DAVIDSON'S

PATENT

"SIROCCO"

TEA DRIERS.

OVER 1,900 NOW IN USE!

The natural Up-Draft or T "Siroccos" dry tea with a self-acting current of hot Pure Air, neither fan nor air chimney being required to create the air draft, which is produced entirely by the action of the "Sirocco" Stove, wherein any description of fuel may be used—wood, coal, patent compressed coal, bamboo, eknr, grass, &c.

The tea leaf is exposed on wire-web trays to the action of the hot air. The trays are arranged in superimposed order, in sets of four, with by-pass spaces on two sides of each tray to allow a portion of the fresh hot air to reach the upper trays, at its initial temperature, without passing through the lower ones, whereby a brisk drying heat is maintained on the top trays, and promptly arrests fermentation in the damp leaf when freshly put in. The natural Up-Draft "Siroccos" are now made for the trays either to pass through the drying chamber one in front of the other, like a continuous web on slides—and which form of the apparatus is designated the End-slide—or for the trays to work as individual drawers through separate openings for each tray in the side of the drying chamber, and this arrangement of the apparatus is defined as the Side-drawer.

Working with this natural up-draft of air at a temperature of 240° F. the tea is dried in twenty-five to thirty minutes.

The waste hot air from the apparatus when in work is useful for withering green leaf, when the leaf rooms are suitably arranged for this purpose on the upper floor of the tea house.

The natural Up-draft "Sirocco" can also be worked with the direct heat from a Coke or Charcoal fire, the hot gases from which are mixed with a sufficiency of cold air to produce a proper temperature for tea drying.

The difference between the Pure Air "Sirocco" and the Coke "Sirocco" is altogether in the stove, which for the latter is of brickwork, with the requisite iron fittings for the fire-place and air-ports built in.

It is generally considered that hot Pure Air produces a finer flavour in tea than air impregnated with fumes from coke or charcoal, and in this respect the Coke "Sirocco" is relatively less perfect for drying tea than the Pure Air "Sirocco," but this is the only disadvantage which has to be set against its cheaper cost price.

THE PURE AIR T "SIROCCOS" AND COKE "SIROCCOS" ARE MADE IN SEVERAL SIZES, PRICE AND CAPACITY OF EACH AS UNDER:—

SIZE OF "SIROCCO."	OUTTURN OF TEA PER HOUR	PURE AIR "SIROCCO."	COKE "SIROCCO."

THE NEW PATENT "DOWN-DRAFT SIROCCO"

Dries tea leaf in eight minutes, with a very strong "down-draft" of pure hot air at 240° F. through the tea, at which temperature this very rapid rate of drying produces the highest quality of tea obtainable from the leaf used.

A powerful suction fan draws the air through the tea with a speed and force equal to that of a high gale of wind, and the operating principle and construction of the "Down-draft Sirocco" are such that notwithstanding the great strength of this air-blast, the tea does not get disturbed, or whirled about on the trays when in the Drying Chamber, nor blown off them when being inserted or withdrawn through the tray-ports.

The leaf is exposed to the hot air on wire-web trays, eight of which fill the Drying Chamber. Each tray with the damp leaf is put in through the lower, or inlet tray-port, and an easily worked and strongly constructed mechanical lift moves all the trays upwards to the outlet port, where the finished tea is withdrawn.

One movement of a hand-lever works the lift, and simultaneously opens or closes the door of the inlet tray-port, and inversely operates the throttle valve of the fan, whereby when the tray-port door is open, the fan valve is closed, and *vice versa*. By this arrangement the trays can be inserted in calm air; but when the tray-port door is closed again the fan acts on the trays with its full suction power.

Any of the damp leaf which may drop through the meshes of the lowest tray falls direct upon the cool floor of the Drying Chamber, from whence it can be removed occasionally, through the basement door, and any fine tea that falls from the trays above is caught by and carried up on the succeeding trays. One man is sufficient to attend the apparatus with the assistance of a boy to prepare and spread the leaf on the trays, a fresh one of which is required every minute, and as the leaf passes through so quickly, it requires no turning or attention until it reaches the upper tray-port.

The "Down-draft Sirocco" dries about 1½ maunds of tea per hour, and final fires for packing about 5 maunds of whole leaf teas, or 3 maunds of broken teas per hour.

The Apparatus works on ground level, neither pit nor platform being required, and when set upon a layer of tiles or bricks, it can be worked as safely on a loft as on a ground floor. If worked on a loft, the fan can be driven by a belt through the floor. A short belt is sufficient, as less than half-horse power drives the fan at the necessary speed.

The air is heated by our Patent "Sirocco" Stove, which, with latest improvements, is now very durable. Any fuel may be used, and considerably less than one maund of dry wood, or about one-third maund of good coal, will dry one maund of tea.

The Apparatus is easily erected, and can be put together in about an hour, as the principal working parts are sent in made-up sections, and merely require to be bolted together to form the complete machine, which, when erected, occupies a floor-space of only 5 feet, and its extreme height is under 8 feet.

Price of "Down-draft Sirocco" is £120, complete, with fan, 10 trays, stove, smoke chimney, thermometer, etc., inclusive of packing and delivery f. o. b. the outward steamer at Glasgow or Liverpool. Terms—Cash against documents.

Orders will be telegraphed from abroad, free of charge, by our Agents for sale, as noted below.

BETTS' PATENT IMPROVED INCORRODIBLE TEA LEAD.

BRAND.

BRAND.

This article will be found greatly superior to the ordinary Rolled Lead, combining advantages as an hermetic metallic envelope for Tea.

The *Tin* surface prevents oxidation or change of color from the effects of climate, and with the Body of Metal beneath forms a kind of Solder when in contact with the Soldering Iron, which materially assists the workmen in securing an air-tight seam or joint. The Metal is pliable, tough, exceedingly close in grain, and free from holes.

PRINTED AT THE "CEYLON OBSERVER" PRESS: COLOMBO, CEYLON: 1889.

TO OUR READERS.

In closing the Eighth Volume of the "**Tropical Agriculturist**," we would once more direct attention to the large amount of useful information afforded, and to the great variety of topics treated in our pages. From month to month, we have endeavoured to embody in our pages the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, beside being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have always taken care to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of commonsense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

The official Reports on the Royal Botanic and Economic Gardens in Ceylon are republished in full in the present volume, and throughout our pages will be found reviews of, and extracts from, the Reports of other Botanic Gardens situated in or near the tropics. We are ready to give copious extracts from, if not to reprint *in extenso*, the Reports of all other sub-tropical Public Botanic Gardens which may reach us. Most of these Reports we already receive and utilize as abovementioned for the benefit of our planting readers.

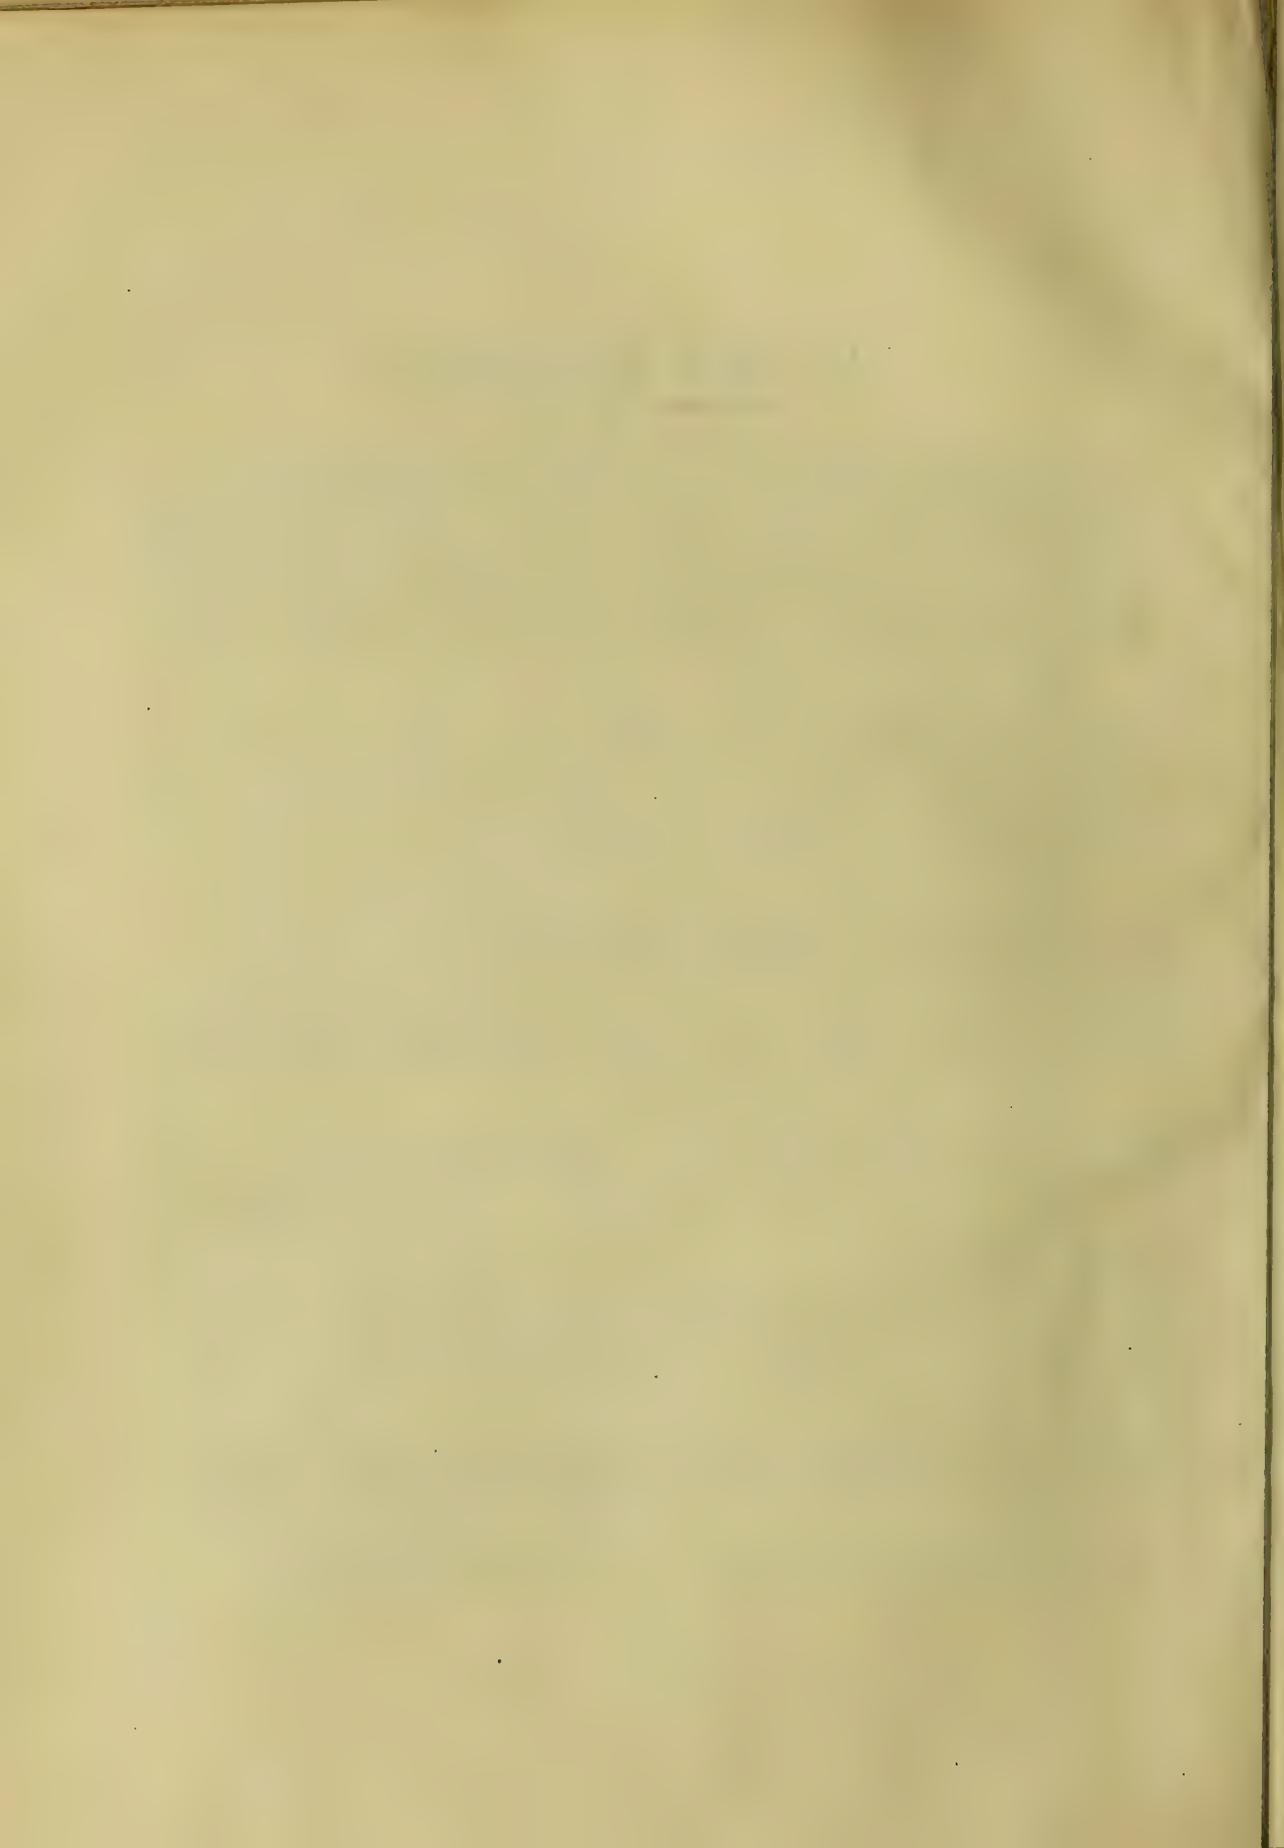

A full and accurate Index affords the means of ready reference to every subject treated in this, the eighth volume, which we now place in our subscribers' hands, in full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

We are convinced that no more suitable or useful gift can be made to the tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the eight volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industry.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval: for then, indeed, must the "**Tropical Agriculturist**" continue to do well.

A. M. & J. FERGUSON.

COLOMBO, CEYLON: 1st June 1889.

COLOMBO, JULY 2ND, 1888.

[No. 1.]

THE FUEL QUESTION IN CONNECTION
WITH TEA CULTURE: PROGRESS IN
THE USE OF PETROLEUM.

The following paragraph appears in the London *Globe* of May 4th:—

"PETROLEUM AS A SUBSTITUTE FOR COAL.—The sittings of the ordinary general meeting of the Institution of Mechanical Engineers were resumed this afternoon at the Institute of Civil Engineers, 25, Great George-street, Westminster, Mr. Edward H. Carbut, president, occupying the chair. —A paper was read by Mr. Thomas Urquhart, locomotive superintendent of the Grazi and Tsaritsin Railway, South-Eastern Russia, on 'The Use of Petroleum Refuse as Fuel in Locomotive Engines.' He stated that since November, 1884, the 143 locomotives under his superintendence had been fired with petroleum refuse, besides 50 stationary boilers, two brass melting and other furnaces. Petroleum was, in fact, the fuel used for all steam-generating purposes to the complete exclusion of all solid fuel except a very small quantity of wood for starting the fires in horizontal boilers of pumping engines. For all metallurgical operations also at the central works petroleum was used as fuel except for the smiths' fires and the foundry cupolas and it was thought that the present difficulties in its application to these two remaining exceptions would be overcome. With a locomotive in first-class order and in the hands of a skilful driver 50 tons of petroleum refuse were equal to 100 tons of first-class coal, while in special trains this ratio had even been exceeded. Now that petroleum seemed destined to occupy a prominent place in India, as well as in many other parts of the world, its value as a lubricant, as well as its use as fuel, was of especial interest to engineers.—A discussion followed."

The information thus conveyed is interesting to us, because while it is not very likely that petroleum fuel could ever be prepared so as to render it suitable for use in tea factories, yet if it comes to be employed on our railways, in the brewery and in the projected cotton factory, that would help tea planters greatly by lessening the pressure on the limited available supply of wood fuel. The cost of bringing petroleum fuel to Colombo might seem a strong objection, but from the fact stated by Mr. Urquhart that the refuse from the Baku wells yields double the force derived from coal, and, therefore, probably twice that given by wood fuel

On our railways, therefore, an experiment ought at once to be instituted. We shall be anxious to see the paper in detail, and meanwhile we may glance at a few points in a paper read and discussed at a meeting of the Society of Engineers in November 1886. It was prepared by Mr. Percy F. Tarbutt, who had, in the estimation of the able President, Mr. Perry F. Nursey, been largely successful in adapting marine steam engines and furnaces for the use of liquid fuel. That is scarcely the term to employ, however, for our readers will be interested to learn that the Russian petroleum wells, which are now supplying Colombo so largely with oil for lighting purposes, differ essentially from those in America, by yielding 75 per cent of thick residual stuff suitable for fuel against 25 per cent in the case of the North American borings. Mr. Tarbutt, in the course of his paper, said:—

"The quality of the crude oil in different localities varies greatly; the Pennsylvania petroleum yields about 75 per cent. of lamp oil and 25 per cent. of heavy oil suitable for fuel, whilst at Baku, on the Caspian, the proportions are reversed, only 25 per cent. being obtainable as lamp oil, and 75 per cent as residue. The petroleum now being worked at Sibi in Beloochistan, contains scarcely any lamp oil, and is suitable only for fuel. The second source of liquid fuel is derived from the distillation of coal. From the gasworks of the United Kingdom alone there is now an annual production of tar amounting to about 115,000,000 gallons, and this is increasing at the rate of from 5 to 7 per cent. per annum. The employment of tar and its products in the arts has been decreasing for some years, and unless some new commercial products in it, or applications of it, are discovered, there seems every prospect of its continuing to decrease. Tar and the green oils and creosotes obtained from the refineries are not substances which can be stored with ease or without expense, and consequently any profitable method of utilising the surplus production is of importance, even in countries where coal is cheap and plentiful, as is the case in England. Other sources of present supply of liquid fuel are coke ovens, shale oil works, and blast-furnaces in which the adoption of systems for obtaining the bye-products (including creosote oil) is increasing. The author has not yet had any opportunity of studying the question of the supply which will be obtainable from the immense shale deposits of the south of England; but according to Admiral Selwyn, who has given many years' attention to this subject, a practically inexhaustible supply of cheap oil may be obtained from this source when it is needed."

Admiral Selwyn, above referred to, took an active part in the discussion which followed the reading of Mr. Tarbutt's paper, and indicated his belief in the use of oil fuel even in war ships, but he naturally objected to the British navy being dependent on foreign nations for a supply of such fuel, and advocated the use instead of the products

of the shales which are so plentiful in many parts of Britain. Whether it be natural oil from wells bored in the earth, or oil distilled from shales which is used, anything which will lessen the run on coal and wood fuel will be in favour of the tea planters of Ceylon. Here in Ceylon we are not so favoured as some of our brethren and competitors in India and China are. In both countries constant discoveries are being made of coal, a mineral which, it is about as certain as anything can be, does not exist in Ceylon. It seems from the paper read by Mr. Tarbutt that over and over again machinery for consuming oil fuel, tar and other residual matter was invented and employed, but laid aside with much loss to its projectors, in consequence of an immediate and large increase in the price of the oils, tar, &c., the moment a demand for them set in. But apart from tar and the product of shales, the discoveries of natural oil of various qualities in America, Batoum, Burma, India, and many other places have been so numerous and the supplies on so large a scale, that we are not surprised to hear of great progress made in the use of petroleum oil or its residuum for furnaces on shore and afloat, in lieu of coal. This wonderful mineral has merits of its own which will secure its being largely used, but what we desire to see is, so large a use of substitutes as will prevent a rise in the price of coal and not merely avert increased cost in the case of wood fuel but the danger of the exhaustion of supplies within easy reach of our tea factories. While on this subject we may ask if anthracite coal would not be a good fuel for tea factories if it could be laid down cheaply enough? It is largely a natural coke. At the opposite extreme is the lignite we recently mentioned as likely to reach us from Siam and about which we hope soon to hear further. The cost of transport to any great distance is the great difficulty, and if, as we were told, it may be possible to lay down from Siam at Colombo good quality lignite, fit for use in tea factories at R5 per ton, our fuel difficulties will very largely disappear. Meantime we cannot but watch with interest the enormous stores of liquid fuel, ready as distilled by natural action, which this old globe of ours is constantly revealing for the supply of light and warmth and force, as well as the progress of inventions whereby liquid fuel is used instead of solid blocks of coal or pieces of wood. In the United States there are already 9,000 miles of "oleoducts" (pipes for conveying petroleum), and a pipe is to be laid down between the oil wells on the Caspian and the Black Sea, which is to be 600 miles long (from Baku to Poti or Batoum), the estimated cost being two millions sterling. Our readers may be surprised to hear how much of the effect of coal is lost each time a furnace is charged with cold material, and how great the superiority of petroleum oil is in this respect and others of importance. The case was thus stated in Mr. Tarbutt's paper:—

"Turning from the sources of supply to the relative values of liquid fuel as compared with coal, we find in studying their theoretical evaporative values that the heat-producing constituents of different oils vary almost as much as those of different descriptions of coals, and it is therefore only possible (without going into a labyrinth of figures) to take a standard in either case, which shall approximate as nearly as possible to the average composition of the two fuels. The average composition of English, Welsh and Scotch coal is then about 80 per cent. carbon, 5 per cent. hydrogen, 8 per cent. oxygen, the remaining 7 per cent. being nitrogen, sulphur, and ash, which for the purposes of this comparison may be disregarded. The average of the liquid hydrocarbons available as fuel may be taken at 87 per cent. carbon.

12 per cent. hydrogen, and 1 per cent. oxygen. The total quantity of heat evolved by the combustion of fuel is of course equal to the sum of the heating powers of its elements, except that when oxygen is present a deduction must be made for the equivalent constituent of hydrogen neutralised by it. The heat evolved by the combustion of 1 lb. of carbon is 14,500 English units, and by 1 lb. of hydrogen 62,000 English units, or about 4½ times as much.

"Now in the case of coal a great part of the hydrogen is neutralised by the oxygen, being in fact present in the fuel in the form of water, whereas in liquid fuel nearly the whole of the hydrogen is uncombined with oxygen, and is therefore available for combustion; and it is to this fact that its higher theoretical evaporative value is mainly due. The value of the two fuels is then as follows:—

	English Units.	Lb. of water evaporated per lb. of fuel at and from 212 degrees Fahr.
Average coal ...	14,000	14'48
Average liquid fuel	20,000	20'7

In practice, however, other circumstances in connection with the methods of combustion of the two fuels considerably increase the theoretical difference between them. The hydrocarbons in coal, being in the solid state absorb a considerable amount of heat in volatilising, and, in the ordinary method of hand stoking, each time fresh coal is required a large excess of air must necessarily be admitted to the furnace, which has the effect of cooling it down at the very moment when the greatest heat is required. Mr. D. K. Clark gives the following description of what occurs in the furnace when freshly stoked:—"A charge of fresh coal thrown on the furnace in an active state, so far from augmenting the general temperature, becomes at once an absorbent of it, and the source of the volatilisation of the bituminous portion of the coal—in a word, of the generation of the gas. Now, volatilisation is the most cooling process of nature, by reason of the quantity of heat which is directly converted from the sensible to the latent state. So long as any of the bituminous constituents remain to be evolved from any atom or division of the coal, its solid or carbonaceous part remains black, at a comparatively low temperature, and utterly inoperative as a heating body. In other words, the carbonaceous part has to wait its turn for that heat which is essential to its own combustion, and in its own particular way. If its bituminous part be not consumed and turned to account it would have been better had it not existed in the coal, as such heat would in that case have been saved and become available for the business of furnace. To this circumstance may be attributed the alleged comparatively greater heating properties of coke or anthracite over bituminous coal."

"In an ordinary coal furnace the temperature is subjected to frequent and extreme variations. The generation of gas is greatest when the furnace is first charged, and therefore at its lowest temperature, and the quantity of air required for the perfect combustion of the fuel (which is constantly varying as the conditions of the charge vary) is not practically ascertainable, nor is it under control. The consequence is that one of two evils is constantly at work—either too much air is being admitted, causing smoke and carrying off both fuel and heat up the chimney, or else there is not enough air passing through the charge to convert the carbon into carbonic acid, resulting in the production of large volumes of carbonic oxide, which escape unconsumed producing only 4,325 units of heat per lb. of carbon instead of 14,500 units, which would be obtained were the combustion of the carbon completed. A proof of the wasteful manner in which coal is generally consumed by steam users was obtained during the investigations made by the corporation of Birmingham about two years ago, when a proposition was before them for laying power mains through their streets. Non-condensing engines of good type work with 2½ lb. of coal per gross horse-power per hour, but it was found on indicating six engines of this class in Birmingham, taken incidentally, and

ranging from 5 horse-power to 30 horse-power, that the average consumption was 18½ lb. per horse-power per hour, the highest being 27½ lb. and the lowest 9½ lb.

"Now, in firing with liquid fuel, the supply of fuel to the furnace being constant, and the fuel itself being homogeneous—that is to say, not consisting of volatile and non-volatile portions, as is the case with coal—the supply of air required is constant also, and the right amount is readily ascertainable by observing the chimney and so regulating the air inlets as to allow a thin transparent smoke to be evolved. If there is no smoke, too much air may be passing, and carbonic oxide may be escaping; if, on the other hand, there is not enough air, the thick volumes of smoke given off indicate the fact in an unmistakable manner. With these advantages, it is not surprising to find that when properly consumed liquid fuel yields in practice a higher proportion of its theoretical value than coal. The author has carried out a great number of trials with various classes of liquid fuels in different kinds of furnaces during the last two years, and has now some fifty furnaces working on his system in this country. The system has been successfully applied to marine, locomotive, Cornish, Lancashire, and vertical boilers, with and without cross tubes, and to vertical boilers with Field tubes, to gas retorts, tar stills, steam superheaters, and brass melting furnaces, the average duty performed by the liquid fuel employed being from one and a half to two and a half times that of coal."

No wonder if the President and others, in view of such facts, predicted a great future for oil fuel. From the very comprehensive and interesting observations of Admiral Selwyn we must give an extract:—

"He believed that the first person to use jets of any kind for liquid fuel was a certain Major Schapowski in Russia; but his patent was simply a table apparatus, and he had never carried out the operation on a large scale. The first persons, according to his knowledge, who had used the jet in a form in which it was really a success were Messrs. Wise, Field, and Aydon. He believed that the next person was a Mr. Crow. Mr. Crow used one pipe over the other, one carrying steam and the other carrying oil. This apparatus had been in use ever since 1871, at the establishment of Messrs. Johnson and Matthey, the great metallurgists in Hatton Garden. By means of it they were able to melt platinum like lead. The next person who made an improvement was Mr. Donald, of the firm of Donald and Miller, chemical manufacturers, of Glasgow. This firm introduced the fire-brick furnace which was an absolute necessity for the thorough burning of the hydrogen of the steam, which required a temperature of 4,000° Fabr. The question of the production of oil in the country was of the greatest importance. Shale existed in this country in greater quantities than coal had ever been found. It existed right across England in beds 650 feet thick, and in some cases 1,100 feet thick, and it lay close to the surface. The development of a sufficient supply of oil to take the place of coal for the commercial marine would, however, be a slow affair. He proposed to turn his whole attention to the obtaining of English oil, so that everybody might rely upon being able to obtain a sufficient quantity, and until this was done he would not allow his apparatus to be used."

Admiral Selwyn takes the patriotic view of the question, but commerce is cosmopolitan, and will not reject foreign oil while the distillation of our home supplies is delayed. Again:—

"Admiral Selwyn said that there had been an experience of twenty years of the use of oil in every kind of boiler, and in no case had any damage been done to the boilers. The matter was one of constant experience, and not at all one of theory. For ten years the Russians had been running their ships across the Caspian and Black Sea, with oil fuel, and they all said that they would never go back again to coal. They used a much lighter class of oil than we had in England, and the results showed that the oil fuel was only one-fourth the cost of coal, when space and weight saved, as well as other minor consequences, were taken into account.

"Mr. Mackie said that for about two years past he had seen the experiments which were carried out in London by Admiral Selwyn, and he could confirm what had been said as to the perfect combustion which had been obtained. Rock oil and other liquid fuels required a philosophical mode of stoking. The rough method of throwing on the fuel, which was common in the case of coal, was not suitable for oil. There was no doubt that there was a quantity of shale in this country which would yield rock oil. There was no reason to doubt, either on account of the supply of oil, the perfection of the combustion, or the results obtained, that liquid fuel would be the fuel of the future."

Mr. Tarbutt, in his reply, said:—

"Steam was certainly the most handy way of diffusing oil into the furnace in the state of spray; but unfortunately in the case of sea-going vessels, in which salt water had to be used to replace the steam so employed, there would be a danger of salting up the boilers. It was for that reason that he preferred the use of heated compressed air. He had been delighted with Admiral Selwyn's remarks as to the amount of oil which could be produced from the shale deposits in England. He was sure that Admiral Selwyn must be right in what he stated, as he had given much study to the subject, and that the oil would become available when it was required. He had had some experience in the use of tar for firing gas retorts. At some works the tar could not be sold for more than 8s a ton, and as it would do double the work of the same weight of coal, that would be equivalent to getting coal at 1s 6d a ton, which, he thought, was a desideratum.

"No doubt England owed her greatness to the fact of her iron deposits and her coal deposits being near to one another; but if liquid fuel was coming to the front it was of no use for Englishmen to bury their eyes in the sand, and say that oil was of no use because they had got coal. If shipowners could not run their ships at remunerative rates with coal, engineers must look beyond the selfish question, and see whether they could not make both ends meet by means of liquid fuel."

The President, in closing the discussion, dwelt on the importance of the large supplies of oil and residual matters becoming available in our own and other countries, but he evidently believes that coal has not yet shown all it can do, for he said:—

"Science was progressive, and means would doubtless be found for using coal to increasingly greater advantage. In the Engert boiler the coal was being used under a new set of conditions. So, he took it, it would be with liquid fuel, just as indeed it had been with gas. The more scientifically perfect the conditions the better would be the result, and although theoretically a fuel might only have a given value, yet practically by extraneous aids it might be made to give a higher result than that for which theory would be responsible."

Whether more oil is used or less coal is required for the production of the vast amount of force needful for the world's work, we who use wood fuel until we can get lignite or coal at prices which we can afford must benefit as science progresses in the direction indicated by Mr. Nursey. We submit that it is the duty of the Ceylon authorities, now that petroleum is abundant in the colony, to institute experiments with reference to the use of this substance instead of coal and wood in the furnaces of the railway and the Government Factory. The Gas Company might also find it worth while to try experiments with petroleum refuse.

SNIFE SHOOTING IN CEYLON.

(*Daily's Magazine* for April.)

If the question were put to a meeting of Ceylon sportsmen—"What do you consider to be the best shooting in the island?" the answer would be almost unanimously, "Snipe."

Not the most dangerous, certainly, nor perhaps the most exciting, but taken all round, undoubtedly the best.

An universal favorite, his arrival in September or October creates at the clubs, in the mess-rooms—everywhere, the greatest delight. "Snipe are in; Brown got four couple yesterday," some one says; then follows a lot of eager, questioning as to the how and the where of Brown's luck, on which points it is not wholly improbable that Brown, with an eye to another quiet morning to himself, on the same ground, will give evasive, if not misleading, replies.

What a thoroughbred, game-looking little rascal the snipe is! The smooth round little head, the bead of an eye, the graceful shape and elegant markings on the back and wings, all stamp him a little aristocrat among birds. Good to look at; good to shoot at, and good to eat! he has all these excellent qualities, and deserves from all sportsmen the highest commendation.

He comes in to the island in small numbers about the middle of September, and is "well in" about the end of November, and is to be found up to the end of April. On one occasion I made a fine bag of twenty-two couple of snipe on the 4th of May, but this was exceptionally late for them to remain with us.

Snipe are ubiquitous in the island; occasionally some pretty shooting may be had quite close to Colombo: and the sea-side railway running down south will quickly convey the shooter to some excellent snipe-grounds; so that, when the thrilling cry "Snipe are in!" is raised, there is everywhere a great demand for No. 8 shot, and all sorts and conditions of sportsmen go for them at once. Even the German element among the Colombo merchants finds, in the pursuit of the snipe, a means of banishing the melancholy engendered of too regretful thoughts of the Vaterland.

The question is often asked if Ceylon snipe are more or less difficult to shoot than English ones. They do not, as a rule, go off with the dash of the home bird, it is true, but that is no doubt owing to the heat, and to the heavy feeding they get. But I have no doubt that, if a large number of shots at the Ceylon snipe were compared with a similar number at the home bird, the hits and misses would be found to be about equal in both cases. The walking in Ceylon is often very bad—far worse than anything we get at home. You usually have to "totter" along the thin ridges which separate the beds of the paddy-fields—most precarious footholds—or else to plough your way through heavy mud; this, combined with the heat, counter-balances any advantage which may be obtained from the bird's easier flight.

In the early morning of a cloudy day, when the ground is very wet, and the shooter has to go "splash, splash," through the fields after his game, snipe are very wild and give most difficult shots, getting up at thirty or thirty-five yards every time, with a scream and a dash equal to anything done in that way by the home birds; and a man who, without picking his chances, can account for five out of every twelve shots, must be a long way beyond the average shot to be found in the island. On the other hand, if snipe can be driven into good holding cover, such as rushes, or better still, young paddy, about a foot high and not too wet, and if the sun is hot, they lie well and get up easily, and then a good shot will bag his seven or eight birds for every dozen cartridges.

Most people, who do not care to make a labour of sport, are content with two or three hours in the cool of the morning, or the last two hours before sunset, but the most deadly time to bag snipe is, undoubtedly, the middle of the day.

If the sun is not too hot, and one gets to a ground full of snipe in strong cover, the shooting is really glorious, and a noble bag may be compiled between noon and sunset.

A very pretty and profitable way of working snipe is by driving them. Often owing to the roiteness of the ground, or the heat or other cause, walking is objectionable.

The plan then is to send a lot of men and boys by a circuitous route to the bit of ground you want to drive, and make them walk in line towards you,

Beautiful shots may be had in this way; the birds having been flushed near the beaters, steady in their flight before they get to the gun, although they come at a rattling pace, and it is very pretty to see them cut over in their flight overhead. By the time the drive is over, seven or eight birds will probably be lying round each gun.

There is no difficulty about getting beaters; unfortunately they are too common. No sooner does the firing begin in the fields, than native men and boys will be seen pouring out of their gardens and houses to see the fun. They enjoy it thoroughly and, if allowed to act of their own sweet will, will have a floundering race for every bird that is dropped.

It is most intensely annoying to find oneself the head of a mighty procession of native villagers, and, owing to this crowd of chattering, to see bird after bird going away out of shot. It is a very difficult thing to get rid of them. If you happen to be a big-wig of the district, such as Magistrate or Assistant Government Agent, you may, by virtue of your "pride of place," persuade them to leave you in peace; otherwise it is not an easy thing to accomplish. It is no use to lose your temper with them. The best plan is to enlist on your side two or three of the leading barbarians and by promise of a fee to get them to drive back the others.

Another great nuisance of shooting in populous districts is the danger of hitting some unseen individual, perhaps gathering rushes or standing behind a bush. One cannot be too careful. In my experience I have known numerous cases of natives being hotly peppered with No. 8; and although as a rule, little damage is done, and a few well-timed words, accompanied with a *donneur*, set matters all right, yet I have known instances where the peppered one and his friends have cut up uncommonly rusty, and have refused to hear the voice of the charmer, and have given an immense amount of trouble before affairs could be brought to a favorable adjustment. So much for snipe-shooting in populous districts. The finest sport, however, is to be met with in the wild parts of the island.

Some four years ago, I was with a friend on an elephant-shooting trip of a week's duration. One day, as we were coming back to camp, we came to a very large grass-field—about eighty acres, I should think; the ground was soft, and there were little pools of water all over it.

It was full of snipe. We at once sent a man to camp to bring a supply of shot cartridges, and rested in the shade till he returned. Never before or since have I seen finer snipe-shooting. The birds had probably never been fired at, and lay well. The walking was delightful, the moist grass scarcely soiled our boots, and the birds were as thick as peas. We took a beat through a field, and at the end of it had bagged thirty couple. The snipe were wheeling round and round in the air, making their shrill "skeep," and pitching in all parts of the field. "Shall we cut it through again?" I said. "No," said H—. "What is the use; besides, we have not got too many shot-cartridges." This was true, for, when after big game, it is never advisable to have a very large number of shot-cartridges, as they weigh so heavy. I remember we sent off some twenty-five couple of fine fat snipe to some coffee-planting friends, living about thirty miles from where we were, and were very pleased to learn afterwards that they arrived all right, and were much appreciated.

Snipe are most commonly sought for on paddy land. The shooting in the wet stubbles about Jan. and Feb. is often excellent. Very good sport may also be had in what are known as "deniyas," or waste lands, and round the edges of tanks. Mingled snipe and wild fowl shooting on tanks is perhaps the finest sport which the colony affords.

Although ubiquitous, snipe are far more plentiful in some parts of the island than in others. Tangle-gam, in the Eastern Province, is a celebrated ground. There is a well-known place in the Central Province known as "Bintenne," from which very large bags have been obtained. From this ground the largest

bag to one gun of which I have heard, in my seventeen years' experience of the Island, was made by a well-known sportsman in the Civil Service, who got 110 couple to his own gun in a day. This was some seven or eight years ago. The whole of the Western Province is very good. On the sea side and all the way down to Galle are many first-rate snipe grounds; and in the Saffragam district of the Western Province the shooting is perfect.

The snipe-shooting in the Jaffna Peninsula is perhaps the worst in the island. Some ten years ago I was stationed there with two other brother civilians, and we used to be very energetic in pursuit of snipe and partridge. We thought three brace of partridges and perhaps two and-a-half couple of snipe a capital day's sport; and, if to this very modest little bag a hare was added, we were really proud of our day's work. The partridges were found in bushes, very thorny and difficult to push through, so much so that we inaugurated the wearing of leggings after the English pattern, as well as we could get a native shoemaker to turn them out for us. In going through these bushes, the ground being as hard and dry as a hot brick, an occasional snipe would spring up. We used to wonder what the birds could be doing there, in a place where there was not a vestige of feeding ground, and still more we marvelled that they were always in first-rate condition. We need not have looked far for the cause, though at the time none of us hit upon it. The snipe, no doubt, feed on the ooze of the lagoons all night, and took refuge in the bushes from the sun's rays during the day. We frequently shot a few couple of snipe out of the bushes growing on the ooze itself, and on one occasion a friend and I came upon several jack snipe, and we bagged four.

This was a very remarkable thing for Ceylon. There had long been a doubt among naturalists whether the veritable jack was to be found in the island. Captain Legge, the well-known ornithologist, who had seen many spurious specimens of so called jacks which had been sent to him, was of opinion that there was no such bird in Ceylon. However, the question was put at rest by our sending our jacks both to Captain Legge and to a professional naturalist, by whom the birds were clearly identified.

These are the only jacks I have seen in seventeen years' shooting in the island, and I have never met with any one else who has ever seen one, except my friend above referred to.

Painted snipe are very common in many parts of Ceylon.

They are very handsome birds, but owing to their lazy flight and poor flavour when brought to table are not held in great estimation; indeed, where the real snipe are plentiful, a "painter" is often allowed to go away without a shot.

There are two birds known as painted snipe, which are nearly always met with together, and which differ very much in appearance. One, the larger—a bird weighing between 6 and 7 ozs.—is most beautiful. It has a large, round, dark eye, exactly like a woodcock's and a fine chocolate-coloured head; a broad white collar round the neck, its back and wings are of a magnificent green colour, of different shades, while the pen feathers of the wing are marked with round spots of gold.

The smaller bird is marked all over the back and wings with round golden spots.

It is commonly supposed that these two are cock and hen, the bigger bird being the cock; but last season I found an egg in the larger bird, clearly proving its sex.

It may be that the two birds are entirely different species; this a question for a naturalist.

The weight of the ordinary snipe is very much the same as that of the home bird. They get very fat towards the end of the season, about April; and I have known them to weigh a full 6 ozs., but from 4 to 4½ ozs. is the usual weight of a bird in good condition. That snipe visit Ceylon in less plentiful numbers every succeeding season has been constantly remarked, and is undoubtedly true. Grounds which, twelve years ago, would in December yield any quantity of birds are now

considered scarcely worth beating. The large bags which were made in the old days, even with the muzzle-loader, are very seldom reached nowadays. It is almost impossible now to find a ground where, in a fair day's shooting, a good and quick shot can fire a hundred cartridges at snipe, to say nothing of bagging a hundred birds. Thirty couple is a very good bag now for one gun, and he who can make it, must be far and away beyond the average shot, unless, indeed, he has the luck to find some entirely undisturbed ground where the birds are very plentiful. But twelve years ago thirty couple would have been thought nothing more than moderate sport.

No doubt this decrease year by year is owing to the improvements in guns and ammunition, and the increasing number of shooters all over the world; but it is consoling to reflect that the snipe supply is still so abundant that there is no danger, at any rate in our time, of our failing to have annually a large number of these much appreciated birds in the fields of Ceylon.

J. E. S.

LIBERIAN COFFEE.

Mr. F. O. Maxwell writes to the *Sarawak Gazette* under date Kuching, 25th April:—

As the planting of Liberian Coffee is spreading rapidly in this district, I have requested the Manager of the Matang Coffee Estate to give me some information as to the precautions to be taken in planting out young seedlings, and so enable me to assist the many native gardeners here with advice. This cultivation is not confined to Kuching but is spreading at the outstations, and I therefore enclose you the Manager's letter and would ask you to insert it in your paper for the information of Officers there. The rules to be observed are few and simple, but such as they are, they are of vital importance, and neglect of them means failure:—

After burning off the clearing, run a few small roads through the place, if practicable 3' wide with a back drain of 1'.

Lining.—Insert in a strong rope about 100 yards long a piece of colored cloth at intervals of 8 feet. When lining put a man at each end and a few men with small pegs about 2' long along the rope, to stick a peg in the ground exactly at each piece of cloth. When one line is pegged out, the men at each end measure 8' with a stick, and the line is again stretched for a new row and so on until the place is all pegged out at a distance of 8' by 8'.

Holing.—It is not necessary to cut holes, [but preferable, as the plants thereby get a start; holes 1' square and 1' deep are ample, and any larger size is a waste of money. In soil free from stones a man should cut 80 in a day. Holes should be cut an inch or two below (or above) the pegs, so that there will be no need to move the pegs and perhaps get them out of line in replacing them.

Filling in.—Keep the holes open as long as possible, and if filled in by wash from rains all the better, but if not, men should fill them up (slightly heaped) with the top soil around the holes and not put back the soil from the hole, which they generally try to do; small pieces of charcoal mixed with the soil put into the hole is a good thing; a man should fill in about 150 carefully.

Planting.—If the plant is about the thickness of a pencil, cut off the top of it, leaving about 4 inches of stem above the top lateral root. In 18 months' time they will have overtaken a plant put in without cutting, and have much stronger roots. All the roots should be carefully trimmed with a sharp knife, leaving the lateral roots about 1 inch long and the tap root about 4" to 8" according to the size of the root; it is of the utmost importance to plant the tap root straight down and not bend it, and also to be sure that it is completely surrounded by soil, and no space left at the end of the root, where water can lodge. Be careful that the plant is not planted too deep; the top lateral root should be about ½ an inch under the soil, and if eventually exposed, in this climate it will be a good thing, but a too deeply planted tree is no use and will be sickly.

Earth should never be heaped around the stem at any age of the tree. Only allow one stem to the tree; all other shoots (from the stem) should be broken off; this work requires constant attention, as Liberian coffee is always throwing out suckers (shoots) all the way up the stem.

Topping.—Cut off the top of the tree when about 7 feet high to 5 feet.

Weeding.—Weed once a month from the time of burning, but if the weeds have got a good hold of the place, a space of about 2' in circumference around each tree should be kept clear and the other portions cut down about once a quarter or as often as circumstances will permit; if kept clean from the first a few small boys should be kept going over the place regularly once a month, carrying away all weeds.

Supplying.—Replace any sickly looking plants by good strong plants, and if any die off, try and find the cause and supply the vacancy.

COFFEE AND ITS CULTURE IN MYSORE.

All the coffee consumed in the European and American world was originally derived from Arabia. The plant, however, is not a native of Arabia, but of Abyssinia, and was not introduced into the former country until A.D. 1454, and, consequently, not until eight centuries after the time of Mahomet. The Arabians found coffee to be stimulating and agreeable, and, substituting it for forbidden wine, called it *kawah*, of which the European name coffee is a corruption through the Turkish—the world in Arabic meaning wine. Thereupon the Mahomedan doctors fell to disputing about the legality of the potation. Coffee is not narcotic, but the contrary; the Arabian theologians, however, occupied themselves with the name not the thing. In the end, the wholesome and agreeable beverage beat the doctors, and for nearly four centuries the use of coffee has been orthodox and extensive in Arabia. Dr. G. V. Poore, in a lecture upon coffee and tea, delivered recently at the Parkes Museum, said:—"I firmly believe that if a man, under the influence of mental or physical exhaustion, were offered a glass of gin, or a cup of real coffee, he would unhesitatingly choose the latter if he were aware of the marvelously stimulating effect which real coffee has." About the middle of the fifteenth century coffee was introduced from Arabia into Egypt, and from thence it spread over the rest of the Turkish Empire. A Turkish merchant took the first bag of coffee to England in 1650, and in the same year his Greek servant made the first cup of English coffee. About the same period it was introduced into France. In sixty years' time it was familiarly known in England, as we find from Pope's well-known lines in the "Rape of the Lock."

"Coffee, which makes the politician wise,

And see through all things with his half shut eyes."

For at least half a century Arabia yielded the whole supply. In the year 1690 a certain Dutch Governor-General of India, one Jan Camphius, sent as a curiosity to Holland a single coffee plant which he had raised by seed at Jeddah, in Arabia. The plant in question was carefully reared in a hot-house at the Hague, and bore fruit. Some berries from it were sent to Surinam, and these berries are the progenitors of the whole coffee plantations of America and its islands.

There is, however, another version of the West Indian supply. It is said to have been due to a distinguished French botanist. Two plants were, under his care, taken to the West Indies from the Botanic Gardens at Paris, but on the voyage the supply of water became nearly exhausted, when this person was so anxious to preserve the plants that he deprived himself of his own allowance in order to water the coffee plants. From these two, it is added, all the coffee grown in West Indies has sprung.

The first coffee plant known in Brazil was cultivated by a Franciscan monk of the name of Velloso, in the garden of the Convent of St. Antonio. The monk

presented its fruit to the Viceroy, the Marquis of Laurado, who judiciously distributed it to the planters. This was in 1774. The date when the coffee-plant was first introduced into Ceylon has, we are told, never been definitely ascertained. It is generally supposed to have been brought from Arabia during the time of the Dutch occupation of Ceylon. The origin of coffee in Mysore is due to a Mahomedan Saint, named Baba Budea. About two hundred years ago, this person proceeded on pilgrimage to Mecca, and, on his return, brought some coffee seeds in his *calabash*, and, settling down on the hills, which are called after his name, planted the berries near his cave. But local tradition also associates its introduction with one Rid Jamal Alla Magarabi, who was one of the successors of Baba Budea. Over a century had elapsed before other gardens were raised, and about half a century more before British capital and enterprise were employed upon its cultivation. The pioneers of the industry in Mysore were Mr. Cannon, "who formed an estate on the high range immediately to the south of the Baba Budengiri where the original coffee plants are still in existence, flourishing under the shade of the primeval forests;" and Mr. Green, who, in 1843, raised a plantation near Agur, in South Munzerabad. The fact that Cannon's coffee trees are still extant proves that planters who have good soil and carefully cultivated and manured estates, need not fear their dying out at an early age. The elevation at which coffee is produced varies from 2,200 to 4,200 feet above sea-level, and it is known that the plant refuses to grow a mile distant from the coffee zone.

The coffee of Mysore is known by three or more descriptions namely, "Old Mysore," the "Coorg Kind" and the "Cannon" brand, the latter being of the best description and most in favor in the London markets. The produce from the plantations in the Koppa Taluk is a successful rival of its neighbours. In the Kadur District, where the coffee cultivation of Southern India is said to have had its origin, the results of the industry for 1887-88 are encouraging, and its further development is expected. The number of acres assigned to coffee is 86,908, of which mature plants occupy 49,162, immature 18,717, and the unplanted area is 19,029. The total area is divided into 11,531 plantations, Europeans owning 334 and Natives 11,187, covering, respectively, 27,428 and 59,480 acres, against 11,303 plantations (English 320 with 2,506 acres, and Native 10,983 with 59,875 acres) in the year previous. Mudgeri and Koppa have the largest number of English estates, 176, and 79 respectively. Within the last decade upwards of thirty estates have been opened out by Europeans in the latter Taluk.

Of native estates Chikmagalur is credited with the greatest number, viz. 6,492, while the Europeans possess 49. The approximate yield was, under European management, 2,914,588 lb., and under Native, 2,780,780 lb., total out-turn 5,695,368 lb. In the year 1886-87 it was, 2,857,496 and 1,305,020 lb. respectively, total 4,162,516 lb. The average produce of a full-bearing acre was 120 to 360 lb. under English management, and from 28 to 239 under native.—*Madras Mail.*

SOME VEGETABLE PRODUCTS FROM MINCING LANE.

To those acquainted with vegetable economic products, but who at the same time have no commercial training, it is interesting to watch the reports from the principal centres of commerce, showing, as they do, the fluctuations to which certain products are liable. The reports of the London drug sales are peculiarly striking in this respect; for though, like other trade reports they are clothed in the usual technical language, they give a pretty good idea of the value of some regular articles of trade which in the course of the year make up a considerable total.

Under the head of Essential Oils, for instance, we find, perhaps, the widest range of prices, from oil of Sweet Almonds, at 1s. 6d. per pound, to Mitcham

Peppermint oil, at 32s. per pound, and oil of Cubebs, at 58s. per pound, or Ylang-Ylang, at 20s. per ounce, besides many at intermediate prices, all of which however, are liable to considerable fluctuation according to the supply and demand. Thus, at the close of last year it was stated that the shipments of Citronella oil from Ceylon were the largest in record, having amounted, from October 1 to November 17, to 1,657,752 ounces against 313,632 ounces in the previous year. This oil always fetches to low price here, being quoted at the present time at about 2d. an ounce. It is largely used in perfumery. This forms a striking contrast to another perfume oil, Patchouly, which ranges from 2s. 3d. to 3s. per ounce.

Amongst other well known products that have attracted much attention of late may be mentioned Coca leaves (*Erythroxylon coca*), Kola nuts, the seeds of *Cola acuminata*, and *Ipecacuanha*. Of Coca leaves it was reported in December as follows:—"Of forty-eight bales of Huanoco leaves, mostly rather dark, five bales, the best of the lot, good greenish, of new import, sold at 1s. 4d. per pound, one penny more than was recently paid; fourteen bags of low brown, badly sea-damaged, 1 cwt. each, were offered at 2s. 6d. for half the lot, but could not find a buyer. A commission which was appointed some time ago to report upon a scheme for assisting the development of minor planting industries in Guadeloupe, has recommended the introduction of Coca cultivation into the island, and suggests that loans upon easy terms of repayment be granted to planters embarking in this industry. It is suggested that 400 francs per hectare (equal to about £7 per acre) should be the maximum amount lent." The latest quotation for fair Huanoco was 1s. 4d. per pound. Regarding Kola nuts, very large quantities of freshly gathered seeds have recently found their way into the market, realising 9d. per pound for very fine quality, 4½d. to 5d. per pound for good, and 2½d. to 3½d. for ordinary mouldy.

Some time since four bales—in all about 400 pounds—of a root imported from Bombay as "Medicine Root," appeared at Mining Lane, and was sold for *Ipecacuanha* at from 1s. 11d. to 2s. per pound. It was soon found, however, not to be *Ipecacuanha*. The root occurs in pieces about an inch long, and an eighth of an inch in diameter. It is not so regularly annulated as *Ipecacuanha*, and is apparently more branching, or with stronger root fibres; internally it is nearly white, with a very pale ring, and apparently very starchy. It has very little taste when first chewed, but shortly reveals an acrid and biting taste. The root has been proved to contain neither emetine nor any other alkaloid, and its botanical affinity cannot, at present, be determined. This false *Ipecacuanha* has created a good deal of interest amongst pharmacists, and all those interested in the purity of drugs. The *Ipecacuanha* supply has been exclusively brought from Brazil until a short time since, when a sample of very good quality found its way to the London market from Singapore, where it had been cultivated. It having thus been established that the drug can be grown in the East, no doubt led the buyers to believe that this new root was Indian grown *Ipecacuanha*.

Speaking of adulteration, we may refer to the fact that Cubebs are now so frequently mixed with various other berries having so similar an appearance externally, that it is difficult to ensure the purchase of the genuine fruit. Quite recently it was reported that the supply of genuine berries is very small, and that as much as £29 has been privately paid for them.

Regarding Vanilla, it was stated during December that the cultivation of the plant in Madagascar was progressing, and that a splendid crop had been secured during the past season on two new plantations in the island, one of which is owned by an Englishman, and the other by a Frenchman. The former is laying out plantations on a very large scale, and it may now be considered certain that,

under favourable circumstances, Madagascar Vanilla will ere long be placed on the European markets in considerable quantities. The beans cured last year are said to be by far the best ever produced in Madagascar. In connection with the spread of Vanilla culture, we learn from Zanzibar that it has been successfully tried at one of the East African German settlements, and that 55 lb. of Vanilla from the Knigaru (Usaubara) settlement are ready for shipment to Germany by the first steamer.

Some time since a good deal of interest was excited by the statement that 537 packages, amounting to about 50 tons, of gum of the Arabic character, had been received in London from Para, under the name of Brazilian Gum Arabic. We now learn that only an overland sample has been received, and that the bulk is shortly expected. Referring to this gum, *The Chemist and Druggist* said:—"Since the great advance took place in values of gums generally, certain varieties of gums found in Brazil have received considerable attention at the hands of merchants in that country, who recognised in the product an article well worth collection and exportation. Accordingly, during the past two years, regular supplies of gum have been received at Liverpool from various Brazilian ports—Mirauham, Paranyhu, and Para. These imports at first realised as much as 85s. per cwt., but it was found on trial of the quality that this was too high a value compared with other descriptions of gum, and as the imports increased, the price declined to 65s. per cwt. for good quality, at which figure the article sold very readily, until laterly the supply has somewhat exceeded the demand, and stocks have accumulated to about 95 tons, the market value of good quality being thereby reduced to 55s. or 57s. 6d. per cwt. Hitherto the Brazilian gum has been chiefly bought up by export druggists, but recently consumers in this country have turned their attention to it, and employed it successfully for various purposes. The tree yielding Brazilian Gum Arabic is called 'Angico' by the natives of that country."

The writer of the foregoing in *The Chemist and Druggist* suggests the source of the gum as *Bowdichia major*, but the Angico tree is referred to *Acacia angico*, *Martius*—*Piptadenia rigida*, Benth., which is described as yielding a gum very similar to Gum Arabic.—JOHN R. JACKSON, Museum, Kew.—*Gardeners' Chronicle*.

NOTES ON COCA LEAVES.

We announced a few weeks ago that Dr. H. H. Rusby, of New York, had been lecturing at the Philadelphia College of Pharmacy on South American drugs and remedies, as investigated by himself during a recent journey through parts of Brazil and some of the adjoining republics. When describing coca the doctor showed specimens of the two principal commercial varieties, viz., Bolivian and Peruvian coca, and explained the difference in their appearance.

The specimen of Peruvian coca Dr. Rusby gathered at the confluence of two rivers, one coming from Cuzco, in Peru, and the other from La Paz, in Bolivia; but unfortunately the names of these rivers are not given, nor are there, so far as we are aware, any rivers originating near Cuzco and La Paz which meet at all on Peruvian or Bolivian territory, Judging, however, from the doctor's subsequent remarks, the River Purus, which divides the two countries, is meant. All the way down this river, coming from Bolivia, continued the lecturer, we find the wild coca. It is of the Bolivian form, but soon as we strike the other river we find the larger leaves, the Peruvian form.

There is also a form of diseased coca, called Taja. It is probably a fungus which produces this peculiar condition. We know the disease can be produced in the leaf by simply picking them carelessly so that the twigs are wounded. Then when the new leaves are produced they present this appearance. This is a sufficient comment upon the idea which has lately been advanced by a writer, to the effect that some

of the coca leaves which reach the market are beaten off from the plants with poles, an opinion which is evidently erroneous. If an attempt were made to beat the leaves from the plants with poles, the owner would never get another crop. Two other forms of coca, or rather erythroxyton, grow throughout the eastern part of Bolivia and even through Brazil. The two main varieties of coca, the Bolivian and Peruvian, are so different that one Bolivian writer has described the Bolivian form under the name of Erythroxyton Bolivianum. The name, however, is not correct; both are Erythroxyton coca. Two varieties are distinguished not only by the leaves but by the fruits, which are larger in the Bolivian species, while the leaves are larger in the Peruvian species. The Bolivian variety is much esteemed by the Peruvians, they saving enough from their scanty earnings to purchase one-third of the Bolivian product, although you can obtain the native article at a much lower price. Dr. Rusby then entered into the question of the chemical composition of the leaves, and spoke about the two methods of estimating the cocaine which the coca leaves contain. The first is to extract it in the pure form and weigh it. This method, the lecturer said, was impossible for me; I was therefore obliged to resort to the test by titration, and this test is as follows:—We obtain the cocaine in an aqueous acid solution, about two drachms of the solution representing two and one-half grammes of leaves. This can now be tested with Mayer's reagent. As the precipitate is formed this precipitate is filtered, and the reagent again added. When no more precipitation occurs we assume that the right amount of reagent has been used, and for every cubic centimetre so used we have eight milligrammes of cocaine in the leaves. Now, estimating by this test in this country the leaves will yield from about one-half to three-quarters of one per cent. of cocaine. As I estimated them in their own country, the leaves being fresh or recently dried, taking an equal weight of fresh leaves, drying them, and then assaying them, I obtained from two to four per cent. of cocaine. I took specimens of the same leaves which I had thus assayed and sent them to the United States, where they were assayed, and they yielded the same amount which they are said to yield in this country, namely, from one-half to three-fourths of one per cent. It was evident that I had made a mistake in my process, or that the composition of the leaves was very different in their own home. On my return to La Paz for the second time I made a very elaborate series of experiments, looking towards the assaying of the different parts of the plants. I took the best methods I could, collecting and drying at the proper time of the year, taking into account the age of the leaves, and I found my former results confirmed. But I also found on this occasion that on rendering my solution slightly alkaline and washing it with ether, the ether carried away only the cocaine, which was found to be about three-fourths of one per cent as in this country. This is, then, one of the means of accounting for the difference—an entirely different substance from the cocaine, but producing the same reaction with Mayer's reagent, being left behind in the alkaline aqueous solution, seeming to prove that the composition of the leaves is different in their own home from what it is after they are exported.—*Chemist and Druggist.*

PEPPERMINT AS A DISINFECTANT.

It is a fashion with some people to treat with contempt the traditions handed down by our forefathers. Before, however, we discard valuable drugs which have been used for generations past, it is always well to search for any new properties which can perhaps be added to their past history.

Many of your readers may not be fortunate enough to have copies of the *Lancet* or *British Medical Journal*, or would care to wade through their contents. I therefore wish to chronicle in your widely read journal the results lately arrived at in favour of Peppermint Menthol.

It has been found, after laborious research, that of all substances and chemicals yet discovered there is nothing known more fatal to bacterial germs of

diseases, &c., than Peppermint (*Mentha piperita*). It is found that one three-hundred-thousandth-part of Menthol is sufficient to destroy the bacterial germs. It must be known to many of your readers, by the letter from Mr. E. M. Holmes, F. L. S., of the Pharmaceutical Society, that after a long search the home of the true Menthol plant was discovered to be in Japan. This plant I have discovered largely throughout Europe and America. Mr. J. W. Colcord, of the Pharmaceutical Society of Massachusetts, U. S. A., writes me that Peppermint has withstood 10° below zero of frost; this will prove that the plant is a hardy one. Some correspondents write to tell me they tried the Menthol by pouring hot water upon the foliage, and drinking the infusion in the hottest weather. They experienced great relief to their fatigue, and it was as refreshing as Tea, and they thought it more stimulating. I have had letters asking me if I could supply any of the foliage, so that experiments might be tried by boiling it, and bringing the infusion into a sick-room for its perfume and antiseptic properties, but on looking over my large beds of roots I found none sufficiently advanced to cut. I have no plants being forced, and regret that these experiments must be deferred until later in the spring. One experiment made with the Menthol crystals, which can now be bought of any chemist at a few pence per ounce, will show how preferable is its perfume to the objectionable smell of carbolic acid when exposed in the usual manner in an open vessel.

Medical men, when they come to ponder over these facts, will welcome the results of the experiments showing that Menthol can now be safely relied upon as yielding better results than carbolic acid.—THOMAS CHRISTY.—*Gardener's Chronicle.*

PERSIAN SILK.—After China, Persia was believed to have been the first place where silk was grown, but whilst the Chinese silk was white cocoons, those of Persia were yellow. Among savants who have studied the question of silk it is believed that Persian silk was different from Chinese. Persian silk is very little known, and has been little studied in Europe. At the request of M. Natalis Rondot, the Minister of Foreign Affairs desired the French representative at Teheran to make inquiries on the subject. The Persian Government informed him that the original kind of yellow Persian cocoons had not been preserved pure except in one locality, namely, Schezevar. M. de Balloy, the French Minister at Teheran, has procured 737 grammes that M. Natalis Rondot has placed at the disposition of the Chamber of Commerce of Lyons, who will proceed to make experiments at certain points in France and Italy.—*London and China Express.*

MANURES.—M. Deherain, professor at the "Conservatoire des Arts et Metiers" made a report, at yesterday's meeting of the "Académie des Sciences," on his researches upon farm manures. It follows from this report, that the black matter which impregnates dung, and forms and colours liquid manure, is the result of the dissolution of the alkaline carbonates formed by urines:—1° from the vascular deterioration of the straw; 2° the azotic matters arising from the straw itself, from the solid excrements of animals and from the transformation of the ammoniac into azotized matter, vital activity of the ferments, being the cause of this metamorphosis M. Deherain concludes that in consequence of these reactions it would be advisable: 1° Never to add to manure any substance likely to decompose the alkaline carbonates: consequently the use of sulfates of iron or lime must be prescribed, and above all, acids, often employed to avoid the evaporation of ammonia;—2° To frequently water with liquid manure, which dissolves the carbonic acids abounding in the confined atmosphere of the dung—heap retaining the ammonia, accelerates by this dissolution, the diminution of the interior pressure allows the air to penetrate the heap, and facilitates fermentation thus transforming the ammonia into azotized matter, the principal result to be obtained in the preparation of manure.—*Universal Press Association.*

AMERICAN FRUIT EVAPORATOR.

From the Bulletin of the Botanical Department, Jamaica.

COFFEE.—Mr. John MacLean, Cold Spring, and Mr. Marshall, Chester Vale, imported one of these Machines (N^o), for the purpose of testing its value in drying Coffee. They cured a certain amount with this small machine in a single day, but were of the opinion that the berries were "over cured," on account of the temperature being kept too high. A small sample of this Coffee was sent to England just as it was, without picking or sizing, and the following Report was sent back by the Brokers:—"We have carefully examined the sample of Jamaica Coffee cured by the hot air, and report that the size of the berries is good, but that the Coffee appears soft and watery in character. The colour is dull, approaching that known in Central America as cloudy, and it is mixed with pale bleached berries which detract from the value. It would be more easy to say how far the process is answerable for these defects, if we knew the Estate's marks so as to compare it with Coffee cured on the Barbecues. The market value to-day is 92/ to 93/ per cwt." Mr. MacLean mentions that the same Coffee, sun-dried, realised 123/, but that the machine-dried Coffee sent was not a fair sample, as it had not been picked. He says, "there can be no doubt about the curing of Coffee, for what we did, being over-cured proves the success beyond a doubt."

Mr. James Francis, Cedar Valley, has tried this same Machine, and has sent the following report of his experience:—

"The O machine with its eight tray capacity, will only hold a quarter of a tub of parchment Coffee. Coffee from the washing tank, which has been drained upon a barbaque, will, with a temperature of 140° to 180° F. dry coffee sufficiently in six hours to place it out of danger, another six hours will almost cure the berries; two hours longer, and the Coffee will be cured as for shipment. It can be readily understood that as it would take 160 days, of 14 hours each, to cure one tierce of Coffee, I had to confine myself to limited experiments, and though I would be rendering greater service to the Coffee growing community, if I cured a certain quantity in the first stage only by the Machine, completing the process in the sun and testing the market with it. The silver skin comes away more readily from machine-cured Coffee than from sun-cured; this is an advantage. The colour is changed, and it may prove not so pleasing to the eye as sun-cured. Coffee cured in the Machine yields, or goes back, much more quickly than sun-cured; this defect would, I think, be obviated by allowing a certain time between each of the three or four stages of curing. Curing in the Machine needs constant and careful attention, or one set of trays will give Coffee cured irregularly, and in the last stage, much might be spoiled for the market, by over-curing; the Coffee then takes on the appearance of semi-parched berries. The question will naturally be asked, is the Machine good for anything? Yes. I consider it a valuable addition to any Coffee works, particularly in districts where there is rain during the early picking of Coffee. With a Machine of sufficient capacity, Coffee could be put out of danger, bagged in coarse bags, and piled up so as to let air pass through. Its use in this way would save many Coffee growers from much loss. I would willingly, and with much interest, have carried on further experiments, had the Machine been larger. I have tasted really good Coffee from berries cured in the Machine."

"TEA.—The evaporator has been tried in the manufacture of Tea at Cinchona. Three samples were sent to Kew with the view of testing whether the Machine-dried Tea was superior to that cured on iron over a fire. A sample of the latter was labelled No. 1, the samples of the machine Tea were called Nos. 2 & 3. These samples were sent to England, unfortunately, in mustard tins, which impaired their value considerably, and this is what the Brokers refer to in their letter and report subjoined.—

A. G. STANTON, Esq., TO ROYAL GARDENS, KEW 3, Rood Lane, London, E. C., 21st December, 1887.

DEAR MR. MORRIS,—I duly received your letter of the 29th instant, together with the three samples of Jamaica Tea, two being marked Nos. 1 and 2 and the third having no number; this letter I have called No. 3. As I have given in the enclosed Report a pretty full statement of the various characteristics of the samples, I will only here add that the liquors of all are very serviceable for the London market; the samples are all slightly impaired, No. 1 being especially so. I shall always be happy to report upon any samples and to do whatever I may be able in the way of assisting intending Planters with any information or suggestions which they may require.—Believe me, &c., (Signed) A. G. STANTON.

MESSRS. WILSON AND STANTON TO ROYAL GARDENS, KEW.

13, Rood Lane, London, E.C., 31st December, 1887.

DEAR SIR,—We beg to hand you our characters and valuations of Musters Packages of Tea per mail from Jamaica:—

Sample Species and Character. Value per lb.

No. 1 UNASSORTED TEA £0 1 1

The dry leaf is well rolled but is much too grey in colour, and wanting in tip; somewhat uneven and inclined to be dusty.

The liquor is fairly dark and full with some flavour. The infused leaf is regular and of a fairly bright colour.

No. 2 UNASSORTED TEA 0 1 2

The dry leaf is good colour but is too crinkley, and has not been properly rolled.

The liquor is dark and full, and of a nice flavour. The infused leaf is regular and of a fairly bright colour.

No. 3 BROKEN ORANGE PEKOE £0 1 8

Dry leaf is good colour, and with a few tips; but is rather open ragged and too uneven.

The liquor is dark, full, and of good flavour. The infused leaf is bright and regular.

General.—The above Teas are chiefly valuable in the London Market on account of their liquors, the manipulation of the dry leaf being faulty. We prefer the samples marked Nos. 2 and 3, the leaf being better in colour; and liquors of finer quality and flavour. No. 1 is too soft in liquor and resembles China Tea, Nos. 2 and 3 being more like Ceylon Tea.

All the samples have a peculiar smell, and taste of some substance quite foreign to Tea; for this defect we have made due allowance in our Report. The leaf of No. 1 is quite limp instead of being crisp, the sample has probably been damaged in transit.

(Sgd.) GOW, WILSON AND STANTON. D. Morris, Esq., Royal Gardens, Kew.

Mr. Morris writes:—"We want now some good samples of Jamaica Tea sent over in chests, and grown and manufactured by private planters. This would be a decided step in advance."

CINCHONA BARK.—One lot of Bark has been dried in the Machine at Cinchona with very fair results. It was evident at the time that the temperature was too high, and that the bark would consequently suffer by dissipation of a portion of the alkaloids. It was however submitted to the Island Chemists, together with a sample of the same bark dried on a barbaque. He reports that from the barbaque dried bark, he extracted 3.55 per cent of alkaloids, whilst from the machine dried he obtained 3.38 per cent, and that the latter was harder and more difficult to grind. This experiment is quite sufficient to show that the Machine would be useful to Cinchona Planters in drying their bark in plantations high up on the mountains, and distant from any barbaques.

CORN (Maize) Although there has been no opportunity here of drying Corn in the Machine, it is certain that either by kiln-drying or by the use of

this Machine, sufficient corn could be grown and dried in the island for all our needs without having to import any.

PIIMENTO.—The preliminary drying might well be done in the Machine, and it would probably much improve its appearance. It would be generally advantageous if those who have tried the Machine with the curing of Cacao or in any other way would communicate with the Director, Cinchona, Gordon Town P. O.

COTTON SPINNING IN TRAVANCORE.

[A correspondent sends us the following extract as of special local interest at this time.—Ed. C. O.]

A correspondent of the *Textile Recorder* writes: Cotton spinning, under proper management, would appear to be a profitable business in Travancore; and indeed, with money at a very low rate of interest from Government, land cheap, taxes light, fuel for cutting and carriage, and the cheapest of labour markets there seems no good reason why it should not be very profitable, especially when cotton does not need to be brought much more than about 100 miles, and when all the twist spun can be easily sold in the local markets and bazaars. The Darragh Spinning Mill, which was started about three years ago with 11,000 spindles, and is now being increased to 18,000 spindles, is, it is understood, to be increased to its full complement of 25,000 spindles. The machinery, mostly by Howard and Bullough, and other well-known makers, would appear to wear well, and the only difficulty in spinning seems to have arisen from the fact that the South Sea cotton introduced into Travancore, is far too good to mix with ordinary Indian cotton, being itself fit to spin up to 200's while the ordinary cotton is best adapted for about 40's. It would thus appear only to need extensive cultivation of the imported South Sea cotton to enable the finest muslins to be produced. Honesty would appear also to be, if not the best, at any rate, a profitable policy, and manufacturers at home might learn a lesson from the experience of an Indian manufacturer. The native weavers, at first, had their doubts about the twist spun, probably both as regards its quality and also its quantity, but a steady perseverance in simple honest statements and marks as to both very soon resulted in a ready sale, and the consequence, as reported, is the local sale of all the twist spun. I am not sure as to the cause or causes of it, but of the fact there can be no doubt, that a native who wishes to buy a cloth that will wear, prefers to buy a native woven one but if he wishes a cheap cloth he will get one of English make. I have wondered whether the sizing has anything to do with it. I have seen the natives with a web at least 200 yards long, stretched out in the open air, and the sizers carefully going over the web with soft brushes and simple rice water (and have thought of the 200 per cent of size a home manufacturer told me he was able to put in). Whether it is in the sizing or weaving, or quality of the material, or all three, one thing is plain, that a careful study of the local needs as to quality, kind, and price, would result in a larger consumption of English-made goods. I am sending you a native (blue) cloth, made from yarn, spun in the Darragh Spinning Mill, but woven by the native weavers and coloured an æsthetic shade of blue, which I bought in the bazaar, from a native hawker, for six chuckrams, about 3½d, which will give you an idea of the kind of cloth worn and preferred by many of the natives of this part of India. The blue is not and is not intended to be a fast colour, but I think the shade of blue, and the same is the case with yellow cloths, could not be more tastefully done at home. I send you also a

native calico hand-printed cloth. You will see that the calico is English make; but the whole of the work on it is done by hand, by the native dyers here. I paid one and a half rupee for the cloth (about 2s 3d), but this is probably much more than its value, as "Sahib" bought it. The whole of the printing work is done by hand, even blocks are not used, nor stencils, just a patient painting or tracing out of the pattern. The colours are fast and will only look better for washing; and the black, chocolate, brown, and blue will show what the native dyer can do. Sometime I hope to send you details of the process and materials used, but this time I can only send the results, as shown in the cloth.

PULQUE: ITS SOURCE AND MANUFACTURE.

The question recently asked in the House of Commons by Dr. Cameron, of the Secretary to the Treasury, regarding the decision of the Commissioners of Inland Revenue to impose a licence on an importer of Mexican pulque in Edinburgh, has raised some interest as to the origin and nature of the spirit in question. The following notes on the subject may therefore be of interest.

Pulque is the national drink of the Mexican people, and is obtained from the American aloe (*Agave americana*), a plant which is much cultivated in green-houses in this country. It is known in Mexico as the "Maguey," or "tree of wonders," and is considered, in its numerous varieties, as one of the most important productions of the Mexican soil.

The best account of the *Agave americana* and its uses was given in a report by Her Majesty's Secretary of Legation on the commerce of Mexico in 1865, from which the following notes are taken. Pulque, it seems, was well known to the ancient inhabitants of the Mexican continent, from the fabulous traditions connected with it, and which were collected by the missionaries who came to the country in the early days of the Spanish occupation. One of these is the destruction of a race of giants indigenous to the valleys of Atozac and Matlacueque, and of cruel propensities, by more civilised races who had come to settle there, the former having fallen asleep from the somniferous effects of the juice of the maguey, whilst the discovery of the juice itself, whether under its ancient denomination of "Metl," "aguamiel" (honey-water), or "pulque," was attributed, by a portion of the ancient inhabitants of Mexico, to the god Izquitecatl, as would appear from various symbolical inscriptions found in the country. More modern tradition, however, has fixed the epoch of its discovery to about the years 1045 to 1050, under the reign of the eighth king of the Taltec tribe, named Tepaucaltzin, at whose court a relation of his named Pepautzin presented himself and informed him that his daughter had discovered that a sweet and aromatic liquid sprang from the metl plants in her garden. The king ordered her into his presence, and she brought him a "tecometl," or vase, of the liquid she had discovered, which he tasted and then ordered her to bring him more, and subsequently becoming enamoured of the maiden—whose beauty was great, and whose name was Xochil, or flower—he married her, of which union a child was born, to whom was given the name of Meconetzin, or "Son of the Metl," or maguey, in allusion to the circumstance which was the origin of his parents' first interview.

Whether the discovery of the use of the juice of the maguey is really to be attributed to the god Izquitecatl, or to the Queen Xochil, there is no doubt that the various properties of the plant itself were known many years before the discovery of Mexico by the Spaniards, for, not only is it mentioned as furnishing thorny scourges, as well as whips, made of the fibres of the plant's leaves for the multitudes who annually met to celebrate a festival in honour of the god Tex

catlipuca in the great temple of Tenochtitlan (the modern Mexico); but the use of the juice became so general that many severe laws against the drunkenness resulting from it were issued by the ancient Mexican kings, mention being made of a widow, who sold it promiscuously, having been put to death by the order of the King Netzahualcoatl, only women suckling infants, old people, and soldiers upon the march being allowed to drink it.

Notwithstanding that the primary object of the Spaniards who came to Mexico in the earlier periods of its subjection was to search for the precious metals, the maguey plant also occupied their attention very considerably, especially when increased intercourse with the natives revealed the varieties of uses to which the plant was put by them, and it was fully treated of by the authors of the time. The plant may be cultivated at an elevation of 10,000 feet above the level of the sea, but is grown with greater success at an elevation of about 9,000 feet. Though the plant is grown in many parts of Mexico, the great maguey district is that of the plains of Apam, embracing a range of territory of more than 600 square leagues, almost covered with plant, either in its wild or cultivated state. This vast maguey district is now entirely destitute of trees, although vestiges remain of cedar forests which formerly existed there, the soil being light, stony, and apparently arid in many places—indeed, nothing can be less agreeable to the eye or promising in its general aspect than these or any other maguey plantations, although so surprisingly productive. In the district referred to, there are maguey-growers whose estates are not worth less than some millions of dollars, taking into account the quantity of pulque produced.

As far as can be ascertained from the meagre statistical record of the time, not more than from 50 to 60 pulque estates existed during the last two centuries, whilst, in the several districts of the Mexican table-land of Teotihuacan, Pachueca, Apam, Texcoco, there are now 178, and from 80 to 100 in the district of Ilixcala.

The following is the mode adopted for the extraction of the juice of the plant, and the manufacturing from it of pulque. So soon as the leaves begin to turn yellow, a small concave aperture is scooped out, by means of a keen-edged knife called an "iztetl," in the core of the plant, which is usually from 18 to 20 centimetres in diameter, and this aperture is gently scraped round, care being taken that no incision be made in the leaves or fibres around it, for fear of imparting a bad taste to the juice. This operation produces a sediment denominated "raspa," through which the juice, generally known under the technical name of "agua-miel," or honey-water, exudes from the grooves of the plant; this juice is extracted by the "ilachiquero," or maguey labourer, by means of an elongated gourd formed into a tube, called an "acocotl," the air in which is exhausted by suction, and which he thrusts into the incision in the core of the plant, stopping the aperture at one end with his finger, and emptying its contents into his "zurron," a sort of impervious sheepskin bag inserted in a net and strapped to his back. Each labourer has usually the care of from 50 to 60 plants, from which he extracts, or, as it is technically expressed, sucks from about 110 to 120 arrobas of honey-water per week. As soon as his zurron is full, he carries it to the "tinical," or pulque manufactory, very commonly returning to each plant, and performing the same operation of scooping round the incision and exhausting the juice it contains, twice in the day, taking particular care to cover up the aperture with leaves and stones, lest the cattle, dogs, or eagles—a small species of jackal, which infests the country in large numbers—should get at the juice.

The honey-water varies in quantity, colour, and quality, according to the variety of the plant, the producing time of which may be said to extend on an average to about three months, although some sorts only yield juice during a period of twenty days, and other sorts are so plentiful that they yield it during six months, and that in large quan-

ties. The least productive variety of the plant is calculated to yield about 60 arrobas of juice, that of an average sort about 30 arrobas, while the finest sort of all, the "manso legitimo" of the plains of Apam yields, when it has attained complete maturity, from 140 to 160 arrobas. The average quantity yielded by each plant, one with another, may be roughly estimated at about 100 arrobas.

The "tinicales," or pulque manufactories, of the different maguey plantations, consist of a long covered-in-gallery, well ventilated, and containing rows of vats made of bullock's hide stretched over a wooden framework, and smeared with lime on the outside, into which the honey-water is emptied as soon as it is brought in from the plantations, and which in about thirty-six hours begins to ferment, throwing up large bubbles of froth, losing its pristine transparent colour, and assuming a milky-white tint, which it permanently retains. It was formerly the habit to throw lime or a plant called "oegractli" into the honey-water, in order to produce a greater degree of fermentation, but now only a small quantity of "madue del pulque," or pulque already manufactured, is poured into the empty vats, which quickly deposits a thick and whitish-coloured sediment, upon which the new juice or honey-water is thrown in: the mixture after fermentation being ready for use is then sent off to the city of Mexico, Puebla, or the nearest market within a radius of twenty or thirty leagues, the pulque very often undergoing a considerable dilution with water by the way at the hands of the "arrieros," or carriers, who convey it in sheepskin bags upon mules and donkeys. The quantity which thus annually enters the city of Mexico alone may be estimated on the average to be about 2,000,000 arrobas, and about 500,000 arrobas go to Puebla. The cost of transport alone has been calculated, taking the approximate average of one real as that of each arroba, to amount to 312,000 dollars. Not less than 20,000 mules and donkeys laden with the beverage enter the city every month by the gate leading to the maguey districts. To the quantity paying duty must also be added a considerably quantity which is smuggled in, and including this it may be calculated that about 50,000,000 bottles are now annually introduced into the city of Mexico, and the amount of money annually expended in the drink, at the average rate of about a quarter of a real per bottle, represents a sum of about 1,600,000 dollars, the number of "pulquerias," or pulque stores, within the capital (which, in the year 1771, when the increasing popularity of the beverage compelled the Spanish Viceroy to issue special regulations respecting licences to sell it, &c., amounted to thirty-four, afterwards increasing to eighty) now amounts to over five hundred. These stores are usually painted in gay colours outside, the wall behind the counter almost invariably exhibiting a rudely-executed allegorical fresco setting forth the "power of love" under the stimulating effects of the maguey plant: Venus, Bacchus, and the nymphs occupying prominent positions in the background, whilst a little image of the Virgin, with a lamp burning before it, occupies a retired corner of the establishment.

The best quality of the beverage is known under the different denominations of "pulque fino," "pulque dulce," or "pulque fuerte," whilst the inferior sort, the produce of the maguey planted in an inferior soil, and which is commonly consumed only by the poorer classes of Indians, by whom it is often manufactured in earthen pots, is called "ilachique," and there is another sort sold in the pulquerias composed of an admixture of this with some other sort of a somewhat better description, denominated "pulque criollo," or creole pulque. On account of the manufacture of ilachique being erroneously supposed to be carried on by the poor Indian population alone, it is subject to the payment of a very slight duty, and little is known of the real amount of its consumption.

It is stated that a chemical analysis of pulque shows it to contain in different proportions, according to its quality, alcohol, mucilaginous leucula, sugar, water, and potash. It has been observed that the drunkenness produced by it under its different varieties is of a less violent description than that produced by another

common beverage of the country, "chinguirits" (brandy made from the sugar-cane), and that *delirium tremens* is rarely produced by the immoderate use of the former, though often by that of the latter. It is also affirmed that the pulque-drinker is commonly long-lived, whilst the reverse is the case with regard to those addicted to chinguirits, and that the former beverage, notwithstanding its somewhat acid taste, is, probably on account of the fecula contained in it, peculiarly beneficial to women suckling their infants, and to those requiring a wholesome stimulant. The excesses committed by the lower orders during a riot occasioned by the high price of maize in the city of Mexico in the year 1692, being attributed to pulque-drinking, its use was prohibited altogether; this prohibition, however, was afterwards removed, and the Crown of Spain allowed its sale again under certain restrictions, incorporating the tax upon it with other colonial imposts, in which, in course of time, it became a highly important item, producing in some years a sum of more than 1,000,000 dollars to the Treasury. During the few years which preceded the war of independence the annual amount of the pulque tax was from about 600,000 to 700,000 dollars, but in the year 1810 it fell to about 500,000 dollars, and in 1811 to 400,000 dollars, and from that time to the present it has continued falling, until it has reached the present comparatively low average of about 200,000 dollars, annually, the cause of so sensible a diminution being alone attributable to the extensive system of smuggling carried on, and to the increasing neglect and indifference prevailing amongst public functionaries during a long lapse of years of anarchy and confusion.

A spirit called "mezcal" is also made from the sap of the maguey plant, heated in a kind of oven which is made in the ground, and which is of the simplest possible construction; and after fermentation has taken place, it is passed through an alembic two or three times until it attains about 60 to 80 degrees of strength. It can be made from every description of the maguey plant, but the varieties best adapted for its manufacture are called the "chino," "manso," and "tenemetl." The consumption of this product, however, is trifling compared with that of pulque. The manufacture of this spirit, often erroneously called a wine, "vino de mezcal," is almost exclusively carried on in the States of Guadalajara and San Luis de Potosi. That manufactured in the former State, generally distinguished under the name of "tequila," from the name of the place where it is principally made, is very generally consumed throughout the country, but that manufactured in the latter is almost all sent to Guanajuato and Zacatecas, and is consumed by the mining labourers of those districts. In the two first named States there are extensive tracts covered with what is termed "maguey verde," or green maguey, which is too poor to produce any but the worst quality of pulque, and is consequently turned to the manufacture of mezcal. The plants, which grow spontaneously, are cut down at certain seasons, and are never allowed to flower which causes a greater proportion of sap to concentrate within the trunk.

Besides these spirits the agave yields gum, said to be used in medicine, vinegar, sugar, &c. On this point we are told that "the belief in the efficacy of the medicinal properties of the plant is universal among the Mexican peasantry, to whom it has been handed down from time of remote antiquity; thus the juice of the leaf is said to be a specific for bruises and contusions, the gum which is engendered in the lower part of the stem to cure the toothache, whilst various experiments upon the curative properties of the plants under different forms have been made by members of the medical profession in Mexico with satisfactory results." More recently, namely, in 1874, it was stated that General Sheridan, the United States officer, when in charge of a small army in Texas, had the misfortune to have an outbreak of scurvy amongst his men, and having heard that the juice of the Mexican agave possessed anti-scorbutic properties, and being entirely without lime-juice or any other remedy, started in search of

the *Agave* plants, and having found a number, the juice was expressed, and the men compelled to take it in liberal doses, the effect of which was to entirely stay the disease. It is stated to have a fetid smell, like putrid meat.

Perhaps some trials may be made in this country as to the medicinal value of pulque now that it has become introduced to our notice.—*Chemist and Druggist*

CINCHONA BARK FROM S. AMERICA.—There was a report current in commercial circles in March last that an export duty would be levied upon all cinchona exported from Bolivia, South America. But the rumour turned out, as all such rumours do, to be a canard, for instead of an export duty being placed on the bark, the now existing duty will be removed by the end of June. This will lead to an increased shipment of bark from that country, and in consequence the dealers are holding back their shipments until that time.—*Indian Agriculturist*,

HEMIDESMUS ROOT.—At a recent drug sale in London there came up for disposal a number of packages of hemidesmus, or Indian sarsaparilla, root, which comprised the first consignment of the drug received here after a rather unusual interval of thirteen years. It was perfectly natural, therefore, that before these packages came up for sale the drug should have been reported to be scarce—indeed, it was unobtainable; but as retail druggists are so rarely called upon to supply either the root or its preparation, the fact that the drug is scarce or otherwise is not likely to create much excitement. Yet it happens that in St. Bartholomew's Hospital, the largest medical institution in the metropolis, Indian sarsaparilla takes the place of the similax root, so that all preparations of sarsaparilla used therein are characterised by the absence of what is generally known as sarsaparilla, and the hospital has the distinction of using more hemidesmus root than all other consumers put together. Before the last arrival the hospital stock became exhausted, and one of the customs of the institution appeared to be threatened with extinction. The physicians of the hospital report that they find the preparations of hemidesmus to be as satisfactory as those of sarsaparilla, that is perhaps not saying much; nevertheless, when Dr. Ashburner introduced it in this country in 1831 it was said to increase the appetite, to act as a diuretic and improve the general health, plumpness, clearness, and strength succeeding to emaciation, muddiness and debility. It was also said to be useful in affections of the kidneys, scrofula, cutaneous diseases, and thrush. It had long been used in India, where it is held in high reputation, and is known under the names *Nannari root* and *Ananto-mul*. It is the root of *Hemidesmus Indica*, which is the same plant as the *Periploca Indica*, of Willdenow and the *Asc. epias pseudosarsa* of Roxburgh. The root has a strong odour resembling tonka bean, this characteristic being particularly marked in the recent consignment. The odour is believed to be due to a volatile crystallisable "acid," which was separated by Garden in 1837. Some years later (1843) Scott obtained a stearoptene from the root by simple distillation with water, this body being probably identical with Garden's "acid." Garden proposed to call the "acid" "smilasperic acid," but it may, according to Pereira, "with more propriety be termed 'hemidesmic acid' or 'hemidesmin.'" The comparative unimportance of the drug is probably the reason why no pharmacist in these enlightened days has attempted to clear up the uncertainty regarding its active constituents. Mr. Pocklington made a careful microscopic examination of it in 1871, and found it to possess such characters as entitled him to say that "hemidesmus is much more interesting to the microbotanist than to the micro-pharmacist." It was introduced into the British Pharmacopœia in 1864, and still remains with its preparation, syrupus hemidesmi, but no other pharmacopœia has had the hardihood to give the drug a place.—*Chemist and Druggist*.

COCONUT PLANTING IN THE WESTERN PROVINCE.

CEYLONESE AND CAREFUL CULTIVATION—TRENCHING AND DRAINING ON COCONUT ESTATES

Siyane Korale, April 1888.

