer these questions. 17. There is no higher ground very near the station that could be advantageously occupied as a hill station. 18. Rocky soil in India undoubtedly has the advantage over all others for sites of stations. 19. I am not sufficiently experienced to offer an opinion as to the best age for soldiers to proceed to India, but they should land here in the cold season. 20 to 24. No experience to enable me to answer these queries.
Diseases.	1. There are no inspection parades here for the discovery of incipient diseases. 2, 3. There has been no case of scorbutus or hepatitis at this station, and the natives are not subject to hepatic disease on the sea-coast. 4. Dracunculus is not an endemic of Rutnagherry. Sufferers generally recover from this disease, contracted before their arrival here. 5. There are no European soldiers here, and the natives usually are treated by native doctors for venereal disease; no fair proportion as to the amount of venereal disease can be stated. 6. The following are the more prevalent diseases at the station:— *Fevers.*—Simple intermittent fever, generally connected with functional derangement of the liver. *Dysentery.*—In a mild form as above. *Rheumatism*—occasionally, but the proportion is insignificant. No proportion which admissions and deaths from the above diseases bear to the total admissions and deaths can be stated. Fatal cases are very rare, and intermittent fever only proves fatal when complicated with internal congestion. 7, 8. Zymotic diseases are unknown here. 9, 10. Small doses of quinine, as a prophylactic against malarial disease, have not been administered at this station.
VII. Dress, Accoutrements, and Duties.	1. The dress in use at this station is as follows:—Tunic, linen pantaloons, forage cap, half-boots for sepoys, pouch and belt, waist-belt, knapsacks and slings. This applies only to natives, there being no European soldiers at Rutnagherry.
Duties.	No information under this head.
VIII. Instruction and Recreation.	There are no European troops at this station, consequently no information on this head can be afforded.
IX. Military Prisons.	1. There is one cell only attached to the Native Infantry Quarter Guard, and this is in every respect well adapted to the purpose required.
X. Field Service.	1. There are local regulations for field medical service, not included in the General Presidency Regulations. 2. There are no medical officers attached to the detachment of troops here. 3. The medical officer has little to do with the troops at this station, except in hospital. The huts are few in number, and well ventilated. The troops belong to a local corps. 4. No answer to this question.

By order of the Acting Principal Inspector-General Medical Department,
W. C. COLES, Assistant Surgeon,
Secretary.

Office of the Principal Inspector-General, Medical Department,
Bombay 5th September 1860.

XII. HOSPITALS.

1. A plan of the hospital at Rutnagherry is transmitted.
2. The hospital is about 10 minutes' walk from the sepoys' lines, and the same distance in a southerly direction from the native houses. There is a high wall round it; but it is well adapted for a native hospital. The site, generally, as regards the elevation, drainage, absence of malaria, &c., is healthy.
3. The water supply is abundant and wholesome.
4. No means of drainage for the removal of refuse water and other impurities from the hospital, but sweepers for this purpose are employed.
5. The floors of the hospital wards are of earth, and raised two feet above the ground. The roof water sinks into the subsoil: the drainage of the hospital generally is good. The hospital is built of stone, with a tiled roof, and is cool. There are verandahs on both sides of the hospital of about six feet in breadth, but they are never used for the accommodation of sick, convalescents, or others. The hospital consists of a ground floor only.

Table of Hospital Accommodation.

Date of construction—about 40 years ago.

Total number of wards—1 large ward and 2 small rooms.

Total regulation number of beds / Cots in charge at present only - - - - - 17

Number of Wards or Hospital Huts.	Regulation Number of Sick in each Ward or Hut.	Dimensions of Wards. Length.	Breadth.	Height.	Cubic Contents.	Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows. Number.	Height.	Width.
		Feet.	Feet.	Feet.	Feet.	Feet.	Feet.	Feet.		Feet.	Feet.
Large ward -	40	80	$20\frac{3}{4}$	$13\frac{3}{4}$	22,825	570	41	$1\frac{1}{2}$	14	$4\frac{1}{2}$	$3\frac{1}{4}$
Small ward -	4	$16\frac{1}{2}$	$20\frac{3}{4}$	$13\frac{3}{4}$	4,707	1,177	$85\frac{1}{2}$	$1\frac{1}{2}$	2	$4\frac{1}{2}$	$3\frac{1}{4}$
Do. -	4	$16\frac{1}{4}$	$20\frac{3}{4}$	$13\frac{3}{4}$	4,634	$1,158\frac{1}{2}$	$84\frac{1}{4}$	$1\frac{1}{2}$	3	$4\frac{1}{2}$	$3\frac{1}{4}$

The hospital is so placed as to receive the full benefit of prevailing winds. The windows are in two frames, and open outwards, and are conducive to ventilation.

6. The means of ventilation are the doors and windows, usually kept open. The wards are free of closeness or odour. There are no jalousies or jhilmils.

7, 8. No means for either cooling or warming the wards are used. The walls and ceilings of the wards are cleansed and lime-washed annually.

9. The privy is in one corner of the enclosure apart from the hospital, and consists of three partitions. Sweepers are employed to cleanse it daily.

10 to 13. No answers to these questions.

14. The cots are simple frames over which broad tape is stretched, and this forms the bedding. Nothing better could be devised.

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	15, 16, 17. These queries are applicable to European troops only. 18, 19. The hospital is very healthy, and no epidemic disease, hospital gangrene, or pyœmia, have appeared in its wards. No improvements are suggested. 20, 21, 22. No replies to these questions. 23. Every recommendation of the medical officer, as regards the sanitary state of his hospital, diet, medical comforts, &c., is attended to. 24. There is no ward for convalescents at this station.
XIII. Burial of the Dead.	1, 2. There is a small enclosure half a mile from the station used as a burial ground. Its soil is rocky concrete, and subsoil trap. 3, 4. There is no burial ground for Hindoos, but there is one for Mussulmans near the European burial ground. It is never offensive. 5. The dead of bazaar people are disposed of according to caste; Hindoos are burnt, and Mussulmans buried. 6, 7. No injury whatever accrues to health from the present practice, and no improvements in respect to disposal of the dead can be suggested.

(Signed) C. A. S. Milton, Lieutenant,
Commanding Detachment Kol. Infantry.
Eyre de Crespigny, Assistant Surgeon,
Civil Surgeon.
Edward Holland, Lieutenant,
Executive Engineer, S. Concan.

30th June 1860.

Replies to Questions issued by the Royal Commission on the Sanitary State of the Indian Army, made by Dr. B. P. Rooke, Principal Inspector-General, Medical Department, Bombay Presidency.

References to Subjects and Queries.

Replies.

No. 1.—A List of all the Stations in each Presidency, arranged according to their order of salubrity, with notes on the general sanitary condition of each.

The following are the principal stations for European troops in the Bombay Presidency:—

1. Bombay and Colaba.
2. In the Deccan.—Poona, Kirkee, Ahmednuggur, Sattara, and Sholapore.
3. In the Northern Division.—Deesa, Ahmedabad, Surat, and Baroda.
4. In the Southern Division.—Belgaum.
5. In Sinde.—Kurrachee and Hyderabad.
6. In Malwa and Rajpootana.—Mhow, Neemuch, and Nusseerabad.
7. Aden.

It is only since the mutinies that European troops of the Bombay army have occupied the stations of Mhow, Neemuch, Sattara, Surat, Baroda, and Ahmedabad, and from the two latter places they have been now withdrawn. The statistics of all these new stations, therefore, only extend over three years, whilst at the other places they embrace a decade from 1850 to 1860, as will be seen from the accompanying table, marked A.

Arranged according to their comparative salubrity, as judged of by a minimum of deaths, the several stations stand as follows:—

Stations.	Proportion of Deaths per 1,000.	Proportion of Treated to Strength per Cent.	No. of Years referred to.
Asseerghur	13·5	152·7	3 years, 1858–61.
Kirkee	13·7	166·3	10 „ 1850–60.
Aden	16·7	138·6	„ „ „
Poona	17·3	184·2	„ „ „
Belgaum	17·8	144·3	„ „ „
Sattara	18·9	180·8	3 „ 1857–60.
Deesa	19·5	185·4	10 „ 1850–60.
Ahmedabad	20·8	208·8	3 „ 1857–60.
Sholapore	20·9	245·4	10 „ 1850–60.
Ahmednuggur	27·2	237·7	„ „ „
Kurrachee	27·4	185·6	„ „ „
Mhow	28·4	233·3	3 „ 1857–60.
Hyderabad	28·7	230·6	10 „ 1850–60.
Neemuch	30·3	279·0	3 „ 1857–60.
Colaba	32·0	177·5	10 „ 1850–60.
Nusserabad	37·8	215·8	„ „ „
Baroda	42·3	260·7	3 „ 1857–60.
Surat	51·7	403·4	„ „ 1857–60.

European troops were temporarily stationed at, for a short time after the mutinies, but have since been withdrawn from, Dharwar, Rutnagherry, Kolapore, Kulladgee, Vingorla, and Malligaum.

No. 1.—Asseerghur.

This is a well known hill fort on the borders of Candeish and Rajpootana. It was formerly garrisoned only by native troops, but since the mutinies one or more companies of Europeans have been stationed at Asseerghur. The statistics extend over three years, from 1858 to 1861, and show that the average annual strength has been 74, of which 112 have been treated in hospital, being in the proportion of 152·7 per cent. The number of deaths has been only one

References to Subjects and Queries.	Replies.
1. Asseerghur—*cont.*	a year, giving a death rate of 13·5 per thousand. There can be no doubt that it is a very healthy locality for European troops, although the barrack accommodation has been hitherto indifferent. Two new barracks have, however, been lately erected and occupied. The climate is excellent, moderately dry, and not very variable. Fuller details will be found in the separate sanitary report already transmitted.
No. 2.—Kirkee.	This has been for upwards of a quarter of a century the chief European cavalry station in the Bombay Presidency. It is now occupied by the head quarters of artillery. The annual average strength for the last 10 years has been 802; the average number of sick 1,335, being in the ratio of 166·3 per cent. of treated to strength; the average number of deaths 11 per annum, being a death rate of only 13·7, the lowest rate, with the exception of Asseerghur, of any station in the Presidency. The chief diseases, with their classes and numbers, will be seen in the accompanying table (A). Cholera, it will be observed, has visited the station in 1853 and 1855 and last year. The barracks and accommodation for troops are everything that could be desired. The details with respect to climate and meteorology will be found in the separate sanitary report already transmitted.
No. 3.—Aden.	This station has been occupied by both European and Native troops of the Madras and Bombay Presidencies since its capture in 1840. The statistics of European troops for the last 10 years furnishes the following results. The average annual strength, consisting of a wing of one of the line or local regiments, with a company of artillery, has been 479; the average number of sick treated has been 664, and the average number of deaths 8. This gives, therefore, an amount of sickness of only 138·6 per cent., being one of the lowest of any station in the Presidency, and a death rate of only 16·7 per thousand. The principal classes of disease will be seen in the accompanying table (A). Cholera, it will be observed, was altogether absent from Aden. The barrack accommodation for the troops is, on the whole, good, and additional barracks are about to be erected.
No. 4.—Poona.	Is a well known station for European troops in the Deccan, within a few hours' reach of Bombay and of the sea coast by rail. The average annual strength of European troops, consisting of horse artillery and infantry, has been 2,191, of which number the admissions into hospital average 4,037, being at the rate of 184·2 per cent. The average yearly number of deaths has been 38, giving a death rate of 17·3 per thousand. The chief classes of disease will be seen in the accompanying table (A). Cholera has been epidemic last year, and in some former years. Weak and delicate soldiers and invalids are sent to the neighbouring sanitarium of Poorundhur, which is easily accessible, and those requiring the air of the sea coast to the Colaba Sanitarium. The new barracks, hospitals, and appliances for troops at this station are of a superior description, and have been made as comfortable and salubrious as possible, and are a great contrast to the old barracks.
No. 5.—Belgaum.	This has always been a favourite station for European troops in the Southern Division. During the last 10 years, the average yearly strength of European troops has been 1,286, consisting of artillery and infantry; the average number of sick yearly treated has been 1,856, being in the proportion of 144·3 per cent. The number of deaths has been annually 23 on an average of 10 years, making the death rate 17·8 per mille. The principal classes of disease will be seen from the accompanying table (A); and it will be observed that, with the exception of last year, epidemic cholera has been almost entirely absent from the station for the past 10 years. The barracks and accommodation for troops are of a superior description, and the camp is well drained. This station is 2,500 feet above the level of the sea, the climate partaking in some degree of both the N.E. and S.W. monsoons, and very agreeable to the European soldier.
No. 6.—Sattara.	Sattara has only been occupied by European troops since the mutinies, and the accommodation has been of the most temporary nature. A site for permanent barracks has been chosen contrary to the recorded opinion of the present Deputy Inspector-General of Hospitals of the Poona Division. The statistics only extend, therefore, from the year 1857 to 1860. The average strength of artillery and infantry has been 369, whilst the admissions into hospital have been 667, or about 180·8 per cent.; the average annual number of deaths has been seven, showing a low death rate of only 19 per mille (18·9).
No. 7.—Deesa.	At Deesa, European troops have been long stationed, usually one troop of horse artillery and a wing or an entire European regiment. During the last 10 years the average annual strength has been 769, and the treated in hospital 1,426, being in the proportion of 185·4 per cent. to strength. The annual average number of deaths has been 15, giving a death rate of 19·5 per mille. The chief diseases are fevers, peculiar to Guzerat, from which the mortality is high, but has been reduced somewhat by the severe cases, which would admit of it, being sent to the neighbouring sanitarium at Mount Aboo. The accompanying table (A) will show the chief diseases from which the troops suffer.
No. 8.—Ahmedabad.	This station was only occupied by European troops since the mutinies in 1858, 1859, and 1860 and they are now withdrawn, with the exception of a company of artillery. The barracks were only of a temporary nature, but there is good and sufficient accommodation for the artillery. During the three years under report the average annual strength was 670; the average sick treated per annum was 1,399, being in the proportion of 208·8 per cent. The annual number of deaths was 14, in the ratio of 20·8 per thousand.
No. 9.—Sholapore.	A company of European artillery has been stationed at Sholapore as a portion of its regular garrison during the last 10 years, but between the years 1857 and 1860 detachments of infantry were located there. These have, however, now been withdrawn. The average annual strength has been 143; the number of sick treated has been 351 per annum, being in the proportion of 245·4 per cent. The average yearly number of deaths has been three, making the mortality rate 20·9 per mille. The chief classes of disease will be seen by the accompanying table (A). Even if it were desirable to locate a larger body of European troops at Sholapore than at present, there would not be sufficient accommodation, although the facility of easy access by rail makes it otherwise a convenient position.

References to Subjects and Queries.	Replies.
No. 10.—Ahmednuggur.	This, although a favourite station, and for many years the head quarters of the Bombay artillery, has been far from a healthy location for troops, as must be evident from it being placed *tenth* on the present list. The average annual strength has been 440, whilst the admissions and treated in hospital have amounted to 1,046 per annum, in the proportion of 237·7 per cent. The number of deaths has averaged 12 per annum, making the death rate 27·2 per mille. At Ahmednuggur, the increased hospital statistics is due chiefly to the arrival of recruits from England and to their being located there during the period of acclimatization. The barracks, hospital, and accommodation are all of a comparatively old date.
No. 11.—Kurrachee.	During the last 10 years the average annual number of troops at Kurrachee has been 1,566, consisting generally of one troop of horse artillery, a company or more of foot artillery, and a full regiment of infantry. The number, however, has been augmented by troops proceeding to or arriving from the Upper Provinces of India, and halting at Kurrachee until their arrangements were completed. There were 2,907 patients treated annually in hospital, being in the proportion of 185·6 per cent. The annual average mortality was 43, showing a death rate of 27·4 per mille. The number of deaths from the chief classes of disease is shown in the accompanying table (A). Cholera prevailed in 1853, 1854, and last year to a very considerable extent. The new barracks at Kurrachee are superior to any other, except at Hydrabad, in Scinde.
No. 12.—Mhow.	The station has for some years previous to the mutinies been occupied by Bengal troops. It is only since 1857 that a portion of the Bombay army has garrisoned it, and hence the statistics embrace only the three last years. The troops quartered at Mhow have consisted at different times of horse and foot artillery, of cavalry, and of infantry. The annual average strength of all arms has been 983; the number treated in hospital 2,295 per annum, being in the proportion of 233·3 per cent. The average annual number of deaths was 28, giving a death rate of 28·4 per thousand. The barracks and accommodation for European troops have hitherto not sufficed, and were of a temporary nature, but new permanent barracks of a superior description are now ready.
No. 13.—Hyderabad in Sinde.	Portions of different arms of the service have occupied Hyderabad during the last 10 years, but the strength has varied greatly, from 905 in 1856 to 52 in 1857. In the former year, the whole of the 2nd European Regiment was stationed at Hyderabad, previous to the Persian Campaign. The average yearly strength has been 418, and the average yearly number of patients treated in hospital 964, being in the proportion 230·6 per cent., chiefly, as it will be observed from the accompanying table (A), from fevers; but the number of deaths was only 12 per annum, making the annual death rate about 28·7 per mille. During the decade under notice, not a single instance of admission or of death from cholera took place. The barracks for European troops at Hyderabad surpass any other upon this side of India for loftiness and airiness.
No. 14.—Neemuch.	This station has been occupied by native troops of the Bombay army for a long time, but only since 1857 have European troops formed a portion of its garrison. These have consisted of artillery, infantry, and a few squadrons of cavalry. The barracks occupied by European troops were the best that could be restored and re-constructed out of the hospitals and other buildings formerly appropriated for natives. The mean annual strength of the last three years was 658; of these, 1,836 were treated in hospital, being in the proportion of 279·0 per cent. The average annual deaths were 20, giving a death rate of 30·3 per thousand.
No. 15.—Bombay and Colaba.	The average annual strength of European troops at Colaba and in Bombay appears by the tables to be 818 per annum, but this is fallacious, as the garrison merely consists of a wing of a European regiment and a company of artillery. The additional numbers are made up by the arrival of troops, chiefly invalids, for embarkation to England, and by drafts proceeding up country. In this way invalids arrive very often only to increase the sick list, and to swell the high death rate of Bombay, which, for the decade 1850 to 1860, reached as high as 32 per thousand. This state of things will not probably again happen, as the establishment of the Khandalla depôt relieves Bombay of invalids, whilst the railroad to Poona permits invalids from that large station being kept in their own hospitals until the eve of embarkation. Still, there is no doubt but that Bombay is a very unhealthy station, both for European and native troops. Very severe epidemics of fever prevailed in 1858 and in the present year, owing to the bad structure of barracks and hospitals, insufficient drainage, and unwholesome effluvia from the neighbouring beach.
No. 16.—Nusseerabad.	Between the years 1850 and 1857 only one company of European artillery belonging to the Bombay Presidency was stationed at Nusseerabad, and even this company was withdrawn in the early part of 1857; but since that period, in addition to a troop of horse artillery, some portion of a dragoon regiment and a wing or more of infantry have occupied Nusseerabad. During the first seven years of the decade, the average annual strength was about 60, but for the whole period of 10 years the average yearly strength amounts to 449, and the treated in hospital to 969, or 215·8 per cent. The number of deaths was 17, which, in proportion to the strength, makes the death rate 37·8 per mille. The accompanying table (A) shows the chief forms of disease met with at Nusseerabad.
No. 17.—Baroda.	This station was temporarily occupied by European troops from 1857 to 1860, but it has since been given up. A battery of Royal Artillery, with a few companies of an infantry regiment, formed its garrison, the annual average strength of which was about 354. Of this number, the treated in hospital amounted to 923, being in the proportion of 260·7 per cent. The annual mean mortality was 15, being at the rate of 42·3 per mille. This large mortality was due to a peculiar form of "*sun-stroke*," which, with "*apoplexy*," carried off 21 individuals out of the total number of deaths (45). The barracks and accommodation were merely temporary.
No. 18.—Surat.	A few European troops have been quartered in the fort at Surat since the mutinies, any continue to be so located, although the sickness and mortality has been greater than at any other station in the Bombay Presidency, as the following table (A) will show. The strength of the detachment was annually 58, the number of admissions and treated in hospital 234,

References to Subjects and Queries.	Replies.
No. 18. Surat—*cont.*	being more than 400 per cent., whilst the deaths averaged three per annum, in the proportion of 51·7 per thousand. Out of the total number of deaths, viz., nine in the (3) three years, six occurred from diseases of the stomach and bowels, diarrhœa, or dysentery. The Castle at Surat has been always considered unhealthy, and the room used as a guard room unfit to be occupied by European soldiers, whilst the drain is occasionally very offensive.
	No. 2.—A List of all existing Sanitaria in the Presidency, with an account of the advantages or disadvantages of each. (1.) As places of residence for preserving health. (2.) As places of recovery from sickness, with diseases for which they are adapted or not adapted.
	Existing Sanitaria. The existing sanataria are,— 1. Mahableshwur. 2. Poorundhur. 3. Mount Aboo. 4. Ghizree. 5. Taraghur. 6. Sulabat Khan's Tomb, near Ahmednuggur.
I. Mahableshwur.	Mahableshwur is situated on the western slope of the table land of the Ghâts, 17° 56″ N. L., 73° 30″ E. L., and is 4,500 feet in height at its highest point. The climate is very pleasant, the annual mean temperature being 66 F., the mean range 9·7. The air is moist from the influence of the sea breeze, which reaches the hill in full force, and preserves it from the aridity so common on the hills further eastward from the coast. Mahableshwur is not made use of as a sanitarium for troops in the Deccan, as it is unsuitable during the monsoon from the amount of rain which falls, the average being upwards of 250 inches. Invalids would have to descend to the plains in the hottest period of the year, and at a season when cholera generally prevails, so that this hill is not calculated either as a place of recovery for the sick or as a permanent residence for persons in health. In the year 1829 a party of invalid soldiers was sent to this sanitarium, but the results did not warrant the experiment being repeated. Since that period it has been resorted to chiefly in the hot months of October and November, April and May, as a hill station to escape the heats of the plains. Since the introduction of the new furlough regulations few officers are sent to Malableshwur for any continued or for any serious chronic disease, as a change to England has a more beneficial and enduring effect than a resort to any hill station in the tropics. A full account of the medical topography and meteorology of the Mahableshwur Hills will be found in the 1st, 2nd, and 7th Nos. of the Transactions of the Medical and Physical Society of Bombay (copies of which are obtainable at the India House), and in Dr. Morehead's published reports on the Sanitaria of Western India (*see Morehead's Researches on Disease in India, new edition, page* 728).
II. Poorundhur.	Poorundhur has for the last eight or nine years been used as a sanitarium for troops in the Deccan. During that time about 2,000 invalids have been treated on the hill, 1,500 have been cured and returned to duty, 29 only have died, and the remainder were either returned to the plains, the climate being unsuited to their complaints, or are now occupants of the sanitarium. Its height is about 4,200 feet above the level of the sea, its climate is cool and invigorating, it is within the influence of the sea breeze, and the fall of rain, about 70 inches, is not so heavy as to render it uninhabitable the whole year. Poorundhur, like all the hills arising from the plain on this side of India, is not useful in cases of organic disease, but those from debility, fever, dyspepsia, derive great benefit. There is not space at Poorundhur for a cantonment for troops in health, but it is most useful as a sanitarium. A full description of Poorundhur will be found in a memorandum published by Dr. Morehead, at page 747 of the 2nd edition of his Researches, and a later Bombay account in the appendix to the sixth volume of the Bombay Medical and Physical Society's Transactions.
III. Mount Aboo.	Mount Aboo is situated in the territories of the Rao of Sarowy in Rajpootana, 50 miles N.E. from Deesa, the principal station for European troops in Guzerat. It is in 72° 50″ E. long. and 24° 37″ N. lat., and is about 4,500 feet in height. Aboo has been resorted to for the last 20 years as an agreeable retreat in the hot weather, and since 1851 European invalids have been located there. The climate is cool and favourable for Europeans, the scenery is picturesque, and the sites for building are very eligible. Troops remain on the hill the entire year, and Mount Aboo is, therefore, not only fitted as a sanitarium for invalids suffering from the debility of fever, induced on the plains of Guzerat, but from the ample space and excellent climate it is well adapted for a permanent station for European soldiers. The barracks have been placed in a disadvantageous position, which, however, is about to be changed. A general topographical and medical report by Assistant-Surgeon Ogilvy up to the latest date will be found in the sixth volume of the Bombay Medical and Physical Society's Transactions, page 192.
IV. Ghizree	Ghizree is not a hill, but a coast sanitarium, and as such has been for some years occupied for the troops in Sinde. It is elevated scarcely 60 feet above the level of the sea, but the plateau rises abruptly from the shore, and enjoys in an eminent degree the full force of the sea breeze, pure and uncontaminated, from the Indian Ocean. It is in the purity of the air, the strength of the breeze, and consequently slightly lower temperature than the camp of Kurrachee, that the value of Ghizree as a sanitarium consists, and a residence there is calculated to give a healthy tone to the weakened system, whether arising from fever or from chronic visceral disease.