A healthy sign of the times is that more attention is being paid to agriculture now than a year or two back, and by the sons of the soil. This is undoubtedly a step in advance. Hitherto the sole aim of wealthy Ceylonese has been to become possessed of land to satiate an earth hunger, and to boast of owning so many acres of land. Cultivation was a word with a very vague meaning in their vocabulary, and seldom comprised more than weeding the land once a year. We seem to be on the eve of a revolution, and landholders are beginning to realize that cultivation means more than keeping down the native jungle, and includes the returning to the soil the elements of fertility removed by crops. The habits of the coconut tree are to a great extent responsible for this neglect of the first principles of agriculture. Speak of crop drawing on the latent elements of fertility in a soil and of impoverishing it in time, unless the constituents removed from it are returned in the form of manure. Why the fact that there are properties in existence of a hundred years old, that are bearing now as they did fifty years ago without the aid of fertilizers, say our friends, goes to disprove the teachings of science. They generalize from individual and exceptional experience. Ours is essentially an agricultural country whose prosperity depends mainly on agriculture. It, therefore, behoves those in authority to make agriculture one of the principal subjects of study in all our public schools. In this utilitarian age, when we are beginning to place a £ s. d. value on education, and doubts are being raised of the utility of a knowledge of the classics and the higher branches of mathematics for those treading the humbler walks of life, and the universal cry seems to be for "technical" education, agriculture will not come amiss in the curriculum of studies, and will possess a money value if it does nothing more than induce a love of gardening. A full and liberal supply of vegetables for the table will lessen the household expenses and the druggist's bill. A long-felt want is a course of popular lectures on useful subjects by the different talented men in our midst, in some central public building, and on Saturday afternoons when all public offices are closed early.

To return to my subject, it is regrettable to find that trenching, a necessary branch of agriculture in coconut cultivation, and which is intended to take the same place as draining in upland cultivation, receives but scant attention at the hands of coconut planters. For trenching to be of any use, it must be taken in hand as soon after the land is burnt off as possible. The conservation of the valuable surface soil and ashes was considered of so much importance in coffee cultivation, that the veteran Mr. George Wall propounded a plan of his own to lose as little of it as possible, by draining land when the forest was standing. Old and experienced planters vetoed it as impracticable, but to prove its practicability, one of his superintendents, Herbert Tucker, I think it was, did actually drain land before it was felled. It is beyond my purpose to discuss the system. I mentioned it only to show the importance attached to the conservation of the surface soil and ashes. In coconut cultivation trenching is resorted to only after the trees have reached maturity. A case of closing the stable door after the steed had escaped. On an old and well-grassed coconut estate, there is no wash except in the hollows where the water from the surrounding land finds an outlet. In the first few years after a plantation has been opened, the soil is constantly disturbed and prepared for minor cultivation. It is then that all the surface soil is displaced by the monsoon rains, and finds a resting-place either in the hollows on the estate or in your neighbour's paddy fields. To prevent this sad and irreparable loss, trenching ought to be undertaken as soon after the burning is possible.

There is one essential difference between draining as it is practised upcountry and trenching on coconut

plantations. By the former system all the rain that falls on the land is caught in drains of easy gradient and led on to ravines. With the steep hill-sides in our mountain country, this is the only practicable system, for any attempt to catch the rain water and confine it in trenches to gradually percolate through the soil, will result in huge landslips, and the gradual subsidence of the hill-sides in the neighbouring valleys. But all the same one great objection to the system is that by directing the water that falls over a large surface to ravines, these with every heavy fall of rain get wider and deeper till in time they become unsightly and encroach on the cultivated land. In trenching a coconut estate, it is sought to catch all the water that falls on it so as to allow it to gradually percolate through the soil. No cultivated tree requires so large a quantity of water for its successful growth as coconut, and the advantages arising out of storing in the soil large quantities of water for use when no rain falls are obvious.

Let me now discuss the systems in vogue amongst coconut planters. Trenches of varying depth and width, according to individual idiosyncracies, are cut continuously between rows of coconut trees. Some planters throw the soil so displaced on the upper side of the trenches, others on the lower side. One of the first things that struck me when I took to coconut planting was that there was a manifest disadvantage in continuous trenches. The water caught in these naturally gravitated towards the lowest points in them, and then found an outlet carrying everything before it to be for ever lost to the estate. They did not in my opinion answer their purpose either as catchwaters or silt-traps, except to a small extent. To overcome my objections to these continuous trenches, I left a portion of them uncut between every two trees. This gave them more the appearance of water-holes than of trenches. By this system only the overflow of these water-holes or sections of a trench found an exit at every sensible depression; and the overflowing was dependant both on the capacity of the trenches and on the fall of rain. The system was not perfect, but was an improvement on the practice in vogue. Further consideration satisfied me that no system of trenching will be perfect, or will answer the purpose for which it is intended, unless trenches are traced level following the contour of the land. The exorbitant price of a tracer stood in the way of my carrying out my idea for a long while. At last it struck me that I might devise a "level" by inverting the triangular level (*mattanlalla*) in use amongst carpenters, and fixing it on to a staff and taking "shots" at the usual staff in use with a tracer. The work of my invention was approximate, but it answered my purpose admirably. I traced contour trenches, not continuous, with it in a field of coconuts at intervals of from 5 to 7 trees, and they caught all the water of the late N.-E. monsoon, heavy and long-continued though the rains were, without a single breach.

I am averse to deep trenches except in very stiff soils, for they drain away all the moisture from the land, and the water that is caught in them sinks beyond the reach of the roots. I usually cut shallow trenches about a foot deep and six feet wide, and throw the soil on the lower side of the trenches. By throwing the soil on the lower side of the trenches, their capacity as catchwaters are increased; by their being shallow, the water they catch does not sink beyond the reach of the roots, nor is the soil drained of moisture too much during the dry season; and by having them wide the surface extent exposed to the beneficial influence of the air is increased. These are the reasons for my system. I suppose those who adopt other systems have as cogent reasons to support them.

CHINA V. INDIAN TEA.

In commenting on the great struggle of China *versus* Indian tea, we have more than once referred to the great advantage which Indian tea planters possess in the large areas which

they cultivate. Tea-growing in China is *la petite culture*; in India it is, above all things *la grande culture*. And the tendency, we observe, is to amalgamate the gardens in India more and more for the sake of greater economy in working them. Thus a recent return from Assam shows that while there were 941 gardens in 1885-86, there were only 883 at the end of 1886-87. In the same period the area under tea cultivation increased by 18,288 acres. In the former of the two years in question, the average size of each garden was 973 acres, while in the latter it was 1,058 acres. The return goes on to say the production of manufactured tea in 1886-87 was the largest ever recorded, amounting to 61 million pounds. "Improved methods of cultivation," the report says, "are increasing the average yield per acre. This average for the whole province last year is variously stated at from 349 to 353 pounds, and it rose to 518 pounds in Lakhimpur, which is the most productive district." It appears, however, that the planters this year will have to reckon with heavy losses caused by the epidemic of cholera in Assam, which slaughtered large numbers of coolies who were brought at heavy expense from Bengal, but who died before they could work for their masters.—*L. & C. Express*, May 4th.

CINCHONA IN JAVA.

The report of Mr. Von Romunde, director of the Government cinchona enterprise in Java, for the first quarter of 1888, dated Bandoeng, 3rd April, has only just reached us, the translation being as follows:—

The weather was very wet during the past quarter. On account of the abundant rain the putting out of plants in the open could be carried on uninterruptedly, but the continuous moisture was not favourable for the development of the plants and seedlings, and the growth of the plants recently has been extremely slow. The gathering and drying of the bark was greatly hindered by the excessive rain. The crop of 1887 was dispatched by the end of February to Tandjong Priok and amounted to 703,313 half kilograms of bark. The crop of 1888 is, in consequence of the slow growth of the trees during the last few months and the continuous rain, very small as yet, and amounts to not more than about 75,000 half kilograms for bark, of which at the end of the quarter 5,017 half kilograms had been dispatched to Tandjong Priok. On the 8th December 1887 the last sale of cinchona bark of the crop of 1886 was held at Amsterdam, whilst at the sale of 23rd January 1888 the first lots of bark of the crop of 1887 were sold. The average price realized at each of these sales was 56³⁴ and 51⁴³ cents per half kilogram. On 3rd March a sale of cinchona seed was held. The demand for ledgeriana seed was comparatively very small, except for that obtained from analysed trees, while the succirubra seed offered for sale was all sold. The net result of the sale was f454. During the first few months of 1888 the plantations on the Malabar mountains, especially Tirtasari, suffered very much from caterpillars, which appeared in such numbers, that they caused a serious check to the growth of the plants by eating the leaves, and must also be mentioned as a cause of the small harvest realized by thinning out. Some plantations at Nagrak had also to endure a formidable attack of caterpillars. On the older plantations on the Malabar mountains, especially on those affected by caterpillars, the *Helopeltis antonii* also made a vigorous attack. As the catching of insects on high trees is impracticable, working of the soil and manuring were utilized as a means of combating the plague, whereby a vigorous growth was induced, and the results of the plague reduced to a minimum. At Rioenggoeng the ledgeriana plantations had to suffer much from canker, which attacked the branches and stems of the trees. It was stated in the report for the last quarter of 1887,

that the crop of ledgeriana seed in 1888 promised to be pretty abundant, but these prognostications have been swept away by the excessive rains, which have hindered the setting of the fruit. The erection of buildings intended for six Davidson's T sirocco driers was proceeded with vigorously on the establishments to the south of the mountains, to the end that as soon as these machines are received a beginning may be made with their erection. In spite of the unfavourable conditions for the growth of the plants in the early months of 1888, the crop of this year promises to largely exceed that of last, although it very probably will not be so great as was estimated at the beginning of 1888.

The number of plants in the various gardens at the end of the 1st quarter of this year is given as follows:—In the nurseries: 1,440,000 ledgeriana (including 40,000 grafts), 670,000 succirubra—total, 2,110,000. In the open: 821,000 ledgeriana (including 190,000 cuttings and grafts, and exclusive of the more or less 3,000 original ledgerianas), 14,000 calisaya and hasskarliana, 609,000 succirubra and caloptera, 166,500 officinalis, 1,000 lancifolia—total 1,611,500. Grand total, 3,721,000.

THE MANUFACTURE OF QUININE AT THE BRITISH SIKKIM CINCHONA GARDENS: WHY NOT IN CEYLON?

FULL PARTICULARS OF MR. GAMMIE'S
SYSTEM;
NOTHING DIFFICULT ABOUT IT;
A NEW LOCAL INDUSTRY WHICH MESSRS.
SYMONS & COCHRAN OUGHT AT
ONCE TO START.

We have a very interesting letter from our good friend, Mr. J. Gammie, the superintendent of the Mounpoo (Darjeeling) Cinchona Gardens. In responding to our congratulations on his discovery of a cheap and effective mode of manufacturing quinine, Mr. Gammie writes:—"We have undoubtedly hit at last on an almost perfect plan both for the manufacture of quinine and febrifuge. The plan can readily be worked on a small scale in bottles. We have only made about 500 lb. of sulphate of quinine as yet, but hope soon to be making it on a largish scale. Machinery for it is now being rigged up. The professional reports on our quinine have all been most favourable. The only objection to it as yet has been that it is too good, and that a slightly inferior product would pay better. The oil plan appears to bring out the alkaloids from the bark in a pure and highly crystallizable state, and, best of all, *perfectly exhausts* the bark. It costs us about R12-8* to work 100 lb. of dry bark. We may yet find out how to lessen our loss of oil, but I hardly think we can reduce the cost by very much, the carriage of fusel, &c. being so very expensive. It appears to be nearly as expensive to bring the oils &c. to the bark as to send the bark to the oil &c. I hope cinchona matters are to look up soon! At present prices there can be very little profit going for either grower or manufacturer.

"I am very glad to hear that your tea is doing so well. 600 lb. per acre is just about double what the best Darjeeling hill gardens produce, and the most of them pay well. It appears to me that for steady profits the high up tea gardens are much more to be relied on than those low down. No doubt the lower gardens at times give enormous profits, but they are more subject to blight, &c. *Helopeltis* was very bad on many of the Terai gardens last year, and on some of the lower hill gardens. In consequence scarcely any the Terai gardens paid

* R12-50 Ceylon currency.—Ed. C. O.

their expenses, and many of them made a loss on the year's working."

Mr. Gammie wrote again giving full directions:
 How TO MAKE SULPHATE OF QUININE.
 17th May 1888.

As promised a day or two ago, I have drawn up fuller directions for making quinine by the cold oil process which we have adopted here. I am sure you will admire both the simplicity and efficiency of the process. To me it appears to be nearly as perfect as any process can be. I may trouble you with a few more details by-and-bye.

Take 1,000 grains finely powdered yellow bark,
 " 80 " caustic soda,
 " 11½ oz. water,
 " 16 oz. kerosine,
 " 4 oz. fusel.

Put the bark in a bottle of about 50 fluid oz. capacity.

Dissolve thoroughly the caustic soda in the water, and mix the solution with the bark in the bottle. Then mix and add the oils, and shake the bottle well for three or four hours. Then let the bottle stand quietly until the oil has become quite clear. The oil has now taken up the greater part of the quinine that was in the bark.

Then draw off the oil and put it in another bottle along with 2½ oz. water, in which has been mixed about 25 drops of strong sulphuric acid, shake well up for five or six minutes. Should crystals form in the mixture, dissolve them, by adding a few drops more sulphuric acid, previously diluted, allow to stand quietly for the two liquors to thoroughly separate. Draw off the acidulated liquor, and again wash the oil with 1½ oz. water mixed with 5 or 6 drops sulphuric acid, which, in its turn, draw off, and put the oil back in the bottle containing the bark, taking great care that none of the acidulated liquor is put back with it: shake again for an hour or two, draw off the oil as before, and wash it with the 1½ oz. acidulated liquor already used, allow to separate and draw off. To make sure of exhausting the bark, it may be shaken up with the oil a third or a fourth time, but usually twice will be found sufficient.

Now mix the two acid solutions (which contain the quinine), heat to near boiling in a porcelain glass, or enamelled dish, until the smell of fusel has mostly gone off, and neutralize by adding drop by drop, and steadily stirring, a very weak solution of caustic soda, say one part of soda to a hundred of water, until the liquor shows neutral to test paper, when, if the solution be rich the crystals will immediately form out, but, if poor, not till the liquor cools.*

To purify the quinine:—Allow the dish, in which the crystals have been formed, to stand over night, and in the morning separate the crystals from their mother-liquor by throwing them into a filter made of blotting paper. Dry the crystals and dissolve them in about fifty times their weight of boiling water. Then add a pinch of animal charcoal, say as much as can be held between the finger and thumb, and keep stirred for a few minutes: should many crystals form on the top, add a little more quite boiling water. Then filter through blotting paper, having previously made both filter and funnel quite hot, returning to the filter the first liquor to pass through, as it usually contains a few specks of charcoal. It is better to make the stream from the filter fall against the side of the catching vessel, which will prevent agitation and consequent smashing up of the

*Should an excess of caustic soda solution be accidentally given, add sulphuric acid, drop by drop, till neutral.

crystals, also have the catching vessel quite hot. Everything in purifying should be as hot as possible, else there will be loss by the crystals forming in the filter paper. The filter paper should be washed with a little boiling water to take up any crystals that may have formed in it.

When quite cold, transfer to a blotting paper filter as before, and after the mother-liquor has drained away, put the filter containing the crystals in a warm place to dry. As soon as the crystals can be easily teased asunder with forks, they are sufficiently dry.

Both the oil mixture and acidulated liquor can be readily drawn off with a glass syphon. But the best thing for separating the acidulated liquor from the oil is a separating funnel. This is a cylindrical shaped glass vessel with a narrow tube with tap fixed in it at the bottom. But, if this is not at hand, a clear glass bottle with a hole bored close to the bottom would answer. In the same way the oil can be readily separated from the bark mixture by a hole bored in the bottle just above the meeting of the oil with the water. And other ways will readily suggest themselves.

The mother-liquors, both from the crude and purified quinine, contain more or less of the alkaloids. To recover the most of what is crystallizable from the first mother-liquor, *i.e.*, from the crude quinine, heat it up with a pinch of animal charcoal stirred into it, filter, and then evaporate the filtrate to one-half or less, cool and separate the crystals as before. The liquor will now contain what is uncrystallizable. To get that add an excess of caustic soda solution, when it will be precipitated.

The quinine in the mother-liquor of the purified quinine can be recovered by evaporation in the same way, or can be precipitated.

The animal charcoal we use is what is known as bone or ivory black. The caustic soda is Gaskell, Deacon & Co.'s white, of 60 per cent. Much of the success depends on the quality of the soda.

Fusel is miscible in water to a small extent, hence there is a greater proportionate loss of it than of kerosine. So in working repeated batches of bark with the same oil mixture it is necessary to add a little fresh fusel from time to time. If the fusel fall very much below the proportion given, the oil mixture loses its efficiency to a considerable degree, and becomes difficult of separation from the other ingredients. The fusel which has united with the soda solution and exhausted bark may be mostly recovered by distillation.

J. GAMMIE.

The above was intended for the guidance of the proprietors of a particular estate, with the hope that an experiment would be tried by them, with their own bark. But we feel bound to avail ourselves of the discretion kindly allowed us, by making the details public. Added to the official instructions issued by the Government of India, (which are reprinted in the *Tropical Agriculturist*), they ought to be sufficient to encourage what has long been projected and discussed, the establishment of a Quinine Manufactory at Colombo, where the large quantities of bark still in Ceylon could be worked up, so as to find, or wait, a remunerative market. The only objection is the very low price to which quinine has already fallen, but increased demand, the result of this cheapness, is sure to lead to improvement ere long. Quinine ought to be much more largely used in Ceylon than it is at present, not merely as a cure for fevers contracted, but as a prophylactic. For instance, if the Kelani Valley planters gave their coolies a dose containing a few grains of dissolved quinine each morn-

ing at muster, during the fever period, we cannot doubt that a much larger proportion of their labour force would continue to be available steadily and constantly for estate work, than has been the case recently and in past years. Paludal and jungle fevers periodically claim their holocausts of victims in Ceylon, and as for India, of the eight millions or thereabouts of human beings who die within its bounds every year, the vast majority are killed by fevers, "malarial" or "typhoid" (enteric). Cholera, dreadful as its ravages often are (in retribution for allowing water to get foul and the neglect of sanitary laws generally), but for the terrible symptoms of the disease and its awfully sudden termination in death, would not deserve to be mentioned as a cause of mortality in connection with the Indian death-roll. It is a question worthy of consideration whether a judicious use of quinine might not ward off, modify and even cure attacks of cholera. But no one doubts that for fevers (uncomplicated with serious internal disease or lesion of the vital organs) it is as much of a specific as any material substance can be. There is room for a large increase in the consumption of quinine in Ceylon, and for an enormous expansion of the demand for this valuable medicine in India and in China; in the latter country not only as a remedy for the prevalent paludal fevers, but as a cure for excessive indulgence in opium. So in all marshy countries, such as a large portion of the United States, Russia, parts of every country on the face of the globe, in truth. If quinine can be manufactured cheaply in Ceylon by Mr. Gammie's method, and we can see no possible obstacle which cannot be overcome, we think our leading planters and merchants ought to lose no time in establishing a factory, or in the encouragement of a chemist, or firm of chemists, to embark in the enterprise. Whether cinchona trees continue to be planted in our island or not, it is certain that the quantity still growing on estates would afford supplies for a local manufactory for many years to come, yielding, we should say, a moderate profit to the owners of the raw product, and also to the manufacturers of the alkaloids.

CINCHONA IN JAVA.

A good deal of information on this subject has just reached our hands. The Quarterly Report of the Director of the Java Government Cinchona Gardens is, as usual, succinct and business-like without any colouring of exaggeration or of great expectations. It will be seen from the document (specially translated for our *Tropical Agriculturist* that the total crop of bark for 1887 was only 703,313 half kilograms, or under 800,000 lb. After all we have heard of what the Java Gardens as well as Private Enterprise were going to do with the market, this result is certainly reassuring. But there is more behind; the crop of bark for 1888 is not at all promising, unfavourable weather has retarded the growth of trees, and altogether we infer that Mr. Von Romunde does not anticipate to ship as much bark (800,000 lb.) up to February 1889 as he did in the twelve months ending Feb. last.

So far we have some comfort for the much-trying Ceylon cinchona planter; but the other side of the shield is presented with a vengeance in the letter of a Java proprietor writing to us from Amsterdam. We certainly do not feel that M. Van Son, however good his intentions, has presented us with a reliable picture of the enterprise in Java. We have no hesitation in denouncing any writing about qualities of bark reaching to 10, 13 and 18 per cent as averages, as great exaggerations. No bark

at an Amsterdam sale yst has averaged above 4 to 5 per cent. Neither can we bring ourselves to believe in cinchona estates of large area as being fully planted and aggregating so many millions of trees. This statement altogether is in wonderful contrast with the moderate one last received from a Java correspondent, and we suspect the latter is more reliable. That Java bark again be harvested, dried, packed and transported "f. o. b.", all for a penny per lb., is at direct variance with every report we have ever read before. A penny per lb. is the very lowest at which this can be done under the most favourable circumstances in Ceylon, while the average is probably nearer 2d, and the Java average was given some time ago in an Amsterdam or London commercial report at 4d per lb. All this varying and in some cases, highly-coloured information, only makes us the more regret that a well-informed Ceylon planter cannot go to Java to visit, inspect carefully and report on the centres of cinchona culture there. No doubt Java (and Uva in Ceylon) will ultimately become the two great sources of supply for good bark in the world; but Java planters are evidently not in a hurry even with the trees they have fit to harvest, and there will be no rush from that quarter, so far as we can judge for some years to come.

THE POSITION OF CEYLON TEA AND ITS FUTURE.

Far too much we consider is made of the recent fall in Ceylon tea. It is distinctly stated by one London Broking authority that apprehensions as to future large supplies had to do with the fall. Now, apart from the possibility this year—as last—that the fall may be temporary, and that poor quality teas are also now given as a cause, we have all along had to face the fact that the superior position obtained by Ceylon over Indian teas in price could scarcely be permanent, save for our best qualities. A fall to the Indian standard for Ceylon common teas should scarcely take us by surprise. Below the Indian average we are not likely to fall, and if China teas are year by year superseded, we shall share in the benefit; while should a special taste for Ceylon teas be developed in America, Australia, &c., the superior position in prices may once again be won. We are reminded also that an average price for a whole sale—as telegraphed to our contemporary—is scarcely a safe test for purposes of comparison. An unusual proportion of poor (or very good) teas may affect one sale abnormally, as compared with its predecessor or successor. We are arranging for a weekly telegram from Mincing Lane, which shall give a quotation for a recognised standard quality in Ceylon teas, week by week. This message we hope shortly to receive, and to be continued weekly, and we think it will offer a safe index for purposes of comparison of the exact state of the Ceylon market.

Messrs. Stenning, Inskipp & Co. in a report dated 7th May, express the belief that the full crops estimated from India and Ceylon for the year May 1888 to May 1889,—“at the present large and increasing rate of consumption of Indian and Ceylon kinds, this quantity (118 million lb.)—should be readily dealt with.”

CULTIVATION OF FRUIT TREES.—The Quetta authorities are on a fair road to make that promising place one of the best cantonments in India. They have now turned their attention to the cultivation of fruit trees; and the Ranikhet and Simla nurseries have recently been indented upon for a large number of English fruit trees.—*Indian Agriculturist*, April 21st.

COTTON CULTIVATION IN JAFFNA.

Mr. Charles Morrison, our well-known bank agent at Jaffna, has proved himself well worthy of the gratitude of the Jaffna people. He is also ready to do anything in his power for the welfare of the people. He called a meeting of the leading men of the community, on the 3rd May, to nominate and appoint a committee to consider and take the necessary steps to form a company for encouraging the cotton cultivation in the Northern Province. The chairman, Mr. Charles Morrison, explained in a lucid speech the object of the meeting and the bright prospect before the people. He concluded his speech by saying, "the ball is set at the foot of the Jaffna man and it is now for him to roll it." Yea! we shall roll it, was the silent response. Mr. Vitianata Chetty Curryappa Chetty addressed the meeting, at some length, giving a detailed account of the different species of cotton, the mode of cultivation, and of his own experience of the industry. Hitherto, cotton, has been cultivated, here and there, in the district in small extents, but finding no proper market, the cultivation has been discouraged. Now that the Spinning and Weaving Company having been organized at the capital of the Island, is ready to buy any quantity for ready cash, the bank would be ready to advance money on cash credit system to the cultivator whenever and whatever required. Unlike the tobacco or paddy cultivation, very little labor is required and no manure is needed. If it be sown in August, the first crop, it is said, can be reaped in the following month of January.—within about six months. The plants are kept up for years together, yielding a harvest every six months. Very extensive acreage is available for this industry in the Pachilaipalle district, the Islands and the Wanny. It is hoped that the Government may help the new company by giving lands now lying waste or overgrown with jungle, on easy terms, for utilizing them with the industry. Thus, we see the required land is available. Again, the labor is very cheap. There are hundreds of people in every division of the district thrown out of, or wanting, work to do. They can be easily enrolled for the required work. All things considered, the prospect is bright and we may predict that good days are in store for Jaffna.—*Com.*, "Morning Star."

BOLIVIAN CULTIVATED CINCHONA.

South Americans allowed the planters of the Old World a good start in the cultivation of cinchona before they thought fit to repair the waste and the ravages in their native forests by rearing the bark-yielding trees in a systematic manner. It is perhaps a tribute to Spanish indifference to progress that a commencement in the cultivation of cinchona was first made in Bolivia ten years ago by German planters, one of the most successful being Mr. Otto Richter, of Cochabamba. Plantations exist at Mapipe Longa, Yungas, and Mapipe, north and east of La Paz, and in those localities over six million plants were first placed in cultivation. For some time the Bolivian cultivated calisaya, sent to our market in quill form, has been a standing feature in the London bark auctions; but quite recently one of the principal cultivators has made a bold attempt to provide us with a cultivated substitute for the so-called flat Bolivian calisaya, which is a bark much sought after on the Continent, and for which prices are paid greatly in excess of its mere alkaloidal value. A sample of this cultivated flat bark, recently submitted to us by the importers, shows it to have been carefully harvested. It is quite dry and powders readily, leaving little fibrous material. An assay of the bark showed us that it contains 3 per cent. of total alkaloids, a percentage considerably under the standard of the British Pharmacopoeia, but comparing favourably with the quality of many samples of natural yellow cinchona. Unfortunately the appearance of the bark under notice is somewhat against it. Of course the trees on Mr. Richter's plantation are still young, and do not, therefore, yield such stout bark as the wild cinchonas which provide the ordinary flat bark of commerce. The pieces, in fact, are

merely, if they may so be called, flattened quills, one-eighth of an inch in thickness, and which in the ordinary process of drying would have curled up into quills, but were artificially prevented from so doing. The colour is partly a deep orange, partly streaked and spotted with rusty brown, which gives the bark a queer look. Druggists, therefore, who merely appreciate appearance shun it; but we understand that on the Continent the bark is beginning to find a ready sale, and it might be worth the while of our own export druggists to devote some attention to this new variety before it gravitates, as too many other drugs are already doing, towards rival markets.—*Chemist and Druggist.*

GOLD AND COAL (?) IN CEYLON:
COPPER AND MANGANESE.

Is Mr. Judd (see his letter elsewhere) sure of his date, in stating that he helped to dig for gold at Nuwara Eliya in 1851? We suspect it must have been in 1854, because he says that "soon after this," that is, the digging by himself and his friends, the Australian diggers came to Nuwara Eliya. We know that some of the Australian diggers, when driven by fever and paucity of appreciable gold from the Mahaoya, in 1854, went to Nuwara Eliya and dug pretty deeply under the auspices of Sir Samuel Baker, who, with his late brother, was then settled in Nuwara Eliya. If experiments were made in 1851, we think they would have been mentioned by the press of the day and by Sir Samuel Baker in his book. But, we well remember, that it was the advent of the Australian or Californian diggers in 1854 and their operations in the Mahaoya, near Ambepussa, which first drew attention to the matter, and led us then and subsequently to publish the information which appears in a collected form in "All about Gold, Gems, and Pearls," respecting the notices in ancient records of the existence of gold in Ceylon. Those records and the action of the diggers, with Mr. Power's exploration of the auriferous stream to its sources in the mountains of Dolosbage, and the information of a miscellaneous nature which poured in upon us, once we commenced the inquiry, proved that the eminent geologist, Dr. Davy, had grievously erred in denying the existence of gold in Ceylon. The geological and mineralogical structure and constituents of our Ceylon rocks so closely resemble those of Southern India, except that our quartz is not reddened so deeply by pyrites, that, gold existing in the one, it was only natural to infer that the metal would extend into the other. We have now abundant and conclusive evidence, not only that gold exists in Ceylon, but that it is about as widely distributed, if not more so than the precious minerals (rubies, sapphires, "catseyes," and the ubiquitous and varicoloured tourmaline) for which the island had been celebrated for ages before Arab imagination gave the world the sensational tales of Aladdin (Allah-ad-deen), and Sindbad, whom Miss Jewsbury, in her imagination, saw, the one in the cave while she followed the other on the shore. But there is no proof that in the days of old, although gold was collected and coined in Ceylon, the metal was found in quantity to remunerate the collectors. This work, like others, was a species of Rajakariya: men collected gold dust from the river sands when the king or any potent chief gave the order. What was gathered was

chiefly minute dust, and such is the case as a rule still, the dust being so minute and so much resembling "a grain of wheat in a bushel of chaff," that the question in regard to gold searching—"Will it pay?"—has not yet been solved in the affirmative. We shall know more when the weather permits wider and deeper search in the alluvials of the Morawak Korale. Even there, however, the men who are represented as finding nuggets regarded the gold as merely a subsidiary find in the main pursuit, which was for gems. In California and Australia it was the gems which were reckoned subsidiary and, until recently in Australia, of very secondary consequence to the gold. If really appreciable nuggets were found near the surface, then it would seem by all analogy to follow, that still heavier masses of the metal will be found farther down in the alluvial until the bed rock is reached. This expectation is founded on the well-known principle that the heavier the specific gravity of a substance, the greater is its tendency to sink through decomposed and yielding rock. But the experience of 1854 renders us, if not sceptical, at least very cautious as to nuggets alleged to be found by natives. When Mr Armitage, in the course of the operations which he will resume, when the violence of the monsoon is abated, finds as we trust he may, plenty of nuggets and describes their composition and character we shall feel on safer ground. Meantime, the history of other gold-bearing formations in other countries seems to favour the probability of rich finds of appreciable agglomerations of the precious metal, if they exist at all, rather in the lower than in the higher formations of our mountain system. The alluvial swamps and flats in the latter, however,—the "Moonstone Plain" in Nuwara Eliya and similar formations, stretching along the great elevated tableland, to Uva, have been more or less dug for gems, and in some of them the slight colour of gold has been recently, as well as in 1854, seen. Small nuggets, too, have been found, leading to hopes being cherished of further and richer finds in the direction of the matrix which have never been realized. We have heard so much of "the matrix" in Ceylon, from the time of Gygax, with reference to precious stones, until now in regard to gold, while we have seen or heard so little of the identification of any such mother-rock, that we begin to suspect that in our Ceylon mineralogy "matrix" and "myth" must be synonymous. Sir Samuel Baker, on arrival in Ceylon, on the occasion of his latest visit, told us that one of his main objects he had in view was to search up to the heads of certain streams in which during his previous residence he had seen abundant fragments of precious stones. But, although the great traveller lost jewels at Nuwara Eliya, he said nothing of having found the matrix of the rubies, any more than he found the matrix of the minute gold specks which showed in his Nuwara Eliya diggings of 1854. Then, as now, it was asked why Government do not directly aid the settlement of the question whether paying gold deposits exist in Ceylon. We have frequently urged a regular geological survey, and we would now strongly recommend the introduction of an expert with a diamond drill from Australia. What is specially needed is that our lower quartz reefs should be tested. It is, however, significant enough that in all the digging of plantations in Ceylon and all the cuttings for the railway, even in the mountains, we should have heard nothing of finds of gold. But such diggings and cuttings are, after all, not much more than superficial. The only quartz reef of any importance cut through in the line to

Nanuoya was that on St. Andrew's estate, Dimbula. But much of the section to Haputale will run through quartz formations, which ought, simultaneously with the blasting, cutting and tunnelling operations, to be thoroughly examined by experts and diggers for gold. Recently a small nugget was found in one of the streams running down from the side of Totapala, and also some copper pyrites and black oxide of manganese. But it is the usual tale of only small quantities found and futile searches for more. Still gold may be found on the bed rock below the marshes on the railway line near Patupola, none of which Mr. Waring found to exceed 9 feet in depth. The black oxide of manganese suggested to its finder the idea of coal, and we took it for peaty matter mixed with the magnetic iron sand in which gold is so often found. Experts, however, decided that the stuff which had blackened the quartz was manganese, the substance which gives colour to our "rose quartz" and our purple amethysts. There is no great market for it at present, but mines of manganese as well as of copper would be welcome additions to our resources. As for Mr. Judd's coal, it was of course English in every case. We only wish coal could be discovered in Ceylon; it would be more valuable to us than gold. But, while Dr. Davy's case teaches caution, we feel that it is about as certain as anything can be that coal in Ceylon is more of a myth than even the long-sought-for but never found matrices, teeming with brilliant gems and coloured richly by auriferous metal.

CHINA TEA IN 1887.

No article of the exports of China during 1887 attracted more notice and engaged more attention than tea. Opinion seemed to point to it as a waning business. The total quantity exported from the treaty ports was 2,096,097 piculs in 1887, against 2,217,295 piculs in 1886. Judging by quantity, 120,000 piculs, say 5 per cent., less left China in the later of these two years, the earlier of the two being an unprecedented year. But as between the two years, there is a vast difference in the values. Thus, the assessed value of the export of 1886 referred to was Hk. Tls. 33,504,820, and that of the export of 1887 referred to was Hk. Tls. 29,379,838, the difference being Hk. Tls. 4,124,982, a fall of over 12 per cent. on a diminished export of 5 per cent. It is therefore to the depreciation in value, with its likely effect in bringing about a diminished production in years to come, that we must attribute the apprehensions entertained for the prosperity of this vast industry.—*Hongkong Daily Press.*

TEA PLANTING IN JAVA.

An upcountry correspondent favours us with the following extracts from the letter of a well-known Java resident:—

Parakansalak, 15th May.—I duly received your favour of the 5th March, and thank you for the *Observer* you send. Unhappily, I am not in the opportunity of sending you tobacco seed. I have done my best, and wrote to different people at Deli (Sumatra), but all refused to let me have the seed, and plainly wrote that they will give seeds to nobody, even if there is more than they want for their own tobacco fields, and better destroy it, but to help swamping the market with tobacco just as the tea does now. I am also interested in a large tobacco company at Brit. North Borneo, and wonder how the manager, who was former employed in Deli, will be able to secure seed; the next monsoon they must commence planting. Tea planting in Java is not so bad as many people in Ceylon would believe: I for instance, made clear £8,000 in 1887 out of Parakansalak. The smallest dividend paid by a tea company

was 6 per cent, others paid 8½, 10, and 12 per cent, and this is on account of our cheap labour, water-power for machinery, and boxes which do not cost more than 46 cents for 80 lb. chests. My expenses in full in 1887 did not exceed 27 cents per half kilo; I wonder what expenses are in Ceylon free on board.

NORTH BORNEO NEWS: PLANTING ITEMS.

(From the *British North Borneo Herald*, May 1st.)

We are glad to learn that Mr. T. C. Bogaardt of Singapore is a partner in the 30,000 acres of land secured by Mr. van der Hoeven. Mr. Bogaardt's name is a guarantee of the soundness of any enterprise and will have much weight with planters when enquiring about tobacco planting in British North Borneo.

We are glad to be able to say that offers have been made by a large Shipping Firm in Singapore to run a steamer from Singapore to Hongkong, calling at Sandakan and Kudat both going and returning. The terms offered are low and we hope they will be acceptable to the Government. The number of coolies brought down from Hongkong by the S. S. "Afghan," 287, is an earnest of the passenger freight obtainable and Count Geloës tells us that over 1,000 coolies will be required by the tobacco planters at the end of this year. This means \$10,000.

We also hope to see some other estates opened this year for next year's planting. The facilities afforded by Rivers for transport and the probability of finding large areas of flat land adjoining necessarily makes them the leading point of search. We cannot do better than mention that Mr. van der Hoeven informed us that he found better land a little further back from the River (Labuk) with better water. The drainage, if requisite, of lands on the tidal limit is not easy but above the tidal limit it becomes simple and inexpensive and there is little doubt that the upper waters of our big rivers will shortly be visited by planters.

A correspondent from the West Coast writes informing us of the arrival of the S. S. "Afghan" at Kudat with over four hundred Chinese coolies, most of them on their own account. Count Geloës d'Elsloo has returned with 100 coolies and we are pleased to inform our readers that so far from sharing Mr. Abrahamson's views, he says any amount of coolies can be procured at a moderate rate, provided means of communication be secured. The Count received valuable assistance from the Hongkong Government and his visit to China has practically solved the difficult problem of labour. This is of vast importance to the country as it was the only possible stumbling block in the way of the success of the tobacco enterprise. With cheap labour, cheap land, and no taxes, British North Borneo should become a keen competitor with Deli, with many advantages in her favour. We hear that the Ranow yield last year was over ten piculs per field and that, if the price which it is expected to command in Amsterdam be realized, the Company will pay a good dividend the first year. This has not been excelled even in Deli, and we may expect a "rush" in the latter part of the year.

Selectors of land from Holland and Java continue to arrive and whilst we do not begrudge them the profits which their concessions of land will surely bring we cannot but regret that British investors are not more enterprising. Perhaps when the facts are clearly demonstrated by the balance sheet of the Ranow Company the lithargic British may be prepared to share the confidence in the Country and in the Company, which has already been so abundantly shewn by the capitalists of Amsterdam, Rotterdam and Antwerp.

Mr. R. Doorn has also taken up land on the Sugut for tobacco planting. We learn that the lands conceded to Mr. Jan. C. Teves are to be worked by a Company under the style of the *Borneo Tabak My. Sugut*. Messrs. A. van Citters, Tromp and H. Sampson left Sandakan for Kudat on the 19th April in the "Kimanis" to visit the Tobacco estates in Marudu Bay. Mr. van Citters proposed to go on to Singapore by the following "Paknam."

The Commissioner of lands visited the Kinabatangan river in April and finished the road-trace to the Suanlamba the distance from Messrs. E. E. Abrahamson & Co.'s Timber depot to Bilit being 12 miles through easy country. The River Tenne-gang was twice visited and on the second occasion Mr. Walker took the "Thistle" about seven miles up that stream. From Bilit Mr. Walker expects to carry his trace to the Segama without much difficulty.

Mr. H. Sampson, a brother of our former Superintendent of Public Works, arrived here on the 1st April in the S. S. "Spaniel." Mr. Sampson is a tobacco planter from Langkat who is in search of land suitable for tobacco planting, has visited Assahan, Siak and Palembang and is now looking at the lands of British North Borneo. Mr. Sampson has seen the lower Kinabatangan and has gone to Kudat to visit the upper Bongon Lands. Mr. Sampson represents large Shanghai interests but apart from our desire that he should select lands in British North Borneo we shall be glad to welcome, as a resident, the brother of an old Government Officer.

OYSTERS ON THE AUSTRALIAN COAST.

The official report of Mr. A. Wilson, engineer in charge of ports and harbours, in reference to his recent efforts to ascertain whether oyster beds exist along the Ninety-mile Beach, in the vicinity of the Gippsland Lakes entrance, has been placed before the Commissioner of Trade and Customs. Mr. Wilson states that a dredge was put down two miles to the eastward of the entrance and a course was continued at the slowest possible speed to the westward, keeping in about five fathoms of water. The ground tested extended over 20 miles, the dredge being lifted and examined at short intervals, with the result that there was no indication of oysters in any form. Mr. Wilson, however, does not think that this test can be taken as sufficient evidence that there are no oyster beds along the Ninety-mile Beach, inasmuch as the fishermen at the lakes state that after a southerly gale they have gathered basketsfull from the beach, about 16 miles to the westward of the Lakes Entrance, and although a portion of the ground was tried, the space covered was very limited. It is suggested, therefore, that if the question is of sufficient importance, opportunity be taken, when the Government steamer "Lady Loch" is available, to make a more exhaustive examination of the ground, extending over 20 miles on each side of the Lakes Entrance. —*Australasian*, May 5th.

A NEW EXCAVATOR.

[Is there any chance of applying this machine to Irrigation Work in India and Ceylon?—Ed.]

Messrs. Chant and Pateman, blacksmiths, of Young, are the inventors of a new excavator, and the first trial of their machine took place at Brunswick, on April 27th, in the presence of a considerable number of city men and two or three representative squatters of Victoria and New South Wales. The machine is very simple. A wheel

boxed right in on the outer, and over half of the inner side, runs down in the furrow or on the floor of the cutting. Iron plates are fixed at regular intervals all around the inner surface, which act as carriers for the soil. An ordinary plough-coulter and share run beside the wheel, and turn the turrow into it. It is raised then on the steps through the completely enclosed portion, and dropped into a truck or hopper fixed above the axle. The outer wheel is small, similar to that of a reaping machine, and the hopper takes a position similar to that of the machine board. The larger wheel is about 8ft. in diameter, and the hopper or truck is constructed to hold about a yard of earth. The discharging process is very simple. The whole machine is dragged out to the spot where it is desired to deposit the earth, and then a couple of turns of a screw lets the bottom fall, and the load is discharged instantly. The trial yesterday was with a couple of good horses on hard ground, and was very successful. Some slight modifications were suggested, and more power would be required for continuous work, but there is little doubt that the machine has been produced here for which Australia has long waited, and will gladly welcome. Working steadily it is estimated to cut and take out a yard of earth per minute, requiring only two men to attend it. Indeed it is quite possible that a skilful driver with a well educated team could manage it alone.—*Australasian*.

DELI NEWS.

(Translated for the *Straits Times*.)

The *Deli Courant* of the 28th March takes note of the starting of a company in London for mining enterprise on the East Coast of Sumatra. The company will be conducted under the style of the "Siak Tin and Planting Company." The capital has been fixed at two hundred thousand pounds sterling. The Company has been started for buying and working a concession which had been granted by the Sultan of Siak to one of the directors, under sanction of the Netherlands India Government. It takes in an area estimated at three quarters of a million of acres. A German geologist, Dr. Seelhorst, has reported from personal examination, that the company's selection abounds with tin, which may be put out at less expense than is incurred in Banka and Billiton, the chief seats of mining for that metal in this part of the world. In his opinion the Company may rest assured of realising handsome profits from this branch of enterprise at no distant date. He is confident that all will go well with the Company, and has offered to enter its service as manager. The Company also is hopeful of making a good thing out of tobacco cultivation, owing to the land it has secured being admirably adapted for that purpose. The Company is domiciled at Amsterdam, but has the right to establish a branch office in London.

A map of the tobacco districts from Siak to Langkat on the east coast of Sumatra, has seen the light at Amsterdam. The explanatory memoir attached shows that there are no less than 193 tobacco estates in the tract mapped out, the area taken up being estimated at 600,000 acres. The yield from them in 1886 reached thirty two millions of guilders in value.

There is now a great demand for "old hands" from Deli to open up tobacco estates in other neighbouring tobacco growing colonies. Planters in Deli seem mostly to be unmindful of the detrimental effect on their own interests, of this emigration of old hands. The local *Courant* urges them to retain the services of these experienced assistants, by allowing the latter a share in the estate profits. This course is held advisable, on the ground that mere increase in salary would hardly benefit the employees. At present, owing to the expensive style of living indulged in, only a few of them live within their means.

So that they are not satisfied with their lot, and readily cast about for situations abroad. To fill up vacancies arising from resignations, the planters have mainly to rely on new hands who have every thing to learn.

THE RUSSIAN TEA TRADE.

As regards the Russian tea trade from Tientsin the Commissioner at that port notes that a British firm has entered it, that the "trade was conducted in the usual way and by the customary means. Camels were plentiful, and Chinese and Mongols carried off the million of taels which the transportation of tea overland yields nearly every year to the people engaged in it. How long this source of revenue is going to benefit them depends on the progress which the construction of railways in Siberia will make. It is reported that the ground for laying rails between Vladivostock and Stretensk on the Amoor has been surveyed already, and that before the end of 1888 the construction of the road will be commenced. Another danger to the Transit trade of the port is the growing consumption of Indian teas in Russia. These teas are imported into Russia from London and direct by way of Odessa, and are mixed by retailers with Chinese teas. Already the leading Russian firm at Tientsin in anticipation of the further deterioration of Chinese teas and the tendency to improve the same by mixing them with Assam or Ceylon tea, has despatched an agent to India to participate in the purchases of the commodity for which Russia affords, next to England, the greatest market." It is obvious that if Russian taste in tea drinking is turning to Indian teas, another and a very serious danger threatens our trade.—*N.-C. Herald*, May 18th.

INDIAN VERSUS CHINESE TEA.

We have received in the printed documents upon the decline of the China tea trade issued by the Foochow Chamber of Commerce, a comprehensive, clear, and conclusive series of reports that throw full light upon questions whose issues threaten the virtual extinction of the Chinese export trade in tea at no distant date.

In a letter of 3rd November, 1887, Mr. Wood, Chairman of the Chamber, addressed to Mr. Hannen, Commissioner of Imperial Customs at Foochow, one of the principal hindrances to any improvement in the now waning trade is dealt with. The average value of tea exported during that season from Foochow was estimated as Tls. 14 per picul. But the tea had to pay out of this price Tls. 2.75 for export duty, and for *likin* and various taxes Tls. 1.75, or in all Tls. 4.50, equal to 32 per cent. on the value. This levy is now intolerable, since Chinese teas have to compete with Indian teas that are exempt from all local, provincial, or Imperial taxes, and, besides, pay no export duty whatever.

About twelve years ago the competition of the strong and well-flavoured Indian teas began to press heavily upon the inferior and ill-cured teas from China, and the Foochow Chamber of Commerce, foreseeing the inevitable consequences of the gradual deterioration of quality, the avoidance of scientific processes of manuring the plants, the refusal to adopt mechanical and chemical improvements in the preparation of tea for shipment, and the excessive admixture of dust, stalks, and siftings for adulteration, endeavoured to move the Chinese authorities to consider the matter, and in 1876 a full report was laid before the provincial officials pointing out the degradation of the trade and the right measures that should be taken to reform it. But to this report no attention was paid; on the contrary, tea has since been burdened with additional levies of taxation; in consequence of which the trade has fallen away, and seems likely in a few years to become insignificant, if not to cease altogether.

In former years, certainly up to 1866, the Foochow teas were of fine quality. The plants were well manured with fresh grass, the trees were des

troyed, as worn out when eight years old,* fresh shrubs were planted in their place, and only three crops or pickings were taken in one year. Now the plantations are neglected, there is neither trenching, manuring, nor pruning, four or five crops are taken in one season, and the old trees are not destroyed and replaced. In former times cured tea would keep for at least a year without perceptible deterioration, in fact many kinds were rather mellowed and improved by a year's storage, whereas, at present, owing to the inferiority of the leaf and the imperfections of the curing processes tea commences to deteriorate in from three or four months from the date of packing it for export.

The Foochow teamen, once a very creditable class of traders, have also deteriorated, and false packing, fictitious samples, and various dishonest and fraudulent practices have become common, so that, as is now the case in Tientsin, the native dealers are doing all they can to destroy what might even yet, under honest auspices, be a flourishing trade. The Foochow Chamber of Commerce has made its report very complete by appending tables of the deliveries in London of Indian and China tea from 1879 to 1887, with statistics of values, details of the average percentage of dust admixed, &c., and in a letter addressed to the resident Consuls on 1st September, 1876, it is shown that although the demand for Oolong tea exists, the trade—for reasons of inferiority, dust, bad packing, &c.—has now left Foochow. In 1871 the supply of Oologs sent to Foochow for export was 213,600 half-chests; in 1876 the demand had fallen off so much that the supply would not exceed 40,000 half-chests.

We are afraid that as far as Foochow and Hankow are concerned the tea trade must be regarded as in rapid decay and almost past recovery. The Chinese Government is too short-sighted to grant any reduction of duty, much less the total abolition of the export dues that now help to crush a very important native industry, and the provincial authorities will not consent to abate the levy of *likin*. No lessons of the results of fiscal follies have so far had any effect upon the Chinese authorities, as is shown in the way by which the most valuable and growing trade in fruit between Foochow and Shanghai, and the Yangtze and Northern ports, has been completely destroyed by the gradual increase of taxes, which at last became so great that the farmer got nothing for his produce.

As an appendix, the Foochow Chamber reprints a very lively, interesting, and valuable lecture delivered by Mr. J. Berry White before the Indian section of the Society of Arts in London, upon the Jubilee of Indian tea. The Indian tea industry, which now rivals in importance and promises to surpass or even extinguish that of China, dates from 1834, and the history of the investigation revealed the fact that the tea plant was indigenous in Assam, in the *Thea Assamiensis*, a tree twenty-five to thirty-five feet high, with leaves six times larger than the China variety, and giving a yield per acre double that of the Chinese plants. The lecture also records the first serious mistake made in Assam, by importing seed and cuttings from the inferior Chinese plants instead of utilising the fine, hardy,† and productive indigenous trees.

The introduction of Chinese seed and cuttings led to the growth of a hybrid variety, which appears to have been almost as mischievous to Assam as the introduction of rabbits into Australia. The native trees became hybridized and lost their fine distinctive qualities, and now the most strenuous exertions are being made to root out all Chinese and hybrid plants, so that in a few years all the fields will be planted with pure native trees.

* Worn out at eight years old! On the higher estates in Ceylon the plants only come into full bearing at this age, and it seems certain they will not be worn out in five times eight years.—Ed.

† It seems beyond doubt that the indigenous plant is not hardy, and that a good hybrid has this quality added to the other superior characteristics of indigenous.—Ed.

Every year improvement is being made both in India and Ceylon. The plantations are carefully manured, as suitable manure not only almost doubles the yield of the plants, but also improves the strength and flavour of the leaf. Besides, the most ingenious mechanical methods are employed for drying, curing, rolling and packing the leaf, which is now, except in picking from the plants, not touched by hand. These mechanical processes make the tea uniform in appearance. The curing is thorough and the methods used are also very much cheaper than coolie labour would cost. In consequence, the yield of Indian tea, which this year will not be much under 95,000,000 lb., and of Ceylon tea, which will reach and may exceed 12,000,000 lb., will displace China tea, which is now of marked inferiority of quality. As the Chinese Government and provincial authorities will not abolish, and probably will refuse to reduce taxation, and the Chinese farmer has no means of providing proper manure for his fields, or of purchasing machinery for the preparation of the leaf, we are disposed to agree with Mr. White that China must, in her tea growing industry, give way in the near future at a more rapid pace than hitherto, and the world will ere long be supplied almost wholly from Java, Ceylon and British India, although the United States may continue to draw its supplies of special kinds from Japan and Formosa, and Russian consumers adhere to their liking for the finest China Congous.—*Chinese Times*, May 5th.

CHINA TEA.—The *Shunpao* says that in Kiukiang, on the 9th instant, Messrs. R. Anderson & Co. purchased three chops of Keemen teas, consisting of upward of 100 half chests, at Tls 40, Tls 41, and Tls 40.50. On the 10th instant, Messrs. R. Anderson & Co. and Butterfield & Swire and Mr. A. Campbell purchased two chops of Keemen, consisting of 200 half chests, at Tls. 39 and Tls 37. On the 11th there were over 200 chests of Keemen, for which the foreign hong offered Tls. 34, but the teamen would not sell at that price, and shipped it to Hankow by the S. S. "Shanghai." There being very few teamen this year, only small quantities of tea are placed on the market at Kiukiang, and only from 100 to 200 chests of tea arrive there daily.—*China Mail*.

TEA AND TEETH.—A correspondent of the *British Medical Journal* (Surgeon W. T. Black) makes the following interesting remarks on the injurious effect of tea on the teeth:—Some years since, when on duty at recruiting stations in the North of England, I took observation on the great amount of disease and loss of the teeth existing amongst the class of men offering themselves. It became a cause of rejection of itself in great numbers. As far as my inquiries went I was led to trace it to the excessive tea-drinking indulged in by the working classes in the manufacturing towns, and this went on all through the day, whether with food or not. In fact, instead of five o'clock tea being the invention of the upper classes, it was found to exist to an injurious extent in the working classes long before that time. Tea seems to have a peculiar tendency to cause hyperæmia in the tooth sacs, leading to inflammation and, eventually, abscess of the fang, with, of course, dentalgia at every stage. Whether this special tendency was due to theine or tannin having an elective affinity for dentine it is not possible for me to say. It would be curious to know if medical men, practising in such manufacturing districts, had observed the deterioration of teeth to be coincident with tea drinking. We can scarcely accept this view: how about the greatest of European tea-drinkers, the Russians? we never heard of their having bad teeth, nor the Chinese and Japanese, at least unless directly traceable to other well-known causes.—Ed.]

PERU: EXPORT OF SALTPETRE FROM IQUIQUE.—In 1887, there were exported from Iquique 619,000 tons of saltpetre to Europe, and 75,110 tons to the United States, together, 694,110 tons, 431,500 tons in 1886. In December alone the export amounted to 96,000 tons.—*Chamber of Commerce Journal*.

PRESERVATION OF BOOKS FROM INSECTS.—In certain parts of China, the British Consul at Swatow observes, books are extremely liable to be attacked by insects. They first destroy the glue used in the backs of books, and gradually perforate the whole volume. Cockroaches, too, entirely disfigure the covers by eating away patches of the galzing. The remedy for both these nuisances is easy. The late Dr. Hance, who had a large library, used the following recipe:—

Corrosive sublimate	5 drachms
Cresosote	60 drops
Rectified spirit	2 lb.

This mixture, a violent poison, he applied with a brush in the joint of the book between every six or seven pages, and as a preventive of the ravages of cockroaches, he varnished the cover of the book with a thin clear spirit-varnish. In binding books, it would be only necessary to add a small quantity of the above mixture to the glue used, and to give a coating of spirit-varnish to the cover, to secure complete protection from the attacks of insects of all kinds.—*Chemist and Druggist*.

CINCHONA CULTURE IN JAVA.—The Amsterdam correspondent of the *London and China Express*, writing on April 25th, says:—

The West Java Kina Cultuur Maatschappy held its annual meeting on the 23rd inst., when information was given regarding the condition of the undertaking, which was considered satisfactory. The cultivation is gradually extending, and the number of trees is about 3,285,000, of which 3,160,000 *Ledgeriana* and 125,000 *Succirubra*. According to the profit and loss account the total profit amounts to fl14,273, from which an expenditure of fl56,794 has to be deducted, the net profit being thus:—fl57,479, of which the shareholders will receive a dividend of 5½ per cent, or fl55 per share. The cinchona crop of the estates is estimated at about 93,000 kilos, and taking into consideration that the average price made for the last crop was c. 93 per kilo, while the cultivation in Ceylon is further decreasing, the directors express as their opinion that the prospects for the company are favourable,

AUSTRALIAN TIMBERS.—Mr. J. Laurie is on his way to the old country in the S. S. "Oceana," with a view to the introduction of Australian timbers to the markets of Great Britain. He is sending a sample cargo in the S. S. "Rosetta," consisting of some 12,000ft. of hardwood, including blue-gum, ironbark, tallow wood, black butt, &c. He proposes to visit the leading timber merchants, and explain to them the qualities of the various specimens, and the uses they are specially fit for. He will also take a number of samples of wooden blocks, for street paving, among which are some that have been in actual use in the Sydney streets, to show how they are affected by the street traffic. These have been supplied to him by the Government. Mr. Laurie takes with him letters of introduction from the Mayor of Sydney. His object is to give such information to the parties interested at home as may, it is hoped, lead to a large trade in colonial timbers; for although specimens of our timber have before been sent home they have attracted little or no attention, in consequence of there not being any practical man there to point out their advantages. Mr. Laurie expects to be away from the colony about five months.—*Sydney Mail*.

LIBERIAN COFFEE seems still to be a popular product with planters in the Eastern Archipelago. Mr. F. O. Maxwell writes to the *Sarawak Gazette*, under date "Kuching, 25th April," that, as the planting of Liberian coffee is spreading rapidly in that district, he has got the Manager of Matang coffee estate (Mr. Loyalty Peake, we believe) to draw up a paper of instructions to guide planters and officers of Government all over the Settlement. We shall give the paper—a brief one—in our *Tropical Agriculturist*.

PLANTING HINTS FROM HAPUTALE.—Has any one thought of the plan suggested by our Haputale correspondent of using the 'Victoria Drier' as a Witherer; and if tried, with what result? As our planting friend says:—"My idea of the Victoria being used as a Witherer may not be new to those who have them in use as a drier; but if it has not been tried, I think someone should give it a trial. The threeweekly weeding arrangement is certainly preferable to once a month, as others as well as myself can testify."

A RECIPE FOR A WHITEWASH WHICH DOES NOT EASILY RUB OFF.—1 maund clean white or shell lime, slaked thoroughly with hot water in a covered vessel. Add 5 seers salt dissolved in hot water; 3 seers coarse rice pounded or boiled to a thick paste; half a seer of glue cleaned by dissolving in hot water, the dirty refuse being rejected. The ingredients to be well mixed and brought to the required consistency by the addition of hot water, then allowed to simmer over a fire for a few hours, strained and laid on hot.—*Indian Engineer*.

THE QUININE WORKS OF THE WORLD.—Says Burgoyne, Burbidges & Co.'s Monthly Circular:—"Excluding the Government factories (and plantations) in India, where the mixed 'bark alkaloids' are prepared, to some extent, for local use, and also leaving the experimental Russian works out of the calculation, there are some eighteen quinine factories in the world, of which the total yearly output is about four and a half million ounces. The number comprises one establishment in Holland, two each in England and Italy, three in France, four in the United States, and no less than six in Germany."

SEA-SAND FOR CEMENT.—It will be remembered how the Chief Resident Engineer (Mr. A. W. Burnett) poohpooed the suggestion that it was important to wash or prepare sea-sand—to free it from salt—before using with cement. It is very striking to note in Mr. Kyle's paper on the Colombo Harbour Works, how carefully he had the sand prepared for his cement concrete purposes; and not only so, but in erecting his "cement shed," being close to the sea, he had it "walled in on three sides and roofed without ventilation—so as to exclude the sea air from the cement." Would that the engineers' and workers at Maligakanda had been as careful.

BALI coffee figures so prominently in our market reports that the prospects of the produce article in question will arouse close attention in commercial circles. By last advices, the coffee crop on that island promises to be unusually abundant. The port of Buleling through which most of the coffee trade of the island passes, will thrive still more in consequence. Buleling is expected to increase considerably in commercial importance when it comes into telegraphic communication with the outside world. Preparations are actively going on there in building a telegraph office. Within a few months, a cable will be laid between Java and Macassar with Buleling as intermediate station.—*Straits Times*,

INDIAN TEA SEASON 1888-89.

LONDON, 7th May, 1888.

In view of the approaching Season, we beg to submit the following remarks for your guidance:—

PRESENT POSITION.—The very poor quality of the great bulk of the past Season's Crop of China Tea has directed more attention to Indian and Ceylon growths, resulting in a largely increased Consumption, so much so, that the supply, until the arrival of the New Crop, will only be about equal to requirements.

COURSE OF MARKET, 1887-88.—The decline, which began in August, continued until the close of the year, but was most marked during November, when prices ruled very low, quotations for medium Teas being then about as follows: Pekoes, 9d to 9½d; Broken Pekoes, 11d; Pekoe Souchong, 7d; Souchong, 6½d; and Broken Tea, 6d. A slight rise took place in January, but this was lost again by the end of the month. With the beginning of March commenced a decided upward movement, which has since been well maintained, and resulted in an advance from the lowest point of about 2d per lb. on Souchongs, Pekoe Souchongs, and Broken Teas, and fully 3d per lb. on finest classes. Medium to fine Pekoes and Broken Pekoes, however, have not appreciably shared in this advance, and are relatively very cheap, with a slow enquiry.

IMPORT AND DELIVERY 1887-88.—1st June to 31st May (May being estimated), are as follows, viz:—

	Import.	Delivery.
	lb.	lb.
Indian ..	86,500,000	86,000,000
Ceylon ..	14,250,000	12,750,000
Java ..	3,000,000	2,900,000
China ..	118,000,000	116,500,000
Total ..	221,750,000	218,150,000

Deduct China Tea for Export .. 30,000,000

Home Consumption .. 188,150,000

PROBABLE SUPPLY, SEASON 1888-89.—1st June to 31st May, may be estimated as follows:—

	lb.
Indian ..	93,000,000
Ceylon ..	25,000,000
Java ..	3,000,000
China ..	100,000,000
	221,000,000
Deduct China Tea for Export ..	30,000,000

Total-available for Home Consumption .. 191,000,000

At the present large and increasing rate of consumption of Indian and Ceylon kinds, this quantity should be readily dealt with; but it must not be lost sight of that improved and rapid transit from the Gardens throws an undue proportion of the Crop on the London Market during four or five months of the Season—say, from the beginning of September to the end of January, thus causing a very moderate range of prices to prevail during that period.

The quantity that will be exported from China during the ensuing season can only be roughly conjectured, but may not amount to more than 100,000,000 lb. or a further reduction of about 25,000,000 lb. The falling off in the past season was due to the continued inferiority of the teas, and it remains to be seen whether growers in China are able, or are determined so materially to improve the quality in future as to meet the requirements of the present day, and thus enable them to hold their ground. The production in Indian and Ceylon having now attained such large dimensions, the future of the China trade will naturally be followed with much interest.

Garden managers are advised to watch the course of the market as should the China supply shew a further large falling off and be of the same poor quality as hitherto, it may lead to an expanded demand for souchongs, pekoe souchongs, and leafy broken; but it is of the utmost importance that these be of good quality in cup. On the other hand the enquiry for

the higher priced teas would appear to be on a diminishing scale, and hence it may some day become a question whether, in order to meet the altered conditions of the trade, due to the gradual displacement of China tea, some modification of the present system of sorting the leaf may not be advisable. A well made leaf should be combined with a good liquor, if possible; but less attention is, perhaps yearly paid to mere appearance, provided the leaf be free from any special defect, such as dust, or other common admixture. The character of the liquor, on the other hand, is all important, because what buyers require is a bright deep red coloured infusion, possessing both strength and flavour. Dull, weak and characterless teas can no longer be depended upon to bring a paying price. Greenish, pale coloured liquors should in all cases be avoided; there is a small but rather uncertain enquiry for lightly fermented teas throwing a pungent liquor, but only when the flavour is distinctly fine.

STENNING, INSKIPP & CO.

COL. CLARKE'S FOREST REPORT.

Meantime our able Surveyor-General is doing good service in triangulating and mapping out our *terra firma*, and suggesting the best means, moderate and practical, of turning what sylvan resource are left to the colony to the best account, and advising measures for adding to those resources by encouraging natural reproduction, or by active artificial cultivation of trees, the most useful for timber and fuel purposes; the cultivation of tea in the island as well as the existence and extension of railways, giving fresh importance to plants suitable for the latter purpose. While in doubt whether we were at liberty to publish Col. Clarke's report, we re-read with reference to it the very able and marvellously comprehensive review of the forests and timber resources, actual and possible, of Ceylon, which Mr. Vincent, of the great and successful Indian Forest Department, framed and presented (with a number of illustrative maps), just five years ago. Many of his recommendations, which were within the scope of the means of the colony, have been adopted, entire or with necessary modifications, while his report* remains a mine of information on our forest flora generally and especially with regard to such individuals in that flora as are of economic value, more or less; or which can be made valuable, either for supplying cabinetwood or building timber, or for firewood. We can understand a man of one idea like Mr. Vincent being shocked and horrified at the barbarous destruction of our forests, during long ages by the wasteful system of chena cultivation,—the best-grown and most valuable trees, the accumulated growth perhaps of several generations, being sacrificed to secure one or two temporary crops,—and in the past half-century by timber speculators and contractors, who were permitted to discount for their own selfish purposes, resources which, properly husbanded and brought to market, ought to have been a steady and permanent source of revenue to the Government,—which means wealth to the community. We make allowance, therefore, for much of the denunciatory and pessimistic tone of Mr. Vincent's report. But we rejoice that Col. Clarke feels justified in speaking much more cheerfully, at any rate, of the powers of natural reproduction of our superior timbers, such as ebony, satinwood, halmilla, palé, &c., than Mr. Vincent did in his report. Although all the statements of so long a report, dealing with so many topics, could not, in the nature of

* Reprinted, with the large and elaborate illustrative map, shewing the climate zones of the island, in the *Tropical Agriculturist* of May 1883.

things, be perfectly consistent with each other, yet the general impression created by Mr. Vincent's utterances was, that in the struggle between forest seedlings, resulting in "the survival of the fittest," the victory was likely, most frequently, to rest with the least useful forms of vegetation, the most valuable being smothered out of existence in the process. The mode in which we saw satinwood and hal-milla plants asserting themselves in the forests of the North-Central Province, especially in the neighbourhood of the great Kalawewa tank, give us impressions much more akin to Col. Clarke's cheerful and hopeful vaticinations, than at all in accord with Mr. Vincent's despondent views. All that is wanted, in such fine forests as we have referred to, is, that felling and thinning should be so carefully and judiciously carried out that sufficient light and sunshine (without too much of the latter) should be admitted to the young plants and seedlings on the floor of the forest, inferior kinds being occasionally weeded away. Then, apart from artificial planting in suitable localities (the bunds of tanks presenting most favourable conditions for nurseries), our natural forest vegetation would get fair play and give grateful returns in proportion. We are also glad to find Col. Clarke (in this case supporting Mr. Vincent's views) pleading for fair play to our native hard woods as material for railway sleepers capable of holding iron spikes immovable, in lieu of the soft and short-lived Norway pine, almost exclusively used. What is wanted is that our native woods should be properly selected and well seasoned. The tree most commonly known as ironwood (*Mesua ferrea*, the Na of the Sinhalese) is, evidently, better suited for telegraph posts than for railway sleepers, and *Mi* (*Bassia onjifolia*) seems unsuitable for sleepers,—unless further experiments should be more successful than those already made. But Col. Clarke strongly follows up Mr. Vincent's recommendation of one of our most common woods, the PALE' or PALAI of the Tamils, *Mimusops indica* of the botanists. In the northern forests this tree especially abounds, and the only cause of regret for the disappearance of many thousands for conversion into railway sleepers, would arise from the fact that the natives of the northern and some of the eastern portions of the island would be thus deprived of a considerable, pleasant and nutritious food resource. For, as the blacks of Queensland, once in three years, flock to fatten on the cone seeds of *Araucaria bidwillii*, so the natives of the Ceylon palé region resort to those trees when the fruits are ripe, to eat them fresh and to preserve the surplus. Instead of climbing the trees to gather the fruits, however, the natives lazily and mischievously pursue a method which, as being very injurious to the valuable timber trees, ought to be stopped: they chop off the branches to obtain the fruits. The result is considerable injury to many of the trees, but it seems certain that excellent sleepers at a moderate cost could be obtained from the species of "ironwood" known as palé (*Mimusops indica*).

But we are specially pleased to find Col. Clarke go beyond Mr. Vincent and demand that the wood of one of our most common and most remarkable trees; a tree always found where water exists, on the banks of rivers and the borders of tanks,—the KUMBUK (*Terminalia gabra*),—should also receive a fair trial by the railway department, as a material for sleepers. Our visit to the North-Central Province has left on our mind the feeling, that, beautiful as are the foliage of the Tammana whence Tammana kadu and probably Taprobane) and the blossom of the satinwood, the very king

of the Ceylon forests (if the grand "talipot" palm is kept out of view) is the mighty KUMBUK. Often vast in size, so that its trunk reminds the spectator of the baobab, it combines the magnificent and the grotesquely picturesque. Hollows of the size of caves in very old trees are lined curiously on the edges with layers of young wood and bark which are constantly reproduced. The foliage is vari-coloured and the blossom beautiful and sweetly odorous. The abnormally thick bark, which is also vari-coloured and polished, is rich in lime and we cannot doubt that the timber will be found exceedingly useful, and also cheap, for the tree is ubiquitous. The wood, which is handsomely coloured, makes excellent fuel and charcoal. Although on sentimental grounds we should regret the disappearance of large numbers of these truly noble trees, yet for the sake of the colony we trust many thousands of them will be utilized and yield from six to ten good sleepers each.—But here our introductory notice of Col. Clarke's valuable Report must close. On the whole question of our forests, their resources and their influence, there is much further to say.

INSECT PESTS: THE GRAIN WEEVIL.—We are glad to hear that one of the results of the recent Delhi Conference has been the confederation of the Provincial Departments of Agriculture with the Calcutta Museum for the comprehensive and continuous investigation of insect pests injurious to agriculture. The Trustees of the Museum had, as we have previously intimated, already committed this work to Mr. E. C. Cotes, one of their staff; and we understand that in pursuance of the recommendations of the Conference that officer is now placed in direct communication with the Directors of the Departments, with whose assistance and that of planters and agriculturists interested in the matter the facts and circumstances surrounding the subject will be gradually collected. Already Mr. Coates has issued a preliminary paper on the life history of the weevil, an insignificant little animal which eats up about one million of rupees worth of the exported wheat every year. He indicates that the grain-dealers of the large trading centres cultivate this destroyer in breeding houses almost as a nurseryman rears a stock of plants for seed. The wheat merchant of Cawnpore, Agra or Delhi is ignorant of the fact that every perfect female insect lays an egg in each one about 150 grains, and accordingly during the winter allows a large brood of weevils to enjoy the protection of the warmth and shelter of his then empty godowns, and in the spring provides them with a plentiful supply of fresh juicy wheat on which the offspring grubs may eventually fattened. A few days after the commencement of the rains 150,000 of the perfect insects emerge as the descendants of the 1,000 parents carefully fostered during the winter by the grain-dealer. So free however, until the moment of birth, is the shell of the wheat grain from any sign of the inconvenient tenant that the incurious owner of the grain believes that the swarm of weevils was sent like locusts by the interference of an unkind but irresistible Providence from—he does not know and does not care where. He attributes to the voracious appetite of the newly-born animals the tunnels bored through the affected grains by the patient and long-continued gnawing of the unsuspected grubs. Might it not be useful if the Educational Department were to teach a little elementary natural history in our schools?—*Pioneer*.

CEYLON UPCOUNTRY PLANTING REPORT.

NEW TEA SIFTER—TOBACCO—CACAO—COOLIES.

Central Province, 28th May 1888.

Mr. BARBER'S NEWSIFTER is the coming machine. That gentleman has already made his mark in regard to tea manufacture, and has gained such an honourable position therein, that the best marks in the market have found it hard to keep up with him, and harder still to beat him. Now his new sifter is about to be offered to the planting public, and those who are going in for sifting machinery will act wisely to see it, before they buy any other maker's. I had heard of the merits of the machine in question, and, being desirous to see it at work, with Mr. Barber's kind permission I visited Blackstone. The account of the combination of qualities which the sifter was said to possess, and which was sent me by its inventor, read like a romance. He put it thus:—"Quantity of outturn:—Equal to the wants of any Ceylon garden. Quality:—Leaf unbroken, bloom preserved, no dust. Power:—One cooly to work and feed. Highest merit:—Resolved on selling it at a fourth or fifth of the price asked for any of the fashionable monsters of the day, needing motors to move them." The note sounded above is pretty strong, and it has a sweetness in its "highest merit," which, if ever known here before, has all but died out of the land; certainly never heard in these days of big sterling prices; and becomes all the more welcome to the planter's ear from its extreme rarity.

The machine is not a very imposing thing, takes up little room, and when working makes hardly any noise. I won't describe its construction or principle, as Mr. Barber's patent papers are not yet completed, I believe. What I have to do with is the work it turns out, and its quality. It was proposed to put through 50 lb., and complete it in half-an-hour. This was done by one cooly who fed and worked the machine at the same time, and with several minutes to spare. Indeed an old woman or a boy would have found it easy work. Working ten hours at that rate would put through 1,000 lb., which I fancy fairly covers the first advantage claimed, "equal to the wants of any Ceylon garden."

As to the quality of work, it was as stated above, "leaf unbroken, bloom preserved," but I would qualify the "no dust" to "hardly any dust." There was a very little, which needs only to be noted for the sake of strict accuracy. I fancy very few would trouble to sift it out.

The proportions of the 50 lb. were as follows:—

Broken Pekoe 12 lb.
Pekoe 15 "
No. 1 Pekoe Souchong..	.. 13 "
" 2 do 3 1/2 "
Coarse and red leaf	.. 2 1/2 "

46 lb.

The missing 4 lb. remained in the machine, adhering to the sifter, as the brushes which are to keep them perfectly clean were not fitted on. Had a second 50 lb. been put in, it would have weighed correctly, I doubt not. Indeed, had the four minutes which were to spare in the half-hour allotted to the experiment been occupied in working the sifter, very likely a good deal of the attached leaf would have been detached without any other aid. The 2 1/2 lb. of coarse leaf were all that called for after manipulation by hand; the red leaf to be picked out, and the balance broken through a No. 7 or 8.

I have already spoken of the power. The cooly turned the machine with the one hand, and fed the tea in with the other. It is proposed to have a hopper above, big enough to hold say 50 lb. or

more at a time, which will be so regulated as to feed the sifter itself, and when that is done, it will be child's play for a cooly to put 1,000 lb. through in an ordinary working day.

Then as to the "highest merit," the price asked is to be R200, I understand. "I expect an unparalleled run on it," writes Mr. Barber, and I expect he is right. As I said at the beginning, this new sifter is evidently the coming machine, and while its inventor has doubtless had his own interests in view while spending his thought and labour in the perfecting of it, still we will all benefit by its use, and in offering it at that moderate rate to the public, he puts it within the reach of many, who would think twice before they would buy any of the higher priced sifters.

THE CULTIVATION OF TOBACCO is being so warmly taken up, and the desire for accurate and detailed information so general, that it is not to be wondered at that those who do know should utilize their knowledge. I have seen the MS. of a brochure on the "cultivation and preparation of tobacco" which may soon see the light, and which should be very welcome to many. Besides treating on the best European methods of planting and curing tobacco, information will also be given regarding the most approved native styles of preparation.

CACAO is making up now in the way of blossoming, and better still in setting. You hear on all hands of the promise of a good crop.

COOLIES keep flocking in. It is a sight to see them at the railway stations, clustering in the railway carriages like bees, and this thing keeps going on day after day. Whatever rocks are ahead of the tea planter of the high districts, that of want of labour is not likely to be one. PEPPERCORN.

THE GLASGOW EXHIBITION.

(By "Aberdonensis.")

Glasgow, 17th May 1888.

MY DEAR "OBSERVER,"—I have been four times at the Exhibition and am tired of it, but I am not tired of escorting young friends there. It is a grand success. The glorious weather that introduced the first week of the Exhibition was extremely fortunate. At the Ceylon tea-room I met two "Moses's." One "Moses" used to be in Dumbara and dabbled in the fine arts in the way of amateur photography, and is now in a most elastic business in Glasgow. The other "Moses" was one of the boys. At least if he was not pulling my leg his name must be Mosee. I spoke to the two boys in their tongue, and they became demonstrative, and I was being reduced to an exhibit of the show instead of a spectator. I told them "molla peysa venum" and "sattam podu wanda," and they were quieter. They seemed happy, but it was funny to see soldiers and others shaking hands with them, I asked if they were taking a white wife out, at which they hugely laughed. The tea-room is a splendid success, judging from appearances. One very familiar face was often to be seen,—the form more portly, but still familiar, I mean the Ceylon representative. I saw Mr. Shand repeatedly I met "W. McK.," who was well and was on the eve of going off to America. The Ceylon Court is very nicely arranged. The *growing Tea Plants* are, in my opinion, the best feature. The next best is the choice collection of Jewels and Precious Stones. The next is the series of Photos showing tea planting from the clearing to the steamer. There ought to have been a Sinhalese family engaged at some work. In the Indian section some natives were cooking, and crowds were there. The smell of

ghee did not seem to trouble them. The models of all kinds were grand. A tea planter's bungalow was being unpacked, and was not quite adjusted. Seeing the planter lying on his back behind the bungalow, I remonstrated at the bad effect on the crowds of the sight of the helpless planter, but the "man" thought my wit was very poor. When I came round again the Sahib was sitting up and trying to look sober in the back verandah. The Indian Court was very effective.

The Machinery section was very grand. One thing would have driven me mad if I had looked at it long. Beside a revolving disc and apparently resting on nothing was a brass ball which turned round with a brass rod connected with the disc. I cannot describe it better, but the effect of the ball's position, when in motion, was that it was *suspended* in the air. I believe when the machine is at rest that the whole thing is easily understood.

TOBACCO AND CHICORY.

BY THE SCOUT.

"Good day. You've got that bit of wheat harvested, I see, off the little ten-acre paddock?"

"Yes, I've got it in, what there is of it, and that's little enough, too much wet when it went in and not enough afterwards."

"What is the yield?"

"Seven bushels, and barely that."

"What are they paying at the mill?"

"Three shillings; so I'll get 21s an acre for seed, ploughing, harrowing sowing, stripping, putting into sacks, winnowing into the shed and into the dray, and carting."

"That other 10-acre piece on the flat—the corn, don't seem to cob well?"

"Cob; no, if I get 15 bushels to the acre, it's more than I expect."

"Well, if you could get a crop of another sort with a little more trouble off this 10 acres of wheat land; that would bring you quite 20 times as much money, and another crop of different sort again, off that black soil in the flat; that would bring you 20 times what the corn will with a little more trouble. I suppose you would try something else besides wheat and corn?"

"Not I. I've always grown wheat and corn, and it ain't much trouble—the wheat anyway—now we've got the stripper."

"Well, but you've plenty of other land—good wheat land and good corn land too—you can grow wheat and corn still, and square 10 to 20 acres for other crops that will pay you better, though they are a bit more trouble."

"No, I'll touch nothing but what I've always grown; I'd rather grub along and chance the seasons with wheat and corn than bother about any other crops, though they'd pay me over 20 times as well."

The possibility of such a conversation as this will hardly be believed, and yet there are hundreds who will read this who are acting as though they entirely agreed with the farmer, and preferred a return of 21s to one of £20 or £50 per acre.

The fact that valuable products other than the ordinary cereals can be, and are, in some few cases grown in this colony with complete success, has been stated in these columns, editorially and by correspondents, over and over again. The agriculturist is proverbially conservative and averse to experimenting; yet I have met instances where the desirability of increasing the number of eggs, and multiplying the number of baskets, as suggested, from time to time, in the *Mail*, has been recognised as a practical and highly-beneficial thing. These instances are, however, few in number at present, and could be multiplied by hun-

dreds with benefit to the producers and to the colony.

"How is it to be done?" is probably in the mind of the reader. In many ways. I will refer again to two, to which attention was specially directed in this paper about 12 months ago, as well as before and since that time. I will suppose you are in a part of the country but little affected by frost and hail, and that you have, as so many men have, a bit of flat, low-lying or river bottom land on your farm. It is black soil and almost any depth. If it is not growing corn it is probably producing a magnificent crop of black thistles, which are spreading all over the country each season.

You are disposed to proceed cautiously at first, though the risk is but slight if you do not succeed. So you fence off a patch of five acres of this black soil; you cut down and burn off the thistles and weeds, and then put the plough in and break it up and harrow it, and it is clean and ready for a crop. In the meantime you have written to your seedsman for his catalogue, and probably to Messrs. Dixon and Sons for their pamphlet on tobacco, and you are ready with your pound or two of tobacco seed. This you sow in a small bed, say in your garden, thickly, as you would cabbage seed, and by the time your patch is fenced in, and the ground ready, the seed is probably up several inches, and ready to transplant. It being spring time then and the ground well worked and clean, you put in the young tobacco plants as you would plant out cabbages only you set them in rows 3ft. apart, and each plant 3ft. from its neighbour, so that each plant has a space of 3ft. all around it. Now your crop is in, and your care is to see that the ground is maintained clean, so that the plants derive all the nourishment possible from the soil, and that insects are not encouraged and propagated. Your lowlying black deep soil has much moisture in it, and the plants need it, and they require a fair supply of rain. If you are able to supply irrigation in case of need, so much the better. As you go through your crop from time to time you will see that caterpillars are not making free with it, and these you will pick off when they make their appearance. When the flower of the plant appears, you will remove it—that is, cut the flower off, which is termed heading it—and the strength then goes into the leaves, which are the valuable part. While the plants are growing you have prepared your drying or curing shed. If you have not one suitable, you have built an open shed, 9ft. to 12ft. in height, having a roof—bark will do, but not any walls. Across this shed just as the rafters go, you have placed numbers of light saplings a foot or two apart. Now, when the plants have attained their full growth, you cut and carry them to your shed, where, having made a deep cut into the heart of each, you set them by means of that cut, astride of the sapling rafters, until all are thus hung up to dry, which is the sole purpose of the curing shed. The drying of course is dependent upon the weather; it may be a matter of weeks, or three or four months. If the season be a very wet one it is usual to dig holes in the floor of the shed and keep slow fires going. In the large tobacco-producing countries, the planters in some cases having drying-rooms with artificial draught and heat. I believe, however, that natural atmospheric drying produces the best tobacco. What is desirable to be known with reference to qualities of tobacco, &c., you will have obtained from the pamphlet to which I have referred. Your tobacco being now cured and ready to send away, you pack it into bales and send it down to Sydney. Now, what have you got for your trouble? A yield of one ton per acre is a comparatively small crop,

and under ordinarily favourable circumstances a ton and a-half, and for a heavy crop two tons per acre will be obtained, and if the sample be a good one 5d. per lb. is paid by the manufacturer. I will suppose that from the time you put in your plants to the time you sent off your bales has been nine months, and that, excluding the cost of the fence, which cannot be charged against one crop, you have spent what is equal to £1 worth of labour per week for the nine months, which should be a liberal allowance for a five-acre patch, so that your tobacco crop has cost you £39—say £40—for labour and seed.

Now, on the other side, what are you likely to obtain? Taking the yield at the low estimate of one ton per acre, you have sent to Sydney five tons of tobacco, for which at 5d. per lb. you receive £46 13s. 4d. per ton, and for your five tons, £233 6s. 8d.; or, deducting £40 as cost of working, you have made a net profit of £193 6s. 8d. on the little five-acre patch of tobacco, which would have been £386 13s. 4d. if the area had been 10 acres instead of five.

On the same piece of ground, if you had got 25 bushels to the acre, and 3s. 6d. per bushel for the corn, you would get £21 7s. 6d. gross. Allowing that all does not go well each season—drought, hail, frost, or caterpillar possibly reducing the yield—yet it promises a better return in comparison with other crops for the size of ground and labour expended. Nearly all the labour is light, too, being such as young folks can undertake. The planting-out, weeding, removing caterpillars, heading the plants, cutting them, slitting and placing them in the shed is all light work, and a farmer's children can in many cases undertake it.

With a likelihood of such a return, it is certainly worth the trial; and, again, the work on five acres is not a very serious matter, however it results. So far, you say, then for the black soil; what about the 10-acre piece of wheat land?

This, that many a farmer of late years has found growing chicory tide him over a bad harvest, when in some cases he would otherwise have gone to the wall, and what is good in that way in bad seasons is money made and available for other purposes in good years. You prepare your land for chicory as for wheat, and fair wheat land will do for it. The seed is supplied by Mr. R. Harper, of Darling Harbour, who buys the crop, and buys only what is grown from the seeds he supplies. You state how much land you propose to cultivate, and the suitable proportion of seed is sent at, I believe, 3s per lb. It is nearly always sown broadcast, I think to save trouble and expense in drilling it in. The latter method produces a larger root, and the crop can be kept clear of weeds.

The root is like a several times forked parsnip, and the leaves like small dock leaves. Stock greedily eat the tops. In the Blayney district the sowing takes place about September, and the crop is dug up about March or April. The roots are dug with a spade or long hoe, such as Chinamen use, and care should be taken to get all up, as any portion left in the ground grows again. For this reason two consecutive crops are not grown on the same ground, as self-sown chicory is not saleable.

Three tons per acre is a light crop, and seven tons, which I have several times seen, a heavy one. The average will be from four to five tons. When the crop is dug up the tops are wrenched off and the roots put into sacks, which I believe are sent to the farmer by the merchant. They are then taken to where there is water, washed, put back into the sacks, and sent off to Sydney at once—the wetter they are the better. Allowing, therefore, five tons to the acre on your 10-acre piece, you have 50 tons, and at £1 per ton a gross return of £20 per acre, or £200 for your 10-acre paddock, as against £11 to £30 for the wheat.

Dry weather, of course, makes a poor crop. Even then if the crop be reduced half, a yield approaching £100 for 10 acres is good. If 50 farmers were to cultivate one or other, or both, of these products in the coming season, they would in all probability receive from £10,000 to £15,000 more than they otherwise would, and the trade of the colony be proportionately benefited. The possible loss cannot be otherwise than small, the profit very good—why not then try it?—*Sydney Mail*.

THE QUININE SITUATION.

The following circular, which was issued recently by Messrs. Roessler & Hasslacher, and which to some extent may be taken as an answer to an editorial article in the *Reporter* of April 25th, will be read with interest in view of the unsettled condition of the quinine market:—

“Quinine has declined within the last month 10 cents per ounce, our April list quoting 45 cents, where we are able to offer it today at 35 cents. With this considerable decline the trade is therefore in the favorable position to find quinine cheap at the very beginning of the season's increasing consumptive demand. The reason for the present decline is found in the increased bark shipments. But as the rapid decline has already brought us pretty near to a price for the barks that does not even cover actual expenses for bringing them to the European market in merchantable condition, the trade can calculate that while waiting now may save a few cents, it is more than probable that by waiting too long it will find itself confronted with an advancing market. For it must be considered that as true as it is that there is anything but a decline in the world's crop of cinchona barks, and that the barks may be had in such abundance at Ceylon, Java or Bolivia as to make them worth nothing there, it is equally true that they are not for any length of time available to the Quinine factories of this country and Europe at prices that do not fully cover the expenses for gathering, drying, packing, shipping and negotiating the sale of them. This fact was not considered by those who last fall waited for 'twenty-five cents quinine,' and if the large speculative buyers have now made up their mind to go into quinine when the price of 30 cents an ounce is reached, they may find themselves left as badly as those who waited for the 25 cents limit last year.

“A few words also about the 'decrease in the consumption of quinine' on account of the increase of the numerous febrifuges, a reason advanced always when a bearish tendency is desired. How true this statement is you can best prove by your own books. Certainly the demand for the various febrifuges has largely increased with you, but has the demand for quinine decreased? Not with us and we are sure also not with you. That the increased consumption of the new febrifuges does not lessen the demand for quinine, is that none of these are really a substitute of quinine. None of them is a tonic, nor has any of them healing properties. They, one and all, can only effect a reduction of the temperature, and are of great value to the physician whenever he desires to reduce a too high a temperature of his patient. To better explain this we quote the remarks with which we introduced Acetanilid. On authority of a Berlin physician we then stated:

“The scientific theory of fevers goes to show that fever heat is in all cases a secondary appearance, brought about in most, or perhaps, in all cases by germs; the struggle of the system against these intruders producing fever heat. In most cases it is of importance to destroy the primary cause of the fever, its germs, suppressing at the same time its secondary effect, the fever heat, as for

instance, with sulphate of quinine against malaria, which destroys the germs. But it very often happens that the secondary effect, the fever heat is more dangerous to the body than its primary cause. Either the primary cause is not dangerous at all if only the secondary effect, the fever heat, can be prevented, or the fever heat threatens to grow dangerous to the body before the primary cause, the germ, can be destroyed. In both cases Dr. Seyferth's Acetanilid is by far the most effective febrifuge that can be used."—*Oil, Paint and Drug Reporter*.

TEA PROPERTY INVESTMENT.

A correspondent writes:—"Tea property is never likely to attract the ordinary investor. Unless something is known of the garden, and of the inner working of the company, it is not advisable to buy tea shares." This is rather a wild statement. Pray what is known of the property and the "inner working" of ninety-nine out of every hundred of the joint stock companies formed except that given in the companies' reports. One would think that there was some hidden mystery about the production of tea. Information is obtainable about Indian tea companies, and those responsible for their management are certainly as frank and explicit as the managers of joint stock companies generally; and we venture to think that this form of investment contrasts very favourably in all respects, including "inner working," whatever that may mean, with joint stock companies generally. The average investor in mining shares, for instance, is in a very hazy position as to "inner working." He reads the report of a mining expert full of technical expressions meaning nothing and he has to live on this sort of thing. If he receives a dividend he is extremely fortunate. "Inner workings" in this case are cloudy indeed, and the investor who thirsts for knowledge in this direction is usually sadder and wiser. Tea shares, provided the selection be made with care and judgment, are a positive haven of rest and dividends for the investor, as compared with the majority of industrial undertakings.

JAVA CINCHONA BARK CROPS.

IMPORTANT CONTRADICTION.

(Copy of letter to one of the leading firms of Brokers in London, dated Java, April 6th, 1888.)

Gentlemen,—“Referring to your fortnightly market report upon cinchona bark dated 15th Feb. past, in which you fixed the attention of parties concerned upon the publishing of a letter headed Amsterdam, and in which a most exaggerated account was given of the quantity of sulphate of quinine Java is going to produce in the course of this year and next, we have resolved to act upon the advice you have given to planters on page 3 of said report. In consequence we are now drawing up by taxation of planters themselves a statistical survey of the quantity and quality of cinchona bark Java will probably deliver on the market in the course of this year, and we intend in future to do the same at the beginning of each new year.

As soon as our taxation will be ready we shall be happy to forward a copy of the results to your firm, but in the meantime, while waiting for the exact figures being published, we beg to state "that in our estimation the contents of the letter mentioned are wholly inexact and utterly untrustworthy."