References to Subjects and Queries.	Replies.
IV. Ghizree—*cont.*	Ghizree is not at all fitted for a permanent encampment for a large body of troops, owing to the want of water, of which it is entirely destitute, as all required at the sanitarium is brought from the cantonment of Kurrachee. A further account of Ghizree will be found at pages 15 and 16 of the published report on the extent and nature of the sanitary establishments, in the selections from the records of the Government of India (Military Department), Calcutta, March 1861.
V. Taraghur.	Taraghur is a hill fort, about 14 miles from Nusseerabad, close to Ajmere, which has been made use of as a hill sanitarium, and with great success. The ascent is easy, but the space on the plateau is not sufficient for more than 40 or 50 invalids. The hill is 2,800 feet above the sea, and about 1,000 above the plain. Water is collected in tanks, and supplies are abundant. The statistics do not extend beyond the present year. From April 1860 to March 1861, 178 invalids have been sent to the hill for change of air; of these, only 14 were returned without having derived any benefit. No death occurred. The cases were, however, well selected, and the experiment has proved that men suffering from debility, the result of sickness and long confinement in hospital, recover rapidly at Taraghur.
VI. Salabat Khan's Tomb.	Salabat Khan's Tomb, near Ahmednuggur, has lately been resorted to as a sanitarium for weakly and delicate soldiers from Ahmednuggur during the hot months of April and May. It is a small hill about six miles from Ahmednuggur, about 2,000 feet above the level of the sea, and 600 or 700 feet above the level of the camp of Ahmednuggur. The temperature is about two or three degrees cooler than Ahmednuggur. It is freely exposed to the high winds which prevail during the hot months in the Deccan, but on the hill these are cool, whilst in cantonment a furious hot wind may be blowing. The tomb has received certain additions and improvements since it was first occupied in 1859, and the buildings are now well adapted for the reception of invalid Europeans. About 50 or 60 men have been sent there during the hot season, with advantage and improvement to their general health. The site, from its elevation, is cool and healthy, and recent experience proves that a temporary residence is very beneficial to soldiers in a debilitated condition. There is ample space for the erection of other buildings, but the access is not good and water is not obtainable on the hill, but from a distance.
	No. 3.—A List of all Places within the Presidency where Hill Stations might be advantageously fixed for the Health of the Troops, or where Sanitaria might be established, with particulars as to the elevation, topography, climate, means of access, distance from stations, &c.
	There are many hills met with in the Ghauts and spurs leading from them well calculated for sanitaria, and where hill stations might be advantageously fixed, if they were accessible. These hills are generally about 4,000 feet above the level of the sea, and enjoy the same climate as Mahableshwur, but are for the most part inaccessible, deficient of supplies, and out of the line of the railroad. In the Satpoora range in Kandeish there are also hills varying from 4,000 to 6,000 feet in height, and one of these would probably be found very useful to the troops serving in Malwa, who have as yet no nearer resort for invalids than Poorundhur, which entails a long and wearisome march of 350 miles. The general height of the most elevated hills in this Presidency seldom exceeds 4,000 feet. In one instance alone in Kandeish is there a mountain of 6,000 feet, but the plain surrounding it is said to be very unhealthy. Between Sattara and Mahableshwur the hill of Euteshwur possesses great advantages, and is likely to prove a good locality for preserving the health of the troops. Its height is 3,600 feet, with good water, soil, and plenty of space, as well as easy of ascent. As places of residence for preserving the health of European troops, there is no want in the Bombay Presidency. One of these, Paunchgunny, 12 miles to the eastward of Mahableshwur, is sheltered from the monsoon. The fall of rain is so slight as to be of no inconvenience, the average being about 50 inches per annum. Troops might reside at Paunchgunny the whole year. The soil is laterite, and water does not remain on the surface. The sea breeze, although late in arrival, blows regularly for many hours in the day. There is ample space for drill, and the climate is favourable for horticultural pursuits. Its mean maximum temperature is 77°, and mean minimum 62°, whilst the extremes are from 56° to 86°. It is perfectly accessible. An account of Paunchgunny will be found in Dr. Morehead's Note on Deccan Hill Climates, before referred to. The sanitaria in this Presidency are generally free from malarious fever; neither does the climate produce abdominal complaints, as noticed at the hill stations of Bengal. There are two coast sanitaria for such diseases as hill climates do not suit, one at Colaba, the other at Rairee, on the southern Mahratta coast, near Belgaum. Colaba, although a convenient locality, is unhealthy, and it is to be hoped that some more pure and salutiferous site will be erelong selected on the coast of the Concan. Rairee is only now being tried, and as yet the results are not known.
	No. 4.—State in what Months Troops usually arrive in the Presidency from England, whether any restriction for preserving their health is placed upon the men on arriving, whether there is any place of resort provided for the men, or whether they are allowed to go at large; whether there is much drunkenness among the men after landing, and whether much preventible disease arises from such irregularities; how long the troops remain at the port after disembarkation and before proceeding to the interior; what precautionary measures are in use for protecting their health during the voyage or journey.
	1. Troops have of late years arrived at Bombay in the cold season, *i.e.*, from November to March or April, but instances have occurred of earlier and later arrivals, although not common. Formerly they remained in Bombay after arrival, often many weeks, until the season permitted of their marching to their destination, and they became infected with the licence and debauchery so natural to soldiers after a long voyage, and so easily indulged in at the Presidency, but now, immediately upon the ship anchoring, the troops, if recruits,

References to Subjects and Queries. | Replies.

are inspected by a committee of two military and one medical officer, and every man undergoes examination as to his fitness to proceed or to remain.

2. Those who are too sick are again seen by the Deputy Inspector-General of Hospitals, and immediate arrangements are made to land and place them in hospital.
3. The disembarkation of the remaining troops devolves upon the Deputy Quarter-Master General, and is made within a few hours after the ship has anchored, not earlier than 3 p.m., nor later than 9 a.m.
4. The troops as they arrive from the ship by boat loads are formed on the bunder, under the officers who accompanied them from England, and are marched the distance of about half a mile to the railway terminus, *en route* to Khandalla, distant 70 miles. They are conveyed by rail to the foot of the Ghauts, and they make the ascent of the Ghauts either on foot or in country carts, the baggage in the meantime having overtaken them. At Khandalla, they are received into the new barracks prepared for them, called the "General Depôt." Here they remain along with their own and the officers of the depôt until arrangements are made to draft them to their different regiments.
5. Every precaution is taken to restrain the men from irregularities on the line of march, if it can be so called when performed by rail, and afterwards on arrival and whilst at Khandalla, which is a cool healthy locality on the top of the Ghauts and in the direct road to Poona, where the men are under discipline and without much facility of obtaining spirits.
6. If the troops are destined for Poona, they do not halt at Khandalla, but proceed on by rail to their destination. If for the stations in Malwa, they remain at Khandalla for a few days, and then proceed by bullock train in parties of 20 or more, each accompanied by a due proportion of officers, military and medical. Again, troops destined for the North and South Divisions remain at Khandalla, it may be for a few days only, or for a week or more, until steamers are ready to take them to their port of disembarkation. The steamers, often of the Indian Navy, are well found, and the numbers embarked are not large. They have then only a few marches to make on land, either to Belgaum or to Deesa, and, in the latter instance, the Bombay, Baroda, and Central India Railway takes them half the distance.
7. I do not think that anything could be better arranged than at present regarding the disembarkation of troops at Bombay, their temporary sojourn at Khandalla, and their future destination. The opening of the several railways, the establishment of a bullock train to Mhow, and the employment of steamers, have quite changed the character of "*moving troops*," and have rendered easy of accomplishment, free from danger or exposure to sickness or irregularities, what was before often attended with great trouble, risk, uncertainty, and loss of life.

No. 5.—State the general result of Experience as regards the Queen's Troops and European Troops of the Indian Army on the following Points:—

(1.) As to the best age for a soldier landing in India.
(2.) As to the amount of previous service desirable before arriving in India.
(3.) How he ought to be disposed of on landing, and what would be the best mode of life during his first years of service.
(4.) The routine of stations, the length of time he should serve on hills and plains and the total length of his service in India.
(5.) The marriage of soldiers, the present regulations in regard to this, with any suggestions for improving such regulations.

1. Experience has, I think, sufficiently proved that lads under 20 years of age are not fit for any arduous duty in India as soldiers; even the severe exertion of learning their drill is too much often for the unformed constitution in this country. In times of perfect peace and with light work lads of 18 would not incur much risk of their constitutions suffering from climate, but if the recruit is likely to be employed in the field, or in marching, and with much exposure, he ought not to land in India till 20 years of age. Although the mortality of lads of 18 is not large, yet they are very liable to fall sick and fill the hospital if submitted to hard work at that age.
2. I do not think there is any necessity for previous service in any intermediate climate, beyond that if a lad is enlisted at 18, it would be better to keep him in England for two years, and let him be thoroughly drilled during that period.
3. The great danger to troops upon first arrival is their propensity to indulge in vicious excesses after the irksome restraint of a long sea voyage, and it is their indulgence in all kinds of vice, intemperance, and exposure to the sun, with their heads unprotected by sufficient covering, that is the source of so much mischief to newly arrived troops, as before mentioned. Troops on arrival are now sent to Khandalla, where they are comparatively free from such exposure.
4. The routine of stations in this Presidency is very confined, and is only between the Deccan, Southern Mahratta Country, Guzerat, Sinde, Malwa, and Rajpootana. The Deccan and Southern Mahratta Country are comparatively very healthy, being elevated from 1,800 to 2,500 feet above the sea. As many European troops as possible should be massed in those favoured stations, and only such a number as the requirements of the country render absolutely necessary should be stationed in the plains of Guzerat and Malwa, and their reliefs should take place at least every three years.

Fifteen years is, in my opinion, the longest tour of Indian service that an European regiment should make.

5. I think that the marriage of soldiers should be by all means encouraged, as the greater number of diseases under which European soldiers are admitted into hospital are *enthetic* diseases, arising from illicit sexual intercourse, and the only truly moral and effectual check to this is the marriage of the soldier.
6. Lock hospitals and the licensing of bazaar females are only an encouragement of vice, and all police regulations have failed in checking venereal disease among either sex.
7. In a report, dated 1st April 1861, Dr. Arnott, C.B., Deputy Inspector-General of the Mhow Division, states, "From the accompanying return, which shows the amount and nature of "the sickness in the European hospitals at Nusseerabad and Mhow on 1st March 1861, it "appears that out of 193 sick no fewer than 103 are venereal cases."

"The loss to Government of the services of 103 men throughout the year must be enormous, but this return does not and cannot show the worst features of this unhappy state of matters. The consequences of the effects of this horrible complaint upon these men's

References to Subjects and Queries. | Replies.

constitutions, together with the confinement in hospital, will be felt for years. Whatever disease may prevail, wherever they may be, they will be its surest victims. Independent of the debility and rheumatic affections, which every medical officer knows they will for years suffer from, and after years of little duty and much sickness, they will have to seek a restoration to health in their mother country. The expense to Government of such men it is impossible to calculate, but there can be no doubt it would be a most economical measure to establish some institution that would protect these unfortunate men from much suffering, and the state from the enormous outlay bestowed so unsatisfactorily to all parties."

No. 6.—State any additional Recommendations or Suggestions which past experience has shown to be requisite for protecting the Health of the Troops after landing, during the transit to the interior, in stations, on the march, or in camp.

This subject has been so well cared for in this Presidency that it does not occur to me that any further steps are necessary to protect the troops from disease after landing.

No. 7.—A List of Hospital Equipments, according to existing Presidency Regulations, for 100 or any other convenient number of men,

(1.) For Station Hospitals.
(2.) For Field Hospitals.

With any additions or improvements in these equipments that can be suggested, and in the hospital regulations generally.

By Art. 45, p. 63, of the Medical Regulations of 1859, the following is the equipment of a fixed hospital :—

Presses for holding medicines	2
„ clothing	6
Compounding table	1
Writing table	2
Chairs	5
Medicine trays	2
Tables and forms as required.	
Teapoys	50 per cent.
Night chairs as required.	
Cooking utensils of all sorts.	
Crockery ware.	
Bedding, clothing.	
Table service.	

The list of clothing and bedding per 100 is as follows :—

Shirts	60
Bedgowns, single	20
„ double	20
„ warm	5
Banians	30
Drawers	33
„ warm	5
Caps	30
„ warm	5
Socks	10
Slippers	30
Belly bands	5
Bed cases	20
Pillow cases	60
Sheets	60
Quilts	30

By late regulations, the Barrack Department supplies presses, tables, chairs, cots, forms, teapoys, chests for clothing and for medicines, night chairs, bathing tubs, lamps, cooking utensils, close stools, crutches, diet boards, horses wooden, rat traps, screens, steps mussal, tables, camel trunks, urine tubs, punkas, tubs for fomentation; whilst the Commissariat Department furnish bedding, clothing, table service, and petty supplies.

There is no fixed scale of the number of each article per cent., but they are furnished in such proportions as are required, and with the sanction of the Deputy Inspector-General of the Division.

The following is the equipment of a field hospital, as per G. G. O. No. 500 of May 1858 :—

Bedding.

Bed cases	16 per 100 men.
Blankets, country	8 „
„ Europe	8 „
Sutterungees or carpets	8 „
Pillow cases	16 „
Quilts, lined with looie	16 „
Sheets	40 „

Clothing.

Banians, flannel	32 per 100 men.
Bands, belly	6 „
Bedgowns, lined with looie	16 „
Caps, lined with flannel	16 „
Drawers, cotton	8 „
„ flannel	8 „
Shirts	48 „
Slippers, pairs	12 „
Socks, worsted, pairs	32 „

References to Subjects and Queries. | Replies.

Cooking Utensils.

Cooking pots	2 per 100 men.
Dishes, tin	8 „
Forks	8 „
Frying pan	1 from 100 to 500 men.
Kettles, camp	1 per 100 men.
Knives	8 „
Plates, tin	8 „
Spoons	8 „
Tins, quart	8 „

Necessaries.

Bathing tub	1 from 100 to 500 men.
Baskets, rattan and pan	1 per 100 men.
Bed pans	1 „
Camel trunks, with straps 33 inches in length, 18 inches in breadth, 20 inches in depth	1 „
Crates or cajavas, to contain cooking utensils	2 „
Chairs, rattan	2 for 100 men or a regiment.
Fomentation tub iron	2 for 100 to 500 men.
Gindee	1 for 100 men and upwards.
Inkstand	1 for 100 men or a regiment.
Lantern, hand	2 „
Leather choggles for water.	
Pickaxe	1 for 100 to 500 men.
Powrah	1 „
Ruler	1 for 100 men or a regiment.
Table lamp	1 „
„ operating	1 on service for 200 men or a regiment.
Tarpaulin to cover stores	1 per 100 men.
„ to place under beds	2 „

B. P. Rooke, M.D.,
Bombay, 10th August 1861. Principal Inspector-General, Medical Department.

(The Mortality Tables for each Station, referred to in Dr. Rooke's report, which follow this General Return are the same as those given in the Bombay Statistical Returns, and are not therefore reprinted.)

CEYLON.

COLOMBO.

European Troops	Artillery	90
	Infantry	920
Native Troops	Artillery	195
	Cavalry	22
	Infantry	503

References to Subjects and Queries.	Replies.
I. Topography.	1. Colombo is a luxuriantly-cultivated flat tropical country, on the south-west coast of Ceylon, with a few patches of low jungle, grassy plains, and slightly undulating ground. The littoral parts are covered with cocoa-nut, and beyond it are seen extensive plantations of cinnamon, mango, and other fruit trees. It is intersected by a river and branches of a fresh-water lake, which communicates with the ditch round the land side of the fort and with the canal within it. There are many rice fields and swampy ground in the surrounding country.
	2. The elevation of the station above the sea is from 12 to 18 feet, and it is nearly on a level with the adjacent country. It is from 7 to 13 feet above the level of the lake and canal. The nearest hills are about two miles from the fort, but their height is so inconsiderable, scarcely 80 feet, that no commensurate advantage could be expected to be derived from them for sanitary purposes, surrounded as they are by a dense native population. About seven miles south of Colombo, on the sea coast, is Mount Lavinia, a military station for rifle practice. It is about 50 feet higher. The atmosphere here is purer, from not being tainted with the effluvia of a large town or swampy ground. To this station might be added a convalescent hospital, both for officers and men, whose recovery is long and tedious in Colombo.
	3. The nearest mountain land is Kandy, which is 72 miles from Colombo; height, 1,670 feet. Pusilawa is 87 miles distant; height, 3,200 feet. Newera Ellia, 111 miles distant; height, 6,200 feet. Horton Plains, 127 miles distant, 6,900 feet in height.
	4. The Fort of Colombo, where European troops are quartered, is bounded for more than half the extent by the sea. A wet ditch filled with lake water bounds the remainder. A canal communicating with the lake near the fort runs through the fortifications to the sea front. The barracks and huts of the native troops are on a peninsula called Slave Island, on the fresh-water lake, and in their vicinity are some marshy grounds and stagnant streams and ditches. The Calany river is about four miles north of the garrison. It communicates by a canal with the fresh-water lake. The low land near the river and lake is liable to be overflowed in the rainy season. The inundation of the river lasts for some weeks, that of the lake only a few days. The rainy seasons are in the south-west monsoon, generally in April, May, and June, and at the commencement of the north-east monsoon in October and November. There is not much broken ground near the station. The ravines and water-pits are so few that they have not been observed to affect health, particularly of the troops who are quartered far from them.
	5. The barracks for European troops at the station are within the fort, and consequently have not the free ventilation from without so desirable in a tropical climate, and of late years upper stories have been added to Government and private houses in the fort, which have still more reduced the free circulation of fresh air in the barracks. The native troops are quartered in an airy situation outside the fort, on the south side of which is a race-course, used for military exercises, public promenade, and recreation, and an esplanade planted with ornamental trees on the north. In many parts of the fort the reflected heat of the new whitewashed houses increased the temperature of the air. In the staff surgeon's quarters, where 20 years ago the temperature was not observed higher than 86° Fahrenheit, it is frequently now at 90° in the hot season. The station is exposed to both land and sea breezes. Variable winds also prevail in the decadence of one monsoon and the commencement of another. Land wind is chilly, and considered here an unhealthy wind, and produces rheumatic and catarrhal complaints.
	6. The country surrounding the station is cultivated, and there are works of irrigation within about three miles. They are deemed prejudicial even at that distance, but not materially so. The cultivation of rice is not prohibited within certain limits. No indigo, flax, or hemp is cultivated near the station.
	7. The pettah, or native town, is within half a mile to the north of the fort, and is densely populated. There is also a smaller town on Slave Island, near the Ceylon rifle barracks.
	8. In the geological structure of the district, granitic, gneiss, laterite, and lithomargic earths predominate. There is a recently-formed sandstone belt on the sea shore. The soil is chiefly clay and sand, and sea sand is found inland in sites of ancient beach. There is no alluvial soil. The station had long since been occupied by natives, previous to European conquest.
	9. Water is usually found in the fort after a long drought at from 11 feet 6 in. to 28 feet, according to the level of the ground. In the rainy season it is found at from 7½ to 24 feet; outside the fort, from 12 feet 6 inches to 5 feet in the dry season, and from 9 to 3 feet in the rainy season.
	10. There are no surface springs, but the rain-fall is rapidly absorbed by the very pervious sandy soil. There is no higher adjacent ground the drainage from which passes into the subsoil of the station.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	11. Drinking water is derived from wells. A large water supply is also derived from rain-fall for bathing, &c. There are no tanks, so defined, but the fresh-water lake extends inland from the fort. The lake is generally full, forming a defence to the fortress and an inland navigation. The plants it contains are the white and purple lotus in great abundance, several species of grasses, algæ and confervæ. Of animals, there are eight or ten species of fish, shrimps, frogs, and water snakes; also the otter. The lake is used for bathing by the native troops and population, and in dry weather the water is occasionally drunk by natives. The lake and canal are liable to pollution from impurities draining into them. A large part of the drainage of the fort empties into the canal, and there are latrines and drains discharging into the lake. Some of the wells in the fort appear too near cesspools, but are not used by the troops for drinking. In the dry season some malaria would proceed from the receding of the lake, leaving its banks exposed to the sun's action. A new system of drainage for the fort, contemplated by the Colonial Government, and embanking the lake, is suggested.
	12. The water supply for the present garrison is abundant. A slightly brackish and occasional ferruginous taste is sensible in some wells. The quality of the water is generally good, and the amount sufficient. Alumen, saline substances, and traces of iron and nitrogen have been detected in some wells. The ordinary means of raising and distributing the water is by pumps, buckets, earthen vessels, and barrels. A better supply seems unnecessary.
	13. Cleanliness and more frequent emptying of cesspools by the inhabitants, and the ventilation of latrines, are suggested.
	14. No new station has for years been selected in Ceylon. The rules laid down in the Queen's army hospital regulations appear to regulate the selection of stations.
II. Climate.	1. The instruments available for conducting meteorological observations are, the barometer, thermometers for registering temperature in air, in sun, on grass, temperature of evaporation, maximum and minimum; anemometer; two rain gauges, one on the ground, and one 23 feet above the ground. The amount and nature of cloud is also registered at the Royal Engineer Observatory.
	2. The following table shows the observations for seven years, from 1st January 1853 to 31st December 1859 :—

—	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain, Inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks as to Clouds, Dew, Wind, Storms, &c.
January -	29·888	78·47	9·9	83·42	73·52	81	76·1	108·9	3·73	N. & N.E.	Calm.	23	The atmosphere of Colombo is generally unclouded in the dry season, except in the early morning or at night, when light clouds appear. It is clouded in the wet season, and at the changes of monsoon, about May and November, when heavy clouds are accompanied by gales. These gales do not usually continue for more than a week, and during the remainder of the year light breezes prevail. There is generally a heavy dew perceptible in the morning.
February -	29·883	78·57	8·18	82·66	74·48	82·24	77	110·9	2·28	N.E. & N.W.	Calm.	23

October -	29·862	79·47	5·82	82·38	76·56	81·15	78	103·4	10·542	W. & S.W.	Ditto.	21	
November	29·868	79·015	8·29	83·16	74·87	81	77·67	106·7	11·462	E.N.E.	Ditto.	23	
December	29·896	78·515	9·33	83·18	73·85	80·85	77	106	5·659	N. & N.E	Change of Monsoon, high wind.	22	

3. The climate of Colombo varies from great dampness, during south-west monsoon, to the opposite state of atmosphere in that of north-east. A cold and trying wind, called locally a long-shore wind, prevails. Towards the close of the year occasional fogs have been observed. The canal and irrigation are not extensive enough to influence the climate. Clouds of red dust are annoying in the vicinity of the station in the hot and dry seasons. The health both of European and native troops is materially influenced by the climate. Meat and vegetables must be immediately cooked, and cannot be so preserved. Verandahs and Venetians are required as shelter from the driving rain and great heat, and moisture is deposited on the walls and floors in the wet season. Clothing requires constant care and airing to preserve it from damp and insects. Drill duties and exercises take place in the open air only in the cool of the morning and evening; the latter being preferable on account of dew. About an hour at a time is as much as the troops can bear, not daily nor even in marching order. The most healthy months are July and August, December and January. The most unhealthy, April and May, September and October, at the decadence of one monsoon and the commencement of the other. The prevailing diseases are, fevers of the intermittent and remittent types, liver and bowel complaints.