FOREST CONSERVATION IN CEYLON.

COL. CLARKE'S REPORT FOR 1887.

(See pages 33-36.)

Our regular readers are aware that we hold modified and moderate views, formed on a long and close observation of facts in Ceylon, as to the climatic influence of forests. That the denudation of forest for planting purposes on our mountain system,—trees averaging forty feet high being replaced by plants averaging four feet (not to speak of portions of the natural forest reserved and ornamental and useful trees planted on portions of estates),—can affect the absolute rainfall, we decidedly disbelieve. In the south-west of Ceylon rises a mountain system equal to one sixth at least of the whole area of the island. This mountain system stands right in the track of the moisture-laden ocean currents, the offspring of a series of cyclones ("long drawn out") to which we give the name of "monsoons." As the currents and clouds approach our hills and mountains, their temperature is reduced, and they are compelled to part with their moisture. Hence the existence of our moist zone in Ceylon, embracing not only the mountain system and the outlying hills but a large portion of neighbouring "lowcountry." All this wet region was once densely covered with forest, produced under the influence of equally perennial heat and moisture. And if our good friend Col. Clarke, quotes the scientists and endorses their opinions, as to the good effects on climate of forests and the evil effects of their destruction; we refer him to the history of the early military operations of the British in the then "Kingdom of Kandy," for proof of the evil effects of excessive dense and damp forest growth on climate and human health. The Kandyans, whether in the wars at the early period of this century, the conquest of Kandy (for such it really was) in 1815, or the rebellion of 1817-18, were contemptible as enemies in the field. The real enemy the British had to contend with was a dense covert of forest in which the wily foe lay in treacherous ambush, and the damp, land leeches and malaria of which proved so fatal to our poor fellows, leading Capt. Anderson to say of what is now one of the very finest climates of the world,—

"For thou art fatal as thou'rt fair,
As many other beauties are."

What the late Emperor Nicholas of Russia said of "Generals January and February" as the most formidable enemies of the allies in the Crimea, might have been said of "Generals Damp and Malaria" as the real enemies of the British soldiers in the forest fastnesses of Kandy. The victims of the Kandyans fell to foul treachery and cruel massacre. But they who so fell were a mere fraction to the victims of the dense, damp, malarious forest, on far-extending and unbroken ramparts of which the Kandyans had always relied as their first, last and complete line of defence from foreign invasion. Take the case recorded in the annals of early British rule in Ceylon, of the British regiment which, within a short period of its return to Colombo from traversing the Kandyan forests and serving amongst them, buried three hundred of its number including the commanding officer from "jungle fever." We are no advocates of the entire "destruction" of forests, even in our wonderfully recuperative moist climate, but we most strongly hold that one of the first and chief benefits conferred on the mountain region of Ceylon by the energetic soldier-Governor who pierced it by a grand road and by the European planters whose enterprise that road rendered possible, has been the amelioration of climate which has followed the clearing away of so considerable a portion of the damp and dark

forest. That clearing, be it ever remembered, was followed by regular planting; by tillage which enabled the soil to absorb large quantities of the rainfall and by drainage which carried and led off into streams and rivers water which was superfluous and calculated to be injurious if left to collect in hollows and then rush away in tearing floods. We unhesitatingly commit ourselves to the position that the whole of the regular operations of the planting enterprise in Ceylon for the last sixty years or so have been, in a climatal point of view, not only not injurious, but markedly beneficial. After all is said and done, the area cleared in the mountain and hill region, say about 350,000 acres, bears but a small proportion to the vast expanses left untouched, on the higher summits and ridges especially. In consequence of Sir Joseph Hooker's representations in 1873, founded on reports of the late Dr. G. H. K. Thwaites, c. m. g., the fiat of the Secretary of State has now rendered *taboo* all the region above 5,000 feet elevation, the region of our upland prairies covered with lemon and other coarse grasses, but also the region of forests which Mr. Vincent carefully and repeatedly estimated at two-thirds of the whole. With so much forest left and in the best position for cloud-compelling purposes, we may make our minds easy about rainfall, much of which could, indeed, be dispensed with by estates in the neighbourhood of Adam's Peak, where the annual supply ranges from 150 to 250 inches. The question of so-called "denudation" for estate purposes becomes one of merely local effect, and Mr. Vincent, with all his prejudices as a forester in the opposite direction, not only admitted the force of the arguments we have adduced, of re-planting, tillage, and drainage, but he dwelt specially on the exceptional mechanical condition of the soil on Ceylon mountain estates,—fertile yet tenacious,—so that, except in periods of exceptional floods, the drainage water runs off clear. The discoloured condition of rivers is most frequently referable to the very different cultivation and soil of the native rice fields. It happens too that in the clearing and burning of hill forest for European planting operations, at any appreciable elevations, the trees destroyed were generally of but little value. Care was taken of SAPU (*Michelia nilagirica*) and a few other superior kinds, which were utilized by the planters for buildings. No obony and but very little, if any, satinwood was thus sacrificed, for Mr. Vincent states that what the natives called *burutu* (*ual burutu*) was not real satinwood. Col. Clarke's recommendation, therefore, that the cultivation of trees should be specially directed to indigenous kinds, must be materially qualified with reference to operations in our higher altitudes, where foreign trees, especially the Australian *Eucalypti*, *Acacias*, *Grevillea robusta*, with the *Toon* (*Cedrela toona*), *Cryptomeria japonica*, *Pinus longifolia* and several species of *Cupressus* grow much faster and yield more timber and firewood than any indigenous trees, especially if the latter are brought up from lower zones. We once saw *Cassia sinea* (popularly *C. florida*, the *Wa* of the Sinhalese), growing at an elevation of about 4,000 feet in a swamp at the entrance to Dehigama estate, Dimbula, but the position was specially sheltered and warm. On the other hand we may mention a case in our own experience as showing the superiority of exotic to indigenous trees for cultivation at high altitudes in Ceylon. Dr. Thwaites of Peradeniya, who had advised us to cultivate, at an elevation of 4,000 to 6,000 feet, indigenous trees in preference to Australian and other foreign species sent us with Australian plants in 1874, a specimen of one of our most ornamental low-

country plants, PEHIMBIYA (*Filicium decipiens*). Most of the Australian plants then received are now approaching or above 100 feet in height, and a blue-gum was cut down last year, which was at least 103 feet high and yielded a large amount of timber. This is at an altitude of 4,800 feet, and the effect of the climate on the PEHIMBIYA is that it is still a dwarfed tree,—little more than a shrub in truth. For timber and for firewood both, therefore, we believe that foreign will be superior to most indigenous trees at altitudes from 4,000 or perhaps 3,500 feet upwards. The SAPU, DAMBA, KINA and a few others may be exceptions, as regards quality of timber, but we suspect all will be found slow growers, comparatively.—Coffee plantations, as a rule, were confined to a zone between 2,000 and 5,000 feet altitude, to which zone as a general rule our remarks apply. But the case is very different with tea plantations opened in the lowcountry, where the vast majority of our best timber and firewood trees,—we were going to say abound, but we must use the alternative of exist. For the destructive chena cultivator, the ruthless timber contractor, and the reckless timber thieves have in too many cases been before the lowcountry planter of tea, cacao, coconuts, &c. But a few really fine forests wholly untouched, or only partially denuded of really good trees, are scattered at intervals over the lowcountry (we are speaking of the moist zone, for there are vast expanses of "forest primeval" in the dry regions of the north and east of the island where large numbers of the best species of our timber trees still abound), and we quite concede the propriety and even the duty of Government taking measures to preserve and restore to a proper timber-yielding condition suitable reserves, for the sake of the planters themselves as well as for the sake of the general community. Colombo is very largely dependent for supplies of timber, bamboos and firewood on the new tea districts known by the general term of Kelani Valleys as well as on the Valley of the Kaluganga, which the railway has now reached, to supplement abundant facilities of cheap water carriage. Timber and firewood reserves of some magnitude are, here, therefore, absolutely necessary, but in choosing them, careful and liberal regard must be observed with reference to the legitimate demands and aspirations of the class on which the colony is so largely dependent for the revenue which has enabled us even at this eleventh hour in the history of forest devastation to add a Forest Conservancy Department to our other numerous establishments. Happily, it would seem (we judge from observation during a visit to the Kelani Valley), that tea seems to flourish where coffee would absolutely refuse to grow, on chenaed cabook (laterite) soil, the prevailing vegetation of which is the small species of bamboo, BATALI (*Beesia stridula*); although, of course, the better the soil, the better the tea.

So long as the Forest Department is guided by a gentleman so well-informed and sensible as Col. Clarke, we feel very confident there will be no extreme reaction from former blameable and regrettable neglect of the forest resources of Ceylon, but that the *via media* will be pursued, between due regard for the rights of the Government (that is, the general community) on the one hand, and the interests of European capitalists and native cultivators on the other. Even in measures taken to check the process most inimical to the existence and the production of good timber in Ceylon, that of chena cultivation, caution must be exercised. There have been and are, doubtless, cases where the chena cultivator can say "I and my family *must live*," and a benevolent

Government is not likely to adopt the language of Napoleon's Police Dictator by responding: "We do not see the necessity." In a large proportion of cases, however, we believe, that chenaing is not only adverse to the public interests, but to those of the improvident and lazy cultivator, who is thus enabled to neglect the duty, while he, his family and the community lose the benefits of systematic cultivation of rice, edible roots and fruit-bearing trees.—Before closing this article, we feel bound to say, that, while adhering to our position that the clearance of the hill and mountain forests, so far as it has gone, has improved instead of injuring the climate, many of the planters acted in antagonism to their own future interests and those of their successors, when they made a clean sweep of the forest on their estates and did not plant trees in compensation along roads and paths and on *tundus* (patches) of their land not suited for ordinary cultivation. This a mistake which, we trust, the tea planters who "open" in forest will not repeat. We also hope that tree planting will receive due attention on estates already opened, and on which timber and firewood have been or are fast being exhausted. While we do not believe in the benefit of large expanses of unbroken natural forest, we have a vivid sense of the value of trees properly cultivated and scattered in lines and groups over the land. We hope to recur to the interesting subject.

LETTERS FROM JAMAICA:—No. 23.

(Written for the "Ceylon Observer.")

THE WEATHER—STOCK AND CROPS—LEGISLATIVE COUNCIL—RAILWAY EXTENSIONS—LAW COURTS—JURORS—HOTELS—KINGSTON HARBOUR—JAMAICA PROVERBS.

Blue Mountain District, Jamaica,

For packet of 25th April 1888.

In my last letter I observed that December had been an unusually dry month. This fine weather has continued to the present time, insomuch that there has been an actual drought, especially in the southern parishes, where, I learn, on some of the "pens" cattle are dying for want of water. It is strange that, while England and other northern countries have experienced such a severe and prolonged winter, we in the tropics should have had such a long spell of splendid weather, and it is to be hoped it may not be followed by excessive rains and floods when the rain does come.

The dry weather has so far been most beneficial for the highest coffee fields in the Blue Mountain district, which often suffer from wind, cold, and damp, and if all the good that has been done is not undone by untoward weather, it should bear a fine crop next year. As to present crops, the lower and medium elevations have done remarkably well, and the coffee berries are large and of fine quality. But our friend "Quashie" is not likely to do as well this coming crop as he did last, for not only did he get excellent prices for his coffee—(when he was wise enough to sell in the cherry, for those who pulped and kept it were, of course, losers by the sudden fall in the market early in the year),—but had plenty of wet weather, which is now so much needed at the lower elevations. It is doubtful now, if the blossoms can come to much good unless we soon have sufficient rain: I heard of one lowlying property which had not got a leaf left upon the trees, yet the owner said, so enduring is coffee, and as the drought acts as a species of wintering, that if rain came in time the trees would blossom and he would get a fair crop; let us hope for his sake as well as for the settlers, rain may not be far off.

Our Legislative Council has assembled for its short spring session: the Governor was able to announce the revenue had "so far" done better than was expected by some £26,000. Several useful measures are to be brought forward, and the question of the extension of the railway to the north-side will no doubt be discussed; the preliminary surveys are completed, the two extensions, one to Port Antonio, the other to Montego Bay, are calculated to cost over one million pounds. It is therefore improbable that our timorous Legislative Council will embark in such an expensive enterprise, and borrow such a large sum; but until the country is better opened up, and transport shortened and cheapened, I cannot see how the colony can go farther ahead. Additional taxes would, of course, have to be imposed, to pay interest on the guaranteed loan, but on the other hand the money would, in large measure, be spent locally, and much benefit the labouring classes in the districts through which the iron horse was about to pass, and in some of those parishes the peasantry are very badly off, and have to be content with very low wages. Another item that is coming before the Council is the payment of Supreme Court jurors' board, lodging and mileage as is done in Ceylon. I represented the matter to the Governor, who evidently saw the justice of the plea, and sent a message to the Council on the subject. Lately, by a new law, the Supreme or Circuit Courts, as they are called here, are now held in the principal town of each parish, so the distances to be travelled will not be so great, nor will the sessions last as many days as when held at Kingston. Still the business man, the planter, the artisan, the cultivator, the shopkeeper, who have *volens volens* to serve, are entitled not to be losers by the transaction; they lose enough as it is by the loss of time and proper supervision of their work, and I trust the Council will see it in that light, and grant a fair allowance. I was hauled off to Morant Bay 23 miles distant for the first session of the new Court; there is now no hotel or lodging-house in that town; so, had it not been for the kindness of friends who live near, I might have been in a fix as to quarters. Besides there were only three cases which were got through in one day; but fancy 32 men having been summoned to accomplish this mighty work, and being put to the inconvenience and loss of leaving their homes at their own expense. It cannot be said I have been selfish in endeavouring to get these allowances, for my age from next year will exempt me from again serving my country as a juror. Our new Resident Magistrates law came into operation on the 2nd inst., so that the same Magistrate now holds both Petty Sessions and District Court at the same place one after the other, as there are generally so few cases. The right of a suitor or person sued to have the case tried in which court he preferred is now done away with, so that the chance of being dragged away miles to Easington by the spite of a vindictive person is now at an end; the powers of Petty Sessions are likewise enlarged.

I have heard nothing lately of the Jamaica Hotels Company's doings, and hope the scheme is not about to collapse; nothing is more needed in Jamaica than a few good hotels, and believe they could be easily worked with assistance from America.

The Kingston Municipality continue to disagree, and waste valuable time; nothing has yet been decided upon for the proper drainage of the town, both surface and underground, neither has anything been done towards making Kingston harbour what it should be, viz., building a stone quay along the foreshore of the business portion of the town, with

rails laid along it, so that ships could lie close to the quay, and receive cargo from the railway trucks, in lieu of the present system of ugly jutting out wharfs which spoil the appearance of our magnificent Kingston harbour, and prevent the public walking along the sea face of the town, as at present it is all divided off into private yards.

We have lately had a visit from the Admiral and fleet, and, though it was Lent, the Kingstons appear to have done their best to entertain the officers, and the civilities were mutual.

To end this somewhat stupid letter and amuse your readers, I add a few Jamaica proverbs:—

1. When you sleep wid dog, you catch him flea.
2. When man no done grow, him should nebber cuss long man.
3. When hand full him hab plenty company.
4. Rock-a-tone ribber bottom nebber know sun hot.
5. Ebery dog hab him day, and ebery puss him Sunday.

W. S.

P.S.—Since writing the above we have had a few good showers, which have already much refreshed the country.

INDIAN TEA IN AMERICA.

We copy the following article from the *Indian Planter's Gazette*. It will be observed that the "evolution" argument of the writer amounts just to this, that Indian tea should be at first prepared like Japan Oolongs. But, if it finds acceptance only in that shape, large quantities must be made on the chance of a market in America, which, if rejected there, will not sell elsewhere? Must not the Americans gradually, like the English, recognise the superiority of Indian and Ceylon teas, without such teas being highly fired?

THE AMERICAN SCHEME.

By the "PERIPATETIC PLANTER."

The American scheme is still the chief topic of interest. Some people are a trifle disinclined to put their names down for a definite sum of money. Others argue that they would prefer to see some well drawn up plan of action and know *who* is to be the selected representative sent over to America, before they make up their minds. Whilst, on the other hand, others prefer that these points should be open to discussion; that they may have a voice in the matter, and so feel reasonably sure that the enterprise is not the bantling of a clique having axes to grind. These, however, are the usual differences of opinion which were to be expected as part of the not to be avoided worry of a start. Only a few leading firms have so far been appealed to, to lead of the list well, with good round sums against their names, and already over £3,000 are down against less than half-a-dozen names. One firm alone is down for £1,000, others are down for £600 and £500 and so forth, and several of the largest companies have the matter still under discussion, such as the Assam Company, the Doom Doona Company, the Darjeeling Company and the Jorehaut Company, &c., &c., &c. Much of course will depend upon support from your side before the £30,000 is guaranteed. From advices received from Calcutta it appears that the idea of consignments of tea is there preferred to cash subscriptions—thanks presumably to the state of exchange. The consignment of tea I fear will be found quite impracticable in this connection, for reasons I have already given relating to the exceptional circumstances connected with the American market which almost preclude the possibility of Indian teas, *as now manufactured*, finding immediate favour in America, although, by a process of evolutionary education, that end must, *of course*, be the sole object of our educational process. This attempt to prematurely compel Americans to overcome all their taste prejudices at once is surely tantamount to expecting a miracle to be worked in favour of Indian tea. Has any race ever shown any encouraging symptom of the possibility of such a sudden revolution in a nation's taste? How

was it in England here, where we had all the adventitious aid of shareholders in Indian properties and friends innumerable of planters, &c., in India, to lend their friendly aid in advertising Indian tea? Notwithstanding all this in favour of the growth of popularity in England, which Indian tea lacks in America, for how many years was it that Indian tea only reached the British public as a bolster under the guise of China tea? Not that for one moment do I recommend that any of our blends for America should contain China or Japan tea, far from that. But the lesson is there, and is worth attention. If in England it took many years so to change the taste from China tea to Indian tea, and that, too, by the *extreme* method of introducing it under the guise of the then popular China tea, how long would it take to change the American taste from the *still more markedly different* Japan tea, to Indian tea *as now manufactured*, and that without recourse, too, to the *extreme* method which favoured Indian tea's acceptance in England? Has history no lessons for us? If it has then there is none so certain, as, that by evolution alone can you assault national prejudices, particularly in the matter of taste, with any chance of success. Grant that as an axiom, and then the necessity for specially preparing the teas intended for the exploitation of America will be evident. Grant such special preparation to be a necessary feature, and then what becomes of the suggestion to supply ordinary Indian teas as contributions to the venture? This is distinctly a case in which the interests of the new enterprise—whilst working in the end, and as its *raison d'être* to benefit the Indian Tea Industry—*must keep its own interests intact*, and the shareholders in it must be prepared to work it as a business undertaking on true business principles unprejudiced by side issues. Its scope must be free to allow it to work to the best possible advantage in the interests of its own shareholders—and in doing so will lie its power, for good or for evil, over the future of the Indian tea interest generally. Otherwise, it requires no pointing out, that if the new enterprise is to be hampered and driven off the track by untimely attachment to outside conditions in India, the addition of this extra and unnecessary complication will be fatal to the success in view. There are surely sufficiently difficult problems to solve and complications enough in America without quite unnecessarily adding others in India to the rest.

So much for the trouble apparently awaiting the enterprise on your side. The chief trouble here still is to desire to rush the venture without taking the fullest precautions to ensure success. Many seem to think so lightly of national prejudices and so much of their Indian tea, that they chafe at any suggested preliminary exploration of the ground upon which the battle is to be fought, and they would risk the shipwreck that awaits their hopes rather than wait one year more whilst information should be collected, plans settled, and tea specially prepared. And yet, a good number of Anglo-Indians at one time and another, have taken their *ordinary* Indian tea to America *to their cost*. Here again, I ask, has history no lessons for us? But I need not repeat again the arguments I have already used upon this point. Suffice it, that if *actual owners* travelling in charge of their *own* property could find no profitable opening for that property, is it likely that non-owners will exhibit a keener sense or nose for scent, in the hunt for a market? *Verb. sap. sal.*

INDIAN TEA ASSOCIATION.

Among other matters dealt with in the general report of the Indian Tea Association for the year ended 29th February, 1888, the first of importance was the communication of Mr. William Aitchison of Cachar, made to the Council through Messrs. Barry and Co., anent the loss inflicted on him by the Deputy Commissioner for his refusal to submit returns of free labourers. The case was referred to the solicitors of the association, and their opinion, that the decision of the Deputy Commissioner was right as the law stands at present and that they could not advise Mr. Aitchison

son to appeal to the High Court, was upheld by the Council. With reference to the scheme of opening a large retail establishment in one of the first cities of America for the sale of Indian teas, the association did not see its way to give it support, but the general committee were of opinion that some good might be done in pushing the sale of Indian tea in Canada, if some arrangement could be made with the Canadian Pacific Railway Company. The committee, however, disapproved of the proposal of employing the officers of the railway as agents of the association, as such a step would place the railway company in direct antagonism to all other traders in Canada. As to the scheme for opening out the American and Canadian market formulated by Mr. Allies, lately manager of the Teesta Valley Tea Company, a general opinion was expressed that, in order to carry it out successfully, it would be desirable to go direct to the consumer with a supply of suitable blends of pure Indian tea or of such teas as could be drunk without being blended in small packets. The funds of this association, unfortunately, did not admit of direct support, but the committee were agreed that any well-considered scheme would meet with strong support from all interested. The terms offered by the Steam-ship Liners Conference for the carrying of tea, viz., £2 12s per ton with a rebate of 7s 6d to those who shipped exclusively by their lines being considered unfair and one-sided, an arrangement was entered into with Messrs. James Hay and Sons, of Glasgow, to carry the tea of all shippers contracting with them for a term of three years ending with the season of 1889. The rate of freight was to be a net rate of £2 per ton to be fixed for the entire three years irrespective of war or any other contingency arising in the interval; and on all tea landed direct in Butler's wharf a rebate of 2s 8d per ton was to be allowed by the proprietors of the wharf. It was further provided that these steamers should carry any persons connected with the business from Calcutta to London and *vice versa* (not exceeding eight by any one vessel, unless otherwise mutually agreed upon), at a rate of passage money fifty per cent. less than the British India Company's rates, with a minimum of £30 for each first class passenger. It was part of the conditions of the agreement that shippers should make provision for the carriage of, say, for the first season, about 40 or 50 million pounds of tea, whereas in sixteen voyages made by these steamers they carried only 17,116,563 lb. This want of support led to the steamers being withdrawn, so that in the coming season there will be no competition with those of the Steam-ship Conference. Owing to the unexpected increase of production of Dooars Gardens during the last few months of the season the crop probably exceeded 88 million pounds, as up to the end of March the exports to all places has been 86,699,876 lb. and the local consumption is estimated at 1,500,000 lb. The committee were able to report that there now existed a general completion and acceptance of arrangements under which contracts had been entered into, both as regards the Assam and Cachar Steamer Services, on terms considerably more favourable to shippers than those previously current. On the notice of Messrs. Begg, Dunlop & Co. a representation was made to the directors of the Darjeeling Himalayan Railway for a reduction of rates for the carriage of tea by that line, but, in reply, the directors declined to make any further reductions at present. A letter dated 1st April was received from the Secretary to the Chief Commissioner of Assam, bringing to notice a recent decision of the High Court, in which it was held that a contract purporting to be executed under Act 1 of 1862 was invalid, owing to the omission there-

from of the words stating the price at which rice was to be sold to the labourer, and also because having been made under section III. of the Act it had not, within one month from the date of execution, being forwarded in duplicate to the inspector for resignation. Copies of this letter were sent to all honorary secretaries of the association for general information.

The suggestion of the general committee to the agents of tea gardens to confine the working of their sirdars to the local agency of Babu Heralall Mookerjee, and the district labour supply, with a view to limit the number of agents and contractors in the labour recruiting districts, did not unfortunately meet with general support. From the answers received from district committees as to what alterations in the provisions of Act I. of 1882 would be necessary or advisable in the event of planters being deprived of the protection afforded to them by Act XIII. of 1859, the general opinion appeared to be that Act XIII. should continue to apply to coolies working on a tea garden, and it was unanimously resolved at a meeting of Cachar tea planters, held in May last, to protest against the report of the Act. It was also suggested by an experienced planter of Mungledye to strike out sections III. and 111 and 112 of Act I. of 1882, and the Act made really an Emigration Act, which would enable the advocates of Act XIII. to ask for a Local Labourers' Act to be applicable to all agricultural industries. The power given to inspectors to examine registers of labourers kept on the gardens, and to muster all labourers and other persons employed was objected to, and the urgent want of a clause dealing sharply with acts of insubordination and refusal to obey lawful orders was pointed out. In reply to the communication from the Chamber of Commerce asking the views of the general committee as to the proposed relief of the River Steamer Companies from certain liabilities attaching to them under the operation of the Carriers' Act III. of 1865. It was stated that the application of the steamer companies as to the alteration of the law relating to common carriers was approved, provided the change of law did not come into effect before the end of season. But, as there was reason to believe that certain London representatives of tea property did not insure their teas being river transit and depend for protection on the provisions of the Carriers' Act, the question of approving the concession asked by the steamer companies would be referred to the Indian Tea Districts' Association of London in order to ascertain the views of that body. The reply of the London Association was against the alteration of the existing law. The Committee of the Chamber of Commerce, in addressing the Government of India on the subject, accordingly stated that, in view of the diversity of opinions arising from divergencies of interests, they felt themselves precluded from expressing any definite recommendation on the subject. Mr. Hannay, the honorary secretary of the Luckimpur local committee appealed to the Deputy Commissioner against the order of the Income Tax Collector levying tax on commissions earned by managers on the profits of tea gardens. The matter was referred to the solicitors of the association, who held that no appeal to the High Court would lie against the decision of the Deputy Commissioner. They advised the association to address the Government on the subject of the levying of such tax. This course was taken, but no definite reply had been received. The following reply was received from the Chief Commissioner of Assam with respect to the representation of the association and on the draft settlement rules for the province of Assam:—
"As regards the rights of settlement-holders over

timber and other forest produce on pottah lands, the new settlement rules introduced no change, as the Government has always asserted its right over reserved trees, and the clause in the pottah now objected to was prescribed in its present form so far back as 1883. The apprehensions expressed in the Association's letter were, therefore, groundless, and the Chief Commissioner hoped that endeavours would be made to remove them as far as possible."

At the request of Mr. Williamson, of Messrs. Finlay, Muir and Co., a special meeting of the general committee was held on the 8th September to consider the question of railway communication between Bengal and Cachar, the result of which was a letter to Government drawing attention to resolution No. 868 R. C., dated 25th August, the decision contained in which the general committee thought most unfortunate, as an ample supply of labour was required at the tea districts, and to secure this desideratum a railway was what was needed. After pointing out that by the construction of this railway the journey between Cachar and Calcutta would be reduced to two days, and that its importance was incalculable in the matter of the transit of labour and the reduction of mortality, the committee showed by figures the enormous expansion of the Indian tea trade during the last few years, and the important portion of the crop produced in the districts of Sylhet and Cachar. The committee also drew attention to the probable importance of these districts as being on the line of possible communication with Upper Burmah, so that the railway would serve other purposes than those of a purely commercial character. The reply of the Government of India was to the effect that it was unable to re-consider the question of a guarantee on the outlay on any portion of the proposed scheme or to offer any concessions beyond those named in para 12 of the resolution of 25th August, which mean the grant of the land required for the railway free of charge. The question was accordingly referred to the Indian Tea Districts' Association of London, in order that the scheme might be brought to the notice of the people in England likely to be able to form a public company for the construction of the line on the terms offered by the Government of India. In respect to hailstorms in India, the opinion of the District Committees that, even if a scheme of insurance were adopted, the difficulty of estimating the damage inflicted on tea gardens by hail would be great, if not insurmountable, was communicated to the Chamber of Commerce with a request to be informed as to how the insurance against hailstorms was worked in France, Germany, and England, and by what means the amount of damage to crops was ascertained. Upon a reply being received from the Chamber after a reference to England, the general committee ordered the issue of their circular of the 12th December giving extracts from the prospectus of the country Hailstorm Insurance Company, containing certain conditions of insurance which appeared applicable to the insurance of Indian tea. It is understood that the insurance would extend to damage done by hail only and not by wind, water, or other causes, and that the risk would be limited to the "flush" actually damaged by hail, and would not cover any subsequent depreciation of crop through injury done to the bushes, so that it is thought the loss can easily be determined. The inspection of the crop would be performed by the company's local agent. The Cachar committee, who have considered the above conditions, are of opinion that they are not applicable to tea gardens, but they say that it is possible the word "flush" is meant to stand for annual crop in which case the proposals would be worth while taking into consideration.

On the representation of the general committee, the steam companies had together arranged to place a receiving flat at Lohit Mookh to minimise the risk of sending teas across the main river at Luckimpur, in country boats. The Chief Commissioner of Assam was also addressed on the subject of opening a road from Lohit Mookh to Kalahari, where it would form a junction with the northern trunk road, and become a direct postal road to north Luckimpur. The scheme of Mr. Consolo to open a market for Indian tea in Italy fell through owing to the little demand for the commodity in that country. The Indian Tea Supply Company was formed during the year for the development of the consumption of Indian tea in India. R3,000 was subscribed by the Association out of the balance of the funds of the late Tea Syndicate towards preliminary expenses, and 100 shares were taken at a cost of R1,000 out of the same funds. The company commenced working as soon as 10,000 shares of R10 each had been taken up, and is understood to be making satisfactory progress in sale of tea in packets. The report also referred to the tea sent to the Brussels Exhibition and the grant of R2,500 made by the Government of India to cover expenses at the Belgian end. The association during the year has represented a planted area of 139,489½ acres, being about the same as the previous year, but as the rate of subscription was reduced at the last annual meeting from one anna to half an anna per acre, the year's subscriptions have amounted to only R4,400-11-3, while the expenditure has been R6,541-6-0, so that the balance at credit of the association on the 29th of February was reduced to R2,174-9-5.—*Times of India.*

FOREST CONSERVANCY IN CEYLON.*

REPORT OF THE CONSERVATOR OF FORESTS FOR 1887.

The necessity for the conservation of the forests of Ceylon was first brought into prominent notice in 1873 by Doctor (now Sir Joseph) Hooker, who, on the report of Doctor Thwaites, then Director of the Botanic Gardens, Peradeniya, addressed the Secretary of State for the Colonies on the subject of the destruction of the forests in Ceylon, and the evil effects resulting therefrom upon climate and upon the natural resources of the Colony in future generations.

The Government of Ceylon had been alive to these evils, and to a certain extent had endeavoured to provide against them, but as forest conservation on a sufficient scale demands a considerable expenditure at the outset until the revenue derived renders a Forest Department self-supporting, it did not feel itself in a position to grant the necessary supplies for the purpose. Notwithstanding this, efforts were made by the Government in other directions to mitigate the evils attending indiscriminate sales of land. In 1882, Mr. Vincent, of the Indian Forest Service, was, on the application of the Ceylon Government, deputed by the Government of India to report on the forests of Ceylon. His valuable report was published as a Sessional Paper, No. 43 of 1882.

As the result of this report, and of a desire on the part of the Government to carry out forest conservation on a satisfactory basis, an Ordinance was passed in the session of 1885, intitled "The Forest Ordinance." The object of this Ordinance and of the rules made under it is, in the first place, to select suitable areas of forest lands and to constitute them State reserved forests; to buy off or to commute by the grant of land any rights which the population in the vicinity may have acquired in these lands; to mark off on the ground the boundaries in an unmistakable manner; to place these areas under effective protection; to improve them by sowing and planting wherever necessary; and, generally, to introduce system where there had been no

* See Review of this report on page 28.—Ed.

system. As the result of systematic treatment, it is hoped to guarantee a permanent sustained yield of timber, fuel, and minor forest produce, not only for the existing, but for future generations, to improve the climatic conditions, and by judicious restrictions in regard to harmful cultivation to meet the wants, and safeguard the interests of all classes of the community. There can be little doubt of the success of these measures, provided they are carried out with intelligence, fairness, and firmness on the part of the Government officers, together with an appreciation on the part of the people of the general benefit to the community that the Government has in view.

Although the object of the State in the execution of the important trust committed to it, both in regard to the welfare of the present and future generations, is strictly conservative, and has higher aims than the mere acquisition of revenue; still, judging from the results of forest conservation in India, the revenue to be derived from proper management is far in excess of the cost of establishments and working. Ceylon has in its forests timber and minor produce of not less value, comparatively, than those of India, where the receipts in the year 1883-4 amounted to £1,052,190, and the clear profit to £403,815. Up to a very recent period this valuable State property in Ceylon, more particularly the forest produce, has not been disposed of to the best advantage. The Crown forests have been systematically plundered by a gang of native timber thieves, who, often with the connivance of native headmen, gained a rich harvest, thereby depriving the people generally of a revenue which should have passed into the Colonial Exchequer, and should have thereby benefitted the community at large. An organised Forest Department will in the future aid the Government Agents in securing to the country this important branch of the revenue.

Not only are our forests worth preserving for the valuable timber, fuel, and minor produce they contain, and for the employment that forest management provides for a certain proportion of the population; but by judicious conservation, their indirect value as affecting the climatic conditions, and therefore the wants and interests of the people generally, will be greatly enhanced. There can be little doubt that forests render climate more equable, increase the relative humidity of the air, and possibly augment the rainfall. In tropical countries like Ceylon, where the rain falls at certain seasons only, and then falls in heavy showers a covering of forest protects the soil from being washed away, and thereby mitigates the silting up of rivers and low lands. In this respect Ceylon has in the past suffered much by denudation. Again, forests regulate the water-supply, insure the sustained yield of springs, and render the flow of water in rivers more continuous; they reduce the velocity of the wind, and afford protection to the neighbouring fields. Further, forests afford shelter to cattle and useful birds, and under suitable treatment improve the healthiness and picturesqueness of the country.

Many instances might be cited of the evil effects of forest denudation in almost every country of the world; but some very striking ones were given in evidence in 1885 before the Select Committee of the House of Commons on Forestry, affording a useful warning of what might happen at no distant date in Ceylon, unless preventive measures are taken. It was given in evidence by the late Political Agent of Jinjira, in Western India, that that native state, about forty miles long and from fifteen to one hundred miles wide, was at one time entirely covered with forest, but owing to the demands of the city of Bombay, three-fourths of the forest, in consequence of indiscriminate felling, disappeared within seven years, and the remaining fourth was only saved with difficulty. The result to this native state was simply ruinous, and if unchecked would have deprived it of all its resources. Another instance was brought before the notice of the Committee. The district of Ratnagiri, fifty years ago, used to be the great rice-producing district of the west of India, when there were dense forests extending up to the Western Ghats. In the

present day, the country up to the crests of the hills has been laid bare of forest growth, and the people complain bitterly of the yield of the rice land below, which has been attributed to the destruction of the forest operating to prevent the water from being stored upon the hillsides: it runs away in violent floods instead of flowing gently over the country. There are parts of Ceylon at this moment, in the Southern and North-Western Provinces and in the Province of Uva, where the havoc of the chena cultivator threatens to repeat the disasters of Ratnagiri.

In the middle of 1887, Mr. A. Thompson, of the Indian Forest Department, was deputed from India to advise the Government of Ceylon on the conservation of its forest. That officer, however, speedily lost his health, and in September of the same year resigned his appointment. Before leaving the Island he expressed the opinion that the most pressing matters to be undertaken were the selection, demarcation, survey, and settlement of reserved forests. Mr. Thompson, owing, it is presumed, to want of time, left behind him no scheme of operations for the coming year. On his departure in October the Surveyor-General was appointed Acting Conservator of Forests in addition to his own duties. One of the most important matters that the Acting Conservator had to submit for the instruction of Government was the position of Foresters in relation to the Government Agents and the newly-created appointment of Conservator of Forests. There is much to be said from a technical and departmental point of view in favour of Foresters being entirely under the control of the Conservator of Forests; and, on the other hand, there is a good deal that may be adduced from a political point of view in favour of placing the Foresters under the Government Agent. From a technical point of view it is of the first necessity that the working of the forests and the cultural operations connected therewith in order to ensure the proper continuity of the work, should be considered solely the business of the Conservator of Forests, subject of course, to the supervision of Government. This reason alone might by many be considered sufficient cause for the Forest Officers to be placed beyond possibility of interference by Government Agents. On the other hand, from a political point of view, it might be very properly urged that a Forest Department, working entirely without the knowledge of the Government Agent, might be neglectful of the interest and requirements of the people, and be prone to press the provisions of the Forest Law too hardly against them.

With these chief considerations in view, I submitted to Government that a middle course was advisable, and that the Forester of a Province should carry out the various forest works of demarcation, conservation, cultural treatment, &c. (as agreed upon annually by the Government Agent and the Conservator of Forests, and approved by Government) under the authority and protection of the Government Agent, while in administrative matters connected with discipline, pay, promotion, transfer, &c., he should be directly under the Conservator of Forests. By this dual subordination, provided the Government Agent and Conservator of Forests worked harmoniously together and co-operated towards the common end both have in view, I conceived that the interests of both forest conservation and of the people would be met, in that the just demand and requirements of forest conservancy will be attended to under the full authority of the head of the Province, while full control over the Departmental finance and over the organisation and technical part of the work, is reserved to the Conservator of Forests, Government was pleased to approve of this recommendation.

The matter next in importance was to draw up a project of operations for 1888. The Acting Conservator of Forests placed himself in communication with the Government Agents, and after learning their views drew up the following plan of operations for the year 1888 under the respective heading of—(a) Forest Demarcation, (b) Timber and Firewood Supply, (c) Re-forestation, (d) Extra Establishment. The plan of operations was sanctioned by Government in March, 1888,

(a) *Demarcation.*—This subject is considered to be of primary importance, because, until the forests are selected for reservation, and the rights of the neighbouring population judiciously inquired into and settled, and the forest boundaries properly defined and marked out on the ground, the law for their protection against encroachment and illicit felling cannot be satisfactorily enforced. It was therefore recommended to Government that the surveys required as preliminary to the examination of claims, and for the demarcation of boundaries on the ground should be actively proceeded with so far as the resources of the Survey Department would allow. It was further represented that the first measures of forest conservation should be directed to the neighbourhood of the large cities and towns, where, owing to the requirements of a dense population, the forest is rapidly disappearing for want of effective protection. At the same time, the firewood supply for the railway, both as it exists at the present and its probable requirements in the future, must not be lost sight of. It was submitted to Government that, speaking generally, there is no immediate necessity to demarcate the forests in the vast tracts which cover the whole face of the Northern, Eastern, and North-Central Provinces, as these are less open to encroachment, but that all available strength should be concentrated for the present on the remaining provinces. In the event of this suggestion meeting with the approval of Government it was proposed, in the Western Province, to demarcate the Mitirigala and Kanappella forests, both of them important from their situation near to Colombo on the banks of the Kelani. The survey of the Kelani reserve, which was commenced in 1887, will, it is hoped, be completed in 1888. Nearly the whole of that part of the so-called reserve which lies in the Central Province is found to be almost non-existent; while that part which lies in the Western Province will only be of value as a climate reserve. The rest has disappeared before the squatter and chena cultivator.

With regard to the large surveys carried out under the Adam's Peak range in the villages of Gilimale and Bambarabotuwa, the plans of which are now ready, it will be for Government to determine what parts of the forest should be reserved for climatic and timber purposes, and what should be sold. When this is done, the reserved forest should at once be demarcated and the rights of the natives determined and judiciously settled.

In the North-Western Province it is proposed to demarcate important reserves just outside the towns of Puttalam, Kurunegala, and Chilaw, as a first step. There are other important forests in this Province which must be demarcated at an early date, before they become a prey to the chena cultivator.

In the Central Province there is work to be done in the selection and demarcation of forests in the Matale District, while in the Nuwara Eliya District the importance of maintaining the boundaries of Crown forests against encroachment becomes more and more marked.

In the Northern Province it is desirable to select and demarcate several thousand acres as a reserved forest within accessible distance of the town of Jaffna.

(b) *TIMBER AND FIREWOOD SUPPLY.*—By consensus of opinion among the Government Agents, the present system of allowing timber to be cut in Crown forests by contractors for the use of the Public Works Department or by private individuals on permit is universally condemned, as little or no check can be exercised, and the revenue fails to get the value of the timber carried away. It is proposed to introduce an entire change in the system, or want of system, and in lieu of it to establish depots at the chief centres where there is a sufficient local demand for timber and firewood to warrant the expense of their establishment. The trees in demand for timber will then be felled as they arrive at maturity, allowed to season, and be transported to the depot to be sawn to the best advantage. In cutting out these trees there will be much branch wood which has hitherto been left to decay in the forest, but which will now be brought to depot for sale as firewood. By thus utilising every part of the tree, whether cut down for timber, or in thinning out, or in

opening out the necessary cart tracks, there is little doubt that considerable revenue will be derived. Moreover, the firewood supply being undertaken by the Forest Department, traders and their coolies will be kept out of the Crown forests which they have been accustomed to rob with impunity. It may be well here to mention that there seems a tendency in some places to fell timber before it arrives at maturity. In this green state timber lacks strength and durability, is more susceptible to dampness and to the attack of white ants, and is especially liable to split while seasoning. Where firewood is sold by weight there is an especial tendency to fell in the green state, for then the firewood is much heavier than when mature. There is a certain age at which a tree reaches its maximum weight; after that it loses in weight but gains in strength and durability until the age of maturity is reached.

Further, it is proposed, that instead of, as heretofore, the Government Agents felling separately, each for his own Province and without reference to the others, the annual felling should be regulated by the Conservator of Forests in communication with Government Agents according to the demands for Government use, the local demands of the public, and for export. In this way the balance between demand and supply will be better maintained.

It is proposed to have two main depôts, one at Colombo and one on the east coast. To the former depôt would be consigned all ebony, the best satinwood, and the better classes of cabinet woods, such as find favour for use in the capital or for export to Bombay, China, or England; while at the latter depôt would be sold such woods of the better classes as are in demand at Madras, but whose prices would not bear the cost of freight to Colombo. All inferior logs of cabinet woods and other timber of inferior sorts should be sold locally.

The principle of this arrangement may be summarised, that all superior classes of timber should be sold at Colombo when competition is rife, while the inferior classes that would not pay the cost of transport should be disposed of locally.

During the year 1888 it is proposed to establish depôts at the following places:—

Western Province.....	}	Colombo
		Kalutara (later on)
North-Western Province	}	Kurunegala
		Puttalam
Northern Province ...		Jaffna
North-Central Province	}	Trincomalee (Eastern Province)
Eastern Province ...		Batticaloa
Southern Province ...		Galle
Central Province	}	Nuwara Eliya, Nanuoya,
		Kandy, Matale
Province of Uva ...		Badulla, Haputale

The question of supplying sleepers to the railway will have serious attention. The woods of Ceylon have not had a fair trial up to the present time, and it is very important that we should, if possible, meet the demand for sleepers from our local resources. Palai (*Alnusops indica*) and Kumbuk (*Terminalia glabra*), which are most abundant in this Island, would, it is believed, be excellent woods for sleepers, and there are several others deserving of trial.

(c) *RE-AFFORESTATION AND CONSERVATION.*—It is the opinion of experts that questions of re-afforestation may, speaking generally, wait in this country until the more necessary measures of demarcation have made progress. In regard to re-afforestation there seems to be some misapprehension. It appears to be supposed that any kind of tree, whether indigenous or exotic, only requires to be put into the ground in order to grow. No greater mistake could be made, and disappointment and waste of money can only result from any such treatment. Some seedlings require sun, others shade; while soil, aspect, climate and altitude have all to be taken into account in determining what species will thrive in a given place. Projects of re-afforestation must be very carefully considered, and nothing done with precipitation. One great defect hitherto is, that some of the plantations in this country are neglected after they are once started, and for want of the

requisite thinnings the young trees have grown up weakly, and are of little value in consequence. This is, of course, due to the want of the necessary establishment to look after the trees until they have become well started; but it is none the less an unfortunate circumstance. As a rule, it is desirable to take up large areas rather than small for re-forestation—say, not less than 500 acres—to fence it in properly in proportion as it is planted, and not to spare labour until the young trees are well established. Small areas incapable of extension are costly in supervision. Indigenous timbers should be cultivated in preference to exotic, except in special localities. The mainstay of our work for some years should be the planting of the species which are known to thrive and produce good serviceable timber in the localities where they are to be planted. Many of our forests have been overworked, and require rest; for instance, in parts of the Eastern Province, it will be the duty of the Forester to make a careful survey of such forests, so as to determine the period of rest, to examine what prospects there are of seedlings of the better species growing up, or, if not, what areas should be replanted, and with what species. I do not quite share the view held by Mr. Vincent that reproduction is generally bad in this country. On the contrary, I have been much surprised at the way in which satin and halmilla, two of our most important trees, reproduce themselves vigorously in unexpected places, such as on the borders of chena lands or in places where the leaf canopy has been destroyed, and light accidentally let into the forest: given, of course, that the conditions in other respects are favourable to the growth of these species. In some of the ebony forests, too, the reproduction is satisfactory. All that is required is the establishment necessary to assist the saplings, and by fellings to preserve them from being choked by inferior species. With respect to the conservation and working of the forests, we shall, until the surveys and demarcation are complete, have to limit our cultural operations of the system known as that of *natural regeneration*, whereby the trees are only gradually removed as they arrive at maturity, so as to effect the regeneration of the forest by seed in the natural way, and to afford protection for a time to the young growth. With this cultural treatment we must combine the mode of working by compartments, whereby all the different compartments included in a forest are worked annually in rotation and given complete rest during the remainder of the period, so as to admit of their being properly protected during the years of reproduction. By this arrangement timber-cutters and coolies will be prevented from indiscriminate felling over the whole forest, which has done so much harm in the past.

(d) *Extra Establishments.*—As it is most important to check the illicit felling, which goes on unimpeded more or less over the whole Island, it is proposed to augment the present establishment by adding to it river-watchers, forest-rangers, and forest-guardes, in order to help in the detection of these malpractices, and to bring them to official notice.

F. C. H. CLARKE, Actg. Conservator of Forests,
Office of the Conservator of Forests,
Colombo, April 14th, 1888.

PROGRESS IN NORTH BORNEO.

The *North Borneo Herald* of 1st May, opens with a brief but telling review of the progress of the Colony during the six years of its existence. We append the more interesting portion of this review, summarizing the table furnished by the Treasurer, Mr. Cook, as follows. Mr. Cook shows that 1883 was the first complete financial year of the Company. The revenue which was then 50,738 dollars rose to be \$142,687 for 1887 and is estimated for 1888 at \$157,682, or say R350,000, about the revenue of the Colombo Municipality. It is still, therefore, "the day of small things" with this "New Ceylon" of 31,106

square miles, and an estimated population of 150,000; but there is the promise of great things in the near future. One good sign is the bringing down of Expenditure—which was five times the revenue in 1883—to within the current means of the Government for the present year. The imports of the Colony have risen from 429,000 dollars in 1883 to a value of a million dollars last year, and the Exports from 159,000 to 535,000 dollars. Mr. Cook summarizes the principal products as follows:—

Beeswax, birdsnests (edible), blachan, braesware, bricks, camphor, coconuts, coffee, dammar, fish salted, fruits, gutta percha, hide, indiarubber, ivory, live-stock, old jars, pepper, rattans, rice and paddy, sago, seed pearls, sesik tingeling, sharksfins, shells—tortoise and others, tobacco, trepang, bilian, cedar and many varieties of other woods.

Most sensibly have the North Borneo Company taken warning by our bad example in Ceylon, and by the exhortations we have so long offered: they treat the proceeds of their land-sales not as current revenue, but as belonging to capital account. Up to the end of last year, it seems, 120,000 acres have been sold for agricultural purposes, and during the first quarter of this year no less than 158,365 acres additional have been applied for—doubtless chiefly for tobacco cultivation. We now quote from the main portion of the review under notice:—

The British North Borneo Company has now been in existence for nearly 6 years, and our readers are fairly entitled to know what progress has been made and to ask the Company for some account of the undertaking entrusted to them by the Royal Charter dated 1st November 1881. By this Royal Charter, the Cession to the British North Borneo Company of that part of North Borneo between Kimanis on the North-West Coast, and Sibucro river on the East Coast, was confirmed, and the Company allowed to possess and govern the country. In 1884 the Company made an addition to their territory by the acquisition of Padas district (Province Dent) thus extending their Southern boundary to Si-Pitong and making the total area 31,106 square miles, with a coast line of 987 miles.

The first and most important movement was the appointment of competent Officers, and in this the Company was singularly successful, especially in securing for the post of Governor, William Hood Treacher, then administering the Government of Labuan. This gentleman's intimate acquaintance with the Natives of North Borneo, from the proud Sultan, Datus and Pangerans to the humblest of their slaves, made him eminently suitable for this high position. In London the Directors were also fortunate in having, as adviser and Manager, William Maunder Crocker, a successful Resident in the Sarawak Service. Mr Crocker has just returned to London after a year's Administration of the Government of the Country. This additional experience will make his services the more valuable.

Harbours and stations had now to be selected, the jungle cleared and houses built. In the Bays of Sandakan, Gaya, Maruda and Silam (Darvel Bay) the finest harbours were found. At Sandakan, Papar, Kimanis, Gaya, Kudat (Maruda Bay) and Silam, stations were successively opened, Constables were recruited daily from the material at hand—Sumalis, Nubians, Indians (Sikhs) Dyaks, Malays and Sulus. Every steamer arriving, brought immigrants, rice, provisions and building material to supply the wants of the pioneers who kept playing the axe and hammer. These stations soon began to show their importance. Natives drew near, to benefit by the protection and presence of the white man, and their houses soon appeared round the Company's flag. Stores, Offices, Police Courts, Barracks, Hospitals, and Gaols, Chinese and other shops were hastily erected; boats appeared bringing the produce of the surrounding country and seas; sales of land were made to eager buyers, trade and civilization had begun.

The Company soon found it possible to collect a revenue from the sources allowed them viz:—A duty on

opium, tobacco, spirits and salt, with power to create a farm for each of these or other commodities. Also an export duty on the jungle, and other produce, of the country. Court fees, land rents, Postal and Inland Revenue including Excise. Although the Royal Charter was granted in November 1881 it was not till June 1882 that the British North Borneo Company came into existence. Previous to that date the country was governed by a Provisional Association.

During the period under review the Company have not been idle. The resources of their territory though not yet fully known are being gradually tested. Explorers have travelled from West to East and from South to North. Payable alluvial gold fields have been found in the Segama river, while in many of the rivers falling into Darvel Bay, we have proof that they either pass through, or have their source in a gold bearing country. In the Southern Provinces rich coal fields are known to exist. In Province Dent, the coal is of superior quality and is considered as belonging to the Labuan and Muara measures. The Mineral wealth of North Borneo though known to be great, cannot be fully discovered and developed in a few years. When the country is intersected by roads and becomes more denuded of its dense forest, these riches may be expected to appear. Meantime the Company are wisely developing the agricultural resources of the country, these are more stable than minerals and are daily proving more valuable.

The soil and climate of North Borneo have been proved to be eminently adapted for tobacco, coffee, pepper, sugar and other tropical products, a late successful Manager of the Dali Maatschappi Company—one of the largest Tobacco Planting Companies in Sumatra thus describes it:—"the soil, vegetation and insect life, is the same as Lankat, but your climate is better." North Borneo tobacco is now a successful competitor with that of Sumatra, and it is grown by Planters from that country, who have every reason to be satisfied with their undertakings, the last consignment of North Borneo leaf sent to Europe having realised 185 G. cents or about 98 dollar cents per pound. At the present time there are five Companies planting tobacco in North Borneo; three in Maruda Bay and two in Darvel Bay, and as the greater portion of the land disposed of is for Tobacco, it is anticipated that in 1889 about twenty Companies will be in full operation.

In 1888, North Borneo Sugar Canes will be exported to Java as stock. A Company is being formed with the sole object of growing "tops" for export. The representative of the Java Sugar Planters has secured land with which he is satisfied "beyond his expectations." He promises that North Borneo will be a great sugar-growing as well as a tobacco-growing country. The coffee estate at Kudat belonging to Mr. Christian may be pointed to as a proof of the soil's capabilities in this respect.

The Government experimental garden at Silam has served a good purpose in proving tropical products in North Borneo soil. The forests of North Borneo produce a large variety of the finest known woods, including the famous bilian. The supply is inexhaustible. Two enterprising Companies have taken advantage of this and are preparing large Exports for China and elsewhere. A large Saw Mill fitted with the latest improvements has been erected in the vicinity. The same Company are planting Coffee, Pepper and Pine-apples; from the latter they intend to extract the fibre and are erecting machinery for the purpose.

North Borneo now enjoys all the advantages of a settled Government; its laws Civil and Criminal are taken from those in force in India. Local Ordinances are made from time to time as require. A Money Order system facilitates transactions with almost every civilized country. The treasuries at the different stations negotiate bills and perform any banking business. At each station permanent buildings, such as offices, barracks, gaols, hospitals, dwellings, wharves, and custom-stores, are taking the place of the temporary buildings at first erected, roads and bridges are being made where required.

The whole country is in a prosperous state of advancement, and the population is steadily increasing not only at every station but throughout the country. Tribal feuds are becoming occurrences of the past and the inhabitants now enjoy the benefit of freedom. North Borneo presents many tempting advantages to the planter and settler such as are rarely met with; a soil that will grow almost any tropical product. Chinese labor only 1,000 miles distant; with regular communication, a moderate rainfall, with distinct seasons and fine climate. The natives of the interior welcome and assist the planter, and the country is without a pauper.

The British North Borneo Company have a fine property. It has taken much energy and care to bring it to its present state. We congratulate its Court of Directors on having reached this stage of progress, with their Revenue equal to their Expenditure and wish them continued success. We have a guarantee in our new Governor, Charles Vandeleur Cregh, whose long experience and success in Hong-kong and the Native States under the Government of the Straits Settlements, make him eminently qualified to govern North Borneo.

We have no doubt that great as has been the progress in the past six years, the advance which the next similar period up to 1894 inclusive shall witness will be far more considerable. Hitherto rough exploring and pioneering work have occupied a great part of official attention; now the success and occupancy of large agricultural districts have been pretty well assured, capital and settlers are arriving, and the results in increased trade and revenue will speedily become visible.

CEYLON UPCOUNTRY PLANTING REPORT.

THE MONSOON—MARKET QUOTATIONS AND CEYLON TEAS—VARYING TEA VALUATIONS AND RESULTS—HOW TO TEST TEA TASTERS: A HINT FOR THE COMMITTEES OF AGRICULTURAL SHOWS—JAT AND LEAF—PLANTERS AND ICE-PUDDING AND KEROSENE OIL.

11th June, 1888.

The Monsoon we are having is quite a model for mildness. I suppose it will make up for this by and bye: meanwhile we are thankful for the present state of things, and taking every advantage we can, and, if it were not for the severe fall in the price of tea, we would be happy.

By the way are the present market quotations wholly the result of depression and big deliveries? I know it is said that much of the tea which is reaching home now was not by any means up to Ceylon's high standard, and that spite of other influences which are affecting the market to our detriment, the fact that many of the teas were so inferior could not but have acted to our disadvantage. Even in the small list of estates which form the basis of comparison in your last London telegram, one of them was so wanting in rolling power, when the big rush of leaf was on, that the manager himself speaks in anything but a respectful way of the teas sent therefrom. He did not expect much from them, and I fancy he must be mightily amused to find them advanced to the high position of "standards." They may be good of their kind, but then the kind was not good. Whatever may be the cause or causes of the low range of prices, we will be all glad to see them removed.

As to tea valuations, it is sometimes not a little surprising to see how near they come, and also how far they can be out. A good estate in Dembulah had a tea valued at 1s 8d in Colombo, and which got only 1s 1d in London. Another was valued here at 1s 6d, the London tasters put it down at 1s 1d, and it sold for 1s 4½d. "These be mysteries." In New York it is said, that a proof of an accomplished tea master is to have twenty-four samples placed before him which he tastes,

makes what notes he likes, and then leaves the room. During his absence the cups are all rearranged, then he is re-admitted, and has to taste again and place them in their original order.

I would offer as a suggestion to the spirited committee of the Matale Agri-Horticultural Society, that at their next meet they ought to get up a contest of this kind, and invite our professionals to a display of skill. Even the merest tyro in tea-tasting could appreciate a test of this kind, and the laity generally would be as ready to applaud and take as hearty an interest in a tasting tournament as the professionals themselves.

As to the planters, the work of whose hand has been condemned or otherwise by brokers' reports, they would be all alive, and there. It might be necessary if the tea augurs proved themselves inefficient to have a "sandwich man" ready to parade the show, intimating that no swearing was allowed. The best men in the competition might be, for the day, judges of the teas.

But it is not the broker and professional taster who alone is possessed of a hidden knowledge in regard to our new product, for it was only the other day I heard of a fine distinction being drawn between green leaf and green leaf, which had no connection whatever with the style of plucking. Jât was to rule the price. A seed-grower, who prides himself not unjustly on the high-class seed he has for sale, was getting exuberant over this, and would like to have the idea taken up to the total extinction of all who are daring enough to offer seed under R40 a maund at the very least. He admits with some sorrow that the man has more to do with the quality of the tea manufactured than the jât or the land on which it grows, and that some of the estates which have had the highest prices have not much in the way of jât to boast of. He has also known very fine jât get very poor prices. Spite of this there may be something in it. If the next Matale Show were to have samples of leaf plucked from various jâts, it would not be a bad feature to invite the knowing ones to come in and distinguish them, which would be the first step toward our education in these high matters.

An estate manager went down to Colombo for an outing, and was hospitably entertained by the proprietor there. All the delicacies of the capital were at his command, but he cared for none of them as he did for ice-pudding. That he would have had morning, noon, and night if the household arrangements would have allowed of it; and when he got back again to the hills his mind would revert to the toothsome morsel, and his regrets were deep at the loss of it. Since the proprietor has found out the weakness of his manager, he is endeavouring to arrange that all future advances of salary are to be paid in the shape of extra ice puddings when the superintendent visits Colombo. This, it is hoped, will satisfy all parties.

A V. A. whose hair was getting thin, and who had been applying kerosene to the bare patches, was on a visit to a cacao property. The manager was eloquent on the borer, and how it could be got out of the tree by squirting kerosene into the hole the troublesome and destructive insect had made for itself. The V. A. was much interested, would like to see the boys at work, and the manager said that that would be easily shown, as the boys must be in the neighbourhood. After looking about and walking a little, no trace of the workers could be seen, which non-plussed the manager; for, as he said, they *must* be in the vicinity, "for I smell the kerosene." The search was continued with renewed vigour, but was still

barren. Meanwhile the V. A. was convulsed with laughter, especially when the planter appealed to him if he did n't smell the oil. By and bye the V. A. uncovered, and told how he, too, had been using it for strengthening his hair, and that probably the odour that had been with them during their walk, and which had proved such a snare and delusion, was explained in that way.

PEPPERCORN.

PLANTING NOTE FROM LABUGAMA LOWCOUNTRY, DISTRICT, CEYLON.

11th June.—The heavy rain upcountry, and that which we have had here, has caused the floods so frequent at this time of the year. The coaches and all wheeled traffic was stopped for some days between Colombo and Awisawella. Those who were obliged to get down to Colombo, and were not in a hurry to come back, went down by river, and I learn that the current was so strong, that some friends who went down in this way were unable in consequence to put in at Kaduwela, where they had arranged for breakfast, and being not overburdened with food and liquid, arrived in Colombo with huntsmen-like appetites for dinner. The Kelani Valley Hunt is about to be broken up, and the dogs either sold or raffled. The dogs have afforded sport to some and mostly so to those in the immediate neighbourhood of Awisawella; there are some members who have been so unfortunate as not even once to have followed the pack, but the Master of the Hunt had so provided, that should any member require the dogs on giving due notice he could have them any day, of course holding himself responsible for the pack.

There appears to be a wonderful demand for "hâl" timber for tea boxes. Timber dealers kindly offer 1,000 square feet 20 odd miles from Colombo at 38 rupees, thus with cart hire added this would come to something like 43-44 rupees per 1,000, and may be some will give this sum. I learn that R20-14 per tree was the figure accepted by Government for the 400 "hâl" trees in the Indikadamukalana reserved forest in Hewagam Korale, two miles from Welikanna on the Labugama road; however, I am given to understand that on the trees being marked and passed by the person whose tender was accepted there were not found the precious 400, but only something over half that number.

The Forester, W. P., when last in these parts, went to visit the Labugama reservoir, and was charmed with the picturesque beauty of the place; he is very strong on planting up forest and other trees all round the tank. At present the waterfall in the distance with its brilliant spray adds greatly to the beauty of this spot. Our loneliness has been pleasantly broken into of late, and amongst our various visitors was Mr. A. M. Gepp, en route to Awisawella, where he held classes towards the end of last week in tea tasting. I enclose rainfall for May 1887 and up to June 10th, 1887, also for same dates of present year.

NOTES FROM THE PLANTING DISTRICTS
NORTH OF KANDY.

REVIVAL OF COFFEE—COTTON CROPS—TEA AND INCREASING TRAFFIC—NATIVE COFFEE FLOURISHING—A WORTHY MEDICO.

June 11th.

You may perhaps find room for a few notes of what is going on north of Kandy. A very marked change for the better is coming over what coffee there is left in the district. The Lewella road, which I passed over yesterday, really reminds one of old times. The coffee along the roadside is covered with berries: in some places the overhanging branches and suckers being weighed down with crop. The foliage also shows a luxuriant growth which has not been seen for years past. The dead naked sticks, we have so long been accustomed to, have all disappeared, and strong rebarked suckers with rich dark leaves 6 or 8 inches in length are growing from almost every tree. I spoke to a good many of the Sinhalese and Moor traders, and was glad to learn that in all the villages the same improvement is observable.—A brisk trade was being carried on all along the road in cotton, of which there seems to have been a very good crop, and altogether there was an air of cheerfulness and brightness about the people which I have not noticed for many years past.—On the estates in this neighbourhood there is very little coffee left; but wherever black bug was not very bad last year, the trees are bearing well, and there is the same change in the character of the foliage which I have referred to above. Figures will perhaps convey the best idea of the improvement which has taken place; so I will add that I expect next season 1,000 to 1,200 bushels of parchment here, as against about 500 for the last two seasons and 500 bushels in 1885-6. I wish we could feel sure that this change points to coffee again becoming productive which would mean an almost immediate return of prosperity to the villagers who have not pulled out their coffee trees as we have done. The coffee at Aratenna and the other villages along the Hulganga is bearing equally well.

Our road is in fairly good order, but more liberal expenditure will be necessary if it is to be kept so. The well-known Sirocco chimney, or a long end of 3" shafting protruding from the upward-bound cart, is a sure indication of increasing traffic erelong. Tea here, as elsewhere, has been flushing very heavily lately, and most estates will secure the crops estimated.

I was glad to see the remarks in the *Observer* respecting our District Medical Officer, Dr. Candyah, who well deserves the praise bestowed on him. He has not only been successful in his private practice amongst Europeans, but he has done much, following in the steps of Dr. Aldons, to overcome the repugnance the coolies have to going to hospital, and has shown them, by his generally successful treatment and unvaried kindness and attention to his patients, how much they gain in accepting the help offered to them.

AN ASSAM TEA PLANTER ON CEYLON.

An Uva planter writes:—"I enclose an extract from a letter I received a mail ago, from a retired Assam tea planter, though I believe he has still some interests out there. Perhaps you will find some interest in its perusal. The writer is an old experienced planter, and his name is well-known in he Lane":—

(Extract.)

"From Thompson & Co.'s fortnightly circulars issued to all interested in tea, I am always glad to learn that Ceylon comes to the forefront with a

most creditable and sightly article which fully holds its own, both as to demand and price at Mining Lane. In Ceylon, I fancy, you have considerable advantages over tea planters in North-Eastern Bengal, both as to labour and greater production per acre. The question of labour has always been in Assam the great drawback as well as a source of much trouble and annoyance to planters. The Government, instead of facilitating the transport of coolies from the North-West to the North-East of India, has placed so many restrictions and annoyances as almost to amount to the entire prohibition of labour from other sources. Whereas you have abundance of labour at your very doors and at a cheaper rate than can be had in India. From the little information I have had regarding tea growing in Ceylon, your outturn of tea is much larger than in Assam. We thought six maunds or 480 lb. per acre a very heavy yield, and when obtained was looked on as at least 1½ maund above the average production."

TEA PRICES IN LONDON.

The serious depression in the London market for our teas induces us to inquire whether it is warranted; and whether it will be further intensified before "the bottom" is touched. Taking a retrospective view of the subject, we find that not only last year did a similar depression take place, but also during the previous year (1886) at precisely the same period. It will be seen by the subjoined extracts from Messrs. Wilson, Smithett & Co.'s market reports, that during June and July of 1886 the London market was as depressed as it now is, and a similar experience was noticed in June 1887. The important fact to Ceylon planters is, that in both instances the fall in prices was followed by a recovery which commenced in August. The causes which contributed to these depressions were said to be a periodical falling-off in quality, but chiefly to the dread of coming excessive supplies, and these are put forth as the reasons for the present state of the London market.

The question which is of most interest to us just now is, what prospect is there, that prices will begin to recover in August this year, as they did in 1886 and in 1887?

If the Estimate of Supplies for the next 12 months,—as prepared by Messrs. Stenning, Inskipp & Co.—which we published in our issue of the 1st inst., is approximately correct, there is, we think, every prospect of a recovery, immediately a safe opinion can be formed as to the Supply to be expected from China. The Estimate was as follows:—

"PROBABLE SUPPLY, SEASON 1888-89—1st June to 31st May—may be estimated as follows:—

	lb.
Indian	93,000,000
Ceylon	25,000,000
Java	3,000,000
China	100,000,000
	<hr/>
	221,000,000

"At the present large and increasing rate of consumption of Indian and Ceylon kinds, this quantity should be readily dealt with."

If the China supply is found likely to be less than that of last season,—when 123 million pounds were exported to England,—prices will respond assuredly, and it will be seen that the authority who made the estimate given above put the figure for China exports at 100 millions only.

The quantity to be expected from China up to the 31st May 1889 is, indeed the only doubtful element in this estimate. Messrs. Stenning, Inskipp & Co. make out a total supply of 221 millions of pounds: and if they prove to be correct in their estimate of the export from China, there is little doubt, we think, that the present depression will be as temporary as during the preceding two

years, because the total supply will not then exceed the average deliveries during the last four years:—

In 1884-5 the deliveries were 234 millions of pounds against an import of 206½ millions.

In 1885-6 the deliveries were only 208 millions against an import of 219 millions.

In 1886-7 the deliveries were 221 millions against an import of 228½ millions.

The returns for 1887-8 are not yet received, but taking those for 11 months, and estimating the May deliveries and imports, we find that the former will be 217½ millions, against 223½ millions imported. If the re-export from England last year had been as large as during previous years, the supplies and deliveries would have been exactly equal, conclusively proving that the dread of excessive supply which caused the depression in June and July 1887 was illusory. We admit that it was so, only because the China supply was 27 millions below the previous year. This year the advices from China and the extremely unremunerative prices obtained in London for more than half of what is shipped from that country seem to warrant a lower estimate for the current season's export.

We shall know more about this two months hence. In the meantime, even if the China export exceeds 100 millions, the increase from India and Ceylon will not be so excessive as to keep the market in a permanent state of depression. If the deliveries during the next 12 months come up to 228 millions of pounds, as they may easily do, and still not be out of the way, there will be room for 110 millions of pounds from China without adding much to the stocks on the 31st May next.

With these facts before us, we put it to our readers whether there is sufficient grounds for the present semi-panic state of the market, and whether we may not reasonably look for a recovery in August this year as in 1886 and in 1887?

We append, as of considerable interest to all interested in "tea"—and who is not directly or indirectly?—among our readers, the extracts from the Market Reports for the past two years, referred to in the foregoing remarks:—

EXTRACTS FROM MESSRS. WILSON, SMITHETT & Co.'s
CIRCULARS, 1886:—

- May 18th. There is no improved demand, and prices are still very irregular.
- June 4th. The demand continues very weak, and the quality of the majority of the teas offering is not calculated to stimulate it.
- " 11th. The market for Ceylon tea is still very depressed.
- " 18th. The market remains very flat.
- " 25th. There is no improvement in the demand, and prices have again receded.
- July 2nd. Only 850 packages catalogued this week, and went off slowly at very moderate prices.
- " 9th. The demand was again limited, and only moderate prices realized.
- " 16th. The supplies of Ceylon tea have been very large this week; a small demand from the country for the finer grades had a steadying effect on the market, and prevented prices being still more adversely affected by this heavy supply.
- " 23rd. Fine qualities again sold well at steady rates, but poor and dull liquoring sorts met with a slack demand.
- " 30th. Teas of good quality and strength were again in good demand; lower grades are at a discount.
- Aug. 6th. 3,950 packages offered and met a decidedly firmer market for teas possessing point and quality. Burnt and poor liquoring teas continue to be quite neglected.
- " 13th. The higher grades selling well at the former rates established last week.

Aug. 20th. 3,800 packages made a ready sale at strong prices for fine flavory descriptions.

" 27th. The offerings from Ceylon have lately shown considerable improvement in quality and point,—a fact that has been readily recognized by the trade, and has resulted in a rise of something like 3d to 4d per lb. for good broken pekoes. Pekoes and pekoe souchongs have also generally enjoyed better competition.

Sept. 3rd. 2,560 packages offered, and the market for fine qualities.

1887:—

June 3rd. 2,864 packages offered, and met a rather irregular market; the poorest descriptions went firmly for price, but ordinary pekoe souchongs sold at easier rates.

" 10th. This market is also very dull, and the supply has been rather heavy.

" 24th. We cannot report any improvement in the state of the market; less desirable and ordinary medium kinds sold very cheaply.

July 1st. The better kinds have sold at slightly firmer rates this week; but the market is still very depressed for medium pekoes and the less desirable souchongs.

" 22nd. The improvement noticed last week has been well maintained.

" 29th. The supply has been very heavy this week, viz. 8,200 packages; the market however shows rather less irregularity: this large amount evidently attracted full attention.

Aug. 12th. The market has ruled firmly for all fine liquoring teas, and although the lower grades show considerable irregularity, nevertheless a rather better tone has characterized these descriptions.

" 19th. The supply was much more moderate this week; a good demand prevailed, and prices ruled firmer all round.

" 26th. The market has been very firm this week; the quality generally showing considerable improvement.

Sept. 2nd. Ceylon continues firm, but at the closing auctions a rather quieter tone was apparent; the teas bought in have been chiefly sold since at considerable advances on auction bids.

" 9th. The market has continued very firm.

MR. KING, Director of the Geological Survey, gives an interesting account of the Khattan Oil Works, in a letter published in a contemporary. He is of opinion that the conveyance of the oil through pipes, as at Baku, could only be effected by means of a complicated system of forcing pumps. This is due to the thick, viscous nature of the oil, which is described as "black, tarry-looking stuff." Distant forty miles from the railway, and being difficult of access, the works may yet fail to produce oil at profitable rates. Failing the use of forcing pumps, it must be conveyed in tubs on a tramway line.—*Indian Engineer*.

A REPORT has been issued from the Foreign Office on the oyster fisheries of Maryland, as received from Mr. E. S. Segrave, British consul at Baltimore. The report states that the value of these fisheries is more than double that of any other state in the Union, producing on an average about 5,000,000 dol. annually. In spite, however, of this enormous production, the condition of the trade is said to be depressed, owing to the exhaustion of the natural beds and the failure to adopt, in an adequate measure any new intelligent system for keeping up the supply; and if prompt measures are not taken by the Legislature there is reason to fear that the forebodings of experts will be realised, and the oyster property of the state be in imminent danger of complete destruction.—*Australasian*.

MAURITIUS.

THE WEATHER AND THE CROP.—We can but repeat our last advices as to the state of the weather which continues exceptionally fine. Under the influence of a warm temperature and abundant rains the plantations continue to thrive. We are now in a position to state that the next crop will furnish a greater yield than that of last year 210,263 bags of sugar have been received in store up to the 27th instant in excess of the quantity received during a corresponding period of last year and there were 49,493 bags less in store than at the same date last year.

VANILLA.—We entirely confirm our previous valuation, as regard a reduction of more than 50 per cent on the total out-turn of our coming crop.

ALOE FIBRE.—The manufacture of this fibre is briskly carried on and the next steamer for London will ship from 5 to 600 bales. The monthly output is now estimated at from 12 to 1,600 bales, a figure which has not been reached for a long time past. The market is firm and the demand very brisk. A few lots of fine quality, were sold at R310 per ton. Owing to the favourable news received by last mail, holders are unwilling to sell at present quotations and prefer to ship for their own accounts.—*M. & P. Gazette*, May 30th.

THE JAVA GOVERNMENT CINCHONA PLANTATIONS :

DETAILED OFFICIAL REPORT FOR 1886.

This Report given on page 42 is interesting in many respects, although, in consequence of the depression and disappointment connected with the cinchona enterprise, we cannot expect that it will receive from our readers anything more than a reflection of the attention which was wont to be bestowed on Mr. Bernelot Moens' sensational revelations of the riches in pure quinine of *C. ledgeriana*, a species which the Dutch so fortunately secured. Nearly all the species and varieties known have been tried in the Dutch colony, with the result, unless the large-leaved and high growing *C. pitayensis* is found really valuable, that practical attention may be confined to *C. ledgeriana*, *C. succirubra* and a very rich hybrid, the offspring of these two species. It is very true that, now the demand from the Java forest department for succirubra plants as shelter for timber tree seedlings has slackened, this robust kind is mainly appreciated as providing strong stems on which to graft the valuable but comparatively delicate ledgerianas. The accounts given of the results of the junction of the two species and of the influence of the stock plant on the graft are exceedingly interesting, from their bearing on a much-debated question in horticultural operations and vegetable physiology. We believe we are correct in holding that the prevalent opinion hitherto has been that the stock exerted no appreciable influence on the fruit of the grafts. The effect on the bark was not we suppose investigated until Mr. Moens initiated those very interesting experiments in Java, which Mr. van Romunde is so successfully following up. There seems to be a shade of doubt now whether the bark of the famous mother-trees of

ledgeriana analysed by the late Mr. Moens were so entirely free from any taint of cinchonidine as the researches of that eminent observer seemed to indicate. Later analyses show traces of the inferior alkaloid. But this qualification does not prevent Mr. Moens' successor from recognizing as a fact the influence of the succirubra bark on that of the ledgeriana graft, at the point of junction and for a limited distance upwards. The influence is, however, so limited in distance above the junction, that it is regarded as of little consequence, and Mr. van Romunde believes that all fear of the seed of grafted ledgerianas being affected adversely may be dismissed. The question, therefore, as regards this form of cultivation becomes one largely of expense and trouble. Mr. van Romunde does not enter into the investigation of these points, but it seems significant that so few grafted plants were purchased by private planters. We have no information, however, whether, with cinchona bark prices at so low an ebb, the Java planters have themselves deemed it worth their while to follow the Government cinchona growers in the graft method of cultivation. On this question we should be glad to be informed by correspondents in Java, or friends in Ceylon who are in a position to help us. Our inclination is to believe that but few, if any, private cinchona planters in Java have to any extent adopted the grafting system. As pursued in the Java Government gardens, it involves the necessity of conservatory warmth and shelter, pots placed in special positions, and considerable time and attention to secure success. From what we observed on the occasion of our visit to the Tirtasari plantation in 1881, we are not at all surprised to learn, that the grafted plants have continued to develop what they showed then, a dwarf habit, or, more correctly stated, a tendency to throw most of their strength into lateral branches. From what Mr. van Romunde states, too, it will be seen that the grafted plants are inclined to divide their strength between many stems instead of concentrating their juices on one vigorous upright shoot. The account Mr. van Romunde gives of his "intensive" (by which we understand *close*) cultivation; of the excision of all but one stem, and of a modified system of pruning and thinning the abnormally robust branches, will be read with interest. We can understand the influence of close planting in producing humus from fallen leaves, but it seems a new idea that by such a mode of planting the attacks of chafer grubs should be avoided. In respect to weather and attacks by *helopeltis*, and also until recently in regard to labour, Java has been less favoured than Ceylon. But from the first—especially in regard to the cultivation of the very finest species of cinchona, that which bears the name of the inadequately rewarded Ledger,—the Dutch colony has had advantages of soil, with which only a few portions of Ceylon can at all compare. The Preanger Regency districts, in which the Government cinchona plantations are situated, are the scene of numerous living volcanoes, to the activity of which, in former (indeed, in recent) times, the rich soil (uniformly rich to a great depth) is due. There is no poor subsoil to be turned up in terracing such soil, or in digging trenches of two feet deep and "working" the soil to that depth. But our readers will note the excellent effects of tillage on even this naturally rich soil and the benefits of manuring, even where it is merely the spreading on the surface of the waste of such an unpromising material as *abany abany* grass,—what we call *thuk* in Ceylon. Even "mulching" of this sort does good, but the perfection of tillage, to which tea specially responds, is the fork-

ing into the soil of prunings and other substances, not excluding succulent stems of *nilu* from the jungle. The forked-in substances may not, as in the case of *nilu*, have any high manurial value, but they keep the ground open to the ameliorating and decomposing action of the atmosphere on the constituents of the soil. If tillage is necessary and has such rapid and beneficial effects on vegetation in the rich volcanic soils of Java, how much more should the process receive attention where the soil in its fertile components and their mechanical condition is so much less favoured, as is the case in many parts of Ceylon? As a rule, however, our Ceylon soils are fertile enough: what they need is tillage to convert latent fertility into soluble substances, available for the feeding rootlets to convey into the circulating and building-up juices of the plants. If suitable fertilizing matter can be applied, even fresh soil from neighbouring forests, so much the better. Our planter readers know all this, but it is well that lessons even from the cinchona culture of Java should be enforced as of local application. It will be seen that a Davidson's Sirocco had been ordered for use in drying cinchona bark in Java.* As a general rule, artificial heat does not seem to have been much utilized in the curing of Ceylon bark. Drying the bark in the shade has been the prevalent practice here, but it does not seem that sun or furnace heat leads to deterioration of the bark. What is mainly wanted in connection with cinchona cultivation is the restoration of remunerative prices, now that larger consumption of quinine and the other alkaloids has been secured, mainly by the operations of Ceylon planters (for Java is as yet more noted for quality than quantity of produce), and many of us will heartily join in the hope that Mr. van Romunde's sanguine vaticinations as to the return of paying prices, may be fulfilled. It will be observed that in the case of the Java Government plantations, as in that of the similar establishments on the Nilgiris, estimates of plants growing, founded on the numbers "planted out" require periodical revision in the direction of abatement. If any of our friends in Ceylon, with faith in better times for cinchona bark, and looking at the fall which has already taken place in tea, are inclined to try an experiment in the culture of the fever plants, we would advise special if not exclusive attention to the rich, and we doubt not robust, hybrid produced in Java by the existence in close contiguity of *succirubra* and *ledgeriana*. It will probably be found superior even to the fine hybrids we already possess, resulting in Ceylon from the union in fructification of the reproductive principles of *succirubra* and *officinalis*. The latter species has succeeded better on private plantations in the eastern parts of Java than it has done in the Government gardens in the western division of the island. We were interested to learn recently too, from a planter who is the owner of coffee property near Surabaya, that *Hemileia vastatrix* has not as yet injuriously affected coffee in eastern Java.

The report for 1887, if we only had it for reference, might throw valuable additional light on the question of the influence of the *succirubra* stocks on the *ledgeriana* grafts and on other points in this interesting and valuable, if, for purposes of profit to the planter, overdone culture.

* In the report of the first quarter of 1888, which we published recently, it was stated that building were being erected for half-a-dozen more of these machines, which were expected.

REPORT ON THE DUTCH GOVERNMENT
CINCHONA ENTERPRISE IN THE PRE-
ANGER REGENCIES, JAVA, FOR THE
YEAR 1886.

By R. VAN ROMUNDE, DIRECTOR.

(Translated for the "Tropical Agriculturist.")

1. *Weather*.—In the month of January and in the first half of February remarkably little rain fell. From the middle of February to the middle of the month of May the weather continued very wet. The drought that followed, which lasted till about the end of September, was not continuous for any length of time, but was intermitted frequently by gentle showers of rain. At the beginning of October the west monsoon set in in full force, and during the last three months of the year scarcely a single dry day was registered. On the whole the weather was very favorable for the growth of the plants. Storms, which at the commencement of the year, especially on the Tankoebanprahoe mountains, cause much damage to the plantations, were as good as unnoticed, and night frosts, which in the third quarter of the year, when severe drought and strong east wind prevail, do much mischief to the young plants especially, were also not experienced. The severe and prolonged drought during the east monsoon of 1885 had a powerful effect on the weatherbeaten tree-tops, and made its genial influence felt during the past year, when during the whole of the east monsoon also frequent gentle showers fell, whereby the plants were able to develop undisturbed. The continuous rains during the last quarter of 1886, although favorable for the young plants, in the end caused a check in the growth of the old plants.

2. *Increase*.—The number of plants in the open at the end of the year was 1,686,200. While this figure shows a notable increase in the past year, that increase is actually very much greater, as the figure for the old *C. succirubra*, *C. josephiana* and *C. officinalis* in the previous year appears to have been too high. In the nurseries there were under shade 2,108,000 plants, of which 1,433,000 were *ledgerianas* and 675,000 *succirubras*. These figures are to a great extent 'round' ones, especially as in them are counted the still young plants in beds, the number of which, even under shade, it is difficult to ascertain. Among the *ledgerianas* are included 53,000 grafts, all intended for the extension of the plantation at Tirtasari. The graft-plants will for the most part have been put out in the open during the first quarter of 1887. Beside the already thriving 53,000 grafts, there are in the nurseries at Tjijiroean also some 50,000 well-grown graft-plants in various stages of development, which will probably be fit to put out in the open at the end of 1887 and beginning of 1888. For grafts, almost without exception twigs of the richest descendants of the mother-trees Nos. 23 and 38 have been used, which showed at least 11 per cent of quinine in the bark of the 6 to 7 year old plants. These plants are not only richer in alkaloid than their mother trees, but for artificial propagation they have the advantage of not blossoming so early,—a blossoming that causes such disturbance in growth in the case of young trees. The artificial propagation of a rich hybrid of *C. ledgeriana* and *C. succirubra* was continued actively throughout the year under notice, and by this means a large extent of uprooted land at Tjijiroean was planted up, and the area is still being continually extended. Beside the hybrids spoken of in former reports, some graft plants of the hybrid Letter P, analysed in 1885, which must be reckoned as one of the richest in quinine and quickest growing cinchonas, were obtained. Of the five propagating-houses at Tjijiroean one had to be entirely dismantled in 1886 on account of the rotting of the woodwork. In its place a new building was erected, that like the others was partly built of masonry. Much care and expense were spent upon the propagation of *ledgeriana* and *succirubra* seedlings, and the nurseries were con-

tinually undergoing considerable extension. In the first quarter of the year under notice the fields uprooted in 1885 were nearly all replanted with ledgeriana and succirubra, whilst in the last quarter a commencement was made with the replanting of the estates uprooted in 1886, as well as with the planting up of some bits of new land, which was undertaken for the separation of the plantations on the Malabar Mountains. These operations will be continued and as far possible completed during the first quarter of 1887. The graft plantation at Tirtasari also underwent further extension during the second and third quarters of 1886, which was done by the employment of sturdy grafts raised in pots, which suffered little or nothing by the transplanting. The year 1886 was noteworthy from its great production of excellent ledgeriana seed, a result of the long and continuous drought of 1885. The graft-and-stock plantation at Tirtasari especially yielded a superabundance of good ripe seed, a portion of which was planted in the Government gardens, but the greater part was sold by public auction. The yield of seed by the analysed mother-trees was not, when the abundant blossoming of these is taken into consideration, correspondingly large. Especially was this the case with the plants originating from grafts from the mother-tree No. 25, which at the end of 1885 began to blossom so abundantly, that their death was even apprehended, a fear which, thanks to the vigorous repeated stirring of the ground, was baseless; these gave only a very small crop of seed. No other explanation for this phenomenon is to be found, than that in the case of these plants, which, though not entirely isolated, are yet more or less separate, fructification took place with difficulty. In the case of those plantations, however, formed from grafts derived from one and the same mother-tree, legitimate fructification was as good as impossible, but even self-fructification, *i. e.*, illegitimate fructification of the most unfavourable form, could scarcely take place. The large quantity of seed offered for sale during the last quarter of 1886 found buyers, it is true, but in consequence of the great supply as well as through combinations of private planters the result of the sales was very small. Upset prices for grafts and seed were therefore fixed by G. O. of 8th Dec. 1886, No. 1/C. At a sale of ledgeriana grafts held on 30th December, only some fifty found buyers at the upset price fixed by Government of £10 each. The total result of the sales of 1886 was as follows:—

Seed...	£1,385
Grafts	500
Total..			£1,885

As in former years, portions of the seed offered for sale were allowed to germinate on the Government plantations, in order to obviate eventual complaints regarding the non-germination of seed purchased. All the experiments made gave good results, and no complaints were received. Very small quantities of succirubra seed were asked for by foresters, which orders were executed as speedily as possible. Very small quantities also of ledgeriana and succirubra seed were applied for by botanists and representatives of scientific institutions or foreign Governments. In consequence of the mild east monsoon of 1886 the blossoming of ledgeriana and succirubra plants was not abundant, so that the crop of seed from these trees in 1887 does not promise to be great. The question has been raised, whether the influence of the succirubra stem, which is the cause of the formation of by-alkaloids in the bark of the ledgeriana grafted thereon, should also be felt in the plants raised from the seed obtained from the graft-plants at Tirtasari. Experiments to ascertain the truth of this, by means of artificial fructification, all entirely failed, but they will be repeated in the course of 1887.

3. *Cheerung and Uploop.*—At Tirtasari during 1886 some bouws of forest land were cleared intended for the formation of graft plantations. At Tjinjiroean and Tjibeureum also several bouws of forest were felled and cleared, so far as those lots happened to

come within the new roads formed for the completion of those gardens. Some bouws of the gardens mentioned, formerly planted with *G. josephiama*, were not replanted, on account of the difficult nature of the land, so that the actual extension was not of much account. The completion of these gardens has been continued, in proportion as the uprooting of the old inferior cinchonas has progressed, whereby the system of roads is simultaneously extended and improved. The greatest care was bestowed on the upkeep of the plantations. On young fields the ground was at first worked very superficially, only as far as was needful to keep the soil clear from all weeds, which working was repeated when the weeds once more put in an appearance. As the plants developed the soil was dug to a greater depth. In the older fields the making of two feet deep trenches was continued, by which means the whole of the surface soil was worked to that depth. This method of working was not, however, carried out on all the plantations, but more vigorously in the case of ledgeriana plantations, and the good results of such working of the soil have not been backward in showing themselves. In all, a large sum was spent on the upkeep of the gardens and on deep working of the soil, but the expense was abundantly recouped by a correspondingly larger crop, which, as regards the outturn of ledgeriana alone, rose in a single year from 155,287 to 288,764 half-kilograms, without a single plant being uprooted, and which outturn was the result simply of urgently needed thinning out. The results of a thorough working of the soil were most evident in the case of the graft and stock plants at Tirtasari, where from the very beginning a system of high cultivation was carried out, and where gardens of an average age of five years yielded a return of about 1,200 half-kilograms of bark. But even more than can be shown by figures are the good results of a high system of cultivation apparent in the formation of bark by the plants, which results will be seen in future harvests. There was general activity in the formation and conservation of thick plantations. The great attention paid to the upkeep was beneficial to a vigorous growth of the side branches and will cause a speedy formation of a dense plantation. Though the amount of money expended on the upkeep of the plantations is pretty considerable at the beginning, if under "upkeep" is understood simply the freeing of the plantations from weeds, in order to insure for the plants an undisturbed growth, on the other hand that upkeep is of short duration, and is confined to two or at the most three years. The deep digging and trenching then are of actual service only in inducing a vigorous growth, and obtaining as speedily as possible large and regular crops. Beside the thorough working of the soil, the growth was promoted as much as possible also by manuring, but on account of the small quantity of manure available this method of improving the existing plantations could be carried out on only a limited scale. At Nagrak good results were obtained by filling up the trenches with surface soil from the neighboring jungles, but this method also of improving backward plantations could be employed only on a small scale. The most certain and least costly means of improving the top part of the tree is found in a large formation of humus, from fallen leaves, which can only take place undisturbed in dense plantations. Another experiment made at Tjinjiroean is deserving of mention. A succirubra plantation that had remained backward for years, in spite of all attempts at improving the growth, developed vigorously shortly after the surface of the ground was covered with a half foot thick layer of all sorts of rubbish, such as waste alangalang, sawdust, &c. As has been mentioned above, through the continuous keeping clean of the young plantations the branches were able to respond by a vigorous development, but as a consequence of this vigorous growth of the branches these latter entered into competition with the main stem, whence a more or less bushy growth of the plants resulted. By the regular pruning of the trees, it is true, the

evil was remedied, but the disturbance in the flow of sap caused by this operation is always an evidence that the plants are temporarily hindered in their growth. The dispute as to the utility and desirability or otherwise of pruning the cinchona trees, by which is understood the regular removal of the lower branches, is carried on year by year, but the question is still unsettled. Although we have ranged ourselves on the side of those who assert that as few hindrances as possible should be placed in the way of the uninterrupted growth of the trees, on the other hand we have not forgotten, that in consequence of the somewhat bushy development of the cinchonas, the product obtained consisted for a large part of branch and twig bark.* In order to bring about an improvement in this state of things, as an experiment a system of pruning was to begin with, adopted, which immediately seemed to yield such good results, that it was speedily more generally practised. It consists in the regular shortening of those portions of the branches which threaten to press down the higher branches and the stem. This pruning did not cause the slightest hindrance to the growth of the plant so far as could be seen, for, although the tree was deprived of one portion of its mass of leaves, immediately another mass of leaves that had been threatened with extinction took over the functions of growth and bark-forming. The lower branches, deprived of a portion of their mass of leaves and so checked in their growth, are quickly borne down by the higher branches, and can then be removed without harm, and harvested as needed. This method of pruning, at first practised on one year old plants, was, after the favorable results were decidedly apparent, also tried on older trees with the same good result, by which means a very considerable quantity of ledgeriana bark was obtained. The measuring of ledgerianas begun in 1879 was continued. The average height of the eight year old plants raised from seed at Tjibeureum was now 4.92 meters with a stem circumference of 0.33 meter. The maximum height was 6.50, the maximum stem circumference 0.46 meter. At Tirtasari the measurements of the seven year old grafts and cuttings respectively gave an average height of 4.76 and 3.71 meters, and an average stem circumference of 0.37 and 0.30 meter, whilst the maxima of height and stem circumference respectively were 6.15 and 4.90, 0.45 and 0.40 meters. Although these figures, especially as regards the measurements taken at Tirtasari, give no averages in connection with the growth of the plants, because the parts of the plantations selected for measurement had, as rule, developed badly, the conclusion is now drawn from comparisons with the measurements of former years that a more regular thinning out of the crowded plantations is desirable, which can also be more easily performed if the trees, by a rational and at the same time general method of pruning, no longer experience the injurious influence of the lopping. The *Helopeltis antonii* continued to show itself during the year under notice on all the establishments except Kawah Tjiwidei, but, thanks to the vigorous pursuit of the insect and the decrease in the number of affected spots, the damage caused was of small account. During the month of June the *helopeltis* made a somewhat sudden and severe attack on old *succirubra* plantations at Rioenggoenoeng, when their catching was impracticable. The plants recovered quickly, however, after they had been forced into vigorous growth by a thorough working of the soil. Caterpillars caused some damage at Nagrak and Lembang, and the western portion of Rioenggoenoeng again suffered much from the larvæ of chafers, which gnawed off the roots of the trees. The damage caused by larvæ, however, is diminishing progressively with the regular closing up of the plantations.

4. *Harvest of Bark.*—The crop of 1886 amounted to 525,698 half kilograms of bark, which were sent to the Netherlands for sale. No bark was taken by

the military medical service. The bark was obtained from the thinning out of close *ledgeriana* and *succirubra* plantations, and also from the digging out of backward and sickly trees, the rooting out of eleven bouws of *C. succirubra*, which had ceased to grow, four bouws of *C. josephiana* and two bouws of *C. calisaya anglica*. The product consisted of:—

Variety of Cinchona.	Amount.		Net Weight in Half Kilos.
	Bales.	Chests.	
<i>C. succirubra</i> ...	596	466	160,830
<i>C. josephiana</i> (<i>C. calisaya schuhkraft</i>) ...	219	225	65,141
<i>C. calisaya</i> (<i>C. calisaya javanica</i>) ...	3	1	580
<i>C. calisaya anglica</i> ...	97	31	19,281
<i>C. catoptera</i> ...	3	4	810
<i>C. ledgeriana</i> ...	1,516	—	288,764
<i>C. officinalis</i> ...	263	3	37,109
<i>C. lancifolia</i> ...	26	2	4,183
Total ...	2,723	732	525,698

From these figures it appears that the crop of 1886 exceeded that of the preceding year by 92,980 half kilograms. The increase is chiefly due to the much larger return of *C. ledgeriana*, of which the crop in 1885 consisted of 155,287 half kilograms. The noteworthy increase of bark from the *C. ledgeriana* plantations must be ascribed chiefly to the intensive system of culture generally practised for the last three years. For, although it is true that in 1886 some plantations yielded for the first time a crop of *ledgeriana* bark and added to the increase of the production, in the past year a still greater number of plants had to be spared, because, through an untimely harvesting carried out in 1885 on a large number of trees, which, in consequence of the scraping method practised on them in 1884, had assumed a sickly appearance and threatened to die, large openings had appeared in the plantations. As an instance of the favorable influence of the intensive culture on the production, it may be mentioned that thirty bouws planted with grafts and cuttings at Tirtasari of an average of five years old gave a crop of 36,246 half kilograms of bark, in connection with which it may be stated that in these plantations everything was spared that had a chance of further development, whilst at the same time it is deserving of record, that in the greater part of these thirty bouws the grafts were planted at a distance of 8×8 Rhineland feet and contributed for the first time to the regular harvest about the middle of 1886. The rule adopted, to harvest *seasonably, often and moderately*, was strictly observed, a rule which, as it were, naturally results from the well-known fact, that the growth of the trees is for the most part dependent on their mass of leaves, and from which the greater advantage of the close plantations is evident, since in these a maximum mass of leaves is met with. As has been mentioned under section 3, in the brief description of the method of pruning adopted, a large crop was obtained by the pruning practised at first on the young plants but soon afterwards on the older trees. In the case of those that had grown up shrubby it was first determined which of the many stems should be cultivated as the main stem, and then those portions of the other stems which hindered the growth of the main stem were systematically removed, whilst only then was the wholesale removal of branches proceeded with where they were weighed down by the higher ones, or threatened to be soon weighed down. It was found possible by this means to adhere strictly to the rule to harvest only a little in this manner in order to speedily obtain another crop; but this was not the case with a systematic pruning, as it was formerly carried out, by which the tree in most cases was deprived of a very considerable proportion of its organs. In the method of harvesting now followed no sign of a temporary drooping of the plants, of which so many instances are to be seen as a consequence of the former mode of pruning, are to be observed. As the trees treated in the manner mentioned can continue to develop not only in height, but also in breadth, the question, often so difficult to solve, whether in close plantations one should adopt thinning

* One of the most prominent impressions received in our visit to the Java plantations in 1886 was the tendency to a bushy habit of the Ledgers grafted on *succirubra* stems.—Ed.

out or pruning, naturally also falls to the ground. In the method of harvesting now followed thinning out and pruning go hand in hand. The question, to what height pruning should be carried, remains still to be answered. For the ledgerianas, and among them especially the richest kinds have a steady tendency to more or less shrubby growth, a tendency which is promoted by the acute angle at which the branches are placed. The system of scraping was not practised during the past year. Measurements taken showed, that at the close of one year the undisturbed portion of the tree shaved over half its surface bears a proportion to the shaved portion in 6 to 7 year old plants of 4 to 3, while it is moreover presumed that on the expiry of two years the proportion is yet more unfavourable for the shaved portion. The existing drying ovens at Nagrak and Tjinjroean continued to perform good service, but the drying requires a good deal of manual labour on account of the continual moving of the bark, and the drying did not progress rapidly. On the other establishments the want of drying apparatus was more and more felt, and the still existing want of artificial means of drying is the cause that not nearly the amount of bark was obtained that might and ought to have been expected. At the end of the year a Davidson's T sirocco was on the way. The outturn of the harvest of 1885 was sold publicly at two auctions held in Amsterdam on 15th April and 29th September 1886. The prices obtained at the first sale were considerably higher than those realized at the second. The following prices per half kilogram were obtained:—

	1st Sale.	2nd Sale.
<i>C. succirubra</i> ...	33 at 107c	19 at 139c
<i>C. josephiana</i> (<i>C. calisaya schuhkraft</i>) ...	13 at 154c	12 at 212c
<i>C. calisaya</i> (<i>C. calisaya javanica</i>) ...	30 at 386c	— —
<i>C. calisaya anglica</i> ...	— —	19 at 88c
<i>C. ledgeriana</i> ...	65 at 185c	35 at 106c
<i>C. officinalis</i> ...	103 at 131c	52 at 119c
<i>C. lancifolia</i> ...	20 at 41c	— —

The average price obtained at both sales was f0.7065 per half kilogram and the gross amount realized f395,713.23.

5. *Staff: Expenditure.*—A great loss was sustained in the death of the former Director of the Government cinchona enterprise, J. C. Bernolet Moens, in whom the manager of the culture ever found a willing adviser, whose hints and suggestions have contributed, in a large degree, to the increasing success of the enterprise. The only change in the European staff was caused by the retirement, full of honors, of the manager of pupils, which vacancy was immediately filled up. The fixed native staff consisted at the end of December of 4 carpenters, 1 packinghouse mandoor, also postman, 23 mandoors and 203 boedjongs. The supply of labor was very plentiful during the whole year with the exception of some months during the Sawah operations, and the coffee picking, and the labour forces offering could not always be utilized. The wives and children of the fixed boedjongs were supplied with work as much as possible, and they did good service in the upkeep of the young gardens, the catching of injurious insects, and above all in the harvesting. For this last however labor has generally to be obtained from outside. More and more women from the dessas at not too great a distance from the establishments offered themselves for the harvesting of cinchona bark, and with the exception of the period of the coffee picking the supply of female labor was at all times very large. The expenditure on the service of the enterprise in 1886 consisted of:—

Salaries of the Director, Assistant Director, and other European staff ...	31,300 00
Stationery ...	360 00
Travelling and halting expenses ...	2,364 20
Salaries and daily wages of the native staff, building and repair of propagating houses, purchase and upkeep of tools, and other expenses ...	90,144 20
Total...	124,368 40

being f591.60 less than was estimated in the budget for 1886. According to the annual report for 1885 the total expenses including the transport of the product to Batavia amounted during the year to ... 113,412.39

The total cost of the transport of the product to the Netherland beside that of sale &c. amounted to... .. 38,492.63

Total... 151,905.02

The gross result of the sales held in 1886 at Amsterdam was f305,713.23, so that a clear gain was realized from the harvest of 1885 of f153,808.21, not counting a sum of f16,201.25 which was obtained by the sale of grafts and seed. The financial results of the enterprise for the year 1885 are thus considerably less than those for 1884, a consequence of the unfavourable result of the second Government sale, which was held at a point of time when the prices of cinchona bark had declined to the lowest limit hitherto known. On an average the total estimated expenditure per half kilogram of bark including the transport from Batavia amounted

in the case of the product of 1884 to f0.26⁹³
 " " 1885 to f0.26²¹
 " " 1886 to f0.23⁶⁶

being a saving in 1886 of f0.02⁵⁵ per half kilogram of bark, which saving must be attributed chiefly to the great increase in production. The expense of transport to Europe, of sale &c., of the product of 1885 amounted per half kilogram to f0.08⁹⁰, so that the net gain per half kilogram of bark amounted to

$$f0.70^{65} - (f0.26^{21} + f0.08^{90}), \text{i.e., } f0.35^{55}$$

It was determined by the Minister of the Colonies, in consequence of a request to that effect from persons interested in the cinchona bark trade, and after consultation with the Netherlands Trading Company, that as an experiment a sale of Government bark shall take place eight times a year during the years 1887 and 1888.

6. *Condition and Prospects.*—In the yearly report for 1885 it was demonstrated by means of figures, as has been mentioned above, that as yet no proper connection exists between the cost of production and the prices that are paid for cinchona bark in the European market. On this account a regular decline in the prices of bark was prophesied. The prophecy has been fulfilled all too sadly: the decline in prices in 1886 took place even more rapidly than was anticipated. If the general anticipation, which was based on the absurdly high prices that were paid some years back for cinchona bark, has been thereby swept away, it cannot be ignored that even now there is no connection between the cost of production and the prices obtained at auction. For, although it must not be ignored that the fancy prices of f3.86 f2.12 per half kilogram bark which were obtained for certain lots of pharmaceutical bark at both the sales of 1886 are no criterion on which to base the future, it is yet a fact, that plantations which produced such rich bark also yielded a comparatively small crop, as the bark of the thinner branches and twigs was left behind in the plantations as worthless, and indeed that the product of these gardens, being the dust of the thicker branches and portions of the stems, yielded a direct loss at such prices as f0.13 and f0.12 per half kilogram, since these prices gave no return for the expenses of harvesting, drying, packing, transport, and sale. The dust of the young branches and twigs of the least valuable hybrids of ledgeriana, fetched at the sale of 29th September 1886 a price of f0.05 per half kilogram, by which not only the above-mentioned expenses of harvesting &c. were covered, but whereby all other expenses also, such as those for oversight, erection of buildings, laying out and upkeep of nurseries, laying out and upkeep of plantations, &c., &c., were recouped. And, finally, it appears from figures for production obtained, so far as those for Tritasari are concerned, as well as from the fact that the establishment of 150 bouws at Nagrak which in 1886 yielded 194,500 half kilograms of bark,

an establishment which in point of productiveness must rank far behind the extensive plantations of the Malabar mountains, that by continued intensive culture and rational workings the yearly production of the whole enterprise, which consists of about 1,000 bouws of surface, at the prices which are being now paid, can be increased readily to double, nay even treble the lately obtained crops, and also, what will follow as a consequence, that the cost of production per half kilogram bark will be able to undergo a considerable reduction. If, moreover, in the case of the Government enterprise, no calculation has to be made for interest on money borrowed, no taxes, such as rent, polltax, ground rent, &c., on the other hand it must not be forgotten, that the scattered nature and, in the case of a portion, unfavorable situation of the different establishments necessitates a difficult and rather expensive oversight. From the figures given under sections 4 and 5 it appears conclusively, that the distrust in the cultivation of cinchonas, a distrust that has its origin in the steadily declining price of the produce, is not fully justified, and for our own part we believe, that should the market for cinchona bark show a rise during the next few years, a great decline in the selling price of bark cannot be of long duration.

7. *Information regarding the Varieties of Cinchona Growing in Java.*—The plants raised from the seed obtained in 1880 from Heer Schuhkraft have grown vigorously, and the bark of these trees will be analysed in the course of 1887. The anticipations thereanent, judging by habit and blossom, are on the whole rather small. The *C. trianae* (*C. pitayensis*) planted at various heights from 4,000 to 6,000 feet continue to grow well in every way, and in the course of 1887 the product of these cinchonas will be analysed.

8. *Chemical Analyses.*—The analyses of the crop of 1885 were again made in Europe by Mr. J. C. Bernelt Moens. Since his death these operations have been entrusted to the directors of the establishment for chemical analyses, Moens Van dersteen and Hekmeijer. The results obtained will be found in appendices B and B.1. The analyses connected with the culture continued to be made by the Assistant Director of the Government cinchona enterprise. The analyses, the results of which are given in appendix C, had chiefly for object the discovery of the influence which the succirubra stem exerts on the composition of the bark of the ledgeriana grafted thereon. If from what was said in the yearly report for 1885 the influence was even then not to be disregarded, owing to the presence of more or less cinchonine in the ledgeriana bark. The question, at what distance above the junction of succirubra stem and ledgeriana graft the influence was to be felt, remained still to be answered. The analyses were chiefly performed on barks of the grafts of the well-known rich mother tree No. 23, which tree was also subjected to chemical examination (analysis No. 50). From the analyses performed, it appears that the influence of the succirubra stem makes itself felt most in the lowest portion of the graft, whilst the influence is markedly diminished at $\frac{1}{4}$ meter above the junction and thence up to $\frac{1}{2}$ meter is as good as no longer traceable (comp. analyses No. 20-32). From analyses of the graft of the mother tree No. 89 the bark appeared to contain a pretty considerable amount of cinchonidine (vide analyses No. 16-29), but in the bark of the mother tree also a certain percentage 0.97 per cent, cinchonidine was found (analyses No. 49). The high amount of cinchonidine in the bark of the grafts of the mother tree No. 73 (analyses No. 10-15) remains inexplicable, unless one supposes, that in the bark of this tree, which died in 1882, in spite of the analyses made, whereby no cinchonidine was found, that alkaloid was nevertheless present. The appearance of quinidine in the bark of the grafts of No. 23 (analyses No. 24, 25, 27, 28, and 30) raise the suspicion, that, in place of succirubra types, succirubra hybrids have been used, and the analyses give a new proof of the influence which the under stem exerts on the lowest portions of the cutting grafted on to it. Three of the largest almost seven year old grafts of unanalysed mother trees were, in

conclusion, also subjected to a chemical examination (analyses No. 37-48). In the case of two of the grafts, Letters A and C, it appeared, that only traces of the influence of the succirubra stem were to be discovered at $\frac{1}{4}$ meter above the junction, and at $\frac{1}{2}$ meter the influence was on the whole not longer traceable. From analyses of the graft Letter B it was to be inferred, that the bark of the mother tree itself must have also contained cinchonidine. On the strength of analyses made it may therefore be admitted, that the influence of the succirubra stem on the composition of the bark of the ledgeriana grafted thereon makes itself felt on only the lowest portion of the graft. The so much more vigorous growth which distinguished the grafts from seedlings and cuttings, a vigorous growth which is caused by the strong succirubra under stem, fully justify therefore the continuance of artificial increase, in which the certainty exists that only very rich individuals will be propagated. The fear, that the succirubra stem might exert influence on the composition of the bark of plants raised from the seed of grafts, is not shared by us, chiefly because, as has been seen, the influence is not felt on the higher portions of the stem. The analyses No. 51-54 show that a slight retrogression in the amount of alkaloid is to be observed in bark powder, after it has been exposed for about a year to the influence of light and moisture.

Tirtasari, 10th March 1887.

IPECACUANHA.

ROYAL GARDENS, KEW.

(From the *Bulletin of Miscellaneous Information.*)
(*Cephaelis Ipecacuanha*, Rich.)

The ipecacuanha plant is a half-shrubby perennial not more than 18 inches high, which grows in abundance under the shade of trees in the hot, moist forests of many parts of Brazil. It was cultivated in this country at Edinburgh at least as early as 1832, and flowered at Glasgow in 1843.

The part used in medicine is the dried roots. These are collected more or less all the year round, but less during the rainy season from the difficulty of drying them properly. As stated by Bentley and Trimen (*Medicinal Plants*, vol. ii., 145), "From its stimulant action on the alimentary canal, ipecacuanha has always been in repute as a remedy in chronic dysentery and diarrhoea, and in large doses of 30 grains and upwards it is regarded in India as almost a specific in acute dysentery."

For the last quarter of a century a persistent attempt has been made to introduce the ipecacuanha plant into India. This has met with the most varied fortune, and has at last been crowned with success in the Straits Settlements. It is evident that the problem presented was one of no ordinary difficulty. The ipecacuanha plant presents very little elasticity of constitution, and refuses to flourish, except under a very limited range of physical conditions. The result of experiment has however been to show that it can be propagated by extraordinary facility, whether by ordinary cuttings, by cuttings of the roots, or even by merely pegging a leaf to the earth.

The history of the introduction of the ipecacuanha plant into India, may be commenced with the following extracts from a letter addressed by Dr. Anderson, Superintendent of the Botanical Gardens, Calcutta, to the Under Secretary to the Government of Bengal, dated December 8th, 1868:—

"My attention had been directed to the introduction of the ipecacuanha plant into the Botanical Gardens of Calcutta for some years, but I was unable to procure any plants until April 1866, when one plant was sent to me by the overland route by Dr. Hooker, Director of the Royal Gardens, Kew.* I am indebted to the care bestowed on the plant by Dr. George King, Assistant Surgeon of the Bengal Medical Service, during the voyage to India for its having arrived in Calcutta in good health." * * *

"The plant of ipecacuanha originally introduced into the Botanical Gardens in 1866 is dead; but I now possess nine plants in this garden, which have been artificially propagated from the original one, besides five growing at the cinchona plantations at Darjeeling, to which place I sent one last year. I have thus 14 plants of ipecacuanha."

On March 23rd, 1869, the India Office wrote to Kew requesting that some plants of ipecacuanha may be procured and sent with care to Bombay.

Mr. Joseph Hooker replied, March 19th: "I can place two healthy plants at the disposal of his Excellency the Governor in Council at Bombay, and I hope soon to be able to supply more, but the plant of which but one has been imported alive, is still excessively rare and propagated but slowly."

These two plants were taken out by Mr. Henry Gayen from Southampton on May 10th. The India Office wrote to Kew, December 9th following, stating that "the two plants had perished after their arrival to India."

On March 28th, 1870, Dr. Anderson, who had in the meantime come to England, reported to the India Office: "The plants have thriven at Calcutta and at the lowest levels of the cinchona plantations in Sikkim, and also at Ootacamund. There were 20 plants at Calcutta and Darjeeling last November, all the produce of one plant I received in 1866, and 13 at Ootacamund on the 9th of November last: the produce of three plants obtained by Mr. McIvor from

Kew in 1866-67. These four original plants are the only ones from which cuttings have been made in India, all others having perished on the voyage, or soon after reaching the country."

Acting on instructions from the Government of India, Dr. Anderson stated that he "determined to obtain as many plants of *Cephaelis Ipecacuanha* as possible from botanical and private gardens in Britain and Europe." He continues: "I communicated first with Dr. Balfour, Professor of Botany in the University of Edinburgh, and both he and Mr. McNab, the Curator of the Botanical Gardens there, promised to propagate as many cuttings of ipecacuanha for transmission to India as could be safely taken from the two old plants in the Edinburgh garden. It was when examining these old plants, in order that the best method of propagating might be determined on, that it occurred to Mr. McNab that the numerous root-like tubers might be taken advantage of as a means of rapidly increasing the plants. I saw the first crop of these rhizomes taken off without causing the slightest injury to the plant, and before I left Edinburgh I had the satisfaction of seeing that many of these rhizomes had struck root, and sent up a strong shoot. I heard lately that a considerable number of young plants had been obtained in the Edinburgh Botanical Gardens by means of this root divisor, and that many more would be procured as the roots are reproduced, all of which are intended for India. I may mention that the two old plants of *Cephaelis Ipecacuanha* have been many years in Edinburgh, and they are by far the largest and finest I have seen. In addition to these young plants promised by Dr. Balfour from the Edinburgh Botanical Gardens, I procured from Messrs. Lawson and Sons, of Edinburgh, four large plants of *Cephaelis Ipecacuanha*, which I have left in their charge for propagation. * * * There are seven young plants of *Cephaelis Ipecacuanha* in the Royal Gardens, Kew, and the greater proportion of these and all the cuttings that can be obtained from them will be available for transmission to India, along with the stock I may obtain from other sources. I have also procured another large plant of ipecacuanha in London, from which cuttings will be made, both of the roots and stems, during the remainder of my leave in England. I have heard of a few more large plants in nurseries and private gardens, some of which I shall be able to purchase or obtain in exchange for seeds or plants from the Calcutta Botanic Gardens. Cuttings will be got from these in private gardens and will be rooted and grown in Kew."

"I estimate that I shall be able to take out in January, 1871, not less than 50 plants of the true ipecacuanha, all of which will have been obtained in Europe, principally in exchange for rare plants and seed from the Botanical Gardens, Calcutta."

Dr. Anderson was, unfortunately, never able to carry out his plans. He suffered from severe illness and died before his return to India. He was succeeded in the charge of the Royal Botanic Garden, Calcutta, by Dr. King, the present superintendent, who reported May 14, 1872, to the Government of Bengal:—

"At the beginning of the year (1871) the total stock of ipecacuanha amounted to five plants in Sikkim and seven in this garden. These represented the only surviving offspring of a single plant received from Dr. Hooker in 1866. The five plants in Sikkim were early in the present year submitted by Messrs. Gammie, Biermann, and Jaffrey, of the cinchona plantation, to a most successful experiment in artificial propagation, by which about 400 cuttings were obtained, the greater proportion of which have formed good roots, and are now fine healthy little plants. * * * Five Wardian cases containing about 100 plants were received from Dr. Balfour, of the Royal Botanical Garden, and three cases from Messrs. Lawson. In accordance with the orders of the Government of India, based on the results of the experience of the late Dr. Anderson, these plants were forwarded to Sikkim as soon as practicable after their arrival here. The Calcutta climate having proved totally unsuitable to this plant, all attempts to propagate it in this

* It is impossible now to ascertain the exact history of this plant, but it is believed that it was part of a direct importation from Brazil.

garden have been abandoned, and the cultivation of ipecacuanha has been accepted like that of cinchona as an experiment which must form an outlying charge. The plants are at present under the immediate care of the European gardeners of the cinchona plantation, and propagation is being carried on chiefly in one of the hot, deep valleys on the outer slopes of the Sikkim Himalaya, which open towards the terai. * * * Hence to the plant has not perfected seed in this country, although flowers have frequently been produced. We must therefore look to increase by cuttings and other artificial methods."

From the report of Dr. George Henderson, officiating Superintendent of the Royal Botanical Gardens, Calcutta, to the Government of Bengal, May 31, 1873, it appears that the number of plants from Edinburgh which reached Rungbee alive up to the end of March, 1872, were 258. In 1872 and 1873, 122 other plants were received, making a total of 380. Besides these, Dr. Anderson took out to India in December, 1873, 123 plants from Kew and Calcutta. In the summer of 1871 he reported: "We partially stripped the plants of their roots, which we cut into very small pieces and treated as ordinary cuttings. By this method our stock of plants and cuttings was increased to about 300 by the end of August, 1871." By a continuation of the method the total number of plants on the 1st of January 1873 was 3,066, and on March 31, 6,719 in Sikkim and 500 in Calcutta.

On April 28th, 1874, Dr. King reported that this amount had increased to 63,423. He states: "The cultivation has been practically confined to Sikkim, where it has been conducted chiefly by Mr. Jaffrey of the cinchona establishment, to whom is largely due the credit of its success. * * * Until the mode of propagating this plant by root and leaf cuttings was discovered progress was extremely slow. Since this discovery, it has been proportionately rapid. * * * Mr. Gammie, the resident manager of the cinchona plantation, and I quite agree that the ipecacuanha cannot be successfully cultivated in Sikkim except in shady places. In open spots where it gets the full sun, it soon becomes sickly. It is essentially a tropical plant and evidently prefers moist, shady spots, where there is much vegetable mould in the soil, and an equable steamy atmosphere. * * * A few plants had been sent during the year to the Khasi Hills and 100 are about to be despatched to the Madras Government for trial in the garden at Barliar, a low-lying, moist spot in one of the valleys of the Nilgiris."

June 4, 1875, Dr. King reports: "The propagation of the plant by root-cuttings is now thoroughly understood, and there are in the hot-beds, under Mr. Jaffrey's care, at Rungbee, more than 10,000 young plants, while two years ago there were less than 7,000."

On June 7th, 1876, Dr. King further reported to the Government of Bengal: "During the year I supplied a quantity of the drug itself (the dried root) to the Surgeon-General for trial in hospital practice. This was carefully administered in cases of dysentery by Dr. Crombie, late officiating physician to the Medical College Hospital, and was pronounced by him to be quite as efficient as the best South American drug." On July 10th, 1878: "A number of plants have been sent to the Botanical Garden at Singapore, which enjoys a climate that ought to suit ipecacuanha perfectly. * * * We have been perfectly successful in propagating the plant from root-cuttings and seed, and it grows luxuriantly under cover. But out of doors the low night temperature of the cold weather proves too severe for it. During the year 26 pounds of the dried root, taken from plants grown in frames, under Mr. Jaffrey's care at Rungbee, were sent to the medical depot for use, previous trials having established the excellence of the Sikkim-grown drug." Again, July 10th, 1879: "I have been obliged to give up all hope of the profitable cultivation of the drug in Northern India, the climate being unsuitable."

Here its official history in this part of India closes. But the following extract from a letter addressed to Kew by Mr. Gammie, the resident manager of the Government Cinchona Plantations at Darjeeling, N

vember 11th, 1886, illustrates in a striking way the varied fortune which attends the attempt to introduce a plant to new physical conditions in a part of the world distant from its original home, and the impossibility of absolutely forecasting the event of the experiment even under the most discouraging circumstances:—

"I do not think I ever told you the final results from our ipecacuanha growing experiments, but do so now.

Our original stock of plants came from Kew and Edinburgh; the great majority from Edinburgh. The few plants from Kew differed a good deal in appearance from the Edinburgh lot, which again differed greatly from each other. All the Kew plants were of one sort, which we named from the start the Kew variety. It was rougher in the leaf than the Edinburgh sorts, and not so strong growing while under glass.

After we had satisfied ourselves that we could make nothing of ipecacuanha from a commercial point of view, we put all the plants out in the open, under shade, and let them take their chance. By this time we had all the sorts mixed up together, and as we had, originally at least, ten Edinburgh plants for each one of the Kew sort, and the Edinburgh lot had, besides, been much the stronger growers under glass, the Kew plants formed less than five per cent. of the whole. But very soon the Edinburgh sorts began to disappear, until, in the course of a year or two, there was not a single plant of one of the Edinburgh varieties alive, whilst almost every plant of the Kew variety lived. Of it, at the present moment, we have a good stock, and in one place at 1,400 feet elevation, under the shade of living trees, we have plants which were put out many years ago in the most perfect health, but, unfortunately, their growth has been so slow as to render the prospect of any profitable return from them almost hopeless. Still it strikes me that in places geographically better situated for ipecacuanha growing than Sikkim, that this particular variety may succeed although other sorts may have failed. Probably our ipecacuanha experiments may prove another instance of the folly of giving up the cultivation of new crops as hopeless until the most exhaustive experiments have been carried out. It may be that there are even hardier varieties of ipecacuanha than the 'Kew variety' to be found."

Dr. King's prediction in 1878, that the climate of Singapore would be found well adapted to ipecacuanha, has been abundantly verified, as will be seen from Mr. Cantley's report on the Forest Department of the Straits Settlement for 1886, dated July 4, 1887, p. 20:—

"Ipecacuanha (*Cephaelis Ipecacuanha*), a native of Brazil, and a plant which has been found generally very difficult to cultivate, seems to grow in the Straits with all the luxuriance of its native country when a proper situation is hit upon. It enjoys a very moist, still atmosphere, and somewhat dense shade. In the Straits it forms a compact little bush of about 18 inches in height and is very ornamental when well in flower. I lately visited a plantation of the plant in Johore, and saw thousands of plants in excellent health. They were protected from the sun by palm leaves laid side by side on artificial supports about 6 feet in height; hedges of the same material were put down a few yards apart. Soil, chocolate colour, rich in vegetable matter, wood ashes, &c."

There can be little doubt that Johore was the source of the consignment of ipecacuanha which found its way into the London market at the latter end of 1887. This was the first commercial sample of the drug produced in the old world. It was at first supposed to be of Indian origin, and a report upon its examination is given by Mr. Francis Rawson in the Journal of the Pharmaceutical Society for November 12th, 1887, p. 400. He found 1.7 per cent. of emetine in the root, the average strength of the Brazilian drug being 1.66 per cent. He concludes, therefore, that "the Indian [so-called] cultivated ipecacuanha is quite equal to the average Brazilian root."

Nothing is known of the history of the plant grown in the Johore plantation. It is however probable that they were derived from Sikkim, though four plants were sent from Kew to Singapore in 1875.

TRINIDAD COFFEE.

The staple industries of Trinidad are sugar and cacao. The annual export of these two products are sugar, 700,000*l.*; cacao, 400,000*l.* Hitherto the cultivation of coffee has not assumed large proportions. Efforts were made by Mr. Prestoe in the years 1875-8 to draw attention to the desirability of cultivating coffee in Trinidad, and plants of Arabian and Liberian coffee were experimentally grown in the Botanic Gardens and distributed amongst cultivators. "Notes on Coffee Cultivation in Trinidad," were published in the "Trinidad Royal Gazette" of the 29th May and 28th August 1878. In these notes it was stated that "the success which has attended a further extension of coffee planting in the Botanic Gardens is an important evidence of the reward that awaits extensive and high-class coffee cultivation in this island." He further stated that "no more favourable conditions for coffee planting could be desired than exists in the valleys of the northern portion of the island, east of the Maraval Valley. In the upper part of St. Ann's Valley there are extensive plots of coffee trees, which for vigour and fruitfulness are simply perfect." Owing probably to recurring periods of drought and to the absence of suitable shade trees, coffee cultivation has not prospered in the lowlands of Trinidad. In other localities, and especially at a higher elevation, complete success would, no doubt, be attained.

In the report on the samples of Trinidad coffee contributed to the late Colonial and Indian Exhibition, it is stated that "they were of a kind which would be very useful if picked with greater care, and quite free from black, broken, and defective beans. They were worth in their present state 53*s.* to 55*s.* per cwt, but might easily be made to realise 5*s.* to 6*s.* more by careful picking and preparation It is doubtful if the Trinidad planters know how to remove the pulp quickly and well after picking, and if they clean their parchment well."

Mr. J. H. Hart, the recently appointed Superintendent of the Botanic Gardens at Trinidad has turned his attention to the possibility of establishing a coffee industry in the island. In a letter addressed to Kew, dated 3rd March 1888, he mentions: "I send you three samples of coffee grown here called respectively Oreole, Hybrid Mocha, and Mocha coffee. I am very desirous of obtaining the market value of these samples, as I believe with proper appliances the coffee grown here could be increased in market value at least 25 per cent. The samples have been cleaned and prepared by fermentation."

In reply to this request the following letter with enclosures was addressed to the Colonial Office:—

Royal Gardens, Kew, April 11, 1888.

Sir,—I am desired by Mr. Thiselton Dyer to inform you that he lately received from the superintendent of the Botanic Gardens, Trinidad, samples of coffee which had been prepared by him experimentally for the purpose of testing the merits of Trinidad coffee.

2. It appears that coffee cultivation at Trinidad has not so far proved a successful industry. The planters who have hitherto tried the cultivation have not been able to cure the produce in such a manner as to obtain remunerative prices.

3. Mr. Hart who takes an intelligent interest in local industries has very properly sought to improve the quality of Trinidad coffee by curing it according to the method so well pursued in regard to the Blue Mountain coffee of Jamaica.

4. The result of Mr. Hart's experiment according to the reports of the brokers enclosed herewith has improved the value of Trinidad coffee by about 25 per cent.

5. Mr. Thiselton Dyer is of opinion that the report of the brokers, as also the letter of Messrs. Shand and Haldane, who prove of interest to Sir William Robinson, to whom they might be communicated for the purpose of drawing attention to coffee growing as a possible means of extending the industries of the colony.—I have, &c.

(Signed) D. MORRIS.

Edward Wingfield, Esq., Colonial Office.

[Enclosures.]

MESSRS. SHAND AND HALDANE TO ROYAL GARDENS, KEW.

24, Rood Lane, E. O., April 7, 1888.

Sir,—We received your favour of 22nd ultimo, and we now have pleasure in enclosing report and valuation made by Messrs. Wilson, Smithett & Co., 41 Mincing Lane, of the samples of Trinidad coffee sent by you to us. A few words as to the system of coffee preparation generally adopted in Ceylon upon the estates may perhaps be of interest.

The coffee cherries are allowed to get fully ripe upon the trees, and care is taken in picking to avoid green and partially ripe cherries. The cherries are passed through machinery generally as soon as they are brought into the measuring loft from the field, though some planters prefer keeping them for a night in the loft before pulping, and believe thereby a better colour is obtained for the bean when it reaches market, though the parchment skin may not look so clean. In the operation of pulping the beans are squeezed out of the outer skin commonly called the pulp by passage through discs or cylinders and fall into cisterns, from which the water that carries them in is drained off, and they are then heaped up and left to ferment until such time as the mucilage with which the bean is covered can be washed off: a period varying according to temperature from 24 to 48 hours. When the coffee, now termed the parchment, is ready to wash, water is run into the cisterns, and it is kept moving with batons until all the glutinous matter is removed; it is then put on mats or an asphaltic or cement drying ground and left in the sun to dry, and after two or three days' exposure, it is ready to be sent to the mills in Colombo in bags.

A few estates in Ceylon, but very few if any now, prepare their coffee for market by peeling and sizing upon the estates, but the strong sun and heavy machinery required enable these operations to be carried out better in Colombo. The planter has to be careful to pick ripe berries, and ripe berries only, to see that his cylinders or discs are so set that the beans do not get pinched or bruised in passing through them and that the skin is separated from the parchment, not to allow his parchment to ferment too long as though thereby the outer or parchment skin may become whiter and better bleached the bean loses the colour which the trade likes. The various operations of peeling, garbling, and sizing to be properly done require heavy machinery and ample room.

Full particulars as to coffee preparation upon plantations will be found in *Sub-tropical Cultivations* by R. O. Haldane, Blackwood, 1886.—We remain, &c.,

(Signed) SHAND, HALDANE & CO.

D. Morris, Esq.

41, Mincing Lane, E. O., March 27, 1888.

Dear Sirs,—We have examined the samples of Trinidad coffee described as under experimental cultivation at Trinidad and report as follows:—

Hybrid Mocha, of good liquor and flavour, the shape of the berry, approximating to long-berry Mocha - - - 85*s.* per cwt.

Mocha, of indifferent liquor, but fair flavour, very small berry, similar to small East India - - - 72*s.* „

Creole, fair liquor, ordinary flavour, similar to Central American - - - 60*s.* „

All the samples roast evenly, showing that the berry is well prepared and ripened.—Yours faithfully,

(Signed) WILSON, SMITHETT & CO.

Messrs. Shand, Haldane & Co

ROYAL GARDENS, KEW, TO COLONIAL OFFICE.

Royal Garden, Kew, April 24, 1888.

Sir,—In continuation of my letter of the 11th instant, I am desired by Mr. Thiselton Dyer to forward to you, for the information of the Government of Trinidad, the enclosed copy of a letter received from Messrs. Wilson and Part, of Mincing Lane, on the subject of cleaning "parchment coffee."

2. It would appear from this letter that an entirely new aspect has been given to the preparation of coffee for the English market by the establishment in London of a factory to clean parchment coffee in a cheap and expeditious manner.

3. It is proposed to treat this subject as regards its bearing upon West Indian coffee in the *Kew Bulletin* for the month of May next. Owing to the falling-off of coffee production in the East Indies to the extent, it is said, of a million and a quarter cwt. annually, coffee cultivation in the West Indies should be largely augmented. The difficulties hitherto encountered by small settlers in the preparation of coffee are likely to be entirely overcome by the cleaning of parchment coffee in London, and this fact, in the opinion of Mr. Thistelton Dyer, cannot be too widely known in every West Indian Island.—I am, &c.,

(Signed) D. MORRIS.

Edward Wingfield, Esq., Colonial Office, S. W.

[Enclosure.]

MESSRS LEWIS AND PEAT TO ROYAL GARDENS, KEW,
6, Mincing Lane, E. C., April 17, 1888.

Sir.—In reply to your favour of the 16th instant we beg to inform you that the system of importing coffee in the parchment is largely on the increase, and some most satisfactory results have been attained.

We have recently sold large parcels from America which were "milled" here, and against 70s. per cwt. obtained last year for the same coffee cleaned on the plantation we obtained 86s. per cwt., a though prices all round were lower. Experience shows that the husk or parchment protects the bean from atmospheric influences which affect the colour, and in every instance where trials have been made the result has been in favour of cleaning here. The process is quite simple and the cost is 2s. 6d. per cwt., including everything. The coffee must be pulped and the cherry got rid of on the plantation, but the most important matter is the drying. It is absolutely necessary that the parchment must be perfectly dried and kept from moisture afterwards, insufficient drying is most damaging to after results, and must have the greatest care.

There is no advantage in selling the coffee in parchment as much better prices are obtained by cleaning it here. The grower is more than compensated for extra freight paid, loss in weight, &c., by the extra good out-turn of his coffee if properly cleaned here. Any further information we can furnish we shall be most happy to give you. We enclose a sample of parchment which is worth 35s. per cwt. in parchment, and when cleaned 80s. per cwt. The probable loss in weight is about 15 or 16 per cent. There would always be a market for coffee cleaned here, and as much as the West Indian Islands could produce would easily find a market.—We remain, &c.,
D. Morris, Esq. (Signed) LEWIS & PEAT.

PATCHOULI.

(*Pogostemon Patchouli*, var. *suavis*.)

In the *Kew Bulletin*, No. 15, for March, 1888, page 71, an account was given of the patchouli plant used in perfumery. To this account was added some interesting notes respecting patchouli cultivated at Penang, under the charge of Mr. C. Curtis, Assistant Superintendent in the Forest Department. We are now enabled to supplement these notes by the interesting information contained in the following letter, recently received from Mr. Curtis:—

Penang, February 16, 1888.

Sir.—I beg to thank you for the determinations of Penang plants (1,140-1,201), and also for your kind letter of 16th December. Referring to your remarks on patchouli, it may interest you to know the result of an experiment in cultivating and harvesting one-twentieth of an acre of patchouli in the Experimental Nursery, Penang. Cuttings were put in in January, and the last week in February one-twentieth of an acre was planted three feet apart. The soil of the nursery is poor, and the only manure used was wood-ashes.

On July the 21st the whole was cut and weighed in a green state 449 lb. After being dried in a cool airy shed for 10 days the weight was 106 lb. The leaves were then separated from the stems and each weighed separately, the result being, "good leaf," 69 lb.; refuse, 37 lb. Samples were submitted to two London brokers, both of whom said that the sample was good. One valued it at 8d. to 10d. per lb., and the other at 10d. to 11d.

The same patch was cut again the first week in January of this year, and the yield and results were approximately the same as in July; so that there is no doubt an acre of patchouli will yield considerably over one ton of "good leaf" per annum.

If there is a steady demand, nothing better can be planted by native cultivators, as no special skill is required in its cultivation, or machinery of any kind in its preparation. That the system of cutting the whole patch at once is the best system possible I am by no means sure. I think if only one side of the rows were cut at first, and the remainder after that had commenced to grow again, there would be less exposure of the roots to the sun, and consequently less check to the growth.

The principal point to be observed in drying is to dry slowly and not to the point of crispness, otherwise the leaves get broken to powder and are of less value.

I mentioned some time ago, when sending a sample to Kew that the leaves of the *Urena lobata* are used for adulteration.

Can you inform me whether patchouli is used for any other purpose than for perfumery?—I remain, &c.,
D. Morris, Esq. (Signed) C. CURTIS.

COCHIN CHINA VINE.

(*Vitis Martini*, Planch.)

An apparently new species of vine has been received at Kew from the Botanic Gardens, Hongkong. It was sent by Mr. Ford as *Vitis Martini*, Planch. From botanical specimens also contributed by Mr. Ford to the Kew Herbarium, Professor Oliver has identified the plant as *Vitis (Ampelocissus) Martini* of Planchon, but he is doubtful whether it is specifically distinct from *Vitis barbata*, Wall, of Bengal and Burma. As plants of this vine have been distributed from Kew to correspondents in the colonies, it is desirable to place on record all the available information respecting it. In the report of the Superintendent of the Botanical and Afforestation Department, Hongkong, for the year 1885, the following interesting account is given of the Cochin China vine:—

"Another plant of considerable interest is a new tuberous-rooted vine, *Vitis Martini*, Planch., from Cochin China. It fruited this year in Hongkong for the first time. The seeds were procured from the Botanic Gardens, Saigon, in 1883. The seedlings were planted out the same summer and made several shoots, each of which died down in the winter. They began to make fresh shoots about the middle of April, 1884, and grew well during the summer, but showed no inclination to power; and again died down in the winter. Last summer they started vigorously and showed flower about the end of May. Many of the bunches, however, failed to develop fruit, owing, apparently, to imperfect fertilization; but there was a good average crop of bunches on the canes irrespective of the failures. The fruit was ripe in October, many of the bunches weighing a pound each. The berries, when ripe, are jet black, and rather under the average size of ordinary grapes. The seeds are large in proportion to the size of the berry. The flavour is a peculiar blending of sweetness and acidity, very pleasant, but tending, in my case, to leave a curious smarting sensation on the tongue; others might not find this peculiarity at all objectionable. The flavour might be altered, as is well known, by varying the mode of cultivation; but the size of the seeds is likely to prevent the grape becoming popular as a table fruit; it may, however, be very well adapted for a wine producer. A number of seedlings of this vine were distributed amongst residents of the Colony

but I learn that none of these plants have fruited. A few remarks as to the mode of cultivation may therefore be useful. The tubers should be planted at a distance of 12 feet apart in well manured soil, taking care to keep the manure near the surface as the tubers take a horizontal direction, and do not penetrate the soil to any great depth. When the shoots appear in the spring it is well to cut off all the weak ones, leaving only four strong canes; but it will be found that very few bunches will be developed on the lateral shoots, most of the bunches springing directly from the main rods; but in the case of a bunch springing from a lateral branch, the branch should be stopped at the second bud above the bunch. The laterals might be allowed to grow till they are 2 feet long. It will then be seen if they are likely to throw out bunches or not. If not, prune them back as described, and also pinch back all subsequent growth as it appears. It may be found necessary to thin out the leaves to allow the sun to get at the branches, but in doing this, great care should be taken not to break or otherwise injure the leaf directly above the bunch. If this happen to be accidentally removed, the bunch below it will ripen immaturity and soon shrivel up. It is an advantage to thin out the bunches, leaving a space of 15 or 18 inch between them. It is also advantageous to thin the berries, leaving hardly one half of the original quantity on each bunch; but I am afraid this process would prove impracticable if the vine were extensively grown, owing to the labour it would entail. After the fruit is gathered the vines it require no further attention till spring. By way of experiment one lot of plants were allowed to grow at will. Some of them threw up as many as a dozen suckers and produced laterals in profusion, but they all failed to flower. Another lot was transplanted into well-manured ground just as the crowns began to push in the spring; they, too, failed to flower and presented rather a sickly appearance during the summer.

The 'Horticultural Press' has already suggested that this vine should receive the attention of vine growers in the wine-producing countries of Europe where the phylloxera has denuded the vineyards of the old class of vines. There being no phylloxera in Hongkong, I cannot say whether the dreaded insect would spare this vine, but in view of the wonderful improvements that have been and can be brought about by skilful and persistent cultivation, it is not unreasonable to surmise that this new vine may ultimately become a wine producer. It is easily cultivated, and seems to be well adapted for a tropical climate, or a climate in which the resting season is comparatively cold and the growing season hot."

MADAGASCAR EBONY.

The information contained in the following correspondence respecting ebony and sandal wood at Madagascar will be read with considerable interest. In the absence of botanical specimens of the plants in question, it is impossible to express an opinion as to their identification. The flora of the lowlands of Madagascar is very imperfectly known at present, and it is most desirable to draw the attention of Consuls and all who may have the opportunity to the importance of collecting and forwarding specimens of the plants known to yield ebony and sandal wood to Kew for the purpose of identification. Mr. J. G. Baker, Principal Assistant in the Kew Herbarium, has for many years devoted attention to the flora of the mountainous parts of Madagascar, and has described the plants collected for the most part by the Rev. R. Baron, in recent numbers of the *Journal of the Linnean Society*. The work now necessary is to explore the lowlands of Madagascar

and make collections of plants, which it is confidently anticipated will prove of the greatest possible interest.

It is well known that the heart wood of many different species of *Diospyros* constitute the ebony of commerce. There are 10 endemic species of *Diospyros* at Madagascar, but it is impossible to identify any one of these as yielding commercial ebony. Mr. Godfrey T. Saunders, who has an extensive knowledge of the hard woods of commerce, states that, "at present the only Madagascar wood known in this country is ebony, and in this, my house is the largest operator. Hitherto we are depended for supplies on the French and German houses. We understand the wood at present is smuggled out of the country. A properly organised management should put a stop to this state of things and enable us to get the wood under the best possible conditions as to proper felling and shipment. There is a large and increasing consumption for this wood."

True sandal-wood is yielded by different species of *Santalum*. Indian sandal-wood is derived from *Santalum album*, L., and West Australian sandal-wood from *Pusanus spicatus*, R. Br. A "Contribution to the Knowledge of Sandal-woods" is given by Andreas Petersen in *Journal, Pharmaceutical Society*, vol. xvi. [3], p. 757.

According to Mr. Baker there is no species of *Santalum* known from Madagascar, and *Pterocarpus* which yields red sandal-wood or Saunder's wood is doubtfully native. In the northern parts of Madagascar, according to M. Cachin, a wood with properties similar to sandal-wood is known under the Sakalava name of Hasoranto, while another wood called Laza smells of aniseed. The latter is probably *Croton amissatum*, Baill. in *Adansonia*, Vol. I., p. 159.

In the Kew Museums there is a specimen of wood labelled "*Santal vert* (*Oroton* sp.), exported from Madagascar and Zanzibar into India, where it is said to be used for burning the bodies of Hindoos. Also a specimen from Mr. J. Heathcote, from Professor MacOwan, received February 6, 1886, labelled "Wood like sandal-wood (*Croton* sp.). It is ground and mixed with water, and used by the natives at Inhambane to anoint themselves."

These latter are not properly sandal-woods. They are mentioned as indicating the possible source of what is called sandal-wood at Madagascar. The correspondence is as follows:—

THE FOREIGN OFFICE TO ROYAL GARDENS, KEW.
Foreign Office, March 19, 1888.

Sir,—In reply to your letter of the 12th inst and I am directed by the Marquess of Salisbury to transmit to you here-with an extract from Vice-Consul Knott's report, relating to the ebony trade on the West Coast of Madagascar.

I am to add that Lord Salisbury has no objection to this extract being published in the *Kew Bulletin* and communicated to Mr. Ransome.—I am, &c.,
D. Morris, Esq. (Signed) T. V. LISTER.

[Enclosure.]

British Vice-Consulate, M'anga,
December 12th, 1887.

Sir,—I HAVE the honour to inform you that, up to the present time, no person having been granted a concession to export ebony from the West Coast, all that is shipped is smuggled out of the country.

In the Sakalava country, south of Manitirano, there are large tracts of forest in which the ebony tree is found, and cut by the Sakalava and brought to Manitirano, and there sold to the Indian and Arab traders in exchange for cloth for merely nominal amounts. Some comes north to Soalala in Baly Bay and there exchanged.

* Mr. Lewis Ransome (of the firm of A. Ransome & Co., Chelsea) has been preparing himself at Kew for a botanical survey of the English commission in the district of Maroantsetra, North-east Coast of Madagascar. [This is the first we have heard of such a concession. What have our friends the French to say to it?—Ed.]

The Indian and Arab traders send it to Mozambique and Nossi Be, and, if large and sound wood, it fetches from 40 to 55 dollars a ton.

I heard also when I was in Majunba Bay that ebony grows on the banks of Nemsida Bay and is sent to Nossi Be, that there were large trees there, but I was unable to go as small-pox was raging in all the principal towns.

I myself found ebony close to Ampasimerima, about 20 miles N. E. of Mojanga, marked in Oliver's map incorrectly Pajong; it was here both small in size and quantity; from there to Ambolivozy, a village on the southern entrance of Mojamba Bay, I did not discover any, but it seemed to recommence there in small quantities, and extended along the southern bank of the bay. At Ampasamalavatra, on the bay there were large quantities of small wood and a few large trees; and at Androhibe, about 10 miles inland, I saw several fine old trees of ebony. At Amboeliana, not far from there, I cut some samples sandal-wood, and sent the same to London, and informed that its value there is from 25*l.* to 60*l.* a ton.

From Soukala to south of Manitirano (Manitirano excepted) it is said to be unsafe for a white man to go, and impossible for a Hova. And, again, south of Morandava the same thing occurs; but in a few Sakalava villages there are creole traders' agents for McGubbin, of Liverpool.

In my opinion the only way the ebony trade can be worked on this coast is by opening stations on the rivers where the ebony grows, and employing Sakalavas and Makoas at a monthly wage with an English overseer at each station; he, of course, would have to take cotton goods, &c., as the wages are mostly paid in goods, coin being of no value to the Sakalavas. This way would, I think, ensure a regular supply of good wood being obtained, and avoid the cutting of small and useless wood.—I have, &c.

(Signed) STRATTON C. KNOTT,
British Vice-Consul.

J. G. Haggard, Esq.

H. B. M. Consul for Madagascar.

SHANTUNG CABBAGE.

(*Brassica chinensis*, L.)

In a letter dated 21st April, 1887, Mr. George Hughes, late Commissioner of Customs at Chefoo, China, offered the Royal Gardens seeds of a cabbage which has long been in high repute in China, but which appears to be little, if at all known, in this country. Mr. Hughes stated: "I have just received from Chefoo, North China, a small packet of Shantung Cabbage seed, and I should like if possible, to introduce this delicious cabbage into England. It grows in the north of China, is lettuce shaped, and weighs from 5 to 8 lbs. When boiled it is nearly as good, if not quite, as sea kale; eaten raw, in a salad. It is of so delicate a flavour that I know of no vegetable in England to approach it. It is an autumn cabbage, should be planted about 18 inches apart, thrives best with moisture, and in Shantung is well watered every day; there the seed is sown in June. When nearly full grown it should be tied round so as to give it a good white heart. If it can be acclimatized in this country it will be a great addition to our vegetables.

The seeds received at Kew being few in number were carefully cultivated. They were sown in a heated pit on the 3rd May, and in about a fortnight all had germinated. They were pricked off into boxes, and when large enough transferred to pots. They were kept in a cold frame until the beginning of June, when they were planted out in beds of rich soil about 18 inches apart in the rows, and the same distance from row to row. About the middle of July the plants were tied up in the same way as Cos lettuce, and when well filled and blanched were cut for use. They were pronounced to be excellent. The seed ripened only sparingly, probably owing to the dry weather of last summer.

It is possible that this Chinese cabbage may prove a useful addition to English gardens. The kinds most highly esteemed at Peking are those from the neighbourhood of the little town of Ngan-sun. These are said to be reserved for the table of the Emperor. They are eaten either raw in a salad or cooked and seasoned with salt.

Under suitable circumstances the cultivation of this cabbage would doubtless prove as simple and as successful as with the ordinary cabbage. Botanical specimens of Chinese cabbage were received at Kew in 1886 from Mr. F. S. A. Bourne, H. M. Consular Agent at Chungking. Under the native name of Pai-tsai he describes it "when young it is eaten as a cabbage. It is also cultivated for its seed, from which oil is pressed and used for light and cooking."

DIRECTIONS FOR PLANTING (CEYLON) TEA SEED IN NURSERIES.

1. The seed having been already immersed in water for floating off the light seed, it is necessary to keep it wet during transit. 2. It is best to plant the wet seed on arrival at its destination in dry earth in the nursery beds, each seed from 3 to 4 inches apart and from $\frac{3}{4}$ to 1 inch deep *not more*, and leave it to give off to the dry earth its surplus moisture, if any, and thus start its *breathing existence*. (See GRIGOR'S *Arboreticulture*.) 3. After 24 hours in dry weather the beds may then be watered to saturation and covered over lightly for shade with green fern litter. 4. If the earth is now kept simply damp, watering only sufficient to supply the *daily* evaporation, is ample.

Under these conditions, good seed is bound to germinate and (once rain falls), the plants will shoot up vigorously, *i. e.*, better not to force up by excessive watering, the result of which (and too much shade) is spindly and soft-wood plants that won't stand a drought in the open.

These directions, based on my practice during the last 10 years, were submitted to the highest scientific authority for his opinion, and I have been recently favored with the following, his comments thereon:—"Your directions seem to be quite to the point, and I know they are much neglected...You speak strictly accurately when you say *seeds breathe*. During germination they do so with great vigor, and that is why, oxygen being of course essential to the process, you must not bury them too deep in the ground or flood them with water."

W. G. S.

WOOD ASHES.—Wood ashes besides being useful on the farm for soap-making and fertilising purposes, may be used to advantage as a deodorizer. Hog-pens and feeding houses begin to smell bad at this season of the year, but this nuisance can be done away with by scattering a liberal quantity of wood ashes on the floors. Powdered charcoal is better for this purpose than the ashes, but is not usually at hand for use. In building hog-houses a layer of burnt clay or wood ashes one foot in depth should be put in before the floors are laid, and will tend for years after to prevent bad smells and like evils. Such sanitary measures as these are worthy of consideration in improved farming.—*Indian Agriculturist*.

Correspondence.

To the Editor.

EXTENSIVE CULTURE OF HIGH QUALITY CINCHONAS IN JAVA.

Amsterdam, 29th April 1888.

DEAR MR. EDITOR,—Accept my apologies for not sending you the promised letter earlier. The fact is I was under the impression that I had taken the necessary papers about cinchona cultivation in Java with me on board, but when looking for them, I found they had been packed in boxes which I only received a few days ago.

Now, in referring to those papers, I find that your estimate of about 60 cinchona plantations in Java is about right, but you are wrong when you think they have on an average 200 acres of cinchona. You can depend on it that the average is not less than 250 bouws, or about 440 acres, most all planted with ledgerianas and hybrids. I do not know one estate of less than 350 acres; but more than 35 of over 500 acres. Besides these the Government plantations.

These estates are now for more than half the extent, all grafted with such ledgerianas and hybrids all over 10 per cent sulphate of quinine, and a large acreage over 13 per cent. There are even gardens of over 18 per cent.

The age of these varies now from 3 to 1 year old. 1½ year old grafts of 10 per cent. has showed by analysis over 6 per cent. sulphate of quinine.

What has not been grafted as yet are trees from 7, 6, and 5 years old, of which the bark contains more than 3 per cent; in many cases over 5 per cent. You have only to look over the market reports of cinchona bark sales in Amsterdam, to see that I am right. The total acreage of cinchona ledgeriana and hybrids is thus 60 by 225 bouws or 15,500 bouws of 25,500 acres. The cinchona succirubra I do not take into consideration for the present. These 15,500 bouws at 2,000 trees per bouw gives 31 million trees.

In 6 years' time these trees will yield stem and root bark of over 10 per cent. You will rather be astonished at my adding root bark, but this is a fact. I need not enlighten you though on this subject. I do not wish to say what amount in lb. of bark Java will export before and after the next 5 years, so much depends on what each individual owner of each plantation will do. It is easy, however, to calculate what they can do.

Now taking the annual consumption of sulphate of quinine at 400,000 lb. and the increase for the next 5 years at 200,000 lb., or 50 per cent (which, I sincerely hope, will be the case, but do not expect), it would give a result of 600,000 lb. of sulphate, or at 10 per cent barks, a production of only 6,000,000 lb. of bark to supply and meet the world's consumption.

This Java alone will be able to do, and will do if necessary. And as there is more cinchona in the world than in Java alone, as all cinchona growers have learned to their cost, but mostly of inferior quality, it will consequently force the price of the unit down to a limit, which will only leave a profit to rich barks.

At the same time, before the next 5 years, all cinchona growers will still be able to command a profitable price for barks of 3 per cent. and even 2 per cent if they do not swamp the market.

At present Ceylon planters can still do us much harm, but not without spoiling their own market; but if they restrict their export to say 8 million

lb. a year for the next years,* all concerned will benefit by it.

I was very sorry to hear from you that one of our planters, who visited you a short time ago, should have given you a wrong impression about the extent of Java cinchona cultivation, the more so as it appears this has influenced your large exports. Should any of your planters wish to see for himself, I recommend him to visit the following plantations:—Pasir Telagawarna, Goenoeng Melattie, Soeka Negara, Tjitiis, Tjiseurek, Tjipantjoe, Soekawarnak, Lodaja, Kartamanak; and I am convinced he will draw the same conclusions as I do.

The average price of reaping, drying, packing, and railway freight to Tandjong Priok (the harbour), that is to say f. o. b., cost us in Java, about 9 cents per kilo, or a little under 1d a lb.

Freight to England or Holland, expenses on sale &c., will, I dare say, be about the same to you as to us. Hoping the contents of this letter may be of some interest to your planting community,—I remain, dear sir, yours truly,

J. L. VAN SON.

I enclose my card as introduction for any planter who might intend to visit Java.

PAPAW MILK OR JUICE.

DEAR SIR,—Referring to the inquiry made by a planter as to the manner in which the above is extracted or gathered, I may state that the method adopted by some natives (who said they came at the instance of Messrs. Bosanquet & Co.) was by simply slitting the fruits, when the milk began pouring out in small quantities, the same being gathered in small vessels made of some bark. The quantity gathered from each tree appeared to me to be very little, and hardly worth the trouble; but the natives seemed quite satisfied, and were willing to pay for all they received at so much per ree.—Yours truly,

CITIZEN.

TEA IN TRAVANCORE.

Travancore, 17th May 1888.

SIR,—In the *T. A.* for April I notice a letter from Travancore signed "M." having reference to Mr. Cox's report which appeared in the *T. A.* for Feb. I read Mr. Cox's report with great interest, and for his efforts to raise the cloud of depression which has been hanging over the Travancore planter for some time past he deserves the warmest praise.

Your correspondent (I was going to say pessimist) says "talking about tea fetching 2s and 3s the pound carries no conviction." If these exceptionally fine prices carry no conviction, what does? As regards his estimate and his opinion of the capabilities of the soil, these must be based on his own experience.—Yours, &c., OLD DICK.

THE FUEL QUESTION AND LACK OF
TIMBER FOR BUILDING PURPOSES:
THE LARTIGUE RAILWAY.

May 18th, 1888.

DEAR SIR,—I have read with much interest the various articles on the fuel question. I recommended in a previous letter the opening of the Laggala tavalam road as a cart road, the extension of the Rattota-Oodalamana road, the upkeep of the P. W. D. road from Nawula to Elaheera: I hear now that it has been decided to keep the latter road open and to extend southward towards Gallegama. These 3 routes would serve to bring up any quantity of fuel and timber for building purposes, and the

* Sic.—Ed.

trace of either would suit a light tramway or a railway on the Lartigue system should that system be finally approved of by competent engineering authorities as a mountain *climber*. The want of good timber for building purposes is even now beginning to be felt; and ere long, unless some such outlets as above are made, the want will become really urgent. I would suggest the establishment by Government of a sawn timber and fuel dépôt at Matale railway station, from which planters and others could draw supplies; such a dépôt would I am sure prove a source of profit to the Government.

To return to the fuel question, as far as coolies are concerned, the fuel must be in the form of wood, peat or coal: the latter would have to be accompanied by a revolution in the buildings on most estates. Coolies need and will insist on something more than a small fire to cook by; the idea of tea prunings proving a sufficient supply is surely the fruit of some very unobservant nature.

What the coolie requires more especially in such cold districts as Dimbula and Dikoya is a good healthy blaze to crouch over, and dry his cloth and cumbly after a day's work in the driving rain and mist, and if he is denied this supply of heat, which is a necessity to his well-being, he will seek the sylvan slopes of the older districts. From Matale and Tamankaduwa the supplies of timber and fuel must be principally drawn: the supply of either is practically *unlimited*, and given good outlets, either in the form of cart-roads or tramways, whichever prove cheapest in formation and upkeep, we could doubtless provide the necessities of the upcountry districts at reasonable rates.

The case against Government in the matter of grants-in-aid is a good one; and we should allow them no peace until we obtain satisfaction. In Matale East and Laggala the Government have sold to planters alone lands to the value of some R350,000; their return for which is so far something less than 5 per cent in grants-in-aid. The only grants being the bridge over the Rattotaoya and the Laggala road. Were only half of the sum obtained by the sale of Crown lands returned to the district in the shape of the much needed outlets referred to, either as tramway or road, the solution of the fuel question would be not far off. Finally on the subject of the Lartigue or any other system of light railway likely to prove suited to our wants, surely the proposal to lay the railway over *existing* cart-roads is a great mistake: the one great advantage of the Lartigue system seems to me to lie in its capability of penetrating country difficult of access by the ordinary broad cart way. If *Matale* district is to be served, there will be no railway to Cabragala at all; you may give the Matale planter credit for knowing what are his wants. The vote will go *square* for a Rattota and Laggala route.

There was surely something of the facetious in the proposal of your contemporary to connect Madulkele (already only 10 miles from Wattagama by a railway of 25 miles to Matale! Equally amusing is the tirade against the unfortunates of Jaffna, because they expect a railway; but what seems to him quite unpardonable, a broad gauge. In his attempts to throw discredit on the really flourishing settlement of Jaffna (Jaffna of the few roadside caddies), the Ed. "C. T." seems to forget that the caddies of the great Empire lie just over the way.

E. G. R.

SOUTH AUSTRALIAN GARNETS.

Gawler Place, Adelaide, South Australia,

21st May 1888.

DEAR SIR,—I send you an Adelaide paper, in which you will see a small paragraph referring

to some South Australian garnets I sent over to Colombo to get cut, and which, if inserted in your paper, may be of interest to some of your readers. In spite of all that has been said to discourage the enterprise of gem-mining in South Australia, several of the Companies are still going on in the hope of finding real rubies. —I am, yours faithfully, A. M. DRUMMOND.

SOUTH AUSTRALIAN GARNETS.—Messrs. Drummond Brothers, of Adelaide, recently sent to Ceylon to be cut a parcel of stones obtained from the Tug River Gem Mining Syndicate's claim in the MacDonnell Ranges. They have just received from Messrs. Armitage & Co., of Ceylon, the firm to whom the stones were sent, a letter in reference to the matter and two small parcels, one being the Australian stones as cut and the other samples of Ceylon garnets in the rough. Messrs. Armitage write:—"The moment we saw the stones you sent we recognized them as garnets. No mineralogist or lapidary could mistake them for rubies. Their hardness is a sufficient test to show that they do not belong to the corundum. We send herewith six Ceylon stones (uncut garnets), which we value at 16 rupees per lb." Sixteen rupees are equivalent to about 23s of our circulation; and judging by appearances the South Australian garnets are certainly superior to these samples of Ceylon garnets which have been sent out, being clearer and more free from flaws. It seems, therefore, that even as garnets, the local stones have some commercial value. The stones referred to are on view at Drummond Brothers.

SEA SAND FOR USE IN CONCRETE.

May 22nd, 1888.

DEAR SIR,—With reference to your remarks in Saturday's issue *re* the preparing of the sea sand for use in concrete, I am not aware whether Mr. A. W. Burnett did say that sea sand did not require washing; but this I do know, that he was more particular than any engineer I have ever known in the country, with regard to the washing not only of the sand but of gravel and stone, his test was to rub it on his white handkerchief; if it left a stain it had to be rewashed. No better concrete was ever made (of the same proportions) than at Maligakanda; not only that, but the cement was tested daily, and I am sure the record is to be seen, yet. The reservoir failed, not (in my opinion) from bad work, but from faulty design.

Mr. Kyle's shed for the cement was necessary at the Breakwater, but not at Maligakanda, as there was an excellent store on the ground, and being a mile from the sea, makes all the difference, as I have reason to know from experience.—Yours truly,

CONCRETE MAKER.

[Mr. A. W. Burnett *did* say most expressly to one of the conductors of the *Ceylon Observer* that no washing was required to divest sea sand of saline particles. He pooh-poohed the idea of the salt doing any harm as absurd, and staked his professional reputation on the good quality of the concrete in the flooring. But the Committee, of which Col. Clarke was President, condemned this very concrete as porous, and so admitting water to the imperfect cabook foundations, thus leading to the catastrophe. Mr. Burnett's confidence in the soundness of the laterite foundation and the good quality of the concrete was fully reflected by us in an article in the *Observer*. The greater, therefore, was our disappointment and mortification at the adverse judgment on both points of a highly qualified and impartial Committee. The decisions of that Committee we feel now compelled to accept rather than the individual opinions of the Waterworks Engineer and our present correspondent.—Ed.]

QUAILS ON THE HORTON PLAINS: WHO WILL TRY AND CAPTURE ONE?

DEAR SIR,—I notice your further remarks on the quails, and write to suggest that you may have a friend within easy reach of the Plain, who would try and secure a specimen, as the same birds in all probability would be still in the neighbourhood.

As you feel sure they were quails, it would be very interesting, indeed, to identify the species, particularly as the birds seen would almost certainly have been a brood raised on the Plain; the quail family naturally inhabits plains from sea-level to a medium elevation. In India it has been thought worth recording that two or three species have been found so high as 4,000 or 5,000 feet elevation,* but I can find no mention of any species nesting so high.

As to hawks, they are far less numerous, and eagles too than I can remember them. Everybody possessed of a gun seems anxious to try his luck on any poor bird of this family, which may come within range of it, and the race has suffered accordingly.

The term "bevy of quail" is used by sportsmen in the same way as a "covey of partridges;" the terms not being interchangeable, but I cannot tell you why this distinction is made. Another term is a 'wisp of snipe,' and there are many more of a similar character.

I notice a small mistake or two in my letter, due, I dare say, to careless and hurried writing. *C. chinensis*, and *T. taiqoor* are the quails' names. S. B.

[On a visit to the Museum we saw amongst the quails specimens exactly like those we put up on Horton Plains, and we find that the species is *Coturnix chinensis*, judging by the small size and the very dark colour. As this swamp quail is native in Australia, there seems no reason why it should not exist at 7,000 feet altitude in Ceylon.—Ed.]

TEA-DRYING: DAVIDSON'S SIROCCO.

Sirocco Works, Belfast, May 29th, 1888.

SIR,—We are just in receipt of your issue of 1st May, in which there appears a letter dated 28th April, from Mr. R. Morison, Chairman of the Kalutara Planters' Association, complaining that he had been unable to get certain duplicate castings for "Sirocco" stoves from Messrs. Mackwood & Co., our agents for sale of "Siroccos" and "Sirocco" parts in Ceylon.

Mr. Morison's letter in the first part reads as if no duplicate parts whatever could be got for our "Siroccos" in Colombo on the date of his letter, but our last Stock List, received by the previous mail, detailing the number of duplicate parts with our Colombo Agents at the time, shows a full stock in hands of all the castings usually asked for, viz., those which are in immediate proximity to the fire, and consequently liable to burn away. In Mr. Morison's concluding paragraphs, he, however, states that the castings which he especially referred to were Nos. 850 and 851, but as these castings form the exterior of the stove sections, and are not affected by the fire, they do not wear out, hence he had experienced no previous demand for them for renewal of stoves in use, nor had we been called upon to supply them to repair breakages.

We are always most anxious that users of "Siroccos" should be able to obtain any duplicate

* An elevation of 5,000 feet in Northern India is equivalent to 7,000 in Ceylon.—Ed.

parts they may require with the least possible amount of inconvenience, and had we thought these castings would have been wanted, we certainly would have had them in our Colombo stock, and in future they will be obtainable from our agents, now that we know they may be required occasionally to repair accidental breakages. We had considered, however, that it was almost impossible, owing to their position in the stove sections (and more particularly as these sections are packed in very strong wooden cases), that the castings referred to could have received any greater damage inside the packing-case, than being simply cracked, and their being merely cracked does not render the stove unfit for use in the least degree, so that, had Mr. Morison known, he might have used the stove without any difficulty, unless, perhaps, the castings were absolutely broken in pieces, under which circumstances, the external damage to the packing-case ought to have been such as to justify him in refusing to accept delivery from the carrying company, as it would have indicated such gross maltreatment of the package on their part as to render them accountable for the damage sustained.

We do our very utmost to have our "Siroccos" packed so securely that even if a case were tilted from a railway waggon, so as to fall with a clean drop to the ground, as the writer saw actually occurring in India, there would be a reasonable chance that none of the contents got thereby broken. We may here mention that we lately received a testimony to credit of our packing from an engineer in the Assam province, who informed us that he had on several occasions erected a "Sirocco" complete in four hours from the time the cases were all delivered in the tea-house, and on one occasion had won a bet by doing it in three hours, and he stated that he would not have taken up the bet had he not from his experience been able to rely on the apparatus being most carefully packed.

We take this opportunity of stating that we are always glad to receive from planters, directly or otherwise, information of any difficulties that may arise in their practical experience of erecting or working our "Sirocco" driers, as we recognize that the first important step towards obviating such difficulties is that we obtain an accurate knowledge of their existence.—Yours faithfully,

DAVIDSON & CO.

CEYLON TEA NOT KEEPING: A WARNING FROM A BROTHER PLANTER.

Edinburgh, 2nd June 1888.

DEAR SIR,—I write to warn our Ceylon tea planters of a danger which threatens the good name, and therefore the sale, of Ceylon tea in the British and foreign markets. This danger consists in the fact that many of the teas sent home will not retain the strength and style which they possess when placed on the market, and very soon deteriorate by keeping.

This is no new complaint, for we heard of it in Ceylon some time ago; but it is a complaint which, if not attended to at once, and removed, cannot fail to prove fatal in a degree to the interests of Ceylon tea planters. In Ceylon, I think, we do not quite realize it yet; but at home it is a very startling reality; for one hears it mentioned, not only by large wholesale buyers, but even by private consumers. A wholesale dealer has just told me that lately he bought a large parcel of remarkably good Ceylon tea; tasting it some time afterwards, he could not understand why he had bought it; as it could then be beaten by the same teas that it had for-

merly excelled. Such words as—"Ceylon teas, yes! Liquor very well at first, but won't keep, wouldn't touch them."—one often hears; and if the hearer be a Ceylon man, he thinks them ominous; for, if Ceylon teas once get a bad name it means a long run of low prices, and a hard fight to get a place again. But there is another and indirect way in which this same fault retards the sale of pure Ceylon tea. It is this: A very large quantity of so-called Ceylon tea is sent out in packets to be sold by grocers and co-operative stores; and many of those packets contain a small (?) mixture of Java or Indian tea to *keep up* the Ceylon.

Now, making every allowance for the good intention of those packers, I feel certain that Ceylon planters would very much prefer to send out a tea, able to stand on its own merits and which would not require bolstering. Let me ask you, for the sake of Ceylon, to urge the planters to have this reproach removed without delay. It is surely only a matter of curing attributable to under-fermenting and under-firing. Planters have been blamed by London agents and brokers for over-fermenting and over-firing, and seem now to have gone too much the other way. Let them try to strike the proper medium, remembering that to turn out a raw tea, under-cured and under-fired, is much more injurious in its results than a tea fully cured and rather high fired. The former spoils by keeping, while the latter improves.—Yours faithfully,
D. KERR.

"HINTS ON TEA MANUFACTURE, Oolong Manufacture, Tea Tasting and the Future of Ceylon Tea in respect of Consumption and Prices, being Extracts from Papers Read before the Dimbula and Dikoya Planters' Associations by A. M. Gepp," is the title of a pamphlet, a copy of which has reached us, printed at the "Times" press, containing information useful to planters.

ASHES AND SALT ON POTATOES.—The *American Cultivator* says it is an excellent plan, as soon as Potatoes are well up, to go over the piece and throw a handful of a mixture of salt and ashes on each hill. The preparation is soon washed down into the ground by rains. It repels insects, makes the Potatoes fair and smooth, and helps to draw moisture to the Potato during a dry time.—*Gardeners' Chronicle*.

SUN POWER.—Mr. Preece, in a recent lecture before the Royal Institution of Great Britain, stated that on a fine summer's day, the sun expends an average of 1 horse-power on every 30 square feet of the earth's surface in this latitude, or 1450 horse-power per acre. This great gift of energy is neither utilised nor stored by man at present, though Nature presents us with some of it in waterfalls and flowing streams. The sun itself has been more generous. Ages upon ages ago it shone with resplendent glory on a grand luxuriant flora of a uniform but flowerless character in a climate warm and damp. England formed part of a tropical jungle or swamp, where grasses, mosses, ferns, and sedges, Coniferæ, Araucariæ, Equisetacæ, Sizziliaræ grew and flourished, perished and fell *in situ*, to be covered up by the following geological formations and compressed into those grand seams of coal that form now the principal source of England's greatness and wealth.—*Gardeners' Chronicle*.

A NOVEL SYSTEM OF SILAGE.—Mr. J. L. Thompson, principal of the Dookie Agricultural College, has in a report to the Department of Agriculture communicated the result of an experimental conversion of green maize into fodder by means of a novel system of silage. The method adopted was that used in Great Britain for the preservation of potatoes. Last January a plough and earth

scoop were employed to excavate a trench 30 feet in length, 10 feet wide and 2½ feet deep, the depth being increased to 5 feet by banking up the loose earth at the sides. The maize was then cut close to the ground, and packed lengthwise until the pit was brimful, after which the scoop was used to close the silo with earth. The usual covering of straw was dispensed with, but care was taken to bring the earth roofing to a point, so as to throw off rain, and to run a plough furrow round the pit, as a drain for surface water. After a lapse of more than three months the silo was opened by means of the earth scoop, and the maize found to be in excellent preservation. The cows, says Mr. Thompson, eat it with the utmost avidity, and there has been a notable improvement in the quality of their milk. In his opinion silage greatly improves the nutritive qualities of the maize, as the process of fermentation converts the natural starch into sugar, and makes its digestion and assimilation far easier. Mr. Thompson is fully convinced that his method of ensilage presents many advantages over the old system of desiccation, and recommends its adoption by all classes of farmers.—*Melbourne Leader*. [Guinea and other grasses might in this way be stored in the wet season and be available in seasons of drought.—ED.]

WYNAAD PLANTING NOTES.—After a good many excellent imitations in the shape of cyclones, we have now fairly decided that the monsoon has commenced. The weather has been exceedingly unsettled for a month past, and our rainfall during that time unusually heavy. The season, so far, has altogether been somewhat capricious. In February we had sufficient rain to bring out a very fair blossom, though, of course, the bulk of spike was at that time insufficiently developed to be much affected. This was followed by a long and exceedingly trying drought, and that again was succeeded by heavy storms. As much as seven inches in one day fell on some estates, and this was accompanied by a destructive hailstorm, which in many cases did much mischief. Some of the hail-stones measured three and a half inches across, and these literally tore the *succirubra* leaves into ribbons. The second blossoms on most places were destroyed by this untimely weather, and the third and last does not seem to be swelling satisfactorily; so I fear we have not generally much to hope for in the coming crop. Those amongst us who have Mark Tapley temperaments console ourselves (as usual) with the prospect for next year and undoubtedly the trees promise grandly. I have never seen them in better heart, or freer—taking them altogether—from the innumerable ills to which coffee is subject. Unless Fortune wholly means to pass us by, the crop of 1889 should certainly be magnificent. But, after so many heart-breaking disappointments, and so many cases of hope deferred, it is difficult to believe in the possibility of really good times coming. This time, last year, we were in high spirits, and great things were prophesied with regard to bumper crops and high prices. These were but very partially realized, and our ardour was considerably damped by the report of an enormous crop due from Brazil. This, however, we now hope, has been exaggerated; and, altogether, if we can tide pretty fairly over this year's shortcomings, we may suppose it possible that our crops for the following season will be paying ones. Labour is very scarce, but few of our Canarese having come in. Their dilatoriness in fulfilling their contracts is a growing evil, and if we had not the Ohermas from the coast to depend on, we should find great difficulty in carrying on the estate work. June is always a trying month for our planters. The work seems to accumulate in the most uncanny way, weeds flourish exceedingly, the manure pits shout to be emptied, and the suckers on the coffee trees groan for hands to pull them off. At this crisis, we look over our contracts to find our gangs are all overdue, and then, down comes a good old monsoon burst, and the muddle and mess in everything becomes absolutely disgusting.—*Madras Times*, June 1st.

THE UTILISATION OF MOORS.—In some of the provinces in Holland exist large tracts of heath and moorland which at present are of little value, although once covered with dense forests. An effort is now being made to form a company, whose object it will be to attempt a gradual utilisation of the soil by replanting trees. How much good may result from such an enterprise under careful management is shown by a similar undertaking in Denmark, which has started some 400 plantations in different parts of that country.—*Gardeners' Chronicle*.

DESTROYING WEEDS ON WALKS.—In response to "J. S." (p. 566), I beg to inform him I have used sulphuric acid very extensively on our walks and carriage drives, of which last-named there are about two miles. The quantity used was about one pint to a gallon of water, which was distributed with a watering-pot having a fine rose. The mixture is very effectual; so much so, that after a few seasons' use very few weeds grow where it has been applied. Great care is needed in its application, as it is very damaging to clothing and boots [and water-pots.—Ed.]—J. M. JOHNSTON, Hints Hall, Tamworth.—*Gardeners' Chronicle*.

SLAVERY AND FREE LABOUR IN BRAZIL.—While the telegraph announces the important and gratifying news of the total and immediate abolition of slavery in Brazil, the *Rio News* to 24th April reaches us with notices of a very mixed state of feeling amongst the Brazil planters on the subject:—

The *Diario Popular* of São Paulo, of the 18th, states that according to trustworthy information from the vicinity of Jahú the traffic in Indian slaves is being carried on actively. The Indians are captured and sold in S. Manoel and other places for prices even as high as 200\$. The pretext for this infamous traffic is "agricultural education." The attention of the government is invited to this report.

The *Gazeta*, of Mogy-mirim, Sao Paulo, says that a planter in the municipality of Penha has compelled his freedmen to sign a contract, officially attested, in which he agrees to pay each one a salary of 100\$, at the end of the year, and every freedman who fails to remain in his service to the end of his contract must pay a fine of 200\$. This is called *free labor*.

A statistical table just prepared shows that the liberations registered in the province of Sao Paulo between March 30th, 1887, and March 20th, 1888, (why could not the next 10 days have been included to make an even year?) was 31,774, the number of slaves becoming free on account of age 559, by operation of the emancipation fund 116, and by death 833. Returns are lacking from 13 municipalities.

On the 14th inst. a meeting of planters was held at Serraria, Minas Geraes, to take into consideration the questions of emancipation and immigration. The resolutions adopted were: (1) to maintain slavery as far as possible without promise of liberty; (2) to prepare houses for colonists and to promote their establishment at once; (3) not to abandon the freedmen but to advance them in the regimen of useful labor; (4) to protest for the rights of property. It would appear that the Southern Minas planters are a pretty hard-headed lot, and the immigrant will do well to avoid them. They don't want emancipation and are not ashamed to say it. They want unpaid, whip-compelled labor, and when the slaves are gone they will not hesitate to take it out of colonists. On the following day the minister of agriculture helped to found a colony of immigrants at Barbacena, to be called "Colônia Rodrigo Silva," which will probably flourish apace in the neighbourhood of such planters as those who met at Serraria.

VANILLA CULTURE IN MEXICO.—Our contemporary, the *Chemist and Druggist*, quoting from a St. Louis paper, gives some details on the cultivation of Vanilla in Mexico, from which it seems that the plant flourishes in two places, namely, Papantla, in the State of Vera Cruz, and Misantla; the first place, however, is the most important. It is a town of about 10,000 inhabitants, and in the hand of the Totonaco Indians: an extremely indolent and improvident race. The Vanilla plant is found wild in the forests. The fruits

ripen in November or December, when they are gathered and put into sacks and brought into Papantla to market. The buyers are Spaniards or Americans and the competition is described as similar to what "is to be seen in a street where second-hand stores prevail. The old women are generally in the lead, half naked, and with haggard faces begrimed with dirt. Then come the children, equally pitiable in appearance; and finally the old men bring up the rear, with long stiff hair, matted and dirty, sometimes standing out 12 inches, while their beards, filthy and long, lend a finish to a picture that is most revolting." The Vanilla pods are purchased by middlemen at the rate of 42s. to 50s. per 1000, taken as they are put up by the natives. The average weight of 1000 good sized green Vanilla pods is about 60 lb., which, when dried do not exceed 10 lb. The first fine morning after the pods are gathered they are arranged on planks, covered with quilts and exposed partially to the air, this being repeated seven times before the water has all evaporated, and they have become sufficiently dry. This is known as the sweating process, after which the pods are slightly heated and placed on shelves to dry, when they are assorted into lots, each containing fifty beans, and graded according to length. In fine weather the curing process takes three weeks, but such weather rarely prevails, and the curing sometimes takes from four to five months. Last year the beans sold for 58s. per 100, which was about a pound; but owing to a heavy crop this year, and the growing competition in the business, the best beans only bring 50s a pound or 100, and the inferior from 30s. to 42s. The principal markets for Vanilla beans are New York, St. Louis, and Chicago. They are bought chiefly by wholesale druggists and fine confectioners, and are becoming an important article of Mexican commerce. Last year, from the vicinity of Papantla alone, 60,000,000 beans were exported.—*Gardeners' Chronicle*.

EMANCIPATION IN CUBA.—Mr. A. de C. Crowe Consul-General at Havana, reports that negro emancipation has not been followed in Cuba by the same results as have occurred in other West Indian islands. Two crops of sugar have already been grown and worked by freemen, with results equal to those in the best years of slave labour. Wages have, generally speaking, been moderate. Thus neither emancipation without compensation, excessive taxation, foreign competition, nor the other causes in operation have reduced the sugar product. Mr. Crowe adds that the experience of the last two years has conclusively shown that in Cuba white labour can successfully compete with black; that Spaniards, especially, can easily become acclimatised and fit for labour; and that if more expensive, they are worth two slaves or free blacks in any capacity in which they may be engaged. There is still (the report proceeds) an immense amount of soil to be worked up, and room for millions more people. Climate and geographical position are in favour of Cuba; and the opinion is justified that with the removal of the bounty system and a restoration of confidence, the island need fear no competition in the sugar markets of the world. Mr. Vice-Consul Ramsden, reporting on the district of St. Jago de Cuba, expresses the opinion that Chinese labour could be profitably employed in the island. There is little fear of the Celestials being ill-treated, and their industrious habits would tell greatly in their favour. The Chinese are more economical and ambitious than either the negroes or white labourers, and though they have the reputation of not leaving their gains in the country, they make these gains from work done by them which does contribute to the general wealth. The country does, therefore, eventually gain from their presence, for the simple reason that they produce more than enough for their own necessities, while the negroes and others do this to only a very small extent.—*Globe*.

TEA COMPANIES.—Our local contemporaries seem to miss the one point which most strongly justifies the turning of groups of tea plantations wherever possible into a Limited Company proprietary. It is the immense money saving which can thus be effected in factories and machinery. Under separate proprietors, each estate will probably have to provide some sort of a factory and machinery however inferior; while half-a-dozen such plantations under one control could afford a central and fully equipped factory—at the spot perhaps where water-power can be got—and large economy in first outlay, as well as in fuel for all time, together with far better preparation of the tea-leaf, can thus be anticipated. We know how difficult it is—in the case of old properties especially—to get all concerned—proprietors, mortgagers, agents—to agree to merge their interests in a Company. But with competent valuers on both sides, and with shares in the Company to represent the greater part of value, the difficulties ought to be overcome by men of business. Then with well-selected judicious managers—on whom, success must always chiefly depend—and perhaps an allowance in a percentage on profits, we do not see why the properties in Ceylon of Tea Companies should not be worked more economically even than privately-owned plantations.

TEA IN JAPAN.—Says the *Japan Weekly Mail* of May 5th:—

In Settu, Kawachi, and Idzumi the extent of ground under tea has this year been increased by about 10 per cent. The Yamashiro Tea Preparing Company and the Kyoto Tea Preparing Company have each received an order to supply a quantity of prepared and black tea to the Imperial Household.

The paper of May 12th has the following:—

Large parcels of new tea from Kyshu, Kawachi, and surrounding districts, have arrived at Osaka, and prices are said to be 10 per cent. lower than those of last season at the same period. The Tea trade is brisk, over 10,000 piculs of leaf being the business of the week. The commodity is plentiful and good, and this year's growth bears favourable comparison with that of last season. Prices decline as heavy parcels come to hand, and this will have the effect of increasing the quantity fired, the general tendency being towards a cheap article. The total shipments from Yokohama and Kobe to the United States and Canada during the season just closed amounted to 43,357,197 piculs, against 45,455,231 piculs in 1886-7.

ENGLISH TOBACCO.—The London Chamber of Commerce has awarded its prize of £50 for British-grown tobacco to Messrs. Carter & Co., and now it is proposed to submit the tobacco to chemical and practical tests. We may take it that it has been virtually settled that tobacco can be grown very well in England and Ireland. The specimens in their plant form are decisive enough on this point, which has been the one principally in dispute. The curing of the leaves is the other and much more difficult part of the subject, and it is here where the need for inquiry and experimentation is so great. The present demand for light-coloured cigars and tobaccos, under the idea that they are necessarily mild, is causing a good deal of immature foreign stuff to be placed upon the market. If however, we could manufacture light-tinted tobaccos in England, without the necessity for sulphuric acid bleaching, we should have solved the double problem of benefiting agriculture and of satisfying a healthy demand. It is clear we can grow the plant, and that it will be profitable. The rest is purely a manufacturers' problem.

CAPE DIAMONDS.—At present, says the *London Economist* of March 10th, the total nominal capital of the various South African Diamond companies is not far short of six millions sterling, and the value of the diamonds exported from their prop-

erties has been, as we have said, between forty and forty-five millions sterling, of which about fifteen and a-half millions represents the output of the past five years. The following approximately, is the annual export of Cape diamonds since 1882:—

1887	..	£4,033,582
1886	..	3,504,756
1885	..	2,492,753
1884	..	2,807,329
1883	..	2,742,470

THE MADRAS FOREST REPORT FOR 1886-87 has reached us, and from the remarks of the Board of Revenue we quote as follows:—

Upon the whole, the working of the year was successful. The weak points in the department are the paucity of experienced and trained officers and the want of system in working the forests in some districts alluded to above. The conduct of the establishments was on the whole good, though the Conservator, Southern Circle, finds reason to complain of the want of thoroughness in the inspection of Range offices and depôts by District Forest-officers. The Northern Circle Conservator, Mr. Gamble, inspected, during the year, Godavari, Kistna, Ouddapah, Kurnool, Anantapura and the Nilgiris. His inspections were very thorough, and his inspection notes on Kistna and Kurnool and his note on the Nilgiri forests are full of interest. Colonel Walker inspected every district in his circle during the year. The District Forest-officers spent a sufficient portion of the year on tour, and as a rule, showed great interest in their work. The year was not a healthy one and the superior and subordinate establishments suffered much from fever.