4. Mount Lavinia, already mentioned, about 7½ miles from Colombo on the sea-shore, is about 50 feet higher than the station, easily drained, and supplied with water from wells. It is situated in the country, apart from towns, and would be desirable as a sanitarium, but is not of other military importance as a station.

5. The stations on which I have served are in Ceylon, at Colombo, Kandy, Trincomalee, Galle, Newera Ellia, and Pultam. Of these, Newera Ellia, and Galle appear comparatively salubrious; next, Kandy and Colombo, while Trincomalee and Pultam may be considered positively injurious to European constitutions.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	5. The windows of the barracks are on opposite sides, and are generally open, being provided with wooden shutters. In one later-built barrack, Venetian doors are provided in the verandahs up-stairs. There is a verandah on both sides, which is about 10 feet wide. The verandahs are never occupied as sleeping quarters; they are open, and do not require jalousies except in the case of upper-story barracks. 6. The bedsteads are chiefly of the usual kind, iron and wood. The bedding consists of coir (that is, cocoa-nut fibre), mattresses, one blanket each, sheets, and thin cotton coverlids, with coir pillows, for the European troops. The native troops use wooden bedsteads, mats, pillows, and woollen blankets, locally called "cumlies." 7. The tents used at Ceylon are of two sizes, double-poled and single. No. 1 double-poled tent is intended to accommodate 20 men; cubic contents in feet, 2,040. No. 2 single-poled tent, for 10 men; cubic contents, 1,190 feet. Sections of each of these tents are attached, by which it will be seen that the cubic contents of the inner compartment may be increased by removing the inner wall. 8. Besides the windows and doors, there are apertures for constant ventilation under the wall-plates of barracks, huts, and guard rooms, with ventilators at the floors. Tents are ventilated by small openings. Generally speaking, the ventilation is sufficient, but some cases admit of improvement. There are no means in use for cooling the air for barrack rooms. 9. The materials of which barracks are constructed are brick, cabook, or laterite, which cuts easily into blocks, and plastered and whitewashed with lime. They have wooden roofs, covered with tiles. Some of the native troops are in barracks built with wood, plastered with mud, and roofed with cadjans (plaited cocoa-nut leaves, of which a temporary barrack is formed at Mount Lavinia in lieu of tents). 10. Floors are generally of tile or bricks, and are raised from one to three feet above the ground. There is no passage of air under the floor. 11. The construction of floors might be improved by a better description of tiles—asphalte or wood. The barracks are kept in repair by the Royal Engineer Department, and repairs are executed quickly and efficiently. The Deputy Inspector General of Hospitals is responsible for the sanitary state of the cantonment, so far as the troops are concerned. The walls and ceilings are cleansed and limewashed whenever necessary. 12. Lavatories are provided for three barracks, and a sketch of two adjacent to one another is attached. The water which is raised from the well by means of a pump is conveyed to the tank in the centre of the building. Three stop-cocks are attached to the tank, by means of which the water is let into tubs when required for bathing or washing. The water is carried off by a barrel drain into the canal. 13. The cook-houses are provided with open hearths, on which meat may be roasted, fried, or boiled. Wood is used for the fires. An oven also is provided for baking meat. The water is supplied from wells near at hand, and the refuse water is thrown into an adjacent cesspool. The washing of linen is performed by washermen, locally called "dhobies," who are sufficient in number for the wants of the station. 14. The privies are provided with pits, which are emptied when necessary. The pits are provided with man-holes, immediately behind the privies, for access. A rough sketch of a urinal is shown in the sketch of the cook and wash houses. The urinals are provided with drains. In the case of that shown a pipe conducts water from the well, which tends to keep the urinal clean. The contents of the privies are carried outside the fort to the sea shore, where they are buried with a depth of earth of three or four feet above the deposit. 15. These buildings are lighted and ventilated by means of scuttles or windows. The barracks are lighted at night with oil (cocoa nut),

III. Sanitary Condition of Station—*cont.*	16. Most of the barrack drains lead into the canal. The ordinary dimensions are 1 ft. 6 in. diameter barrel drains. The drainage of No. 12 barrack is carried by a drain *under* the canal and into the wet ditch of the fort. All the large drains were constructed in the time of the Dutch. The outlets of these drains are but a few yards from some of the barracks. The drainage is generally sufficient, and no part of the barracks or hospital is damp. Some of the fluid refuse is both evaporated and sunk in the subsoil. Cess pits are provided for most of the privies and urinals. These cesspits are ordinarily about 5 feet to 2 ft. 3 in. deep, and 4 ft. to 2 ft. 6 in. square. From one of the wells a cesspit is but 11 feet distant, and the water is only used for washing. Other cesspits are 22 feet, 55 feet, 76 feet, and 82 feet distant from the wells. The cesspit nearest to the men's quarters is three feet beyond the verandah of one barrack, and sunk eight feet below its level. The cesspit nearest to the hospital is 10 feet distant. They are opened and cleansed out whenever necessary. The water in the ditch around the fort does not flow quickly enough to prevent a large amount of mud, &c., accumulating. Most of the fort drains empty themselves into the canal which runs through the fort, and is filled from the lake and ditch. 17. The rubbish and fallen leaves within the cantonment are regularly swept and removed. The method of disposing of the manure is described elsewhere. 18. Fatigue parties of gun lascars are employed constantly in keeping the scarps and ramparts free of rank vegetation, which grows very rapidly. There are no old walls or hedges. The principal hindrance to free ventilation is the mass of houses built in the fort. 19. The drainage of the pettah and bazaar is imperfect, and open drains in many parts give out noxious effluvia. The ventilation of the rooms and privies of small houses is defective. The houses near the fort are not crowded. The latrines are in some houses too near the wells. The water supply for drinking is sufficient, but not always of good quality. There are no regular sanitary regulations. The commissioners of roads employ scavengers to clean the streets, but the drains, from the want of a sufficient supply of water, cannot be kept always clean. The local Board of Health might show more activity. An officer of nuisances ought to be appointed, and a military medical officer might be added to the board to protect the interest of the troops. The native houses near the station are generally good, but dung heaps and cess-pits are seen within the compounds, and they are not emptied as often as desirable. Several of the inhabitants of the fort keep carriages for hire, and they have neither sufficient space nor care for cleanliness to prevent the accumulation of filth. No nuisance is observed from wind blowing over the native dwellings, except sometimes at Slave Island, near the Ceylon rifle barracks. This nuisance might be prevented by police regulations and opening out the streets of the bazaar. 20. Cattle and other animals are slaughtered in the pettah, about one mile from the fort. Slaughter-houses approved of by Government are under the surveillance of the police. No nuisance is experienced from their condition. The regulation in force is Ordinance No. 14 of 1859. There are licensed butchers. The cattle, before being killed, are exposed to public view for 24 hours; but when troops are marching cattle can be killed immediately on demand by the commissariat officer. The police can seize all unhealthy and diseased animals, and have them destroyed or otherwise disposed of. The offal is thrown into the sea. 21. The inquiry respecting the stabling or picketing of horses does not appear applicable to this station. 22. The governor's "mounted orderly" stables of cadjans are on the Galle Buck, a piece of open ground between the fort and the sea. A range of officers' stables (cabook walls, tiled roof, rail doors) is built in the fort, and the dung is cleared away once a week. It is at a distance from the soldier's barracks. The manure is taken to the sea, a few hundred yards from the fort. 23. The quarters for married non-commissioned officers and men are amply sufficient for the present strength of the garrison.
Officers' Quarters.	1. The sanitary condition of the officers' quarters is generally good. Some details of drainage, &c., are improvable. A new system of drainage is contemplated by the Colonial Government of Colombo.
IV. HEALTH OF THE TROOPS.	1. The district of which Colombo is the capital, and in which the station is situated, (called the Western Province), is considered the healthiest of maritime districts in the Island. 2. The diseases most prevalent among the natives are rheumatism, fever, and bowel complaints. The spleen does not often become diseased in Colombo. Cholera and small-pox do not visit the station as frequently as in former years. Measles and chicken-pox prevail nearly every year. A mild form of scarlatina is occasionally seen. Leprosy and elephantiasis are common. Beriberi is very rarely seen. 3. The causes of so much fever, bowel complaint, and rheumatism are the hot and moist state of the atmosphere, and the presence of malaria in it. Natives are also, from their general debility and poorness of living, more susceptible than Europeans to fevers. 4. The troops at this station came from England in good health—the 50th, after a stay of 10 months; the Royal Artillery, after about 18 months. With the exception of the two companies of Europeans recently arrived from Trincomalee, the European troops have been stationed in Colombo since their arrival in the colony—the Royal Artillery since November 1858, the 50th since October 1857. The diseases from which they have chiefly suffered since their arrival are liver complaints, dysentery, and fever. There is no perceptible difference in the healthiness of the different portions of the men's accommodation. 5. The troops are not camped out except in case of epidemic, &c. 6. The medical member of the board has been in charge of troops at the hill stations of Newera Ellia, and Kandy, and Badulla, and considers that better health is enjoyed there by the troops than at Colombo.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	7. We have not had many opportunities of making observations whether the troops resident for some time on hill stations are more or less liable to disease on returning to the plains, as very few men are stationed at a time at Newera Ellia. But it would appear from the present healthy state of the 50th detachment at Trincomalee, which went there after a residence of two years in Kandy, that they are less liable to fevers than the men who had long resided at Trincomalee. This immunity from the usual frequency of disease is, in our opinion, to be attributed to acclimatization, and the less debilitating effects of the climate of Kandy; the above-mentioned detachment having been moved to Kandy immediately on its arrival in Ceylon, whereas the detachment of the 50th, recently removed from Trincomalee, was sent there direct from England. 8. We approve of selecting hill stations for troops. 9. There are no diseases peculiar to hill stations. 10. The men, while at hill stations, should be supplied with extra blankets and warmer clothing, and abundant means of recreation and out-door amusements provided for them. 11. The dry season at Newera Ellia is preferable for invalids, but to the healthy any period of the year is equally good, if they will avoid exposure to the wet. Four months is the shortest period in which men merely debilitated would obtain the full benefit of a residence on the hills, and eight months or a year would be necessary for those with organic diseases. 12. We cannot speak from experience whether there is any period of residence beyond which injury to health is likely to be inflicted, but we presume that men who have been long accustomed (more than one or two years) to breathe, at an elevation of 6,000 feet, a more rarefied and colder air, are likely to suffer from pulmonary and hepatic congestions if they are brought down suddenly into the hot plains. But as Ceylon affords places for stations at various elevations, troops need not be removed at once from the highest to the lowest post. 13. No special precautions have hitherto been used on returning to the plains, and none seem necessary except greater temperance. 14. It in some measure depends on the height of the hill whether it would be desirable for health to locate troops on hill stations, with short periods of service in the plains. At moderate elevations, such as Kandy, we think residence there, with occasional change to the plains, the preferable alternative. Frequent change of station on the plains is considered beneficial. 15. The site of the former hospital (lately burnt down) and that of the present barrack at the hill station of Newera Ellia appear objectionable, and the accommodation insufficient. At Mount Lavinia, the former invalid quarter for four officers has latterly been occupied by detachments at rifle practice, leaving none available, a deficiency greatly felt. 16. The general opinion appears to point out a range of elevation from 3,000 to 4,000 feet as the best. 17. Mount Lavinia, before mentioned, might advantageously be occupied as a hill station. 18. A sandy or gravelly surface, with a clay subsoil, appears to be less healthy than a loamy soil covered with vegetation. 19. From 20 to 25 years is the best age for soldiers proceeding to Ceylon, and July and August are the best months for landing there. On first landing, the troops go into barracks, and are clothed in white cotton, with white covers to their forage caps, wearing cloth clothing in wet weather and at night. They take the usual duties of garrison and drill, but do not march out in marching order. The precautions necessary are attention to diet and temperance, and to avoid exposure to the sun, also to send recruits to Kandy on landing in Ceylon. 20. Troops might be sent direct from home depôts to Ceylon, as Kandy would answer for an intermediate station. They should be sent to hill stations on landing, and gradually accustomed to the climate. 21. In Ceylon troops proceeding from the port to the interior march 10 or 12 miles in the early morning, and are accommodated at most of the halting places in Government rest houses, and at others in tents, which is objectionable. Permanent cover ought to be provided. 22. I consider, on the average, that six years should be the term of a soldier's service in Ceylon. 23. As regards invaliding, the principal medical officer in Ceylon decides, on the report of the medical officer in immediate charge, without the intervention of a board, except in case of officers. 24. Invalids should leave Ceylon for home in January.
Diseases.	1. There are weekly inspection parades for the discovery of disease. 2. Scurvy or scorbutic diseases are rarely seen in Ceylon. A few cases have occurred at Trincomalee. They are to be attributed to a want of vegetable food, of which a proper proportion is required, but not always procurable. 3. The proportion of cases of hepatic disease amongst European troops is as 35 per 1,000 to total admissions. For native troops, 3·8 per 1,000. This disease is caused by the climate and the immoderate use of ardent spirits. It is sometimes the sequel or concomitant of fever and dysentery. The men should be cautioned to drink spirits watered, and in the cool of the evening, and not to expose themselves to solar influence or chills. 4. The only cases of dracunculus which have come under observation are the few occurring in natives of India who come over to Ceylon. No case is on record as occurring in a native of Ceylon or in a European. 5. The proportion of venereal cases to the total sick from all other diseases is very small indeed, viz., average one in 6 admissions from all diseases. It would be advantageous to the health of the army to establish lock hospitals in Ceylon.

COLOMBO. CEYLON.

References to Subjects and Queries.	Replies.
Diseases—*cont.*	6. The troops suffer chiefly from endemic diseases, viz., fevers of the remittent and intermittent types, of which, however, few die, since quinine is liberally administered. Dysentery is the most fatal of endemic diseases, although the mortality from it is considerably reduced since phlebotomy and mercurial ptyalism have become the exception and not the rule. Cholera seldom visits this station, and troops suffer very little from it of late years. Small-pox rarely affects the troops, even when prevailing among the native inhabitants. Rheumatism is very prevalent, but very few deaths occur from it. The proportion of admissions and deaths is given in the following table :—

—	Europeans.				Natives.			
	Admissions.	Deaths.	Proportion of Admissions from these Diseases to Total Admissions per 1,000.	Proportion of Deaths from these Diseases to Total Deaths per 1,000.	Admissions.	Deaths. 7. The more frequent zymotic diseases are catarrh, boil, diarrhœa, dysentery, dysentery with abscess in the liver, cholera, ague, remittent fever, and rheumatism. Catarrh and rheumatism are most prevalent in the intervals between the monsoons and in the rainy season. Boils generally prevail in the hot weather. Fever, diarrhœa, and cholera occur in any continued hot weather, followed by showers of rain; dysentery generally in wet weather. A form of dysentery, with marked remittent fever, prevails usually in the hot weather succeeding a rainy season. The sanitary condition of the bazaar and native dwellings is very defective. They are very dirty, the drainage generally very imperfect, open drains, and large cess-pits. Ventilation is imperfect, from a deficiency of doors and windows—the latter seldom seen in opposite sides of the house or hut. The zymotic class of diseases generally prevails in the more crowded and unclean part of the native town and bazaars. The habits of the natives make them particularly liable to attacks of fever, diarrhœa, and cholera.
8. The prevalence of epidemic diseases is not materially influenced by the nature of the soldier's duties and occupations.
9. Quinine has not been used as a prophylactic, except in individual cases, where it has proved successful in warding off attacks of fever and dysentery.
10. We think that if the soldier could always have a cup of coffee or tea (as is the case with the 50th Regiment), on rising from his bed in the morning, and before he goes on any duty, it would have a salutary effect. Means should also be within his reach, when on guard, to have some drinks of this kind before he goes on guard at night.

V. INTEMPERANCE.

1. There is not more intemperance at Colombo than elsewhere where British troops are stationed. The native troops are rarely under the influence of alcohol, but frequently under that of opium. In European troops the number of confirmed drunkards is about 5 per cent. Of confirmed opium eaters the average is 20 per cent.
2. The regimental hospital records at this station do not enable us to state the proportions of admissions to hospitals caused directly or indirectly by intemperance. Drunkenness is always punished as an offence, more or less according to the circumstances of the case.
3. Distilled spirits are sold both at the canteen and bazaar. There are numerous shops for the sale of spirits everywhere. The quality of the liquor sold in the canteen is good; the bazaar liquor is very inferior, the probable amount drank is about three drams per man. Two drams of arrack per man is part of the ration in Ceylon; it is good, and the soldier cannot draw this till noon. The soldiers do not draw the spirit part of rations, as they would be obliged to drink it diluted. They are in the habit of taking a dram early if they can get it. Early drinking is most hurtful. Convalescents get the same ration as other men in barracks. There are no drinks sold at the canteen except spirits and beer, but in the bazaar they get toddy, badly made ginger beer, and lemonade.
4. The consumption of spirits is generally injurious to health, and is not conducive to the discipline or efficiency of troops.
5. It might be injurious to restrict or abolish the use of spirits as rations or the sale in the canteens, for the troops would have no difficulty in procuring worse liquor in the bazaars, which are not under military control in Ceylon.
6. Sickness and mortality appear to have diminished since the introduction of malt liquors.
7. Coffee, tea, lemonade, &c., are not much used at this station. We consider that a moderate proportion of spirits, such as the ration, and of malt liquor, used as well as coffee, tea, &c., would not influence health, efficiency, and discipline prejudicially.
8. With troops accustomed to the use of spirits previous to arrival at Ceylon, it does not seem desirable to suppress the issue, but otherwise beer, tea, or coffee appear preferable.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	9. We should think it not beneficial to prohibit the sale of spirits for the reasons already assigned. 10. We would recommend that the canteens be let to civilians under proper and stringent rules and conditions to secure good liquor being supplied. We would place no restriction on the amount of liquor a man might have, because we feel satisfied that if a soldier cannot get good liquor close to his barracks he will go a long way off for bad. 11. The canteen regulations are attached, and appear to be well obeyed.
VI. Diet.	1. The composition of the ration for European troops is beef, bread, rice, tea, coffee, sugar, and salt. The quantities are beef 1½ lb., bread 1 lb., rice ¼ pint, tea ¼ oz., coffee 1½ oz., sugar 1½ oz., salt 1 oz., salt meat once a month 1 lb. The quartermaster of the regiment and an orderly officer inspect the rations daily. 2. The ration does not include any fruit or vegetable; the stoppage is 3½*d.* per day, but the men pay extra for sweet potatoes, yams, and onions. The soldier has three meals a day, breakfast at ½ past 7, dinner at 1, tea at 5 or 6 P.M. For breakfast he has bread, tea, or coffee, and a little meat or eggs. Dinner, beef, bread, rice, soup, curry, and vegetables when procurable. For tea, tea and bread. 3. We would strongly recommend potatoes and Bombay onions occasionally as an improvement in the ration. A sentry is placed at the cookhouse of each company to prevent the rations being taken away except for the use of the soldiers. 4. The means of cooking is in iron pots, frying pans, and kettles and earthen chatties. Wood is always used for firing. The kitchens are not kept very clean; it is most difficult to make natives cook with cleanliness. No soldiers cook in the kitchens, which are open sheds; the water is close at hand and plentiful. The meat is boiled, stewed, or fried. The cooking is at all times inferior; tea and coffee are made well enough. The men have coffee every morning before a march. 5. Gardens could not be established near the station with advantage.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress consists of a cloth tunic, chako, serge trousers, leather or mohair stock, woollen or cotton socks, cotton shirts, cotton jacket and trousers, forage cap and white cover, red shell jacket, and the usual accoutrements of an infantry soldier. The native troops do not wear covers to their caps. The dress is not quite suitable for the climate, and might be improved upon. The soldier should be clothed as loosely as possible, and we would suggest the adoption of the Indian drab clothing for troops in Ceylon. The chako might be done away with, and stock should be totally discontinued. It is never required, either by day or night, at any time of the year, and is most oppressive and uncomfortable to every one who wears it. This climate does not suit patent leather. A felt helmet would be desirable as a protection from the sun. Each soldier ought to have three fine flannel shirts in possession. Soldiers are careless about their health, and cotton shirts do not sufficiently protect them from the draughts of air and the chills they are subject to. The men mount guard in white clothing, and from tattoo till relief of guards in the morning they wear shell jackets and serge trousers and great coats. They wear this last dress also by day in very wet weather. The sentries are protected by verandahs, sentry boxes, and sheds, but the protection in general is indifferent, especially from the sun.
Duties.	1. It would certainly be advisable to send out well-drilled men from home. 2. The usual routine consists of guards and pickets, and now and again fatigues for a short time. Drills are two or three times a week, sometimes from 5¾ to 6¾ A.M., or from 5½ to 6½ P.M. The men do not suffer in health from such drills; the greater number are the better for the exercise. The best hours for drills are from ¼ to 6 to 7 A.M., and from 5½ to ¼ to 7 P.M. Marches should be commenced about 4 A.M. There is a general order that no soldiers are to leave barracks without a pass from 7½ A.M. till 5 P.M. The European troops are scarcely ever exposed to the sun on duty. The men generally have four or five nights in bed during a week. 3. The guards mounted by Europeans are all in the fort of Colombo, the farthest from barracks is about ¼ of a mile. Guards are kept on for 24 hours. The native troops mount guard at the two jails about 1¾ and 2¼ miles from their barracks. There are roll calls daily at 6 A.M., 10 A.M., and at tattoo; none by night. Night duty is no doubt very fatiguing in this climate, and the weakly men cannot but suffer by it. No additional precaution can be taken to make it lighter. Men require six nights in bed
VIII Instruction and Recreation.	1. The means of recreation and instruction consist of a ball court, but which is uncovered and nearly useless, as the men are nearly always on parade at the hours it could be used; a skittle alley; the usual regimental school; a garrison library. The room is a bad one, being dark and low and badly ventilated. There are no day rooms or clubs, soldiers' gardens, workshops, theatre, or gymnasia. There is not sufficient variety of amusement for the men, but in this climate it would be difficult to provide occupation for soldiers. Men are not allowed to be out of barracks, except on duty, between 7½ a.m. and 5 p.m., which is conducive to health. 2. As improvements, we would suggest the building of a larger and cooler room for a library, and a soldier's club room, and that the rooms should be well lighted; that a gymnasium and school of arms be established, a good cricket ground formed and kept in order for the men, and that bats, balls, &c. be supplied. The fives court should be put in proper order, and covered to protect the men from sun and rain. There is a large lake at Colombo, and a couple of good strong six-oared boats would be the means of much amusement and exercise to several men. 3. The institution of soldiers' savings banks is advantageous. 4. There is scarcely sufficient shade from trees or other means to enable the men to take exercise during the day.
IX. Military Prisons.	1. The sanitary state of the garrison provost prison and of its cells is good, but the site at the north gate of the fort is confined. The cells at the Amsterdam bastion admit of better ventilation. A garrison dry room appears necessary and additional cells. European prisoners suffer from want of meat diet, which cannot be furnished for the 6*d.* per day allowed.

References to Subjects and Queries.	Replies.
X. FIELD SERVICE.	1. There appear to be no local regulations for field medical service in Ceylon. 2. There has been little opportunity of judging of the effect of the late War Office medical regulations, but they appear amply sufficient to meet every requirement as regards the conduct of the line of march, of troops camping, billeting, &c. 3. See preceding paragraph. 4. The arrangements for field hospitals, transport of sick, &c., are agreeably to the Army Medical Regulations of 1859 and General Orders of 25th October 1815, para. 13, and 16th June 1860. (G.O. attached.)
XI. STATISTICS OF SICKNESS AND MORTALITY.	1. No forms have been received. The principal civil medical officer cannot supply the information required. Number of women and children of the 50th Regiment treated in Colombo from October 1857 to June 1860:—

—	Number of Cases treated.	Number of Deaths.
Women - - -	38	3
Children - - -	35	11

Annual average strength -	Women - -	25
	Children - -	40
Annual average deaths - -	Women - -	1
	Children - -	$3\frac{2}{3}$

There appear to be no statistical records at this station regarding the native population.