DAVALA, SOUTH-EAST WYNAAD.—We are informed that the country about Davala, in South-East Wynaad, which was at one time occupied by flourishing coffee estates, now presents a scene of perfect desolation. Three or four estates, it is said, have escaped the general ruin, for which the proprietors are no doubt deeply thankful. The numerous, and in some instances stately buildings, that were erected when the gold mining fever was at its highest rage, are, we are told, completely deserted, those constructed of timber having yielded to the ravages of the termites, the white ants, while those composed of more substantial materials erect their silent heads with an air of despondency. The coffee estates, we think, gave evidence of decay, considerably before the gold fever appeared, and this craze gave the finishing stroke to their dilapidated constitutions. So much was expected from the gold, that the coffee became the subject of secondary consideration, and thus an industry which had contributed to the prosperity of Davala, as it has contributed to the prosperity of the Wynaad generally, was allowed to make room for a speculation of a very uncertain character. This uncertainty may have been concluded from the expressed opinion of experts that the precious metal would never be obtained in remunerative quantities. The wealth which Davala has absorbed is not entirely represented by the unfruitful mining operations. To it should be added the enormous sums spent upon the coffee estates which now constitute deserts and wastes, and we should remember that the change was not sudden, but had been approaching by slow, although certain steps. The question therefore arises, is coffee planting thoroughly understood in India? There have been so many men of ability and experience engaged in the management of estimates, that the question may appear absurd; there is, however, evidently, some secret which has not as yet become intelligible, or Davala would not have experienced her devastation.—*S. I. Observer.*

A NEW OIL SEED.—The seeds of a labiate, the *Lallemantia iberica*, a plant common in the Caucasus and elsewhere, have lately been examined by L. Richter, who finds therein $3\frac{1}{2}$ per cent. of a bland fat oil, which congeals at about 34° to 35° C. It is thought that this oil could be cheaply obtained, and that it would probably prove useful in pharmacy and the arts.—*Burgoyne's Monthly Export Price Current.*

CHINA TEA.—The "first teas" of the season were shipped in big lots: our Hongkong correspondent writes:—"The 'Moyune' left Hankow with 24,000 piculs, and on 22nd the 'Glengyle' with 27,000, which makes nearly seven million lb. between these two steamers." In the *Singapore Free Press* of 7th June we read:—"The Blue funnel steamer 'Prometheus' arrived from Hankow this morning, with a cargo of 4,000 tons of tea on board. She left for London at one o'clock this morning."

PINEAPPLE PLANT.—It is beginning to be said that the leaf of the pineapple plant (*Ananassa sativa*) has a future before it, and it goes without saying that, if the leaf is cared for the fruit must be cared for with it. It is said now that the leaf is finer and stronger in fibre than that yielded by any other plant, and that in the Philippines where the West Indian *Ananassa* has become naturalised, a beautiful and strong textile fabric is made from it known locally as "pina cloth."—*Indian Agriculturist.*

WONDERFUL DISCOVERY IN GLASS.—Says *Ironmongery* of April 30th:—

"Perhaps the most remarkable recent discovery is the new glass which has just been made in Sweden. At present, common glass contains only six substances, while the new Swedish glass consists of fourteen, the most important elements being phosphorus and boron, which are not found in any other glass. The revolution which this new refractor is destined to make is almost inconceivable if it is true, as stated, that, while the highest power of the present microscopic lens reveals only the one four-hundred-thousandth part of an inch, this new glass will enable us to distinguish one two-hundred-and-four million-seven-hundred-thousandth part of an inch." What are we coming to? Is it going to be possible to see into the human frame through the pores of the skin?!

THE USES OF PEAT.—"Peat which can be dug on many farms"—says the *Indian Agriculturist*—"can be put to a variety of uses besides that of fuel, which was its primary use in Europe. When thoroughly air-dried and ground there is no better absorbent than peat for use in such places as closets and stables. In fact it forms a perfectly fixative deodorizer, and when thoroughly saturated may be carted off and used as a most easily applied and active fertilizer. In Germany there is in nearly every large town a peat grinding mill, the product of which is used in the manner we have suggested, and is found of the greatest value in enriching the soil of gardens, orchards, hothouses and vineyards."—Query if peat from the great Maturajawella swamp could be cheaply and profitably used for sanitary and fertilizing experiments at Colombo: the cost of carriage off even perfectly dried peat would be the difficulty?

PEAT AS MANURE IN ORCHARDS AND VINEYARDS.—With all our vaunted science, we are far from knowing or taking advantage of the manures most simply and easily obtained. It is only in a very few large towns that peat grinding mills are in use, making a perfectly fixative deodorizer for closets, urinals and stables. The manure thus obtained may be transported in open carts through the busiest streets without annoyance to the inhabitants and passer-by, and is of the greatest value in enriching soils of fruit gardens, orchards, hothouses and vineyards. Were the powder universally used in houses, it would form a perfect disinfectant and afterwards a most valuable adjunct to improve the garden soil. Its value as manure was

demonstrated at Kilzingen in 1884, by Dr. Fuerst, who procured a supply from the Urinals and closets in the town and public buildings and applied it to vineyards which had been formerly manured with ordinary stable straw-manure and dung, varied at regular intervals with Kainite and superphosphate, but a part had purposely been left fallow for this experiment. He divided this part into three, applying to one $3\frac{1}{2}$ tons of ordinary stable dung, to another 150 lbs. of Kainite and 150 lbs. Superphosphate and to another $2\frac{1}{2}$ tons of the peat-manure. A successful result was not long delayed. Even in the first summer a much richer growth was observed in this last lot, finer grapes and increased number of bunches. Plants which had borne only 20 bunches formerly now produced 30 and 40. In September, these grapes were quite soft and sweet whereas the others were still hard and sour. They were fully ripe more than a fortnight before the others and gave to 12 per cent more saccharine. Other trials in 1885; 1886, and 1887 have been still more successful and the old plants are altogether wonderfully improved. Several fruit trees nearly barren and useless were similarly treated and with like results. (From Frankfurt a/M.)—*Universal Press Association.*

CEYLON TEA IN SYDNEY.—M. D. W. Campbell, formerly a Dimbula planter, and for the last few years engaged in business in Sydney, N. S. W., sends us a copy of the *Australian Century*, an illustrated monthly paper, which contains an advertisement of the "Ceylon Tea Company," with which Mr. Campbell is connected. This company not only sells Ceylon tea and coffee in packets, but makes ladies' afternoon tea a speciality, supplying tea, coffee and cocoa in the cup, and bread and butter, scones and pastry. *Society*, a weekly journal also published in Sydney, and a copy of which Mr. Campbell sends us, has the following paragraph under "Society Notes and Fashionable Intelligence":—

An elderly lady said to me the other day: "Madge, the art of tea-making is lost; the very look of it is no longer encouraging. It is either a pale, half-chilled unsatisfactory beverage, or it contains a blackish brown sediment from bad tea leaves." The consumption of tea, no doubt in Sydney, is enormous, and we boast to new comers that we are fond of our cup of tea; and yet where is the heretical foreigner to find a good cup in the city? At the restaurants? Never. At the old standing tea and coffee palaces? Very rarely; for these are opened in most cases to promote sobriety; but these well-intentioned people forget that both tea and coffee are stimulants. Even in private houses, it is surprising that a good cup of tea can seldom be obtained. Everywhere a great reform in tea is required. And I think a prophet has already arisen for our salvation, in the embodiment of the "Ceylon Tea Company," who have opened a charming little afternoon tea-room for ladies at 354, George-street, next to Paling's. I visited this new resort one day last week, and found it crowded with fair visitors, babbling gossip over large cups of Ceylon tea, delicious pastry, and fresh scones. The milk and butter provided here are of the purest and best description, obtained direct from a dairy, at Middle Harbour, owned by the proprietors. The secret of tea-making is also a speciality at these rooms, and is carried out under the management of a lady who has studied the charms of the beverage for years; steeping the leaves by using boiling water, then instantly almost (the most three minutes) pouring off again, by which only the volatile and stimulating portion of its principle is obtained. This pure Ceylon tea is really the cheapest in Australia, as only half the quantity is required in making a good brew. It may be had at the ladies' tea-rooms at 2s 6d per lb. Every convenience is fitted up in this place, which is a perfect picture of bright decorations. I would strongly advise housewives to order some of the Indian tea, but do not listen to the misguided people who will be sure to tell you that it wants to be mixed with Chinese tea.

We wish Mr. Campbell and his Company all success in their efforts to get the Australians to drink Ceylon tea.

COCA GROWN IN INDIA.

It is now three years since Surgeon General Bidie's lecture upon Erythroxylon Coca drew the attention of planters in this country to the possibility of cultivating the shrub at a profit. We were able shortly afterwards to give our readers some information as to the management and yield of the new product, and to show that as long as prices for the leaf remained steady there was money to be made out of it. A considerable demand for plants was consequently created, and seeds were advertised for sale at a rupee a piece. The Madras Agri-Horticultural Society was, however, able to supply its members at a more reasonable rate, and as most estates in our planting districts have now a few specimens growing, it would be possible to largely extend the cultivation if it seemed desirable. Dr. Warden has lately communicated to the Agricultural and Horticultural Society of India the results of a series of experiments made by him with coca leaf grown in the Bengal Presidency, and has shown that its medicinal value is as great as if not superior to, that produced in South America. In Peru and Bolivia, the natural home of the shrub, the coca leaf is by popular belief endowed with almost miraculous qualities. The Indians will work, or travel carrying heavy loads, without other sustenance for days together; and in one form or another these leaves are looked upon as a remedy for most diseases. Coca is grown upon the slopes of the Andes at an elevation of from 2,000 to 5,000 feet; it requires, however, a warm moist climate with almost incessant rainfall. The soil must be very good, and heavy forest land is usually felled for it. It, however, flourishes for as long as forty years, giving three crops of leaf annually. Nursery plants of about eighteen months growth are planted out in pits, very much as tea and coffee, except that it is found advisable not to fill in the pits until the plants are established. The ground is kept free from weeds, beyond which no cultivation appears to be necessary, and, after two years or so, plucking is commenced and carried on regularly. The mature leaves are known by being bright green on their upper surface, and yellowish on their lower surface; they are plucked separately, and with great care to avoid crushing, and are slowly dried in the sun. Dr. Trimen says that the usual yield is over 2,000 lb. per acre annually, and in Dr. Warden's paper the market value in London is quoted at 2s. 6d. a pound. The Peruvians and Bolivians between them are said to produce 22 million pounds, of which only 5 per cent., or something over one million, is exported.

The great attention which has been attracted to coca cultivation of late years was due to the discovery that the alkaloid cocaine, contained in the leaves, was of value in surgery as a local anæsthetic, especially in operations on the eye; and it was believed by some that a demand would spring up for the leaves very much as has been the case for cinchona bark. Dr. Warden's experiments were directed to discovering under what conditions of locality and subsequent treatment the Indian grown coca would give the best yield of alkaloid. It must, however, be remembered that the leaf came from plants that had only been put out for eighteen months or so, and that subsequent experience may largely modify the results arrived at. As far as these results go, it would seem that neither altitude nor rainfall has much to do with the percentage of alkaloid present. Two extreme cases were those of leaves grown at Jalpaiguri 1,700 feet above the sea, yielding 1.022, and at Arcuttipore, in Cachar, at an elevation of only 120 feet, giving 1.3 per cent. In the latter case, however, the soil round the plants had been heavily manured. Coca grown in the Jaunpore district, again, with but 30 to 40 inches of rain a year, gave only four-hundredths per cent. less alkaloid than the sample from the Doars, where they have 180 to 200 inches. The period at which the leaf is gathered seems to be of importance, as samples taken from the Society's garden at Alipore, at an interval of six weeks, showed a difference of nearly 300 per cent.

As to the effects of cultivation and manure the result arrived at are somewhat contradictory. The best leaf came from Arcuttipore, where the plants

had been manured with cowdung and soot; but that from the Jaunpore district, which is also described as having been heavily manured, gave only .571 of alkaloid. In Peru it is found advisable to grow coca under shade, and the *cocales* (as the plantations are called) are therefore closely planted with a small broad-topped leguminous tree. As in the case of coffee these leaves have a better colour; and as for local use their appearance affects their value this is an advantage. The sun-grown leaves, however, give a better yield of total alkaloids, and Dr. Warden's analyses point in the same direction. It is believed that judicious manuring would largely increase the alkaloids; and in the paper under notice the use of some fertiliser containing potash is suggested, as it was in our previous article. It is usually considered inadvisable in cultivation of this kind to manure at all before the tree is about four years old, and it can be only required where, as in the case of some of the samples examined, old tea-land had been planted up. The orthodox method of drying the leaves is to put them in the sun, but no bad results were found to arise from the plan adopted at Arcuttipore; the leaves were first withered in the shade, and then dried in a tea-drier at a temperature of 150° Fah. The object which Dr. Warden thinks should be kept in mind is "to dry the leaves as thoroughly and quickly as possible, at the lowest temperature." As soon as they are cold, the dried leaves should be packed in air-tight boxes to prevent them absorbing damp.

The only way in which the extract of the Indian grown leaves differed from any other was that Dr. Warden could not get it to form a crystallisable salt. However, the solution he prepared was reported on by Dr. Saunders who tried it in thirteen operations for cataract, and declared that as an anæsthetic upon the eye it was perfect. There can then be no doubt as to the activity of the alkaloid obtained from Indian coca, and as the shrubs mature no doubt a larger percentage of it will be found in the leaves. But the question of the commercial value of the leaves to planters is a different matter. Unless the leaves come into general use for some other purpose than medicine,—and there seems at present little probability of this,—its use must be very limited. Firms in Calcutta connected with the tea enterprise seem to have taken a great deal of interest in the new product, and to have introduced it in most of the planting districts. It might be worth while for planters to make a few trial shipments in small lots. As far, however, as we can judge, the market could be just now swamped by parcel post.—*Madras Mail*.

EXPORTS FROM THE CONGO.—Among the exports from the New Congo States during the third quarter of the year 1887, according to the circular reports, were 22,779 kilogrammes of copal, 989,748 kilos of palm oil, 16,312 kilos of sesame, 26,365 kilos of wax, and 12,836 kilos of annatto. Coffee, ivory, and palm nuts, are said to be the most valuable export commodities of the new State.—*Burgoyne's Monthly Export Price Current*.

COFFEE CULTIVATION IN SOUTHERN INDIA.—Says the *South of India Observer* of 31st May:—

We were not a little surprised to learn that in several cases coffee cultivation is being resumed in south-east Wynaad. When the gold fever was on, a few years ago, the abandonment of all cultivation was recommended. Some companies, however, resolved upon keeping it up, on the best fields, in the hope of thus obtaining a return while mining was in progress. Even this limited area was indifferently attended to and was quite a secondary matter in the estimation of the staff. Now that coffee is looking up, the indiscretion of the past is perceived and once more coffee is claiming the attention it merits. We trust the revival may be general. The prospects of crop in the Ouchterlony Valley are not very brilliant. There is no reason however to complain, as the blossom has been pretty fair. The rain was too late for better things.

CEYLON TEA AT EXHIBITIONS.

We fully agree in the general tenor of the letters which Mr. Rutherford has very properly placed at the disposal of the press at this juncture. Of the importance of doing what we can at all Exhibitions to make our products and especially our tea known, there can be no two opinions; and we feel as irate as any member of our contemned Glasgow Committee at their treatment and the treatment of the Ceylon Court, by the officials, all due to the scandalous refusal of the local Government to grant the required recognition which a stroke of the pen would supply. But we do not feel that sufficient effort was made at this end, to obtain this recognition. An ordinary refusal should only have led to a special Deputation, and, if necessary, an "indignation" meeting, and then red-tape would have given way.

As to Mr. Reid's opinion that the mother-country is not yet worked half enough on behalf of Ceylon teas, we only wish that Australia and even a corner of America had one-twentieth of the attention. It would be interesting to learn from Ceylon men at home now, the name of any town or village they may come across in which Ceylon teas are *not* prominently advertised and sold. Our information last year in London led us to believe that from Cornwall to the Shetlands and from Dublin to Cork, "Ceylon teas" had been made known as no product ever before has been to the general public. Of course, there is not the least doubt of further advertising been a most remunerative undertaking. There never can be too much notoriety for an article you want to be bought and used by the million. But certainly, the time has now come, for us to give as much of our energy and means as possible to advertising in Australia and America.

◆

THE OPINIONS OF MESSRS. DAVID REID AND J. L. SHAND ON PUSHING CEYLON TEAS.

The following are extracts from letters received by Mr. Rutherford on his efforts to organize schemes for pushing our teas:—

Mr. REID writes:—"Great Britain, in my opinion, is the country that drinks the best quality of tea, and I greatly doubt if any efforts of the Ceylon planters will be more fruitful of results to them than efforts to push Ceylon teas in this country. It has not been *half* done yet. Indian tea is second-class as compared with Ceylon, and is, in my opinion, a better weapon to combat China tea with in America. I am at one with you in desiring to combat the heathen Chinese rather than our countrymen in India, but I am not sure that you have got hold of the best mode of procedure to effect that object by joining with India in an American tea crusade."

Mr. J. L. SHAND writes:—"I had your ideas as to India and Ceylon joining in a British-grown tea crusade a year or so ago, but having seen more, I think it now impracticable. There is some common ground, but there are many points of divergence, and I think Ceylon would do better alone.

"Samples of a few thousand pounds here and there are all nonsense, and the man that asks for help of this sort is not the right man, and will probably realize the samples; after being fictitiously bolstered up, he will tumble down when the prop is taken away.

"I can think of no better way of pushing our teas than an Exhibition. Personally I am sick of them, and have no reason to speak in favour of them. Any connection from S. Kensington and

Liverpool Exhibitions has not been worth £20 to me, and I consider I should be doing the enterprize much harm if I appeared at Glasgow as a tea dealer and not as a representative of tea growers, and one cannot appear as both.

"The Paris Exhibition will be a great opportunity for Ceylon; but after the Glasgow Exhibition, I hope to shake Exhibition dust off my feet, for one cannot afford to go on losing time and money in the public cause. But what I want to impress upon you is, *don't lose the chance of an Exhibition anywhere*. If it is properly done nothing can be so good as an advertizing medium, but the distribution of samples gratuitously or otherwise is a mistake, and we are always particularly careful of the man who asks for samples. The man who comes and boldly asks for *help* is in another street, and may be worthy of subsidy."

The following letter has been sent to Mr. Rutherford by Mr. David Reid as to Ceylon's part in the Glasgow International Exhibition, with a request to publish the same if considered desirable.

Thomanean, Milnathort, N.B., 17th May 1888.

My dear Rutherford,—The Glasgow Exhibition is a success, as is the Ceylon tea-house—the latter so much so that I don't think we will have to call on the guarantors in this country for anything: we are making about £40 profit weekly.

All the same I do not think that the representation of Ceylon at Glasgow is as great a success as it might have been made; perhaps nothing ever is. We have made the Court pretty, there can be no doubt about that; but it is not sufficiently interesting for want of Ceylon Exhibits. Still I believe it is worth all the trouble it has cost us, and if I had the business to do over again, I should do it in the same way; I mean that I would have both a Court and a tea-house. I know that the view of some of the planters is, "Never mind the Court; let us have a tea-house," but that won't answer. It is of course much easier for the Committee to do what we are doing at Brussels: subsidize a refreshment contractor to sell Ceylon tea, but the effect I am sure is not the same.

The Government have treated us very shabbily. I say nothing about their paltry subscription (though I doubt if it accords well with the dignity of a body like the Ceylon Planters' Association to accept such an inadequate contribution): what I complain of is their refusal to give us the status and influence they might have done by stamping with their cordial sanction our representation of the island. Such conduct shows not only a want of respect towards the Planters' Association and the Chamber of Commerce, but, what is much worse, a want of perception both of their own duty and their own interest; indeed there is something almost ludicrous in a Government spending money by the million on railways that will be worthless unless the tea enterprise continues to flourish and expand, and at the same time ignoring in the most severe manner the efforts of a Committee whose sole aim and end is to advance the success of that enterprise. I impressed on Mr. Noel Walker, whom I saw in London before he left for Ceylon, that it was not so much money the Committee wanted as official recognition, so as to enable us to interest the British public in the island, and to bring our staple product before them not as huckstering refreshment contractors, but as responsible representatives of the colony. If Sir Arthur Gordon, who is at home, had taken the trouble to enquire what we were doing, and shown some interest in the colony whose interests he is paid for promoting, I have no doubt the Prince of Wales would have shown the same inter-

est in Ceylon that he did in other parts of his future dominions: as it was His Royal Highness moved right round us, visiting the Courts on three sides of us, but avoiding us like a plague. I don't blame His Royal Highness for this; I blame the Government of Ceylon, who, when they found the Planting and Commercial Associations of the island taking all the trouble and expense of keeping Ceylon in touch with the mother-country, refused even to assist where it was their duty to have led.—Yours truly,

H. K. Rutherford, Esq.

DAVID REID.

ADVANCING APPRECIATION OF CEYLON TEA.

Mr. John Hughes, the well-known chemist, writes to us:—"I enclose cutting from the *Lady* of last week on 'Afternoon Tea.' It is not written by myself, but as it speaks favourably of Ceylon tea, I thought it would be of interest, especially as a direct indication of an improved taste for a superior quality of tea. As you are aware, these views agree with those I have lately brought forward, and I trust we shall soon see a demand for tea with a fine flavor, but containing little tannin, which characterizes your high-grown Ceylon tea." The article alluded to is as follows:—

AFTERNOON TEA.

At the present day tea is more popular than it has ever been, and yet there never was a time when so little care was exercised in the making of it, or so much of inferior quality consumed.

"Afternoon tea" has become an institution. Call where you may between four and five p. m., you are sure to be invited to partake of the fashionable refreshment. But, alas! how seldom is the proffered cup really refreshing! Too often it proves to be a lukewarm, insipid fluid, which politeness compels one to taste, but inclination hesitates to swallow. Or, if not insipid, it is apt to be harsh and bitter, and suggestive of dyspepsia. It would be seen that there are some people incapable of distinguishing between good tea and bad, and who think that anything will do that is called by that name. They forget that tea is not of one universal quality, and that though a pound is the same in bulk whatever the price, there is a very real difference in value between tea at one shilling, and the same at two or three shillings.

It is a curious fact that it is not the upper classes who buy the best tea, or attach the most importance to the method of making it. Formerly, when the fragrant leaf was more than twice the price it is now, it was customary for the lady of the house to brew it herself, and the task was performed with scrupulous nicety. Nowadays the duty is usually left to servants, and the result is the deterioration of the beverage. Average servants are poor tea-makers. I do not know why they should, but they are. Possibly they make the common mistake of thinking that simple duties require no care, and consequently neglect the few plain rules which must be observed in order to obtain a really refreshing cup of tea. These rules are but four, and brief:—

1. The tea must be good.
2. The water must be boiling.
3. But it should not have boiled long. Water that has been boiling for any length of time becomes flat, and fails to bring out the flavour of the leaf.
4. The teapot should be made hot before the tea is put into it. The vessel being warm will abstract less heat from the mixture, and thus admit of more powerful action.

The infusion made in silver or polished metal teapots is stronger than that produced in earthenware pots; but, on the other hand, the silver or metal pot when filled a second time produces worse tea than the earthenware vessel, and it is advisable to use the latter unless a metal one can be procured sufficiently large to contain at once all that may be required.

This fact is readily explained by considering that the action of heat retained by the silver vessel so far exhausts the herb as to leave very little soluble substance for a second infusion; whereas the reduced temperature of the water in the earthenware pot, by extracting only a small proportion at first, leaves some soluble matter for the action of a subsequent infusion.

When, therefore, a metal pot is used there should be no second infusion. The pot being hot, the tea should be put in and a small quantity of boiling water poured on it. After standing five or six minutes—the time necessary for infusion varying according to the kind of tea used—the teapot should be filled up and allowed to stand, carefully covered with a cosy, for five or six minutes longer. The tea will then be fit for use; and when the pot is empty, another, if required, should be produced.

Ladies accustomed to refilling their teapots may think this plan savours of extravagance. Tea, however, is now a cheap luxury. Compare the price of a bottle of wine and a pound of tea at three shillings. A bottle of champagne is only sufficient for four or five persons, while a pound of tea contains ninety-six teaspoonfuls, and each teaspoonful, at a moderate computation, will make at least one cup of tea. So for three shillings you can offer one cup of good tea to ninety-six persons, or two cups of tea to forty-eight persons. There is therefore, no excuse for poor tea on the score of expense.

Why should not ladies take as much pride and interest in the flavour and quality of their favourite beverage as men do in the flavour and bouquet of their wines? At present it not unfrequently happens that in houses where the master takes care that his guests have good sound wine to drink, the mistress in her drawing-room is not ashamed to offer to her afternoon visitors, under the name of tea, a weak, watery fluid which a poor charwoman would disdain to accept.

India and Ceylon now rival China in the production of tea. Indian tea is chiefly remarkable for the large amount of tannin it contains, often as much as 15 per cent., and even more. This gives it strong astringent properties which make it a suitable beverage for hot countries. In our moderate climate the same need for astringents does not exist, and the quantity of tannin makes the tea indigestible. Judging from personal observation, the cheap, coarse kinds of Indian tea are much used. They can be instantly recognised by their roughness on the tongue.

Ceylon tea has come to the front in a remarkable manner within the last few years. Some five or six years ago the present writer well remembers asking for Ceylon tea at a large, well-known tea establishment in Oxford Street. Such a thing was unknown.

"Tea comes from China," the shopman blandly explained. "Spice comes from Ceylon."

Ceylon tea has now become so popular that advantage has been taken of its popularity to sell inferior kinds of China under that name. Probably not more than half the tea called "Ceylon" really comes from that beautiful island. The amount of tannin in Ceylon tea varies more than in the Indian leaf, and for this reason. Tea grown, as in India, at low altitudes, and on strong, rich soils, contains a high percentage of tannin; while in Ceylon, where the tree flourishes at altitudes varying from one thousand to six thousand feet, and on a poor soil, the amount of tannin varies with the elevation. The greater the altitude, the less tannin, and the finer the flavour. These high-grown Ceylon teas are very delicious, and the small quantity of tannin present—only 6 per cent. in some instances—makes them peculiarly suitable to persons of weak digestion.

THE MADRAS DIAMOND FIELDS.

India was, says a Madras paper, the home of the diamond before Brazil, not to speak of Kimberley, was discovered; and Golcondah is a name that sparkles in the imagination of the romantic like the cave into which the genii led Alladin. The British Districts of Bellary and Anantapur, are supposed to

enjoy with the southern part of the Hyderabad State the possession of diamondiferous soil, and a Company has been started in London to work a promising piece of ground at Wadjra Karur, the "Village of Diamonds," in the latter district, Wadjra Karur has the great advantage of being within nine miles of the Gundakul Junction railway station. Attention was drawn to this place by a curious incident. It chanced about five years ago that a gentleman entered an office in Madras and interviewing the occupant of it whispered in stagelike accents that he had heard of there being a wonderful diamond in the rough in Black Town which could be bought for a mere "song." He named, however, a large sum, and produced a model in lead of the pebble, but the person interviewed, thanked him for his courtesy, and said that he did not trade in diamonds, nor could he pretend to know one in the rough. The interviewer looked pained; and gravely affirmed that "You'll live to repent it!" "You'll live to repent it!" He was again thanked, and he went away more in sorrow than in anger. Two or three days afterwards the stone passed into the hands of Messrs. P. Orr and Sons. In 1884 that firm exhibited a model of it at the Natural History Museum, South Kensington, and last year they sent to the Museum a beautiful model of the stone as cut. In the rough it weighed 6,738 carats, but when cut and polished its weight was reduced to 247.16 carats. For purity of lustre, and for brilliancy it is said to be unsurpassed by any stone in existence. Its estimated value is about 15,000*l.* Mr. Gordon Orr, the head partner of Messrs. P. Orr and Sons, had acted as sponsor for this gem, and conferred upon it the appropriate and ingenious name of "Gor-do-Norr." It is now in the market in London. Its birth place is Wadjra Karur, and Mr. Orr has obtained other diamonds from the same locality. The Company that is being floated proposes to acquire about 250 acres, with perpetual mining rights near that village, and 204 acres with similar rights in another part of the Anantapur District. The former place was examined by Mr. John Brukowsky, an experienced diamond expert of London and Zurich, after he had but recently visited the Diamond Fields in Kimberley and at Jagersfontein. He has certified that "the configuration of the place indicates the basin formation, as well as the pipe, so well-known to South African miners, and if it is opened up according to modern scientific diamond mining, I have the most profound conviction that the results will equal those of Bultfontein and Jagersfontein in quantity, while, in quality, stones of infinitely superior lustre and value may be expected." The Kohinoor, weighing when cut 102½ carats, the Regent 136½ carats, the Great Table 242.5-16th carats, the Great Mogul 279.7-16th carats, and the Nizam (in the rough) 340 carats are a few of the historical diamonds of India that favour the belief that more diamonds are to be found in the places from whence they came. The proposed capital of the Company is £190,000 in £5 shares. The price paid to the vendors will be £160,000 in fully-paid shares, and the first issue of shares in London has been allotted. There is a good prospect, therefore, of the diamond resources of India being now tested in a scientific and workmanlike manner.—*Pioneer*, May 14th.

TEA IN INDIA.

It cannot be said that the present tea season can be looked on as by any means being exceptionally early: on the contrary it is late in some parts, as for example the Terai and Doonars. Red spider blight is very bad indeed on some hill gardens, and has even

made itself felt in many estates both in the Terai and Western Doonars. According to the *Darjeeling News* the cry for rain is again almost universal. The water-supply of the town has dwindled down to its minimum, and though still sufficient for domestic purposes, it is unable to provide for the flushing of drains. What is quite as bad, tea is also suffering for want of moisture; and blight has already fastened itself on some gardens. A good deal of tea, however, has been made, some gardens being even ahead of last year but the tea wants body.—*Indian Tea Gazette*.

GUATEMALA: ITS PLANTING PRODUCTS.*

Mr. Brigham believes that the time will come when the fertile plains of Central America will be the garden and orchard of the United States, not necessarily by annexation, but by commercial intercourse. Sugar, coffee, chocolate, and india-rubber can be raised there cheaper and better than in any other country, to say nothing of oranges, bananas, pineapples, and other tropical fruits so largely in demand in the United States. Yet of the present imports, the United States contributes less than a third part of what England sends, our share amounting to more than that received from all other countries put together. It is satisfactory to our pride to find that Mr. Brigham attributes this to the fact that Great Britain protects the interests of her subjects, wherever invested. Mr. Brigham notes for the benefit of his countrymen in the United States, one way in which English manufacturers have secured a market in Guatemala,—namely, by packing their goods in small cases, suitable for carriage on mule-back. In many places, no systematic cultivation is either known or needed, the crops growing very much as they did in the Garden of Eden. No plough ever furrows the ground; the hoe is all-sufficient for the planter's needs. It is very remarkable that the country is as yet free from foreign weeds, which in so many new countries have upset the balance of Nature. On the coast, bread is very generally made of cassava. The tuberous roots of the manioc are grated into a coarse pulp, the poisonous juice from which is expressed by placing it in a long sack of basket-work, appropriately called a *serpiente*; this is slung by one end to a beam, while on a lever pressed through the loop at the other, the children of the family sit in turn, or together if they are small. On the uplands, maize, ground on a *metate*, is slapped into *tortillas*; and the usual drink is *pulque*, extracted from the aloe, just as in Mexico. Indigo and cochineal, which formerly ranked high among Guatemalan exports, have been so completely superseded by other dyes, the product of the laboratory, that they are now scarcely cultivated; and the cochineal insect, unfed and uncared for, is fast disappearing. In addition to the products already mentioned, sarsaparilla, vanilla, rice, coconuts, *pita* or silk-grass, and Sisal hemp, are exported in considerable quantities, as also are log-wood, and rosewood, as well as mahogany. Mr. Brigham describes the business of mahogany-cutting, the primitive process of extracting sugar, the methods of preparing chocolate from the cacao-bean, and of coagulating rubber from the milk tapped from the *Castilloa* rubber-tree.—*Spectator*.

AN INGENUOUS SLEEPING-BAG which is in use by some mountain climbers consists of a mackintosh sack, one longitudinal half of which can be inflated, so that the camper can have the luxury of sleeping on an air mattress.—*American paper*.

* "Guatemala, the Land of the Quetzal: a Sketch." By William T. Brigham, A. M. London: T. Fisher Unwin. 1887.

PLANTING IN DELI.

(Translated for the "Straits Times.")

Banjarese coolies have taken to absconding from the estates in such numbers, that the Planters have become alarmed. The Planters Association have taken the matter up and pointed out that the only way to stop desertion is for employers never to engage such people without discharge certificates. By law in Deli, it is a penal offence to engage coolie absconders.

Planters have to contend not only against absconders but also against the elements. In Upper Deli and Langkat, the other day, several estates were hard put to it on this account. A whirl-wind destroyed a great number of tobacco sheds and coolie houses. Hailstones of the size of hen's eggs also fell.

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

British North Borneo still continues a favourite field for investing the spare capital available in Java. The *Locomotif* announces for instance the starting of another company at Samarang, for growing tobacco in that rising settlement. The concession for that purpose has been obtained by Mr. R. Doorn, a planter from East Java, from the Government of British North Borneo. The area taken up comes to seven thousand acres. Should the company be floated, the land will be at once put under cultivation. Felling jungle will in that case, be taken in land in August, so as to admit of 100 acres being ready for planting by next April, with every prospect of raising a crop that same year. Tobacco enterprise in Java seems to be almost played out.

A correspondent writes to the Batavia *Nieuwsblad* pointing out the need for bringing Java tea more prominently into notice. Tea planters there neglect such an obvious expedient. In the island itself, there is a prejudice against the local product, deeply rooted enough. Another obstacle is the keen competition of the Ceylon article, which promises to become still more formidable in the near future. The prospect is so discouraging that tea planting in Java offers no chance of extending and making head against the rival industry in Ceylon. The Java tea planters find hard work to make head against the prejudice which tells so heavily against them.

AN INDUSTRIAL ERA IN INDIA.

After the reading Sir William Hunter's paper on this subject before the Royal Colonial Institute—at which there were a number of Ceylon Colonists present, including:—Sir J. F. Dickson, Major J. A. Fergusson, Mr. J. Churchill, Mr. H. L. Moysey, and Mr. George Vane, the following speeches of local interest were made:—

Mr. D. MORRIS (Assistant Director, Royal Gardens, Kew): My studies are chiefly concerned with botanical subjects, and the able Paper read tonight may seem at first sight so purely statistical that it hardly falls within the scope of my knowledge and experience. If you will bear with me for a few minutes, I would desire to point out that we have summarised for us tonight a most effective and complete exposition as regards the production and distribution of Indian staples. To those not directly interested in Indian industries it is pardonable to consider how far the production in India, on a large scale, of certain articles of commerce will affect either ourselves or our Colonies. It is remarkable that although a great part of the Indian Empire lies within the tropics the Indian staples now so largely produced are not essentially tropical productions. Sir William Hunter has adopted as types and dealt effectually with the production and distribution of three Indian staples: these are wheat, oil seeds, and rice. The production of wheat on a large scale will affect to some extent the growth of wheat in some of the Australian Colonies, but in other respects it can only be looked upon as adding one more staple to the self-contained resources of the Empire. Oil seeds are produced in such quantities, and at such

a low initial cost, in India that it is impossible to compete with it. In fact, India in this respect fills a place which is not seriously sought by any of our Colonies; hence in this branch of her industries she occupies a legitimate and a practically unoccupied field specially and suitably her own. Indian rice goes to feed our native populations in Ceylon, the West Coast of Africa, and the West Indies; and in this way India renders valuable service to our tropical Colonies. She provides our labourers with food at such rates as enable them to follow their varied occupations and raise the produce for which the tropical lands occupied by them are especially suited. What I wish particularly to point out is that the Indian staples thus developed are antagonistic to few, if any, of the staples of this country or its Colonies. We can therefore all the more cordially and sincerely help forward the development of industrial subjects in India. Such a development adds to the suitability and welfare of the Empire, and brings prosperity to millions of our fellow-subjects dependent upon us both for the means and the opportunity to become self-supporting. The influence of the Government is apparent everywhere in the development of Indian industries. It is, perhaps, pardonable in one not directly connected with India to venture the opinion that it is greatly owing to the initiation and the direct support of the Government of India that this now industrial era has been so splendidly developed. The extension of railways in India is fostered by Government auspices, and thus Indian products are distributed over the civilised world. As a special instance of the success of direct Government control in India, I would cite the Indian Forest Department, which is a model attempted to be copied in all tropical countries. This department is one of the most efficient and complete organisations known in modern times; while its action in preserving land from being impoverished by injurious and wasteful systems of cultivation, and in protecting and planting valuable timber trees, must ultimately tend to preserve India in a permanent condition of fertility. Again, the great tea and cinchona industries of India, although now largely maintained by private enterprise, owe their establishment to the direct action of Government. With regard to cinchona, it is due entirely to the Government of India that this useful, and, I might add, this indispensable tropical plant, has been preserved from extinction. It was brought from South America at great cost; it was established on the hills of India—and not alone the hills of India, but those of Ceylon and numerous tropical Colonies; and at the present time we owe to the enlightened and enterprising policy of the Government of India the inestimable blessing of a cheap and abundant supply of cinchona alkaloids and quinine within reach of all classes both in India and elsewhere. As the Government is practically the landlord, it is only natural to find all agricultural interests in India are fostered by special department. The reports of these departments, carefully elaborated and prepared, compare favourably with those of any country. I have no wish to underrate the results achieved by private enterprise in India, but from a careful study of colonial as compared with Indian subjects, I feel that in any account given of a new industrial era in India it is important to bear in mind how large a share of the improvement in Indian industries is due to the action of the Government. Many of our Colonies might usefully copy this policy. It is a policy which has attained complete success in a large number of departments of productive industry, and hence it is that the natives of India—so poor in themselves and so little able to help themselves—are enabled, with the powerful aid of the State, to show such wonderful results as we have heard discussed to-night, and to make their influence felt throughout the markets of the civilised world.

Major J. A. FERGUSSON (Rifle Brigade): The soldier who serves in India, even for a life time, has no right to set up as an authority, and my service there was short. I cannot lay claim to much knowledge, but I

did bring away with me from that country a deep interest in, and a warm affection for, its inhabitants. Sir William Hunter has given a sketch of the gradual shortening of the trade routes between Great Britain and her Indian Empire. May I invite you to take a glimpse into the future. I am still one of those who firmly believe that the day is not far distant when we shall see a railway carried through from the Levant to the Persian Gulf, starting from Alexandretta or Iskanderoun, and going on by Aleppo down the Tigris to Bagdad; and I hope that long before that railway is completed the British Government—carrying out the policy of Lord Beaconsfield—will have recognised the enormous importance of Cyprus, and will have spent the trifling sum of 200,000*l.* in making Famagusta a harbour fit for all the navies of the world. But I go further than that, and venture to predict that ere long the overland route to India will be complete. If our engineers are throwing a railway across the Firth of Forth, why should they not bridge the Bosphorus, across which Byron swam? I have a friend who has lately made two or three wonderful journeys through Persia—Colonel Mark Bell, of the Royal Engineers—where no British officer has ever been seen before, and he has returned with the firm conviction that a great strategical line ought to be constructed from the Punjab to the Levant. I hope it is not unsoldierlike to say that I trust that Russia and Great Britain will soon find that the world is large enough for both, and that the two countries will enter into friendly rivalry and construct, not one line from Europe to Asia, but two, and that Great Britain will take the lead in laying down a line, say, from opposite Constantinople to the Punjab. It might first go on from Bagdad eastwards to Teheran, and on through Beloochistan by Kelat to Jacobabad and the Indus; but eventually a line might even be made through Asia Minor. I am aware of the physical difficulties, but they are not greater than have been overcome in the ghats of Bombay, in the mountains of Ceylon, or in the Blue Mountains of Australia. Nor do I believe that the political difficulties are greater than English statesmanship can surmount. Of course, tonight the debate has been entirely about trade and commerce, but I cannot help thinking of what the effect on India would be of a railway to Western Europe. We know how the dominion of caste is already tottering to its fall, but when a great passenger traffic grows up between the Indian Empire and Great Britain caste will disappear for ever, and the enlightenment and religion of the West will drive out the ignorance and superstition of the East. Inheritors of religious light and liberty, I hope and trust that, while conceding to our Indian fellow-subjects religious *liberty*, we shall not shrink from giving them at the same time religious *light*.—*Colonist and Indian*, May 16th.

COCONUT CULTIVATION IN THE WESTERN PROVINCE.

MILD MONSOON WEATHER—THOROUGH PULVERISATION OF THE SOIL NOT PRACTICABLE OR ADVISABLE IN COCONUT CULTIVATION—SPADE CULTIVATION TOO EXPENSIVE FOR COCONUT CULTIVATION—PROPER MANURE FOR YOUNG PLANTATIONS—HOW BRANCHES AND BUSES SHOULD BE UTILIZED—"VAPORIZATION"—EFFECT OF SMOKE ON GROWING PLANTS.

SIYANE KORAR, May 1888.

This has been a most extraordinary season. The little monsoon has been very little with us, and indeed dispensed its moisture very sparingly. We had none of the deluges you were favored with, I am thankful to say, for I have a particular aversion to heavy falls of rain. The big monsoon crept on us like a thief on the night of the 18th. The morning of the 19th was very wet, and I commenced the long deferred planting operations only to find that the weather cleared up the next day, and kept clear for a week after. Since the 21st we have very gentle showers, between long intervals of bright sunshine, which, however well it may suit the coolly engaged in planting, cannot be as suitable to the plants put out. Fortunately what

I am engaged in planting is endowed with a deal of latent vitality and is not affected by the extraordinarily mild season we are having.

Tropical agriculturists labor under a very great disadvantage in that all the handbooks on agriculture available to us deal with a form of agriculture which finds no parallel here. The cultivation of cereals and root crops for stock are the chief occupations of the farmer in Europe. Here we grow cereals, it is true, but under entirely different conditions. The chief branch of agriculture here is the cultivation of perennials. It therefore behoves us not to follow blindly the teachings of science but to adapt them to our particular circumstances. In agriculture in Europe there is hardly anything on which greater stress is laid than on the thorough pulverization of the soil. And why? Because what is cultivated there is short-lived and has thin delicate roots, the spread of which is dependent on the mechanical condition of the soil. The aim of the farmer is to have his soil so finely divided as to permit of the free passage of the roots all through it, so that they may meet and take up all the elements of fertility present in it, and make as good growth as is possible in the short span of life allotted to such plants. To say that because a thorough pulverization of the soil is an essential condition of intelligent and successful farming in Europe, frequent ploughings to attain the same end are necessary in coconut planting here, is to lay oneself open to the charge of being more theoretical than practical. Except on the sandy flats, where ploughing is a superfluity if not a cause of positive harm, I venture to say that not one estate in a hundred has as yet received *one* ploughing during its whole term of existence, and there are many properties over fifty years old without showing signs of decay. In the face of these hard, stubborn facts, to preach on ploughings "annual and oftener" is not politic. I do not for one moment mean to undervalue the immense benefit accruing to the land from its being broken up. All I say is, that only what is practicable should be preached. A coconut tree has strong, hardy roots which will find their way through anything short of an impenetrable substance such as stone. If the soil is broken up in lines at intervals of a foot, the action of the air and rain on it will permit of the roots of a coconut tree roaming freely even on hard, stiff soils. A man can flatter himself for having treated his property well if he can go over it with the plough once in a decade. By the way, would not a cultivator be a more effective implement for breaking up the soil than a plough? Those with three times that Howard advertises would not be beyond the strength of a pair of buffaloes, I think.

Those who have paid any attention to agriculture must be familiar with what is known as cultivation with the spade. This consists in first cutting a trench of the required depth on the piece of land intended to be gone over, and placing the soil so removed on one side, and then cutting the soil before it and placing it in the trench in a reversed position. The trench formed by displacing the soil to fill up the first trench to be filled by the soil before it, and so on till the soil of the whole plot is reversed. It must be apparent to anyone that the process is a slow and expensive one and practicable only over a limited area. I was much amused to find this system recommended for a coconut estate to keep the lateral roots away from the surface and beyond the reach of the plough. This is the preliminary to frequent stirring of the soil I suppose, and is meant to overcome the objection to a frequent disturbance of the feeding roots! The man who first practises this very practical system deserves a prominent place in our Museum after death even although he is positively promised in life the very material reward of having his tree come into heavy bearing between the ninth and tenth years.

A well-constituted mind never refuses to learn truths even though they may emanate from very humble sources. To the best of my ability I have consistently and strongly opposed the recommendation to use bones exclusively in coconut cultivation,

and have asserted that it would be positively harmful to use it for young trees to induce early bearing. Hard names were hurled at me, a pigmy, for daring to hold an opinion opposed to that of the great preacher on bones and for giving expression to it too. Hard words break no bones, and I carried on my crusade till I have been gratified by unmistakable evidence that I have convinced my most uncompromising opponent. Let us now join our forces, veteran "W. B. L.," and we can reasonably hope to storm the great army of coconut planters entrenched though they be in a citadel of conservatism and induce them to keep pace with the times, and go in for scientific agriculture. When you advise coconut planters to manure their young trees that have shown stem with a manure that will develop their constitutions, I can follow your lead, for such teaching is sound and consistent with commonsense. All the same I feel that in the present state of coconut cultivation the advice is thrown away, for where the tendency is so strong to get all one can from one's property and to return nothing to it in the shape of manure, it is unreasonable to hope that people will manure properties that give no return at all. It has nowhere been asserted to my knowledge that an excess of phosphates in the soil causes barrenness to coconut trees: what has been asserted is that an excess of phosphates causes trees to overbear and draw on their latent strength, and that if the general health of the tree is not kept up by some other manure it languishes. "W. B. L." is of the same opinion now.

It has lately been asserted that the by-products of the coconut tree are the poorest in fertilizing elements of all vegetable substances. This view is not supported by the results of analyses, which show that the ashes of the leaves are specially rich in phosphates of lime and the husks in potash, and that both contain large quantities of chloride of sodium, lime and magnesia besides. Both products, however, I must confess are not very tractable in their natural state as manurial agents, and the cost of getting them under the soil is considerable in the stiff soils in which coconuts are generally cultivated. What I have hitherto done in such a soil has been to heap the leaves round the trees, and every other year to turn into the soil, *in situ*, all that had decayed. The husks I buried round the tree in shallow trenches with cattle manure. I have hit upon a better plan for rendering readily available the constituents of the leaves. I heap them in rows between the lines of trees during the dry months when most leaves fall, and after a shower or two have fallen, and when danger from fire is lessened, I spread them out as wide as is consistent with safety and set fire to them during the day, as leaves absorb carbonic acid only during the period of sunlight. If the leaves are damp the fire will smoulder and will envelop the trees in a thick cloud of smoke. Whether leaves absorb more carbonic acid when presented to them in vast volumes, or whether the pores of the leaves assume unwonted activity under the influence of the heat generated by the fire, I am not competent to say, but an old coconut planter, since deceased, in a communication to the *Observer*, declared that "vaporization" increased the number and weight of his nuts, and with commendable public spirit offered to divulge his secret to the G. A. of the Western Province, or to Mr. Green, then A. G. A. of Western Province, for the benefit of the natives of the Western Province. Whether his secret was confided to them or not, I do not know, but perhaps it is in the possession of his son who now manages a very large coconut estate. Inquiry from natives who had been on the estate in question went to show that "vaporization" was simply placing the trees for considerable periods in an atmosphere of smoke, and any substance which on being burnt emitted large quantities of smoke was burnt with the branches. Supposing that benefit did arise from this system, it cannot be credited to smoking alone as soils undergo mechanical, and possibly chemical changes as well on being burnt, and then there are the ashes which are a valuable manure. Possibly all these combined, produced the results attributed to smoke alone. To return to what I have

just been practising, after the leaves have been burnt I spread out the ashes and turn them into the ground. On sandy flats, where the soil is so much in need of body and where the cost of burying bulky substances is not heavy, I would bury husks and branches in trenches cut anywhere and everywhere, and sprinkle on them quicklime to hasten decomposition. Perhaps the cheapest method of utilizing the husks in soils where the cost of burying them is prohibitive is to burn them where the nuts are peeled, and to mix the ashes with the artificial manures generally in use and apply the mixture according to approved methods. If husks in decomposing do not turn into humus "but gradually wear thinner and finally disappear without leaving a trace in the soil," I wonder what does become of them. Is it suggested that they evaporate and are dissipated into space?

DRUG REPORT.

(From the *Chemist and Druggist*, June 2nd.)

ANNATTO.—Several parcels *seed* were offered, and partly disposed of at extremely low rates, 2d per lb. being accepted for good bright Indian seed, and 1d per lb. for 20 barrels (in one lot) dark and common Ceylon. Brazilian *roll* annatto neglected; fine Parã bought in at 1s 8d per lb. nominally.

CINCHONIDINE SULPHATE.—A parcel of 47,000 ounces sulphate of cinchonidine, "Brunswick" brand, 100-oz. tins, was offered, but although the auctioneer stated that it "had to be sold," yet when he found that 1d. per oz. was the highest bid obtainable he refused to sell, and named 1½d. per oz. as his price. The same parcel has been offered before without success. Nominally Howard's cinchonidine sulphate is quoted at 4d. per oz. for bulk, and 6d. per oz. for vials.

CINNAMON.—The quarterly auctions, held on Monday, included 1,726 bales Ceylon, as compared with 1,609 bales at the April sales. A dull tone prevailed, and barely 4,000 bales found buyers at previous rate, to a decline of ½d. per lb., values for Ceylon ranging as follows:—First—medium to superior, 8½d to 1s 4d.; low, 6½d.—Second—good to fine, 10d to 1s 1d.; low to medium, 5½d to 9½d. Third—medium to fine, 8d to 9½d.; low to fair, 5½d to 7½d. Fourth—good, 7½d to 8½d.; low to medium, 5d to 6½d. New Tellicherry sold as follows:—Quill, 7½d to 9d.; broken, 5d to 6½d.

NUX VOMICA.—The arrivals since last week consist of 67 bags, per "Fozle," from Bombay; and 124 bags, per "Clan Fraser," from Colombo. On May 8th there was said to be still 200 maunds in stock in Calcutta.

VANILLA.—286 tins mostly of rather ordinary quality, were all sold at full prices: fair, 4½ to 7½ inch, 9s. to 18s.; fine crystallised, 7½ to 9 inch, 20s. to 24s.; foxy, 3½ to 7½ inch 5s. to 11s. 6d.; damp chocolate, 4 to 7½ inch, 7s. to 16s. 6d. per lb. The shipments from the Mauritius up till April 10th were 68,801 kilos., against 34,050 kilos. and 51,078 kilos. on the respective dates of 1887 and 1886. Nothing definite could yet be said regarding the coming crop. We received four cases from Ceylon this week per "Clan Fraser."

THE DUTCH MARKET.

AMSTERDAM, May 29th.

CINCHONA.—The next auctions here will be held on June 7th, and will comprise 242 cases and 1,263 bales Java bark, and 16 bales Ceylon bark, consisting of:—*Succirubra*.—Quills, 131 cases; broken quills and chips, 2 cases 78 bales; root, 6 cases, 13 bales. *C. Schukkraft*.—Quills, 12 cases; broken quills and chips, 10 bales; root, 1 bale. *Ledgeriana*.—Quills, 2 cases 7 bales; broken quills and chips, 50 cases 674 bales; root, 213 bales. *Officinalis*.—Broken quills and chips 181 bales; root, 14 bales. *Lancifolia*.—Broken quills and chips, 28 bales. *Hybrid*.—Quills, 18 cases; broken quills and chips, 21 cases 33 bales; root, 11 bales. *Ceylon*.—Broken quills and chips, 16 bales. The total weight of this bark is about 106 tons, of which about 84 tons are manufacturers' bark, containing the equivalent of about 7,900 lb. or about 4 per cent sulphate of quinine, and about 22 tons druggists bark.

RUSSIAN PETROLEUM.

From a Consular Report it is evident that over-production in Russia has led to flooded markets and low prices in Russia as much as the United States, so that petroleum ought to be now obtained at very moderate prices. We quote a few details:—

RUSSIAN PETROLEUM INDUSTRY FROM 1883 TO 1886 :

BY CONSUL ERHARD BISSINGER.

As compared with the year 1883, 1886 shows an increased production of over 250 per cent. Not taking into account the local consumption, the export in the former year amounted to less than 30,000,000 pud—150,000,000 gallons—(at 5 gallons per pud equal to 36.113 United States pounds); in 1884 it rose to 261,216,710 gallons; in 1885 to 300,149,775 gallons, while in 1886 it reached the total of 377,006,120 gallons.

It has already been shown how the Russian home market was glutted with petroleum, due partly to the many new refineries that were called into existence in Baku after the completion and opening of the transcaucasian railway, which eagerly bought up and prepared for the market the extraordinarily cheap raw naphtha, but also because of the want of sufficient means of transportation, so that in the beginning of 1886 the accumulation of oil in the Russian Empire is said to have amounted to 40,000,000 gallons; half of this was stored in Zarizyn, the other half in Domnino (the principal depot of the refineries of Nobel Brothers near Orel), in Moscow, in St. Petersburg, in Warsaw, etc., mostly in tanks. In the year 1886, 115,000,000 gallons more were added to this supply, so that the stock for the market amounted to no less than 155,000,000 gallons; only 80,000,000 of this enormous quantity are said to have been disposed of during the year, so that there was carried into 1887 a stock of 75,000,000 gallons.

It is not very difficult to realize that under such conditions the price of raw naphtha has been very much depressed; it fluctuated between 1½ and 1¾ copecks (a copeck is 7.77 cents) per pud of 5 gallons at the wells; the cost of transporting it the refineries by rail is 1½ to 2 copecks (11.3 to 15.5 cents) per pud, or ½ to ¾ copecks (38 to 59) by pipe line, making its net cost at the refinery 1¼ to 3½ copecks (1.3 to 2.6 cents) per pud.

As 3½ gallons of raw naphtha yield 1 gallon of refined petroleum, and as the employment of the residue, besides affording the requisite heating material, produces also lubricating oil, etc., in sufficient quantity and value to about cover the expenses of refining, it follows that the net cost of a pud of Russian petroleum in Baku is about from 6¼ to 12¼ copecks (5 to 9.7 cents.)

The market price of prime quality refined petroleum in Baku shipped to Russia via Astrachan was 12 to 15 copecks (9.3 to 11.6 cents) in the latter part of 1886, while in former years it ranged between 22 to 27 copecks (17 to 20.9 cents) then gradually fell to 20 to 24 copecks (15 to 18.6 cents), and in the beginning of 1886 declined to 14 to 16 copecks per pud (10.8 to 12.5 cents). Second quality petroleum in the latter part of 1886 sold at 8 to 12 copecks (6 to 9.3 cents), while in the winter of 1885-86 it still commanded 12 to 13 copecks (9.3 to 10 cents), and during the period of navigation in 1885 readily sold for 18 to 21 copecks (14 to 16 cents). It will be observed from the foregoing that under the most favorable conditions, the margin on refined Russian petroleum is merely nominal.

From these figures it will be observed that Russian naphtha costs but about one-half of American refined petroleum in the St. Petersburg markets.

Of the naphtha products carried by the railway 1/4 far the greatest part is exported, notably via Batoum. The increase in this traffic has been a most decided one, and no pains or expense are being spared to find new markets outside of Russia.

Among the new markets into which Russian petroleum has recently made its entry may be mentioned

Syria; Egypt, Algeria, Belgium, Denmark and East India.

The number of steamers carrying the naphtha products from Batoum has lately been greatly increased. Freights by steamers from Batoum to Trieste is 10 copecks (7.7 cents) per pud, and to Hamburg, 15 copecks.

The extension of the Transcaspien Railway and the consequent opening up of new markets have developed a considerable increase in the consumption of petroleum in the region traversed by the railway, and a still greater demand for Russian naphtha is therefore expected, all the more so as it is proposed to complete the construction of the road.

NITROGEN IN VEGETABLE SOIL.—Following on the researches of M. M. Berthelot and Schloesing, already mentioned by us, M. M. A. Gautier and Drouin have presented to the Academy of Sciences a paper embodying the experiments carried out by them to determine the fixation of nitrogen by the soil and plants. The paper only refers to the variation of the total quantities of azote in the the bare soil, and comes to the following conclusion:—"Salts containing organic matter can alone fix free nitrogen or the ammoniacal nitrogen of the atmosphere, even in the absence of plants. Again, organic matter existing in any arable soil is the necessary factor in this fixation of nitrogen.—*Universal Press Association.*

COFFEE.—The British Consul at Vera Cruz tells us that whatever their faults, the Mexicans know how to make good coffee. He says "that the worst coffee of the worst inn in Mexico is superior to the best coffee of the best hotel in England, because it is better prepared, and is not adulterated with chicory or other nauseous ingredients. By the Mexicans it is generally roasted, ground, and drunk within twenty-four hours, or at most forty-eight hours, and is thus consumed at its best; whilst in England long intervals elapse between roasting and grinding, and between grinding and consumption, so that little of the coffee's flavour or aroma is enjoyed at the British breakfast-table, and that little is often lost entirely in the coarse flavour and smell of the adulterating root chicory. Whether the United Kingdom will ever recover the lost art of making coffee depends, Mr. Baker considers, on the reform of a vitiated taste, and on whether people can be induced to take the trouble necessary for making coffee instead of indolently spoiling it, as at present."—*H. & C. Mail.*

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. VIII.]

COLOMBO, AUGUST 1ST, 1888.

[No. 2.]

TEA-MAKING IN COLOMBO.

With reference to recent remarks, we may now refer to the opportunity we had a few days ago of looking over one of our long established Colombo mills where, besides the preparing of coffee, cinchona, &c., we had the pleasure of seeing tea-making going on.

Tea-making is, however, no new thing in Colombo; and were it not for the difficulty in delivering the green leaf in an uninjured condition, much more might be done than would seem possible at present. The leaf we saw being manipulated had been brought down the previous day by rail, and on our arrival on the scene it was passing through the rolling process. The well-known Jackson's 'Double-action Roller' was at work, as also a Thompson's 'Challenge', and we learnt that a Law & Davidson's 'Simplex Roller' would probably soon be erected. A Davidson's Sirocco Drier, a Gow's Sifter and other appliances for further manipulating and packing of the tea were at hand. We were also shown tea in the cup which afforded us an opportunity of judging as to the strength and quality of tea manufactured in our capital.

Tea-making up to about 100 lb. made tea per day had, we were told, been carried on at these mills for the past month, but we did not gather that it is necessarily the intention to continue it for any length of time, the present object being merely to afford the mill hands an opportunity of acquiring practical knowledge in the manipulation of what is now the chief product of our island.

CEYLON UP-COUNTRY PLANTING REPORT:

FINE PLANTING MONSOON—TEA LEAF CARRIED LONG DISTANCES—COFFEE.

25th June 1888.

We are all pleased with the fine planting monsoon we are having, and plants are being rattled out while the weather is favourable. It is perfectly astonishing what a number of supplies an estate wants, and how nurseries that were considered more than enough turn out to be a good deal less. These estimates which we make from time to time, and which are falsified so often, do not dishearten us in any fresh efforts, we are always ready again to over-estimate our nurseries, and underestimate our vacancies. This year the long drought did for everything in the struggling way, and even many plants that were well established followed in

the wake of their weaker brethren. Hence, perhaps, many of us are finding out that supplying is a heavier task than was anticipated, and our nurseries hardly so able to bear the drain as at first was fondly hoped.

The despatch of GREEN TEA LEAF for long distances is a common enough thing in China, but not quite so common here. We all aim at our own factory, but I question if it would not have paid us a good deal better if there had been more centralization and less individuality. Perhaps we may have to come to that yet, and then how to despatch leaf for the long distance, while at the same time to keep it sweet, will be one of the problems before us. As a possible solution towards this question, I have heard of leaf being partly withered, and then sent on, and as far as I know this has been a success. It has one advantage,—that the afternoon's pluckings, which often leave an estate late, and arrive late at the factory, can be dispatched early in the morning, with the minimum of trouble to all concerned. There would be the difficulty of loss of weight if the central factory were independent of the estate; but that could be overcome if the usual outturn of made tea were accepted as the basis. Where different estates of the one proprietary were delivering, there need be no difficulty.

COFFEE, which has been looking well, and in some places with a more than usually fine crop on it, is evidently still to be afflicted, as both bug and leaf-disease are too visible. The former, the more to be feared, has been about for a little while, and is showing up more and more every day. As to leaf-disease it seems as hearty as ever. That retirement into its native jungle, which we were led to look for, is evidently not yet, for its attachment to the coffee tree is undying: when you see how it clings to a sickly struggling sucker, which some all-but-defunct stump has thrown out as a last effort, it is hard to believe it will ever leave it.

PEPPERCORN.

FINE SAMPLE OF COTTON GROWN NEAR THE FORT OF COLOMBO.

EGYPTIAN COTTON AND PLANTING INSTRUCTIONS.

A Fort correspondent writes:—

"Here is a sample of cotton grown under unfavourable conditions in what must be almost pure sea-sand and close to the harbour. It is not a bad sample notwithstanding, and goes to prove that the staple can be well cultivated in the island."

A merchant well up in cotton, who has seen it, says:—"This is as beautiful a sample of cotton as you could wish, grown in the Fort of Colombo!"

After that there should be little hesitation about trying to grow cotton. I think you might invite people to go and see for themselves." The cotton, we should have mentioned, has been grown in the foundry yard of Messrs. John Walker & Co., close by the harbour seaside, the foreman in charge having established a hedge of the plant!

Mr. W. W. Mitchell we learn expects some Egyptian cotton seed by the S. S. "Goorkha" due tomorrow or Saturday, and the following are instructions for those who may be inclined to try the cultivation:—

Memo. relating to the Planting of Egyptian Cotton Seed.

1. The cotton seed is not germinated before sowing. It is either planted dry into land recently watered, or it is soaked immediately before sowing in dry land which should be watered in a few days. The operation depends upon the nature of the land as known to the farmer.

2. The land is thoroughly prepared by ploughing and manured when possible the manure being animal dung well mixed with soil, and allowed to rot before being put on the land.

In the western districts of Ceylon, June and July would be the proper months to sow, causing the picking to take place from Dec. to March.

3. Sow from middle March to end of April; if season is fine the earlier the better.

4. Crop is ready 1st pickings 15th Sept. to 15th Oct.
2nd " 15th Oct. to 15th Nov.
3rd " 15th Nov. to 31st Dec.

The exact date of pickings varies according to localities the more north the later, there being at least 15 days difference between the extremes of Lower Egypt. In Upper Egypt everything is advanced 20 days at least on Lower Egypt.

5. The cotton plant is an annual: when last picking is over the plant is pulled up.

6. The seed is separated from the cotton by the Macarthy Gin.

INDIAN TEA COMPANIES.

The report of the Doocars Tea Co., Ltd., which has been recently published, states that

The average quality of the tea showed an improvement over the manufacture of the previous year. The out-turn was 747,578 lb. or only 12,480 lb. less than the estimate, while the expenditure was well within the sanctioned amount. Including Sukanbari, the company had under tea about 3,276 acres, which would, it was expected, reach 3,486 acres before the end of 1888. The net profits for the year exhibited an increase of £3,642 3s 11d.

The cause of the falling-off in the outturn was a severe outbreak of cholera throughout the gardens, which seriously affected the manufacture; and the plucking of coarse tea to make up quantity had, of course, affected the quality. The cost of working was 5 annas, and the cost in London a trifle over 6d. The outturn for this year is estimated at 1,420,000 lb., at a cost of R329,000. The dividend for the year was 7 per cent.—From the report of the Jokai Assam Tea Co., Ltd.,

It appears that the crop estimates and actuals for the past season show an increase of 71,727 lb. over the estimate, and of 83,747 lb. over the out-turn of the previous year. This very large increase was obtained from the same area, and is equivalent to 456 lb. per acre, against 4,111 lb. per acre yielded last season. Notwithstanding the necessary extra expenditure incurred in manufacturing, packing, and bringing to market the additional 800 chests, the cost of production was less than the estimated expenditure. The entire crop, less 6,681 lb. lost in taring, &c., being 785,046 lb. was sold in London, realising a gross sum of £37,795 10s 8d, or an average per lb. of 11.55d, being a third of a penny less than last year's average.

The gross profits on the working of the season amounted to £11,597 1s 9d, and the dividend for the year was 10 per cent.

The estimates for this year forecast a crop of 784,000 lb. of tea for an outlay of R266,650 in India, or £18,333 at 1s 4½d rate of exchange, and of £7,800 for English charges, making together a total of £26,133, or an average cost of 8d per lb. for laying down the tea in London, including administration, sale charges, &c.

—The report of the Samdang Tea Co., Ltd., states that

The quantity of tea made in 1887 was 1,300 maunds, or 104,000 lb. of which 1,078 maunds were obtained from the Samdang Garden and 222 maunds from green leaf purchased. The out-turn of tea from the company's garden showed an increase of 12 per cent over that of the previous year, and of 28 per cent over season 1885. The average price obtained last season was 1s 2½d per lb. and the cost 9½d., leaving a profit of 4½d per lb. The estimated out-turn for the present season is 1,200 maunds of tea from Samdang, and 250 maunds from purchased leaf, a total of 1,450 maunds, or 116,000 lb.

The profit for the year was £1,958 1s 11d, and a dividend of 10 per cent for the year was declared.

—From the report of the Dejuo Tea Co., Ltd., we learn regarding the crop for the past year that

The quantity invoiced was 240,260 lb., showing a decrease of 56,494 lb. as compared with that of the previous season; the gross average realised was 1s 0.20d per lb. The cost of the crop laid down in London was 10.14d per lb. including all charges and commissions, against 8½d per lb. in 1886, the increased cost being due to the large falling off in out-turn as mentioned above. This decrease was caused, firstly, by a severe attack of blight, which affected nearly the whole estate in the early part of the season; and, secondly, by want of labour to take off the leaf in good time when it came on with a rush after the trees had recovered the effects of blight. This deficiency of labour was chiefly caused by several recruiters not returning with the coolies expected. The estimated crop for the current season is 280,000 lb. and the cost laid down in London is estimated at about 8d per lb.

The net profit for the year was £2,323 10s 0d, and the dividend for the year was 5 per cent.—

From the report of the directors of the Land Mortgage Bank of India we extract the following:—

"The estimated crop of 1887 was 25,325 maunds, or 2,066,000 lb., and the outturn was 24,614 maunds, or 1,969,120 lb., being a shortfall on the estimate of 1,211 maunds, or 96,880 lb., attributable to unfavourable conditions of weather and other circumstances, which operated principally in Darjeeling and Assam and at Kolabarree. The teas were laid down in London at 9.195d per lb. being a trifle under similar cost in 1886. The whole of the crop has been sold at an average price of 11d per lb. being the same average price as in 1886, showing a profit of £14,438 16s 4d against a profit of £14,331 19s 11d in 1886, the difference being but trifling, and this notwithstanding the shortfall in the crop of 1887, and the lower range of market values which prevailed generally during the season for some classes of tea."

The chairman did not venture on an estimate for this year, but stated that an increase of 10 per cent had already taken place.—At the annual meeting of the Indian Tea Districts Association, the chairman spoke very hopefully of the prospects of Indian tea in its competition with the China product. He also said:—

The question of opening a new market for tea in America is not advancing as rapidly as could be wished. Deeds have not yet taken the place of words. I will not say any of us are apathetic. My own colleagues, for instance, have signed their agreement to a money subscription, but on the whole more criticism is coming in than cash. I do not think well of the Calcutta idea of subscribing in kind, but would have a limited liability company on the lines that have been laid before our committee.

In reply to this, Mr. Seton said:—

While a number of companies and individuals had given their adhesion to the project and promised substantial support, several of the principal large owners and companies had, before doing so, asked for details

of a scheme and particulars of what was intended to be done. The sub-committee, in originally drafting the prospectus of the proposed company, had, however, on mature consideration, purposely refrained from setting forth precise details, believing that details, which could only be approximate, might possibly provoke adverse criticism. At a meeting of the sub-committee held this day, it had been decided to await the receipt of a letter expected shortly from a correspondent in New York, who had propounded a scheme in detail, based on local information acquired on the spot, and on receipt of this answer some particulars of the course to be pursued would be circulated to members of the Tea Association with a view to ascertain whether general support of the movement was really forthcoming. It would then be decided once for all whether the matter was to be gone on with or not.

DRUG TRADE REPORT.

42 Cannon Street, E.O., June 7th.

CINCHONA.—A rather larger supply was offered for sale this week than appeared at the preceding auctions, the catalogues including 3,294 packages, viz., 1,999 from Ceylon, 492 from India, 69 from Java, and 734 from South America. With the exception of the latter variety, the bulk was disposed of without much competition at some decline on the last auction rates, the unit being estimated to barely reach 2d. The Indian barks offered the best assortment.

QUININE.—It is reported that during the current week a considerable business has been done at 1s 4d per oz. by certain German agents, the B. & S. representatives alone being said to have sold 40,000 oz. or more at that figure. *Jobst & Zimmer's* brands are selling in a small way at 1s 3d, but the agents for these makes do not join in the speculative movement. *Howard's* quinine is quoted at 2s for vials, and 1s 10d for bulk.

VANILLA.—We note the arrival, since our last report, of another case of vanilla from Ceylon, per "Vesta."—*Chemist and Druggist.*

THE DUTCH MARKET.

(Telegram from our Correspondent.)

Amsterdam, June 6th.

At today's cinchona auctions a quantity of 1,521 packages was brought forward, or which 1,499 were sold at a unit averaging from 10 to 11 cents. per $\frac{1}{2}$ kilo. (= 1 4-5thd to 2d per lb.), or about the same as at the London auctions, perhaps a shade less. Druggists' bark, chips, broken chips, and quill, realised from 5 to 126 cents. per $\frac{1}{2}$ kilo. (= 4-5thd to 1s 10 $\frac{1}{2}$ d per lb.); druggists' root from 14 to 29 cents. per $\frac{1}{2}$ kilo. (= 2 $\frac{1}{2}$ d to 5d per lb.); manufacturers' bark, quill, broken quill and chips, from 16 to 79 cents. per $\frac{1}{2}$ kilo. (= 2 $\frac{1}{2}$ d to 1s 2d per lb.), and roof, for manufacturing, from 28 to 74 cents. per $\frac{1}{2}$ kilo, or 5d to 1s 1 $\frac{1}{2}$ d per lb. The bulk of the bark was bought for the Amsterdam Quinine Works, and the Brunswick factory. The bark sold contained over 125,000 oz. quinine.—*Chemist and Druggist.*

CENTRAL TEA FACTORIES AND THE NEED OF CAREFUL PREPARATION OF CEYLON TEAS.

We leave the following extract to speak for itself. It is from a letter received by Messrs. John Walker & Co. from Mr. Dalgarno (Mr. Jackson's agent) now on a visit to Assam:—

"I hope you are all quite well and that business is good with you; here we cannot complain and in autumn we will be very busy for India. Messrs. James Finlay & Co. of Glasgow have now close on 20 Victorias all class A, working on their estates. Most people are going in for large central factories where they can be had, and they are putting down rails for conveying the leaf. It would do you good to see some of the big factories up here; they are more like large works at home now. One is being erected (with our machinery) meantime 400 long by 50

wide, and I have seen several 160 feet by 190 feet with 6 withering-houses 110 feet by 40 feet. Prices for really fine tea are good, 140 chests of 'Hope' tea realized R1-1-6 per lb, last week: that fine property belongs to Messrs. W. Duncan & Co. of Glasgow.

"Most people are going in for tunnels for shafting, and are having all boilers and driers fired from underneath the floor, so that not a piece of firewood or coal is to be seen on the floor. As an instance of what the old kind of 10 feet H. P. class B engine will do, I found one driving 5 Excelsior rollers and two class A Victorias the other day and found a good many driving 4 rollers and 2 Victorias. Rapid rollers are going off well here and Rajahs too."

140 chests of tea selling in Calcutta at R1-1-6 is something that Ceylon has yet to reach.—It is evident that the 10 horsepower engines referred to are equal to some of the 12 and even 14 horsepower engines at work in Ceylon.

ENTERPRISE IN PERAK.

The difficulty in getting Chinese and Tamil coolies has greatly retarded the mining and planting development of Perak. It is indeed a pity that Tamil immigration has not come up to expectations. Judging from the fact that Tamils can mine twenty per cent cheaper than Chinese, the more Indian coolies that swarm in the country, the merrier for the tin industry. Cheap labour will counterbalance the ill effects of the fall in the price of that metal, resulting from monopolist manoeuvres. The artificial rise in price brought on by the tin syndicate gave an impetus to mining operations, which enabled the European companies mining for that metal in Larut to pay dividends. There is too much prospect of this year's Report having a different tale to tell. The auriferous character of some of the tin mines may, after all, lighten the losses from the present untoward turn of affairs. Gold has also been found in quartz rock, apparently in payable quantities. At Papan, tin mines, worked at a loss under European management, now pay handsomely with Chinamen to direct operations. A French company, turning mines to account at Lahat and Klian, has worked them so prosperously and remuneratively with the aid of seven steam engines, that it intends to carry on operations on a still more extensive scale. Experience shows that success under European management depends upon reduction of working expenses by following economical methods. The industry in question will receive a decided impetus by the discovery of lode tin in Selama, Kamunting, and Thaipeng. Galena too counts for something among the minerals of the State. A lode of it found alongside the railway line showed thirty five per cent of silver. Lodes of greater value are known to exist elsewhere in the State. Galena mining has so far proved a failure here, that capitalists are hardly likely to sink money in that line of business for the present, with the price of labour so high. It is satisfactory to find that, in the year under report, paddy cultivation has been extending. The settling of people on the land has made such progress, that a number of foreign Malays have taken up selections in Lower Park, for growing nutmegs, coffee, and pepper. In Kwala Kangsa, Liberian coffee and pepper have been successfully grown by Messrs. Hill and Rathbone with the aid of public money. With the sanction of Sir Cecil Smith, the policy of Government pecuniary assistance to planting enterprise has since been extended, with a view to push on the cultivation of suitable produce articles. Not only coffee but tea have been found to answer in Perak, the former especially succeeding on Waterloo estate, where bat guano happened to lie handy. Sir Hugh Low is particularly anxious to encourage the cultivation of Arabian coffee in Perak, in the belief that the soil and climate there suit it best. Doubtless he means out of its native habitat. In any case, leaf disease will have to be reckoned with as an element of danger. European vegetables

have been found to thrive at high elevations on the mountains. Sugar has taken as kindly to the soil in Krian on the Gula estate. The article, turned out as it is of excellent quality in increasing quantities, commands a ready sale. These results, satisfactory as they look, do not come up to the mark, owing to the extension of roads not keeping up to requirements. To meet the latter, an extension of the railway is under consideration. The growing surplus amply justifies expenditure under this head. Indeed, money spent in this direction would prove of more benefit to the country, than laying it by in Indian securities. —*Straits Times*, June 23rd.

THE AMERICAN TEA MARKET; INDIA AND CEYLON.

BY THE PERIPATETIC PLANTER.

There has been no meeting yet of the new Sub-Committee of the American Syndicate, owing to Mr. Watson, one of the members, not having arrived from India. There has been consequently very little advance made since last week. The New York gentleman has been written to, very much to the effect hinted at in my last; and the hope is entertained that the modesty of the proposal now made to him will "choke him off." Subscriptions are not coming in as fast as could be wished, and it is becoming more and more evident, that the policy of affording subscribers the opportunity of a say in the programme to be adopted, is not popular, and that it will have to be replaced by a cut-and-dried scheme, prepared before-hand, for all to worry over—and for affording excuses for *not* subscribing, perhaps. The proposal, that the Ceylon and Indian interests should unite in this matter seems utopian. If we cannot unite among ourselves, we are not likely to find union with a rival, no matter how friendly, a very easy matter. Indeed the feeling is already "in the air," that such a union will not come off—and this entirely from Indian considerations. The Ceylon people would probably join willingly. On the Indian side one already hears such remarks as, "We shall both do better if we work independently, but in a friendly non-antagonistic way. Especially if, as in England, Ceylon follows India, the new comer will then revive interest in the older, and attract attention to both." Or, again, "The Ceylon people *must* work America, whether we do or not. They are almost at bay already, with their back to the wall. Their teas are already growing thinner as prophesied of them, and, as their teas lose their characteristics and as they increase their outturn, they will be compelled to find new markets, or again find foreclosure on mortgages the rule. Their men are able and enterprising, and this cleft stick, in which they see themselves only too likely to be caught, will assuredly excite their well-known energy, in self defence. We are *not* within measurable distance of any such dilemma. Our estates are not over-mortgaged, but, on the contrary, have done fairly well of late, and if we found no new market, we should hardly see ruin staring us in the face, for some years to come. Why, then, should we draw the nuts out of the fire for Ceylon Planters?" I confess, I prefer the first of these views; and, selfishness apart, is it not rather soon to count the evil prophecy, respecting the *chronic* falling off in Ceylon teas, as fulfilled? One thing, however, seems common to the general run of Indian opinion here, and that is, that we should work independently of Ceylon in this matter; although there are some leading men, too, who would gladly see the Indian and Ceylon interests united, not alone in this, but in all matters, with one Association for both.—*Indian Planters' Gazette*, June 19th.

WHY SHOULD QUININE ADVANCE?

If an account could be published of the money lost and won by speculative dealings in quinine from May 1877, when the alkaloid attained the highest price of recent years, until the present month, the largeness of the balance on the wrong side would probably astonish the most confirmed pessimist. But we question whether even such a review, though eloquent with many a tale of financial shipwreck, would have much effect in checking speculative enterprises. Investors hope against hope, and argue against reason, for a return of the old times. Times out of number have they been disappointed, and yet, whenever the bark shipments from Ceylon show a momentary gap, or the unit value at the auctions advances a point or two, clients are found prepared to lend a listening ear to advisers for whom the tortuous ways of mysterious syndicates are clear as daylight, and who know to an ounce the stock of quinine throughout the world and the precise acreage of the cinchona plantations in every country under the sun. Just at present there are not wanting signs that we may be on the threshold of a fresh outbreak of speculative activity in quinine. The movement, it seems, is expected to set in on the other side of the Atlantic, and its backers are ready with elaborate arguments to prove that quinine ought really to be very much dearer than it is, and why it may be expected to shortly advance to what they deem its fair market price. The principal reasons given in support of these views are: (a) the decrease of the bark shipments from Ceylon; (b) the smallness of the importations of quinine into the United States, coupled with an alleged increase in the consumption, and the smallness of the stock of the alkaloid in that country on the eve of the season of the largest demand; (c) the belief that it does not pay the quinine makers to manufacture the alkaloid at its present market price; and (d) the idea that the syndicate, of which so much has been heard in the winter, is ready to recommence its operations. Very little reliable information is obtainable concerning the "syndicate" in question, and there is no evidence that that body, if it exists at all, has any ideas of buying immediately. It is rumored that during the winter the syndicate bought—mostly through the London brokers, who are represented as its principal agents—over 2,000,000 oz. of quinine, which, even at so low an average price as 1s 6d per oz. represents the respectable figure of 150,000*l.* or more than most people would think it reasonable to risk in quinine now. This heavy stock the "syndicate" is said to hold still, and it is further affirmed that it will presently buy more, until it completely controls the market, and has pinned its opponents securely into the corner. But admitting the existence of such a plan of campaign, the important factor remains that such operations, even though executed by a "syndicate," are hazardous in the extreme, and are abundantly proved by modern commercial history to have a knack of breaking down just at the critical moment. In the vast majority of cases where combinations, corners, syndicates, trusts, or other organisations of that class have been formed, they have either come to grief themselves or brought disaster upon the outsiders who thought it safe to follow in their track. And in the light of this experience it does not seem safe to pin one's faith to the success of the present shadowy combination. The fact is, quinine is now almost too big an article for continued successful manipulation. Even a superficial calculation will prove this. The absence of any official analyses of the bark sold at the London auctions renders it impossible to esti-

mate as exactly as can be done with the Java bark the average percentage of quinine in India and Ceylon cinchona; but taking the standard at 2½ per cent., and that of Java bark (which has now passed the 4 per cent. average) at 3 per cent. only, the sum then works out as follows:—

	lb.	
Exports from British India, season 1886-87	1,286,900	
Do. Ceylon do.	14,389,184	
	15,676,084	

at 2½ per cent. gives 352,712 lb quinine sulphate.

Add to this, say, 2,200,000 lb averaging 3 per cent. or 66,000 lb quinine sulphate, for the Java shipments during the same season, we obtain for the last season a total yield from the principal cinchona districts of the Eastern hemisphere of close upon 6,700,000 oz. of quinine, worth, roughly speaking, £450,000 at a very low estimate. Thus, apart from the fact that it is quite unfeasible, as has been shown by experience, to obtain thoroughly harmonious action on the part of the quinine-makers, it is obvious that a syndicate, to efficiently control the market for any considerable period, must be a very powerful backed one indeed. Neither must it be forgotten that the abortive boom which occurred at the end of last year was not due to any inherent soundness in the position of the quinine market, but simply to a wave of speculation which, beginning with certain metals, swept over all low priced articles. As to the question whether it pays the growers to ship bark, and the manufacturers to make quinine at the current rates, it must be borne in mind that the growers are not free agents, but, having planted their trees and sunk their capital, must ship the bark at any price which repays harvesting, and that there is no conclusive evidence that even at a unit of 1½d. harvesting is quite unremunerative. The manufacturers, no doubt, will always be sufficiently eager to secure business to continue making quinine at any figure leaving the barest margin of profit, and as it has not been proved that when quinine sold at 1s 3½d to 1s 4d per oz. the manufacturers stopped working or even refused new orders at those prices, we may take it that even these figures do not yet represent the irreducible minimum, though they may not be far removed from it. Another penny added probably represents a fair level for German bulk quinine, and at the same time the axis round which, barring exceptional circumstances, this variety is most likely to revolve during the coming summer. War would send up the price, no doubt, but as the year advances, the prospects of peace increase. Speculation on a large scale would probably have the same effect, but all the premises for a successful speculative movement appear to be absent. The probabilities, therefore, seem in favour of a maintenance of the *status quo* at the best, with a possibility of a further decline.

As regards the smallness of the imports of quinine into the United States, as compared with the corresponding period of the year before, no doubt a serious deficiency may be admitted to exist, and it is also quite likely that the smaller dealers all over the States, who once held an immense aggregate stock, are now almost cleared out. If, therefore, America should buy in Europe to the extent of several hundred thousand ounces to cover the deficiency in her imports, some improvement may set in, and this, in fact, seems to be the only real point in favour of a "bull" view. But here, again, an unknown factor enters into calculation, viz., the quantity of quinine made by the American makers themselves. Besides, it does not seem likely, whatever speculators at headquarters will

do, that the smaller American druggists will stock once more heavily of an article which has been such a treacherous friend in the past. Moreover, there is no reason to believe that the consumption of quinine in America is increasing with any exceptional rapidity, while it is pretty certain that it does not increase at a more rapid rate than does that of the new febrifuges, antipyrin, antifebrin, acetanilid, and others, which, according to reliable reports, are becoming as fashionable in the States as they are in many parts of Europe, especially in Germany, where, even two years ago, the consumption of antipyrin was estimated at no less than 25 per cent of that of quinine. Finally, there is the argument of the reduction in the Ceylon bark shipments. Taking, for the purpose of better comparison, the exports from Ceylon, not from October 1st, when the season commences, and which is the date from which they are usually reckoned, but for the nine months between July 1st, 1887, and March 31st, 1888, we find the official figures during that period are 8,382,668 lb., against 10,525,551 lb. between July 1st, 1886, and March 31st, 1887, a deficiency, during the latter part of the two periods, of 2,142,883 lb. But during the same periods the total shipments from Java were: 1887-8, 2,693,088 half-kilos; 1886-7, 1,736,353 half-kilos, an increase of 956,735 half-kilos, or over 1,000,000 lb., which, considering the far higher average alkaloidal standard of Java bark, practically almost wipes out the deficiency in the Ceylon shipments. And there is every reason to believe, as we have frequently pointed out, that during the next few years any diminution in the supplies from Ceylon, which are now generally expected to continue their dwindling course, will be fully balanced by the increasing shipments from Java, where fresh plantations are constantly laid out, and where the richest cinchonas are still unharvested. The exports from Indian and from the South American plantations are also growing, and experiments at cinchona culture are being made in so many countries that it is quite inconceivable that any demand likely to arise should not promptly be met. Indeed, the arguments against any lasting improvement in the value of quinine are so crushing that it is hard to account for the confidence with which the alkaloid is still regarded by many—a fascination almost unequalled since the days of the Loreley and of the veiled prophet Mokanna.—*Chemist and Druggist*, June 9th.

INSECTICIDES.

While wishing every success to the efforts of Mr. Cotes to introduce insecticides like arsenic, kerosine, and pyrethrum into India, for the protection of its crops and fruits, we have some misgiving as to the possibility of what he proposes. The difficulty of introducing improved machinery for agricultural purposes in India is notorious, and although it is probable of course that the cultivator would apprehend, more quickly than the benefit of improved machinery, the possibility of saving his crops from the ravages of the insect tribe, we fear he is not likely to take to applying insecticides, of which neither he nor his fathers have had any knowledge. In many parts of the country our agricultural departments have induced the ryot to use the Behea sugar-mill, but to get him to sprinkle his fields with arsenical solution by means of an aquapult pump with cyclone nozzles will prove a good deal more difficult. The subject, however, is of as much importance here as in America, where the farmer resorts readily to the arsenical and other remedies Mr. Cotes mentions. The fact warranting Mr. Cotes's attempt to make the ryots understand

there is a remedy for a disease they have only too good reason to know exists.—*Indian Agriculturist.*

CEYLON TEAS NOT KEEPING: FIRING BY CHULAS V. DRIERS.

A Visiting Agent writes:—"Touching the non-keeping of Ceylon tea, the following extract from my London correspondence may be useful and supports your views and those of our mutual friend David Kerr:—"It is well to warn planters that the complaints as to Ceylon teas not keeping are on the increase; as this is possibly owing to the teas being too hurriedly fired, it would be advisable to try the effect of slow firing on some of the invoices." We shall probably have a discussion on the merits of chula, desiccator, and sirocco firing. I understand the Loolcondura teas are still chula fired."

THE QUESTION OF POOR CEYLON TEA AND LOW PRICES IN THE LONDON MARKET IN MAY AND JUNE.

It may be taken for granted, looking at the fact that a "break" of tea is rarely despatched from an estate in a shorter period than a full week after the green leaf has been gathered, ten days being probably nearer the mark,—it may, we submit, be taken for granted, that full two months generally elapse between the gathering of green leaf from the bushes in Ceylon and the sale of that leaf as prepared tea in Mincing Lane. The teas, therefore, which are with each recurring year sold in June and July for exceptionally low prices in London, poor quality being adduced as the main reason, must be from leaf collected in March and April. Now March is generally a dry month or a month of gentle showers, and although the burst of the little monsoon takes place in April, the quantity of rain which falls in that month is a mere nothing as compared with the downpour in June and July and we may add August. In the two months of June and July, often, and certainly in the three months of June, July, and August (the great planting and supplying season), more than one-third of the total rainfall of the year occurs over the larger portion of the mountain and hill region of Ceylon where tea is principally grown. If, therefore, as a contemporary argues, the cause of poor tea and low prices are to be traced to wet weather hindering good withering and fermentation, it is the teas made in June and July which ought, as of poor quality, to sell at low prices in August and September instead of the teas manufactured in dry March and moderately rainy April being of poor quality and selling at low prices in June and July? The teas made in May,—itself a moderately rainy month after the little monsoon burst of April, and those manufactured in the very height of the monsoon rains in June and July, which sell at improved prices from August onwards, in spite of the difficulties of withering and fermenting in the wet, wind and chill which prevail in June and July specially and often just as badly in August. It is, therefore, when teas made in Ceylon, in the very worst weather for curing or manufacturing purposes, reach the London market, that the market responds with improved prices! The conclusion seems inevitable that the low prices in June and July, cannot be traced to the weather most unfavourable for the operations of withering and fermenting. The leaf gathered in the wet weather of June, July and August seems to have become possessed of so large a proportion of the chemical constitu-

ents which give value to tea, that the teas sell well in spite of any deficiencies in manufacture consequent on the prevalence during gathering and curing of wet and chilly weather. Abandoning an erroneous although a plausible and apparently justifiable inference, what is the conclusion forced on us? Obviously it is that the flush responding to the comparatively gentle first showers of spring, in March and April, is deficient in the chemical constituents which give manufactured teas the properties of strength, flavour, and colour in the cup, which experts desiderate? Either that, or so large a proportion of our tea fields are pruned in December and January that much of the tea manufactured in March and April is from the first weak flushes of trees which have been pruned. As the months of December and January are amongst those of largest production upcountry, it can scarcely be the fact that they are the months generally chosen for the pruning operation. Submitting this question to the judgment of planters with large opportunities of observation, we confess we feel ourselves shut up to the very unexpected conclusion that it is not bad monsoon weather, unfavourable to manufacture, which tells against Ceylon teas, but some deficiency of chemical properties in the flush produced during the spring months,—the moderately rainy months of March and April.—Or can the habit and practice of the "tea trade" to regard May-July as a slack time, pending the arrival of the new China teas, have somewhat to do with the neglect and consequent fall in price of Ceylon teas, during that period, apart from quality altogether?

The above was written before we had read the interesting letter from Mr. H. K. Rutherford, which only reached us this afternoon. It will be seen that he puts June teas down as poor, and yet they surely share in the rise usually experienced early in August. We cordially support Mr. Rutherford's suggestion as to Prize Essays on the practical questions he details. Chemical analyses may also teach us a good deal: Mr. Hughes made out that Ceylon rain-water was peculiarly rich in certain properties suited to leafage, and it is only reasonable to suppose that the monsoon rains, with all the electric discharges accompanying them, should be about the richest: indeed Mr. Cochran proved this, if we remember rightly. As to the price at which Ceylon teas will pay to grow, a proprietor who was one of the earliest to make and ship good teas told us some months ago that he estimated that all average Ceylon estates could be made to show a margin of profit, even if the average price for Ceylon tea in London fell to 8d a lb.

THE CHEMISTRY OF TEA: EFFECT OF SEASON AND WEATHER ON ITS CONSTITUENTS.

Recent experience and discussions lead us quite to share Mr. Rutherford's regret that the Planters' Association and the Chamber of Commerce did not see their way to agreeing to his proposal for a series of analyses of tea gathered and manufactured during the successive months of the year. And now, on reconsideration, instead of offering R500 for prize essays on the subject, which might not embody the results of actual personal experiment, we would recommend that the money be spent in payment for analyses, to be made twice or thrice in each month of the year, with teas grown in different circumstances of climate and elevation; such analyses to be the property of the Planters' Association and to be periodically published by them with records of the conditions under which the teas were

grown and manufactured. The influences of seasonal and meteorological conditions on the chemical constituents which give tea its value,—potash, phosphate of lime, theine, &c., was conclusively proved by Kellner's analyses of Indian tea, with which Mr. Cochran (himself a thoroughly qualified analyst) favoured us. Those analyses showed, that, while, in the wintry cold of November in Northern India, only 17.31 per cent of potash was present in tea leaves, the proportion in the genial summer month of May had risen to no less than 49.06 per cent. Theine showed a similar rise from 1 per cent to 2.85. In commenting in October last year on a letter which Mr. Cochran addressed to us regarding some valuable analyses of green tea leaves made by him, we used language which exactly represents our present sentiments as to the necessity and value of a series of careful chemical analyses of Ceylon tea, made at frequent intervals during the year, and which would show not only the influence of climate and seasons on the leaf, but that of pruning and, where practised, manuring. We quote what we wrote:—

TEA ANALYSES: VARYING RESULTS.

We draw attention to Mr. Cochran's interesting letter, further explaining the results of his recent analyses of green tea leaves. The conclusion forced on us is, that it would be of importance that planters should have before them the results of analyses of teas grown at varying elevations, and, above all, that such analyses should be spread over such season and every month of the year. For it is now obvious that not only do the constituents of tea differ according to soil and elevation, but that they are most extensively affected by the meteorological conditions of season. We believe we are correct in saying that in proportion to the percentages present of theine and potash, so is the value of well manufactured tea, and Kellner's analyses have proved conclusively that, while those constituents are most abundant in warm, genial summer weather, they are reduced to exceedingly minute proportions by the cold of winter. The experiments having been made in Northern India, where the extremes of summer heat and winter cold are much more marked than in Ceylon, it is, of course, probable that the contrasts between the results of analyses in May and November, may not present such violent differences in Ceylon as was the case in India. But there can be no doubt, that similar variations will be here shown, for we know without the aid of chemistry, by the tests of the London market, that our teas gathered in cold, droughty, windy weather have sold at lower price, and evoked very different opinions amongst brokers, than those gathered and manufactured in warm mildly moist conditions of the atmosphere. The scientific conclusions resulting from such analyses as those of Kellner, the results of which Mr. Cochran placed before us in Ceylon, and those which Mr. Cochran himself has made or may make, possess a purely technical interest of no small value. But we need scarcely point out to intelligent planting readers the importance of the results in a practical and cultivator's point of view. There seems no reason why careful pruning and other treatment of tea plants should not be successful in inducing the heaviest possible yields of leaf in those months which have been proved by scientific and practical tests to give the largest proportions to the vegetation of theine, potash and phosphoric acid, on which the economic and commercial value of the tea leaf so largely depend. Mr. Cochran feeling certain of the correctness of his process for ascertaining the proportion of theine (the crystals of which are very beautiful, largely resembling those of quinine), it is obvious that further analyses are required to settle the question whether the Torwood proportion is normal or, from certain causes exceptional. Indeed, there is no reason why, if Mr. Cochran's attention were specially directed to the matter, the result of a series of analyses might not be to enable planters so to modify the processes of withering and fermenting as to retain in the dried leaf a larger percentage than is at present done, of the theine and

potash, which are evidently in large proportion in the green leaf, and which perhaps (?) may be carbonized in the great heat of the roasting process.

So far we wrote last year, and now we may add that if it is the teas grown and manufactured in the mildly rainy weather of March and April, which sell so poorly in June and July, then our conclusion founded on Kellner's Indian tea analyses, may have to be modified, and Mr. Hughes' opinion of the value of heavy rains charged with electricity to tea leaves seems to be borne out by the teas of June and July selling well in August and September. But what we all want are conclusions founded on careful and repeated local analyses as well as on market prices, and the information may possibly enable us to prune and cultivate and manure so as to counteract unfavourable seasonal and climatological influences. We attract attention to the suggestions offered by "R. M. K." in our correspondence columns.

We also attract attention to the letter of a well-known Haputale proprietor who from his own personal observation at home corroborates the professional opinion as to the recent falling-off in Ceylon teas.

PLANTING NEWS FROM DELI.

(Translated for the Straits Times.)

The *Deli Courant* of the 9th June states that there is every prospect of the North German Lloyd Company actively turning to it, and going ahead in the matter of tobacco shipments from that Settlement. They have now under construction in Europe, a new steamboat fitted with the newest improvements in capacity and accommodation. She is intended to ply between Penang and Deli via the coast ports. These efforts in furtherance of trade and readier communication, deserve every success.

The Company carrying on the Arendsburg tobacco state has just declared a dividend of 152 per cent. Its shares are quoted at 820 per cent.

Negotiations between the Netherlands and British Governments regarding the emigration of Tamil coolies from India to Deli have so far advanced that, it is said, the conclusion of a convention is only a matter of a few months. Should the British Indian authorities make no objection, the Netherlands Government will find it no difficult matter to secure the ratification in London, of the arrangements come to by the representatives of the two powers at Calcutta. In Deli, the planters for whose benefit, this has been done do not apparently make the least effort to profit energetically by the opportunity. Nothing whatever has been set on foot to establish for instance, a direct steamer service between Deli and the Indian coolie ports.

No wonder that the planters look out eagerly for the advent of Indian coolies. They cannot manage to hit it off with the Chinese coolies now available. On all the estates, absconding has been alarmingly on the increase. The absconders too often disappear without leaving a trace, and successfully smuggle themselves away, that recovery becomes next to impossible.

INDIAN TEA.

ANNUAL REVIEW.

June 1888.

The business of season 1887-88 being concluded, we are again enabled by the courtesy of our friends to publish the results of many of the leading concerns. While doing so, without entering closely into details, we would refer to the dominant features of the year, in the endeavour to extract whatever light they may throw on the future. The season has been notable for greater uniformity in the value of the general crop than has usually been the case, due to two causes—a partial failure of quality in some noted gardens, and a decided improvement in others. Upon this levelling of values obviously follow the questions: Will there be further development in this direction? Is it worth while ex-

pending so much care and time in the endeavour to make fine tea? Opinions will differ; we maintain, however, that in the long run individual producers, no less than the whole industry, will gain by steadily aiming at a high standard of quality. The experience of many seasons shows that whenever supplies of low teas are plentiful, they sink to a price which leaves but little, if any, margin for profit. So far as we know, the most careful investigation has not yet been able to explain why some of the best estates have not maintained their position—management, appliances, and system being unchanged; nor why, if climatic conditions are alone accountable, it should be as marked in Assam as in Darjeeling. In the former district it may be that too many have tried to make tea of a particular type, and some have lost the valuable characteristics of body and strength, without gaining the special pungency at which they aimed, and which certainly is not to be attained merely by light fermentation. So much attention has been paid to the subject of fermentation that it is unnecessary to say more: but it should be realized that as a larger portion of Indian Tea enters year by year into the retailers' canister, so a growing preference is shown for those kinds which can be readily used in place of China Congou without entirely altering the character of the blend, not only to the palate, but also to the eye, in the colour of the liquor. Some of the most successful blenders who are among the largest users of Indian Tea now habitually select those with deep coloured infusion and ripe mellow flavour, and pass by the pale pungent variety which a theorist would possibly pronounce to be finer tea. This year they have found what they wanted in the produce of some of the younger Sylhet Estates, which have taken such a leading position in the Trade's estimation—but they buy without reference to district or brand, and care not whence the tea comes so long as it suits their requirements.

Value is now less dependent upon appearance than it used to be—except for the particular Irish demand for stylish Pekoes and Broken Pekoes—for the trade in tea is gravitating towards specialists, blenders and large Tea Houses, both in London and the Provinces, who are provided with the best machinery for cutting and sifting, and prefer to buy whole leaf which they can themselves manipulate as required. The numerous complaints which reach us of depreciated quality, from those who have had occasion to hold Stocks, and the instances of teas landed in low condition need to be referred to, as it is generally believed that the remedy must be sought in a more thorough system of firing, by which high aroma, and the keeping quality which usually accompanies it, can be secured without *overfiring*—a fault which lowers value here, and shuts tea out of many foreign markets. This question, however, has doubtless engaged the serious attention of all estate managers, who are of course experimenting in the hope of discovering the cause of the shortcoming and the remedy.

Writing a year ago we expressed the opinion that low prices would lead to increased Exports to other Markets, and to some extent this has been the case; but no statistics are procurable. Hitherto the demand from the Continent, the States and Canada has mainly been for Kangra and Darjeeling growths of true flavour which throughout the season have been worth more here than the Foreign wholesale buyers will pay: but, latterly, persistent efforts to push trade abroad have shown that some other kinds can be sold in moderate quantities at about the parity of London rates; and there is reason to think that the deterioration of the Japan and China crops—which is felt abroad as well as in the United Kingdom—may open the way, and bring the opportunity which has been waited for so long.

The effect of Ceylon upon the market for Indian has not proved to be as prejudicial as some Indian Planters feared: and an increase in Consumption in one year of 10 million lb. of Indian as against an increase of 5 million lb. of Ceylon shows that the older industry is not outstripped by its younger rival but rather there is room for both.

The loss has fallen upon the China Trade; but it must not be forgotten that the last was an unusually poor crop, and if China were to produce better tea, different results might follow. Our present information points to improved quality from China with a smaller Export; and it is but reasonable to assume that 4d. per lb., the ruling price for common Congou, must lead to alteration in manufacture, and curtail supplies. With the increase, however, from India and Ceylon, twenty-five millions less from China would leave us still fairly supplied, and we must be prepared for the most part of the year to see the lowest grades on the market at the time being, wherever produced, selling at or under 6d per lb. There is, unfortunately, no question but that average retail price has declined—latterly even in Ireland, so long the market for high-priced Indian tea—the "2s canister" being largely superseded by a lower priced one. Nothing but an actual short supply seems likely to remedy this, and until it occurs competition among distributors will keep down the quotation. This seems to contradict the evidence of last season that consumers were discarding "cheap" in favour of "good" tea; but the explanation may be found in the fact that the abundant supplies of Indian and Ceylon, and the extremely low prices which have been ruling even for tea of superior quality, now enable a cheap tea to be sold which satisfies a large portion of the public.

The difficulty which the buyers find in handling the heavy supplies poured into the market between Sept. and March, has been lessened by the policy adopted by some of the principal producers of making much larger breaks than heretofore by shipping several invoices by one steamer, and bulking together in London. Though not so perfect a system as smaller invoices, factory bulked, it appears to have been successful, for it accords with the drift of opinion among buyers—and it is indisputable that more attention is paid to large lines than to smaller parcels—the finest grades of course being an exception, of which large breaks are not expected. The question of reducing the number of days in the week on which Auctions are held has been discussed by the buyers: to carry this out a general agreement among all parties concerned would be necessary.

The following are the statistics for the past three seasons, dating from 1st June to 31st May:—

IMPORT.			
	1887-88.	1886-87.	1885-86.
Indian ...	86,371,000	78,200,000	67,210,000
Ceylon ...	14,705,000	8,660,000	5,060,000
China ...	117,185,000	138,900,000	143,050,000

WM. JAS. & HY. THOMPSON, Brokers.

* Lowered below the average by heavy clearances in March-April 1885, when an increased duty was expected.

IVY ON TREES.—Your correspondent, "R. E. I.," evidently does not understand much about the nature of trees, nor of the Ivy which encircles them, for trees are not rendered tender in consequence, neither does Ivy when it is killed relax its hold, as "R. E. I." can easily determine if he will only take the trouble to try it on one or more trees.—W. H. R.—*Gardeners' Chronicle*.

EARLY MULCHING OF FRUIT TREES.

The highly beneficial effects of mulching are now generally known and admitted by most gardeners, but it is seldom that the operation is carried out in time, to be of the great service it otherwise would be, as when deferred much of the moisture that might have been retained in the ground has evaporated, but when a mulching, even of a very slight nature, is put on, evaporation is intercepted, as the searching winds are prevented from acting on the surface and causing it to crack and gape. This being so, it will at once be seen how important it is to get the work done early, and especially is this so in the case of fruit trees and Strawberries, as not only does it save much time and labour in watering, but it keeps weeds down, and may be carried out more expeditiously now, than when Strawberries get more forward, as the foliage spreads more then, and the stems are borne down by the weight of the fruit. As the lays on the mulching, the most suitable thing to use is clean straw, or fresh stable litter, which latter, if applied now, becomes washed and sweetened by the rain and air, and is not objectionable in any way when the Strawberries are ripe. Where Fern or Bracken can be obtained, and slugs are troublesome, that forms perhaps the best of all protectors, as it breaks and splinters up, forming very sharp edges and fine pointed ends, against which the slugs cut or pierce themselves, and soon beat a retreat. Bracken has also another advantage in that it lays lightly and dries quickly, which is much in favour of the Strawberries, which, on an unsuitable bed, soon taint from mould, and rot if the night dews be heavy or the weather wet. Market growers and others near towns often use tan, which generally may be got for a mere nominal sum, and a very good mulching it is, but when done with it should be all cleared off the ground, as to dig it in is harmful till it has become decomposed. As to the fruit tree, half-rotten manure answers well, but almost any rubbish may be given, the chief object being to shade the land; and prevent any washing when water is given. In regard to Peas and Scarlet Runners, these should always have a good mulching along each side of the rows. For flower-beds, coconut-fibre is most excellent, and may be had cheaply; and leaf-mould and old Mushroom-dung are both excellent for the same purpose, and good afterwards for forking into the ground.—J. S.—Gardeners' Chronicle.

NOTES ON ESSENTIAL OILS, &c.

Abstracted from the April Report of Messrs. Schimmel and Co., Dresden.

Eucalyptus Oils.—It is stated that the demand for the oil of *Eucalyptus amygdalina* has decreased since it has been recognized that it contains no eucalyptol, although its production is increasing, it being now distilled in New South Wales and Tasmania. On the other hand the demand for oil of *Eucalyptus Globulus* increases, and Algeria is said to be taking place as the principal source. Oil equal in quality is received from California, where it is produced in large quantity as a bye-product by the "Downer Boiler Incrustation Preventive Company." In addition to the manufactured oils imported into Germany, it is thought probable that it will be found possible to distil it profitably from *Eucalyptus Globulus* leaves from South France and Africa. The oil obtained in a first distillation corresponded in its general properties with the commercial French and Californian distillates, but the distillation of it yielded some interesting information. This oil showed a specific gravity of 0.925 and was dextrogyre (+50). The specific gravity of the commercial varieties referred to varies between 0.915 and 0.925, and though they are always dextrogyre, their rotatory power varies between 1.3° and 15.4°. Six commercial samples examined varied from 50 to 70 per cent. in the amount of eucalyptol they contained, and as eucalyptol is optically inactive, this property might be utilized in judging the quality of an oil. In distilling the leaves of *Eucalyptus Globulus* aldehydes of the fatty acids were observed; the presence of valeraldehyd was determined with certainty, and ap-

parently butyraldehyd and probably capronaldehyd were also present. The greater part of these bodies was dissolved in the distillation water; but the valeraldehyd could also be detected in the oil; it was also present in two commercial samples of the oil. Messrs. Schimmel state that the oil of *Eucalyptus amygdalina* differs from all other eucalyptus oils known to them and contains probably scarcely any oxygenated constituents; it more likely consists of at least one well-characterized terpene (C₁₀H₁₆) and possibly a small quantity of cymol. Its specific gravity is 0.890, it boils practically between 170° and 180° and is levogyre. Observations on three different samples gave in a 100 m.m. column a rotatory power of -27°, -28.4° and -28.6°; consequently this property allows of it being easily distinguished from the dextrogyre oil of *Eucalyptus Globulus*. Messrs. Schimmel have been favoured by Mr. C. T. Staiger, of Brisbane, with samples of a series of oils from species of *Eucalyptus* which were shown at the Colonial and Indian Exhibition. These appear to be the same as those Exhibited in the Queensland Court and reported on in this Journal (*Pharm. Journ.*, [3], xvii., 142), but in some respects the information given in Messrs. Schimmel's preliminary report on the specimens varies from our supplements that which has already appeared. The oils, eight in number, were from the following species:—

1. *Eucalyptus Bayleyana*.—Strongly resinified; sp. gr. 0.940; boils between 160° and 185°.
2. *Eucalyptus microcorys*.—Strongly resinified; sp. gr. 0.935; boils between 160° and 200°.
3. *Eucalyptus maculata*, var. *citriodora*.—Sp. gr. 0.905; boils from 209° to 220°.

These three oils are very similar to one another. They possess a magnificent melissa-like odour, which especially in the oil of *E. dealbata* is manifest in a surprisingly fine and rich bouquet. It is thought they will prove to possess extraordinary practical value. Chemically the three oils are quite characteristic. Neither of them contains a terpene, but they consist of a ketone (C₁₀H₁₆O), smelling like melissa, and a body that is probably an alcohol (C₁₀H₁₈O?), which possesses a beautiful odour resembling that of geranium.

6. *Eucalyptus Staigeriana*.—Sp. gr. 0.880; boils from 170° to 230°.
7. *Bachkousia citriodora*.—Sp. gr. 0.900; boils from 223° to 233°.

Both these oils are distinguished by an intense odour of lemon or verbena, and for the *Bachkousia* oil especially there is probably a future. The most important constituent of the two oils is a ketone (C₁₀H₁₆O?) with a strong pure lemon odour. *E. Staigeriana* contains a considerable quantity of a terpene, whilst that of *Bachkousia citriodora* appears to consist principally of the previously mentioned ketone.

8. *Eucalyptus hemastoma*.—Specific gravity 0.890 boils from 170° to 250°. This oil differs from all other described eucalyptus oils, and has an odour resembling that of cumin oil. It contains terpene and cymol, and among the oxygenated compounds is one having a peppermint odour, probably menthon.

From the foregoing statements it is evident that the oils of eucalyptus manifest great diversities in properties and character, probably exceeding those of the oils of any other genus.—*Pharmaceutical Journal*.

DISEASE OF COCONUT PALMS IN THE WEST INDIES.

(From the Bulletin of the Jamaica Botanical Department.)

The following article appeared in the *European Mail*, 1st July 1886, and as it sums up what had been done to that date, may be usefully reproduced.

The growing of coconuts is fast becoming a large industry in the West Indies, and we find that Jamaica exports about three millions annually, while the exports of Trinidad are about ten millions. The export value of the coconut industry in these two islands

is, therefore, about 50,000 annually. The other British West India Islands do little or nothing in coconuts. Tobago, so depressed in every industry, has, however, made some progress in the planting of coconut palms, and before long she may show a respectable item in her export list for these commercial nuts. Her present export is about 800,000 nuts, of the value of 2,500*l*. At Grenada, St. Vincent, St. Lucia, Dominica, Antigua, and other islands of the Leeward group, coconuts are grown more or less successfully, but the greater number of the nuts are consumed locally. Indeed, as contributing to the food supply of the inhabitants, and as entering into almost every item of their daily life, the coconut palm is invaluable. Hence it may be safely estimated that for the whole of the West India Islands, the annual value of the produce of the coconut palm is double of that exported, and may be placed at about 100,000*l*.

It is somewhat remarkable, and a strange anomaly in West Indian economies, that the tropical and fertile island of Barbados should be unable to grow coconuts sufficient for its own wants. This, however, is the fact. To begin with, Barbados has a teeming population of about 140,000 souls, and nearly every foot of its beautifully-kept and productive soil is devoted to the growth of sugar cane and sweet potato. A few coconut palms are seen to fringe the coast, but they do not provide a morning drink of the delicious "coconut water" to a tithe of the inhabitants. Hence coconuts are imported to Barbados from any of the neighbouring islands that can spare them, and they provide at once meat and drink to the densely-packed black population, that would otherwise have to subsist on flying fish and sweet potatoes or American corn meal. It is not, however, a matter of choice as regards growing coconuts at Barbados. For many years the few trees attempted to be grown there have presented more or less diseased conditions, and the produce in nuts has been very small. In 1880 Mr. D. Morris, Director of Public Gardens and Plantations at Jamaica, investigated the condition of the coconut palms at Barbados, and found they were attacked by a small scale insect, which covering the underside of the fronds, destroyed them as soon as they attained maturity. The disease was general, and affected every palm alike. As long as this disease is present in force it is hopeless to attempt to grow coconuts at Barbados. Since 1880 Mr. Morris' attention has been given to the condition of coconut palms in other parts of the West Indies, and naturally those in Jamaica have come under particular notice.

In 1882, a disease very similar to that at Barbados was found in certain portions of Jamaica, but it is evidently not confined either to Barbados or Jamaica, but is more or less prevalent everywhere in the West Indies. In a recent report on the subject, from which we are privileged to make a few extracts, Mr. Morris classes the diseases to which coconuts in the West Indies are liable under two heads, viz., the coconut beetle and the scale insect. As regards the coconut beetle, the attacks of this insect are confined to the trunk of the coconut palm or to the terminal bud, sometimes called the "cabbage." If a tree is suffering from the attacks of the beetle the first signs will appear among the young leaves in the centre of the crown of fronds. These will have a withered, drooping aspect, becoming more and more pronounced as time goes on, until at last the whole head will turn brown and withered. With the occurrence of the first strong breeze the head falls off, leaving nothing but the bare stem remaining. The best cure for the beetle, if noticed in time, is a handful of salt or unslacked lime dusted into the centre of the palm, which will gradually dissolve and find its way into the leafbud, where the beetle is at work, and destroy it. This, however, can only be conveniently done when the palm is young and within easy reach. Fortunately, however, although many coconut trees are destroyed by the palm beetle, its ravages are not serious at present, and it is quite possible they may never become so.

With the scale insect, however, it is different. During the last five years this insect has become more and more prevalent on coconut estates in Jamaica, and Mr. Morris appears to have corresponded with planters in different parts of the Island, and kept the disease under observation during the whole time. The result of his investigations, as detailed in the report above mentioned, are briefly as follows:—The scale insect, in appearance like a minute oyster or limpet, attaches itself to the underside of the fronds of the coconut palm, and covers them with a thin silvery coating, which rubs off when scraped with a knife. Underneath the scale,—one of which is only about the twelfth part of an inch in length,—there lies an insect armed with a proboscis, by means of which it penetrates into the tissue of the frond and sucks up its juices. Generally, when lifting up one of the scales, there is found, not only the female scale-insect, but also a large number of eggs, which, when hatched, give rise to a colony of small scale insects. These ultimately escape by a small hole in the scale, or general covering. It will be noticed that the coconut palm suffers from the scale insect by the loss of its juices, absorbed from the leaves by the myriad colonies of insects clustered beneath them. The disease spreads by the colonies of scale insects being carried from tree to tree, or from estate to estate, by the wind. It was first noticed in force in the parish of St. Mary's, Jamaica. Like the aphid blight which appeared on sugar canes some years ago, the scale insect has spread in the direction of the trade winds, and affected estates to the south and west. The first appearance of the scale disease is shown by the outer frond turning brown and withered, and ultimately becoming quite dead and dry. In this respect it differs from the beetle, where the head is first affected and the outer leaves only at the last. If the scale disease is persistent it gradually spreads from the outer to the inner leaves, but, so far as Mr. Morris' observations are concerned, the scale disease does not destroy the trees, although it weakens them to such an extent as to spoil their bearing. To planters the most important considerations, however, are,—(1) How has the disease arisen? and (2) How may it be checked or removed? Quoting a very valuable little book, by Miss Ormerod called "A Manual of Injurious Insects," lately reviewed in these columns, Mr. Morris expresses his opinion that this disease has spread owing to the unprecedented prevalence of dry weather, in the West Indies, and he finds that the severer the drought the worse the disease. "Insects of this class multiply most quickly in dry weather, and on plants which are sickly from drought, exhaustion by insect attack or other causes; so that all measures of cultivation tending to produce vigorous healthy growth are serviceable in counteracting attack; and where circumstances allow of the application of liquid manure, or of water to an extent to make the plant food in the soil invaluable and push on growth that otherwise was being checked by drought, such treatment would be desirable." Several other points are touched upon, such as that coconut palms grown inland, where there is an absence of salt in the soil, being less able to resist the disease, suffer more than those near the sea; that where practicable, coconuts should have a good dressing of manure applied to their roots as soon as the disease appears, and that irrigation be applied whenever practicable. As regards other treatment, Mr. Morris mentions that the fronds affected by the scale insects should be cut down and that they should be heaped up and gradually burned under the trees to give off as much smoke as possible, without, however, injuring the foliage by heat. In fact, it is believed that by thoroughly smoking the insects in the first stages they may be destroyed, but beyond that it is hopeless to cope with a disease so widespread in its habit or so difficult to bring under careful treatment. It is somewhat consolatory to learn that in Mr. Morris' opinion the disease is likely to be greatly reduced on the return of regular rains, and that it cannot ultimately affect the value of coconut properties in Jamaica. Planters in the meantime are, however, specially urged

to take the simple steps noted above, and reduce the effects of the disease on their plantations as much as possible.

Mr. Hart also noticed the disease in his report for the year ending September, 1886, and mentioned various remedies.

The following letter has already appeared in the Jamaica Gazette:—Botanical Department, Gordon Town P.O., 16th January, 1888. Sir,—In continuation of my letter dated 7th September, 1887, No 2424, on the coconut disease in the neighbourhood of Bath, I beg to report that on a recent visit to Port Antonio I found that the same disease was attacking the coconut palms there, and especially the young plants.

2. Mr. Watson, who has charge of Captain Baker's plantations, appears to have been successful in getting rid of the disease on the young plants by a simple and inexpensive method. He placed a heap of dry leaves, &c., round the base of each stem and allowed it to burn for some time. The flames scorched and burnt the outer leaves of the palm, at the same time killing the scale-insects, and new leaves are putting forth, which look healthy and free from the disease. I am inclined to think that the smoke caused by the burning had a greater effect than the heat, for it could penetrate to inner parts where the flames could not act. If so, a similar plan might be tried with even the tallest palms, by packing the bases of the outer leaves with dry bush, rotten wood, or some material which would give dense smoke without flame. Sulphur might also be tried. The application of this or any other remedy should be tried at different times of the year, for a remedy which would have no effect on the eggs might completely extirpate the disease if applied when the young insects are hatched out—probably about May or June.

3. A correspondent from the Grand Cayman informs me that the coconut palms have been infested with apparently the same disease for forty years, and that "tens of thousands" of trees have been destroyed.

4. The subject is of great importance as a coconut palm in bearing is calculated to be worth five pounds, and if the disease spreads much in Jamaica, the total loss will be very considerable.

5. It is to be hoped that the results of any experiments made for the extirpation of the disease will be communicated to me, in order that they may be published for the benefit of others. I have, &c., W. Fawcett, Director, Public Gardens and Plantations.

NATAL FRUITS.

The following interesting letter from Dr. Sutherland, M.D., to the Colonial Secretary, in answer to several pertinent questions put to him in reference to Natal fruits, appears in this week's *Gazette*:—

9th July 1887.

The Hon. the Colonial Secretary, Natal.

Sir,—Referring to your communication enclosing copy of a letter dated the 14th August, 1886, from the Royal Gardens, Kew, together with a series of questions touching the fruit products of your colony, I have the honour to subjoin all the information I have been able to collect.

Question 1.—Please give a list (giving both the local and scientific names) of the chief fruits grown in the colony, in order of their importance.

1. Pineapple (*Ananassa sativa*).
2. Banana (*Musa sapientum*).
3. Plantain (*Musa paradisiaca*).
4. Orange (*Citrus aurantium*), in great variety.
5. Nectarine.
6. Lime (*Citrus limetta*).
7. Lemon (*Citrus limonum*).
8. Shaddock (*Citrus decumana*).
9. Citron (*Citrus medica*).
10. Peach (*Amygdalus persica*), in variety.
11. Apple (*Pyrus malus*), in great variety.
12. Quince (*Cydonia vulgaris*).
13. Apricot (*Prunus*).
14. Fig (*Ficus carica*).
15. Pear (*Pyrus communis*).
16. Grenadilla (*Passiflora edulis*).

17. Loquat (*Eriobotrya Japonica*).

18. Grape (*Vitis vitifera*), Cape varieties and Catawba.

19. Strawberry (*Fragaria virginiana*).

20. Cape Gooseberry (*Physalis pubescens*).

21. Amalouquia (*Arbutin grandiflora*).

22. Tamarind (*Tamarindus Indica*).

23. Mango (*Mangifera Indica*).

24. Avocado Pear (*Persea gratissima*).

Question 2.—During what months are the chief fruits attainable? What quantities of each approximately are available for export, and what are the wholesale prices locally?

Pineapples, generally a coast product, but grown up to 2500 feet in sheltered localities, are available from January to August—in exceptional cases, the whole year. Supply equal to any demand. Prices 1d. to 3d. each, according to season and quality.

Bananas and plantains produced on the coast, and up to elevations of 1500 feet, are available generally throughout the whole year. If there were a demand, the supply would be unlimited. Prices vary from one to two shillings a bunch, according to size and quality.

Oranges, limes, &c., are available from April to August. Grown all over the colony the supply would meet any reasonable demand. The prices vary according to seasons, being lowest between May and August, and highest during the scarcity. Immense quantities are lost annually for want of a market. Marmalade and lime juice may be prepared in unlimited quantity. This industry is extending rapidly, and will soon be sensibly realised.

Peaches are universally grown all over the colony, certain varieties being adapted for the warmer coast districts, and others of the hardier and better-flavoured varieties more suitable for the colder and more elevated districts. They are available from December to February. The supply is far in excess of the demand, and can be pushed to any extent if there were a market. Fully three-fourths of the crop is annually lost from want of a market and the perishable nature of the fruit. Much is preserved for local use. A price, under the circumstances, can hardly be given. When the fruit is offered for sale it is merely to cover cost of gathering and carriage to market.

Apples, like peaches, are grown all over the colony, the hardier varieties being in the upper districts. The supply is far in excess of the demand, there being no market for the produce of every farm and garden. The fruit is in season from December to January, and prices are such as cover cost of gathering and carriage to market, 1s 6d to 3s a hundred, according to size and quality.

Quinces, like apples, thrive best in the upper districts of the colony. They are in season in January, earlier or later according to situation; cultivation capable of extension unlimitedly if there were a market. The fruit is often preserved but seldom sold, there being no demand.

Apricots come into season in November. Any demand could be met by large supplies. The price, 2s and 3s per 100 for first supplies, soon falls; owing to the limited market.

Figs are ready in January, and continue in season for two or three months. Production may be extended indefinitely. Prices just sufficient to cover cost of gathering and carriage to market.

Pears are in season in February, and can be produced to any extent. Prices when sold are nominal.

Grenadillas are in season from November to May. Its growth is capable of indefinite extension. Prices vary according to season, 1s 6d a bushel being a common quotation, and insufficient to cover cost of gathering and carriage.

Loquats are in season in May; capable of extension indefinitely; prices nominal, merely sufficient to cover cost of carriage.

Grapes come into season in December, and continue for two or three months. The price varies from 6d to 1s per lb., according to varieties, quality, and season, the Cape varieties being the most expensive. The Catawba, owing to general hardiness and free-

dom from disease, is capable of extension without limit. A valuable preserve is being made from this grape, which threatens to take the place of black currant jelly.

Strawberry.—This valuable fruit is coming into general cultivation, and may be extended on any scale. It is in season from December to April. Prices vary according to season, 6d a pint being the minimum.

Cape Gooseberry.—This valuable esculent is not cultivated, being permitted to occupy fences and fallow lands in native use. It might be taken into cultivation, and by this means could be extended. The natives enjoy the entire trade, collecting the fruit in their own way and at their convenience, selling it to Europeans in town or country. The price is generally about 4s 6d a bushel. According to situation as to coast or upper districts, the fruit is in season from February to May. This fruit is made into a jam, which is hardly ever known to ferment.

Amatungula.—This is entirely a coast plant, and the fruit is in season from January to May. As a rule the plant has not been cultivated, but it admits of ready extension by cultivation and thereby its productiveness is greatly increased. The natives collect the fruit from the plants in their wild state, and dispose of it to Europeans. The price, therefore, varies from a mere nominal sum to anything they can get.

Tamarind.—This has been tried, but on a limited scale. The fruit ripens in May, but there is scarce any demand for it.

Mangoes can be grown in abundance, and come in to season in May, but there is no demand for them.

Avocado pear can also be grown in abundance, and comes into season in March, but there is no demand for the fruit.

Question 3.—What fruits are at present exported (1) in a fresh, or (2) in a preserved state? Please state the destination, the quantity, and the estimated value of each sort.

In 1886 the dried and preserved fruits exported were entered of the value of £422, but the sorts are not enumerated. The green fruit exported, chiefly bananas, were entered of the value of £2439. Both kinds, viz., the preserved fruits and the green or fresh, were shipped to the Cape Colony.

Question 4.—Are all, or any, of the fruits mentioned above capable of being produced in much larger quantities than at present? If so, what steps are necessary to start or develop a fruit trade, and what inducements, if any, do local men specially desire to open or extend a trade in fresh or preserved fruits, either with the mother country or neighbouring states?

All the above-mentioned fruits are capable of being produced in much larger quantities. The absence of a market has deterred the farming community from pursuing this industry beyond their own special and local requirements. The steps, in my estimation, necessary to develop a fruit trade are, first, the preservation of the fruit either by judiciously drying it or by preserving it in time. Messrs Jameson & Co., Durban; Hulett, Nonoti; Ladds, Mooi River; and Blaker, Estcourt, have made a good start in that direction, and others will follow their example. Local men complain that the tariffs of neighbouring states militate seriously against the use therein of Natal preserved or green fruits, import duty being so high as to prove prohibitive. This, no doubt, is (as the question would be viewed in the light of free trade) omitting the consideration of the question whether the industries of these states do not stand in need of some such protection as is secured by a high import duty. The trade with the mother country is seriously menaced by the long ocean voyage and the risks of damage to green fruit, however well it may be prepared before embarkation. In the case of preserved fruits, the new industry here will have to cope with the same industry established in other colonies and states for many years enjoying a reputation which cannot easily be set aside.

Question 5.—What fruits are now imported into the colony, either fresh or preserved? Please state kind, quality, and value, and the market whence derived.

Dried fruits, unspecified, from the United Kingdom, 80,000 lb.; value £1252. From Bombay, Calcutta, and Madras, 195,867 lb.; value £612. Mozambique, 608 lb.; value £8. America, United States, 850 lb.; value £14. Currants and raisins from the United Kingdom, 183,828 lb.; value £2541. From Cape Colony, 34,548 lb.; value £346. Preserved fruit from United Kingdom, unspecified, 26,378 lb.; value £653. Calcutta, 180 lb.; value not specified. Cape Colony, 38 lb.; value £8. Fresh fruit:—Cape Colony, quantity not specified, value £180. Mauritius quantity not specified, value £10. The total of imported fruit, preserved, dried, and fresh, is nearly £6000 per annum, while the exports are not quite half that sum.

Question 6.—Please add any special points of interest connected with the fruits of the colony herein reported upon, which are desirable to place on record.

In certain conditions of the weather favourable to the development of insect life, fruit is liable to suffer much, the only remedy for which is the maintenance of the trees in the most vigorous possible condition, giving proper heed to the due supply of manure and moisture. Violent hailstorms occasionally do much damage; but as they are very local it rarely happens that a district suffers. Of two plantations a quarter of a mile apart, one may escape entirely, while the other may have been entirely denuded of its fruit.

Regarding the institution of a fruit trade with the mother country, or with the neighbouring states, it appears to me that the first object should be to remove the necessity there is for importing fruit in a preserved state or dried. As I have already observed, steps have been taken towards this end. When imports cease, no doubt there will be a surplus of preserved and dried fruit which may with perfect safety be placed upon the markets at home, or in other colonies or states where there may be a demand for the same. Much experience and unwearied care are necessary in the conduct of the export of fresh fruit. Facilities of shipment are, it is true, so great now, as to lessen the time the fruit requires to be at sea considerably below the period required fifty years ago for the passage from the Mediterranean or the Azores. It should, however, not be forgotten that the latter slow passage was made by a sailing vessel in a cold season of a temperate climate, while the modern quick passage is made through the tropics in a steamer of great heat. Preserved and dried fruits suffer comparatively little from such heat as would be totally destructive to fresh fruit. Much no doubt may be done by careful packing and the maintenance of the lowest temperature circumstances may permit, but these conditions may involve expenses that will exceed the value of the fruit when exposed for sale in the home markets.—I have, &c., (Signed) P. O. SUTHERLAND.—*Natal Mercury*.

NOTES FROM PEERMAAD (TRAVANCORE), April 10th.—The splendid showers with which we were favored last month brought out a grand blossom, and the sorely-tried coffee-planter is beginning to feel a wee bit cheerful again, and almost to realize that the big crops of 15 years ago were actual facts, the "chiefs that wanna ding," and not new creatures of his imagination! Such a blossom has not been seen in this district for many years, and there is, so far, every prospect of the coming crops being a good one. Many of those, both here and elsewhere, who have gone in largely for tea, and whose opinions regarding the utter hopelessness of attempting to cultivate coffee successfully have been so extensively circulated, are, while no less loud in their praises of their pet product—tea, a trifle less abusive of "the Old King," and are compelled to admit that their condemnations were perhaps a little too strong. Tea has also benefited enormously by the showers, and has been flushing nicely, so that planters generally are cheery, and, if not altogether satisfied with their prospects—by the way, when do agriculturists ever admit that they are satisfied?—are decidedly much less dissatisfied than they have been for years.—*Madras Times*.

DESTROYING WEEDS UPON WALKS.

The recommendation of Mr. Horsfield to use arsenic for this purpose is in many ways too dangerous, even though effectual ever to become generally used. Gentlemen who preserve peasannts would, I feel sure, object to the distribution of such a dangerous poison upon the walks, having used muriatic acid with most satisfactory results. I can recommend its use as a most effectual and economical plan of removing weeds from walks, and consider there is no more danger and less inconvenience in its application than there would be with boiling water. I used it in the proportion of one to five of water, and found that of this strength it was certain destruction to all vegetation. To sprinkle it upon the walks, an earthenware watering-can is best; but if an ordinary metal watering-can be used every part of it must first receive two coats of best white paint, because on the paint the acid seems to take no effect, whereas without the paint the watering-can is destroyed after being once used. Zinc causes the acid and water to appear as if boiling, and so much heat is generated that the zinc will be found to have disappeared, so that if any vessels but earthenware are used they must first be well painted.—T. R.

In your last issue there appear two enquiries as to the best method of dealing with weeds on gravel walks, drives, &c., which at this season of the year are particularly troublesome. As I have had some experience with very weedy and neglected paths, I venture to offer the following suggestions. For a very small garden path, a few kettlefuls of boiling water poured over the weeds will immediately and effectually destroy them. This remedy has the merit of being inexpensive, and for a little path always available. In a large way I should prefer to use commercial hydrochloric acid; or muratic acid as it is sometimes called—1 gallon of acid to 50 gallons of water. This is very destructive and complete in its action; it is also very cheap, being obtained as a by-product in the manufacture of sodium carbonate (common soda). I have also used with unequalled success crude carbonic acid or phenol—1 gallon of phenol to 70 gallons of water. This also is very efficient and lasting in its results, and, diluted to the extent which I have mentioned, it is exceedingly cheap; and I may say there is nothing with which I am acquainted that is so utterly destructive of plant life as either of the above. In applying these solutions it is best to walk backward. The diluted H. Cl. will act but very slightly on the zinc of galvanised watering-pot; it will rust iron quickly, and make clothes and boots rotten. Great care should be taken to thoroughly clean all watering-cans, &c., after being used, to prevent injury to other plants. The employment of the above is far preferable to the use of arsenic, which, after destroying the weeds, remains unchanged to be blown about and inhaled by all who frequent the paths, producing the unpleasant symptoms of cold in the head. Its use, therefore, cannot be too strongly condemned. I trust the above suggestions will meet the case of your correspondents and other readers of your journal who may be similarly situated.—W. CHAS. BENEDICT.—*Gardeners' Chronicle*.

CITRIC ACID IN THE CRANBERRY.—It has been long known that citric acid exists in a great number of plants, but in a few only has its precise quantity been determined. This has recently been done by a Russian chemist, P. Kosovic, in the *Oxyococcus palustris*, or cranberry. The amount of citric acid found in three samples of this species was 20, 24, and 28 per cent of the total weight of the berries. As these plants grow wild in vast quantities in many districts of the interior and north of Russia, the author proposes to use the juice of the berries for industrial purposes, for instance, in dyeing, instead of the concentrated lemon juice imported from Italy. We fear the lemon will prove a terrible rival to the cranberry, if the latter will only yield about 24 per cent of citric acid.—*Burgoyne, Barbadoes & Co's Price Current*.

CAULIFLOWERS FROM FINISTERRE.—It is stated in the *Revue Horticole* that for the last fortnight there have been sent away from the railway stations of Saint Pol-de-Leon, Roscoff and Plouenan, to all parts of France and of Northern Europe, from seventeen to eighteen waggonloads of Cauliflowers daily, each waggonload weighing 4000 kilos. It is calculated that the total quantity sent away during the sixty days of the Cauliflower season will reach 4040 tons, which, at the rate of 85 francs per ton, equals 346,800 francs, and the wholesale selling price of these by the dozen heads, at 2:50 to 4 francs per dozen, will realise 1,105,000 francs.—*Gardeners' Chronicle*.

A NEW USE FOR COCONUT SHELLS.—Now that the time for thinning out seedlings has come round, it occurs to me that some of the readers of the *Gardeners' Chronicle* may possibly be interested to hear of a device which has saved the lives of many of my young transplanted annuals, even of *Poppies* and *Eschscholtzias*, which do not take kindly to being moved. I find that nothing does so well as a protection for newly planted out seedling as empty Coconut shells neatly sawn across so as to form two cups. After being soaked in water these little brown nuts (which are not unsightly, being the colour of the soil) effectually shield the young plants under them from the scorching rays of the sun, and keep them fresh and moist till they get accustomed to their new position. After the first twenty-four hours the covers may be removed, but in very dry weather it is safer to keep them on for another day or so, taking them off at night to give the plants the benefit of the dew, and to prevent their becoming sickly from want of light and air. I may add that I have tried these Coconut shells with great success to keep the frost from newly planted *Glaucolus* bulbs, and also to cover newly sown seeds, which we are told ought to be kept moist and in the dark till they germinate. True, a good many shells are wasted, but, packing as they do one in another, they take up little room, and can easily be stored when out of use. I have a large stock, having received a boxful from a friend in Tobago, and if any gardener would like to try them, I shall be most happy to make him a present of a couple of dozen, if he will apply to me for them through the editor of the *Gardeners' Chronicle*.—G. LAYARD, The Crescent, Leatherhead.—*Gardeners' Chronicle*.

BANANA CULTURE IN CENTRAL AMERICA.—From two Consular Reports recently received—the first from Carthagena and Santa Martha, and the other from San Jose, Costa Rica—it would seem that the cultivation of the Banana is receiving a considerable amount of attention in Central America. At Riofoco, some 15 miles beyond Cordoba, the land is described as being very fertile, and with the prospect of the railway shortly connecting this locality with the port of Santa Martha, the Banana cultivation has been started with the view of exporting the fruits to the United States of America, where there is an ever-increasing demand for them. This particular cultivation is said to have the great advantage that the Cocoa tree can be planted beneath its shade, and by the time the Banana begins to degenerate and has to be cleared away, a valuable Cocoa plantation is there to replace it. The lands of Riofoco are also especially adapted for the successful production of Cocoa. The report from Costa Rica says:—"The Banana grows best in the lowlands, hot and even marshy plains, where the tropical rains most abound. There are large tracts of land on the Atlantic coast in the plains of Santa Clara through which the railroad runs from Carrillo to Port Lemon—a distance of about 70 miles—which a few years ago was forest land, but now for the most part is cultivated with Bananas. This forest land can be bought at from £1 to £2 per 2 acres, the cost of cleaning is about £3, and eighteen months or less after planting the sucker the Banana tree bears fruit. Beyond keeping the land free from undergrowth the tree requires but little attention. At present the fruit is brought, delivered alongside the railway, at 43 cents, or 1s 4d. a bunch of nine hands, and 24 cents, or 8d. per half bunch of seven and eight hands."—*Gardeners' Chronicle*.

Correspondence.

To the Editor.

COFFEE FOR HIGH ELEVATIONS.

Soerabaya, 5th June 1888.

SIR,—Can any of your readers assist me with the following information?

Is there any known variety of coffee which will grow well and bear freely at an elevation of from 5,000 to 6,000 feet? Our Java coffee will grow at 5,000 feet and bear fairly also; but the growth of the shrubs is very slow indeed.

Would the "Coorg" and "Mysore" varieties do well at those elevations?" Can any of your readers send me some chosen seed of those two varieties by post? I should like to make a trial of them here and can plant them almost at any elevation, if those sending me some will mention the best height.

Can I reciprocate in any way from here, your friends have merely to mention how.—Yours faithfully,

T. C. W.

[Had coffee only remained free of disease in Ceylon, we should have recommended seed from some of our higher districts, the plant being cultivated close to 6,000 feet successfully before the leaf fungus fully developed. Now, we should say seed from the higher estates on the Nilgiris would do best, and if any of our readers care to accept T. C. W.'s offer about reciprocating, we shall be glad to give our correspondent's full name and address on application.—Ed.]

CEYLON TEAS FALLING OFF IN QUALITY.

Cheltenham, 15th June 1888.

SIR,—I make the following quotation from the market report of the London *Times* of 8th instant, and I may say that for some months past I have seen from time to time unfavourable notices of Ceylon tea in the market reports of the same paper:—

"The feature in the catalogue has been the increased quantity of Ceylon tea *** the bulk being only ordinary in quality, and from some estates comparatively undesirable; the average prices are consequently less encouraging, and in order to compete with the Indian growths it is more than even necessary to produce a liquor brisk and altogether free from burntness, so many Ceylon teas being disliked now on account of the dulness and burnt flavour they possess."

In the *Overland Observer* dated, I think, 19th March last, there was a letter on the subject of Ceylon tea, written from England and signed "W. W." I have neither preserved the paper nor the letter, but I remember that the writer asserted deterioration in the general character of our Ceylon teas. He quoted the opinion of an experienced dealer that they had not maintained their character for flavour or for strength. The same dealer was said to have alleged that they are *soft*, and this, I think, the writer explained as meaning that they become flat, dull, and flavourless when kept for any length of time. If I remember "W. W." said that his own experience supported, or went some way towards supporting, the assertions of his friend the dealer.

It may, perhaps, be worth while to state what has been my own experience since I came home. In January last I applied for samples of Ceylon tea to a London firm connected with Ceylon, gentlemen who may be depended on to sell pure Ceylon tea at fair prices. They sent me four samples, one of which was a high-grown tea of good reputation, and the others, if I mistake not, were

mixtures of high-grown and low-grown blended for the gratification of the common consumer of this country. All these teas were to my taste so flavourless, that I had no inclination to buy even a few pounds of any one of them. In April last I tried again to get Ceylon tea to my liking. I applied to another firm of tea dealers who may be depended on to supply pure Ceylon tea. These gentlemen sent me about half-a-dozen samples, of which three were marks I particularly inquired for and marks which are of the first rank in Ceylon. All these teas were to my taste dull and wanting in flavour. I somewhat reluctantly bought a little of one well-known mark, a high-grown tea, but I may safely assert that it is very inferior in flavour to tea of the same mark which I was accustomed to use in Ceylon. The dealers in reply to my complaints wrote saying that good flavouring Ceylon teas were not procurable at that time, but promised to send me a sample of such if they met with it. I have not heard from them since.

I pretend not to any skill as a taster of tea. I speak merely as a layman who acquired a taste for Ceylon tea in Ceylon and used it there for many years. Howbeit, I think this a notable fact, that a Ceylon planter in England, who, in the quest for Ceylon tea, may be considered to have some special advantages, is unable to find it to his taste.

It can scarcely be disputed that with the great increase of quantity the quality of our teas has degenerated. Might not the matter be profitably taken into consideration by the Planters' Association and the district Associations?

I hope the time may soon come when people shall be able to buy a pound of fine Ceylon tea in any good grocer's shop, but the time is not yet:—

J. H. CAMPBELL.

COLOMBO MILK.

Wiesbaden, 51, Kollupitiya Road,

27th June 1888.

SIR,—I send you the results of an investigation into the composition of Colombo milk,—a subject which must possess interest for many of your readers. The analyses made were carried only so far as is customary with a view to ascertain whether samples of milk are genuine or adulterated.

It was necessary, in the first place, to obtain samples of milk known to be genuine, in order to ascertain between what limits the amounts of the different constituents might be expected to vary. Analyses Nos. 1 to 5 represent the composition of genuine milk from cows fed upon more than one kind of food. Sample No. 6 was obtained by a trustworthy servant who reported that the milk was from a cow fed upon grass only. Besides the chemical analyses, I have given, in tabular form, a few other particulars in connection with these samples of genuine cow's milk:—

	No. 1.	No. 2.	No. 3.
Specific gravity ..	1.029	1.030	1.032
Fat ..	2.97	2.11	5.57
Sugar and casein ..	7.49	7.73	8.66
Salts ..	.60	.76	.77
Total solids ..	11.06	10.60	15.00
Water ..	88.94	89.4	85.00
	100.00	100.00	100.00
Solids-not-fat..	8.09	8.49	9.43
Age of calf ..	4 months	7 months	1 month
Food of cow ..	Grass, cotton seed and poonac,	Grass, cotton seed and boiled poonac.	Grass and rice.

	No. 4.	No. 5.	No. 6.
Specific gravity ..	1.033	1.036	1.032
Fat ..	3.62	1.51	4.55
Sugar and casein ..	8.66	8.66	8.95
Salts ..	.80	.80	.73
Total solids ..	13.08	10.97	14.23
Water ..	86.92	89.03	85.77

	100.00	100.00	100.00
Solids-not-fat..	9.46	9.46	9.68
Age of calf ..	4 months	2 months	4 months
Food of cow ..	Grass, cotton seed, poonac and rice.	Grass, cotton seed and poonac.	Grass only.

The following is the average composition of the six samples analysed :—

Specific gravity	...	1.032
Fat	...	3.39
Sugar and casein	...	8.34
Salts74
Total solids	...	12.47
Water	...	87.53
Solids-not-fat	...	9.08

No. 3 was richest in fat, and was indeed found to be too rich for a young child, with whom No. 2 agreed very well. The milk from the cow reported to be fed exclusively on grass was only second to No. 3 in respect of fat, while it was highest of all in non-fatty-solids. No. 5 was very poor in fat. This was demonstrated both by the chemical determination and microscopical examination; nevertheless, it was a genuine sample of cow's milk, and had a normal amount of solids-not-fat. The amount of fat in cow's milk being subject to wide variation, it is customary to judge of the amount of water that has been added to an otherwise genuine sample of milk, by the amount of solids present minus the fat. In England 9.4 per cent was for a time regarded as the minimum quantity of solids-not-fat present in genuine cow's milk. Then, as the processes for extracting the fat were further perfected, 9.2 and 9.0 per cent were the minima successively adopted. Finally, the Milk Committee of the Society of Public Analysts, after analysing 283 samples of milk between February 1884 and May 1885, recommended that no sample of milk should be passed as genuine, which contained less than 8.5 per cent of non-fatty-solids. Of the six Colombo samples, only No. 1 fell decidedly below this limit; but unless a large number of analyses should prove this to have been a very exceptional case, I fear we cannot fix a minimum for Ceylon higher than 8 per cent, and it may possibly be less.

Having thus obtained a general idea of what genuine cow's milk in Ceylon ought to be, I got a friend on three different days to purchase some milk from passing milk sellers just as it is sold to the people of Colombo, who do not keep cows for their own supply. The first of these bought samples gave the following results:—

Specific gravity	...	1.014
Fat	...	1.95
Sugar and casein	...	4.13
Salts39
Total solids	...	6.47
Water	...	93.53
Solids-not-fat	...	4.52

Basing the calculation upon an 8 per cent minimum of non-fatty-solids, this sample of milk contained 11.6 per cent of added water at least; or in other words the milk had been diluted with

nearly its own volume of water. The following was the composition of the other two samples of bought milk:—

	A.	B.
Specific gravity	1.0185	1.0148
Fat	3.46	2.96
Sugar and casein	5.83	3.17
Salts	.33	.33
Total solids	9.62	6.46
Water	90.38	93.54
Solids-not-fat	100.00	100.00
	6.16	3.50

Neither of these can be regarded as genuine cow's milk. If the 8 per cent s.-n.-f. formula be adopted the sample marked A could not have contained more than 77 per cent, and the sample marked B more than 43.75 per cent of genuine cow's milk. I am of opinion, however, that these were not simply samples of cow's milk diluted with water. The fact that these two samples of milk were whiter in color than cow's milk, and that, while the specific gravity and solids-not-fat were very low, the fat was yet present in quite normal proportions, I draw the conclusion that A consisted mainly of buffalo milk, and that B contained both buffalo milk and added water. Feeling pretty sure of the presence of buffalo milk in these two samples, I sent a trustworthy servant to procure some samples of genuine buffalo milk, which I analysed, with the following results:—

Specific gravity	1.0174	1.0278	1.0163
Fat	4.77	5.57	5.41
Sugar and casein	5.09	7.14	3.45
Salts	.27	.73	.57
Total solids	10.13	13.44	9.43
Water	89.87	86.56	90.57
Solids-not-fat	100.00	100.00	100.00
	5.36	7.87	4.02

It would appear from these three analyses, that, unlike the case of cow's milk, the fat in buffalo milk does not vary in amount so much as the solids-not-fat; but, to establish this as a fact, a much more extended series of analyses would be required. In all three cases the solids-not-fat were lower than, and in one case only half of, the minimum amount found in genuine cow's milk.

The only three samples of Colombo milk purchased in a casual way as cow's milk, which I have analysed, have thus turned out to be abundantly watered, or mixed with buffalo milk, or both watered and mixed with buffalo milk.

I submitted a sample of liquid from a drinking coconut, and also a sample of coconut milk, to the same analytical treatment as the samples of cow and buffalo milk, with the following results:—

	Liquid from drinking coconut.	Coconut milk.
Specific gravity	...	1.0148
Oil23
Sugar and other constituents	...	3.56
Salts61
Total solids and oil	...	4.40
Water	...	95.60
Solids free from oil	...	4.17
	100.00	100.00
		8.47

Supposing the coconut milk, which was rather thick, had been diluted till it contained 89 per cent of water, its composition would then have been:—

Oil	...	8.94
Sugar and other constituents	...	1.85
Salts21

Total solids and oil	11'00
Water	89'00
			100'00
Solids free from oil	2'06

Buffalo milk, coconut milk, the liquid from the drinking coconut, and water, if added to cow's milk, will thus reduce its specific gravity and the solids not fat. Buffalo milk will maintain and, as a rule, considerably increase the amount of fat. Coconut milk will increase the fat still more. If added of the same degree of consistency as the sample analysed, coconut milk would add non-fatty solids in about normal proportion; but the great increase in the fat or oil would lead to its detection. Under the microscope the average size of the fat globules of buffalo milk is somewhat larger than that of cows milk; while the average size of the fat globules of coconut milk is much larger than either of the others. M. COCHRAN.

[The results as to dilution do not surprise us, as the milkman when asked to bring pure milk told us candidly he would have to double his charge!—Ed.]

THE TEA MARKET AND PRICES.

Kotmale, 28th June.

DEAR SIR,—Were there not some certainty that a reaction would shortly set in, the depressed state of the tea market would be serious and alarming, and make one wonder what the result would be were exchange to go up to 1s 8d not to mention a higher figure. How much of all the tea planted at the present time could we afford to cultivate under such circumstances? This is now the third year that prices have fallen to what may be called an unprofitable figure, and each year the fall has been greater than that preceding it. One might well ask what are the causes or reasons for this annual fall in the price of our staple? Is there no means of checking this fall to some extent? One of the principal causes is obviously the anticipated heavy arrivals from China. Another is the larger shipments from Ceylon in April, May, and June compared with the shipments of other months of the year. One more is deterioration in quality of tea made in the months, February to June.

To obviate the first, we should make our finest teas only to meet and compete with the new tea from China till we compel the China tea dealers to curtail their shipments to such proportions as will not materially influence the market. To meet the second and third causes, we should endeavour to regulate our pruning in order that our largest shipments should arrive when high prices are ruling, and make our greatest quantities of tea to catch the best market.

Our aim hitherto has been to prune with a view to having the bulk of our tea area in the finest possible flushing condition for the months of March, April, and May with the result that in most cases two-thirds of the crop has been made from young watery leaf—from newly pruned tea—in January and February, and later on from, want of rain, tough, sapless leaf deficient in strength and flavor.

Last November heavy pluckings in many instances equal to the best obtained in May were harvested from early pruned bushes and where pruning was allowed to lie over, and the tea from such pluckings arrived to a market, averaging 3d to 4d above the rates ruling when April and May, teas were sold. It would appear therefore that our object should be to make November and December our best months instead of April and May, and have a great portion of our acreage pruned at a time when only poor leaf is grown and the market at its lowest.

A. F. S.

[But unfortunately, or fortunately, on account of labour, financial and even climate causes, many proprietors find it necessary to distribute their pruning, so as to do a portion nearly every month of the year and so keep on the plucking from one field after another. To have all pruned at once and no work then for some time for the labour force, would scarcely do?—ED.]

MR. J. HOLLOWAY'S VIEWS ON THE CAUSES OF POOR TEA IN THE DRY SEASON: INACTIVITY OF SURFACE ROOTS.

4th July 1888.

DEAR SIR,—Mr. Thos. North Christie's letter of the 28th ultimo, Mr. Rutherford's letter, and your remarks in issue of yesterday, I have carefully read and seeing so much doubt expressed as regards the low price of our teas in London in May and June—Mr. Christie blaming brokers for doing what they are bound to do, report fair on the tea we send them—let Mr. Christie and others look nearer home for the cause, not in the factory, not in plucking, not in the bush, you may now well say what the deuce is it?

Well, I will tell you, the simple reason why our tea sells so low in London in May and June—(to do this we must go into the formation of the tea bush under ground, so simple and most planters must know it, but knowing, why do they not assist the tree at the proper time instead of being down on brokers at Colombo and in London?)—lies in the inactivity of our surface feeding roots during the dry weather. The heart of the tea bush as we now cultivate, lies in the stem a foot below and a foot above ground, we then have the taproot and other deep roots which give the most sap; this, however, is very poor; we next come to the branch and surface roots: these give the richer sap, they both are then worked up together and send out to the branch leaves; then we have the leaves doing their share by taking nourishment from the atmosphere and ammonia from the soil through the cells of under part of the leaf. Having taken into consideration the formation of the tree or bush, we will now come to account for the poor quality of the tea we make in February, March, and April, which reaches London in May or June.

It is simply this:—

During the dry months of January, February, and March the heat penetrates the soil (in different soils different depths) and makes the surface feeders inactive, the deeper the heat gets the more roots get inactive so to say roots are put to sleep. The earth at top is baked and gives out no ammonia, the atmosphere here is also clear and dry, so leaves also suffer, droop and cannot sustain themselves much less help the flushing; night dew and slight showers will enable leaves to look healthy only.

The tea tree and flushing as the dry season advances, get more and more dependent on the tap and lower roots which must bear all the strain in supporting the tree and give flushing, but the sap then given is very poor, unless the soil is rich at a great depth; hence tea is weak in the cup.

After the rain sets in the earth gets softened; surface roots awoken from their dormant state and contribute their sap; the atmosphere is again moist, there is more or less electricity, and the earth gives up some ammonia, so the leaves again look fresh, new healthy flushes come out, and good tea is made.

The planter has it in his power to assist our trees during their most trying time to enable them to keep their vigour and give good flushes with full strength. We are now in the wet sason; should I not see anyone else giving the way to get our bushes to give strong tea during the dry season, I will take up the matter later on.—Yours truly,

J. HOLLOWAY.

THE ABOLITION OF SLAVERY IN BRAZIL.

BRAZIL CEASING TO HAVE SLAVES—GREAT REJOICINGS—THE OPINION OF AN OLD CEXLON PLANTER ON THE OUTCOME.

Rio, 22nd May 1888.

DEAR SIR,—Rio de Janeiro has been in deliriums for the last fortnight. The Government introduced in the Chamber of Deputies a law for the total extinction of slavery in Brazil without any condition whatever. In the short space of six days the measure passed through the two houses. The Senate sat on Sunday the 13th for the third reading, and the same day the Princess Regent signed the approval, and from 3 p.m. on the 13th of May 1888, Brazil ceased to have slaves.

From the very moment of the signing of the law rejoicings commenced, and for a whole week it continued. The streets were crowded each night, so that tramway and wheel traffic were entirely stopped, public institutions had their processions and feasts, schools and colleges had their displays, public work were stopped, indeed, for a whole week the city looked but for the beautiful illuminations and street decorations as if the good, order-loving inhabitants were taking leave of the serious part of existence and determined ungovernable on hilarity and uncontrollable excitement.

Sunday, the 20th, just a week after the passing of the law, saw a finish to the festivities, and on that day the newspaper press look as their special day. The decorations, processions, fireworks, and the displays from balconies were all very beautiful.

I mentioned in my former correspondence that probably by the month of May, LIBERTY would be declared on condition of three years' service; the most sanguine never expected unconditional liberty. Here is the text of the law No. 3,353 of 13th May 1888:—

Art. 1.—From the date of this law slavery in Brazil is declared extinct.

Art. 2.—Dispositions to the contrary are revoked. Owing to the festivities by the press, and to mark in an especial manner the occasion, only one newspaper out of the many of various languages was published on the Monday, and this was contributed to by all the other journals with very few exceptions. I send you a copy, and you will notice Portuguese, Spanish, Italian, French, and English articles from the papers of these respective nationalities.

The towns are rejoicing, but I cannot say much for the interior and country districts. Accounts from the interior are various: some say that the ex-slaves have left the estates; others that they ceased working, were refused food, and, after feeling hungry, went to work again on promise of being treated as free men; others say it made no difference. I am inclined to think there is truth in all these reports.

My belief is that they will all return to work again and on the old plantations. Farmers who were in debt will be ruined, mortgagees will find securities of little value, and many national banks will lose money, but the produce of the country will not be lessened, as much coffee will be picked and more sugarcane will be planted as before. The townspeople in the interior will now have the value of the ex-slaves' labour passing through their hands, for the free labourer will spend his wages in the interior. Formerly one may say only the value of his clothes and medicines was all that was spent on him, food was always grown on the farm; over and above this either went towards paying interest on borrowed money or to luxurious living of the landlords in the large towns.

The country will be in every way better. Some people predict increase of crime. I do not antic-

pate this through emancipation. The African is not naturally criminally inclined, and is to be dreaded that the European element from the South of Europe. Let us in the language of Lord Salisbury's telegram to the Brazilian Government give our warm congratulations for the passage of a law of such importance for the progress and prosperity of Brazil.

A. SCOTT BLACKLAW.

"CURIOSITIES OF THE LOCAL TEA MARKET."

DEAR SIR,—Can anyone explain the following?—A break of 2,000 lb. of two grades, pekoe and pekoe souchong, was bulked, re-fired, packed, soldered and nailed down on the same day. Both grades were packed in chests of the same wood, same size, made at the same time and leaded with lead out of the same box. Both grades were dispatched on the same day in the same cart. A sample was taken from the bulk of each grade and sent down to Colombo for valuation, the result being the pekoe was valued at fifty-four (54) cents and the pekoe souchong at forty-two (42) cents. All the tea was offered for sale the same day in the local market, the pekoe souchong fetched 42 (the price it was valued at) and only 41 cents was bid for the pekoe, one cent less for the pekoe than the pekoe souchong.

PUZZLED.

HOW TO REMEDY CEYLON POOR TEAS BETWEEN APRIL AND JULY.

Central Province, 2nd July 1888.

DEAR SIR,—With reference to the many complaints about the poor quality of our teas sold in London between April and July, I venture to give the following as the probable cause:—

It is a well-known fact that the first flushes after pruning result in a bad tea—dull as regards fermentation and wanting in strength and body in the cup—owing to the leaf being thin and watery through the vigor of the growth preventing the sap being properly elaborated. Now is it not possible that the April hot mornings and showery afternoons following upon the long drought of January-March would have exactly the same effect on the vigorous growth of flush which takes place at that time? The only possible remedy would be to allow these flushes to run to say 4 or 5 leaves instead of to 3, but this on the other hand would check future flushes for a few rounds—Yours faithfully

R. M. K.

TEA SHIPMENTS: LOSS IN WEIGHT.

Nuwara Ehiya, 3rd July 1888.

DEAR SIR,—Below I send you memo of a shipment of 79 half-chests tea lately sent to London, and shall be glad if you can let me know if others are victimized to the same extent in the shape of loss in weight:—

MEMO.

Tea as despatched from the estate 3,635 lb.
 „ as sold in London 3,485 „

Loss 150 lb. (or

fully 4 per cent) which at an average of say 10^d per lb. = £6 11s 3^d! This is actually more than the freight, which only amounted to £6 6s 6^d.

Of course I know 1 lb. draft per chest is allowed, but that would only come to 79 lbs.—Yours,
 TOMMAGONG.

THE LOCAL TEA MARKET: BROKERS' REPORTS AND QUALITY OF TEA.

July 4th, 1888.

SIR,—Everything which throws light on this subject is of public interest, and that must be my apology for troubling you with my views. There is an undoubted impression that the Colombo market for teas is one not favorable to the seller, and there must be some ground for an opinion which is so generally held. The chief ground for this opinion lies, I think, in the fact that the market is a limited one, and is very much at the mercy of "orders" from home, *i. e.* it is not independent. Owing to this fact the grower who wishes to sell all his tea in Colombo frequently finds that he can sell his pekoe souchong, congou, or dust, but that he cannot get rid of his pekoe and broken pekoe except at an absurd sacrifice, or *vice versa*. Preferring, very naturally, to ship the complete consignment, rather than have it opened and sampled in Colombo for no purpose, he loses confidence in Colombo as a market for teas above the value of his lowest qualities.

Another reason is that local valuations are seldom reached in the local market, which, quite rationally, drives the producing seller to conclude that local buyers will not give a fair price. Add to this that sales are often privately effected at prices considerably over the prices bid in "the room" to those who have been bidding and sometimes to the highest bidder himself. Finally, whereas in the local market both buyer and seller have a court of appeal, the London market, there is no such appeal from the London market.

Now, sir, for the first of these evils there is no remedy, except an increase of buyers, or of orders, or of speculation; and the second evil brings us to the dispute between Mr. Christie and Messrs. Forbes and Thompson, *viz.*, brokers' reports and quality of tea. Owing to my not having at hand files of local market reports as well as of London reports, I cannot dispute Mr. Forbes' assertion that the local experts do not wait for the London "echo," before discovering the improvement in the quality of the tea; but my impression certainly is that they do not do so six weeks before it is noticed in London. I do not see, however, that this is of much consequence to the individual, except in the way pointed out by Mr. Christie, that it may injure the general reputation of Ceylon tea. At the same time, Mr. Christie should not forget that speaking generally only "common" teas are sold or offered in Colombo; and also that Colombo valuations profess only to state present value—not value six weeks hence. Mr. Forbes has candidly admitted that faults are more conspicuous in a weak market (which by the way looks very like a buyer's remark!), which is a considerable concession towards Mr. Christie's assertion, and it is to be hoped some of the London brokers will notice the discussion in their circulars, as the subject is one of great interest.

But, sir, the real cause of all the grumbling about the local market is, that there may be an appeal to London. A seller may grumble to some purpose of the local market, because he can ship his tea. But in London he may grumble to the end of time without the slightest advantage, because there is no going beyond London. As far as my own opinion goes, I believe in the Colombo market, except for fine teas always, and for common teas during three months of year, or perhaps four months. — I am, &c.,
PRODUCER.

P. S.—I have just seen Mr. Rutherford's letter. He is in error, in the present state of our knowledge, in attributing the fall in the price of Ceylon

tea *entirely* to inferior quality owing to climatic cause. Is there no honest and candid broker or expert who can inform us, whether there are not some conditions connected with the trade at certain seasons of the year conducing to, if not causing, a fall in prices?

CEYLON TEA PLANTERS AND COLOMBO BROKERS.

St. Andrews, Maskeliya, July 5th, 1888.

SIR,—The letters signed by Messrs. Jas. Forbes and Somerville, which have appeared in your columns, contain little more than a statement that the Colombo brokers had for 3 months past decried the quality of Ceylon teas, which is precisely what I blamed them for doing, and indeed they are too modest in limiting their period to 3 months, they might fairly claim every month of the year when the market is low. I stated, and I adhere to my opinion, that the Colombo brokers have not been able to detect in advance these great changes in quality of which we hear from London. Their usual complaint of the quality of the teas offered in Colombo is, I believe, quite misleading. One knows that a large proportion of the tea sent to the Colombo market is made up of the inferior grades and odd lots of spoiled or exceptionally inferior tea; but so far as my experience goes the estates which regularly send all-grade breaks to the Colombo market send teas which obtain an average valuation (made on a London basis by these very brokers) and price higher than the London average of the same day. If this be so, and your correspondents will correct me if I am wrong, there is no justification for the sweeping condemnation of the teas offered in Colombo. Condemn as much as you like the sending of red leaf, dust, congou, and rubbish to the Colombo market, but class your all-grade breaks differently, and work out your weekly average from them. If the Colombo brokers so clearly recognised the general and great falling-off in the quality of Ceylon teas, and were consequently prepared for the heavy fall, it is strange that they gave the prices they did for the teas. No tea broker has ever yet been known to admit that he was wrong, and how very like human nature it was for Messrs. Forbes and Somerville to pile on further depreciation of Ceylon teas in their last circulars written after my letter. This wretched product has now reached the "poorest assortment of teas that we have seen as yet this season," and the quality is "very markedly poor." A few more circulars will see it noted as worthless, possibly poisonous! Shakespeare tells us "there is nothing either good or bad, but thinking makes it so." If *saying* will make our teas bad, they ought by this time to have no quality left. Really, I wonder: what the Colombo standard of a good tea is? Something we know not of upcountry.

I did not expect that the Colombo brokers would express agreement with my views, but there is hardly a planter in the island who will not agree with me that the continued disparagement of the quality of our teas has done and is doing harm, and that the poor quality cry has been carried a great deal too far. A Colombo broker who buys as well as sells would need to hold the balance very truly if he wishes his utterances to be believed.

Mr. Jas. Forbes gives us his opinion as to the cause of the alleged falling-off in quality, due he says to the rush of leaf preventing time and attention being given to it. Beyond being, what Mr. Forbes claims for it, "simple," I fear his explanation has nothing to support it. Many of our highest priced teas were made in mere "shanties" possessing no appliances, and much of the "poorest quality" tea of today is made in factories with ample room and every

appliance. As I have said, I disbelieve that the fall in quality is as great or so general as some brokers would have us believe. Whatever falling-off there is, is I think due to excessive drought, but it takes a very prolonged drought before the quality on the higher estates is affected. It is the knowledge that Ceylon estates vary so much, all through the year, in their climate, elevation and periods of pruning, that, apart from my own experience, makes me sceptical of any marked simultaneous change in quality all over the island. Other things equal, fine weather teas are better than wet weather ones, but the difference is in appearance chiefly, the wet weather tea being red and flat, for the liquor remains much the same. In making this statement, I do not, of course, include the extremes of drought or continued pouring rains. One of our tea essayists (Mr. Armstrong, I think) has said that good tea is made in the field, and the more experience I get, the more am I convinced that it is so. The factor towards a good tea is the condition of the bush. Fine teas are not to be made soon after pruning, or when the bush has run too long after pruning, this latter period varying with jât, elevation and soil. Nor is a good tea to be had from leaf plucked from thin wiry shoots or off bushes which are a mass of blossom, but given a vigorous good jât bush about, say, 7 months from pruning, and nothing but deliberate mistreatment in plucking and manufacture will prevent you making an ordinary good tea at any season of the year, save during the extremes above mentioned. Just as I was about to end up, having had my say, I see Mr. Rutherford's letter in your issue of 3rd, which necessitates an addition to this already too lengthy contribution. Firstly, let me direct Mr. Rutherford's attention to an apparent contradiction contained in his letter. He says: "With regard to the falling-off in the quality of our teas, Mr. J. Forbes is, I think, right in entirely attributing this to the season." Mr. Forbes, however, did not attribute it to season *per se*, but to the imperfect manufacture when a rush of leaf came in, just the very accusation which Mr. Rutherford has, on the authority of Messrs. W. J. & H. Thompson, such natural satisfaction in contradicting. Mr. Rutherford will be relieved to hear that my remark, "At the present prices paid for our teas, I do not believe that the enterprise, as a whole, is making any profit whatever," meant literally what I said, prices at the time, not the year's average. I myself cannot see what harm it can do the enterprise to give an opinion less sanguine than that of some others as to the cost of producing our teas. No doubt fewer people will care to buy and open land if they think the cost of production is to be 9d and the selling price 10d than would have been the case had they thought the figures would be 7d and 1s respectively, but the fewer people who open land, the better the chance of the enterprise remaining profitable. The present position is a serious one, and my original letter was written in the hope that one depressing influence might be abated, and it is just as well to let the trade know that the average quality of our tea is unlikely to be other than it is, and that if prices are forced down much lower, but few growers will make any profit, and our 40 millions will cost more to produce than our friends the brokers will hand us as proceeds of sales.—Yours faithfully,

THOS. NORTH CHRISTIE.

CEYLON TEA: CRITICISM OF LONDON BROKERS' CIRCULARS.

St. Helier's, Ambagamuwa, 9th July 1888.

DEAR SIR,—The writer of Messrs. Rucker & Bencraft's Weekly Tea Circular of June 14th

must have been very ill when he drew up that statement. Why it should be the fashion amongst numerous firms in the tea trade to continually damn with faint praise and to do all they can to prevent Ceylon increasing its output, points to the one conclusion that these firms must be largely interested in China tea, and unable to shake off their Hankow connections. The prayer of the whole circular is,—for goodness sake don't interfere with our 3½d congous, or, if you do, "the greater output will be the greater loss, not profit." If you oust our 3½d congous, "there will be little profit to the planter, and precious little to the consumer."

This is one admission that the present China congous afford precious little pleasure to the consumer. So far so good; and the sooner these 50 millions per annum of congous rubbish are ousted, the better.

From beginning to end the circular is dead against quantity from Ceylon (there is no objection made to quantity from China), and the conclusion is that Messrs. Rucker & Bencraft must have a big thing in China congous, which are admitted by them to be next door to rubbish.

ALFRED SCOVELL.

PLANTING AND MANURING.

Tulliar, Devikulam, South India, 5th July 1888.

SIR,—I humbly beg you to give me your opinion on the following heads:—

Planting.—It is generally said that in planting cinchona, putting in the plant, so that any portion of the stem goes into the ground—commonly called deep planting, renders the plant subject to canker, and death eventually. I wish to know whether it is so with coffee or not, and if a tender plant put in with good three inches of the stem into the ground, will do equally well with another not planted deep.

Manuring.—How to best use cattle manure for coffee? Put in a pit in the centre of every four trees, or above every tree, it does not feed all the lateral roots of the tree, and therefore cannot produce the desired effect. Forking up the soil, where it is soft and the slope moderate, with the manure spread on the surface, so that the manure gets buried at a depth from three to nine inches all over the ground, seems to be a good method.—I am, your most obedient servant,

S. JACOB.

[Let our correspondent invest in a copy of the "Coffee Planter's Manual" he will find advertised in the *T. A.*, for the information he requires, and much more.—Ed.]

CEYLON TEA NOT "KEEPING."

9th July 1888.

DEAR SIR,—In my recent reply to a "Buyer" I gave four reasons why I declined to "patronize" the local market: one of which was that I objected to having all my cases opened in Colombo for samples during the south-west monsoon.

Now, it is very evident to me that our Ceylon tea is a very delicate article, and will not bear the rough treatment to which it is subjected in Colombo and in London. Granted, that its keeping qualities *can* be improved by slower and more thorough firing, and also, I think, by harder rolling, all our processes are too rapidly got through, yet is it necessary to check the unfair usage it gets in England itself. The planter is most careful to pack his teas in lead-lined, hermetically sealed packages, hot and dry from the firing; in less than a month, even if it escapes injury from the damp of Colombo, it is ruthlessly opened and turned out in London, and never soldered down again. It is exposed, thenceforward, to the English climate, unprotected, until it reaches the con-

sumer. Fortunately for us the brokers and buyers at home get their samples from the newly opened packages, good and fresh, but if we had to sell on samples taken from the grocers' shops after long exposure, I wonder how much we should get. The "Committee" in London ought to work for a reformation in the treatment of our tea by the revenue officers, by the warehouse people, and by the "trade." We are mulct pretty heavily by the trade, which takes not only one pound from every package but also *all the fractions of a pound* above the gross in round pounds, and *all the fractions of a pound* below the nett weights in round pounds. This is where "Tommagong" (who recently wrote you about his loss) suffered. Samples must be given and work must be expedited, so that I do not know how this "pull" in favour of the trade can be lessened; but we have a right to expect and demand some care for the tea itself in return. The operations of sampling, turning-out, weighing and re-packing ought to be simultaneous, and the cases ought to be re-soldered immediately. Then the grocers ought to be induced to keep their stock in canisters nearly or wholly air-tight, and not to open the soldered chests till required. I am aware of the exigencies of the retail trade, and also of those who supply certain small retailers with pictorial pound and half-pound packets. No mere paper will keep tea from "going off," and is it not a fact that much is retailed after it has been long exposed in the London warehouses, turned out again to be mixed (and adulterated) and packed in paper, in damp cellars, and then necessarily kept any length of time waiting final delivery to the consumer? If the trade at home cannot remedy all this, we shall have to pack it here ready for the consumer, and agitate for such reform of trade practices in London as will meet the new method. Finally, no tea opened in Colombo during the south-west monsoon is safe from serious deterioration.

R. W. J.

THE DETERIORATION OF CEYLON TEAS AND THE BROKERS.

Chapelton, July 11th, 1888.

DEAR SIR,—That the brokers have decried Ceylon tea no one can deny: that they are right in doing so is more problematical. Several attempts have been made in the papers to arrive at the exact season when the said falling-off in quality commences, but so far in my opinion without success. The drought or the early rains succeeding it have been blamed, yet it must be patent to everybody that a considerable time elapses between the despatches of tea from a large and from a small factory. Some estates despatch weekly, while others keep their teas for periods up to three months to allow their sending sampling breaks; yet when the fall in price occurs the latter share equally the defects in quality of the former although they must of necessity be composed in the main of teas manufactured at a time when quality was pre-eminent, judging from the reports of sales of tea manufactured simultaneously with them.

Everybody must know that there are times when tea is not quite up to the mark, either as the result of pruning or from climatic or other causes, just as red leaf is more prevalent from the want of the first or from cold winds; but that the variation ranges from "full flavour" to "very undesirable, weak liquoring teas" nobody but a broker could be expected to discover. To the grower it is also apparent how with the complaint against quality in a low market the burnt and overfired teas seem to predominate. Instead of the Colombo brokers being aggrieved by Mr. T. N. Christie's insinuations, that

they had not discovered the sudden deterioration of quality in teas previous to the wholesale condemnation which was suddenly telegraphed out from the Lane, it would have been more natural if they had congratulated themselves on having failed to detect anything very unusual in their quality.

I lately heard of an instance where part of a break of tea was put up for sale in Colombo some time before the fall in price, which fetched 52 cents per lb. Another lot of the same tea was lately offered for sale locally and fetched 31 cents; yet, if the brokers be right, the cause lies not in the uncertainty of the market or the excessive supplies, but in the quality of the tea itself. Of course we hear a lot about Ceylon tea not keeping its flavour, going off &c., and this may be adduced as a reason for the depreciation of value of the tea I am quoting, but then the tea in question was not subjected to the barbarous treatment it meets with in London where the packages are broken open on arrival in the dock and bulked.

The latter process from all accounts is a sarcasm on the trouble and care bestowed upon packing by Ceylon planters: the tea being exposed to every possible disadvantage, whether from mode of bulking, from climate, from exposure, or from the manner in which the package is finally "fixed up."

It stands to reason that the more flavour a tea possesses the more that tea will deteriorate by exposure, and if we are to believe the brokers, it is better to buy a flavourless China Congou, and so avoid any disappointment hereafter.

No doubt it is to the interest of some firms in the Lane to keep up their connection with China, and, as India has now firmly established herself, they feel it useless to run her down. Ceylon is, however, still an interloper and barely on her legs, and so the attempt is made to thrust her to the wall.

Were our friends (?) the brokers to expend half the trouble in pointing out the defects of fivepenny to eightpenny China teas, they do in decrying Ceylon growths, the former would soon be ousted from the market and the Ceylon planter would find his millennium.

The only present satisfaction is that in spite of the inferiority of Ceylon tea in the present depressed market, its average compares favourably with those of India and China.—Yours faithfully,

F. L. CLEMENTS.

SMALLPOX IN TURKEYS.

Colombo, 13th July 1888.

DEAR SIR,—My wife writes: "I see someone asking in the *Observer* for a cure for smallpox in turkeys: write to the *Observer* and say, I have never known coconut oil and ashes, applied three times a day, fail." To hear in the case of one's wife is to obey, hence this letter.—Yours, &c.,

MARI.

THE ALLEGED DEPRECIATION OF TEAS: EXPERIENCE AT A MEDIUM ELEVATION.

DEAR SIR,—It is with much vexation and doubt many planters receive the remarks of brokers here and in London regarding the falling-off in the quality of our teas. I only work in a small way and cannot speak with authority; but I am certain that my tea has improved in quality during the last six months: at all events I observe no falling-off in taste or flavor, and all these apparent depreciatory remarks unfortunately occur as Indian and China teas come on the London market. Is it not reasonable to draw an inference?

What I want to see is an authoritative statement by our large manufacturers as to their experience of the inferiority in their teas during the last six months, and if they can account for it.

Those annual complaints are becoming a serious matter, and may have the effect of lowering our teas to an unprofitable price, so the sooner we are able to candidly admit or deny the fact, the better, and bring experience to bear upon effecting a remedy.—Yours truly,
PLANTER.

A METHOD of preserving the natural colours of flowers, recommended by R. Hegler in the *Deutsche Botanische Monatshefte*, consists in dusting salicylic acid on the plants as they lie in the press, and removing it again with a brush when the flowers are dry. Red colours in particular are well preserved by this agent. Another method of applying the same preservative is to use a solution of one part of salicylic acid in fourteen of alcohol, by means of blotting paper or cotton wool soaked in it and placed above and below the flowers. Powdered boracic acid yields nearly as good results. Dr. Schonland, in a paragraph contributed to the *Gardeners' Chronicle* recommends, as an improvement in the method of using sulphurous acid for preserving the colour, that in the case of delicate flowers they might be placed loosely between sheets of vegetable parchment before immersion in the liquid, so as to preserve their natural form.—*Madras Mail*.

WOODEN BLOCKS.—One of the latest American industries is the manufacture of wooden blocks from compressed sawdust, an art which may hereafter be of the greatest value. To produce any finished article from wood a great deal of waste is necessary, not only in finishing up the work, but in cutting out the rough patterns from the log, especially when these are large or intricate. Hitherto this waste has been unavoidable, and has greatly increased the cost of all articles above a certain size, but now this loss will be unnecessary. The small pieces of wood (spruce fir for choice) are reduced to pulp on a grind-stone, which pulp is carefully cleaned and sifted, after which it is subjected to hydraulic pressure. The blocks thus formed are used for the manufacture of all wooden articles not required to stand a severe cross-strain, and as the blocks are of large size the cost of production is greatly lessened, since the value of wood increases greatly with any increase in its sectional area. The cutting from the blocks too can be used again and again so that nothing is lost.—*India Agriculturist*.

JAFFNA COTTON CULTIVATION CO., LD.—We have received the prospectus of this company, which it is proposed to form, with a capital of R50,000, divided into 1,000 shares of R50 each, with power to increase. The directors are Messrs. Charles Morrison, Banker; Samuel A. Allagakoen, Advocate; Alex. Toussaint, Merchant; Thos. Mac Gown Tampoo, Proctor; Sinnatamby Nagalingam, Advocate; Saverimutto Manuelpillai, Merchant; all of Jaffna; the Secretary being Mr. Charles Arndt, and the bankers the New Oriental Bank Corporation, Limited. The prospectus states:—

The Jaffna Cotton Cultivation Company Limited is formed for the purpose of growing Cotton in the Northern Province, and it is believed that the undertaking cannot fail to be a financial success, and also be the means of giving employment to many who are now in so much need of such. The starting of the Ceylon Cotton Spinning and Weaving Company in Colombo will provide a good market for all the cotton that can be produced locally, and we may depend upon the Cotton Mills giving preference to Island grown cotton, for as will be seen by the Prospectus issued by it the Directors are those who have the interests of Ceylon at heart due care being taken that only the best seed is sown, and which we hope to obtain through the kind services of Mr. Green of the U. C. S. who has taken the matter of Cotton Cultivation in hand. Cotton of good quality has been grown for years in this Province, but as mentioned above it is proposed to procure and circulate for growth for the future only the very best and most suitable seed, so that every reliance may be placed upon the outturn

of the cotton crop being taken over by the Ceylon Spinning and Weaving Company Limited. The approaching certainty of regular and easy means of communication with Colombo by Steam is also an additional incentive for the starting of this company. We have thus noticed the company, since the object is a praiseworthy one, but to insure success the scheme should be advertised as has been done by the Colombo Spinning and Weaving Co.

SELF-CONTAINED TEA ESTATES.—The editor of the *Indian Tea Gazette*, in an article enforcing the necessity of economy in the production of tea, writes thus:—

Every tea garden, that can afford it, should provide itself, wherever conveniently possible, with supplies of fuel of its own growing, with the means of preparing its own manures, with its own stock of wood for the manufacture of boxes and with its own labour, not only for the proper manufacture of its own tea, but also for its due assortment and careful packing for shipment, when it is intended for exportation. It is possible that very many gardens may not possess these facilities, but they can be gradually brought together by a little tact and intelligent management. In importing labour for a garden, the planter should make it a point to arrange with the recruiting agency that he should, besides the ordinary coolie for ordinary work of the plantation, be supplied with a certain proportion of skilled artisans whose special knowledge could be advantageously utilized in the internal economy of the Tea Factory. With the present available means for constant and speedy communication between the over-populated districts and the planting districts, a little higher rate of remuneration would probably suffice to attract to the certain employment of the Tea-gardens a large proportion of the artisan classes who are next to starving in their own native villages for want of congenial work to do. Much has been done, and much is still being done on our Tea estates, to improve the condition and prospects of the people engaged in the cultivation of the tea-plant and in the manufacture of the tea-leaf. If, besides increased wages, skilled artisans on the tea gardens were allowed a small commission on the savings effected by their manufactures over the purchases that would otherwise have to be made in the open market, the planter would find that he would be greatly gaining in the end. The work would be done cheaper and better, if he took care to see it done under his own eyes. At seasons in the year, when cultivation, gathering and manufacture have for the time ceased, such hands as are fitted for higher work, should be set apart to undertake what may be called the subsidiary labors of a Tea plantation. The inducements we have suggested, would make the additional labor acceptable to the industrious and thrifty classes, as assuring them of a more speedy diminution of the period when they might retire to their native villages and live upon the fruits of their present toils. Each planter will be able to ascertain for himself how, and to what extent, he can utilize his available resources with a view to enforcing economy in the pursuit of his industry, and when he might find it necessary to import extraneous facilities. On a large number of Ceylon tea estates in Ceylon, not only is there no timber for tea boxes, but even the supply of firewood is exhausted. To keep cattle for manure is generally too costly, and the only cattle kept on most estates are milch cows. Ordinary labour is pretty abundant, and artisans are plentiful when wanted. Tea boxes come to us in shoeks from Japan or are supplied by local manufactories at fairly moderate prices, but the fuel question is likely to become serious, unless the railway, the brewery and other large consumers of firewood adopt artificial fuel in the shape of kerosene residuum, of which the supply in the Russian oil region is enormous.