XII. HOSPITALS.

1. Plan.
2. The European hospital is 60 yards from the nearest barrack, and 24 feet from the nearest stable, which is private property. The native hospital is 50 yards from the nearest barrack, and 500 yards from the nearest stable. The houses of civilians in the fort form the opposite sides of the streets and lanes bounding the European hospital, except in the direction of the ramparts. The native military hospital stands apart on Slave Island, and the site is open and well ventilated. The site of the European hospital is perhaps one of the best in the fort, but being lower than the walls of the fort and other buildings it is not the best position. The drains are generally clean, but from the defective system of drainage in the fort, unpleasant odours are not unfrequently complained of. The banks of the lake left uncovered with water in the dry season appear objectionable in the case of the native hospital.
3. The water supply is good and wholesome.
4. The refuse water and other impurities are carried off by barrel drains. The outlet is in the canal, about 90 yards from the hospital, which being at times choked up, causes a regurgitation of effluvia in the latrines, sometimes so abundant as to diffuse itself in the verandahs and wards.
5. In the European hospital the lowest ward is about six inches above the surface of the yard, and two feet above the road outside. In the native hospital the lowest ward is about six inches above the ground. The floors are brick, and have no perflation of air beneath. The roof water at the European hospital is led by pipes into drains, of which there are none at the native hospital, as the ground slopes towards the lake. At the European hospital the gutters and drains are capacious and sufficient, but the outlet of the principal underground drain at the canal is occasionally choked with mud. The rain, however, is carried away rapidly at both hospitals. The hospital is built of brick, laterite blocks, and mortar, wooden beams and rafters, covered with ordinary tiles. The roof is single, and the walls single, but sufficiently thick. The wards of the European hospital are not all supplied with verandahs on both sides. There is, however, sufficient shelter from the sun's rays. The native hospital has verandahs on both sides. Their breadth is 8 ft. 8 in. The verandahs of the European hospital are 8 ft. 4 in. broad. The sick are not accommodated in the verandahs. The convalescents walk and lounge there, but their beds are in the wards. The hospital consists of but one flat.

XII. Hospitals—*cont.*	The European hospital does not receive the full benefit of the prevailing winds, but the native hospital does. The windows open on both sides, but on one side the windows are placed from 8 to 11 feet above the floor, near the roof. This is unavoidable. Some glass windows would be an improvement to the native hospital. 6. There are many windows, and the wards are lofty, but improvements might be made in the ventilation. There are no jalousies or jhilmils. 7. No means of cooling the air admitted into the wards. 8. There are no means of warming. Ceilings and walls of wards are cleansed and white-washed frequently, whenever necessary. 9. The privies in the European hospital are so situated as to be reached under shelter, but their position might be improved. The privy of the Malay hospital is detached, and a covered way to it is desirable. The sketch attached is that of the last built privies and bath rooms. The soil is carried into the large drain of the fort, and thence into the canal. The other privies' soil passes by a drain into a cesspool in the hospital square. It is emptied when required. 10. There are baths and a lavatory sufficient for the sick in the European hospital. 11. The warm and cold baths in the European hospital are sufficient and convenient. Bathing at the native hospital is performed in tubs or in the lake. 12. The washing is performed by dhobies, or washermen, outside the hospital, and is sufficient. 13. The storage is sufficient and dry. 14. The bedsteads are of iron with canvass bottoms, coir mattresses, blankets, sheets, cotton coverlets, and cotton pillows. 15. There are two kitchens in the European hospital adjoining each other, situated at one end of the quadrangle next the store room and near one ward. The native hospital has a small kitchen in an isolated position opposite the large ward. The cooking apparatus are iron boilers, small pans, and earthen vessels, and an oven. The cooks being indifferent, the broths, puddings, &c., are not of the best quality. The new scale of diets is in use, which is sufficiently varied. The native hospital is non-dieted. 16. The diet tables, diet rolls, and all returns in use are those found in the new regulations for army hospitals. 17. For the additional labour required for the working of the new and admirable system, the present hospital staff of serjeants and orderlies is insufficient. A steward and wardmaster, dispenser, and well-trained orderlies are absolutely necessary, and have been applied for by the principal medical officer. The native coolies are not allowed to attend the sick, nor is it desirable. The present allowance of 18*s.* per mensem for a cook cannot secure the services of even a tolerable one. 18. The sanitary condition of the hospitals is very fair. Convalescence is, however, often long and tedious. No epidemic diseases have ever appeared in the wards. 19. The privies of the European hospital are too near the wards; the south-west wind blows the effluvia from one of the privies into one of the wards. The lower parts of the wards might be better ventilated by perflation. Great sanitary improvements can be effected by giving a second story to the European hospital, at least, to one ward of it (which would, however, be thus deprived of the shelter of the ramparts), so that the patients, particularly convalescents, might enjoy the sight of the sea and adjoining scenery. A broad verandah on the eastern side of the large ward would also be an improvement, and enclosing in front of it a portion of the green in the hospital square. 20. The European convalescents walk in the verandahs, and on a small green opposite the front entrance of their hospital. They see nothing but the walls of the hospital, and a few trees and grass. Seats are set apart. A pallisade or wall is required round the native hospital premises, where now the patients walk on the verandah near the high road, and has been applied for by the regimental surgeon. 21. The women and children are treated in their own rooms in barracks. The arrangements are satisfactory for the present strength of Europeans. Very few native women and children seek European medical advice from regimental surgeons. As their offspring supply the ranks of the Ceylon rifles, it is very desirable that a skilled native doctor be attached, as in India, to at least the head-quarters of the Ceylon rifle corps, so as to prevent the children from suffering from native quackery, and proving inefficient recruits hereafter. 22. There are no special hospital regulations in Ceylon, not included in the new regulations for the management of army hospitals. 23. The hospital buildings not being in charge of the purveyor to the forces, the medical officers have to report to the staff officer all repairs required, which are generally effected (if small) expeditiously. But as delays occasionally occur, under a system of obtaining the sanction of the Colonial Government to estimates, it would be desirable to give to the staff officer, or purveyor, some discretionary power in urgent cases, such as emptying privies, &c. The medical officers have ample powers as regards diets.

XII. Hospitals—*cont.*	24. There are no convalescent wards; such an accommodation would be advantageous, particularly if it were situated at Mount Lavinia, or any place outside the walls of the fort.
XIII. Burial of the Dead.	1. The burial-ground used by the European troops is outside the fort, about 330 yards from the nearest barrack. It is not in the direct influence of the prevailing winds. The native troops are buried in graveyards attached to their respective places of worship, which are distant from the barracks. 2. The area is two acres, one rood, 16 perches. The subsoil, clay and sand. The drainage is generally good; some part of it is under water when the lake overflows. Decomposition takes place rapidly. The ground is fenced round, and is properly kept. 3. There do not appear to be any fixed rules in regard to space of burials, but four feet intervals seem the average. The depth of graves is about six feet, and they are sometimes reopened after about two years have elapsed, when decomposition has taken place, but this does not occur when tombstones are erected. There is no compulsory rule as to the time of interment, but European soldiers are usually buried in 12 or 18 hours after death, and little or no difference is observed during epidemics. Of the native troops, the Mahommedans bury within six hours, the Hindoos within 12, and the Caffrees, being Christians, within 24 hours after death. 4. The graveyard is never known to be offensive. The usual forms of a military funeral are gone through in the case of European troops, the coffin being conveyed to the burial-ground in a wheel carriage. 5. The camp followers and bazaar people are buried like other natives, far from the European burial-ground. 6. No apparent injury to health results from the present practice, but the Dutch burial-ground nearest the fort being replete with corpses, might be closed with advantage. 7. During epidemics it would be desirable to inter the bodies in quick lime, and an ornamental cemetery for Europeans at a greater distance from the fort in the cinnamon gardens would be an improvement.

(Signed) C. Wilkinson, Colonel Commanding, Royal Engineer and Commandant.
Richard Waddy, Lieut.-Col. 50th Regiment.
E. F. Kelaart, M.D., Staff Surgeon.

23rd July 1860.

KANDY.

Accommodation — Queen's Troops — Artillery - 21.; Infantry - 486.
Native Troops — Artillery - 32.; Infantry - 374.

I. Topography.	1. The general aspect of the surrounding country is represented by a chain of hills, which rise round the whole of Kandy to heights ranging from 300 to 1,500 feet. There is not very much wood in the vicinity of the town, but the sides of the hills are, as a general rule, covered with low thick jungle, or planted out in coffee, with clumps of cocoa-nut palms interspersed. A large body of water occupies part of the space lying between the base of the hills. This lake is fed by small streams running from the hills, and the height of water in it is regulated by a sluice or spill water at one end. In addition to this lake a large river (the Mahaville Gunge) runs a tortuous course, encircling the immediate vicinity of Kandy. 2. The station is elevated 1,678 feet above the sea, but, on account of the hills before mentioned, it is considerably under rather than above that of the adjacent country. Its elevation above the lake is only a few feet. There is a great deal of more elevated ground in the vicinity, which it is presumed would be more healthy, but in addition to its very uneven nature, it is thought it would not be suitable for the location of troops, on account of the distance that would intervene between them, and such important colonial buildings, as the Cutcherry, Treasury, &c., which could hardly be transferred from the present position. 3. The nearest mountain is about two miles from the station, and is about 1,500 feet above the level of Kandy. There is no table land. 4. The lake before mentioned is the nearest water; it is about half a mile from the European, and one-eighth of a mile from the Ceylon rifle barracks. There is no overflow of water. In the rear of the Ceylon rifle barracks there is a large piece of ground, formerly the bed of a lake; it was drained some years since, and does not now appear to affect the health of the troops quartered near it. 5. The station, from being surrounded with hills, cannot be said to be freely exposed to the winds, viz., the north-east and south-west monsoons. The buildings, however, are not exposed to reflected sun heat. The winds are not cold, and have a beneficial effect on health. 6. The surrounding country varies very much with regard to cultivation. A good deal of land has been cleared within the last few years, and planted in coffee, but still it is thought the uncultivated is in higher proportion than the cultivated ground. There are no works of irrigation near the station, with the exception of the native paddy or rice fields, which are within a quarter of a mile of the rifle barracks, but are not sufficiently extensive to interfere with the health of the troops. There is no prohibition to the cultivation of rice within certain limits. Indigo, flax, and hemp are not grown near the station.

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	7. The town of Kandy, which adjoins the station, contains a population of 11,500 souls. 8. The general geological structure of the district is of the primary order, the surface consisting of decomposed gneiss; limestone rock (dolomite) is found within two miles. The town of Kandy is of many years standing, but the European and rifle barracks occupy, it is thought, new ground. 9. Water is found during the dry season at a depth of 45 feet below the surface, and at 30 feet deep during the rainy season. 10. The rain-fall flows readily away. The station being encompassed with hills is liable to a certain amount of water from the hills passing into the subsoil, but not injuriously to health. 11. The European troops get their drinking water from a spring, which is first led into a reservoir, and conducted thence to filters near the barracks. The men of the Ceylon rifle regiment are supplied from a well near their parade. The water is not stored in open tanks. 12. The station is well supplied with water, except during unusually hot weather. Its colour, taste, and smell are all good. The well water contains a little muriate of lime, magnesa and carbonate of soda; the running water contains a greater proportion of the soluible carbonates. The water is filtered at the European barracks. The lake water contains a greater proportion of the carbonates, with a slight admixture of organic matter from vegetable decay. It is good for washing purposes. At the European barracks the water is raised by hand and taken where required, but it has lately been proposed that the water for washing should be laid on to the different ablution rooms, and it is very desirable that this necessary service for the comfort and convenience of the troops should be carried out early. 13. There are no other topographical points to advert to. 14. No new stations have been selected in Ceylon for many years, but it is suggested, when any are required, that a board of officers, consisting of a military, a medical, and an engineer officer, should always be assembled to report on the various advantages, drawbacks, &c., that may present themselves.
II. Climate.	1. There are no means or instruments available at the station for meteorological observations. 2. The Board transmit the only tables they have been able to obtain, which are, however, far from being perfect. The observations were made at Peradenia, four miles from Kandy, 1,650 feet above the sea.

Climate from 1851 to 1858 inclusive.

From Analysis of the Climate at Peradenia (4 miles from Kandy), 1,650 feet above the Sea.

Months.	Mean Temperature.	Mean Maximum.	Mean Minimum.	Rain, Inches.	Remarks as to Clouds, Dew, Wind, Storms, &c.
January - -	74·06	85·0	52·5	4·04	Fine; sunny; heavy dew at night; hot days, cold nights and mornings.
February - -	75·76	87·75	55·0	1·625	Fine; sunny; dewy nights & foggy mornings; days hot.
March - -	77·42	89·5	59·5	3·669	Generally a very hot and oppressive month.
April - -	77·91	89·5	67·5	7·759	Sultry, showery, and oppressive weather.
May - -	77·7	88·	66·0	8·022	Cloudy, windy, rainy; monsoon generally changes.
June - -	76·69	86·0	71·0	7·155	A very wet and stormy month.
July - -	75·64	83·5	67·0	5·72	Do. Do.
August - -	75·81	85·5	67·0	8·55	Showery, but sometimes more moderate; variable.
September -	76·13	86·5	67·0	6·318	Pretty dry weather compared with next two months.
October - -	75·1	85·75	68·2	15·46	Wind variable; much rain.
November - -	74·79	84·0	62·0	14·73	Wind variable; storms from all parts of compass; wet; monsoon generally changes.
December - -	74·05	82·75	57·0	7·72	Sometimes wet, but generally more moderate; towards end of year like January weather.

Mean Yearly Temperature, 75·92°. Mean Yearly Rain-fall, 90·75 inches nearly.

3. The climate of the station is very healthy. From January to May it may be considered hot and dry, and from June to December moist. There is a good deal of variation of temperature between day and night, which is very perceptible in the months of February and March. Towards the close of the year thick fogs arise in the early morning, which, however, are invariably dispersed by eight o'clock. There is no tree planting, canal irrigation, or irrigation of any kind to influence the climate and the air is free from dust. For a tropical climate the troops are healthy, and no unusual precautions are required, with the exception of avoiding extremes of heat, cold, and moisture. The same may be said of diet. The drills, duties, &c., take place in the early morning and evening, and no particular precautions are deemed necessary. The month of May is generally the most unhealthy at this station, and the

KANDY. CEYLON.

References to Subjects and Queries.	Replies.
II. Climate—*cont.*	months of the monsoon the most healthy. The prevailing diseases in May are fevers, cholera, bowel complaints, ophthalmia, and occasionally small-pox among the natives. 4. We have no acquaintance with any healthier district near than that of the station. 5. One of the members of this board has served at Trincomalee (another station in Ceylon), which he considers much hotter and conducive to liver complaints.
III. SANITARY CONDITION OF STATION.	1, 2, 3. A map of the adjacent country, with plans of the station and barracks, are transmitted.

5. The windows are on opposite sides of the barracks, hung so as to allow them to open to the full space of the window. There are verandahs, generally about eight feet wide, on both sides of the barracks, but they are never occupied as sleeping quarters by soldiers or other persons. There are no jalousies in the soldiers' barracks.

6. The majority of soldiers' cots are of wood (6 ft. 2 in. by 2 ft. 6 in.); a few are of iron; but the men prefer the former as more convenient during the day, and allowing the men to repose with greater ease. The bedding consists of a coir mattress, two blankets, four sheets, a rug, a mat, and a coir pillow. No improvement can be suggested.

7. Troops are not encamped at this station.

8. The windows, doors, and openings in the wall near the wall-plate afford the principal means of ventilation. The ventilation is sufficient in the barrack occupied by European soldiers, but more is required for the Ceylon Rifles. No means are provided for cooling the air of barrack rooms at this station.

9. The barracks are built of brick, and wattle and daub, with brick pillars; the roof is covered with flat or half round tiles. There are no tents or huts in use.

10. The floors of the European, and the last constructed barrack for the Ceylon Rifle regiment, are of bricks; the rest of the Ceylon Rifle barrack floors are beaten earth.

11. The materials used in the construction of the buildings appear suitable for the climate, and no improvement can be suggested. Barrack repairs are executed by the

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	Royal Engineer department, and within reasonable time. There is no special sanitary officer. The walls and ceilings of barracks are cleansed and whitewashed at no regular interval, but a sufficient quantity of lime is allowed to the troops for this purpose.
	12. The wash-houses for the European soldiers are faulty in construction, and too limited as to space. There are six of them at the European, one at the Royal Artillery barracks, and none at the Ceylon Rifle lines. These buildings are too narrow, and no one wash-house provides sufficient accommodation for the barrack to which it is attached. Round the inside walls runs a brick platform for holding the small hand tubs. A large cask, containing the water for washing purposes, and bathing tubs, are crowded into the internal space. Two coolies attached to the pioneer department are allowed to each company to fill the tubs with water. The floor of the wash-houses is sloped to the centre, and an underground drain conveys away the water.
	13. The cook-houses for European soldiers are made in the native fashion. A raised brick platform against one wall acts as a hearth, on which are placed the culinary utensils, consisting of pots for boiling, and frying-pans; but there are no ovens. At the Ceylon Rifle barracks there are no cook-houses. The single men mess with the married, who are obliged to cook their food in their small dwelling-rooms and verandahs. Water is brought by the native cooks. A surface drain carries off the refuse water. All washing for the troops is done by native dhobies, away from the barracks.
	14. The privy at the European barrack is built over a cess-pit, and the soil is emptied by natives, on contract, into pits dug to receive it. As the Royal Artillery barracks are built on the side of a hill, a shallow pit receives the soil, where it remains till washed away into the jungle by surface drainage which is led into it. The privy for soldiers of the Ceylon Rifle regiment is built over a running stream, which carries away the soil. Open brickwork on the level of the ground and in the gables, together with the absence of doors, afford the means of ventilation.
	15. In the barrack rooms 1½ gills of oil are allowed to every 25 men, and half an ounce of cotton thread, every month, and the same for every excess of 13 men or more. Street lamps at convenient distances give light near the barracks.
	16. A brick barrel drain, three feet in diameter, leads from the barracks into the town drainage, and surface drains lead into this from the urinal, kitchen, wash-houses, and different parts of the barracks. The distance from the barracks to the town sewer is about 120 yards. The drainage is sufficient for all purposes. No part of the barracks or hospitals is damp.
	17. The ground near the barracks is kept cleaned by fatigue parties. The police keep the streets of the town clear by means of daily prison labour, and the refuse is carted away and burnt or buried.
	18. The surface of the cantonment is kept free of vegetation, and there are no old walls, thick hedges, &c., to interfere with ventilation.
	19. There is no regimental bazaar, but the town of Kandy is under a civil sanitary board. The drainage and ventilation are good. The water supply is from the lake and wells, and the town is kept clean. There are some public latrines. Local ordinances empower the police to impose fines and other punishment upon individuals who neglect private cleanliness, and prisoners sweep the town daily. The existing arrangements are ample. The native houses or huts are good, and no dung-heaps are allowed. No nuisance is experienced in barracks from wind blowing over native houses.
	20. The slaughtering-houses are situate about 1½ miles from the barracks. A civil ordinance regulates their distance from the town, and provides for cleanliness, &c. The offal, &c., is carried off by a running stream.
	21, 22. There are no bazaar horses, stables, or picketing grounds at the station.
	23. For married non-commissioned officers there is sufficient accommodation. None is provided for the married private soldier, which is owing to the barracks being at present unoccupied. Sufficient separate rooms are found for them.
Officers' Quarters.	1. The sanitary condition of the officers' quarters is generally good, as far as the surrounding ground is concerned. An exception to this is No. 33 officers' quarter, which is too near the native buildings, with their objectionable adjuncts. The condition of some of the quarters is under consideration. As a rule, being in most cases detached bungalows, they are on too limited a scale. The sleeping apartments should be larger and loftier, and convenient bath-rooms should be added.
IV. Health of the Troops.	1. The station, district, and adjoining native population are all healthy.
	2. The most prevalent diseases among the natives are fevers, bowel complaints, cholera, and small-pox occasionally, but the latter has been checked by the introduction of vaccination. There is no spleen disease.
	3. The healthiness of the natives we attribute to the comparative elevation of the district, the general cultivation of the country, the good drainage and cleanliness of the town, and the fact that the people are as a rule in very easy circumstances.
	4. The 50th regiment arrived in Ceylon in October 1857 from England, having previously served in the Crimea and India. The detachment of the regiment at present quartered in Kandy arrived from head-quarters, Colombo, in December 1859, the greater part of the men having been there since their debarkation. On arrival at this station they were in good health, and have not suffered since from tropical diseases. The three barracks at present unoccupied would in all probability be more unhealthy than the others, on account of their relative nearness and their limited width and height; and the board are strongly of opinion that on no account should these three barracks be occupied.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	5. The troops at the station are never camped out.
	6. None of the committee have ever been in charge of troops at hill stations.
	7. The troops from Newera Ellia, the only hill station in Ceylon, do not appear to be more liable to attacks of febrile and other diseases on coming down. The Kandian provinces are not unusually malarious.
	8 to 16. No experience of hill stations.
	17. There is no higher ground near the station which could be advantageously occupied as a hill station.
	18. In this island the soil and subsoil (decomposed gneiss and granite) are sufficiently permeable to allow moisture to pass rapidly away, and therefore they are well adapted for human occupation.
	19. Soldiers should proceed to India at the age of 20 years, and should land there during the months of October and November in all parts except the Madras coast, where the troops should land in September or January. On first landing in Ceylon barracks are available for the troops. The men continue to wear their sea kit until equipped with the light clothing of the country. Drills take place in the morning and evening, and the men take their usual tour of duty. When the 50th regiment landed, two companies marched to Kandy, one to Galle, and two proceeded by water to Trincomalee. All recruits should be provided with flannel shirts and light Indian clothing (khakee uniform and basket helmet). They should not be allowed to expose themselves to the sun, and have a moderate amount of drill and duty, and have sufficient and proper bedding for the specific climate to be found as at present provided.
	20. Troops should be sent direct from the home depôts to India, and it is thought it would be better if the men of a regiment were kept together for the first year or so in order to get them accustomed to the ways of the country, new mode of life, &c., suitable spacious barracks with day-rooms, &c., being provided.
	21. In Ceylon the troops march always in early morning to the interior. Tents are sent on and pitched at the several halting places. The men's packs are carried in bullock bandies. A steamer conveys the troops when sent by water. No additional precaution is required, as every comfort is provided for the soldier.
	22. A British soldier should on no account serve in India longer than 10 years. (P.M.O. is of opinion this term might be extended to 15 years, in certain parts of India.)
	23. No difficulty has been experienced at this station in reference to invaliding by medical boards.
	24. Invalids departing for home should leave India so as to arrive in England in the summer.
Diseases.	1. There is a weekly inspection parade held for the discovery of incipient diseases among the troops.
	2. There is no scorbutus or scorbutic disease among the troops at the station.
	3. The cases of hepatic diseases under treatment were in 1855–6, one; 1856–7, five. In 1857–8 the returns were incomplete, but in 1858–9 two cases occurred, and for the remainder of 1859 the returns show a total of seven afflicted with this disease. Its occurrence is attributed to the tropical climate; it is often combined with dysentery. We have no special prophylactic measure to propose.
	4. Dracunculus is not known here.
	5. The proportion of cases of venereal diseases is 13 per cent. per annum. The only precaution in reference to them appears to be the sanctioned increase of marriage among soldiers. The establishment of lock hospitals is not considered desirable.
	6. Fever occurs to a limited extent among the troops, in the intermittent, remittent, and continued types. Dysentery also occurs, but to a still less extent. Cholera occasionally appears, but there has been no case of small pox for years. A limited number of cases of rheumatism also occurs.
	The following Table shows the proportion of admissions to total admissions from the above diseases, and the proportions of deaths to total deaths :—

Total Admissions in 4 Years from all Diseases.	Admissions from	Proportion of Admissions.	Proportion of Deaths.
736	Fevers, 174 - -	23 per Cent.	1 in 736.
	Dysentery, 27 - -	3½ Do.	Do.
	Cholera, 5 - - -	6 per Mille.	Do.
	Small-pox - - -	—	—
	Rheumatism, 42 - -	5½ per Cent.	—

	7. The zymotic diseases most prevalent are fevers, rheumatism, dysentery, venereal diseases, ophthalmia, and cholera; the first four appearing in the hot season, and the rest being diffused over the year. Cholera has appeared under various and uncertain climatic conditions, often in the month of May, after the first showers of the monsoon. The town of Kandy is not unhealthy, and epidemics have almost disappeared since an efficient system of drainage has been in force. No peculiar habits or conditions have been remarked among the troops or native population as predisposing to these diseases, but cholera and small-pox follow in the train of the immigrant coolies, and generally affect those who are badly fed and housed.
	8. Epidemic disease at this station is not influenced by the nature of the soldiers' duties and occupations in the barrack or habits on the march or in the field.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —Diseases—*cont.*	9. Quinine has not been tried as a prophylactic against malarial disease, the measure being hardly deemed necessary. 10. Epidemic disease is not rife enough at this station to call for any special precaution for its mitigation.
V. Intemperance.	1. The body of the men at this station are temperate, from 18 to 20 men only in the two companies stationed here being confirmed drunkards. 2. During the six months ending the 30th June 1860 there were 131 admissions into the European hospital; of these 105 occurred among 114 temperate men and 26 among 19 intemperate men. Among the latter eight admissions are traceable directly, and 18 indirectly to intemperance.