CEYLON UPCOUNTRY PLANTING REPORT.

TOBACCO—AND TEA—THE COMING CACAO CROP—TEA AND LOW PRICES—COOLY-BACHELORS AT A DISCOUNT—WEATHER.

The activity in regard to the cultivation of TOBACCO still continues, and besides those who are already in the field, there are many more anxious and willing to enter it if the result of the present experiments are at all favourable. The cautious ones are "wanting to know, you know," how the curing is to be managed &c. before the plunge, and are prepared to encourage the sanguine to try their luck as sort of test cases. They don't fear to be too late for the market, nor of its being flooded either: the demand for "the fragrant leaf" all over the world being a steady and increasing one.

You hear of tobacco being tried in all kinds of places, by all kinds of people, and in all kinds of ways. Perhaps the least likely combination of products is tobacco and tea, and yet there is one man who is planting it between his tea lines, and is waiting the result with what serenity he can. It is pretty clear that before Ceylon is done with this new product, it will have had as queer companions as the bed-fellows of poverty. There is very little danger of anything being missed for the want of an experiment, and when you hear of a man having been dispatched to Sumatra on a six months' commission, with the view to pick up tobacco wrinkles, you get impressed with the idea that the local knowing ones are not long to have it all their own way, nor pose for ever before an inquiring public as dungeons of knowledge. A well-known native cultivator was very bitter at the inaccessibility of tobacco lore. He had fallen in with two of our local tobacco authorities, but their information was un-get-at-able. They made a very "square" attempt to impress his mind with the *difficulties*, the vast expenses, the uncertainty, and he felt that their aim was simply to "choke him off" and not to assist him, much less to encourage him to go on. He had not looked for this. "Why," he said, "is there not room enough for all;" and then he added, "but they were not like the usual European planter, they have become just like a Sinhalese!" The fun of the thing was that the speaker belonged to the nation he had levelled the tobacco authorities down to. But these knowledgable gentlemen need not be put out by a rub of this kind. It certainly showed a want of reverence on the part of their native brother, but that after all is only the crying sin of the age. It invades everywhere, even such high mightinesses as V. A.'s don't escape its baneful influence, I heard them once wittily described as being simply on the business level of a tamby: for, like him they had to hawk about from place to place to pick up a living! After that to be compared to a Sinhalese may be endurable.

In one of your "notes" you were becoming jubilant over the prospects of the coming CACAO crop. I hope you are right; but as far as my observation goes, the cacao crop which has set is not as yet either a bumper or an average one. There has been lots of blossom, but it has not left very much behind. There is blossom now and blossom coming which, however, is setting very slowly, and not nearly so regularly as the cacao planter would like. The trees too are showing that the prolonged drought has told upon them, as there are many more dead boughs about than one cares to see. However, it is to be hoped that you have drawn your inspiration from a wider field of facts than mine, and that the good time you have heralded is really approaching us.

Canker in CINCHONA is rather pronounced just now, and those who would keep theirs back are

forced to harvest more than they would, rather than lose all. On many places there is steady employment for a small gang to harvest the dying trees.

The low range of prices of TEA at home has put the factories that buy leaf into a state of excitement and uncertainty. Some wisely wait and see; while others have made a plunge into the abyss, and offered rates for leaf which have caused much dissatisfaction, and are evidently the outcome of "blue funk." If big factories are to flourish they must be less susceptible to panic, and have at least a yearly policy to guide them.

The other day a man offering leaf for sale put it that he was ready to supply "well matured leaf"! The buyer would of course prefer that the leaf he bought was plucked from well matured trees, but he was not quite satisfied that "well matured leaf" meant that—as the expression was certainly capable of covering a good deal more.

The rush of COOLIES from the Coast has abated now for some weeks; but most estates are fairly well supplied with labour, and some have more than they want. One planter who has more men than he has profitable work for, is about to give notice to all the bachelors. Rather hard lines this. As long as Ceylon is a tea-producing country, that question which is beginning to bother the European:—"What to do with your girls," is not likely to come to the surface among the Tamils. If bachelors are to be paid off because they are unattached, the downtrodden woman of the East is clearly in a fair way to become master of the situation. Let this new but powerful factor in her civilization be herewith noted, and due credit given to the Ceylon planter.

THE WEATHER lately has been rather trying on young plants which were put out a little while ago, being somewhat drier than we would like. But too little rain is not worse than too much, and then when you think of it "things maun aye be some way." For the worried, if they dig deep enough, there is a world of comfort in that philosophy.

PEPPERCORN.

NOTES ON PRODUCE AND FINANCE, CHIEFLY TEA.

(From the *H. & C. Mail*, June 22nd.)

Shareholders in tea companies should be in good spirits, for the prospects are hopeful and directors are cheerful. Wonders have been accomplished in the way of economy in working, and the amalgamation movement has played an important part in this. At the meetings of tea companies held recently reports have, as a rule, been well received, and prospects generally are considered good.

By the way, Mr. White is not among those who foresee a large and successful development of the tea industry of Ceylon. He told an inquiring shareholder of the Jokai that he had no great faith in Ceylon ever growing very much tea, for the climate was too forcing, and it produced wonderful results, but only for a short time. Coffee had died out, so had cinchona and cocoa, and, although they certainly had a very hardy plant to deal with in the tea plant, the fact that every man who had a tea estate in Ceylon had it in the market for sale, told its own story.* Here is a subject that has given rise to so much controversy that it is time the respective opinions for and against Ceylon were openly debated.

We are told sometimes at public meetings that the interests of Indian and Ceylon tea planters are identical, a suggestion which the planters themselves do not entirely endorse. Certainly the rivalry up

* The statement is, of course, recklessly incorrect, born of narrow and unworthy jealousy.—Ed.

to now is a friendly one, and it will doubtless continue so while both Indian and Ceylon planters are engaged in competition with a common enemy. It is British grown tea *versus* China tea, and the victory is at present with the former, for which planters have to thank the inventors of tea machinery as well as their own pluck and industry.

As to the prospects of Ceylon, there are two opinions with regard to the suitability of the soil for continued crops of tea. Something on the subject from a scientific man who knows the soil and is not specially interested in tea growing would be useful.

Mr. J. Berry White, the chairman of the Jokai Tea Company, speaking at a recent meeting of that company, referred to the decrease in the cost of production at most of the company's gardens and he indicated that they were now working at a minimum cost. He said that they might possibly reduce the cost of production by a ½d. per pound, and if they did that it would give them another 3 per cent., provided that the tea produced realised the same prices as now. He expressed his belief that in five years time it would be quite as much a matter of curiosity to get China tea as it was a matter of difficulty five or six years ago to purchase Indian tea. They did not know all the difficulties under which the Chinese raised their tea, but they knew that they could not raise it under 8d. per lb. What they were looking forward to and expecting was that China tea would be again displaced this year by another 20,000,000 lb. of tea, and that would be about tantamount to the increased production of India and Ceylon. The reason why China could not compete with India was that it was a case of hands *versus* machines. In China they used the old handlooms, while in India they did nearly everything by machinery, and, cheap as labour was in the Celestial Empire, the tea-growers could not compete against them with their machinery. There was no doubt that the Chinese growers and merchants had made vigorous efforts during the last four or five years to attempt to meet the Indian competition, and that in many cases they actually sold their tea at a loss. In the London market the price of Indian tea had averaged from 25 to 30 per cent. higher than China tea.

PLANTING IN NETHERLANDS INDIA.

(Translated from the *Straits Times*.)

In Java, capitalists and planters still fix their gaze on British North Borneo, as a more promising field for investment than that island. Companies floated there for the purpose find ready support. Planting enterprise meets with such little encouragement, from Government in Java, that it is no wonder wistful eyes are turned towards North Borneo.

According to the latest published official reports, the nutmeg plantations in Banda were in a satisfactory condition. This is more than could have been expected, considering the heavy storms that had raged there a little while before.

Telegrams from Amsterdam announce that all shares in the Marudu Bay Company started for tobacco cultivation in British North Borneo, have been allotted.

NETHERLANDS INDIAN LAND MEASURE.

Aeres.	Morgen.	Bouw
2 1032 +	1	
4 9734 +	2 1383 +	1
600 sq. Rynland Roeden	1 Morgen	
1,283 " " "	1 Bouw.	

The lineal unit of the Netherlands Roede is to 1872 + links of Gunter's chain. As the lineal unit of English land measure, *i. e.* a link, and the Rynland Roede are incommensurable, we may take the 1,000 bouws of the national cinchona plantations in Java to be equal to 5,000 acres + repeating decimals.—*Cor.* [Can any correspondent inform us of the accuracy of the above, or point out any error, and oblige.—Ed.]

DRUG TRADE REPORT.

LONDON, June 21st.

CINCHONA.—At Tuesday's public sales a rather smaller quantity was offered than has been the case lately, the supply consisting only of 1,498 packages Ceylon, 662 packages Indian, 1,428 South American, and 6 bags Jamaica bark. No Java cinchona was offered on this occasion. The assortment of Ceylon, and even more so that of the Indian barks, was unusually good, but there was very little desire to buy, and sales were only possible because holders generally showed no disposition to insist upon the values paid at the last auctions. At a decline ranging from 5 to 10 per cent., and a unit value ranging from 1½d. to 1¾d., nearly the whole of the eastern barks was disposed of.

TEA IN MOROCCO.—Among the articles which enjoy a growing consumption in Morocco is tea, which is nearly all bought in England, "Hyson" tea being the most esteemed. In 1887 the four principal ports imported together £33,553 worth of tea, against £31,519 the year before.

KOLA NUTS.—It is stated that a large proportion of the kolas now imported from the African West Coast at Liverpool, and distributed to the trade from that port, are of a spurious character. We were shown a few days ago a large sample of dried fruits offered by a Liverpool firm under the name of kola nuts, and which are said not to be of the genuine character. But at the same time we were shown specimens of the fresh leaves of the alleged spurious kola, and these correspond in all particulars to the drawings of the leaves of the admittedly genuine variety. In outward appearance the dried lobes of the two varieties of fruit bear a very close resemblance; but while the true fruit has a yellowish-brown uneven fracture, the "false kolas" have a distinctly waxy and smooth fracture varying in colour from purple to buff. Other samples of half-dried fruit offered as kola, which we had an opportunity of inspecting, show a five-lobed fruit, whereas true kola has only two lobes.

WYNA AD NOTES.

27th June, 1888.—Our weather has been lighter during the past week, and everybody is busy, planting up new clearings, and putting in failures. Coolies (Cannarese) dribble in slowly; they have a pleasant smiling way of saying great numbers are coming in "next week," but there is a beautiful vagueness about this period which none but a planter can fully appreciate. Fortunately, we have Chermas to fall back upon,—and for real hard work they are certainly preferable. Can any of your correspondents suggest an easy and effectual way of pulping Liberian coffee? I have quite a fine crop now ripe on my trees, but I have tried all sorts of ways of cleaning it, and found each more troublesome than the last. The husk is so hard and thick, and so great in quantity, compared to the actual out-turn of beans, that even the servants shake their heads over it, and consider a basketful rather in the light of a white elephant; and yet it seems a shame to waste it. The natives like the coffee, saying it is much stronger than the ordinary kind, and they will buy it freely. It is ruinous to any pulper, and apparently the only way is to pound the berries when hard rotten, and extract the beans, by washing. But this is so laborious a process that it is hardly likely ever to be a paying one. The trees grow extraordinarily fast, and crop very freely, and seem to be completely free from all the diseases of coffee. I have never seen a sign of either leaf or borer on any of my trees, some of which are twenty feet high, with ropes of crop on every branch.—*Madras Times*, June 30th.

A CEYLON PLANTER'S EXPERIENCE IN PERAK.

The following extract from a private letter of Mr. A. L. Ingall, now settled down to planting work in Perak, is very interesting. His old friends in Ceylon will be glad to hear he is fit and well, and very enthusiastic as to the vigor of the Arabian coffee in Perak, which appears to have astonished him and reminded him of the old days when the *palam* used to come in *rendue-rendue*-bushel fashion. He says:—The climate is not good, but it is not particularly bad, and the temperature is wonderfully low. The place I am opening is only 400 feet above sea level, and is really very little hotter than Kandy, while the bungalow on Elphinstone's place (1,700 feet) is very like the lower end of Dikoya. The coffee on Waterloo (Elphinstone's place) is looking simply splendid, and had a good blossom out which set well. It makes me wish I had a few dollars to open up Arabian coffee. The country to look at, is very much like Ceylon: long tracts of low land rising up to the hills, though very little of it is cultivated, the Malays being essentially lazy—not at all like those we were accustomed to see in Ceylon. I had tremendously hard work to get men to fell, but succeeded in getting a mixed force of Chinese, Malays, and Sakeis; the latter are the wild men of Perak, and have wonderfully scanty clothing. They roam about and never settle for more than a year in any one place, eat roots mostly, and are entirely uncivilized, but very pleasant and good-tempered people. Their hair is curly like a negro's, and their only weapon a blow pipe with poisoned arrows and a club.—Local "Times."

THE EFFECT OF SEA WATER ON PORTLAND CEMENT.*

By HENRY FAJJA, M.INST.O.E.

The subject of the paper which the author has the honour of reading before the Society this evening is suggested by the reports which have been made public of certain failures of concrete work at Aberdeen; the failures being attributed to the chemical action of the sea on Portland cement. The author would like to call attention to this question of magnesia in cement, which has also lately disturbed the equanimity of users of cement, and he wishes more particularly to make it clearly understood that magnesia in cement—*i.e.*, incorporated in it in the course of manufacture, through the use of improper and unsuitable raw material,—is in a very different form to the magnesia precipitated from the sea water.

Magnesia incorporated in a cement is in a state similar to caustic or quicklime, and on the addition of water, acts in a similar manner, *i.e.*, it heats and expands with considerable force; and if, therefore, it exists in any considerable quantity, it will cause the cement to "blow" or expand, and destroy the structure of which it forms a part. The explanation of this is briefly that the temperature at which a cement is burned is sufficient only to cause a perfect chemical combination between the lime, silica, alumina and a part only of any magnesium carbonate which may exist in the raw materials; the remainder is only deprived of its carbonic acid by the calcination, and is left in the cement as free or caustic magnesia. Cement may be made, and the author has made by heavy burning cement containing as much as 5 per cent. of magnesia, which was perfectly sound, but he is of opinion that 3 per cent. should be considered the limit of safety. It need scarcely be added that 5 or 6 per cent. of free or caustic lime in a cement would be just as dangerous as the same percentage of magnesia. The magnesia in the sea exists principally in the form of magnesium chloride, and is precipitated as hydrate, and in this form it is perfectly inert; in fact,

it is to continue the comparison, similar to a slack lime, and has no power of expansion. That it is found by analysis in cement which has been immersed in the sea there is no question, but the author maintains that it simply fills the pores or interstices of the concrete, without in any way combining with and forming a constituent part of the cement.

The foregoing, though apparently a digression, is really of very great importance, because it shows a continuity of thought—from the effects of magnesia in cement, to the effect of sea water on cement,—and suggests that the latter is considered as the corollary of the former; in the author's opinion incorrectly, for the magnesia in the two cases is in such very different forms that they are in no way analogous. Referring first, to Professor Brazier's analysis and experiments, he first analysed three samples of the original cement, in the form of broken *briquettes*, and also one sample of the cement in powder. In none of these did he find so much as 1 per cent. of magnesia. Analyses of several samples of the "decomposed cement" from the graving-dock were then made, and in them the hydrate of magnesia varied from 13 to 21 per cent.; at the same time, the lime had decreased from 58.49 per cent. in the original sample to about 33 per cent. of carbonate and hydrate combined; he therefore inferred that some of the lime of the cement was dissolved, and some of the magnesia contained in the sea water precipitated. To satisfy himself on this point, Professor Brazier made the following laboratory experiment. Some of the cement in its original form of powder, which contained practically no magnesia, was digested in a pint of sea-water for four days; the analysis of the water and cement were made before and after, with the result, that at the end of the four days, the water was found to have gained 28.16 grains of lime, and to have lost 12.52 grains of magnesia. The argument seems conclusive, but the author thinks it is at fault, inasmuch that, to keep the cement digesting is to keep it on the move, and therefore to prevent it from setting. It is well known that cement will set freely if left alone in sea-water, and it seems reasonable to suppose that if the cement sets, disintegration, except from some cause within the cement itself, is impossible; and that if the disintegration of the cement takes place through the unsound nature of the cement, then the lime in it would be partially dissolved, and the magnesia in the sea-water precipitated. The author is, therefore, of opinion, that the cause of the failures of the concrete at Aberdeen is not to be looked for in the chemical action of the sea on a properly set Portland cement, but that they are due to the cement having never been properly set, or that the cement used was an unsound one, and disintegrated from causes within itself.—*Indian Engineer.*

MANILA HEMP.—The Belgian *Bulletin du Musée Commercial* for May 19th, quoting from the *Deutsches Handels-Archiv*, gives some particulars regarding the trade in Manila hemp in the Philippine Islands. Besides its employment for ropes and cordage, experiments have lately been made to utilise Manila hemp for other purposes. At Madrid last year an attempt was started to make paper out of the waste fibre. It is said that an excellent white paper was produced, without the aid of any other material. If this experiment should be repeated with success, a fresh impetus will doubtless be given to the cultivation of the abaca. It should be understood that the waste fibre is not useless, even at present; it is employed to manure the plantations. The great export of hemp is from Manila and from Cebu some is also sent from the port of Iloilo.—*L. & C. Express*, June 22nd.

* A Paper read before the Society of Engineers on March 5th 1888.

WHEN ARE OUR WORST TEAS MADE?

(From a *Mascleya* Correspondent.)

With regard to the interesting discussion now taking place in your columns as to when our worst teas are made, I feel I cannot do better than send you figures taken from my books shewing date of manufacture, despatch, and sale of this estate teas for the past two years. You can rely on them as being accurate:—

Month of		1886.		
Manufac- ture.	Date of Despatch.	No. of lb.	Date of sale.	Aver- age.
1885	1886	lb.		
December	12 January	4,048	31 March	1/1 $\frac{1}{2}$
1886				
January ...	12 February	6,505	10 May	1/0 $\frac{3}{4}$
February ...	4 March	7,100	15 May	1/0 $\frac{1}{4}$
March ...	8 April	10,290	30 May	1/
April ...	6 May	8,520	24 June	1/11 $\frac{3}{4}$
May ...	9 June	10,605	5 August	1/0 $\frac{1}{2}$
June ...	4 July	7,213	24 August	1/1 $\frac{1}{2}$
July	} 8 Sept.	2,620	*	1/4 $\frac{3}{4}$
August				
September	30 Sept.	1,120	23 Novr.	1/4 $\frac{1}{2}$
October ...	20 Novr.	2,185	19 January	1/4 $\frac{1}{4}$
November ..	7 Decr.	3,881	19 February	1/3 $\frac{1}{4}$
December ...	8 January	5,155	21 March	1/

* Sold in September in Colombo, at an average of 66 cts., and then sold in London under estate mark at 1/4 $\frac{3}{4}$.

Month of		1887.

"You will notice that our wettest months when withering is almost impossible have, two years' running, had the best sales, and, curiously enough, the months in which the largest bulk of tea in these districts is pruned down, viz., June to September, have done the best. That the tea is much better in these months I doubt, as it stands to reason that, in fine weather, when a good wither is obtainable, it is much easier for the manufacturer than in the wet months. You will notice also that the tea sold in Colombo—September, 1886 (my first and last break)—fetched only 66 cents, the same tea selling in London in October for 1s. 4 $\frac{1}{4}$ d. The buyers at that period evidently had not spotted the rise about to take place in the market, as I was told at the time of sale it was a capital price. I still believe that our bad prices are due to speculation in the Lane previous to a certain knowledge of Chinese exports, and almost, if not all, London brokers being interested in the Chinese trade accounts for the absurd yearly cry of deterioration of Ceylon Teas. I would only add that it is not likely that with increase of machinery, and space and general knowledge, we should all make inferior teas at a certain fixed period of the year, viz., from January to May, no matter at what time we prune, or what our elevation or climate may be.

"N. E.—I buy leaf from three or four places, and have done so regularly, and the sales recorded include everything, even Dust and Congou. Red leaf only is sold locally, and a few thousand pounds of best teas have been sold in packets at good prices.—*PRO BONO PUBLICO*."—Local "Times."

A STRAITS TOBACCO PLANTER ON CEYLON.

Sir,—The news contained in a late copy of your Overland issue, which I have just received, is likely to create quite a sensation amongst tobacco planters in this vicinity!—in Java, Sumatra and elsewhere. So far the industry is a paying one. Given good soil, a suitable climate and the knowledge of curing, which is indispensable, there is a good profit such as one has only a right to expect when the distance one has to come from home and the malarious nature of the climate is taken into consideration. Now, I see that tobacco planting has attracted the attention of Ceylon planters, and that there is every probability of the cultivation being largely undertaken in your spicy island. This is simply disastrous. We, tobacco planters, have hitherto congratulated ourselves upon the fact that tobacco was not grown in Ceylon, and, therefore, though prices might gradually fall, tobacco would always command a price. I fear we must now abandon this idea, for it is not safe for anyone to be planting anything grown in Ceylon. Your planters seem no sooner to have discovered something that will grow in, the island than hundreds of them rush in and plant thousands of acres of it, each one calculating that he is to make a fortune on the so-much-an-acre so-much-a-lb. principle. Millions of pounds are produced, but alas the prices fall to zero. Look at cinchona, and I suppose we shall soon see the same thing with tea. It will be like dirt, and as cheap. When I was on the Nilgiris a few years ago an old planter there, discussing my prospects of success as a tobacco planter in Java, gave me the following advice:—"Never cultivate anything that can be grown successfully in Ceylon. Sooner or later you will be ruined." Acting on that advice I took to tobacco, but, now that your planters are going in for that cultivation, I shall have to abandon it, and take to growing potatoes. It will be more profitable.—M. SCHMIDT, Singapore, June 18th.—Local "Times."

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

Dr. Schulze, of the Agricultural Station of Breslau, warns farmers against purchasing oil cake "meal." In the latter form, Continental farmers prefer to give the oil cake to milch and fattening stock. But the market is flooded with the cake meal, and which sells cheaper than the cake itself, although the expense of grinding cannot be counted for nothing. The miracle is explained, not so much by adulterating with other and inferior oleaginous seeds, as by the employment of sulphuret of carbon, instead of pressure being employed to extract the oil. Now sulphuret of carbon, is toxic, and the only agent chemistry has indicated as capable of struggling against the phylloxera, so far Dr. Schulze recommends farmers to grind the oil cake themselves.

The Academy of Sciences of Paris has been since a long time occupied with the rôle of nitrogen in vegetation. In what shape do plants receive it; if from the soil, by what combination: if from the air, through what agency. The difficult question has been treated by Berthelot, Gauntier, Drouin, and Schlosing. It does not appear that the solution has advanced much further than the famous experiments of Bous-singault. All agree upon one point: that a soil destitute of humus, and devoid of vegetation, can neither produce nitrogen nor absorb it from the atmosphere. Less clear is the hypothesis, that microbes, in other words, the agents of fermentation, play a fixed rôle in uniting the elements, or bringing about the changes, to produce nitrogenous compounds. Another fact acquired is, that the plant neither by its roots, nor by its leaves, absorbs free nitrogen. But the latter can indirectly minister to vegetable nutrition; by the air, as when electricity forms nitric acid and ammonia, and both compounds can be washed by rain into the soil: or, the circum-ambient air can, entering the porosities of the soil

can yield its nitrogen to effect new combinations. And no matter in what form the latter may present themselves, they are the roots above all, which are the vehicle for their entrance into the economy of the plant. The phenomena of nitrification are located in the organic matters of the soil.

The success which has followed the efforts of the Norwegian chemists Rohart and Jensen, but especially the latter, to utilize fish waste as a manure, is leading to the establishment of a French company to act similarly in the case of the Newfoundland cod-fisheries. At the Loffoden isles, off Norway, the cod fish come during January into the sheltered fiords or creeks, to spawn, in such shoals, that they have been estimated to be as numerous as 120 millions to the square mile; equal to the rabbit seas in Australia say. The fish when caught are cleaned, boned, decapitated, and docked of their tails: the oil is expressed from the liver; this detritus is dried and ground into a brown powder, possessing the qualities of good guano and bone dust; that is, the two valuable fertilizing elements of manures—nitrogen, to the extent of 11 per cent, and phosphoric acid to 6 per cent. Off the Loffoden Islands, 30,000 men and 7,000 boats capture annually 27 millions of cod fish, whose flesh when salted and dried is exported to Catholic countries. Later in the year the herring fishery takes place. The herring is not netted for exportation, but for manufacturing manure. The fish is pressed by machinery for its oil, and the herring cake then dried and reduced to powder. The French company intends to work up powdered charcoal in its fish manure.

The Minister of Agriculture has just established a practical School of "Agriculture." This is a noun of multitude and means, the breeding and rearing of poultry: their fatting and artificial batching; the management of eggs, their preservation and preparation for market, and the most advantageous races of poultry. The period of residence at the school is limited to three months: the fee 350 fr. board &c. included. The school is situated at Houdan, in the Seine and Oise department, a region famous for its races of barn door poultry. The male and female pucers are alternately received every three months.

Since twenty years M. Marey has been advocating elastic traces for drought horses: habitually, traces are formed of rope, leather, or chains. These, owing to their inelastic nature, subjected the horse to violent shocks at the commencing pulls, as in carts, omnibuses, drags &c. M. Celler, engineer of the Great Eastern railway of France, has since six years employed a saw-ge spring in the chain traces of the horses employed to pull the waggons and carriages short distances in the marshalling of trains. He attests, that the results are most gratifying; fewer traces are snapped: the efforts of the horses are more measured and uniform, and drivers have no occasion to behave brutally towards the animals when they are unable to effect an immediate start as heretofore. The horses display less fatigue, because there is less violent expenditure of strength. The spring will be applied to the traces of the parcels' vans. Germany has, in the *Pferde schoner*, a kindred spring.

PARIS, June 9,

Dutch farmers have been so deceived in their purchases of oil cake, that they now prepare their own linseed. They buy the latter direct from the merchant, and when cooked, mix it with rye or maize meals, and give it to their milch cattle with marked advantage on their health and yield of milk. This is not quite the opinion of M. Mer; he has instituted experiments on the feeding of cows with oil cake. The latter if given to a bad milker, will not sensibly augment the yield of milk, nor prolong the milk-giving period. In this case the animal puts up fat. But if the cow be a fair milker, and a little cake be given to supplement the ration of good hay, the yield of milk will not be increased; but the yield will be maintained uniformly and for a longer period—and the cost of this extra ration will be covered by the supplement of milk.

The same authority maintains, as illustrated by his experiments and analysis, that, contrary to the general belief, oil cake does not add to the richness of the milk. It is good to be given after the calving, but when the yield of milk has arrived at the period of its natural decline—3 to 4 quarts—no cake will sensibly stimulate its augmentation; the animal will put up fat. A well-fed cow in the opinion of M. Mer, will not produce a richer cheese than a poorly fed cow, but its milk will produce a greater quantity of cheese. Why? Because the relation between the divers elements of the milk remain invariable. However, the difference not the less exists, and is due to race, variety, and individuality. This must not be understood as meaning, that a cow poorly fed will not give richer and more milk if well fed; but in the case of an animal of a good breed, intensive rations, according to M. Mer, do not augment the daily quantity of milk, but maintains the secretion at its normal standard for a greater number of days. In this feeding two forces are in antagonism; the milking and the fattening qualities; the former is at its height at the time of calving, but diminishes gradually; whilst the latter is constantly augmenting, till the moment arrives when it gets the upper hand.

The question of pasture land is intimately associated with a supply of water or humidity. The soil may be suitable, the manures appropriate, the seedings select, but without a command of the aqueous element neither natural nor artificial meadows can profitably exist. This explains, why England, Holland, Belgium, French Flanders, Normandy and the Vosges, being favored by a supply of water, are distinguished for their pasturages, while the South of France, and of southern countries generally, the absence of water, is their great drawback. Hence, why the French government is devoting so much attention to measures for creating reservoirs, to constructing dams, to canalizing, and to the sinking of artesian wells. The millions so expended will amply repay the Treasury. The reason why good natural meadow hay is so much in favor, is due to the greater variety of the grasses which afford stock an adequate alimentation; now humidity tends to prevent those varieties from dying out. It is calculated that an acre of meadow ought to have 40 millions plants of grass. In an artificial meadow, there are only five or six distinct grasses, and more generally but one; while in a natural meadow there are from thirty to fifty, and these will generally be in harmony with soil and climate, but above all with the degree of moisture.

Even in the case where permanent meadows have been laid down with all the conditions for success, they will dwindle in yield, and deteriorate in quality, if the land be not irrigated, cared and top-dressed. Good grasses being delicate, are in time suffocated out by worthless varieties. The sown grasses find at first all the essentials in the soil necessary for their growth, and display it in their vegetation; gradually the soil hardens or cakes, and the rain or irrigation water penetrates more slowly, while it rises from the subsoil in dry weather in the form of moisture, with more difficulty. In time, a layer of decayed vegetable matter accumulates on the surface, souring the soil as turf ever does, while altering the mineral ingredients in the plant—feeding area, by the organic acids making these ingredients more soluble and more easily washed into the subsoil. Analysis proves that the latter, in the case of permanent meadow land, contains a larger percentage of phosphoric acid and alkalis than in the surface soil. It is also true that grass and clover favor the accumulation of nitrogen in the soil, while grain and root crops carry it off: hence, the advantage of a rotation, and of spacing the rest under meadow to three or more years following requirements.

Clay soils grass well; but the grass does not grow so high as on medium soils, friable, and well-prepared. Peaty land produces plants of bad quality, while sandy soils consume their store of fertilizing elements very rapidly, and this voracity makes them expensive to keep rich, apart from their natural dryness. Cattle know well the good and appetizing grasses, which

they bite down before coming into flower; on the other hand, they leave the worthless varieties to flower, and run to seed, which seed being shed, bad growths are propagated. In the selection of palatable grasses, sheep, and particularly rams have a remarkable ready power to rip out what is most seductive. Briefly then; always seed land with those grasses for which stock have a predilection, and sow a great variety of the grasses, so that they will arrive successively in spring, summer, and autumn. Foxtail for example, is an early and palatable grass, and so is fed down rapidly, while crested dog's tail is the opposite.

M. Laboulbène has carefully studied that enemy of maize, the *Botys nubilalis*. It is a small caterpillar which on leaving its egg-stage, attacks the infant leaf and stem by tunnelling through their tissue. There may be several insects in the same stem, but never more than two between the knot spaces. In the matured insect, the male is reddish grey, and the female pale yellow. The *Botys* attacks also hops, hemp and millet. Remedy: avoid cultivating the maize on the same soil several years in succession, and burn the old stumps in autumn.

M. de Schlanstedt draws attention to his experiments, demonstrating that everything which fetters the growth of the sugar beet aids to develop in the plant a tendency to run to seed. Thus, when the seed is covered too deeply; when night frosts strike the young plants which have just appeared above ground, or if later, a frost checks the vegetation; all these causes will contribute to produce beet liable to run to seed. Further, seed not sufficiently matured produces plants with a tendency to stalk.

In consequence of the continued frauds in seeds, the French Government intends to have a law voted, creating inspectors of farm seeds offered for sale. The prosecution will be attended with few difficulties, the penalties will be severe, and the compensation allowed to farmers injured by the fraud, will be liberal. A commission is to visit Germany and study how the pure seed-law there works.

Belgian farmers are noted for their success in potato culture. This they attribute to careful attention in the selection of the tubers intended for seed, a selection made in autumn when tubers are carefully stored in a dry and airy cellar. Tubers intended for seed are never kept in silo; never are they planted if moist, or having sprouted. In France the tubers are never planted till they have sprouted. A tuber four ounces in weight, and having few eyes, is the model for seeding; if too large, it is waste; if too small, the shoots will be slender and dwarfy; if too many eyes, there will be too many stems, too many roots, and too few tubers.

The growing favor with which meadow vulpine (*Alpigenus pratensis*) receives, merits the attention of agriculturists who desire a grass which does not suffer from a too vigorous winter and develops rapidly and abundantly. It likes a cool soil, that is to say, a bed not dry. Finland has the reputation of producing the best seed of this esteemed grass, because more care is devoted to its sowing. Satisfactory experiments are being conducted in France to acclimatize it to warmer and drier zones.

In Silesia, the employment of bricks made with an addition of 15 to 30 per cent of saw dust, are much in favor for the interior walls of buildings. If the clay contains much sand the saw dust is never employed. But it must not be forgotten, that such bricks though cheap, are from their porosity, unfit for many purposes. The addition of the dust could never be worked up with the clay intended for drainage pipes or flagging.

The arrangements for the agricultural section of the forthcoming International Exhibition next year in this city are a smiling concrete shape. It will of course be an Agricultural Show thrown open to the world. The never features will be a greater attention bestowed on Congresses. Each department of farm industry, that most conspicuously engages present, and likely future attention, will be prominently dealt with. These subjects will be fixed upon in advance. Questions

relating thereto, will be sent to the leading governments, to have answered through their respective Chambers of Agriculture. When the replies are received, the French Government will have a summary of them made in French, English, German, and Spanish, and suggesting the most points for discussion. Authorities taking part in the discussions can either have their oral or written speeches simultaneously translated.

REPORT OF THE AGRICULTURAL SOCIETY OF MADRAS FOR 1887.

From this very interesting document we quote as follows:—

THE SEASON.—As will appear from a perusal of the following table and extracts collected and compiled from the returns of N. R. Pogson, Esq., C. I. E., the learned Government Astronomer, the year 1887, at Madras, has been in those respects which most affect vegetation quite extraordinary.

RAINFALL AT MADRAS.

	1887.	Average.
January	0.01 ...	0.95
February	0.00 ...	0.31
March	0.30 ...	0.42
In 1st Quarter ...	0.31 ...	1.67
April	0.00 ...	0.65
May	0.06 ...	2.27
June	0.63 ...	2.01
In 1st half-year ...	1.60 ...	6.62
July	2.00 ...	3.78
August	8.67 ...	4.53
September	7.70 ...	4.80
In three Quarters ...	20.36 ...	19.73
October	24.36 ...	10.64
November	13.57 ...	13.38
December	11.95 ...	4.96
In the year	70.24 ...	48.71

The rain, nearly twelve inches, which fell in December, all fell on fifteen days; but the total for the year was made up on one hundred days, the average number of days required to give the rainfall for an average year being eighty-two. "The hottest day in the shade was May 17th, when the thermometer reached 106.7; the coldest night was February 22nd, when it fell to 60.6. The greatest wind velocity was 330 miles on October 9th, and the heaviest rainfall 5.75 on October 28th. The rainfall was deficient until September, but excessive during the rest of the year. Thunder storms were recorded on twenty days, that is to say, one in July, four in August, five in September and eight in October. Lightning unaccompanied by thunder was also seen on forty-one days. A light but well marked cyclone occurred on October 9th, and although the wind velocity never exceeded 21 miles per hour at Madras, it was much stronger on the West Coast after crossing the Presidency. The North-East Monsoon winds began about October 3rd, but were not finally established before the end of the month." Such a state of affairs as evidenced by the above figures could not but be most mischievous to the interests of the cultivator, whether of the Forest, the Garden or the Field. The growers of fuel trees in the neighbourhood of Madras suffered enormous losses from the drought of the first half of the year, beginning the season as they did with a short supply from the year before; and when the rain came, it was all at once, and at a time of the year when experience had not taught those interested to expect it, resulting in the loss from cold and drowning, by all classes of cultivators, of millions of seedlings and young plants, which had been reared and kept alive by hand-watering.

A curious experience was acquired in the Society's Gardens. On the 1st of October, an experimental collection of plants, woody and herbaceous, was obtained from Coonoor. Out of 1,068 received, over 700 perished without a struggle, to all appearance from nothing but the shock of the cold rain, as they did not damp off gradually but died at once

Usually plants received in September, are established and partially acclimatised before the rains begin in the middle of October. A large number of ferns also, received from Bangalore and Ootacamund, nearly all succumbed at once to the same cold rain, a circumstance particularly remarkable in the case of one hundred plants of *Adiantum athiopicum*, a species, which, in its natural habitat at Ootacamund, must often endure several degrees of frost and a vast amount of cold and wet.

The Committee continues to subscribe for the Gardeners' Chronicle, and the Botanical Magazine; and to receive as the Society's most highly valued exchanges, the Proceedings of the Agricultural and Horticultural Society of India, The Indian Forester, The Tropical Agriculturist, L'illustration Horticole, Revue Agricole de la Société d'Acclimatation de l'île Maurice, and the Kew Bulletin of Miscellaneous Information. "Annals of Botany" a periodical issued by a scientific Committee at Oxford has also been subscribed for. The usual distribution of the Monthly Proceedings of the Committee and the Society's other publications, to Members, Correspondents, Societies, Governments and others, was continued.

ECONOMIC PLANTS.—The grievous depression amongst the planting community of Southern India mentioned last year, unhappily still continues and paralyses private enterprise in the direction of new introductions. The stock of such plants is, however, still kept up in the Society's Nurseries in hopes of better times reviving the demand. Numbers of Maragipe Coffee, *Erythroxylon Coca*, Lance-wood, Mahogany, Landolphia, Trincomallee-wood, Edible Prickly-Pear, and other useful plants are still available.

CHOCOLATE.—The large tree of *Theobroma Cacao* of which mention has more than once been made in the Committee's Annual Report, as flourishing and bearing fruit under the shade of the Coconut Palms, succumbed to the drought, but another plant a year or two younger growing near it not only survived, but seemed not to suffer. The old plant was isolated in the grass so had no protection but the shade overhead, and got only such water as was given to it directly by hand; while the survivor is in the new border closely surrounded, sheltered, and shaded by the Coconut Palms and the young trees and shrubs in the border, and got the full benefit of the periodical floodings of the border. The Honorary Secretary is still of opinion that the cultivation of *Cococa* might very possibly be successful in Madras if the cultivators would take the same trouble as the growers of the Betel-leaf do in Bengal, to shade, shelter, and irrigate their crop.

RUBBER PLANTS.—The *Landolphia* plant mentioned in last report successfully ripened its crop of fruit, and from the seeds Mr. Gleeson raised about 80 plants which were in due course placed at the disposal of Government for further experiment. Orders have been issued to various officers to take over the plants and try them in climates and situations which are expected to be favourable to their growth and development. The *Castilloa elastica* plants mentioned in last report still thrive.

BREAD-FRUIT.—A batch of root-cuttings of the tree which bears the seedless Bread-fruit was obtained through the kind offices of Mr. Logan, the Collector of Malabar, and the Superintendent hopes to raise from them a few good plants. A large, rooted plant was also obtained by Mr. Robinson, the Chief Engineer of the Madras Railway, from the Western Coast, presented to the Society, and planted at once in the Coconut tops where it is showing great promise. Three other fine plants are thriving, planted out in the Gardens, two having been presented by Mr. Lavery, and one being the survivor of a number received from Dr. Trippen, Ceylon. Some very interesting papers on the subject of this tree will be found in recent Proceedings of the Committee. In view of Mr. Lavery's success in growing and fruiting the tree, and of the healthy and vigorous appearance of the young trees in the gardens, the Committee sees no reason why this tree, such a safe-guard from famine as it might be, should not be found growin

by the side of the channel of every irrigation well in Madras. The Committee is informed that Mr. Lavery has interested several of the wealthy Brahmins living in and about Mylapore in the subject, the produce of the tree being especially suited to the needs of their community. The Society is of course willing and anxious to do its best to obtain plants from Ceylon or the Western Coast, for every one who is prepared to pay the cost which should not come to more for each plant than that of a young, grafted Mango.

TREE TOMATO.—The Committee still hears frequently from the Hills of the great success of its introduction, thanks to Mr. Morris of Jamaica, of *Cyphomandra betacea*. Unfortunately the plant will not grow on the plains, but in the cooler climates of Southern India, it is an unqualified success, and its popularity continues to increase. Happily its fecundity is so great that the Society has no difficulty in complying with demands for seed by applying to some of its correspondents in more favoured localities.

CARLUDOVICA PALMATA.—In August, 1887, three plants of this Palm were received in a Warden case from Dr. Henry Trippen, Director, Royal Botanic Gardens, Ceylon. Two of them unfortunately died, but the third promises to grow well, and is now five or six times as large as they were when they arrived. The following interesting account of the Plant and its uses is extracted from the Treasury of Botany—

"Common in shady places all over Panama and along the Coast of new Grenada and Ecuador. Its leaves are shaped and plaited like a fan, and are borne on three-cornered stalks from six to fourteen feet high: they are about four feet in diameter and deeply cut into four or five divisions, each of which is again cut. The Panama hats commonly worn in America, and now becoming common in this country, are manufactured from these leaves. Those of the best quality are plaited from a single leaf without any joinings, and, as the process sometimes occupies two or three months, their price is very high, a single hat often costing 150 dollars, and cigar-cases of the same material, £6 each. The leaves are cut whilst young, and the stiff parallel veins removed after which they are slit into shreds, but not separated at the stalk end, and immersed in boiling water for a short time, and then bleached in the sun."

PARTIUM ELATUM.—(The mountain Mahoe) seeds of this plant were received from Kew, on 19th July, 1884* from which a few plants have been raised. Two of them have been planted in the new border in the Coconut Tops where one of them is very promising, being now about 23 feet, 9 inches high and 9 inches in girth, at 3 feet from the ground. † It is stated in the Treasury of Botany, 2nd Edition (page 847), that this plant "affords the beautiful lace-like inner bark called Cuba bast, at one time only known as a material used for tying round bundles of genuine Havannah Cigars, but afterwards imported, particularly during the Russian War, as a substitute for the Russia bast used by gardeners for tying up plants; it is now largely substituted by other materials. The tree, which is found only in Cuba and Jamaica, grows fifty or sixty feet high, and yields a peculiar greenish-blue timber, highly valued by the Jamaica cabinet-makers."

MORINGA.—A species of this tree *M. Pterygosperma* Gaertn., is well known to Anglo-Indians as the producer of the "horse radish" used on the plains, and less generally as the supplier of the main constituent of "Drumstick curry." There is another representative of the family with finer and more beautiful foliage in the Gardens, where it has stood, a solitary specimen, for many years, without flowering. Interest was excited in the subject by "The Kew Bulletin" which, in its first number mentioned another species which produced a tuberous root, reported to grow, and be valued as food by the Arabs in the

* Vide ante Vol. III, New Series, p. 414.

† Measured on 20th March, 1888.

Desert.* The Honorary Secretary wrote to the Director of the Royal Gardens, Kew, on the subject who kindly sent the Society, in May last, three roots which he described as "in the resting stage." One of these roots was destroyed by insects and the other two sent out feeble shoots; the first to shoot dried up altogether, and the third is again dormant. From the account given of this plant it would probably be a very valuable introduction.

FRUIT TREES.—As in most years the Society has complied with considerable orders for grafted mango plants, but has recently set on foot enquiries as to the possibility of obtaining by selection and grafting, or from seed, ripe mango fruits, all the year round. So far as the information received goes, this most desirable state of things seems to be not only possible, but even easily attainable, by any one who can expend the necessary capital and spare the time to await results. The introduction and establishing of the Date of Commerce as grown in Tunis, Arabia, Persia, and elsewhere, has been warmly taken up by Government, and large quantities of seeds and off-sets imported. The subject of the growing of Oranges and Lemons, and their present distribution in India, has been again under consideration during the past year, though there was never any doubt of the feasibility and desirability of the proposals made. Several species of the Order *Aurantiaceæ* are indigenous in the jungles of Southern India, and probably climate and soil suitable to every member of the family could readily be found within the limits of the Presidency if the inhabitants possessed the energy and capital required to grow and carry them to market. Interesting notes on the above, and other Fruit-trees will be found in recent Monthly Proceedings.

LANCWOOD.—No information has been received from the Forest Department or the Government Botanist as to their success, or otherwise with the 74 young plants of *Oxandra virgata* handed over to Government, of which mention was made in last report, but 4 remaining in the Gardens look well.

DINDE.—One of the specimens of this tree, seeds of which were received from Kew, on 19th July, 1884, planted out in the new border in the Coconut tops and mentioned in last year's report is like many of its neighbours of others species growing splendidly. It is over 24 feet high, and girths twelve inches and an half, at three feet from the ground. It is a very handsome and umbrageous tree, in leaf and habit not unlike a Scotch Elm, and promises to be a very valuable introduction being the Fastic Dye-wood (*Chlorophora tinctoria*) of the West Indies.

AVENUE TREES.—As usual, the Society raised and distributed large numbers of shade-giving trees for avenues, and to replace the destroyed Forests of the Coffee Districts. The *Kigelia*, the Rain Tree, and the *Guatteria* continue to be the favourites, but a large supply of *Albizia stipitata* was on special application got through the Conservator of Forests for a firm of Coffee Planter's on the Western Coast.

What the Rain Tree (*Pithecolobium* or *Inga Saman*) is capable of doing in the way of growth, requires to be seen to be believed. Some careful measurements of the great tree in the gardens are recorded in the Proceedings of 4th May† last, from which it appears, though it shrunk a little in the dry weather, to have increased in girth during the latter months of the year 1884, about half an inch a month, and in December, after the rains, a full inch. On 30th July, 1884, it measured 6 feet 3 inches at 3 feet high, and 5 feet 9 inches at 5 feet, with a spread of 85 feet from North to South, and an height of 46 feet. On 21st April last, it measured 8 feet 8 inches at 3 feet from the ground, and 8 feet 1 inch at 5 feet, with a spread of 88 feet from North to South, and 97 feet from East to West, and an height of about 58 feet. It is now (23rd March, 1888) at 3 feet high 8 feet 11½ inches at 5 feet, 8 feet 3 inches with a

spread from North to South, of 92 feet and East to West, of 101 feet, and an height of about 60 feet. In August 1878* when the tree was said to be under six years old, it measured 4 feet 1 inch at 3 feet from the ground, so that in ten years, a tree now only 16 years old, has much more than doubled its girth; the increase at the ground being from 5 feet 5 inches in 1878, to 12 feet on 21st April, 1887. That the growth of this tree is not abnormal, is proved by an inspection of the survivors of a complete avenue of Rain Trees planted by Mr. Burrows, in the end of 1878, when he was President of the Madras Municipal Commission, along Nungunbaukum High Road; though it is sad to think what an avenue Madras would now have if the officers in charge had done their duty and protected the young trees from the wheels of carts and the horns of cattle.

From the North of India, we hear that the planting of the Rain Tree has been tried with success on barren land poisoned by salt and alkaline effluence. The following is an extract from the "Tropical Agriculturist" of December 1st, 1887, page 406:—

"The Guango or Rain tree (*Pithecolobium Saman*) is a native of Brazil and Venezuela. It is fast growing and ornamental, and very suitable for open spaces. It is so much desired in India that in 1880, the Jamaica Botanical Department sent 30 lbs. weight of seed. Dr. King, the Government Botanist, in Calcutta, says of it:—"This wonderful tree grows faster than any hitherto introduced into Bengal with the single exception of Casuarina. It gives a beautiful shade and yields a pod with a sweet pulp which is greedily eaten by cattle. For avenues, cantonments, squares, and situations where dense shade is wanted, no tree is more suitable than this."

The Society has application for large quantities of seed of the Rain Tree for the current season, including one of 20 lbs. from Bengal.

At the suggestion of Colonel Cox and by the kindness of Mr. Peake, the Forest Officer, stationed in South Canara, the Society obtained a quantity of seed of *Vateria Indica* said to form in that part of India avenues unequalled anywhere, from which a fine batch of young plants has been raised. This tree is at present exciting much interest as the alleged producer of "Piney Tallow," but as the name of *Callophyllum inophyllum* which is extensively planted in Tanjore, and used in Travancore, to produce lamp oil, is to any ordinary ear exactly the same in Tamil as that of *Vateria Indica* in Malayalam, there is room for confusion and error.

INGA DULCIS.—As usual the Society has sent on application to Ceylon, Penang, and all parts of India, particularly the north, large quantities of this invaluable and most versatile tree. It is probably, the most universally cultivated tree in Madras being as general for hedging, and nearly as good as the Hawthorn in England. It bears any amount of clipping and chopping, or worse, nibbling by sheep and goats and gnawing by horses and cattle. If attended to, it forms an impassable fence; if neglected, grows into a noble "Bullfinch." It sows itself and grows on all waste land, and that even with its roots in salt or brackish water. Single or surviving hedge plants grow into grand timber trees. The timber is used by the husbandman for cart building; the wood is specially appreciated by the brick-maker; the leaves and twigs furnish a never failing forage for the poverty stricken feeder of milch goats; birds, beasts, and boys scramble for the plump *arillus* which encases its seeds; and in the hot weather while the grass is too dry to be eatable, the hungry cattle eagerly devour the tough outer pods.

SEEDS FOR THE BANK OF THE SUEZ CANAL.—On the introduction and recommendation of Mr. Glegg, the Society supplied to Captain Symonds of the P. & O. Steamship *Desa*, two large collections of seeds especially selected as likely to grow in sandy soil without the very best and sweetest of water. Lists of the

* Vide ante, Vol. IV, page 433.

† Vide ante, Vol. IV, page 446.

* Vide ante, Vol. I, New Series, page 288.

seeds supplied will be found in the Monthly proceedings.

CASUARINA MURICATA, ROXB.—Experiments and enquiries are now on foot to ascertain and bring to notice the value of this tree as a producer of timber useful for building purposes, pavement, and other economic uses, as it seems positively wicked to chop up trees an hundred feet high, straight as a dart, and girthing at breast height five or six feet, for fuel, which is practically the sole use to which they are now put. Mr. Ohisholm, the late Consulting Architect to Government, has spoken very highly of the timber for building purposes; and Mr. Thorowgood, the Engineer of the Madras Harbour Works is now making experiments with it for the pavement of level-crossings over the Beach Railway. Mr. Thorowgood's experiments are yet in their infancy, but it is believed that the traffic will prevent the white-ants, the bane of wood-work in the tropics, from doing much mischief, and that the cement in which the blocks are set will prevent warping, to which this wood, being immature, is specially liable. Should the trial be a success, it may be expected to revolutionize the dusty thoroughfares of Madras. From a paper entitled "A description of Wood and Asphalt, as used for the Pavement of Streets in Cities and Towns" read on 7th April, 1886, before the Institution of Civil Engineers of Ireland, at Dublin, by Mr. Parke Neville, and published in "The Universal Engineer" of 24th April, 1886, we learn that about two dozen different wood pavements have been tried in the City of London, and that the average life of the pavement in streets carrying the heaviest traffic was 9 years, at a cost of two shillings and seven pence halfpenny per square yard. On 29th April, 1879, papers were read before the Institute of Civil Engineers which amongst other facts, demonstrated that hard, tough wood should be selected to creasote, creasoted beech pavement on Sunderland B ridge having worn less in fourteen years than granite sets in four years; that it is an absolute necessity for wood pavement that it should have a thoroughly good concrete foundation; and that the cost of maintaining wood pavement to get seven years life from it is one-eighth and of scavenging one-sixth of Macadam. With such facts before us, there can be no doubt of the advantages of wood pavement generally, and there appears to be every probability that Casuarina timber will, on fair trial, be ascertained to be specially well suited for the purpose. The planting of the tree on a large scale has been practiced for so short a time, and the wood has been so much used in an unmaturing state for fuel, that comparatively little mature timber has been handled; but in hardness, toughness, density, and specific gravity, it is almost unrivalled. Hard wood is scarce and costly in Europe, and if it should appear on experience that Casuarina wood is equal to or better than other woods in use, Madras has in her hands a source of almost incalculable wealth. Another reason why experiments which may lead to the retention of growing trees till they reach something like mature age should be pressed and encouraged, is that the price of Casuarina wood for fuel has fallen during the last fifteen months, nearly thirty per cent; large plantations in the market can find no purchasers, and petty owners are grubbing up their young trees to realise before the price falls still lower without any intention of replanting. Should large clearances be made followed by the abandonment of the fuel planting enterprise, the results may be disastrous. The indigenous and established sand-binding plants have been smothered by the Casuarina trees, and the consequence of the removal of the latter can only be the transformation of, at a moderate estimate, fifty miles of Coast line North and South of Madras, metamorphosed in the last twenty years into fine forest, into a chain of bare and blowing sand-dunes, the inland edges overlapping and hopelessly destroying the cultivated land, while those on the seaside contribute a liberal quota to the already surcharged streams which threaten to choke the new harbour. The fall in the price of firewood was the immediate result of a glut in the market caused by

the Cyclone of 9th November, 1886, intensified by the bringing in of vast numbers of trees killed by the drought in the early part of 1887, but it is not unlikely to continue from the expected introduction of cheap coal from the Singarene Coal field.

JAPAN CLOVER.—This plant, *Lespedeza striata*, so strongly recommended by, and received by the Society from Dr. Schomburgk, the distinguished Botanist in charge of the gardens at Adelaide, has not succeeded. The plant is said to furnish a very valuable bite for stock in the hot season on the Oalafornian plains, and may be worthy of further trial, especially as the seed is observed to be quoted at a not unreasonable price in the catalogue of one of the leading firms of Seedsmen * in England.

TEFF.—A quantity of seed of *Eragrostis abyssinica*, an African cereal, was received from Kew, sown in the gardens, and distributed. The plant grew well both in Madras and on the Hills, and certainly flowered, but the ears did not seem to fill in Madras, at least. The grain is very small, and though the value of the plant for both grain and forage is undoubted, it is not likely to claim a share in attention of the native cultivator who is too poor to grow anything for forage, or to risk any doubtful experiment, and already possesses Cholam, Raggy, and Paddy, which, in good seasons, grow and produce a thousand fold with little more labour and attention than that required to plough the land and sow the seed.

VICTORIA REGIA.—A remarkable and mysterious mortality has over taken all the splendid specimens of this grand water-lily which used to grace Madras. It is believed that no one of the old and large plants survives, but the Society has got seeds from Mr. Storey, in Rajapootana, and from Calcutta, and now has two or three promising young plants.

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

The Government coffee crop in Java, this year, stands a fair chance of being as short as that of last year. The estimate, last month, came to no more than 468,360 piculs. Its compulsory cultivation by the natives, for Government, places the latter at an advantage over private growers. They have to pay quit rent, assessment, coolie poll tax, and export duties. Since 1885, on many coffee estates, the quit rent alone has swallowed up all profits too often. On most estates, owing to the ravages of leaf disease, the taxes alone eat up every cent of profit. Remonstrance to the Government in the direction of securing a lightening of these fiscal burdens has proved of scant avail. The Colonial Minister would not move the load even with one finger. The only concession to the luckless planters was an assurance that newly opened estates will be privileged with exemption from quit rent for ten years. For them only will incidence of the quit rent be materially lightened. Holders of land on long leases have been excused from the payment of poll tax on their tenants, amounting to five guilders a head.

The authorities in Java look with disfavour upon the emigration of the natives of that island abroad, especially to work as coolies. The officials at the head of the different provinces, view with aversion the migration of their people into foreign parts, from fear lest it should be taken as evidence of misgovernment on their part.

MESSRS. THOS. CHRISTY & Co. have sent us samples of their kola chocolate and kolatina, which preparations, they state, are steadily growing in favour among chemists as handy articles for sale over the counter. The kolatina, which is put up in glass bottles, is a sweetened paste of ground kola and cocoa; it is taken as a beverage with boiling milk or water. The chocolate is offered for sale in cakes of eight tablets, neatly put up in tin boxes.—*Chemist & Druggist*.

* Messrs. Oarters & Co.

NORTH BORNEO PLANTING NOTES.

Coolies from Banjarmassin.—We are informed by Hadjis and others from Banjarmassin that their countrymen are willing to work in British North Borneo on the tobacco estates as they now do in Deli, viz., as jungle cutters and house builders. Doubtless our planters would find them very useful on the estates.

Mr. P. Christian proposes to sell his Liberian coffee estate at Kudat to a Company for the sum of \$5,000. This sum does not appear to be excessive when we say that the estate consists of 300 acres about 30 of which are planted and will yield a small maiden crop this year. The appearance of the coffee is such as to warrant very sanguine hopes. A preliminary engagement has been entered into to purchase the estate and shares to the extent of \$6,500 are already taken up. The present position is to limit the shares to \$10,000 of which Mr. Christian takes half and he retains the management. The estate is about 3 miles from Kudat.—*N. B. Herald*.

PLANTERS in the Teesta may well anathematise the Sikkim expedition and all its works. The military authorities are offering the seductive sum of R15 per month for coolies, with the result that the latter are quitting the gardens without furlough, and leaving their masters to shift for themselves. Syces and grass-cutters also do not think it *infra dig.* to serve as coolies on such unheard-of salaries, and are likewise deserting.—*M. Mail*.

CEYLON vs. SUMATRA TOBACCO.—In the Deli news translated for the *Straits Times* we read:—Ceylon threatens to enter the tobacco market as rival to Deli. Some of the tobacco recently grown in the Spicy Isle, have developed an aroma and flavour surpassing those characterising the Deli article. A planter from the latter country, has been so struck by this discovery, that he has gone to Ceylon with a view to embark in tobacco cultivation there.

FUEL.—According to the Russian *Technic*, the administration of the Tambov-Saratov Railroad has made experiments as to the relative cost of wood, coal and Baku petroleum with the following result:—One cord of wood is equal in value to 3,420 English pounds avoirdupois (95 poods) of coal, and 2,736 pounds (76 poods) of petroleum; while the cost of these quantities is \$15.73 (1 silver rouble—75 cents) for the wood; \$15.68 for the coal; and \$13.16 for the petroleum. Results still more favorable for petroleum have been made on the Orenburg, the Warsaw-Terespol, and on the Dunaburg-Vitebsk railroads. Besides these lines the Trans-Caspian, the Trans-Caucasian the Grjisi-Zarizyn, the Morniansk-Syran, and the Rjasan-Korlow railways use petroleum for fuel.—*Indian Engineer*.

EXPORT OF CASTOR SEEDS.—The exports of castor seeds from India, commencing with a shipment of 329 cwt in 1877 have gone on increasing by leaps and bounds until, in 1887, 610,893 cwt worth £281,688, were shipped from that country, while the exports of castor oil also show an increase, though not to the same extent having been 1,411,216 gallons (worth £192,642) in 1878, and 2,676,012 gallons, of a value of £271,837 in 1887. Of this quantity, nearly one-half goes to the United Kingdom, one-fourth to Australia and the rest is distributed among various other countries. The extent which the cultivation of oil seeds in India has now assumed may be inferred from the fact that about 8,000,000 acres are under cultivation in that country with oil-yielding plants.* The imports of castor oil into the United Kingdom in 1886 were

175,818 cwt worth £244,675, of which nearly two-thirds came from India. From Italy which yields the finest oil we only received 3,823 cwt. worth £7,478.—*Indian Agriculturist*, April 28th.

PROPOSED EUCALYPTUS CULTIVATION IN MELBOURNE.—Mr. Weld, C.S., urges the advisability of introducing eucalyptus from Northern Australia, as being more likely to flourish in the plains than those obtained from Victoria and other southern parts of the Australian Continent. The Board of Revenue are of opinion that further efforts should be made in carefully selected places where a reasonable amount of care and supervision can be secured, with a view to still further testing the possibility of introducing some of these very valuable trees. Experiments made at Saidapet have shown that many of the commoner eucalyptus will grow in the plains with care; but possibly some hardier and more suitable varieties may be obtainable from the northern parts of Australia, which will flourish if left to themselves.—*Madras News*, July 14th.

PEARLS.—George Harley and Harold S. Harley recently communicated to the Royal Society a paper on "The Chemical Composition of Pearls." They examined three kinds of oyster pearls—British, Australian, and Ceylonese. The qualitative examination showed that they had an identical composition, and that they consisted solely of water, organic matter, and calcium carbonate. A remarkable feature is the total absence of magnesia and all the other constituents of sea-water except those mentioned. Quantitative analysis of two pearls from each variety gave the following composition:—carbonate of lime 91.72 per cent.; organic matter (animal) 5.94 per cent.; water 2.23 per cent. It was found that the whole of the mineral matter could be removed by steeping the pearls in nitric acid, without in any way altering the shape and to only a very slight extent the naked-eye appearance, so long as they were allowed to remain in the acid. When taken out they soon dry and shrivel up. The analysis of a so-called coconut pearl gave an almost identical result, and the authors express a doubt as to the genuineness of the specimen. Mammalian pearls—such as are met with in human beings and oxen—were found to have a totally different chemical composition. They were composed of inorganic material called cholesterol.—*Madras C. C. Magazine*.

COCONUT CULTIVATION.—A little pamphlet in Sinhalese on this subject, by Mr. W. A. De Silva, Agricultural Instructor at Andiambalama, Minuwangoda, has been sent to us by the author who says in the preface:—

This little book is intended for the guidance of native cultivators. The book contains valuable practical hints on the cultivation of this palm, and is written in easy language while the author has endeavoured to make the information given therein to be in as few words as possible and at the same time thoroughly explanatory. With many deficiencies which may be found in it, still the author hopes that his feeble efforts would tend to benefit his fellow-countrymen.

The contents are as follows:—

1. Introductory; 2. Soils: Clay soils, Do Red, Do Yellow, Do Light, Sandy soils, Lime soils, Peaty soils, Loamy soils; 3. Analysis of Soils; 4. Growth of a Plant; 5. Nursery; 6. Preparation of Land for Planting; 7. Drainage; 8. Hoing; 9. Treatment before Flowering; Insect pests, Weeding, Tilling; 10. Subsequent Treatment; 11. Manuring: Cattle Dung, Bone, Lime, Ash, Leaf refuse, Sea weed, Poonr, Salt; 12. Conclusion.

Mr. De Silva deserves the thanks of his fellow-countrymen for showing them, in regard to coconut cultivation, "how to do it," and we hope his efforts will be crowned with success.

* Apart from coconut palms, probably.—*Ed*

COCONUT REFUSE is thus alluded to in an article in *Forestry* on the "Resuscitation of Choice Trees by Top-dressing":—"Failing loam, the next best top dresser is, on the whole, coco-fibre refuse. It is less feeding, and perhaps almost more conservative alike of heat and moisture, also free from offensive odor, decomposes very slowly, and finally forms a fine mould of which the roots of all trees seem specially fond."—*Planters' Monthly*.

POTATOES.—It is somewhat disheartening to read in the report of the Calcutta Botanic Gardens that the ravages of potato disease in Sikkim and the Khasia hills have been very severe during the past year, and have given a shock to the introduction of English seed. No one knows whence the disease derives its origin; but there is no doubt of the fact that English seed is most liable to attack, and the Superintendent of the Gardens advises that in future imports of seed should be made from Malta, Australia, or elsewhere where the conditions of growth differ less widely from that of the Indian hills. Better a good plum than a bad apricot.—*Pioneer*, July 10th.

IVY ON TREES.—As several of your correspondents are asking for information on this question I willingly give my experience and observation, and first I would say that Ivy does no harm to any building provided the walls are in good repair and the spouting round the caves perfect; and here often lies the cause of all the mischief, the rain running down behind the Ivy and causing the wall to become damp, whereas Ivy itself has quite an opposite tendency and makes buildings much drier and positively thatches the wall against rain and sucks up the moisture from the base of the buildings. The walls of the Castle here are covered with Ivy of eighty years' growth, so that I speak with considerable experience. Ivy ought never to be allowed to grow on any tree unless it shows signs of decay, when, it will for years form a picturesque object, but on healthy trees it is injurious because it binds around the stem and branches—hinders the flow of sap and the proper development of stem and branch. But then is it wise to cut it on trees now? Yes, at once, at the base, and leave it on the stem to die; and before long it, will wither and decay, and the tree will get used to the loss of the greatcoat before winter arrives.—J. RUST, Eridge Castle.—*Gardeners' Chronicle*.

EUCALYPTUS AT WHITTINGHAM.—For the information of Dr. Landsborough, and others who may feel interested in the matter, I have pleasure in forwarding you notes of measurements of the above tree, taken this morning. The height is 63 feet, girth of trunk, 10 feet; and of the four main stems, 5 feet 6 inches, 4 feet 5 inches, 4 feet 2 inches, and 3 feet respectively. I may mention that Dr. Landsborough is not quite correct in stating that it was cut down to the ground in 1860; as a matter of fact it was sown over at a height of 9 feet, and so remained to all appearance dead for more than a year. In the belief that it was quite dead; they had begun to root it out, and in doing so fortunately observed a young shoot making its appearance, was followed by others, one of them from just below where it had been cut over. Whatever may be the true name of the tree, I think Dr. Landsborough right in saying that it is not *urigera*—at least, a young plant of that variety which we have here bears no resemblance to a plant of the same age, raised from our own tree, the leaves of the former being quite green, and of the latter glaucous, as well as being both shorter and rounder. *John Garrett*, May 14. [We have no doubt from the fruit figured on p. 360 that our determination is correct.]—*Gardeners' Chronicle*.

CEYLON TEA IN AMERICA.—From the *Grocery World* we take the following paragraph:—

"FINLEY ACKER.—This indefatigable grocer and business man takes unto himself a help meet—Ceylon Tea. As we go to press word comes that Mr. Finley Acker, of Finley Acker & Co., retail grocers and dealers in food products, 123 North 8th street, this city, has embarked in still another business enterprise. He has become associated with the famous Ceylon Tea Co., and has accepted a sub-agency for

this city and State. This was learned by a *World* reporter from the agent of the company. The company have removed their offices for this State from 13th and Market street, to handsome quarters under St. George's Hall, 13th and Arch street. Mr. Acker is a very live business man, being the head and front of the *Table Talk* Publishing Co., the Keystone Manufacturing Co., Pratt's Poultry Food Co., the big grocery house bearing his name, besides being treasurer of the National Pure Food Association, a leading member and committeeman of the local Retail Grocers' Association and interested in real estate, banking and other enterprises. He successfully does his share of all, and we congratulate him on his accession."

TEA IN JAPAN.—Says the *Japan Weekly Mail* of June 16th:—"The tea inspection regulations appear to be pretty well understood now, and seizures are not nearly so common as they used to be. People are occasionally reminded, however, that they cannot easily dispose of leaf that has not passed examination."—"The principal portion of first crop Tea has been fired and shipped, and purchases of leaf during the week have fallen below 10,000 piculs. The second picking has not come in yet in quantity. Prices have been steady, present quotations being a dollar a picul less than at the same time last season for good common to medium, and two or three dollars less for the higher grades. Stocks are ample. Shipments during the week have been heavy. The 'Gaelic' took 741,228 lb., the ship 'W. F. Rotch' 2,466,145 lb., the 'Glenshiel' (via Canal) 1,630,079 lb., and the 'Port Adelaide' 1,033,317 lb." The same paper, in its issue of June 23rd, says:—"The Tea trade is on about the same scale as last reported, and prices remain firm. Small quantities of second pickings have come to hand, the quality of which is about on a par with last year's productions."

MR. DRUMMOND DEANE ON JAPAN TEA BOXES.—We find the following letter in the *Indian Tea Gazette*:—11th June, 1888, Kintyre, Maskeliya. Sir,—In answer to "Inquirer," I believe that "Japan tea packages," machine made, can be obtained from Messrs. Williamson, Magor & Co., Calcutta—anyhow I know those gentlemen have recently imported a good many. The price and quality of these packages leave little to be desired, and I believe I should not be far wrong in saying that at least half the Ceylon tea crop was packed in them last year. Like all new things, the introducer is generally a loser, and in my case this proved the rule. A set was made on the boxes by merchants and others, who made, of course, a far bigger profit out of local made packages. Slowly, but surely, however, the planters found out the saving in trouble, expense and time in using these packages, and with improved times were enabled to steer clear of agents. The result being that the boxes are so much approved of both at home and here that other kinds of wooden packages are quite at a discount. My agents here are Messrs. Mackwood & Co., Colombo, and should "Inquirer" have any difficulty in getting the packages in Calcutta, he should write to these gentlemen for price lists and state sizes required. The stock sizes in Colombo are

24 x 19 x 19	23 x 18 x 18
17 x 17 x 17	16 x 16 x 16

in half inch cedar wood, but any size can be made to order. The weight of full chests, 24 x 19 x 19 including nails, lead, and hoop iron, is 26 lb. and the price of the chest in Colombo 92 cents. It would probably be the same price in Calcutta inclusively of importer's profit, say 5 per cent. I myself have shipped 300,000 lb. tea in these packages in the last three years, and have never had a complaint from my London friends Messrs. Rathbone Brothers & Co., to whom all my teas are consigned. I believe, as before said, that Messrs. Williamson, Magor & Co., are getting consignments through my Japan friends who gave them the agency at my request, or at any rate offered it them.—Yours faithfully, dear Sir,

H. DRUMMOND DEANE.

HORTICULTURE IN CEYLON AND JAPAN.

Messrs. Cocking & Co., of Yokohama, Japan, in writing for a copy of our *Directory* and sending their subscription for the *Tropical Agriculturist*, make some inquiries, which we consider are worth publishing on account of their interest to horticulturists. Their letter says:—

"The writer is much interested in horticultural matters, having a large private garden, and if the editor of your *Tropical Agriculturist* is acquainted with anyone in Ceylon who makes it a business to collect and ship plants, we shall be very much obliged to be placed in communication with such person.

"We are wanting some specimen plants of *Cycas circinalis* with stems from 6 to 10 feet or so long, and should like to know the probable cost of same. There is also a very tall bamboo growing in Ceylon, which we should like to get; also names of tree ferns, orchids, etc., or in fact any interesting plants we should like to have particulars of."

We submitted this letter to Dr. Trimen, who has kindly favoured us with a reply, in which he says:—

"There are really very few Ceylon plants either wild or cultivated here that would grow in Japan, except some of our hill kinds. I think, however, that the *Cycas circinalis*, a plant of quite exceptional hardness and vitality, would do there. The giant bamboo would be very unlikely to succeed, nor would it be possible to transport a specimen. Moreover, they have as fine bamboos of their own there.

"The reverse of the above is equally true. It is rarely that any Japanese plants are found to succeed here even in our hills. At Hakgala at all events we have been very unsuccessful in raising plants from Japanese seed. The conifers are best worth trying perhaps, especially the species of *Chamaecyparis* called 'Sawara' and 'Hinoki' in Japan, and of *Podocarpus* called 'Koya-maki.' There is also a fine *Magnolia* ('Honoki') which might do with us.

"I could no doubt suggest a few more as possibly worth a trial here by looking through the Japanese flora systematically."

TEA AND OPIUM AT FOCHOW.

Mr. Haunen's report from Fochow deals chiefly with the questions of opium and tea. The new system of collecting *licences* on opium has not only led to a slightly larger importation of the drug, but has "given a stimulus to the spread of appreciation and consumption of opium generally such as is likely to afford more satisfaction to the trader than the philanthropist." It will be remembered that early in the year there were complaints of the high rates charged for the storage of opium in the Customs' bonded godown. Mr. Haunen makes no reference to these complaints; but he writes enthusiastically of the convenience that this institution has afforded to the Chinese importer, who will soon be enabled by it to exclude the foreign importer altogether. "Formerly, owing to the valuable character of the article, none but those who had large capital and suitable premises, in regard to security against fire or robbery, were in a position to hold stocks; now anyone may do so in large or small quantities, with the facilities and security provided by the Customs' bondings system." As to the competition of native opium with the India import, Mr. Haunen says that there is nothing much more reliable than rumour to the effect that the new Convention has given a considerable impetus to its cultivation. Mr. Haunen is hopeful that the recent reports by the various foreign Chambers of Commerce, on the steps necessary to rehabilitate the China tea trade will not be neglected by the Chinese government, and that "it will not be long before a re-

vival takes place such as to place China tea in its proper position in the world's consumption and appreciation;" and he is comforted by the assurances of some of the most experienced merchants in Fochow that "China has little to fear from her Indian rival"—if her teas are only brought up to the standard of twenty years ago—for the Indian teas themselves "already begin to show signs of deterioration similar to those which now at length are engaging the serious attention of the Chinese government." The critic might be disposed to ask, what is the "proper position" of China tea, and how is it to be determined? How much has it really declined from the standard of twenty years ago?—for we must remember that we are all of us *laudatores temporis acti*, and that we have to trust entirely to memory for a comparison—and, is Indian tea showing such signs of deterioration as Mr. Haunen mentions? for if it is, they certainly do not arise from the causes mentioned by the Fochow Chamber of Commerce in the case of China tea,—*N.-C. Herald*, June 29th.

COFFEE AND THE NEW LONDON CLEARING HOUSE.

(From *I. A. Rucker & Bencraft's Weekly Price Current*.)

LONDON, JUNE, 28TH 1888.

COFFEE.—London Produce Clearing House.—The statutory meeting of the above Company was held last week at the Cannon Street Hotel, E.C., under the presidency of Mr. F. J. Johnston.

The Chairman said that, although they had only met in obedience to the requirements of the Companies Act, and had neither report nor motion to submit to the shareholders, yet the Board were glad to have the opportunity of stating, somewhat more fully than could be done in a prospectus, the grounds on which the Company had been formed. Some of them were old enough to remember the time when, in the absence of ocean telegraphs, and even of steamers, merchants had to guess for weeks and months ahead what was passing on the other side of the globe, and their representatives could only deal with their merchandise a few days before the goods actually arrived—the arrival of the merchandise and the advice of its purchase being alike dependent on the slow and uncertain speed of sailing-ships. Those were the dark ages of commerce, very favourable, no doubt, to the sagacity and foresight of individuals, but exposing us to those disastrous commercial crises—the result of overtrading—which were witnessed in 1857 and 1847, and preceding decades, when those who held commercial bills found themselves in so many cases the victims of very unsatisfactory paper contracts. Along with the development of ocean telegraphy a complete change had come over commerce. The merchant abroad had lost his initiative, and the movements of trade were now entirely directed from the great consuming centres of Europe and the United States, where the chief trading capitalists and fullest trading information were found. The foreign merchant had thus ceased to be an adventurer, and had become transformed into a mere agent, anxious by an increased volume of business and complete security of sale to obtain compensation for the reduced profits which resulted from the much keener competition induced by the more universal knowledge of and greater facilities for trade now existing in all parts of the world. The manufacturer too could no longer continue the antiquated system of buying, storing, and insuring the goods necessary to cover his forward contracts, for if he did so he found himself placed at a great disadvantage with those of his competitors who could command the same security of delivery without incurring warehousing and insuring charges or loss of interest on capital. All that proved that here there was a want of methods and institutions which would give facility and security to forward purchases and sales; and when it was remembered that such methods and institutions existed abroad,

the want became an absolute necessity unless our merchants, brokers, and manufacturers were to be placed at a very serious disadvantage. That was the motive for which the Company was formed—it was intended to be a solid and very powerful insurance office for the fulfilment of forward contracts. They might hear it said that the existing machinery private contracts was sufficient to meet all the legitimate wants of the case. But those who said that ignored the true bearings of the position, and might just as well say that the trade of the United Kingdom could be carried on without joint-stock banks, or that the traffic of the London and North-Western Railway could be efficiently carried on upon a single line of railway. They forgot that ocean telegraphs had created both the power and the desire to sell the produce of the world before even it was ready for shipment. So that unless consumers could be induced to contract for their clothing and food six or more months before they were required, they must have, under the present conditions of trade, a body of men called jobbers or speculators, who were always ready to deal in forward merchandise, and thus give a backbone to that class of commerce.

The object for which the Clearing House existed was to regulate and secure such contracts for the advantage of our traders, and the Board were satisfied that it was only under the conditions on which they proposed to work, viz., the obligation of both buyer and seller to make an adequate deposit on each contract by way of margin, and to keep up that margin from day to day, that the present requirements of trade could be satisfied. Undoubtedly that was the system of the future, and they therefore feared no competition based on any other methods. It was, too, the only system by which over-trading could be prevented, and by which traders would be placed on a perfectly fair footing towards each other, as it would secure the fulfilment of every contract, and each trader's deposit would be in exact proportion to his transactions. Such a system would treat the millionaire and the moderate trader alike, and no credit would be given to either.

Compared with the old system of trading, the operations of the Clearing House would be like a currency based on gold, as against a paper currency without any metallic backing. The only persons who would have any reason to fear at the establishment of the Company would be those speculators who exercised an influence on prices far beyond their means. While they recognised the usefulness and even the necessity of legitimate speculation resting on a solid money basis, the Company was bound, in its own interests as well as in those of sound commerce, to check all attempts at cornering, and it could do that by the power it had reserved to refuse the registration of contracts, and also by the influence it would necessarily have over its authorised agents—the experts, through whom alone contracts could be made with the Company. To initiate a new system of contracts, and to settle the regulations necessary to each trade, required, of course, time. So far the only article in which they were actually dealing was Rio Coffee, to which the Clearing House had already given a recognised position in the London market. While, however, the Company gave the security of sale enjoyed abroad, our merchants also naturally asked to be put on an equal footing with Continental ports as regarded ocean freights, in which respect London had hitherto been at a disadvantage.

He was glad to say that they had succeeded in removing that disadvantage, which would allow London to make use of its superior position as compared with Antwerp and Havre for dealing with the North of Europe. The depot business of the port of London was also likely to be assisted by concessions which were being offered to them in other directions. They were now completing regulations for admitting sugar into the Clearing House, and other important articles would follow. When next he had the pleasure of meeting the shareholders he trusted they would be able to report that they were doing such a business as would fully meet their expectations, and also prove of material advantage to the trade of this port and to all connected with it.

A vote of thanks to the Chairman for presiding concluded the proceedings.

PETROLEUM IN THE PUNJAB.

(From the *Times of India*, June 19th.)

As we briefly stated a few days ago, a concession has been granted to Mr. John D'Oyly Noble, of Petrolia, Ontario, for the development of the earth oil deposits of the Punjab. The agreement, which is dated March 23rd, 1888, is between the Government of India and Mr. Noble, and has received the final sanction of the Secretary of State. It grants to the concessionaire the exclusive right to bore for oil in the northern part of the Punjab, the Rawalpindi district being of course that which will be chiefly prospected. Mr. Noble is an oil refiner of great experience gained west of the Atlantic, and he represents a syndicate of Canadian capitalists anxious to explore the Punjab oil-fields. They have formed a company, known as "The Punjab and Oriental Oil Co. (Limited)," and if the borings prove successful this company will have the option of selecting five square blocks of land at different points where they may find oil, containing ten thousand acres each. The Government go to no expense in the matter, but are to receive, by way of land revenue, five per cent. of all the crude earth-oil obtained from the ground. The company do not interfere with the surface area, except at such points as they may require to put down wells.

Mr. Noble has associated with him six other gentlemen, all of them practical oil refiners and experts in petroleum, who are largely interested in producing and refining oil. Already these gentlemen own four-fifths of the stock in the company, which is composed of 2,500 shares of £100 each, for the purpose of more easily sub-dividing their different interests, and the other fifth is owned by capitalists in India, whose commercial experience and legal knowledge will be of great advantage to the company. The names of these stock-holders have to be submitted to the Government for approval, and one of the principal features of the agreement is that none of these original stockholders can assign or sell their stock to an outsider without the consent of the Government of India first had and obtained to such transfer. This condition has been insisted on by the Secretary of State in order to prevent the stock of the company falling into the hands of speculators and jobbers, and to secure the development of the industry in the Punjab by oil experts. The capital of 2½ lakhs is considered sufficient to strike oil with, after which the company should be self-sustaining. The Government have acted very liberally with Mr. Noble in granting him special rates of freight for five years over all railways controlled by the State for his oil and plant, &c., &c., and if the company are successful in striking oil in large quantities, they have agreed to erect works at Rawalpindi, or some other suitable place on the North-Western Railway, for the manufacture of kerosine and railway lubricating oil. The Government have also agreed to take from the company a certain quantity of lubricating oil every year for five years from the completion of the works for use on the State Railways, at the present price of castor-oil, which is now used for lubricating purposes by the different railways in India.

If the operations of the company are successful, kerosine oil will also be manufactured in large quantities, and the Government have agreed to furnish tank wagons on the North-Western Railway for distributing the oil over India in bulk, in the same manner which has been so successfully established by Messrs. Noble Brother (of dynamite fame) in Russia.

One great advantage the company will have will be their close proximity to the densely populated central portion of India, where there will be a market in the large cities for all the oil the company can manufacture for some time. The freight inland from Bombay or Calcutta on American and Russian oil is so great for that long distance that it will be equal to a protective tariff for the company, to say nothing of

the small tax which has recently been placed on kerosine oil in this country.

The Punjab oil-fields lie between Baku, on the Caspian Sea, and the oil-producing regions of Burma, and experts who have examined them consider them to be very favourably situated. They hold that they are similar in formation to the oil territory of Baku. There are spouting wells so graphically depicted by Charles Martin, in his *Region of the Eternal Fire*, and have given Russian oil a hold upon the markets of the world. The company have adopted as their seal the picture of a flowing well which figures on the cover of Marvin's book. The North-Western Railway, running west from Rawalpindi, goes right through the centre of the property and the first well is to be put down at a place called Fatehjung, 30 miles west from Rawalpindi, where oil can now be seen oozing out of the ground forced up by the pressure from below. It is the intention of the company to bore down there 1,500 feet, unless a spouting well is sooner obtained.

Marvin says these wells are worked at Baku at a depth of from 300 to 800 feet, the deepest well there being 825 feet; and that when the oil is struck the force of gas from below is so great as to frequently blow the heavy drilling tools and apparatus out of the hole up into the air, which is followed by an immense flow of petroleum, saturating everything with oil all round, and rising sometimes to the height of 300 feet before it can be controlled. In describing one of the oil fountains at Baku, he says: "At 420 feet there was a terrific outburst of gas, which was repeated at 490 feet; the oil each time mounting to the surface, but disappearing after the cap was fixed. The third time, at 546 feet, the explosion of gas was terrific, hurling the pumping cylinder into the air, and smashing the top of the derrick to pieces. Afterwards dry sand began to spout with terrible force, forming a fountain of grit from 350 to 400 feet high. Bits of rock were hurled so high as to be lost to sight; all the windows of the neighbouring engine houses were smashed, and the metal roof of a boiler house was broken through by a falling stone. This 'sand-volcano' lasted 45 minutes, and was succeeded by a blast of gas which poisoned the atmosphere at Balakhani the rest of the day. After a considerable time a cap was fixed on the tube, and directly afterwards the oil began to spout."

It is to be hoped the "Punjab and Oriental Oil Company" may obtain something of this sort at Fatehjung and that oil will be found in India to take the place of the Russian oil which is now coming into this country in such large quantities.

BRITISH NORTH BORNEO.

We have been favoured with a copy of the latest Report of Acting Governor Crocker, together with the Report presented to the shareholders in the North Borneo Company at their meeting on June 27th. We are glad to notice that the Directors are careful to keep land sales proceeds separate from general revenue; moreover they write off for depreciation of assets and make allowance for exchange. This may be seen from the following:—

The total Receipts for the year amount to £23,570 2s 6d, comprising £22,592 2s 9d from Revenue proper, £2,296 12s 6d from Sales of Land in Borneo, and £681 7s 3d from Interest and other sources in London. A reference to the comparative statement of Borneo Revenue and Expenditure for the years 1886 and 1887, which is appended, will show that while the receipts from Revenue proper amounted in the former year to \$127,731-23 they have risen in the latter to \$142,687-20 giving an increase of \$14,955-97 or over 11 per cent., and this has been distributed over almost all the various items of Revenue. The Expenditure in Borneo shows a decrease in 1887, as compared with 1886, of \$6,649-66.

The Home Expenses amount to £2,984 19s 4d against £3,825 18s 1d in 1886; the latter, however, included an item of £719 13s 2d as extraordinary expenditure in connection with the Colonial and Indian Exhibition.

Capital Account has been debited with £2,154 17s 11d for Expenditure on additional property and improvements in Borneo, and credited with £2,296 12s 6d for Sales of Land and other property. In addition to this a sum of £3,149 10s 7d has been written off for depreciation of Assets throughout the Territory, and charged to Revenue Account; the result of the year's operations being a decrease of £2,991 5s 2d on the Capital Account.

The Advances outstanding (Sundry Debtors—Borneo) at the close of the year have increased by £1,310 0s 1d, and now stand at £24,405 17s 2d.

The rate of Exchange has been taken at 3/2 the dollar as against 3/4 in 1886, and the result is shown by the item of £1,390 9s 10d at the debit of the Revenue Account.

The Directors have again the satisfaction of reporting a steady increase in the Receipts, and a decrease in the Expenditure of the Colony. Since these Accounts were prepared large sales of land have been made for Tobacco planting, which bids fair to become an important element in the development of the Company's Territory. The introduction of capital and labour, which must necessarily follow, will result in an immediate benefit to the revenues of the country.

Mr. Charles Vandeleur Creagh, late Assistant-Resident of Perak, has accepted the appointment of Governor of the Colony, and Mr. Crocker, who has been acting in that capacity for the last year, has returned to resume his duties as Manager of the Company in London.

The Directors have pleasure in announcing that Lord Brassey has accepted the seat at the Court which was vacated by the resignation of Mr. James Brand. From the Governor's Report we quote:—

SANDAKAN, 1st November 1887.

LORD BRASSEY showed his confidence in the Company by investing in its shares, and in the Country by taking an interest in a mercantile firm in Sandakan, which is engaged in the Timber Trade with China.

The Settlement of Deli, in the Island of Sumatra is one of the most advanced of the Colonies under Dutch rule, and its prosperity is also owing to such a large number of Chinese being employed in the Tobacco Estates. The tobacco grown in Deli is highly esteemed by cigar manufacturers for covers, it being remarkable for its pureness of leaf. The production of this tobacco has been steadily increasing, the exports being in 1883, 93,000 bales (of 80 kilos, or 177 lb. each); in 1884, 128,000; in 1885, 125,300 and in 1886, 140,000 bales. Land in Deli and Langkat suitable for tobacco growing is now running short. I have found it impossible to obtain the actual figures of the Revenue derived from Deli by the Dutch Government, but a resident of the country gave me as a safe estimate \$80,000 a year, whilst the expenditure does not amount to one-half that sum.

The territory of Sarawak on the North-west coast of Borneo comprises an area of 41,000 square miles with a population of about 300,000 souls composed of various races, out of which it is estimated there are 20,000 Chinese. Although the revenues of this state have not advanced by leaps and bounds the progress has been steady and satisfactory (especially since the introduction of Chinese Gambier and Pepper planters in 1875), as the following figures will show.

Revenue	1875	\$158,435
"	1880	229,718
"	1885	315,261
"	1886	346,661
"	1887	350,813

Here also the bulk of the Revenue is derived from Licenses, the Chinese contributing directly and indirectly about \$200,000 a year or \$10 per head in the population—and their introduction into Sarawak resulted in doubling the revenue in ten years.

The Revenue of the country is steadily increasing as the following figures will show.

	From Revenue		Land Sales.
	Revenue	Proper.	
1883	\$51,654	...	\$2,449
1884	" 82,448	...	15,458
1885	" 110,452	...	2,863
1886	" 127,731	...	12,034
1887	" 140,000	...	10,000
1888	Estimated 158,000	...	86,000

When reviewing the growth of the revenue it must be borne in mind that the Company in trying to attract population and capital had to compete with adjacent countries where free trade prevailed, and therefore they had to set up a most liberal form of Government. All import duties were abolished; land had to be almost given away; and no direct taxation was imposed as it was necessary at first to gain the confidence and good will of the native races. Tobacco planters were given land without a quit-rent, the only condition being that after 5 years the Tobacco exported will pay an Export duty which shall not exceed one per cent. per pound avoirdupois. Under these conditions three Tobacco Estates have been commenced and two more are about to be opened, and it is only this year that the Court could declare that no more Tobacco land will be sold under the price specified in the Land Regulations. The same remark applies to native taxation, and a scheme for increasing this in 1888 is also under consideration.

The subject of Taxes on the people requires very careful handling. The Company has already been accused of sucking the life blood of the people in order that they might pay dividends to Shareholders. In answer to such charges and to show the liberal form of Government which has been set up in British North Borneo I may quote the following examples:—

A. The natives of Java pay one-fifth of the produce from the land, and one day's gratuitous labour in the European week of seven days or from 6s to 16s. per head of population.

B. The natives of India pay a heavy land tax, and in the gross revenue from 5s to 12s. per head per annum.

C. The natives of Fiji pay £2 per head in direct taxation in produce; and, including heavy import duties on all goods, pay over 6s per head.

D. The natives of Ceylon pay 8s per head, and in addition six days' gratuitous labour towards the upkeep of the roads. The latter is now commuted by a money payment and yields a revenue of £83,000 a year to the Colony.

The natives of all British Colonies might be cited but it is unnecessary, as I believe there is no country in the world possessing any semblance of a Government where the inhabitants are so lightly taxed as the people under the Company's rule; as, should the measures now contemplated become law, the gross native taxation will not amount to 1s 3d per head on the total population.