Return showing the Admissions and Diseases of 19 Men of the Detachment, 50th Regiment at Kandy, reported intemperate, from 1st January 1860 to 30th June 1860.

3. Arrack is sold at the canteen and in the town. The quality of that sold at the canteen is good, but that vended in the town is much adulterated. Some confirmed drunkards will drink 10 gills a day, obtained from various sources; the temperate men drink from 1 to 2 gills. Spirit is not given as a ration either in quarters or on the line of march, but the troops are allowed to draw one gill daily from the commissariat for 1*d.*, but this must be watered, and the men do not avail themselves of it. No spirits are issued at the canteen except between 5½ and 8 p.m. The men do not take a dram before morning parade. Spirit is never given as a ration to convalescents. No deleterious drinks other than intoxicating drinks are sold at the canteen.
4. Spirits are not injurious to health in moderation, nor do they then affect the efficiency of a corps or its internal discipline.
5. Spirituous liquors are not part of the ration at the station. It would be injudicious to abolish their sale at the canteen, the article sold there being genuine, but that sold in the town bazaar is much adulterated.
6. The influence on health of malt liquors and wine is more beneficial than the use of spirits.
7. Tea and coffee are very little used, except at meal time, when the former is used. Lemonade, &c. are not drunk by the men. The effect on health of these drinks, as compared with spirits and malt liquor, cannot be stated for the want of data.
8, 9. It would not be beneficial to prohibit the sale of spirituous liquors, as the men would procure adulterated liquor in the bazaar.
10. The men at this station are, as a body, anxious to drink malt liquor, and would prefer it to arrack, but the price at present prevents their making very much use of it, and it would be of advantage if the Government could reduce the cost by importing beer on their own account. The canteen itself is badly situated, being too far from the barracks, and destitute of internal comforts.
11. The canteen is opened from 12 o'clock a.m. to half-past 1 p.m., with the exception of Sundays, when it is opened from 1 to 2 o'clock p.m. for the sale of beer, and from half-past 5 p.m. to 8 p.m. for beer and spirits. Serjeants or married men can take from the canteen one bottle of wine or two quarts of beer daily, and companies' messes, on the requisition of the orderly non-commissioned officer, at the rate of one pint of beer to any soldier at dinner time on payment.

VI. Diet.

1. The ration supplied daily to British troops by Government is 1½ lbs. fresh or 1 lb. salt meat, 1 lb. bread, 4 oz. rice, 1½ oz. sugar, 1½ oz. coffee, or ¼ oz. tea, and 1 oz. salt. The soldiers themselves buy 1 oz. sugar, 8 oz. bread, and vegetables. Salt meat is issued two days in the month, and the men have coffee one half, and tea the other half of the month. The rations are inspected by the officer on duty, assisted by a board if necessary.
2. The ration is supplied at the rate of 3½*d.*, in addition to which the soldier spends 2*d.*, and provides his own vegetables, of which about one-half is the proportion in the ration. The soldier takes three meals, breakfast at 8 a.m., dinner at 1 p.m., and tea at 5 p.m. He has also a cup of coffee at half-past 5 a.m.

KANDY. CEYLON.

References to Subjects and Queries.	Replies.
VI. Diet—*cont.*	3. No practicable improvement in the ration can be suggested. A soldier looks after the ration while it is being cooked, and an officer visits the dinners to see if they are good and complete. No instance is known of the troops disposing of their ration improperly. 4. The means of cooking are by chatties, iron pots, and frying pans; there are no ovens. The kitchens are clean, light, well ventilated, and sufficiently supplied with water. The food is boiled, fried, and curried, and the cooking is properly done and sufficiently varied. Ovens with an additional supply of fuel would be advantageous. Tea and coffee are properly prepared, and the men have coffee provided for them previous to a march. 5. Garden patches are allowed to such men as wish for them, and are cultivated by more than half the men quartered here, who find their own seeds, tools, &c.
VII. Dress, Accoutrements, and Duties.	1. The soldier's dress consists of a regimental shako, leather stock, coatee, shell jacket, one pair cloth or serge trousers, four white twill cotton jackets, four white twill cotton trousers, six cotton shirts, regimental cloth cap and peak, with two white cotton cap covers, two pairs of boots, four pairs of socks, and regimental great coat (about half the men wear flannel shirts under their cotton ones.) The accoutrements are a pouch belt over shoulder, with pouch for 40 rounds of ammunition, waist belt, with bayonet and pouch for 20 rounds. The present dress is suitable for the climate, and for the day and night duties. It is considered that the introduction of the basket helmet and the khakee uniform would be beneficial. The climate of Kandy being very variable, each relief is ordered to mount sentry with clothing accordingly,—either with great coat, shell jacket, or white clothing. Sentries are posted under verandahs of buildings, and sentry boxes are provided in addition.
Duties.	1. Troops should be thoroughly drilled at home before being sent to India. 2. The routine of a soldier's duties is as follows:—The men rise at half-past 5 a.m., morning parade at 6 a.m., breakfast at 8 a.m., dinner at 1 p.m., afternoon parade, tea at 5 p.m., and roll call at 8 a.m. The men do not suffer from drill. Early morning and evening are the best times for drills, parades, and marches. There are, however, local general orders to meet the requirements of the country. The men on an average have four or five nights in bed during the week. 3. The greatest distance at which guards are mounted from their private parades is three-quarters of a mile. Guards last 24 hours; sentries are relieved every two hours. There are no roll calls by night, unless there is reason to suspect some men are absent. The men do not appear to suffer from night guards, as they are clothed according to the weather. The roll is called at meal times and parades.
VIII. Instruction and Recreation.	1. The means of instruction and recreation at the station are as follows:—There is one ball court, not covered, one covered skittle ground, a detachment school held in the barrack room (no room being assigned for the purpose), under a corporal, a good schoolmaster, and garrison library, sufficiently lighted. No room is assigned for reading, and the one in which the books are kept is not large enough to allow the men to assemble there. A barrack room is lighted at night as a reading room. There is no day room or soldiers' clubs, but there are gardens, and the men have every facility afforded for cultivating them. A temporary theatre has lately been erected in an unoccupied barrack by the men, but there are no workshops or gymnasia. The present means are not sufficient to keep the men occupied during the wet season and the heat of the day. The men are not allowed to leave barracks from 8 a.m. till 4 p.m., and this restriction is beneficial to health. 2. The improvements suggested are, that a proper reading room should be told off, and a supply of books of a lighter description than those now on hand be furnished. A gymnasium also would be of service. 3. The institution of no other savings' bank besides the Government one is thought desirable. 4. There is sufficient shade for all purposes, the barracks being supplied with verandahs, but there are no sheds, except the skittle alley.
IX. Military Prisons.	1. The military prison has lately been erected. It is surrounded on three sides by a brick wall, and as this tends to impede a free circulation of air, it would be advisable to substitute an iron railing on a dwarf wall.
X. Field Service.	The queries under this head do not apply to the station.
XI. Statistics of Sickness and Mortality.	Return showing the Admissions and Deaths in the European Military Hospital at Kandy from 1st January 1855 to 30th June 1860 (inclusive).

XII. Hospitals.

1, 2. The European hospital is about three-quarters of a mile from the European barracks, and the Ceylon rifle hospital is about one-eighth of a mile from the Ceylon rifle barracks. Both hospitals are about half a mile from the bazaar. The sites are open and freely ventilated. Trees surround the buildings, but do not interfere with ventilation, rather acting as a screen. The European hospital, although on the edge of the lake, suffers no disadvantage therefrom; that of the Ceylon Rifle Regiment is on more elevated ground, and both are well drained.

3. The water supply from wells is abundant and wholesome, and the lake offers an ample supply for washing purposes.

4. At the European hospital there is a brick barrel drain to convey refuse water away to the lake, which is a few feet distant.

5. The wards are all on the ground floor, slightly raised above the outside ground, the floors being of brick. At the Ceylon rifle hospital a raised brick platform, three feet high, on which are placed the cots, runs round two sides of the ward. The roof water from this latter building runs freely away, guttering being provided at the European hospital. The surface drains are of brick, laid with a slight slope. The guttering is of wood and tin, and these means are sufficient for carrying away the rain-fall. The European hospital is an old Kandian building, and was originally occupied as a zenana. Its walls are of solid mud. The Ceylon rifle hospital walls are of brick. The roofs and walls are sufficiently thick to keep the buildings cool, although neither are double. The Ceylon rifle hospital has a verandah all round seven feet wide. At the European hospital the roof projects about five feet, which is barely sufficient to give shelter from the sun's rays. The verandahs are never used for the accommodation of sick soldiers or others. The hospitals consist of ground floors only.

References to Subjects and Queries.	REPLIES.
XII. Hospitals—*cont.*	The hospitals are so placed as to receive the benefit of the prevailing winds, especially of the south-west monsoon, but the European hospital is not so fully exposed to the north-east. The windows are usually hung on each side of the frame, and open back to the full width of the window.
	6. The means of ventilation is by doors and windows only, there being no roof ventilation, which would be desirable if occupied by a greater number of men. The present means would be quite inadequate if the hospital was occupied according to its calculated accommodation. There are no jalousies or jhilmils, only wooden shutters.
	7, 8. There is no apparatus for cooling or warming the wards. The walls and ceilings are cleansed and limewashed at irregular intervals, averaging once in six months.
	9. At the European hospital the soil falls into the lake, where it rapidly disappears. The patients' privy is about 30 feet from the wards, and is approached by a covered passage. There are no water-closets or urinals. At the Ceylon rifle hospitals there is an ordinary cess-pit. The privies are never offensive.
	10. No room is specially provided for washing in, but there are empty wards, which are made use of. Large tubs and hand tubs are placed in them, and filled with water by hand. These arrangements are quite sufficient.
	11. Large wooden and tin baths are provided for bathing the sick, which are sufficient.
	12. All hospital linen is given to dhobies, who wash the things away from the building.
	13. The storage is sufficient and dry.
	14. The bedsteads used in hospital are of iron (6 ft. 6 in. by 3 ft. 0 in.), and the bedding consists of a coir mattress, cotton pillows, four cotton sheets, and two blankets.
	15. At the rifle hospital there is no cooking carried on, but the men's diets are brought to them from their barracks. At the European hospital the kitchen is similar to those used in barracks. Chatties and pots are used for boiling, and there is a brick oven. The means are ample, and the diets are cooked in accordance with the recent regulations from the Secretary at War. Sufficient variety is allowed by this scale, which is strictly adhered to.
	16. The diet tables and diet rolls used in hospital are those issued by the Secretary at War. The forms are precisely the same as in England.
	17. The attendance in the European hospital is one hospital corporal, with an orderly (a soldier) for every 10 sick. A native cook and cooly are also allowed.
	18. The hospitals are in a good sanitary condition; no epidemic disease has ever appeared in the wards.
	19. The woodwork of the roofs of both hospitals was much decayed in parts, but they have recently been put in order. A quarter has been provided also for the hospital serjeant, Ceylon rifle regiment. The European hospital is a decayed antiquated building, and will not bear much alteration. A new structure ought to be raised in preference.
	20. There is sufficient ground near the hospitals to allow the patients to take exercise under the shade of trees, and seats are provided, but in the verandah only. No shaded walks are available for the men.
	21. Soldiers' sick wives and children are treated in their quarters. No provision has been made for them in the diet tables issued by the Secretary of War, and no hospital accommodation is provided for them. In consequence of this omission the women and children suffer, and a remedy is required, which would be afforded by their being permitted to be dieted in their quarters till hospitals with nurses are provided.
	22. The hospital regulations in force are those of the Secretary of War.
	23. The medical officer is entirely guided in matters appertaining to the sanitary state of the hospitals, by the regulations of the Secretary at War, and any suggestions he offers are attended to.
	24. There are no convalescent wards or hospitals here, and none are urgently required, although it would be desirable to have a part of the hospital so apportioned by proper authority.

References to Subjects and Queries.	Replies.
XIII. Burial of the Dead.	1. The burial-ground for British troops is close to the European hospital, but on a higher level. The south-west monsoon blows freely through it, clear of the hospital. 2. Its area is 3 acres, 1 rood, 33 perches. The soil and sub-soil is decomposed gneiss, which stands at a very steep slope. The ground is carefully kept. 3. The general space for a grave is seven feet by four feet, and the graves are put as close as possible together. They are from three to five feet deep, and are occasionally re-opened. The number of bodies in the same grave depends on the depth. There is no regulation as to interment, either at ordinary times or during epidemics, but an interval of 24 hours usually takes place between death and burial. 4. The grave-yard was never known to be offensive. The burial of British troops is conducted in every respect as in England. 5. The natives are buried in a ground about one mile distant from the town. The bodies of Buddhist priests and chiefs are burnt. 6, 7. No injury accrues to the public health from the present practice, and no improvement in the mode of disposal of the dead can be suggested.

(Signed) H. E. Weare, Bt. Lieut.-Col. 50th Regiment, Commandant.
J. MacGregor, Surgeon Major.
J. C. B. De Butts, Captain, R.E.

8th October 1860.

1. Topography.	1. Near the station, the surrounding country is flat, but in the distance many lofty hills are seen. There are no swamps in the immediate neighbourhood, excepting a few "paddy fields," the nearest being about two miles distant. There is an abundance of wood and jungle in the vicinity of the station, and Fort Frederick is almost entirely surrounded by the sea. Fort Ostenburgh, situated at the western extremity of the range of hills so called, has the sea on three sides, and thick jungle on the fourth. The lines occupied by the native regiment are separated from the sea by a short street. 2. Fort Frederick is about 130 feet, and Fort Ostenburgh about 180 feet, but the native lines are only a few feet above the level of the sea. Fort Frederick is about 130 feet, and Fort Ostenburgh about 175 above the adjacent country; but the native lines are on a level with it. The native lines are about 150 yards from the sea, and there is a large tank supplied by the rains, about 600 yards from the latter, used solely by dhobies. There is no healthier ground near the station. The ridge of mountains on which For Ostenburgh stands at one extremity is a little higher than Fort Frederick. 3. The ridge of mountains alluded to in the foregoing answer is about two miles in length. The western extremity of the range is about two and a half miles from Fort Frederick, and is about two miles from the eastern extremity, which is the highest part of the ridge, and is about one and a half miles from Fort Frederick, and about 75 feet higher. 4. The sea washes the walls of Fort Frederick. Fort Ostenburgh has the sea on three of its sides, and the native lines are about 100 yards from the sea. No overflowing of water takes place in the vicinity of the station. There are no ravines, water pits, or broken ground near the station, but the water in the ditch on the land side of Fort Frederick, after a continuance of dry weather, is liable to become offensive; but neither Fort Ostenburgh nor the native lines are exposed to this inconvenience. 5. The station is open and freely exposed to the winds. No difference in the temperature of the station has been remarked from the buildings being exposed to reflected sun heat. The different barracks at the station are open to both land and sea breezes, both of which have a sanitary effect on the health, except the land wind during the night. 6. The surrounding country is uncultivated, and there are no works of irrigation near the station. There is but little land fitted for the cultivation of rice, and no restrictions are necessary. The nearest "paddy field" is about two miles distant. No indigo is cultivated, nor is there any cultivation of hemp or flax near the station. 7. The town of Trincomalee, containing a few Europeans and a considerable native population, is about half way between Fort Frederick and Fort Ostenburgh, about a mile from each. The native lines are in the town. 8. Quartz ridges, running north-east and south-west, intersect the country, and the low country is the alluvial deposit of these, and consists of sand and clay. The ground was occupied long previous to the present station being formed. 9. Water is found, during the dry season, at a depth of about 25 feet, and in the rainy season at a depth of about 20 feet below the surface. There are no wells at Fort Ostenburgh.

TRINCOMALEE, CEYLON.

References to Subjects and Queries.

REPLIES.

I. Topography—*cont.*

10. Fort Frederick and Fort Ostenburgh are well drained. The rain-fall flows readily away, and the drains empty themselves into the sea. At the native lines the rain-fall remains upon the surface until it is absorbed. There is no adjacent higher ground.

11. At Fort Frederick and the native lines the water supply is derived from adjacent wells. Fort Ostenburgh is supplied from a well at the foot of the hill, about 350 yards distant. There is only one tank, which is at Fort Ostenburgh. Its dimensions are 60 feet by 9, by 9 feet 10 inches; but it is not in repair. The wells are so constructed that no leaves or other matter can fall into them to injure the water.

12. The water supply appears to be inexhaustible. The water is good, has no peculiarity of colour, taste, or smell; is soft, and not injurious to health. It is drawn, at Fort Frederick, from wells in buckets, by coolies employed for that purpose. They carry it from the wells to the barracks in earthenware chatties. Owing to the distance of this well from the barracks, about 250 yards, up a very steep ascent, the labour is very fatiguing. This would be avoided by means of a force pump. No better supply could be obtained. The native troops have wells close to their lines and supply themselves, and the water at Fort Ostenburgh is carried by a cooly from the dockyard well. We do not know of any other means of supplying this fort, excepting by a force pump, which would in case of a siege be absolutely necessary.

13. We are not aware of any other topographical points that are worthy of remark.

14. No new stations, that we know of, have been selected.

II. CLIMATE.

1. There are no instruments for conducting and registering meteorological observations at this station, excepting a thermometer at the European hospital.

2. There are no meteorological records going back beyond three years.

TABLE of Meteorological Observations for Three Years, from 1st May 1857 to 30th April 1860:—

Months.	Mean Temperature.	Mean Maximum.	Mean Minimum.	Winds. Direction.	Winds. Force.	Remarks as to Cloud, Wind, Dew, Storms, &c.
January - -	78 1/3	83 1/3	73 2/3	N.E.	Moderate	Rain in small quantities.
February - -	81	85 2/3	77	Do.	Do.	Very little rain, with occasional thunder and lightning.
March - -	82 2/3	88 1/3	76 2/3	Do.	Do.	Do. do.
April - -	85 2/3	92	79 1/3	Do.	Do.	Do., with more thunder and lightning.
May - -	85 1/3	92 1/3	78	S.W.	Do.	Much rain, with thunder and lightning.
June - - -	86 2/3	93	80 1/3	Do.	High winds	Little rain.
July - - -	84 2/3	92	77 1/3	Do.	Moderate	Do.
August - -	85 2/3	92 2/3	78 2/3	Do.	Do.	Do.
September - -	85 2/3	93 2/3	77 2/3	Do.	High winds	Do.
October - -	85 1/3	91	76	Do.	Do.	Much rain, with thunder and lightning.
November - -	81 2/3	88 1/3	75	N.E.	Do.	Do. do.
December - -	80 1/3	85	75 1/3	Do.	Do.	Do. do.

3. Trincomalee is considered the hottest station in Ceylon. From March to August the atmosphere is dry and hot, with very little moisture, rain falling but seldom. No tree planting or irrigation is carried on, and there is nothing to affect the atmosphere excepting the land wind, which, passing over such a dense jungle, renders it unhealthy. The station is, however, so situated as to prevent the land winds from having much injurious effect. The diet, shelter, clothing, duties, drills, &c., at this station, are so regulated as not to interfere with the health of the troops. On minutely examining the returns kept at the hospital for a back period of several years, it appears that the monthly admissions so vary that it is impossible to say which are the most unhealthy months. The prevailing diseases are liver, dysentery, and intermittent fever.

4. The nearest station to this, which is considered more healthy, is Kandy, almost 120 miles distant, the road to which station is impassable for a wheeled conveyance. We are unable to give any information respecting its elevation, drainage, water supply, &c. &c.

5. Staff-surgeon Cogan is the only member of the board who has had any experience of the stations in this command. The Kandy district is the most salubrious, and that of Trincomalee the most injurious.

5. All the barracks at the station are so constructed that the windows are on opposite sides and open outwards. There are verandahs on both sides of all the barracks at Trincomalee, which extend their full length and are almost 9 feet in width. At each end of the different verandahs at Fort Frederick there are small rooms for married men, but no verandah in any of the barracks is used as sleeping quarters. There are jalousies at Fort Frederick, but none at any of the other barracks.
6. The bedsteads for Europeans, used in the barracks, are of iron, and each European is supplied with two pairs of sheets, one blanket, one rug, and a coir mattrass and pillow. The native soldiers have wooden cots, a cumlie, and a mat. We have no improvements to suggest.
7. There are no tents used at this station.
8. The ventilation of the buildings is effected by means of doors and windows opposite to each other, and in the European barracks by ventilators above and below, which produce a good circulation of air. These means are sufficient to keep the air pure, by night as well as by day. There are no other means used for cooling the air admitted into the barracks.
9. The barracks for Europeans are built of brick or stone and mortar, with tiled roofs. The native lines are constructed of mud, and also covered with tiles. Tents are not used here. The married native soldiers live in huts, which are constructed of mud, with tiled roofs.
10. The floors of the European barracks are generally made of satin-wood, and are raised about two feet above the level of the ground, with provision for a slight passage of air below. An asphalte floor has lately been laid down in the barracks at Fort Ostenburgh. The native lines have earthen floors, and there is no free passage of air beneath.
11. The materials of which the barracks are composed are very good. We think that all barracks should be ventilated along the ridge of the building, which would make them very much cooler, and would allow the impure air to escape. The barracks and cantonments are kept in repair by the Royal Engineer Department. The repairs are, however, very slowly executed, owing to the extreme backwardness of the place and the want of machinery. No one in particular is responsible for the sanitary state of the cantonment. The walls and ceilings of the barracks are cleaned weekly, and lime-washed when necessary.
12. There are two baths in Fort Frederick, of which a plan is transmitted. The water for them is supplied by carriers, and escapes by an open drain into the sea. The natives bathe in the sea. There are no lavatory arrangements at Fort Ostenburgh.
13. A plan of the barrack cook-houses is transmitted. They are supplied with iron boilers, and in each kitchen at Fort Frederick and Fort Ostenburgh there is a range, built of brick, on which smaller cooking utensils are used. The native soldiers have no cook-house. There is an ample supply of water, and the drainage at the European barracks is good. The refuse water at the native barracks is absorbed in the earth. The linen of all the troops is washed by the native dhobies.
14. The privies, of which a plan is transmitted, have soil-pits from 8 to 14 feet deep, and the urinals generally are near a privy, with a drain leading into its soil-pit.
15. These buildings are ventilated by means of doors and windows, which are opposite each other, and are lighted at night by oil lamps.
16. At the two forts the rain is carried from the barracks to the sea by open drains, which are of sufficient dimensions for the purpose, and in no case is the distance to the sea

References to Subjects and Queries.	Replies.
III. Sanitary Condition —*cont.*	more than 250 yards. There are no sewers or drains at the native barracks. The drainage at the forts is generally sufficient. Most of the buildings are very damp in wet weather, the roofs not being water-tight. All fluid refuse not carried away by drainage evaporates on the surface. There are no cess-pits, neither are there any foul ditches, except the one at Fort Frederick, which is only offensive after a continuation of dry weather, and then but for a short time, as the water soon becomes absorbed. 17. The surface cleansing of Fort Frederick is performed twice weekly by strong fatigue parties. It is efficiently done, and the refuse, &c., is thrown into the sea at some distance from the fort. Fort Ostenburgh and the native lines are surface cleansed daily, and the refuse from them is also thrown into the sea. 18. The immediate proximity to all the barracks is kept free of vegetation, but the slopes of the hills round the two forts are thinly covered with jungle. There are no old walls, thick hedges, &c., interfering with the ventilation of any of the barracks. 19. The bazaar occupied by the natives is about one mile from Fort Frederick, about two miles from Fort Ostenburgh, and half a mile from the native lines. It appears to be kept very clean, and is well ventilated and drained. All bazaar arrangements and regulations are entirely in the hands of the civil power. Cleanliness appears to be strictly preserved. To all outward appearance the native houses are neat and clean. Manure and other refuse is carried to a large common at some distance from the town. No nuisance is experienced in barracks from wind blowing over the native dwellings. 20. All arrangements for the slaughter of animals are in the hands of the civil power. The slaughter-house is a considerable distance from the barracks, and no nuisance is experienced in the station from its condition. 21, 22. There are no bazaar horses at this station, neither are there stables nor picketing grounds for cavalry or artillery horses. 23. The accommodation for European married non-commissioned officers and men is insufficient. There are no married men in the barrack rooms at present, but an increase of one married family would cause inconvenience. The quarters constructed for the married non-commissioned officers and men of the native troops are sufficient.
Officers' Quarters.	1. The officers' quarters are generally good and well drained, but the same complaint exists as with the other buildings—the roofs are not water-tight. As these quarters are all situated in the hottest part of the fort, we would suggest that they should be two-storied.
IV. Health of the Troops.	1. The district in which the station is situated is considered to be one of the most unhealthy in Ceylon, yet the mortality is not so great as might be expected. The adjoining native population is not healthy. 2. Intermittent fever and bowel complaints are most prevalent among the native population, and small-pox occasionally breaks out amongst them. 3. These diseases are attributable to the climate. 4. The two companies of the 50th Regiment came here from Kandy, where they were stationed upwards of two years, and left it in September 1859. They were not subject to any particular disease in Kandy, and on their arrival here they were generally healthy. The artillery arrived here in January 1859 from Colombo, where they had disembarked three weeks previously from England, and they were also generally healthy. One company of the Rifles came here in 1856, and the other in 1858, from Colombo. Three years is the average length of time at each station. The Europeans have chiefly suffered from liver diseases, dysentery, and fever, and the natives from the two latter, since their arrival at this station. No part of the men's present accommodation appears to be more unhealthy than the rest. 5. The troops at this station are never camped out. 6. Staff-surgeon Cogan, one of the members of this board, has twice been stationed at Newera Ellia, the only hill station in the island. The result of his experience is that the health of invalids rapidly improves by removal from the plains to hill stations. 7. Staff-surgeon Cogan is not aware that troops returning from the hills to the plains are more or less liable to attacks of febrile and other diseases. 8. After a length of service in the island, Staff-surgeon Cogan approves of selecting hill stations for troops. 9. There are no diseases peculiar to hill stations, that we are aware of, to which troops are liable to be attacked on going to them, except those arising from too great exposure to cold. 10. Every precaution is taken for the preservation of the health of the men, and they certainly do derive great benefit from a residence in hill stations. 11. The time best adapted for a residence in the hills is from January until May; but we have not had sufficient experience to say what is the shortest period of residence in the hills which would enable troops to obtain the full benefit to their health. 12. There is no period of residence in hill stations, that we are aware of, beyond which injury is likely to be inflicted on the health of troops on their return to service in the plains. 13. No precautions are required in this island for protecting the health of troops on their leaving hill stations for the plains. 14. As the hill station is a small one there is not sufficient accommodation for many of the troops. We are of opinion that an occasional change from the plains to the hills would prove most conducive to the health of the troops, and we would strongly recommend that the reliefs should take place more frequently. Frequent change of stations in the plains is beneficial to the health of the troops. 15. The barrack and hospital accommodation is sufficient for the small number of troops stationed at Newera Ellia, but no provisions have been made in the shape of games and exercises for the men, which would relieve the monotony at such a lonely station. 16. No greater or more commodious elevation than that of Newera Ellia can be found in Ceylon. It is upwards of 7,000 feet above the level of the sea. 17. There is no higher ground near this station which could be advantageously occupied as a hill station.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*cont.*	18. We have found no difference in the healthiness of stations from the different classes of their surface and subsoils. 19. Soldiers should certainly not be sent to India under 20 years of age, and they should land there between October and January. The men on disembarkation are marched direct to their barracks, where everything necessary has been already prepared for them. They are supplied with white clothing and taken on the regimental roster at once. I would recommend recruits on first landing in India to avoid the sun as much as possible. 20. We have no experience to say whether troops should be sent direct from the home depôts to India, or sent first to some intermediate station for a certain time. It would certainly be advantageous to send new arrivals to the hills, but in Ceylon this would be impracticable. 21. Troops landing in Ceylon are marched from the port to the interior, and the hours of marches are so arranged as not to expose the men to the effects of the sun. 22. From my experience, I consider that a British soldier should serve from seven to ten years in India, not longer. 23. The manner of conducting medical boards is not such as to avoid conflict of opinion as regards invaliding, but we have no suggestions to make. 24. Invalids proceeding home should leave India so as to arrive at their destination at the commencement of the summer months.
Disease.	1. There are inspection parades for the discovery of incipient diseases at this station every Saturday, and on Sundays for the native troops. 2. Scorbutic disease is of rare occurrence in the island, and preventive measures are consequently unnecessary; but should it make its appearance at any time, oranges, lime juice, and vegetables are the best prophylactic. 3. During the last 10 years there have been 4,002 Europeans admitted into hospital, of which cases 172 were hepatic diseases, of which 15 were fatal. Amongst the native troops for the same period there were 2,787 cases admitted, nine of which were hepatic, and two of which died. The climate alone is generally the cause of this disease, and we are not aware of any prophylactic measures to diminish its frequency. 4. No case of dracunculus has occurred amongst the troops during Surgeon Cogan's experience in the island, which embraces a period of more than seven years. 5. Out of the 4,002 cases admitted into hospital, amongst the Europeans for the last 10 years, 186 have been from venereal diseases; and out of 2,787 cases amongst the natives, for the same period, there have been 47 cases of venereal treated. There have been no deaths. No precautions can be suggested for diminishing the liability of soldiers to this disease. Lock hospitals would not be advantageous. 6. The troops at this station suffer from the following diseases, viz. :— *Fevers.*—Intermittent fever is most prevalent, but is not of a very serious character when treated in its first stage. *Dysentery* is of common occurrence at certain seasons, and is generally of a very severe form. *Cholera.*—No case during the last 18 months amongst the Europeans, and only seven cases amongst the natives during the last 10 years. *Small-pox* is almost unknown among the European troops, and there has been no case of this disease amongst the native troops since 1855. *Rheumatism* has been of rare occurrence lately. The following table shows the proportion which admissions and deaths from these diseases have borne to the total admissions and deaths for the last 10 years :—

Diseases.	Troops.	Total Number of Admissions from each Disease.	Total Number of Deaths from each Disease.	Total Number of Deaths from all Diseases.	Total Number of Admissions from all Diseases.
Fevers	European	1,338	19		
	Native	1,393	6		
Dysentery	European	335	32		
	Native	28	2		
Cholera	European	9	3	Europeans - 89	Europeans - 4,002
	Native	7	5	Natives - 28	Natives - 2,787
Small Pox	European	—	—		
	Native	10	2		
Rheumatism	European	181	—		
	Native	148	—		

	7. The more frequent zymotic diseases are—intermittent fever, dysentery, and diarrhœa, of which dysentery is the most virulent. They vary according to the seasons, and a sudden change of weather from wet to dry, or *vice versâ*, generally precedes or accompanies their appearance. There are no bazaars or native dwellings within one mile or thereabouts of the European barracks. The sanitary condition of those portions of the station, bazaar, &c., near the native lines is good. No personal habits or conditions among the troops or the native population have been remarked to predispose to the above-mentioned diseases. 8. The soldiers' duties and occupations in barracks do not appear to have any influence in contracting any diseases. 9. Small doses of quinine have not been tried at this station as a prophylactic against malarial diseases. 10. Owing to the nature of the climate we are unable to suggest anything that would prevent or mitigate epidemic disease.
V. Intemperance.	1. With a few exceptions the soldiers at this station are temperate, and the per-centage of confirmed drunkards among them is about four per cent. 2. During the last 10 years there have been 49 cases (out of 4,002) admitted into hospital from diseases caused directly by intemperance amongst the Europeans, but none

TRINCOMALEE.

CEYLON.

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	amongst the natives. It is found almost impossible to go back more than 20 months for information; but during that time there have been eight cases (out of 411) admitted for diseases caused indirectly by intemperance. Intemperance is almost unknown among the native troops, on account of their religion. There are no records at this station that will enable me to show what effect total abstinence, temperance, and drunkenness have on the amount of sickness, mortality, and crime at this station. Drunkenness is always punished as an offence. 3. Distilled spirits are sold both at the canteens and in the bazaar. The quality of the arrack at the barrack canteen is good, but that sold in the native bazaar is very bad. It is impossible to say what amount is consumed out of barracks, but at the military canteen no man is allowed to exceed. Spirit does not form part of the ration for soldiers either at the station, on the march, or in the field, but it is given to convalescents, according to the discretion of the medical officer. No injurious drinks, other than intoxicating drinks, are sold either at the canteen or bazaar. 4. Spirit is never given to convalescents unless it is considered conducive to their health. Its consumption by the troops, when carried to excess, is certain to prove injurious, but when taken in moderation it is conducive to the efficiency and internal discipline of the corps. 5. Total abstinence would be likely to prove injurious to the health of troops. 6. Malt liquor is far preferable to spirits, but wines are not procurable at this station. 7. Coffee and tea are used here morning and evening, and are indispensable as far as regards the men's diet, but lemonade, soda-water, &c., are not available. 8. There is no spirit ration here. 9. A small quantity of spirits is considered necessary for the troops. 10. I have no further recommendations to make on these points. 11. The canteen regulations are as follows:—No European or native, except the garrison, is allowed to enter the canteen without authority, nor is any liquor allowed to be taken out except under the following rules:—(1st) To a married man to the extent of one bottle of wine or one quart of beer daily; (2ndly) to companies messing in barracks, on the requisition of orderly officers of regiments, at the hour of dinner only, and then not to exceed one pint per man, or half a bottle of wine; and (3rdly) upon an order from the officer of the garrison or standing order from the commandant or staff officer. The canteen is open from twelve to one o'clock at noon, and from half-past five to eight p.m. It is closed during Divine service on Sunday. No one is allowed to enter the canteen while in liquor. No man is allowed to take liquor at the bar (except at twelve at noon, when it is peremptory) or at any other place excepting at the table, where it is delivered by the canteen attendant. All liquor issued from the canteen must be paid for on delivery.
VI. DIET.	1. The ration for Queen's British troops is composed as follows, viz., 1½ lbs. of fresh meat, or 1 lb. of salt meat, 1 lb. of bread, 1½ oz. sugar, 1½ oz. coffee, or ¼ oz. tea, 1 oz. salt, and 4 oz. rice. Salt provisions are issued twice per month. The rations are inspected previous to issue by a commissioned officer. 2. A complete ration, with vegetables (when procurable) is provided for the troops. The stoppage is 3½*d.* for the commissariat, and 2*d.* for extras, daily. The soldier takes three meals per diem. Breakfast at eight a.m., of tea or coffee and bread; dinner at one p.m., of soup, meat, rice, and vegetables, and supper at six p.m. of bread and tea or coffee. The foregoing refers to Europeans; the native troops diet themselves. The proportion of vegetables that enters into the composition of the ration varies, not being procurable every day. 3. The ration is quite sufficient in point of quantity, and it is of as good quality as can be procured. The rations are never disposed of at this station. 4. The means of cooking, available at this station, consist of large iron boilers placed on brick ranges and wooden fires. The kitchens are clean, light, well-ventilated, and well supplied with water. The food consumed by the troops here is generally boiled. The cooking is properly done, but there is no great variety. Tea and coffee are properly prepared for the men, and they have the latter beverage always before a march. 5. Gardens for the cultivation of vegetables by soldiers could not be advantageously established near the station, as the nature of the soils and climate would not admit of the cultivation of vegetables.
VII. DRESS, ACCOUTREMENTS, AND DUTIES.	1. The soldier's dress at this station is composed as follows:—Jacket, trousers, and cap cover made of white American drill, in which all the duties are performed. The accoutrements are according to regulation. The present dress is suitable to the climate, and for the soldiers' duties by day and night, and we cannot suggest any improvement in it. The guards mount in white, and the sentries are protected from the sun and wet by verandahs and sentry boxes.
Duties.	1. Men should be thoroughly drilled at home before being sent to India. 2. The usual routine of the soldiers' duties at this station is as follows:—Parade at 6 a.m. and 5 p.m., each lasting from 30 to 45 minutes; guard mounting, and the usual fatigues. Their duties do not affect the health of the men. The above are the best hours for drills and parades, and there is a general order relative to the marching of troops in the morning. The average number of nights the men at this station have in bed during the week is four. 3. The guards are all mounted in their own barracks at 6 a.m. daily, and remain on duty 24 hours. Three guards, viz., the dockyard, the Cutcherry, and the Admiralty guard, mounted daily by native soldiers, are a considerable distance from their barracks. There are roll calls at ½ past 10 a.m., at every meal, and at tattoo. The night guard does not appear to affect the health of the troops. In case of inclement weather the sentries wear their great coats. The native troops have roll calls at 6 a.m., at midday, and at tattoo.
VIII. INSTRUCTION AND RECREATION.	1. There are two schools at this station, one for Europeans with a schoolmaster of an ordinary description, one for native soldiers with an indifferent schoolmaster; a library and reading room, which is also used as a day room, sufficiently lighted at night, and well supplied with books in Fort Frederick. There is also a theatre, but neither ball

References to Subjects and Queries.	Replies.
VIII. Instruction and Recreation—*cont.*	courts, skittle grounds, soldiers' gardens, workshops, or gymnasia. The library is the only resort for the troops in hot or wet weather, and in addition to the books it contains chess, backgammon, and other amusing games. The men are not allowed outside the forts until after evening parade, after which time the sun does not affect their health. The native troops are not so much confined to their barracks, nor do they feel the effects of the sun as do the European troops. 2. We suggest there should be gymnasia, a covered ball court, and skittle grounds for Europeans and gardens for the native troops. 3. There are regimental savings banks for the Europeans, which have proved highly advantageous, but no such institutions exist for natives. 4. There are verandahs and trees, but the heat is too great at this station to admit of exercise being taken during the day.
IX. Military Prisons.	1. The military prison is in a most healthy locality, well ventilated, and is in every way suited for the purpose for which it is intended.
X. Field Service.	1. There are no local regulations for field medical service not included in the general presidency regulations. 2. Any means thought necessary by the medical officer to preserve the health of the troops on a line of march he suggests to the officer commanding. 3. The men at this station are never encamped. 4. There are no arrangements adopted for field hospitals, transport of sick and hospital supplies, ambulances, &c., &c.
XI. Statistics of Sickness and Mortality.	No information under this head.
XII. Hospitals.	1, 2. The new European hospital, which is not yet occupied, is situated in the lower part of the fort, and is about 300 yards from the men's barracks. The native hospital is adjoining the barracks. There are no stables at this station. The bazaar and the houses of the civil population are nearly one mile from Fort Frederick hospital, but the native hospital is very near the civil population, and about one mile or thereabouts from the bazaar. The site of the European hospital hitherto unoccupied is partly open; but there are trees, buildings, mounds, &c., which interfere with the ventilation. The native hospital is, however, open and freely ventilated. We are of opinion that the site of the former is unhealthy as to elevation, but the drainage appears to be sufficient, and there are no river banks, or marshes, &c. in its neighbourhood. The site of the native hospital is good, and there are no ditches, nullahs, marshes, foul ground, &c., near it. 3. The water is abundant and wholesome. 4. The European hospital has not yet been occupied. Judging from appearances the drainage is sufficient, and the refuse water, &c., is emptied into the sea by drains. There is no drainage at the native hospital. 5. The centre of the roof in the European hospital is 21 feet from the ground, with a free perflation of air underneath the floors. The floor of the native hospital, which is made of cow-dung, is about six inches above the ground, and there is no perflation of air beneath. The roof water of the European hospital is carried away by drains into the sea; but at the native hospital it sinks into the subsoil. The surface drainage and guttering round the hospital are quite sufficient to carry away the rain-fall rapidly. The European hospital is composed of brick and mortar, with single roof and walls. A space is left along the wall plate, and trap-doors are provided in the walls near the ground, which ventilate to some extent; but the wards might be made cooler by adding a canvass ceiling. The native hospital is a temporary building with mud walls, and a cadjan or cocoa-nut leaf roof. The walls are single, but are sufficient to keep the building cool. The buildings are supplied on both sides with verandahs about 9 feet in breadth, which afford sufficient shelter from the sun's rays. The verandahs are never used for the accommodation of sick, convalescents, or others. The hospital consists of one flat.

Table of Hospital Accommodation.

Date of construction	-	European hospital, commenced 7th March 1853. Not yet occupied. Native hospital unknown.
Total number of wards	-	European hospital - - 3 Native ditto - - 2
Total regulation number of beds	-	European ditto - - 40 Native ditto - - 20

Hospital Wards. No.	Regulation No. of Sick in each Ward.	Dimensions of Wards. Length.	Breadth.	Height of Walls.	Cubic Contents.	Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows. Number.	Height	Width.
		ft. in.	ft. in.	ft.	ft.	ft.	ft.	ft. in.	ft.	ft.	ft.
European - 1	14	52 0	21 0	17	22,386	1,500	78	1 8	13	7	3
European - 2	14	52 0	21 0	17	22,386	1,500	78	1 8	13	7	3
European - 3	12	53 0	16 0	17	17,384	1,500	70·33	1 8	13	7	3
Native - - 1	8	19 4	17 2	13	5,634	704	41	1 8	4	5	3
Native - - 2	12	48 0	17 2	13	13,872	1,156	68	1 8	8	5	3

The hospitals are not placed so as to receive the full benefit of prevailing winds. The windows all open outwards, and we are of opinion that in the European hospital their arrangement would be improved by their being nearer the ground, and venetians substituted in the place of glass.

6. In the European hospital there are ventilators on each side of the wards, both above and below the flooring; but should it be found necessary to keep the windows in their present form closed, the ventilation would be insufficient. The native hospital is sufficiently ventilated. There are no jalousies or jhilmils.

TRINCOMALEE. CEYLON.

References to Subjects and Queries.	Replies.
XI. Hospitals—*cont.*	7, 8. There are no means either for cooling or warming the air admitted into the wards, and the latter is not at all necessary. The walls and ceilings of the hospitals are cleansed and whitewashed when thought necessary by the medical officer in charge. 9. The privies are built of the same material as the hospital, and are placed over cess-pits without drainage. From the position of the privy at the new European hospital, we fear it will eventually prove offensive. 10. At the European hospital a room is applied for lavatory arrangements, but there is no such provision at the native hospital. The patients use tubs in the verandah, and convalescents are allowed to bathe in the sea. 11. The means for bathing the sick are neither sufficient nor convenient. 12. The washing and drying of the hospital linen are performed by the native washermen, of whom there are no complaints. 13. The storage is sufficient and dry. 14. European invalids are provided with iron bedsteads with sacking bottoms, and the natives have wooden cots, but all are provided with mattresses, pillows, sheets, blankets, and coverlids. We have no improvements to suggest. 15. The European hospital kitchen is in the back range of the building, and the means and apparatus for cooking appear to be ample. This is applicable to the native hospital also. 16. Copies of the diet rolls, diet tables, &c., are transmitted. 17. There is a hospital serjeant, assisted by one orderly, at each hospital, which is sufficient attendance for the average number of patients. 18. The sanitary condition of the barrack used as a hospital for the European sick and of the native hospital is good, and no epidemic disease, hospital gangrene, or pyæmia have appeared in the wards. 19. In the present temporary hospital for the European sick there are many deficiencies, which will not exist in the new one when completed. There are many deficiencies in the native hospital, and the building not being suited for its purpose, I would suggest its removal to a more suitable site, and its accommodation bineg made more commodious. 20. The verandahs are the only places for taking exercise. There are no shaded walks or seats set apart for the use of convalescents. 21. The sick wives and children of the soldiers attend at the surgery for casual complaints, or, if their case require it, the medical officer attends them at their own quarters. No improvements in the present arrangements are necessary. 22. There are no special local hospital regulations which are not included in the general army medical regulations. 23. The medical officer can only report on the necessary repairs of the hospital, and forward requisitions accordingly, but he has discretionary power regarding the change of diet and the issuing of medical comforts. 24. There is no convalescent ward or hospital for convalescents at the station, nor is there any advantage in having one.
BURIAL OF THE DEAD.	1. The burial-ground for British troops is about three-quarters of a mile distant from the station, and its position to the latter is such that the prevailing winds have no effect on the health of the troops. 2. The area of the burial-ground is nearly three acres. The soil is chiefly sand, and there is no drainage but that which is natural, and this is found to be sufficient. Decomposition takes place neither very readily nor very slowly. The ground is walled in and is carefully kept. 3. The space allowed for a grave is nine feet in length by three feet in width, and the ordinary interval between the graves is three feet. They are dug six feet deep. The area of the ground is so extensive that graves are never designedly reopened, but when one is accidentally reopened it is in ground which has been undisturbed, as far as can be ascertained, 15 years and upwards. Interment is compulsory from 12 to 18 hours after death. No epidemics have occurred in our time. The natives are buried according to their own religion by their friends. 4. The graveyard is never offensive. 5. There are no camp followers or bazaar people at this station. 6, 7. No injury accrues to the public health from the present practice, nor are there any improvements to be suggested.

(Signed) F. HAMLEY, Major, 50th "Queen's Own" Regiment, Commandant, Trincomalee.

References to Subjects and Queries.	Replies.
I. TOPOGRAPHY.	1. The aspect of the country surrounding the station is undulating and pleasing to the observer. The hilly parts are covered with a thick luxuriant jungle, interspersed with trees of various kinds, whilst the lower portions are thickly studded with cocoa-nut trees, which grow to the water's edge, and are swampy. There is plenty of jungle, wood, and water in the vicinity. 2. The elevated part of the station is 20 feet above the level of the sea, but the elevation of the adjacent hilly country is greater than that of the station, the average height of the hills being 130 feet above the sea. The elevated part of the station is about 25

References to Subjects and Queries.	Replies.
I. Topography—*cont.*	feet above the nearest canal. The surrounding undulating country is higher than the station, but the site of the latter is equally healthy. 3. The nearest mountain, known as the Haycock, is distant about 40 miles from, and about 3,350 feet above the level of, the station. 4. The sea washes up to the fort walls, and is, therefore, the nearest water. There are also a river, named Ginduruh, the nearest mouth of which is about one and a quarter miles from the station, and a canal about 200 yards from the fort. In parts, the vicinity is liable to overflow in the wet season (*i.e.*, during the months of October, November, December, May, and June), but they are seldom under water for more than a couple of days at a time. There are no ravines, water pits, &c., near the station. 5. The station is freely exposed to the south-west wind, which prevails during six months of the year, but the free circulation of the north-east wind, which prevails during the remaining six months, is somewhat impeded by the fort walls. The temperature of the station is not raised by exposure to reflected sun-heat. The station is exposed to both land and sea breezes. The land wind that blows during the night at certain seasons should be avoided, as it has been known in many instances to paralyze the limbs. The sea breeze is beneficial to health. 6. The surrounding country is in parts cultivated, but there are no works of artificial irrigation near the station. The cultivation of rice within 250 yards of the station is prohibited by the military authorities, who exercise a right of control over this land, and will not allow it to be cultivated. Indigo is not cultivated, nor the preparation of hemp or flax carried on near the station. The preparation of the cocoanut fibre, however, is carried on at a distance from the station of about one and a half miles, and the odour arising from the stagnant water in which the husks are soaked is very offensive. 7. There is no large city in the vicinity of the station. The native population within Galle, which comprises an area of 36 square miles, is,—males, 11,700, and females, 11,250; total, 22,950. The native town commences at about 450 yards from the fort, and there is also a native town within the fort. 8. The geologic condition of this district is as follows:—The surface soil is of red sand and gravel, termed cabook, with black earth in some parts, and this is mixed with a quantity of rock of a granitic character. The subsoil is slightly argillaceous, based on rock of the same granitic formation, mixed with coral. 9. Water is usually found, in the dry season, at a depth of about 15 or 16 feet, and during the rainy season, at a depth of about 10 or 11 feet below the surface. 10. Part of the rain-fall sinks into the subsoil of the station, and so drains off, and part evaporates. There is no drainage from higher ground passing into the subsoil of the station. 11. The water supply of the station is derived from wells, but there are no tanks. The water used for drinking purposes is free from pollution. 12. For the use of the troops there are six wells, with an average diameter of six feet, and the average depth of water in which is, in the wet season, four feet, while in the dry weather it seldom exceeds two feet. The water from the wells is only used for cooking purposes and for ablution. All drinking water is either purchased by the troops or procured by means of matboys (soldiers' servants). The water is brought from a well about 650 yards from the fort. The water obtained from the wells within the fort has a brownish tinge, is slightly brackish, and has an earthy smell. We have no means of testing its chemical qualities or of ascertaining its microscopic character. The quality of the water obtained from within the fort is such as to render it unfit for drinking, but that from the wells outside is good and sufficient. The water from the wells is usually drawn up in hand buckets. The supply could be improved by means of pipes, which might be laid down from the wells outside; but this would be at a considerable expense. 13. The station is remarkably healthy, and there are no other topographical points bearing on its health to be remarked on. 14. No new stations have been selected, either on hills or plains, within our experience.
II. Climate.	1. There is no thermometer, barometer, rain-gauge, or other instrument at the station for conducting meteorological observations, and the subject has not been much examined into in former years; but I have arranged, from the data in my possession, such facts as the returns will admit of. From examining several years of observation on the rain, I should conclude that it rains on an average about 180 days in the year; but having been here only two months and some days, I cannot give any clear explanation of the amount of rain which falls during the year. 2. Table of meteorological observations:—

Months.	Barometer Mean.	Mean Temperature.	Mean Daily Range.	Mean Maximum.	Mean Minimum.	Mean Dry Bulb.	Mean Wet Bulb.	Mean Sun Temperature.	Rain, inches.	Winds. Direction.	Winds. Force.	Days of Sunshine.	Remarks.
January	–	80	–	84½	78	Not tested.				Not in returns; but the N.E. and S.W. monsoons occur at stated regular periods.	Not explained with any accuracy.	It would appear from the returns that it rains on an average 180 days in the year.	Thunder storms of great severity, with thunder, rain, and tempestuous winds occur during the S.W. monsoon, and in the intervals oppressive heat prevails, relieved by the sea breeze, which acts most agreeably on the atmosphere.
February	–	79½	–	84	78¼								
March	–	80	–	84	77½								
April	–	82	–	85	78								
May	–	82½	–	84½	78½								
June	–	82	–	84½	78½								
July	–	81½	–	84	77½								
August	–	81	–	84	78								
September	–	81	–	84	77½								
October	–	80	–	85½	77½								
November	–	80	–	83	77								
December	–	79	–	83½	77½

II. Climate—*cont.*	3. The climate of this station is variable, but the variations are extremely regular. There are two seasons or monsoons—one commencing in May and ending in October, while the other lasts, as a general rule, from November to April, and between these there prevails a season of dry heat from February to May. The climate of Galle is marked by being very damp at all periods, everything being soon covered with a blue mould. This peculiar condition arises, I think, from the quantity of rain which falls during the year. I do not attribute it to the trees, which are numerous over the district, or to the irrigation or non-irrigation which exists in the surrounding neighbourhood; and the air, as a general rule, is not, I believe, charged with any atmospheric admixture injurious to the health of the troops. The men are clothed judiciously, and the barrack-rooms are large and lofty and cool, considering the great heat which prevails outside the buildings. Parades are ordered at such hours as are suited to the climate and the health of the soldiers serving in it. It would appear that May is the most unhealthy month, and April the next, but not in a very marked degree. The heat is generally greater at this period of the year, to which, I suppose, the amount of sickness is to be attributed. The prevailing forms of disease are fevers, affections of the stomach and bowels, and catarrh. The first may be referred to the heat, and the catarrhal affections to the indiscreet exposure at night, after the great heat generated during the day, the men throwing off all covering and getting chilled in consequence. At this period also the men eat a quantity of fruit, probably unripe and indigestible, and thus affections of the bowels are often produced. 4. There is no district at or near this station more eligible than the present, compatible with the defence of the station (which must have its due weight), to which the troops could be removed. This station is generally considered to be healthy. Having been less than three months in the colony, I have no further suggestions to make.
[illegible]	5. I have not served at any other station in this colony than the present.
III. SANITA OF STATION.	1, 2, 3. Plans of the station, with the barracks and Malay lines, are herewith transmitted. 4. TABLE of Barrack Accommodation. Total number of barrack-rooms, 2. Total regulation number of non-commissioned officers and men, 99.

Barrack-Rooms.	Regulation Number of Men in each Room.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents in Feet.				Number.	Height.	Width.
		ft. in.	ft.	ft. in.			ft.	ft. in.		ft. in.	ft. in.
Barrack-room not occupied by European troops.	53	106 6	27	16 6	62,542	1,180	54	1 7	8	6 5	7 0
Barrack No. 2 -	46	94 0	27	16 6	55,201	1,200	55	1 7	8	6 5	7 0
Guard-room - -	23	48 0	21	15 2	19,152	833	43	—	5	5 5	5 3
Prison cells - -	1	9 8	6	7 3	425	425	58	—	4 Ventilators.	8 0	20 0

5. The windows of the rooms are on opposite sides, and consist of an open grating, which admits a large amount of air. These do not open outwards, but there are shutters attached to each, which are capable of being opened or closed, as is most convenient. On both sides of the barrack-rooms there are large verandahs, extending their whole length. The front verandah is 9 feet broad, and that at the back 9 feet 4 inches. They are not used as places for the soldiers or others to sleep in. There are no jalousies to the barracks; but, as I have above mentioned, an open grating with shutters.

6. The bedding for each man consists of one blanket, one rug, two sheets, one mattress made of coir, and two pillows of the same material. This makes a mattress of a firm, uniform nature, which is of as cool and smooth a quality as any substance generally used. These remarks apply chiefly to the European soldiers' quarters, and I have no further suggestions to offer.

7. There are 25 tents in the commissariat store at this station—12 small and 13 large. The small tents contain a cubic space of 1,132 feet, and the large 1,800 cubic feet each, and are constructed of canvass, having a lining of blue serge. Many of them are out of repair, but still capable of being made serviceable. The small tents are returned as intended for 10 men in each, and the large are constructed for 20 men each. I should consider that six men in the small and 15 in the large would be more compatible with the preservation of health in this climate

The tents are very defective in point of ventilation, having no means of admitting air but the doors. The barrack-rooms have no other means of ventilation than the doors and windows, but if a few openings were made in the side walls, I am of opinion that the purity of the air would be improved. The only way of cooling the rooms is by sprinkling water occasionally over the floors and doorways. The guard-room is of the most convenient description. It is large and airy, and has five large circular holes made in the walls for ventilation. The cells are dry, and of the usual dimensions, with two openings in each, facing the sea. One of these is grated, and opposed to them are two oblong openings, on a lower level, on each side of the door of each cell, so that I think they may be considered as being well adapted to the purpose intended.

9. The barracks are constructed of bricks, stones, and a species of mortar, with laths or sticks interlaced.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of Station—*cont.*	10. The floors are made of tiles and bricks, and have a stone paving running through the centre of the rooms. They are not raised above the level of the ground, that is to say, there is no room for the passage of any air beneath them.
	11. The barracks are built of solid masonry, on the Dutch principle. I believe that brick walls will keep out heat, and I must state my opinion, that, as a general rule, the barrack-rooms are as cool as in this climate could be expected. The floor of one barrack-room of the Ceylon rifles is made of sand, and I think a brick paving to it would be a decided improvement. The barracks are kept in repair by the Engineer Department, on requisition made by the Assistant Quartermaster-General. The medical officer is responsible for the general sanitary state of the barracks, and he makes any suggestions which may appear necessary to the commanding officer. There are no stated times for lime-washing the barracks, but it is done as often as is considered desirable. The walls are kept clean by the men.
	12. There are no large baths provided for the men at this station, but they bathe in the sea twice a week. The lavatory is a square building, with a stone flooring and a large channel running down its centre, which affords free drainage to the refuse water. It is open all round between the roof, which is tiled, and the body of the building, by which means a sensation of coolness is perceived on entering. The building is furnished with eight washing tubs for the men. The water for washing is obtained from the wells in the fort, and conveyed by puneins kept in the barracks for that purpose. The water for drinking purposes is obtained from the wells outside the fort.
	13. The cook-house at the 50th's barracks is constructed under a verandah, which is kept waterproof. It is close to the men's lavatory, and a channel of communication for the purpose of drainage is established between them. The cooking is performed by natives. The washing of the men's linen is performed by natives outside the fort.
	14. The privies for the men are built over the shore; the sea at high tide washes completely underneath them, and thus the places are kept in a pure state. At night the men have urine tubs in their rooms or in the barracks. These are removed every morning at early dawn to a place erected for the reception of their contents. There is a sort of tank, which is connected with the main sewer, which empties itself into the sea, and no perceptible nuisance of importance arises from this source.
	15. The barrack-rooms are ventilated by large grated windows and doors, and are lighted by two large lamps suspended from the ceiling. These do not afford the men sufficient light to read after dark.
	16. On each side of the men's barracks runs a broad, but not deep drain, with sides and bottom of brickwork, which carries the refuse water from the cook-house into a deep sewer, having communication with one of the main sewers of the fort, which carries all refuse matter into the sea. The sea does the duty of scavenger to the privies, and the urinals are removed from the barrack-rooms at daylight to a cesspool which is in connexion with a main sewer. The ground in front and rear of the European barracks is flat, and wants draining, as after rains the water collects and remains on the surface, causing, doubtless, an increase of dampness in that quarter. There is a projecting wall at one side of the hospital, which receives the droppings from the eaves of the buildings, and which has been noticed to generate dampness. A verandah on this side would be very beneficial, and it would have the effect of carrying the drainage from the roof beyond that point. There is only one cesspit connected with the barracks. It is not emptied at any time, but discharges itself into the general drain leading to the sea. The fort has a broad ditch, filled with stagnant water and rank weeds, on the land side, immediately under the ramparts. Within the fort there are cocoa-nut trees, bananas, and other vegetation.
	17, 18. There is no regular surface cleansing resorted to, except such as is adopted by the residents themselves; but the prisoners are daily employed in keeping the surface of the ramparts, esplanade, &c. free of rank vegetation. The cesspool is near the men's privies, and not far from the European hospital; but no offensive odours are produced thereby. The ventilation of the fort is rendered in a measure imperfect by the ramparts and the numerous houses belonging to civilians.
	19. The sanitary condition of the fort, taking the drainage, ventilation, water supply, &c. into consideration, must be considered as favourable. I have no remarks to make relative to the police of the bazaar. There is a fish market and a market for meat about a quarter of a mile from the fort, in and near which there is a bad odour; but this is not greater than is generally noticed in such places, and they are kept in good order. The houses of the natives inside and near the fort are of simple construction and kept tolerably clean. There are no dungheaps or cesspits within them to all appearance. No nuisance of a very noticeable character is caused in the fort by the wind which blows from the direction of the native buildings; yet at the same time I must remark that all along the beach human excretions are to be observed, which after all is greatly corrected by the strong sea breeze which blows over the fort.
	20. The slaughter-house for the military and the whole district is built some way out on the sea shore. The sea washes at high tide much beyond it, and carries away with it the offal. It is at least a quarter of a mile from the fort, and does not produce any offensive effluvia in the interior of the station. These places are under the supervision of the police, who have strict injunctions to enforce cleanliness, and to cause the removal of offal.
	21, 22. There are no horses, stables, or picketing grounds at this station.
	23. The married non-commissioned officers and men occupy separate rooms from the single men, and are tolerably well supplied with room. The "Ceylon Rifle" married men are also separated from the single men; but there is a part of their quarters which is objectionable, and which has been officially represented to the military authorities as being so.
Officers' Quarters.	1. There is a range of officers' quarters for four, which is just completed. It is high in elevation, opened to the sea breeze, and thus not deficient in ventilation. The drainage is of an ample nature, and the buildings are well furnished with every convenience.

GALLE.
CEYLON.

References to Subjects and Queries.	Replies.
IV. HEALTH OF THE TROOPS.	1. The station and surrounding country, as well as the small locations in this district, are almost free from epidemic diseases, and the general state of health of the population is very satisfactory. The military have also enjoyed a fair amount of health. 2. The diseases most prevalent among the native population are fevers, bowel complaints, and a peculiar disease arising from the impoverished condition of their blood, and also from hereditary syphilis. About two years ago cholera appeared in this province. Diseases of the spleen have not been particularly frequent. 3. The causes of unhealthiness among the natives are want of cleanliness, imperfect ventilation of their inside dwellings, and an impoverished diet. The hereditary syphilis to which sometimes a whole village is subject is kept up by these causes. 4. The 50th regiment, or rather a detachment at present at Galle, came to this station about 2¾ years since from Ireland. This detachment was six months at Colombo previous to being ordered to Galle. I cannot make the comparison between the present health of the men at this fort and that which they enjoyed at other stations without reference to the books at head-quarters. With regard to the general health of the company of the 50th regiment stationed here, I can speak favourably. The principal diseases have been febrile, for the most part of a severe nature. Rheumatism, boils, ulcers, and bowel complaints are the diseases from which they have chiefly suffered. I do not think there is any difference in the healthiness of the men's accommodation at Galle, comparing the 50th regiment with that of the Ceylon rifles. One portion of the men's barracks at this station is certainly more healthy than the rest by reason of its great height from the ground and openness to the sea breeze, but unfortunately that portion is occupied, by order of the local civil authorities, as the Custom House, P. and O. Company's office, &c., though essentially military buildings. 5. The troops have not been camped out since their arrival at this station. 6 to 16. No experience of hill stations. 17. There are few elevated sites near this station which would be advantageous over the present position occupied by the troops, as in the fort we get the full effect of the sea breeze unpolluted by passing over any land near it. There is a place about 1½ miles from this called "Bona Vista," which, I should suppose, is about 300 feet above the sea, and which also receives the effect of the sea breeze; but at its rear are paddy fields, and it might not prove much superior as a station to the present; and though its climate might be better than that of Galle, yet there might be many disadvantages. 18. The soil of the above-named place ("Bona Vista") is one of sand or gravel, with a subsoil of a clayey nature, and this I have observed to be the most favourable for military stations. 19. The best age for a soldier to be sent out to India is at 20 or 25 years. 20. I should think it would be of little advantage delaying troops at an intermediate station; they should be sent to India direct from the home depôts. I am of opinion that if the troops are landed in India at a favourable season, and precautions taken to prevent excesses, the men would suffer as little during the first months as at any other period of their service. 21. The mode of transport for troops from the port to the interior is by easy marches, there being no railway. No additional precautions are required for preserving the health of the troops on the route, but they should arrive at the halting place for the night before 8 o'clock a.m. 22. I should think 5 or 6 or 7 years for a continued time the longest period a British soldier should serve in India. 23. There is no conflict of opinion in the medical boards as regards invaliding. 24. I should consider that the best time for invalids to leave India for England would be about the month of March.
Diseases.	1. There is a health inspection in this garrison every Wednesday morning for the detection of cutaneous and every other disease. 2. Scorbutic disease has been almost unknown at this station for the last 10 years, only one admission into hospital having taken place from this cause; and this man was *en route* from India to Australia, and contracted it on board ship. The disease is attributable to the want of fresh meat and vegetables, combined with the want of exercise and the confined atmosphere between the decks of ships, and is for the most part prevented by the removal of these unfavourable circumstances. Bad water, or a too scanty supply, may also be considered as a great cause of this disease. 3. The proportion of hepatic diseases for 10 years was as follows:—Out of 1,581 cases treated during that period, 42 of hepatic diseases were admitted; and this is by no means a large number. Only one man died from hepatitis in 10 years. The causes of this disease may be considered to be obstructed perspiration, in consequence of incautious exposure at nights, redundance of bile caused by long-continued heat, irregular habits, and bad spirits. 4. Dracunculus I have never seen; and no case is recorded as having occurred among the troops for 14 years. 5. The venereal disease is by no means common among the troops at Galle; but I understand it prevails to a great extent among the native population. One hundred and ninety-five cases have been admitted in 10 years in all its forms. A lock hospital would be a benefit to the community at large, as well as to the soldiers. The only precaution for diminishing the liability of the soldier to this disease would be to cause all the infected women to go to hospital. The proportion of admissions from venereal diseases is 195 to 1,581 admissions from all diseases. 6. I am of opinion from my short experience that epidemic and endemic diseases are rare among the troops in this garrison, and I find that for 10 years there has been very little of either. Small-pox occurred in 1855, when three of the Ceylon rifles were mildly attacked by it. The following is a statement of the number treated in hospital during 10 years; viz., 1,621 admissions, of which 205 were from fevers. The medical officers in charge, at different periods, have all agreed in stating that they were mild in form; and this is clearly proved by the fact that out of 205 cases treated, only one death resulted. There were three forms of fever; remittent, of which 46 cases occurred.

References to Subjects and Queries.	Replies.
IV. Health of the Troops —*Diseases—cont.*	quotidian, five; and the remainder were common fevers; the death was referred to the common order. Three cases of cholera and one death occurred during the period referred to; a casual case or so, not justly referable to endemic or epidemic causes. Sixty admissions from dysentery, acute and chronic, occurred, with only two deaths out of that number. The cases of rheumatism were, acute, 52; chronic, 23. It appears, then, from the records of the European hospital for 10 years, that out of 1,621 soldiers treated, there were only 14 deaths, a proportion under one per cent.; and this must be a proof that the diseases generally were not of a severe nature, and the climate and station not inimical to the European constitution. 7. The most prevalent form of fever is the common continued. Ague is rare, and the remittent not of a severe nature. Rheumatism is not very common, and presents no remarkable appearances; in fact, the zymotic diseases are not of common occurrence. These diseases prevail, for the most part, during the hot weather; but there are no atmospheric conditions connected with their appearance that I am aware of. The irregular habits of some of the men are a common cause of fever and rheumatic affections; but I do not believe that want of ventilation, over-crowding, or bad drainage has been actually a cause of these diseases. The men bathe regularly twice a week, and attention is paid to cleanliness. There is one disease of a local nature, which is very common among the natives, viz., elephantiasis; this affects the lower extremities very frequently, and often the scrotum. It partly owes its rise to a venereal taint, want of cleanliness, and the relaxation of the climate. Europeans are also subject here, more than they are elsewhere, to a swelling of the scrotum and enlargement of the testes of a temporary nature, and not venereal. 8. Epidemic disease is of very rare occurrence, and there is nothing in the description of duty which can be considered as likely to have an injurious effect on the troops. Habits of irregularity are the only actual or apparently real causes of disease, with the continuance of hot weather during the dry season. 9. Small doses of quinine, as a prophylactic against malarial diseases, have not been tried at this station, as such a precaution did not appear necessary. 10. The station has been exempt from any epidemic disease for many years. My experience, and that of the medical officers who have preceded me, is of this nature, that the station is not one which has demanded any exertions of ours in the prophylactic department.
V. Intemperance.	1. The soldiers at this station are usually temperate; and I believe there are but few confirmed drunkards among them. 2. I find, on consulting the records of the European corps for 10 years, that only 14 cases were directly produced by drink. Intemperance I believe to be an indirect cause of an injurious character on the health of the troops. I cannot exhibit a table of the effect of total abstinence among soldiers, as there is no notice furnished on that point; but of this I have no doubt, that a man of temperate habits is much more likely to retain his health than either a total abstinence man or a drunkard. The statistics I have obtained from the records are as follows:—Out of 1,621 admissions in 10 years, only 14 were admissions from diseases caused directly by intemperance; but this, of course, is no positive criterion of the amount of drunkenness during that period. Drunkenness is always punished as an offence. 3. Distilled spirits are sold at the military canteen after evening parade; but they are to be had at the bazaar almost at all hours. The quality of the spirit is good. Some men drink more than others, and therefore no average quantity could be arrived at of any value. There is no spirit ration at this station; but on the march the men (Europeans) are allowed one gill a day, and in this instance I have very little doubt it is attended with very good effects. This allowance is in the shape of arrack, which is obtained from the commissariat department, and is of the best quality. One or two men may take an early dram; but it is not a common practice at this station. Spirit is never given as a ration to convalescents. Lemonade and soda water are sold at the canteens in the bazaar; but I am not aware that any injury to the health of the troops has resulted from the use of them. 4. The moderate use of spirits to most men is perfectly innocent, and indeed beneficial to many; but excess in this respect is injurious to health in all instances. If used in moderation, spirit is not conducive to any departure from discipline; but if taken in excess, it is often subversive of discipline. 5. There is no spirit ration at this station, and I do not think it necessary to recommend it. There are, however, two or three canteens of a low description inside the fort, over which the military authorities have no control, and if these were abolished good must necessarily result. The men get cheaper and inferior spirits at these places, which is a strong temptation for them to avoid the military canteens. 6. Malt liquors and wines, when of a good quality, have a great advantage over spirits; but cheap wine is generally very injurious to health. 7. Coffee, tea, lemonade, and soda water are used at this station in moderation, and are not injurious to health. As a rule they are superior to beer or spirit; as regards discipline certainly so. 8. There is no spirit ration, and I cannot recommend one to be resorted to. No case has come under my knowledge of convalescents being allowed spirits. 9, 10. No good would result from prohibiting the sale of spirituous liquors. If the men are inclined to drink spirit, they will if it is unattainable in the military canteens, go to places outside the fort, where bad spirits are sold by natives, over whom the military authorities have no control. Indeed this nuisance is carried to such an extent that we have at present a native canteen inside the fort, and it is not in the power of the military authorities to prevent it, though it has been represented as a positive nuisance, involving a bad example to the soldiers of the garrison, and causing additional work in the shape of soldier policemen, to prevent one from entering it. 11. The military canteen regulations are as follows:—The canteen to be opened from 12 o'clock to 10 p.m. for the sale of wine and beer only. No liquor of any sort to leave the canteen without a pass; but married men are permitted a restricted quantity for home consumption. No soldier is allowed more than a bottle of beer or a pint of wine in the afternoon. From 5 p.m. (or after parade) till 8 p.m. arrack is also

References to Subjects and Queries.	Replies.
V. Intemperance—*cont.*	sold. No civilian is allowed liquor without a pass. The serjeant in charge of the canteen is held responsible for due order.
VI. Diet.	1. The ration of the Queen's British troops consists of 1 lb. bread, 1½ lbs. beef, 4 ozs. rice, 1½ oz. coffee, ¼ oz. tea, 1 oz. salt, and 1½ oz. sugar. Vegetables and other condiments or extra articles are purchased by the men themselves. These things are done in messes, which constitute a very superior diet to that which would be the result if they were cooked separately. The orderly officer of the day goes round the barracks with the view of examining the rations, and inquiring if the men have any complaints, and he is responsible to the commanding officer for the due performance of this duty. 2. There is not a complete ration at this station, including fruit and vegetables, but there is a stoppage of 1½*d.* a day from the men's pay for these articles. The men have three meals a day, viz., breakfast at a quarter to 8 a.m., dinner at 1 p.m., and tea at half-past 5 p.m. The whole stoppage daily from the men for messing is 5*d.* At breakfast they have coffee, bread, and ½ lb. meat fried; at dinner soup, made of beef and vegetables and bread. Tea consists of bread only, but most of them purchase milk for themselves, also eggs and fruits. The vegetables, for which the men themselves pay 1½*d.* a day, and which are made into soup for dinner, are generally in good quantity. 3. The ration the men get is very excellent, if vegetables were supplied by Government. The men are stout, active soldiers, and as a rule are in very strong health, and this is the best criterion that the ration is excellent in quality and sufficient in quantity. The men eat their meals in companies, and are all present at breakfast, dinner, and tea. They are not allowed to sell their rations, but they are permitted to exchange them for eggs, puddings, rice, and curry. 4. The cooking is performed by natives, who are supplied by the commissariat with the necessary utensils, viz., boilers, frying pans, saucepans, and pots of different descriptions. The kitchens are clean, well ventilated, and sufficiently supplied with water. The cooking is properly done, and there are no complaints among the men. Vegetables are supplied in good quantity, and tea and coffee are properly prepared for the men. They have coffee before a march. 5. The climate of this station is not suitable for gardening, as it requires much exposure to the sun, which is prejudicial to the health of European soldiers.
VII. Dress, Accoutrements, and Duties.	1. The soldiers' dress and accoutrements at this station are as follows, viz., forage cap with a peak and white calico cover, white calico shirt, jacket, and trousers made of white American drill, boots of the usual ammunition pattern, and socks, either worsted or cotton. On night duties the red shell jacket is worn; pouch-belt with a waist-belt, from which are suspended the smaller pouch and bayonet. The present dress is considered as suitable to the climate, and I have no suggestions to offer regarding it. The guard dress consists of white American drill trousers, with jacket of the same material. Men on guard have the protection of good substantial guard-houses with verandahs.
Duties.	1. It is advisable that men be drilled at home before being sent to India; but so far as regards their health it makes no difference. 2. The usual routine of the soldiers' duties here is as follows, viz., gun fire at 5 o'clock a.m.; morning parade at 6 a.m. till half-past; garrison fatigue bathing or drill without arms; roll-call at 10 a.m.; evening parade from 5 till half-past p.m.; drill with arms. On Saturday marching order. Mounting guard about every fifth day. Company fatigues few. The best time for drills and parades is between 6 and 7 a.m., and between 5 and 6 p.m., and for marches between 3 and 7 a.m. There are general orders respecting these. The average number of nights the men have in bed during the week is four or five. 3. All the guards, with the exception of the Cutcherry guard, which is about a mile from barracks, are within a few hundred yards of each other. Guards last 24 hours by day and night. There are two roll-calls by night, and by day two and sometimes three. The effect of night guards on the health of the troops is not prejudicial. No additional precautions are requisite at this station.
VIII. Instruction and Recreation.	1. We have no ball courts or skittle grounds at this station, but there are a school (with a schoolmaster), a library, and a reading-room, which are sufficiently lighted at night. The detachment of gun lascars has a small garden attached to their quarters, which the men manage themselves. The school-room is now and then converted into a theatre, which is managed by the detachment of the 50th regiment. The detachment of the rifles and that of the 50th regiment play at cricket twice a week on the esplanade. These means of recreation and instruction appear sufficient to keep the men employed off duty. European troops off duty are restricted as to exposure to sun and rain out of the green facing their barracks, which is planted with sooraroo trees. 2. I have no improvements to suggest. 3. Soldiers' savings banks are in existence, and they are advantageous. 4. There is sufficient shade from trees called sooraroo, which are planted before the men's barracks and all round the parade ground facing the barracks.
IX. Military Prisons.	1. The military prisons here are well ventilated and arranged, and no case of sickness has originated, since my arrival here, out of any defect in their construction.
X. Field Service.	1. There are no local regulations for field medical service not included in the General Regulations. 2. The practical working of the powers of the medical officers is harmonious enough. 3. No reply to this query. 4. The sick are generally transported in the "Pearl" steamer; but there are no special regulations bearing on these matters. The hospital supplies are conveyed in carts drawn by bullocks.

XI. Statistics of Sickness and Mortality.

The following table shows the strength of white and native troops for ten years, with total admissions and deaths for that period:—

White.		Native.	
1st year	96	1st year	163
2nd ,,	126	2nd ,,	88
3rd ,,	127	3rd ,,	65
4th ,,	126	4th ,,	75
5th ,,	116	5th ,,	92
6th ,,	117	6th ,,	99
7th ,,	123	7th ,,	103
8th ,,	127	8th ,,	129
9th ,,	109	9th ,,	163
10th ,,	100	10th ,,	189
	1,167		1,166
Total admissions	1,846	Total admissions	1,163
Total deaths	14	Total deaths	7

This is a remarkably small per-centage of deaths. Colonel Tulloch gives the proportion of deaths to strength at Ceylon as 23 per 1,000; but this is less than half that proportion.

XII. Hospitals.

1. Plans of the hospital are herewith transmitted.
2. The position of the hospital as regards the barracks is very convenient. It is within 100 yards of the European barracks, on its left, right, and rear, with the exception of the quarter occupied by the royal artillery, which is about 450 yards from the hospital. There are no cavalry stables at this station. The bazaar, properly so called, is outside of and about half a mile from the fort. The houses of the civil population inside the fort are close to the hospital. The site of the latter is open, freely ventilated, and decidedly healthy.
3. The water supply of the hospital is abundant and good.
4. The hospital is built on a point of land projecting towards the sea. The impurities, refuse water, &c. &c., are emptied at the extreme point, and the sea at high tide effectually removes them.
5. The ward, the only one in use, is built on the solid earth, with no perflation of air beneath it. The soil is generally dry, and the ward also, but the atmosphere is damp. This arises from the strong sea breezes which prevail. There is a broad drain which runs along the side of the hospital, into which the roof water empties itself. This only occupies two sides, and on the others the rain is absorbed into the earth. On one side of the hospital the surface drainage requires to be attended to, but on the other side it is sufficient. The walls of the hospital are built of coral stones laid in mortar, and the roof is a tiled one. The walls and roof are single. The floors of the rooms and verandah are paved with tiles. The verandah of the patient's ward is 7 feet 8 inches wide. It affords sufficient shelter from the sun's rays, and is not used for the accommodation of sick, convalescents, or others. The hospital consists of one flat.

Table of Hospital Accommodation.

Date of construction unknown. It is believed to have been originally built by the Dutch.

Total number of wards, 1.

Total regulation number of beds, 16.

Ward. No.	Regulation Number of Sick in Ward.	Dimensions of Ward.				Cubic Feet per Bed.	Superficial Area in Feet per Bed.	Height of Patient's Bed above the Floor.	Windows.		
		Length.	Breadth.	Height.	Cubic Contents.				Number.	Height.	Width.
		ft.	ft.	ft.	ft.	ft.	ft.	ft.			
1 - -	16	70	21	11	19,845	1,240	92	21	—	—	—

The hospital is placed so as to receive the full benefit of the prevailing winds. The front windows consist of a frame, to which are hung vertically, on pivots, venetianed shutters opening outwards. The back windows have not venetian shutters, but paneled ones, opening outwards. This arrangement is conducive to ventilation and coolness.

6. There are no artificial means of ventilation to the wards, the air being admitted through the doorways and windows, and when the doors are closed, by means of the venetian shutters above alluded to, this arrangement is sufficient to keep the wards free from closeness and odour. The jalousies consist of flat pieces of wood, half an inch in thickness, and three inches in breadth. The circular mortices are drilled in the shutter frames, into which circular tenons, projecting from either end of each flap, are let. They are opened by means of a wooden rod, passing down the centre of the jalousies, and fastened to each flap with a wire, and the rod is kept in position by means of a button at top and bottom.
7, 8. There are no artificial means used either for cooling or warming the air admitted into the wards. The hospital is cleansed and lime-washed twice a year, or whenever it is considered advisable, on the requisition of the medical officer.
9. There are no waterclosets. The privy is situated at a projecting point of the ramparts, overhanging the sea shore, and is kept well washed by the waves at high tide, and it may be stated that it is very little offensive.
10. The patients are supplied with china or earthenware washing basins, and there is a large bath tub, which is only used when specially ordered. The convalescents are allowed to

References to Subjects and Queries.	Replies.
XII. Hospitals—*cont.*	bathe in the sea occasionally, in charge of a non-commissioned officer. A bath-room is required. 11. For the men who are seriously ill the only means of bathing is a bath tub, which is used when ordered by the medical officer. The washing basins are supplied by the commissariat. 12. The washing and drying of the hospital linen is performed by the natives per contract. 13. The store-room is sufficiently large and dry, but is much infested with rats, which often do much damage. 14. The bedsteads are large sized (of iron), with sacking bottoms, and some of them are furnished with the power of being elevated to any required height. The beds are filled with coir, but rather scantily at times, and I should recommend a larger quantity than that ordinarily used. The rest of the bedding is good in every respect. The hospital kitchen is situated in a back yard, sufficiently convenient to the wards, but not so close as to be in any way an annoyance from smoke or other cause. It is rather dark, and not sufficiently ventilated. There are boilers, frying pans, and other means of cooking, but there is no convenience for baking or roasting, otherwise than in chatties, which is inconvenient and not an efficient means. 16. The diet tables, diet-rolls, &c. in use at this station are received from head-quarters, Colombo. The statistics of sickness, mortality, &c. are gathered from the annual sanitary returns of the station. 17. There are an acting hospital serjeant and one orderly to the European hospital. There are no nurses; but the two men are quite sufficient. 18. The sanitary condition of the hospital is such as to render any complaint unnecessary. No epidemic disease, hospital gangrene, or pyæmia, or any infectious malady has prevailed at any time in the wards. 19. There are really no suggestions required, except an additional drain along one side of the building, where at present the rain from the roof is absorbed into the ground at the base of the building. 20. The patients who are in the stage of convalescence have a broad verandah to walk in, which runs the whole length of the hospital. This, however, is barely sufficient, and of course a more extended means of exercise would be very advantageous. 21. Soldiers' wives and children are entitled to medical attendance and medicines. No further arrangements are made on this point; but I am of opinion that they should be entitled to medical comforts, such as wine, sago, milk, and other support, as the nature of their cases seem to require. At present there is always some difficulty in this respect. 22. There are no special local hospital regulations not included in the General Army Medical Regulations. 23. The medical officer has the power of suggesting improvements in everthing connected with the hospital. He can vary the diet, and has the power of giving such medical comforts as he may deem necessary. 24. There is no separate ward for convalescents. The hospital has generally been so little crowded that there has been no difficulty on this point; but should the hospital have its full complement of sick, a convalescent ward would be a great acquisition.
XIII. Burial of the Dead.	1, 2. The burial ground for British troops is outside the fort, and the wind generally blows from the fort over it, seldom indeed from the burial ground. The distance is at least a quarter of a mile from the fort, and no perceptible influence springs from it, such as to affect the garrison. Its area is about an acre. The ground slopes very much, and the greater part is kept drained. The soil is Cabook gravel and some black earth, and underneath rock. No means can I discover of ascertaining the rate of decomposition positively. The burial grounds are kept in good order. 3. The regulations for the interment of bodies are as follows:—The graves are generally 7 feet 3 inches, or 7 feet 4 inches in length, 3 feet or 4 feet in breadth, a space of about 2 feet being allowed between each. The graves have never been re-opened, the burial ground being only of recent adoption. The depth of graves is about six feet. The general practice with respect to the military interments may be stated thus:—If a man dies during the night, he is generally buried about 5 o'clock on the following evening; but if the disease is of an epidemic nature, or very infectious, interment takes place sooner. This refers to native as well as to European troops. 4. The graveyards are never offensive. The usual practice is for the burial to take place about 18 hours after the decease of the soldier, but this rule is not strictly adhered to; if the disease has been of an infectious or putrescent character, it is performed earlier. The distance between the fort and the burial ground of the natives is greater. 5, 6, 7. No injury accrues to the public health from the present mode of disposal of the dead, nor are there any suggestions to be made.

(Signed) Wm. C. Vanderspar, Major, C.R.R., Commandant.
F. R. Waring, Surgeon Major.
W. S. Boileau, Lt. R.E.

20th September 1860.

NEWERA ELLIA.

Accommodation—Queen's Troops—Infantry - 100.

References to Subjects and Queries.	Replies.
I. Topography.	1. The plain upon which the station of Newera Ellia is situated is surrounded on all sides by a mountainous country. The hills are covered with wood, and a dense forest intersected with ravines, which latter after a fall of rain are filled with water, envelopes the station. The plains upon which the cantonment is situated are swampy. 2. The elevation of the station above the sea is 6,200 feet, the adjacent country being on the same level. There is higher ground, called the "Horton Plains," about 20 miles distant, which is not subject to the continuous rains that fall in Newera Ellia during seven months of the year. The frosts, however, are more intense, and the air clearer, but there is not a plentiful supply of water near the plains. 3. The station is situate at the foot of a range of hills, without any table land near. Pedro-talagalla, the highest point in Ceylon, overhangs the plains, its summit being about two miles distant from the barracks. 4. The only water near the station is a small stream, which runs through it, and empties itself into the Mahawhilla Ganga. The vicinity is not liable to overflow at any season. There are several ravines running from the mountains above the station, but they have no injurious effect on health, being nearly dry during the fine season. 5. The station is freely exposed on all sides, and there is no impediment to free ventilation. The buildings in the cantonment are not exposed to reflected sun heat. The only two winds that blow over the station are the two monsoons, viz., the N.E. and the S.W., which are the only ones to which it is exposed. 6. The surrounding country is uncultivated, the cultivation of rice being prevented by the frosts. 7. A small native town, containing about 200 inhabitants, stands about a mile distant from the station. 8. The general surface of the soil of the district is black peat; the subsoil being either gravel or a species of soft cabook stone. There is no appearance of the ground having been occupied before the present station was formed. 9. There is always an abundance of water during the dry and rainy seasons, both from springs and small rivulets, which rise in the mountains over the station. 10. All the water, both from the rainfall and surface springs, is conducted by various streams into a small river, which, owing to the fall in the ground, carries off any quantity with great rapidity. No drainage from higher ground passes into the subsoil of the station, the drainage from the high lands being carried off by the ravines, which lead at once to the river. 11. The water supply of the station is derived partly from the river and partly from surface springs; none being stored in tanks. 12. The quantity of water at all seasons is unlimited, and its quality is good in every respect. 13, 14. No reply to these queries.
II. Climate.	1, 2. There are no instruments of any description for meteorological purposes. 3. The climate from the beginning of January to the middle of May is very dry; during the day the sun is powerful, but the nights are cold, the thermometer falling frequently below freezing point. For the remainder of the year the temperature, day and night, is much the same, the thermometer varying between 56° and 63° in the 24 hours. During this season few days pass without rain of a small drizzling kind, which sometimes lasts for weeks without intermission, accompanied by a dense fog. The climate is considered healthy for Europeans, as it has been selected as the sanitarium of the island; it is not, however, favourable for dysentery or acute disease of the lungs; in other cases the cool air has a very bracing effect on the constitutions of invalids sent from the low country. A portion of the men are employed by the Royal Engineer Department in keeping the buildings, &c., in repair, and they are able to work during any part of the day without injury to their health. There is no difference in the salubrity of the station during the wet or dry seasons, nor are there any diseases, except chronic cases sent here from the low country. 4. There is no district near the station the climate of which is more conducive to health than that of the station. 5. No reply to this query.
III. Sanitary Condition of the Station.	1, 2, 3, 4. Table of Barrack Accommodation. Total number of rooms, 2. Total regulation number of non-commissioned officers and men, 100.

Barrack-Rooms.	Regulation Number of Men in each Room.	Dimensions of Rooms.				Cubic Feet per Man.	Superficial Area in Feet per Man of Floor Space.	Height of Men's Beds above the Floor.	Windows.

References to Subjects and Queries.	Replies.
III. Sanitary Condition of the Station—*cont.*	5. The windows are on opposite sides, and open in two pieces on hinges. There are no verandahs to the barracks, nor any jalousies or jhilmils. 6. Wooden cots are in use in the barracks, the mattresses and pillows for which are filled with loose coir. Iron bedsteads would be much preferable, as they would not harbour the fleas, which abound at the station, so much as the wooden cots. 7. No reply to this query. 8. The ventilation is kept up principally by means of the windows, but there are holes in the walls beneath the floor boards, which admit a current of air. The ventilation is sufficient to keep the air pure night and day. 9. The barracks are built of stone and roofed with felt. 10. The floors are of plank raised about 2½ feet from the ground, and have always a free current of air under them, introduced by ventilators in the walls. 11. The materials used in the construction of the barracks are quite suitable in a sanitary point of view. The barracks are kept in repair by the Royal Engineer Department, but from want of labour are not executed with any rapidity. The walls are coloured about once every year. 12. No reply to this query. 13. There is no washing carried on in the barracks. 14. The contents of the privies, which are collected in cesspools, are emptied from time to time as required, and buried at some distance from the barracks. 15. The barracks are lighted at night by four lamps in each room, which, however, give a very indifferent light. 16. There are no sewers ; the barracks are drained by gutters on the surface, the contents of which fall, after traversing about 10 yards, into a small brook, which has always a certain amount of fresh water in it ; the drainage is quite sufficient for all purposes. No part of any of the buildings is damp. There are no foul ditches. 17, 18. There are no old walls, hedges, or other obstructions to interfere with the ventilation of the station. 19. The bazaar is generally clean, with plenty of water flowing through it. The general condition of the native houses near the station is very filthy. No nuisance is experienced in barracks from wind blowing over the native houses. 20. Animals are slaughtered more than a mile from the station by a contractor, and no nuisance whatever is experienced from the condition of the slaughtering places. 21, 22. No reply to these queries. 23. The married men at the station are provided with separate accommodation.
Officers' Quarters.	1. The sanitary condition of the officers' houses is good.
IV. HEALTH OF THE TROOP	1, 2. The station, district, and adjoining population are very healthy, the prevailing disease with the latter being bowel complaints. 3. No reply to this query. 4. The troops at the station are composed of invalids from all parts of the island. No part of the men's present accommodation is more unhealthy than the rest. 5. The troops at the station are never camped out. 6 to 24. No reply to these queries.
Diseases.	1. There are inspection parades for the discovery of incipient diseases once a week. 2. There has been no scorbutus among the troops. 3. No hepatic disease occurs at this station. There are sometimes a few chronic cases sent from the low country for change of air. 4. No case of dracunculus has occurred at the station. 5. Venereal disease is of very rare occurrence here. 6. There are occasionally cases of dysentery and rheumatism among the troops ; the proportion of admissions from these diseases to total admissions,—between the 1st January and the 30th September 1860,—being 7 in 26, and that of deaths to total admissions during the same period, being 2 in 26. 7. Dysentery is the only zymotic disease, and occurs generally during the wet season ; but there is nothing peculiar in the atmospheric conditions which precede or accompany its appearance. 8. There is no epidemic disease at the station. 9. Small doses of quinine have not been tried as a prophylactic against malaria diseases. 10. No reply to this query.
V. INTEMPERANCE.	1. Intemperance is not greater here than at other stations in the island. There are no confirmed drunkards. 2. From the 1st January 1860 to the 30th September there have been altogether 26 admissions into hospital, and out of this number two cases have been directly from intemperance, but none indirectly. Drunkenness is always punished as an offence. 3. Distilled spirits are sold at the canteen, but the probable amount consumed by each man cannot be ascertained. Spirit is part of the ration at the station, but not on the march. One gill of arrack is issued daily at the dinner hour. It is never given to convalescents. No drinks other than intoxicating drinks are sold in the canteen or bazaar which are injurious to health. 4. The amount of spirit consumed by the men does not appear to have any injurious effect on their health. 5. If the sale of spirits was abolished in the military canteen, it would drive the men to the native arrack shops, where they would obtain a very injurious kind of spirit. 6. If malt liquor could be obtained at a reasonable price by the men, it would be much more beneficial than spirits. 7. Coffee, tea, lemonade, &c. are not much used at the station. 8. If beer could be substituted for spirits as a ration, it would be much better for the men. 9. It would not be beneficial to prohibit the sale of spirituous liquors in the canteens, and to permit only beer, coffee, &c., to be sold to the troops, because those men who prefer spirits to malt liquor would be driven to the native arrack shops. 10, 11. No reply to these queries.

References to Subjects and Queries.	Replies.
VI. Diet.	1. The soldiers' ration consists of fresh meat, 1½ lb., or salt meat, 1 lb.; bread, 1 lb., or biscuit, ¾ lb.; rice, 4 oz.; sugar, 1½ oz.; tea, ¼ oz., or coffee, 1½ oz. The ration is inspected by the officer commanding the detachment, or the surgeon. 2. Vegetables are paid for by the soldiers themselves, in addition to the stoppage for rations, which is 3½*d.*; they do not form part of the rations. The men have breakfast at 7½ a.m., which consists of ½ lb. of meat, tea or coffee, and bread. Dinner at 12 o'clock, consisting of 1 lb. meat, bread, rice, and vegetables. Supper is at 5½ p.m., at which the remainder of the bread and either tea or coffee are then taken. The quantity of vegetables bought daily is about 1½ lb. of either potatoes or cabbages for each man. 3. The ration is good and sufficient. It cannot be disposed of, at least not in an uncooked state, as the whole of the ration is handed over to the cook by the orderly corporal, who sees that the whole is returned when dressed. 4. There is an open fire-place with boilers and frying-pans for cooking the food. The kitchen is light, well ventilated, with plenty of water near. The food is boiled, baked, or fried, and is cooked in a satisfactory manner. Coffee is always taken before a march. 5. The men are at liberty to cultivate any portion of the ground in the vicinity of the barracks, and a great many gardens are in cultivation, filled with potatoes and the ordinary vegetables grown in England.
VII. Dress, Accoutrements, and Duties.	1. The dress and accoutrements of the soldiers are the same as those in use on home service, and are quite suitable to the climate at all seasons. The guard dress is exactly the same as that used on home service. The sentry is protected by a wide verandah in front of the guard-room.
Duties.	1, 2. The men at this station are either invalids sent from the low country for the benefit of their health, or artificers sent up for the purpose of building and keeping in repair the military buildings. The drill is only occasional, and takes place in the early morning. The climate will permit of drills, parades, and marches at any hour of the day without injury to the health of the men. The average number of nights the men have in bed during the week is four. 3. There is only one guard mounted, which is about 50 yards from the barrack-room, and is relieved every 24 hours. There is a roll-call three times a day, but none after 9 p.m. The night guard does not affect the health of the men.
VIII. Instruction and Recreation.	1. There is no ball court, and only a skittle ground at this station and a library, but no light is allowed at night. Soldiers are at liberty to cultivate any portion of the military reserve in the vicinity of the barracks, of which privilege about one half of the detachment avail themselves. The means are not sufficient to occupy the men, and some additional recreation is required during the wet season. No restriction is placed on the men with regard to exposure to the sun and rain when off duty. 2. A covered ball court would be the best additional means of recreation. 3, 4. No reply to these queries.
IX. Military Prisons.	1. The cells at this station have been built so far from the other barrack buildings that they are quite useless.
X. Field Service. XI. Statistics of Sickness and Mortality.	No information under these heads.
XII. Hospitals.	1, 2. The hospital was destroyed by fire a few months ago. One of the barrack-rooms is used as a hospital till a new one can be built. 3 to 13. No reply to these queries. 14. Iron bedsteads are used. The mattresses are stuffed with loose coir and the pillows with cotton. The bedding consists of blankets, sheets, and bed covers. 15. No reply to this query. 16. The diet tables and returns in use are those laid down in the Medical Regulations of the year 1859. 17. One hospital corporal, a private as orderly and another as cook, is the attendance provided for the sick, and is quite sufficient for the number of patients usually in hospital. 18, 19. The sanitary condition of the hospital is good, and no epidemic has occurred therein. No deficiencies are recorded. 20. No provision is made for the exercise of convalescents. 21. Soldiers' wives and children are treated in their own quarters. The present arrangements are merely temporary. 22. There are no special local hospital regulations not included in the General Army Medical Regulations. 23. The medical officer has the sole management of the sanitary matters connected with the hospital, as also of the diet and medical comforts. 24. There is no convalescent ward or hospital at the station, and none is required.
XIII. Burial of the Dead.	1 to 4. The dead of the British troops are buried in the church-yard, which is nearly a mile from the barracks, without particular regulation as to graves, &c., but the graves are made about 6 feet deep, and are usually about 4 feet apart from each other. 5, 6. The dead of camp followers or bazaar people are buried in a piece of ground outside the bazaar. No injury accrues from the present practice.