The last balance sheet will show that out of a total revenue of \$139,765, the native population, numbering some 150,000 souls, paid only in Poll-tax and Inland Passes \$8,037, all of which was paid away in salaries and allowance to native chiefs and collectors. As they do not consume excisable goods this is their only contribution towards the up-keep of a large Police Force and expensive administration so, that it is evident Chinese must be attracted to the country before the Revenue will show any material increase.

The expenditure of the Colony has been reduced from \$391,547 in 1883 to \$189,154 in 1887.

These remarks might have been written about British North Borneo today, and I would point out that in 1876, after rigid economy, Sir Arthur Gordon expended in the Colony of Fiji, which contains an area of 7,400 square miles and a population of 128,000 people, £71,000 or \$420,000, whilst to manage British North Borneo, which contains an area of 31,000 square miles and a population of about 150,000 people, more scattered and discordant than the inhabitants of Fiji, the Company will expend in 1887, £29,000 or a total of \$176,000, which is about one-half of that required to conduct the affairs of the Colony of Fiji under Her Majesty's Government.

In Sandakan Bay a large number of sawyers now find profitable employment. One European Timber Company is paying good dividends by shipping to China, and coolies are finding their way down in their vessels. Another Company has been formed in Europe and will I hear erect powerful Machinery immediately. The timber resources of Sandakan Bay are almost inexhaustible, and from its advantageous position the trade must continue to develop.

If a pessimist view of the future be taken, and the failure of Tobacco and Gold is assumed, it must still be remembered that the shareholders possess a country larger than Ceylon, with all its land timber and minerals. A country which there will be no difficulty in holding and governing as combined opposition from the natives is impossible. A country which cannot retrograde but must advance, so that it would seem that the worst that could possibly happen would be a retarded development and capital locked up for a longer period without yielding any return.

An optimist however, will see Tobacco doing for Borneo what it has done for Deli, and point out that when the Export reaches that of Deli in 1886, viz; 140,000 bales at 177 lb. each, the duty of one cent per pound which the Company can impose in 1892 will bring in a revenue of \$240,000 alone, to say nothing of the increased revenue from a large Chinese population. He will see Gold doing for Borneo what Tin has done for Perak. He would point out that British North Borneo is larger than Ceylon, where the land sales between the years 1833 to 1884 realized over two millions sterling, and ask why Borneo should not do likewise? In fact I would defy the most confirmed pessimist to write anything but a hopeful report after visiting this country. It would be impossible for him to avoid writing about the magnificent harbour of Sandakan; the beautiful bay of Silam, and the glorious tropical climate; and, even the most prosaic Shareholder, after steaming for three days from one boundary of the country in Brunei Bay to the other in Sibucco Bay, passing the most lovely scenery all the way, could not help feeling proud of his proprietary rights over such a fine territory, but I have tried to take a dispassionate view and to place the actual position of the Company before the Court and the shareholders, at all events as it appears to me, so that they may form a correct idea as to the value of their property.

Supplement.

SANDAKAN, 15th March 1888.

As stated in paragraph 15 of my first Report, Deli exports about 14,000 bales, or 24,780,000 lb. of tobacco a year. Should our out-put reach that amount an export duty of one per cent per pound avoirdupois would, without any indirect taxation, yield an annual revenue of \$247,800. Up to the end of 1886 I find the land taken up in Deli and adjacent states for tobacco growing amounted to 255,000 acres. We have already sold 112,000 acres, and have received and accepted during the last four months applications for 200,000 acres more. We have still, according to Estimates, 600,000 acres in accessible places suitable for raising tobacco, and over a million acres if the heads of our rivers and plains in the interior be taken into consideration. As no other country has yet been found to produce the same class of tobacco as that grown in Deli and British North Borneo, and as no more eligible land seems to be available in the former country, the possibilities of advancement in British North Borneo are so illimitable that it is difficult not to take a sanguine view of the future. The Ranow estate in Murudu Bay will pay a dividend the first year, and next year they hope to pay the greater part of the subscribed capital. Here the manager is thoroughly experienced both in the management of coolies and the manipulation of the crop.

As PLUMBAGO alone, as a lubricant in marine engines, is often washed away by the condensed water, Mr. J. Dewrance, under a patent, mixes it with an insoluble soap of lead or lime.—*Indian Engineer.*

INDIAN TEA NOTES.

Tea is doing well in Sibragor.

The weather has been wet in Cachar.

Some damage has been done to tea by red spider in South Sylhet.

Seasonable weather is reported from Kamrup, Darrang and Nowgong.

DEBRA DUN, 3rd July.—The rains have begun at last. We have had general showers, but no rain heavy enough to bring down the kalas and rats.

LALAMOOK, 2nd July.—The rainfall to the end of June has been 78.19 against 39.10 last year. Since the 13th May we have had 10 days on which no rain was registered. On the 14th May 8.38 fell, and 15th June 6.60. Gardens in Hailakandi are doing very badly some have made a $\frac{1}{2}$ less tea than last year.—*Indian Planter's Gazette*, July 10th.

A VETERAN ON CEYLON PLANTING PROSPECTS.

No one is better able than Mr. Peter Moir to compare the past with the present in Ceylon after a thoroughly sound practical fashion. He has had experience as planter in a number of districts above most men, and he has had at intervals the benefit of good long spells of leisure for reflection and comparison after renewed visits to the scenes of his early labours. He has, moreover, lived through the coffee era into that of cinchona, cacao, rubber, and now above all to that of the young giant tea. Mr. Moir has just been on one of his periodical visits and has been a close observer for several months past of what is going on, more especially in the districts North of Kandy, where he so long resided and worked in the Dumbara Valley; in the Hewahettes, Pussellawa, Ramboda; through the younger and higher districts; and lastly down through the Kelani Valley.

To take the last-mentioned first, Mr. Moir, as an old planter well acquainted with good and poor soils in Ceylon, was rather astonished to see the poor stuff—that is the shallowness of soil—on most of the Kelani Valley plantations, from which nevertheless crops of leaf are plucked averaging double the quantity gathered per acre in the hillcountry. Mepitikande, Mr. Moir pronounced to be the best piece of soil and lay of land he saw in the district. Mr. Millington's estate is also a good one, giving fine returns; but some of the newly-opened land, with drains fully cut so enabling the soil to be judged, astonished him by the shallowness of surface material although the tea plant seems to rejoice in the hard-looking sub-soil on which coffee would have starved. As regards the high districts,—Dimbula, Dikoya and Maskeliya—Mr. Moir is sanguine, tea will grow and yield profitable returns for a long period to come. Profits rising from R6,500 to R7,000 from 100 acres of young tea in such a season as the present, are not out of the way. As regards the old coffee districts there can be no doubt that tea keeps backward over large portions of Pussellawa, Ramboda, Hunasgiriya, Kelebokka, Knuckles, Rangala and especially Matale West. The clearings may come on in time, but the estimates originally framed will not be realized for two or three years after the time fixed for them. On washed-out hill-sides such as may be seen in Kotmale and other old districts it is questionable if tea will ever pay. Very extraordinary is the fact that the first 50 acres' clearing on elevated tea land on Ellabawa should have been the means of milchew, so many in the Northern districts. "If that miserably poor stuff grow such fine tea, why our old coffee fields should do splendidly" was the general thought. But as a matter of fact

the old coffee fields do not do half so well. Had they been left abandoned or fallow for two or three years' interval, the case might have been different. There are large exceptions of course to this rule, good and poor fields in these northern districts being wonderfully intermixed; but the old coffee estates with the best soil—rich black loam—more particularly North and West of Matale are really most backward in tea. It is very curious. On the other hand, there are in Matale North some very fine tea clearings—notably on Hapugabalande which is pronounced a second Mariawatte. Selegamma too is likely to do well in tea. Wattegodde and Galgawatte as well as part of Poengalla and Dumbulagalla are spoken of, as doing exceedingly well in tea.

Mr. Moir visited his old protégé, Mr. Taylor on Loolecondura, and found him busy erecting new machinery with which he expects to turn out even finer teas. The twenty years' old tea bushes here are looking as vigorous as when they were only ten years. The Loolecondura average plucking from the old fields is said to be about 350 lb. per acre. The story has been current in some parts of the country that one reason why Loolecondura teas maintained their high average was due to the admixture of the small-leaved China variety, of which a good deal was grown on the estate. Never was a greater mistake, as any novice might know, for the finer the jât the finer the tea. The small China leaf is no advantage, quite the reverse. The fact is that Loolecondura has not many China bushes, and these are scattered along the roads. The leaf is plucked and prepared, despatched and sold separately and generally fetches 1d to 2d the lb. below the Assam-Hybrid tea.

Finally in Dumbara as Managing Director of the Rajawella Estates Company, Mr. Moir had a good deal to see of cacao, and he says it is wonderful how the supposed areas planted have dwindled down, through the trees not prospering but dying out wherever exposed to wind, or on bare ridges or poor soil. In sheltered valleys, with rich moist soil, cacao grows splendidly. But elsewhere the trees are so sparse that the supposed cultivated acreage had to be cut down nearly one-half. A good crop is now maturing on the trees throughout Dumbara. During a drive through Pallakelly—which has the advantage over Rajawelly, of large reserves of virgin land—Mr. Moir was much struck with the superiority of the Nalkanad (Coorg) coffee over the Ceylon coffee, both being in young fields divided only by a road—the one looking very vigorous, while the other was drooping. As regards crops of coffee Mr. Moir fears there will be none at all this coming season: at least in Bogawantalawa and Agrapatana the outlook is very poor. Native gardens are doing well, but North of Kandy there is scarcely a bean on plantations. Nevertheless Mr. Moir and Mr. Hadden have been discussing the propriety of opening some of their low-lying land in the Hunasgiriya district with coffee, getting seed of course from Coorg and planting under shade. If the experiment is made it will be watched with much interest.

SOME EXPERIENCES OF TEA-PRUNING, &c.

About twelve months ago, there was a great diversity of views upon the right way of pruning tea and the general opinion was that most of us had over-pruned; and thus, like many other men, judged upon immediate results, was, I think, then generally admitted to be right. To prevent any mistake, however, I pruned two pieces, in similar soil and exposure, the one heavy and the other light, which has given me the following experience.—

1st.—I am of opinion that, if the jât is very high, heavy pruning is a mistake.

2nd.—If ordinary, like most tea, that it does not matter considerably whether pruned heavily or lightly.

3rd.—If the jât be inferior, heavy pruning is the only way of getting anything from it.

The good jât tea flushed well from not necessarily very strong wood, while the ordinary and bad flushed best nearest the heaviest cutting.

With ordinary and inferior kinds, too, what was pruned heavily continues to show no present necessity of requiring again pruning, while such tea pruned lightly is already requiring the knife again.

In all districts above 3,500 feet, I am inclined to consider the less frequent pruning is done the more satisfactory in every way will be the plucking and consequent making of tea, therefore, on the whole, I incline to the more severe pruning, unless very high jât has to be dealt with. My reasons for this are that it can thus be the more thoroughly done, and it will run fully three months longer before pruning again becomes necessary, and, expect for the first few months, is in every way more satisfactory.

When mixed jât exist in a field, I prefer, with old tea, to have two heights, the one six inches above the other. The higher level I use for all the good kinds, and the lower for all the inferior.

With ordinary kinds, especially if the estate is at all exposed, I prefer low trees to high, and my heavy pruning takes the form of cutting down to a low height rather than much clearing out of the bush. In bad jâts, merely opening out the bush without cutting down very low is only followed by it merely growing up to the original size it was before pruned, and then again remaining inert. The only way to get at really bad tea is by cutting out all knotty, wiry stuff, or, indeed, anything indicating a desire to produce flower and seed, though, taken any way, it does not give satisfaction.—PEKOE SOUCHONG.—Local "Times."

CULTIVATION OF ECONOMIC PLANTS IN CEYLON.

The annual reports by Dr. Trimen upon the gardens under his charge in Ceylon are usually highly instructive and the latest is no exception to the rule, as it contains some very interesting notes on economic plants and products. Tea cultivation and manufacture is said to have now attained the position of the leading agricultural industry in the colony, about 180,000 acres being under cultivation with the plant, whilst the exports of tea in the last financial year exceeded twelve million pounds, the average price realized being nearly 1s. 1d. per lb. Coffee, its less fortunate rival, fell off in export to 180,000 cwt., and the coffee plants that have escaped the leaf disease are now being destroyed by a new scale-insect. Cinchona bark has still maintained a high position among the exports from the island, the quantity exceeding fourteen million pounds in the year; but much of it has been sold at a price insufficient to pay expenses on producing it, and it is expected that the exports of bark will now rapidly decrease. The moral drawn is that quality and not quantity should have been the object of the cultivators, and reference is made to the more far-seeing policy adopted in Java. Seeds of *Remijia pendunculata*, the tree yielding "cuprea bark," have hitherto failed to germinate in the gardens. The cultivation of the cubeb plant in Ceylon has been suggested as a probable remunerative industry in view of the enhanced price of the drug, and Dr. Trimen contributes some valuable remarks on the subject. *Piper Cubeba* is considered to be native in Java, Sumatra and Borneo, but can scarcely be said to occur wild now anywhere. Its cultivation appears to be carried on only in certain parts of Java and Sumatra, the business being almost entirely in the hands of the natives. So far as the mode of cultivation is known it appears to be similar to that of ordinary pepper, the stems being allowed to climb over the trunks of trees and the fruit being plucked before it is quite ripe and then carefully dried. The true *Piper Cubeba* plant is however but little known, and is imperfectly understood by botanists. Several other species approach it very

closely, and even the plant cultivated at Kew from which the figure for *P. Cubeba* in 'Medicinal Plants' was drawn has since turned out to belong to another species. A figure taken from a dried specimen of the true plant from Java will be found in the 'Kew Miscellany' for December, 1887. One difficulty in commencing the cultivation of *P. Cubeba* arises from its diœcious character, all the plants that have flowered in Ceylon since the commencement of the experiment having been male. Ipecacuanha appears to be doing somewhat better at Henaratgoda than hitherto had been the case at Peradeniya; but although by more care in the preparation of the soil and choice of situation for the beds some roots of finer growth have been produced, not much progress, on the whole, can be reported. Incidentally it is mentioned that by order of the Madras government a plantation of ipecacuanha is about to be formed at Nilambur, on the Malabar coast. The coca bushes at Peradeniya have yielded a large crop of seed, a considerable quantity of which has been sold. The stock was introduced from Kew, and the plant, which bears leaves differing somewhat in form from those of the typical *Erythroxylon Coca* was probably derived originally from New Granada. In Java two varieties of coca are now being cultivated, the leaves from one of which are reported to have yielded 0.87 per cent. of cocaine. Plants of *Piper nigrum* introduced from Singapore give promise of being a more vigorous and better variety than the native ones; but out of two hundred cuttings of the *Uncaria Gambier* plant from the same source only one sickly specimen had survived. The report also contains information respecting the cacao, tobacco, and several india-rubber plants, and a number of introduced fruit-bearing species.—*Pharmaceutical Journal*.

THE OIL PALM AT LOANDA.

The following notes on the African Oil Palm (*Elais guineensis*) are from a report on the products of Loanda, and are interesting as supplying an authoritative account of the manufacture of Palm oil from an eyewitness. Although the Oil Palm may be said to be a wild plant of these regions and requires no planting or cultivation, it nevertheless receives a certain amount of attention at the hands of the natives in the shape of pruning, lopping off dead and dying leaves, tapping some of the stronger leaves, with the object generally, it is thought, of improving the fruit. The huge spadices are said in some instances to bear, probably, as many as a thousand nuts or fruits, each about the size and nearly the shape of a pigeon's egg, of a bright red colour, tinged sometimes with yellow and in some cases deepening into black. The outer covering of the fruit is from $\frac{1}{2}$ — $\frac{1}{4}$ inch in thickness, composed of fibrous matter and pulp, and containing the oil. To extract this the nuts are boiled and beaten to separate the oil from the pulp. This is afterwards skimmed off and put into pots ready for sale, and requires no further preparation. The hard seeds are cracked, and the kernels form an article of commerce, a fine white oil being produced from them. A few years ago the oil from this district was sold in Europe at about £40 per ton; it has now gone down to £20 and there is no prospect at present of any improvement in price, so many substitutes of a cheap kind, notably petroleum, being now employed in manufactures where at one time only Palm oil was used, such as soap, candles, &c. The substance of the kernel after the oil is expressed is used to make cattle cake. The only agricultural implements in use are the hoe and the hatchet.—*Gardeners' Chronicle*.

PEPPER AND ITS ADULTERANTS.

BY E. DAVIES, F. C. S., F. I. C.

(A Paper read at a Meeting of the Liverpool Chemists' Association.)

Mr. Davies said the plant which yielded the pepper of commerce was one of the Piperaceæ, *Piper nigrum* being a climbing plant bearing its flowers in spikes. The flowers were inconspicuous, and were

succeeded by green drupes which became red when ripe. They were gathered before ripening and dried, the fleshy portion becoming wrinkled and black. When white pepper was to be made the berries were soaked in water, sometimes, it was said, in cow's urine, and the outer layer rubbed off. Black pepper was manufactured by grinding the whole of the dried grain; white pepper, on the other hand, by grinding the decorticated berry. To meet the demand for an exceedingly light coloured pepper, the outer layers of the seed were sometimes ground off, and only the nearly white kernel used. As the starch of which the berry was largely composed was largest in proportion in the centre, the pepper so made was deficient in pungency and flavour, and it was a nice question whether such treatment was allowable under the Food and Drugs Act. Nothing was indeed added, but the removal of the most valuable portion of the berry was akin to skimming milk. One of the constituents of pepper was an essential oil, which could be obtained by distilling crushed pepper with water. Of this black pepper yielded 1.17 per cent., and white pepper 1.04 per cent., and it had the smell of pepper but not a strong taste. Its composition was akin to turpentine. The perfume of pepper being largely due to it, to obtain the best result the pepper should be fresh ground, or kept tightly closed. The custom of keeping pepper in castors with perforated tops was unscientific. Little mills by which the pepper could be ground when required was the best method of obtaining it pure and pungent. Other constituents were a resin soluble in caustic potash, and piperine, an alkaloid, the amount of which was very variable. In black pepper, from a recent analysis, the percentage was 7.14 to 6.62, and in white pepper 6.47. It was soluble in alcohol, and was said to be febrifugal, it being curious that its composition was identical with that of morphine. Other ingredients were starch, which in black pepper amounted to from 49 to 56 per cent. and in white pepper from 77 to 85 per cent., and cellulose, which in white pepper ranged from 12 to 14 per cent. and in black pepper from 21 to 26 per cent. Under the head of impurities, Mr. Davies dealt first with the mineral ingredients of the ash. In black pepper this was generally due to impurities adhering externally to the pepper seed, but except where sweepings had been added ought never to amount to more than 6 or 7 per cent. Of vegetable adulteration, the first to which he called attention was long pepper, made from the wild plant *Cherica Roosburghii*, which belonged to the same natural order as pepper, and also contained piperine, but in much smaller quantity. The essential oil yielded by it was stronger in smell, and there could be no doubt of the injury caused to pepper by the admixture of even a small quantity of this product. Rice was added to pepper for two reasons: first, to improve the colour by whitening it, and so gratifying the taste for white pepper, and secondly, to increase the bulk with a cheap adulterant. Fortunately the angular starch grains of rice, being twice the diameter of pepper starch, rendered its detection easy. Spent ginger, which had also been used, was likewise easily detected for the same reason. They would be well acquainted with the history of the ingenious adulteration known as pepperette or pivoirette. The discovery of it by Dr. Campbell-Brown, and the publication by him of a method for its detection, had stopped what might have been a very successful swindle. The great advantage of this adulterant was that it contained no starch granules, and the cells which composed it were almost identical in form with those of the cortical layers of pepper. Only by careful comparison of the two under ordinary polarized light could they be distinguished. The olive stones from which the adulterant was made possessed neither pungency nor flavour. Under the microscope the centre of the cells of bleached pepper was light coloured, like the centre of the cells of the ground olive stone; but when polarized light was used there was a difference in colour, the olive cells being light bluish, and the pepper yellowish.—*Pharmaceutical Journal*.

SERICULTURE IN CEYLON: THE MATALE AGRI-HORTICULTURAL ASSOCIATION.

MR. REEVES ON THE INTRODUCTION OF SERICULTURE.

The CHAIRMAN said the meeting would now proceed to the business on the paper, and called upon Mr. Reeves to propose the resolution which stood in his name, viz.:—"To consider the introduction of Sericulture into the district of Matale."

Mr. E. GORDON REEVES who was well received rose and said:—Gentlemen,—I do not intend to detain you very long, neither do I propose to deliver a lecture on the history and progress of Sericulture. What I propose to do is to bring forward arguments in favour of an attempt to introduce silk growing, and explain my scheme for starting this industry. In the first place I should state that my principal object is to introduce silk culture as a native industry. In what follows therefore I shall speak of the silk industry only as it may affect our native population. Now it is well known that the Sinhalese cultivator, the goyiya, with whom I purpose more especially to deal, has if not a great deal at least some unoccupied time on his hands. If he have a family the unoccupied time of the household collectively would be considerable. It is this at present wasted time that I wish to see turned to account for the benefit of the villager and his family. Now later on I am going to charge the goyiya with being apathetic; but it will be no contradiction if I now say that the goyiya has his spells of fairly hard work in which his family also shares; therefore in searching for an industry to employ his leisure hours any that would involve much labour would be out of the question. What is required is some light occupation in which the women and children of the household would take the principal part; what is also necessary is employment of a thoroughly simple character and one which could be engaged in at home and in all weathers,—an industry which, in fact, would afford continuous, easy and remunerative employment. I believe that the silk industry meets these various requirements to the fullest degree. No hard labour is required, no skilled labour, it is simple in the extreme, all it demands is a certain amount of careful attention. Now I need not, I think, detain you with a whole string of arguments in favour of my proposal. I will only bring forward a few of those which I consider most to the point. It will be necessary in dealing with such a very practical audience to prove in the first place that Ceylon possesses a suitable field for silk growing. There will be little difficulty in this. We may notice the fact that Ceylon is the home of no less than seven silk-producing moths, and that the few experiments made, notably that carried out by a member of this Association, Mr. Alexander Ross, prove that silk produced in Ceylon need be second to none in quality and strength.

The speaker then proceeded to read the report of the samples sent to the Manchester Jubilee Exhibition, and reports from the best silk-producing countries, such as New South Wales, Victoria, South Australia, Natal, Cyprus, etc.

Mr. REEVES continuing said:—I think you will allow that these figures are sufficiently good to justify a further attempt. The climate of Ceylon is regarded by experts as favourable. The present time has also, I consider, its advantages for the introduction of this industry. An Association has recently been formed in England (the Silk Association of Great Britain and Ireland) for the promotion of the silk industry and the encouragement of the production of raw silks in India and British Colonies. The President of that Association, Mr. Thomas Wardle, has been good enough to promise all the assistance he can afford in the furtherance of the proposals I lay before you. We shall, therefore, be setting out under good auspices. As to further arguments, I think, gentlemen, when we consider the advantages that would accrue to the Sinhalese villager by the gain of even a few rupees annually, and what is to my mind a more important factor in the scheme for his advancement the gain of some economic advantage by some extra display of energy on his

part; when we consider that an industry of this kind once fairly implanted is likely to bring both considerable pecuniary and moral benefits to many a now almost destitute family, I think we shall have but little difficulty in coming to a fair decision as to the merits of the proposal before us. From time to time we hear of loss of crops through drought or excess of rain and the consequent distress; we hear also of fever epidemics. The famine-stricken villagers must be relieved by the distribution of grain, the fever-stricken by the issue of quinine. These measures, however, should only be regarded as good in so far as they are but temporary expedients. Surely we are not going to allow people living in the same district as ourselves to continue in this hazardous existence? Our object should be, not to make the villager more dependent on Government protection, but to encourage him to provide for himself in the case of emergencies; by so doing we shall also encourage in him a spirit of thrift and of honorable and manly independence. Now with regard to ways and means: it is here that our difficulties will at once present themselves. I have already hinted at what I consider the most insuperable difficulty. The apathy and more than apathy—the obstructive apathy—of the goiya will be a hard nut for us to crack. I do not pretend that I have any new scheme or invention for overcoming this very strongly entrenched position; on the other hand, I think it is too strong to be taken by assault; we must proceed to its capture by the slower means of investment and siege. The apathy of the goiya is so deeply ingrained in his character, that I believe in nine cases out of ten, were his ordinary means of subsistence withdrawn he would rather sit down and literally starve than attempt a new and untried means of gaining a livelihood. Nevertheless in spite of the strong opposition with which we shall assuredly meet I propose to undertake the campaign with every assurance of its ultimate success; I say *ultimate* success advisedly, as I cannot venture to think that we shall suffer no reverses, but these very reverses will I believe only stimulate us to carry the right war into the enemy's country. I have spoken of the goiya as apathetic. I assure you I do so in no depreciatory spirit. I have a very great respect for the Sinhalese as a nation, and I may say I have a great regard for many of the more enlightened Sinhalese whose acquaintance I have been fortunate enough to make. So far from attempting to depreciate the character of the cultivator, I hold that we are ourselves in no small degree responsible for his present character. Eighteen centuries ago our ancestors were not a very active-minded race. It was not until the Romans, who at that time represented the energy of the known world, came and stirred the ancient Britons up, that they began to show that they were made of good stuff. The Romans persuaded and encouraged our forefathers to undertake certain industries, and what they could not persuade them to undertake they forced them to do. Yes, the Romans must have considered our forefathers a very mean lot; but we owe much to the very practical way in which they cracked our nut for us. Now, gentlemen, the Roman Empire and its methods of civilization have alike passed away, we cannot go in for coercion, and I am thankful to believe that we have no need for it. We may effect all the improvements that the nineteenth century demands by the more moderate systems of example and encouragement. I have said we may effect improvements, I will go further and say that our very presence in this island is only justified as long as we can prove that we are effecting a continuous and steady improvement in the circumstances of the native race. The planting enterprize has provided work for an immense number of people, Tamils chiefly, but also both directly and indirectly to many Sinhalese. Work on estates in these days of tea cultivation is being offered to and accepted more freely by the Sinhalese. This is encouraging, but still the greater portion of the Sinhalese rural population is unaffected by this enterprize. The outlying villages benefit in no way by the European's enterprize. These, the inhabitants of the more outlying districts,

are the people that I wish to encourage to undertake the production of silk. I do not wish to substitute one industry for another. I should be very sorry indeed to find the villager forsaking his paddyfields owing to the greater attractions of work on the estates; so with silk growing it should be regarded as an additional source of profit to the villager, not as a substitutive industry. You will ask me to give you some idea as to my scheme for introducing the silk industry: on this point I can be very brief. All I propose at present to do is to encourage the production of silk cocoons. Though we might go further and undertake the winding off of the silk from the cocoon, this is not absolutely necessary. The cocoons themselves are of good marketable value. Just as one step in the way of a beginning, I should propose to offer a prize of £10 at the Agri-Horticultural Show for the best collection of indigenous silk cocoons. Should we find, however, that the raw silk could be reeled at a small cost and commanded in that form a proportionately better value, we might establish a small factory under the auspices of this Association, with one or two silk reeling machines (the newest improvement in the way of reeling machines costs about £15 in Manchester), charge a sufficient sum to cover cost of reeling and upkeep of factory and credit the producer with the balance proceeds of sales. Such an institution, I think, would soon prove profitable enough to attract private enterprise, and would not long be under the care of this Association. In conclusion I need hardly say, gentlemen, that I shall be extremely obliged to you for giving my proposal any consideration you may think it worth; my hope and belief is that the introduction of the silk industry into Matale will mark the commencement of a new era of progress in the district over which this Association extends its labors. (Applause.)

Mr. R. S. FRASER inquired if Mr. Reeves would inform the meeting how the eggs of these silk-producing moths could be obtained.—Mr. Reeves thought Mr. Fraser himself had introduced the eggs with which Mr. Alexander Ross had experimented some time ago.—These, Mr. Fraser explained, were obtained from Japan, but were not quite the best species.

Mr. REEVES said he had been in correspondence with the President of the silk manufacturing company referred to, and he was of opinion that Ceylon should take to the cultivation of silk of an indigenous species. The President also wrote that he would sell for us the moths of two or three kinds of an indigenous species. The speaker was of opinion that if the Association would advertise for moths the Sinhalese would find them and bring them into market, and it would be easy enough for them to do so. Producing a handbook of the Manchester Exhibition, Mr. Reeves proceeded to exhibit plates of a number of different species of silk-producing moths together with the plants on which they feed. The larger number of these moths and plants, Mr. Reeves was of opinion, were found in Ceylon. He had no doubt Ceylon was intended as a silk-producing country.

In reply to a question from Mr. BORRON, whether any of the Ceylon moths lived on the mulberry or only the foreign worms, Mr. Reeves on the authority of Mr. Haly of the Museum replied that a species of the Ceylon moth also subsisted on the mulberry leaf.

Mr. BORRON pointed out that electric storms have a killing effect on silk-worms: a gentleman who had imported a large number of them into Uva and sent home some very good silk of his own cultivation had to give up the enterprize owing to a large number of his worms being killed by the thunder-storms.

Mr. REEVES replied that in Assam thunder-storms prevailed to a large extent and withal it was an extensive silk-producing country, and he did not see why Ceylon should fail.

The CHAIRMAN said they would be obliged to Mr. Reeves if he would put down facts on paper re information about sericulture, so that it could be translated and distributed among the Sinhalese. At the forthcoming Show sericulture might be encouraged, and by offering a good prize for the best collection of cocoons later on they might induce the villagers to bring in cocoons for sale and export them.

Mr. FLETCHER inquired whether it would not be a good thing to get together a large number of cocoons and exhibit them at the next Show, also to ascertain where Mr. Reeves reared his cocoons.

Mr. REEVES:—At Kowdappellella.

Mr. J. H. EATON, by way of affording some information on the subject, said that about 30 years ago a Mr. Barton had a large number of silkworms and a great many mulberry plants in his garden in the Southern Province. He invented or discovered an engine, and a good deal of the silk went out of the island and it proved a profitable concern.

Mr. REEVES in reference to what fell from Mr. Fletcher said that Mr. Haly had referred him to a gentleman (Mr. Braine of Kurunegala) who, for some years, had been collecting moths and cocoons, and if the Association would write to him he would be glad to send some of his collection to be exhibited at the forthcoming Show.

Mr. BORRON suggested that Dr. Trimen might be able to give some information with regard to the plants the moths would live upon etc.

The CHAIRMAN said the least would be to write to Dr. Trimen, Mr. Braine, and Mr. Green for information about the silkworms and of their food, the different species, etc., etc.

The outcome of the discussion on sericulture was that cocoons should be exhibited at the forthcoming Show, Mr. Reeves to draw up a pamphlet to be translated into Sinhalese and circulated.

CEYLON UPCOUNTRY PLANTING REPORT.

HOW CEYLON HAS ADVANCED WITH TEA—THE "TROPICAL AGRICULTURIST" NEW SERIES—CEYLON TOBACCO SHIPPED BY THE AMSTERDAM SYNDICATE.

23rd July 1888.

Perhaps one of the most striking illustrations of the advance Ceylon has made in the way of tea cultivation is to be found in the pages of the last edition of the *Encyclopædia Britannica*: under the article "Ceylon" there is the following:—"Tea.—The cultivation of tea has recently been introduced. A small quantity of pure tea is produced annually, and finds a ready market in the island. It has not yet become an article of export." In these few words the future king is heralded and dismissed. Since the article on "Ceylon" was written the great *Encyclopædia* has been slowly progressing. Volume after volume has been issued, and now that this noble work has reached its twenty-third volume we come upon the article "Tea." The writer has it that "attempts were repeatedly made to introduce tea culture in Ceylon under both Dutch and British authority. No permanent success was attained till about 1876 when the disastrous effects of coffee leaf-disease induced planters to give serious attention to tea. Since that period the tea industry has developed in Ceylon with marvellous rapidity, and it has every prospect of taking the first rank among Sinhalese productions." To emphasise this wonderful growth there is a table of the British tea trade, and in it the progress Ceylon has made, which is a striking contrast to the paragraph "Tea" under the article "Ceylon" published a few years before.

"Pekoe," we are told, "is derived from *pak-ho* (white hairs), the pekoes showing the fine downy tips of the young buds: Souchong is from *sioung-chung*, little plant or sort; Congou from *kung-fu*, labour." The "Olongs" which are the taste of the American people are named after a particular district, and mean "black dragon."

The compiler of the article "Tea," Mr. James Paton, may be a trustworthy enough guide: he is certainly an all-round man, for he writes among other things on "Safe," "Shoemaking," and "Tobacco" as well. Still I would rather some other fellow

would try the following, which Mr. Paton offers under the directions for manufacturing black tea:—"Between the fermenting and firing operations it is desirable," he says, "to expose the leaves to the direct sunlight for an hour or thereby. This cannot always be done, as it is impossible to keep the fermented leaves after they have attained their proper state: nevertheless the best result is always attained in bright weather, when it is possible to expose the fermented leaves to the sun!" How does it come about that we are offered rubbish of this kind? One would have thought that an article like tea, in which so many of the British public are interested, would have had a specialist to write on it, instead of being handed over to the care of a compiler, who was as ready to take up shoemaking and iron safes, as the cultivation and manufacture of the tea plant. In the "bibliography" at the end of the article, the work of Ceylon authors is wholly ignored, which may perhaps account in part for such a humbling exhibition, as the above extract displays. Certain it is, if the compiler had followed them, he would have known better about manufacture than he does, and his article would have been more of a credit to the great work, to whose pages he has contributed such questionable stuff.

While on books, let me congratulate you on the improved appearance of the *Tropical Agriculturist*. The new style of index is a great change for the better; easy to refer to, and taken in at a glance. As to the contents, they are as varied as ever, and "wrinkles" on all kinds of out-of-the-way products are common enough. To keep pace with the Ceylon planter the original scope of the magazine must need constant revision. Now you will have to go into leather, as I hear of an intention at the Matale side of utilizing old coffee cisterns for tanning. Hides about there are plentiful, and Ceylon leather can well stand being improved, both as regards smell and texture. Why the native leather should be so very inferior and so odoriferous there is really no good reason as far as I know. If India can produce good dressed hides, Ceylon need not, nor will be, a day behind it, if the venture be energetically tackled, and by the proper men.

The first shipment of tobacco from Ceylon grown by the Syndicate of Amsterdam brokers has already been made, and as it is cured by an expert it will be interesting to observe what price it will fetch. The former high prices which Ceylon tobacco got and which wakened us all up, were, I am told, the result of "a fluke." They did not represent the true value of the article, and it came about in this way:—The Dutch brokers had heard of the experiment of growing tobacco in Ceylon on a big scale, and being jealous and wanting to see what kind of leaf could be produced, they sent orders to London to buy the Ceylon article. When the tobacco was exposed for sale, the keenness of the foreign buyers excited the home trade, and as the former had positive orders to buy, the price ran up, and the Ceylon grower was landed with a good thing. This is the tale that is told to me. I don't pretend to be behind the scenes; but with patience we will learn by and bye what Ceylon cured tobacco is really worth. There is one thing, the Amsterdam brokers did not allow the grass to grow under their feet after they had seen the Ceylon leaf before embarking in the venture themselves. But we are always told it was n't because the tobacco was properly cured, oh no; or that its market value was likely to show a profit for the grower. Far from it, indeed how could this be, for the knowledge of how to cure properly does not exist in

the land, and those who professed to know, their knowledge is worse than ignorance. It's an amusing thing this tobacco.

What is to be done about the weather? Still dry, and no sign of a change. This certainly is a season.
PEPPERCORN.

OUR CINCHONA BARK INDUSTRY.

The result of a careful inquiry into all the information at our command in connection with the periodical Review which we give as a preface to our Handbook will be found tabulated below. We look to Messrs. Rivers Hicks, Hamilton and other friendly critics in Europe, to say where our forecast is likely to be erroneous. There must, of course, be great uncertainty as to future exports from Java, and, indeed, from Ceylon; for no one can say how far a slight rise in the price of bark would tempt Ceylon planters to harvest in any one year, though, of course, the exports in later years would suffer in a corresponding degree. The following, however, is our present forecast of the WORLD'S REQUIREMENTS IN QUININE and of the EASTERN SUPPLY OF CINCHONA BARK IN THE COMING FOUR YEARS:—

Years.	Quinine required: total in ounces.	Java exports. lb.	Total Quinine out of bark from Java, Ceylon, and India.		
			Ceylon exports. lb.	India exports. lb.	Ceylon, and India. oz.
1889 ..	7½ mils.	5 mils. (3½ p. c.)	2 mils.	2 p. c.	6½ mils.
1890 ..	8½ " "	6 " 4 " "	2½ " "	2 " "	7½ " "
1891 ..	9 " "	7 " 4½ " "	3 " "	2½ " "	8½ " "
1892 ..	10 " "	8 " 4½ " "	3 " "	2½ " "	9½ " "

The margin left here for South American Bark to supply is certainly not large, but there is against this the probability of new uses being found for quinine: its gradual supersession of opium and its more general use against colds as well as fevers, among the masses in England and America.

CEYLON TEA IN AMERICA.

Planters' Association of Ceylon,
Kandy, 25th July 1888.

The Editor, *Ceylon Observer*.

DEAR SIR,—I beg to transmit copy of a letter received from Mr. R. E. Pineo with enclosures from Mr. T. Ellwood May regarding his scheme for making known Ceylon tea throughout America.—Yours faithfully,
A. PHILIP, Secretary.

Haldummulla, 23rd July 1888.

A. Philip, Esq., Secretary, Planters' Association of Ceylon, Kandy.

Dear Sir,—I have the honor to enclose copies of Mr. T. Ellwood May's letters to me dated 11th and 18th June respectively, and to beg you will have the goodness to lay them before the "Ceylon Tea Fund Committee" at its next meeting, and to make them public if you think it desirable to do so. I take this opportunity to state that my investigation of Mr. May's record led me to conclude that it was honorable and reliable. My informants were the eminent banking house of Messrs. Brown Brothers & Co., the American branch of the well-known firm of Messrs. Brown, Shipley & Co., Liverpool, the Dun Agency, the Bradstreet Agency, the State Examiner of the Banks of the State of New York, and many others, all of whom spoke in the highest terms of Mr. May, both in respect of his private and business character. The

writer of a letter above the initials A. M. W. and dated Maddukele the 28th June desires to know what my connection with Mr. May is. It is quickly told: I am Mr. May's agent and nothing more. When I purchase tea on Mr. May's account I get a commission for doing so. My remuneration comes *when and only when* I make a purchase. Neither Mr. May nor anyone else has ever contributed a cent toward my expenses, and my three years' crusade in America and Canada in trying to introduce Ceylon tea has left me a poorer if not a wiser man.—I have, &c.,

(Signed) R. E. PINEO.

New York, June 11th.

"As written you before, I am ready to start the tea as soon I receive it. I have read very carefully all of the printed matter sent, and I see that the press takes in the situation. If the tea planters do not take interest enough in this matter and in your and my plans to contribute the small amount of 6,000 lb. asked for, it would certainly show they could not be counted upon to aid in this enormous work, and it would pay a capitalist better to spend his time and money, in any one of the many other good projects constantly being offered in America, and where the producers often join in sharing all the expenses.

"I have known of English manufacturers to spend as high as £20,000 per annum for newspaper and magazine advertising. However, it is too small a thing to dwell long upon, and after you have obtained their decision you will at once kindly inform me.

"My plan is, as soon as I get the samples of tea asked for, to push its sale into this market, trying my various methods until I find the right one. I think I demonstrated to you very clearly that if it was necessary and would pay, I could readily obtain a million dollars with which to push the business. Before I can do anything I must show that I have the tea planters with me and they desire to aid in working up the American market. I would be entirely in your hands as to the quality. It would be ruinous and undermine all my projects and against all my ideas of a continued success if I at any time put upon this market anything but a pure, reliable and uniform article. The history of all American trade has clearly proved that there is no continued success where there is anything unreliable or falling off from the standard. People eventually find it out. Besides, I would not enter into the sale of or put upon this market anything, but was as represented and thoroughly reliable.

"I am confident, if the planters will aid and work with me, of a very large annual sale of Ceylon tea. And I will take great pleasure from time to time as matters come up to keep them advised of what can be done to add to their and my success."

(Signed) T. ELWOOD MAY.

(Copy and Extract.)

New York, June 18th, 1888.

"We are in receipt of your cable."

"All we need at first here is the samples, as it will take some time to pack them and distribute them intelligently as we don't propose to be reckless in their distribution.

"However, the main reason that I refuse to purchase the small amount of 12,000 pounds is that it clearly shows a lack of confidence in me on the part of the Tea Planters' Association. I do not want to go into this thing unless I have their full and entire confidence.

"I spent a great deal of time and gave you every opportunity for a full investigation of my standing and record. Should they wish to ascertain for themselves you can readily put them in the way of doing so. It would not be policy for me to go into this unless I have a letter from the planters making me their accredited agent and stating the superiority of their tea, and that they will send nothing to me but what is absolutely pure. This I would require for advertising purposes and to win the confidence of the public. There are a great many teas constantly advertised here all claiming to be pure and superior to all others, and as they are thoroughly impure and unreliable something like an assurance of quality from the planters is positively necessary. My plan for ordering should be

calbe as tea coming by every steamer.

"You surely will grant that I am the best judge of when and what I require.

"The samples I require first and also the letter as herein stated. If I carry out the plan you have suggested all through this scheme I should make a dismal failure of it. The successful business records in the country show that one must be conservative and not recklessly go ahead, thus locking up capital unnecessarily and ahead of time. This to be sure is a very small matter, but I transact my business on certain principles and I do not wish to break them. If the tea planters have the confidence in me to permit me to follow out my own course, it will not take long to prove to them that they have found a large outlet for their production. You must be aware that samples that I ask for will call for an immediate and large expenditure on my part, as soon as received, as I would at once publish their letter with other matter. This alone would amply repay them more than the tea would cost them.

"In conclusion the tea planters have nothing to lose in sending me 6,000 pounds, while I am required to invest largely in order to gain anything. You will understand that the 12,000 pounds they desire me to order I consider a very small matter when taken by itself. To be candid with you it looks as though they did not have much sympathy or confidence in our scheme and wanted me to purchase the 12,000 pounds to make them as near whole as possible on the transaction." (Signed) T. ELWOOD MAY.

THE MAZAWATTEE TEA COMPANY AND CEYLON TEA AGAIN.

A colonist who has just settled for a short stay in Worcestershire writes to us by last mail as follows:—

I thought you might be interested in the enclosed letter which I received this morning from the manager of the Mazawattee Ceylon Tea Co. in reply to one I sent him a few days ago. The grocer of this village came and asked me if I knew anything about that Co., and as I did not remember anything about it, I thought perhaps there was some trick in it, especially as it stated on one of the packets (the 2s tea) that "it was composed principally of teas grown in the sweet-scented island of Ceylon," so I took upon myself to write and ask where the Co.'s land was, and told them of the quantity there would be in the course of 3 or 4 years, and how important I thought it to educate the Europeans to the taste of Ceylon tea, &c. &c. Their letter only bears out the fact that you have been pressing on the planters, that it is necessary to keep up the quality, but the remark about the last two months shows this has not been done. For good Ceylon tea there seems a ready sale: all who have tasted the tea (Blackstone and Warwick) I brought over with me declare it is delicious, yet they buy as Ceylon tea they don't like, at least the majority are against it. Lord and Lady Forester liked the teas I gave them a sample of so much, that they wished to know where they could get it, as they desired to be always supplied with it. The 2s 6d and 3s Mazawattee Co. tea the grocer thinks will take here and he will order some at once, and I think he will be able to sell a lot about this locality. The Company's letter is as follows:—

London, E. C., July 3rd, 1888.

Dear Sir,—In reply to your letter we beg to say that our Company has no connection whatever with any Ceylon garden or estate. Mazawattee is a corruption of the two eastern words *Mazalar-watte*, signifying luscious growth, and is simply a trade mark, or word registered for the purposes of advertising.

With regard to the 2s quality being a blend, we have been fully justified in our judgment that to allow the grocer a fair profit it would be simply impossible to produce a blend composed entirely of Ceylon all the year round that would have the slightest chance of pleasing the public at 2s and insuring a large permanent sale. A very large proportion of the lower

grades of Ceylon pekoe souchongs are poor wasty teas with an utter absence of that point and briskness, which is necessary to make a blend that the public will take to. With regard to the 2s 6d and 3s qualities the case is very different, and we have established a large demand for these classes of teas, and there has never been a single leaf of any other than Ceylon tea put in these blends.

We claim to have done more than any other firm for the development of and popularizing a taste for Ceylon tea in England, and if you are interested in Ceylon tea, we shall be only too pleased when you are next in town to show you our warehouse and let you see what we have done for the Ceylon tea trade in England. Ceylon has a wonderful chance now; but there is grave reason to fear that the planters are seriously jeopardizing the reputation of their teas by studying quantity rather than quality. There has been a serious deterioration in the quality of the arrivals during the last two months.

We taste and value every sample of Ceylon tea that is sold on this market, and at present we mark at least *thirty per cent* as valueless so far as our blends are concerned. This is very ominous.—We are, dear sir, yours faithfully,

pr. MAZAWATTEE CEYLON TEA CO., S. D.

TOBACCO IN SUMATRA.—The amusing and instructive account by a correspondent of the *North-China Herald* (given on page 116.) of a visit to the Deli tobacco region will be read with interest in Ceylon. An export valued at two millions sterling on the spot and realizing double that amount, so putting £4,000 profit on an average into the pockets of each of 500 planters! constitutes a big and prosperous concern; and we can understand why ex-Ceylon men over there—like Messrs. A. Forsyth, Van Cuylenburg and others—should be rather reticent, and also why so many in the Kandy districts at this time should be anxious to cultivate a field of the best paying product of the day. There has been a good deal of inquiry lately for practical information about tobacco planting and curing. It is wonderful how often men overlook what is under their noses. In going over the latest volume of our *Tropical Agriculturist*, we have simply been astonished at the amount of valuable matter in respect of tobacco and almost every new product that can be mentioned, worthy of attention in the tropics. Here for instance are the headings of the several notices in this *one* volume, of tobacco:—

Tobacco in Netherlands India, pages 21, 101; in Manila, page 22; in India, page 65; in Deli, page 101; a Deli tobacco plantation, the land, the coolie, the work, the European staff, pages 120 to 124; new use for tobacco plant in England page, 260; tobacco in Reunion, page 336; home and colonial tobacco culture, page 439; tobacco cultivation in Southern India, manure, seedbeds, transplanting, outturn, curing, soil, irrigation system, pages 451 to 453; tobacco in the Straits Settlements, page 509; tobacco in Java, page 519; tobacco in Netherlands India, page 530; Indian tobacco at home, page 568; tobacco the coming product in Ceylon, pages 605 to 606; tobacco in Siak, page 628; tobacco planting in Ceylon, page 629; home-grown tobacco, pages 630 to 631; tobacco in Borneo, pages 660 to 661; tobacco cultivation in the United Kingdom, page 717; tobacco in Natal, page 740 to 731; tobacco cultivation in Uva; page 759; tobacco cultivation in Sumatra, pages 763 to 764; tobacco cultivation in Ceylon, page 767; tobacco cultivation in Western and North-Western Provinces, page 775; tobacco cultivation in Hambantota, page 811; tobacco cultivation in Uva, pages 829 to 830; tobacco cultivation in Jaffna, page 832.

If the seven volumes were gone over, we venture to say a would-be tobacco planter would find every possible question he could ask fitly answered.

PLANTING IN THE LOWCOUNTRY.

COCONUTS AND CINNAMON—THE WET SEASON—FEVER AND CRIME.

SIYANE KORALE, June 1888.

This month has been a very favourable one for planting. With the exception of the fall on the 2nd-3rd, which gauged 3.73 inches, we never on any one day had two inches of rain. All the rain that fell was in slow gentle showers so favourable for planting. Before the planting season commenced in May, I was warned not to plant after the end of May, as I had let the season pass! It is only now that we are in the season of heavy rainfall and floods. It is well to be as early as possible in planting, but to be asked to stop operations before we had well entered on the planting season, shows to what lengths we can go in trying to emulate the early bird of the well-known proverb. The planting months of the south-west monsoon are generally June-July, while if the rain falls in abundance in May we may commence in that month. Except in abnormal seasons we have no month without rain between the south-west and north-east monsoons, so that the planting of the south-west season has a very fair chance of success. The same cannot be said of the north-east season except in Uva.

As is to be expected, coconut trees are flourishing in this weather, and the blossoms the trees are throwing out this month, and which are to yield our big crops, are really very cheering. Before we can reap the resulting nuts from them, however, the trees have to run the gauntlet of the annual drought at the beginning of the year, which usually affects the coconut crops a good deal. As far as crops go prospects of next year are very hopeful, but then there are the prices. The three big coconut crops are harvested between April and August, and it is then that prices are low. This season has been no exception to the rule. The local demand for coconuts and copra is very slack in spite of the fair prices ruling for the latter in Colombo.

As far as I am concerned I am in the full swing of the cinnamon crop. During my experience I have never known cinnamon peel as well as it does for the last two or three weeks. Hardly a mature stick escapes the cattle of the peeler, and a field of cinnamon after the peelers have been through it looks for all the world like a young plantation. This exceptional state of things is probably owing to the mild weather we are having, moisture and heat combined, which produce a free flow of sap. The wintering the bushes received during the early part of the year caused them to throw out a heavy seed bud with the first rains that followed. As long as the seed is on the bushes, which is pretty well on to the end of the year, the sticks carrying them do not peel, owing possibly to the growth being checked and with it the free flow of sap, in the effort to mature the seed. To estates with a rich soil and where the growth of the wood is rapid, this causes great loss, as by the time the seed-bearing bushes are peelable they will have grown so much as to yield coarse bark fit to quill coarse cinnamon or not fit to be quilled at all. Owing to having had a very heavy crop of seed, which, if the bushes were allowed to carry till the usual period, my crop of cinnamon would have been seriously affected both as regards quality and quantity, I hit upon the novel expedient of stripping the seed to obviate this. The result has exceeded my expectations, for within a short period of the stripping almost every stick peels, and as far as I am concerned the cost of the work—75c. per acre—has been amply recouped.

The peeling season ends with the *Ehela daluwa* or July bud which usually makes its appearance in July-August. This is the natural interval between the two crops when the bushes enjoy rest and make much growth. The bud or flush usually lasts for two months, during which peeling has to be suspended. This brings us on to the N.-E. monsoon or the season of the small crop, small because the wet months are so few, and during which another period of enforced cessation from peeling intervenes owing to another bud. We have another six weeks or so of the season to run.

Fever is again prevalent in the villages. Relief will be immediate if either Mudaliyars make it part of their duty to inquire of the minor headmen after the health of the people committed to their charge, and make it their duty to report to them when sickness breaks out, or if the Medical Department recognises it to be part of their duty to have medical officers itinerating through the villages during the usual fever season. But what the villages want is systematic not spasmodic medical aid.

Crime, I am sorry to say, is on the increase. Numerous petitions and letters to the Government Agent have received the stereotyped reply that steps will be taken to put down crime. So far as is evident nothing has been done, for no diminution of crime is apparent. We want young active Mudaliyars, who will move freely through their korales and who have the minor headmen under proper control, to cope with crime. The usual procedure when petitions are sent to the G. A. is for them to be referred to the Mudaliyar. These latter officials will be more than human if they knowingly report anything that will be to their discredit. They get up their minor headman and ask for an explanation; as the proceedings are *ex-parte* the usual reply is that crime does not exist, but that the petition is the result of a conspiracy. Hence it is that crime flourishes unchecked in the villages and its inhabitants get gradually demoralized. One remedy will be for Mudaliyars to be required to periodically travel through their korale and to report fully on its state as regards agriculture, crime, &c.—LOWCOUNTRY PLANTER.

A TRIP TO DELI: SUMATRA TOBACCO.

The port of Belawan has recently jumped into importance in the world of commerce as the place whence £2,000,000 sterling worth of excellent tobacco is exported every year. Within the past few months the river route to the old mart of Laboean or Labuan, *i. e.* "the anchorage," has been abandoned by all but very small craft, and a good second rate railway has been constructed between Belawan, Laboean, Medan (the present seat of the Dutch Resident for Deli), Langkat, and other places in the interior. Langkat may also be reached by steamer from Penang. So far, the whole of the east coast of Sumatra is destitute of lights, not so much as a tallow candle being provided to mark even the outer buoys. The buoys, again, two long lines of which now guide the mariner into the mazy port of Deli, are only the after-thought of the past six months, whilst a bar, exposed to ugly washes from a cross sea, exists here also to impede navigation, as at the majority of ports in the East. A new lighthouse has just come out in pieces, but owing to the extreme unhealthiness of the swampy coast, it has not yet been found possible to obtain European workmen to aid in the erection of it. The entrance to the Laboean River is walled in on both sides by a dense jungle of mangroves and tropical trees like every other sea-port in Indo-China. Belawan is on the right bank, about three miles up the river, and consists of a railway station and three hulks, with a few rush huts built on piles in the usual Malay style, and inhabited by a dozen or so of sampanmen, chiefly, of course, the ubiquitous Chinaman, who seems able to live anywhere and to eat anything,—of which there is here nothing visible to eat at all. When the tide retires from the jungle, it leaves bare a reeking, sweltering mass of ooze and slime suggestive of water-snakes and crocodiles (which last, indeed, used to swarm until the steamers frightened them away): and so deadly is the Deli fever said to be, that every man-jack of the railway staff retires with the last train to Kampong-Besaar, a place about 10 miles inland. The train travels

along a narrow causeway which forms a lane through the dismal forest, and crosses the Laboean River by an iron bridge $\frac{1}{2}$ of a mile long, which has cost the Railway Company about £80,000 and which requires constant tinkering to keep it from sinking in the oozy bottom. From the bridge can be seen the former entrance to the river, now "barred" up, which was used before Belawan was "invented." There is all the red tape on this strip of private railway that the nations of the European continent have been able to invent. First the baggage must be removed, at the passenger's own cost, in a blazing sun to a shed, where a miserable Malay, who cannot even speak Dutch, gesticulates, turns things about, goes to ask somebody what he must do, hunts for a piece of chalk, and, after marking the box, assists another Malay coolie to demand an extortionate fee for carrying it 200 yards. A quarter of an hour before the train starts a bell rings violently, as if something were going to happen. As there are about two first-class carriages to each first-class passenger, the guard does not insist upon your sitting in a given compartment as in France and Germany, but he glares at you just as suspiciously, and takes a vicious snip out of your ticket. About 10 minutes later the ticket is examined again. One luckless passenger, who has been waiting two hours for the train to start, discovers at the last moment that his baggage (30 or 40 lb) is more than it is allowed by law to carry gratis; but as there are only five more minutes before the train actually does start, the box is hustled, amid a great flush of excitement, into the luggage van, and half a dozen officials make hasty arrangements for payment to be made at the other end where there is time. After a comparing of watches, blowing of whistles, waving of hands, ringing of bells, etc., (during which a luckless Chinese coolie hastening up with a load of fresh fish, is told it is too late to enter the train), the coupling-chains jerk and we are off. The first station of any importance is Labuan, and here there is 20 minutes halt whilst the train makes various manoeuvres, changes from one line to the other, &c. The "cabs" which come to meet the traveller at Laboean may be described as a square box on two wheels. After diving in head foremost across the horse's tail from a small iron step which nearly pulls the whole concern over the would-be inmate, the traveller rolls himself round right way up, thrusts his legs straight out, leaving part of the splash-board for the Malay to sit on; gets his feet entangled in the reins, alarms the horse, and goes careering at a good pace round a nasty corner up a dusty street, over wobbly wooden bridges, through ruts and ditches until he at last reaches the Imperial German Consulate. This is one and the same place as the Labuan Hotel, and is also the office of a mercantile firm. Labuan is practically a Chinese town of one street about a mile in length, but perhaps one-third of the population consists of Malays and Madrasses. As usual, the gambling, spirit, and opium farms are the chief features which distinguish this town from one which has not enjoyed the civilising influences of the West. About twenty miles above Labuan is the thriving and interesting town of Medan, the metropolis of the great tobacco industry. A very fine square, at least a quarter of a mile in diameter, intersected by a ditch, serves at once as a drain for excessive moisture, a drill-ground, a promenade, and a people's park; but somehow or other the Chinese do not seem as happy in Dutch towns as elsewhere, and do not swagger about with that sleek though harmless bumptiousness which the easier-going British colonies develop in such a high degree. Even in the French colonies, in spite of over-

legislation, the Chinaman seems happier than in Sumatra, and it must be admitted that the French, when once they have got their many-fangled rules into working order, treat the Chinese with liberality and public spirit even though they may be strict, and perhaps severe. In Deli the Dutch do nothing, everything is left to private enterprise. Around Medan, and far into the country in every direction are the tobacco estates which have prospered so much within the past ten years that an annual profit of 100 per cent has come to be looked upon as a natural state of things, and a planter expects to make his fortune, and usually does so, in five years. All foreigners are admitted on an equal footing with the Dutch. Chinese alone are debarred from the coveted distinction of being plantation owners. Amongst non-Dutchmen, Germans are in a decided majority, but most nationalists are represented. The foreigner receives his concession from the native Rajah, with the approval of the Dutch authority, and then at once commences to cut down the trees and set fire to both the timber and the thick overgrowth. No manure is required, and a few hundred Swaton coolies soon transform confusion into order. The tobacco is then planted in rows two feet apart, and the magnificent climate, which hitherto has always enjoyed a happy distribution of rain and sun, does the rest. The tobacco is gathered in July, and is sorted out into qualities and dried. It is then hung up to dry in the huge sheds which are such a prominent feature in the Sumatra landscape, and finally thrown into heaps and carefully stirred up under the personal superintendence of the planter: it is important during this process to prevent heating or sweating, and to preserve the exact aroma and the oiliness which give this tobacco such a peculiar value. It is exported in bales, of about $1\frac{1}{2}$ piculs each bale, and nearly all goes to Holland, where the Deli Company exercises a sort of monopoly. The price in Sumatra is about 2s. the pound, and the selling price in Amsterdam is seldom under 4s. Over 20,000,000 pounds were exported last year, chiefly by the blue funnel line of steamers *via* Singapore; and consequently about 500 planters divided £2,000,000 profit between them. The largest employer of labour is the Deli Company, which owns 24 large estates, and pays 50,000 Chinese coolies. The Sumatra tobacco is utilized for one purpose only—that of making the outer skin of cigars; the taste for it is spreading in America, whither, as also to Bremerhaven, a considerable quantity of the weed is shipped. The planters find it difficult to obtain a sufficient supply of cheap Chinese labour, and therefore, in order to avoid the "bounties" which the Chinese dealers in Penang make them pay, they have lately endeavoured to arrange for the direct shipment to Deli of coolies from Amoy and Swatow.—*N. C. Herald*, July 7th.

"ALL ABOUT GOLD" IN CEYLON.

Colombo, July 28th.

At the Nanuoya terminus on my way down two days ago I met Mr. Moorhouse who looked quite innocent and chatted on indifferent subjects just as if he were not conscious of being art and part in a dark design to tear asunder and enter "the bowels of the land." The secret has been well kept, but is now out, although it was not even hinted at to me by Mr. Moorhouse. A correspondent writes to me:—

"You saw Moorhouse at the station. Did he tell you what he was there for? It was to transport to Blackpool bridge three railway waggon-loads of planks, posts, talipots, &c., for the erection of lines some-

where along the Haputale path. Dr. Tothill, Maitland, and others have formed a Gold Company, and have purchased 50 acres of land on the patanas. An Australian (German) Hirst is their head man, and Horsford is under him. Have n't they kept it all quiet? They evidently mean business, because the freight alone on the three loads of posts, &c., was £179."

As was stated some time ago in the *Observer*, Mr. LeMesurier, the Assistant Government Agent of Nuwara Eliya, has for some time back been prospecting the country along the Haputale path and railway trace, especially the quartz formations near Padupola at the foot of the Totapala range, where, if anywhere, we should suppose gold will be found in the rocks in quantity worth working for. As to appreciable nuggets in the alluvial, none that I am aware of have yet been found in this region such as were some years ago reported from Ratnapura and recently from the neighbourhood of Akuressa in the south of the island. In one of the streams which run down from Totapala Mr. LeMesurier found a small nugget of gold weighing about a couple of grains, but all attempts to discover the matrix failed, as they seem always to have failed in Ceylon, perhaps because the quantity of gold discovered in the alluvial has not seemed to justify the expenditure necessary for digging and crushing operations on a large scale. Associated with the gold,—at any rate in the same formations, Mr. LeMesurier found pieces of very beautiful and very promising copper pyrites and also black ore of manganese. Both copper and manganese, like tin, are at present selling at such depressed prices, that the existence of those metals in the loftiest of our Ceylon formations is more a matter of scientific curiosity than of economic value, even if they were found in quantity. But the world is hungering for fresh supplies of gold, which, as the great medium of currency and exchange amongst the nations, has so appreciated in value as compared with silver, that the rupee which we remember to be worth 10 per cent more than two shillings is now down to 1s. 4d., or close on that. It would be a great matter for Ceylon therefore if gold in quantity were discovered in her rocks, and it would be specially interesting if the region through which the long-delayed Haputale railway runs should be found to be so richly auriferous that active gold mining may proceed *pari passu* with railway cutting through the beautiful upland prairies which stretch from Nuwara Eliya into Uva, and the quartz, quartzite, and schist formations which extend from "summit level" near Padupola (6,215 feet above sea level) into Uva, which ought itself from its appearance to be in many places auriferous. A truly enormous quartz formation, the most extensive, probably, in Ceylon, extends from beyond Haputale round by Padupola, New Galway, Hakgala, and across to Fort Macdonald in Udapussellawa on the inside of the Uva basin. Mr. LeMesurier in looking about him very naturally came to the conclusion that if a gold-bearing lode exists, it must be found in an offshoot of this reef.

From the steps taken by the Syndicate of which Dr. Tothill and Mr. Maitland are members, it seems probable that Mr. Hirsch has improved largely on Mr. LeMesurier's finds, and we trust, for the sake of the country as well as the individuals who are going to considerable expense in thoroughly testing an appreciable area, that success may crown the digging operations. The swampy upland patanas or prairies of the region which stretches from the base of Pidurutalagala to the foot of Totapala and away into Uva must be formed largely of decomposed rocks, for precious stones have been found in many of them, and with precious stones gold is very frequently associated, as has been proved at Ratnapura and recently beyond Matara in the

south. Gold, as the heavier substance, naturally sinks further in the soft formation than do the gems. It will be interesting, therefore, to learn if gold has been found in the swampy patanas resting on the bed rock which Mr. Waring found at a depth of 9 feet, or whether Mr. Hirsch, like Mr. LeMesurier, has found his gold in the streams which run through the quartz formation on the side of Totapala. How far up, beyond 6,215 feet above sea-level, the quartz goes, I am not certain, but in all probability it goes to the summit of Totapala and may underlie the magnificent expanses of the Horton Plains. What with digging operations about to be actively carried on at Wakwala near Galle, at Dewurangala near Akuressa, and on what is likely to be a large scale between Nuwara Eliya and Haputale, we ought soon to know if really Ceylon is to be classed with the paying and productive gold countries of the world. Curiously enough, the map which accompanies that most comprehensive and useful publication, "All About Gold, Gems and Pearls," does not give Nuwara Eliya as one of the places where gold has been found, but surely, in view of Sir Samuel Baker's operations in 1854 and Mr. Judd's recent letters, it must be included in a revised edition which is likely soon to be called for, with Wakwala, Akuressa, and the spot on which the operations of the Syndicate represented by Dr. Tothill and Mr. Maitland are to be carried on.

At present there is no indication that gold in any quantity is found farther north in Ceylon than Rangala, the very name of which translated into English, means the gold mountain, as Ranwela means gold ground. Ambepussa, the scene of the gold digging operations of 1854, is nearly on a line with Rangala. Then farther south we have, in a group, Kegalla, Dolosbage, and Ruwanwella. Finally Ramboda is indicated. And there the list of places which had shown promising quartz ended when the map was framed. But it looks as if many additions would have to be made, southwards beyond Matara and eastwards into the extensive quartz formations of Uva. Not that gold is confined to quartz: indeed it would be difficult to say in what ancient series of rocks it has not been found. Black iron sand is one of the most common accompaniments of the precious metal, and iron pyrites is often as rich in gold as it is in arsenic. The great drawback to gold-digging is the uncertainty which, after all the discoveries of science, remains as to where and how digging should be conducted so as to reach gold in quantity. If in the alluvium in any abundance, it is soon found, but the difficulty is in regard to deep diggings in quartz rock and the profitable crushing of such rock by appliances which, including stampers, mercury, &c., are costly. We trust those who are spending money to solve the gold problem in Ceylon may be well rewarded for their enterprise. So far at present, but more remains to be said about possible paying gold finds in Ceylon.

SANDALWOOD.—The Mysore Government estimate that in the present year (1888-89) the receipts from the sale of sandalwood will be not less than £6,66,400. This is a very handsome return in 1886-87—a favourable year,—the Forest Department realized the good round sum of £6,48,349.—*Bangalore Spectator*.

A CURIOUS BRINJAL has been sent to us, which seems to have been grown at Batticotta, Jaffna. It is the white fruit of an egg-plant, or rather a combination of three. The main fruit closely resembles the body of a child, the two minor fruits going off like stumpy arms. The monstrosity has a droll effect.

CAFFEINE FROM TEA-DUST.—We have on former occasions referred to the proposal which came before the chemical section of the London Chamber of Commerce regarding the manufacture of caffeine from those qualities of tea which are unsuitable for dietetic purposes, yet contain alkaloid in such quantity that it would be profitable to work up the tea in the manufacture of alkaloid. Large quantities of this tea are so worked up in Germany, and it would be possible to retain the greater proportion of the material in this country, and to establish practically a new industry here, provided the Customs would allow the kinds of tea in question to be landed duty free. Overtures having been made in the proper quarter and the Board of Customs have expressed their willingness to meet the demands of the chemical section, provided a suitable method for denaturalising the tea was submitted to them. The addition of asafetida or lime has been recommended for this purpose, and although the Board of Customs have not yet given their decision as to which method will be adopted, matters have advanced so far that Messrs. Howards & Sons, of Stratford, and Mr. Thomas Whiffen, of Battersea, are about to commence the manufacture of caffeine from tea.—*European Mail*.

THE BANANA DISEASE IN QUEENSLAND.—Fiji evidently cannot boast a monopoly of the banana disease, as is testified by the following paragraph from the *Queenslander* of April 16th:—"Of late years little has been heard of the banana disease in Queensland. It was known to exist indeed to be always present, in any large plantation. It was recognised as the special enemy of the *Musa maculata*—the large bananas so common in the shops until a few years ago but now so seldom seen—and consequently this banana was never planted. But the varieties known as the "sugar," the "lady's finger," the "cavendish," the "dacca," &c., were supposed to have sufficient natural vigour to withstand the disease. Up to the present year this has been the case, but of late the disease has again assumed prominence, more particularly among the sugar variety, and we hear of great ravages among the plantations in the area extending from the Logan River to the Mary River. Whether the trouble has appeared in the tropical North we have not yet heard. The cavendish variety, so far, seems quite able to hold its own against the disease, although an examination of the roots may show it to be affected, but circumstances seem to point to the complete extinction of the sugar banana from Southern Queensland fields, as has already happened with the old *Musa maculata*."—*Fiji Times*.

THE CEYLON TEA ENTERPRISE AND MR. J. L. SHAND.—It is expected, Mr. Shand is to render to the tea planters and the Colony the same special service at the Paris Exhibition next year, that he has already rendered at the Colind, at the Liverpool and it may be said at the Glasgow and Brussels Exhibitions, he will indeed establish a claim worthy of special recognition. But we submit that a contemporary has not at all chosen an appropriate or convenient moment in suggesting or calling for a "Shand" testimonial. He supposes support may come from the "tea fund," when that fund can scarcely meet the year's claims already booked, and we hardly think any attempt at special subscriptions just now, would be so successful as it deserves to be. The case with both the "fund" and the planters generally, we may expect to be rather different twelve months hence, and what will then make the move very timely and appropriate is the fact that Mr. Shand will have closed all his heavy work for the Paris Exhibition—and very likely for all such Exhibition—for a good long spell. Then, we submit, will be the fitting and most convenient time for the tea planters of Ceylon to show their

sense of Mr. J. L. Shand's special services to them in a suitable testimonial.

PLANTING IN NETHERLANDS INDIA.—The *Amsterdam* correspondent of the *London and China Express* wrote on June 6th:—

At a meeting of the Siak Tobacco Company held here on the 1st inst. a proposal was adopted not to limit the cultivation to Siak only, but to extend operations to the east coast of Sumatra. The capital, amounting to \$250,000 in shares, will be increased to \$500,000. The Internationale Credit and Handels Vereeniging Rotterdam will pay a dividend of 4 per cent, to shareholders for the year 1887. With regard to the establishment and the loan of the East Sumatra Tobacco Company, some further particulars have been published. The object of the new company is the continuation of the tobacco cultivation on grounds for which the concession was received from the Sultan of Siak by the Handels Vereeniging Amsterdam in 1886. The concession was transferred to the new company against payment to the Handels Vereeniging Amsterdam of an amount of \$150,000, in 300 shares of \$500 each, to add an amount of \$15,000 as restitution of charges incurred during the time of working by the last named company. The concession comprises nominally 10,000 acres, and is situated north-west of the Siak river, at a considerable distance from the sea, and near Pekan Baroe, from whence the crop can be shipped by the regular line of steamers to Singapore. The crop, which may be expected in the market here next year, is estimated at 1,400 piculs, equal to about 175,000 Amsterdam pounds. The capital of the new company will be \$1,000,000 divided in two series of \$500,000 each, each share amounting to \$500. As stated above, the first series will consist of \$150,000 shares paid for the concession, and of the remaining \$850,000 an amount of \$140,000 has been placed already, the balance being offered here by tenders on the 4th inst., amounting to \$210,000 at par. It is said that most of the shares have been taken up.

A RARE FLOWER.—The *Vienna* correspondent of the *Standard*, telegraphing June 3, says:—"Tomorrow there will be witnessed in the Palm-house at the imperial palace of Schönbrunn a spectacle which has hitherto been seen only once before in Europe—to wit, the Palm tree, *Brownea ariza*, in full bloom. This tree, which is named after the celebrated English botanist, arrived at Schönbrunn forty years ago from London. It was then an insignificant sprig, but now it vies in magnitude with the *Maria Theresa Palm*, which is 170 years old and in the same Palm house. It blossoms only once in fifty years, and the bloom lasts only forty-eight hours. The last time the blossom of the *Brownea ariza* was seen was, I believe, in June, 1851, in the Duke of Norfolk's conservatory at Chiswick." If the political and other information which special correspondents forward to daily papers is as accurate as the above how delightful their notes must appear to those who really know. No doubt our gardening friend in Vienna was in sore need of something worth nothing, and he has fallen into the hands of some merciless wag of a gardener. *Brownea ariza* is not a Palm, but a member of the Bean and Pea family. It flowers at Kew annually, the last time about two months ago. It was discovered in New Grenada by Hartweg in 1842, but was not known in cultivation till about thirty years afterwards. It was first flowered in Belgium by M. Linden, and in the United Kingdom by the late Dr. Moore, of Glasnevin. From the latter plant a plate was made and published in the *Botanical Magazine* in 1880. It is not nearly so grand as *B. grandiceps*, which flowered for the first time at Kew in 1855, and probably every year since then. All the *Brownias* flower regularly every year, and their blooms last about a week. In the *Gardener's Chronicle* at p. 70, 1851 it is stated that *Brownea grandiceps* flowered at Kew, and the correspondent probably confounded the Royal Gardens, Kew, with the gardens of the Duke of Norfolk at Chiswick, and the species *ariza* with *coccinea*.—*Gardener's Chronicle*.

Correspondence.

To the Editor.

CEYLON TEA IN AMERICA.

Philadelphia, 9th June 1888.

DEAR SIR,—Your *Overland* issue becomes more and more interesting on the subject of the introduction of Ceylon tea into America. Mr. R. E. Pineo's arrival in the island is timely. His advice will be valuable, and it is to be hoped that a well-considered scheme will result from the deliberations of the Planters' Association. I take this opportunity of thanking Mr. Pineo for the eulogistic terms in which he speaks of me and my pioneering work here. Any determination I have shown is but the natural result of the fact that *my heart is in my work*. Since I put my hand to this particular plough I have not looked back. Discouragement is, as Mr. Pineo can tell you, scarcely suggestive of what I have had to face, and although now well-known and established in Philadelphia, I have nothing but tedious uphill work to look forward to for some time to come. "Never venture, never win," is a truism applicable in a special manner to business in America. Success cannot come to the man who waits for business to come to him. To be progressive in this country one must be *aggressive*, and in such a work as I have undertaken it means money and venture; what money I have obtained from private sources has been spent to the last cent in the interest of Ceylon, depending for my livelihood upon the success of my venture.

Now that general attention is being directed to America as the great field in prospect for our tea, I feel that I ought to speak very plainly when anything like a general introduction of Ceylon tea into America is contemplated.

Let me therefore place before you a few suggestions which I can assure you are worthy of serious consideration before concluding upon any scheme which can be looked upon as a *general* introduction. If you mean success in your undertaking, you must study the taste of the buyers, your customers, and apply yourselves to the preparing of a tea similar in character to that in general use over here.

Now the teas appreciated in America, although sold under a variety of names, may be divided into two orders:—Congou and Oolong, the latter being far and away the more popular of the two. If you wish to appeal to the American you have but one channel by which you can successfully do so—the *palate*; and in spite of all the good things that can be said in favor of Ceylon tea, *the fact remains* that not more than one out of ten like it and will buy it, whereas nine out of the ten will appreciate and use a good Oolong.

What I wish to impress upon the minds of the planters is that all prejudice in favor of any particular make of tea must be abandoned if it is their wish that their teas be accepted and welcomed by the American people, and the introduction thereof made easy. In saying this I do not mean to suggest a general distraction of their attention from the present system of manufacture, but I do mean that, with the purpose of making Ceylon tea popular in America in view, they ought to experiment, and in time perfect themselves in the manufacture of an Oolong which will at once recommend itself to the palate of the American tea-drinker.

Shanghai is, I believe, the centre for the fine Oolong districts. Failing a local authority on the manufacture of Oolongs, would it not pay one of our best men to go there and thoroughly master the art of manufacturing these teas so that he could teach our planters and assist in overcoming this difficulty if indeed there be any difficulty about the matter?

So far as coloring teas is concerned, I hope and trust that this custom will remain with the originators.

Let every planter follow the banner of purity on his march through the battle fields of America. People fight shy of colored teas now, and the first question asked of Ceylon tea is invariably regarding its purity.

"I can recommend this tea as an absolutely pure and wholesome tea" is a weighty answer to such inquiries.

I have been for some time back been in almost daily communication with a gentleman whose general knowledge of and experience in teas of all kinds is perhaps unequalled in the States. I refer to Mr. C. K. Reid (late of Messrs. J. H. Catherwood & Co., and now broker in this city), and Mr. Pineo can endorse what I say of him.

Let me quote Mr. Reid's own words on the subject of Ceylon tea for America:—"I have been in the tea trade for over a quarter of a century. I, like you, came over here to establish myself as a tea-dealer with Assam teas as a speciality. I very soon found that I would starve if I confined myself to that branch of the business, and so, as a matter of discretion if not of actual necessity, I redirected my attention to the study of China and Japan teas. I have already read one paper under the heading of 'The Tea Leaf of Commerce' before the Grocers' Association, and am now preparing a more exhaustive pamphlet on the subject (with map of tea districts) which will be at the disposal of the Ceylon planter as an aid to further developments in the art of making tea suitable for the American market. China Congou, India and Ceylon teas will no doubt be used here in increased proportions, but they will not, in our generation, be so popular among Americans as Oolongs, Moyones and Japans; and such missionary work as trying to revolutionize the palate of a country can only be compared to establishing a new religion.

Rather than seek to convert Americans, convert your Ceylon planters."

Mr. Reid is a good adviser, and my own experience goes to confirming his views.

With the aid of machinery and superior science, a fine Ceylon Oolong could surely be manufactured, and I hop that before the year is out it will have been satisfactorily proved that such is the case. It would give Mr. Reid and myself much pleasure to receive and report on any samples you can send. So far as I am concerned, I wish my next 'boom' to be in a Ceylon Oolong tea. That is what I wish to see and expect to see ere long from Ceylon.

Let me remark here that all teas shipped to the American market ought to be packed in extra strong chests not to exceed 50 lb. in weight. Six or eight of the chests sent me lately by the planters required no opening. Had it not been for the heavy lead lining, which in two cases was torn and the chests half empty, the loss would have been good 20% of the tea sent. Out of 10 chests containing 90 lb. net weight of tea, only three arrived in anything like sound condition, and whatever may have been the wood used it was certainly unfit for tea chests. "Gingranoya" chests are strung and arrived here in good order, but I cannot tell what wood they are made of. "Campden Hill" tea also arrives in good order. Small light tea chests protected by matting are the best, in fact indispensable so far as this market is concerned. The chests now used get completely smashed and unfit for the market, as every second chest arrives with the lead burst and more or less in a leaking condition.

I have just received a note from Mr. Reid which I enclose, as it is of interest to all, and I have not the time at my disposal to write as fully as I had intended. Indeed I have been so disturbed in my attempt to get this letter written, that I am almost inclined to tear it up and write when I have more leisure. I will follow this up, and let you know what I have done with the sample teas &c. Meanwhile accept apologies for a rather disconnected letter. —Yours very truly, J. McCOMBIE MURRAY.

4th June 1888.

Mr. J. M. Murray.

Dear Sir,—Agreeable to promise, I send you a few lines on my ideas of tea classification &c. in view of your trying to get the Ceylon planters and curers to send you certain descriptions of tea, specially prepared for this market.

Congous, as you know, now constitute a very small proportion of the 70 to 80,000,000 lb. used in the United

States. The teas exported from Ceylon, India, and Java I class as Congous or Congou kind. Every tea-growing country exports Congou teas, more or less every district and country grow and cure kinds on the same order, though each differ in appearance, flavor, strength, and quality, yet they may all be of the Congou order. I class all other teas as Oolongs or Oolong kinds. The difference lies in the curing. The species, climate, soil and preparation constitute the difference between all teas. Some districts and some countries are better adapted to producing Oolong varieties, others Congous. I am under the conviction that Ceylon can furnish Oolongs as well as Congous to compete with China from whence we get the finest Oolongs. I need not name every variety of tea here, but the following are the most prominent for examples and the most popular in this country:—

Formosa Oolong grown on the island of that name and shipped here from Amoy.

High district or black leaf Oolong.

Red leaf Oolong from Foochow and Amoy.

Moyune and Fyehow Hyson tea Oolong kind, colored green to represent Mandarin teas.

Japan basket-fired tea (Oolong kind).

Scented orange pekoe and espu on the Oolong order.

Scent pekoe and powchong on the Oolong order.

I would recommend your sending samples of the

1 Formosa,

2 High district,

3 Moyune, as representative teas.

The last paper I wrote was published in the *Pennsylvania Grocer* under the heading of "The Tea Leaf of Commerce" in its commercial and domestic aspects in the United States. The next which is nearly ready will have the same heading and treat of the various descriptions of the teas, namely the green, black, red, and brown varieties of China teas, accompanied with a map of the tea districts.—Yours very truly, O. K. REID.

DISEASE AMONG TURKEYS.

Colombo, 14th July 1888.

SIR,—The disease, about which your correspondent "B. A." spoke of in one of your later issues, is one of infectious kind, which is caused by microscopic germs, and it may be either "smallpox in turkeys" or any other cutaneous eruptions. Such germs can only be destroyed by disinfection, and all other remedies will be utterly useless.

To effect disinfection, the diseased birds must be separated from others, and kept in a cool and shady yard, which is thoroughly disinfected by tar smoke and sprinkling of strong carbolic acid. The afflicted part must be washed either with a weak solution of carbolic acid or Condy's fluid and rubbed with carbolic powder.—I am, sir, yours faithfully,

N. SWAMY NATHAN.

THE OUTTURN OF TEA FROM GREEN LEAF.

Kandy, 18th July 1888.

DEAR SIR,—We are much exercised at present regarding the outturn of tea to green leaf, and I should be much obliged for the necessary space in your columns for the following question on the subject, which, I trust, some of your tea experts will be good enough to answer.

Striking an average for twelve months from Jan. to Dec., how many pounds of green leaf does it take to make a pound of tea? The weighing to be done strictly all round without deductions of any sort for wet leaf. It's commonly supposed that 4 lb. of green leaf give a lb. of made tea, but such is not the case within my experience.

Your correspondents will please bear in mind that the reply must be free of all deductions. Many planters deduct heavily for wet leaf, but that is not a fair test, for we may take off 10 per cent, whilst another would be satisfied with nothing less than 30 per cent.—I am, yours faithfully,

INDOCTUS.

TEA; GREEN LEAF AND THE OUTTURN.

26th July 1888.

DEAR SIR,—With reference to the letter from "Indoctus" appearing in your issue of 18th instant re outturn of tea, I enclose an account made up from July 1886 to June 1888 showing the amount of leaf and tea made during each month. I also show rainfall, as some people are under the impression that 100 lb. leaf will turn out 25 lb. tea; however, such is not the case in this district, where the rainfall is pretty evenly distributed over the 12 months. The average outturn for the year ending June 1887 is 23½%, and for 1888 23¼%. I have made no deductions for wet leaf or anything else. The total quantity of made tea includes the 1 lb. allowed on each chest of tea.—Yours faithfully,

SWEET WILLIAM.

MINERALOGISTS (says Dr. Taylor in the *Australasian*) are now coming to the conclusion that kaolin, or China clay, is not so much the product of decomposed felspathic minerals by carbonic acid, as by the agency of various compounds containing fluorine. Mr. J. H. Collins has succeeded in producing artificial kaolin by the operation of hydro-fluoric acid on felspar.

THE LOQUAT.—A branch of this Chinese plant, bearing a score of thoroughly ripened fruits, was kindly sent for our inspection by Mr. G. DONALDSON, gardener, Humewood Castle, Co. Wicklow. The plant from which this was cut has borne this season about 300 fruits, and is growing in the open air. Ripe fruits are very nice eating, and would, were the cultivation of the fruit carried out in an organised manner in mild districts in Ireland, and elsewhere at home, prove a marketable commodity very remunerative to the growers.—*Gardeners Chronicle*.

COFFEE AND COCOA SUBSTITUTES. (No. 3,602. 1881.)—The patentee, Mr. A. J. M. Bolanchi, describes this invention as a method of treating the fruit known as *ceratonia siliqua* and the seeds known as *vicia sativa*, also *dhol* and the date fruit, so as to combine the extract with coffee or cocoa, thereby producing substitutes for these foodstuffs. The patentee details the process to which he subjects each of the above-named substances—it simply consisting of decoction of the roasted or unroasted substance, and evaporation of the decoction to the consistence of an extract. The coffee substitute is made from the following:—

Ceratonia extract	50 parts
Coffee	25 "
Chicory	0 "
Sativa or dhol	5 "

Cocoa substitute is made in a similar manner.—*Chemist and Druggist*.

OUTTURN OF MADE TEA IN PROPORTION TO GREEN LEAF.

The correspondent who sends us interesting figures or proportion of made tea to green leaf in two years within his experience accounts a good deal for an average lower than the normal and accepted 25 per cent, by the figures he supplies for copious and well-distributed rainfall. Further information would have been interesting as to the system of dealing with the green leaf, and, in the absence of desiderated details, we suppose we are justified in assuming that our correspondent's calculations are founded on the weight of the green leaf exactly as it was received at the store, with all the moisture included, no deduction being made by either arbitrary or settled formula, or by actual testing of a portion of the leaf for proportion of wet. We heard recently of a tea-store superintendent, who secured a good return of cured leaf in proportion to green, by regularly and systematically deducting 10 per cent from the actual weight of the latter! We believe that, as a general rule, the pluckers are credited with the full weight of the green leaf brought in, without any deduction for moisture. That is,—if 16 lb. is the *nerrick*, as they call the daily task in India, leaf weighing 16 lb. is accepted on wet days as well as dry, and so if extra payment is made for extra quantity plucked? But various means and appliances are resorted to in factories to rid the green leaf of excessive wet, before it is spread on the lofts or trays for the withering process. From leaf merely placed on a cemented ground floor a good deal of moisture is deposited, but naturally the leaf parts much more readily with moisture when placed on sacks or other absorbent substances. In some cases, we know the moisture is forcibly expelled from the leaf by the action of a rapidly revolving cylinder, with orifices along its surface; (a green leaf sifting machine answers the two purposes, indeed). Now it is obvious that the average proportion of dried to green leaf must vary with the system pursued in dealing with the green leaf, and must largely depend on whether the calculation refers to leaf as received from the pluckers, or leaf divested of superfluous moisture. We suppose the usual mode adopted is to compare the result in dried leaf with the quantity of green divested of excessive moisture. And so, we suspect the received proportion of 1 lb. cured tea to 4 lb. green leaf is fairly correct. But we should be glad to hear from tea planters as to the general practice and results.

LIFE AS A TEA AGENT IN THE OLD COUNTRY:

(By an ex-Ceylon Planter.)

[The following extracts from the graphic letter of a well-known planter to a friend in Ceylon will be read with interest by all connected with tea.—Ed.]

Since coming North I have been struggling hard to make a living by selling tea, but find the work uncongenial and discouraging. I doubt very much if I shall ever become reconciled to it. A revolution is taking place in the tea business. The consumer fixes his figure about 2s per lb. which is 1s 6d duty unpaid, and from this has to be deducted commissions, brokerages, warehousing, freights, and profits to dealers and grocers, and a host of other charges which would fill a page and add 2d or 3d per lb. to the cost price. The grocer must have 6d and 8d per lb. for retailing. If you consider all this you will see at a glance how impossible it is to do anything in first grades of Ceylon tea, *i.e.*, with a view to retailing it at 2s per lb. Taking the lower grades I find they come into competition with Assams, Oachars, and Darjeelings,

which can be purchased at 2d per lb. cheaper in the Lane. Appearance goes for nothing in this class of tea, and Ceylons cannot compete in strength with the kinds I have mentioned. So it is next to impossible to do a decent turn-over in Ceylon teas unless one starts on a large scale in London, and sells it to grocers for mixing and flavouring cheap teas! I cannot bring myself to this game, even if I had the means, and the consequence is I am obliged to deal principally in Indian teas! Better to run the opposition than aid and abet those who are adulterating Ceylon teas. The tea business is run very close, some of the large London houses selling at $\frac{1}{3}$ d profit per lb. I dare say they score more off China stuff which they can buy at 4d and 5d per lb., but Ceylons they supply at little over cost price in order to secure their regular customers. If I could get a good unassorted Ceylon tea landed *in bond* at 11d to 1s per lb., I would guarantee to do good business with it, but where is it to be found?

Apart from business, home life in these parts is far from congenial to one who has spent half his life on a coffee totum. The hardest work I have yet experienced is attending office and sitting there for hours on and expecting people to "turn up" with orders for tea! I would much rather walk all day at four miles per hour than continue this game. I am at my office at 9 a.m., and get out of it about 7 p.m., reaching home about 8 p.m. more tired and fagged than if I had been doing a twenty miles' walk. There is no relaxation except what I can find on Saturdays after 3 p.m. and on Sundays.

The haunts of my boyhood in the adjoining shire are in the possession of strangers, and the rivers and pools we used to fish are preserved. The old country lairds who used to allow us to shoot over their moors and covers are dead, and their properties are in the hands of retired comb-makers, and soap-boilers, and carpet-weavers, whose income runs from £20,000 to £40,000 per annum, veritable snobs of the first water, void of manly pride, but stinking with the pride of filthy lucre!

CHINA TEA.

The indefatigable Governor of Formosa, Liu Ming-chuan, is planning to draw away the greater portion of Amoy's tea trade to his island. Hitherto the want of harbours in Formosa has sent her teas to be loaded on the ocean steamers at Amoy; but Liu Ming-chuan is building a railway from the centre of the Formosa tea trade, Twaatua, to Keelung, and is improving the capabilities of that port, and to use Mr. McLeavy Brown's words, "whatever may be the upshot of the activity now being displayed in developing communications in and with North Formosa, the effect on the prosperity of Amoy of the schemes in hand and projected can scarcely, in the long run, be favourable." There will still be the Amoy Oolongs to be shipped from that port; but they only amounted last year to some 42,000 piculs, while the re-exports of Formosa tea were nearly 120,000 piculs, and a diminution in the production of Amoy Oolongs is expected in the future.

In Canton, according to Mr. White, the general trade was of a satisfactory character last year, and pursued a steady and fairly progressive course. Mr. White is the only commissioner who is able to write with satisfaction of the tea trade of his port. Canton teas, he says, are holding their own in the home markets, and "Indian competition has not decreased the demand for them; in fact, they are largely used for mixing with the latter, and this should preserve them from a rivalry that would be disastrous to their interests."—*N. C. Herald*, July 7th.

PROGRESS IN SUNGEI UJONG, STRAITS SETTLEMENTS.

Coffee cultivation is making headway in Sungei Ujong. The Liberian coffee on estates belonging to Messrs. Hill and Rathborne, is reported upon as yielding a crop of seven and a half hundred-weight an acre. On another plantation the outturn

was only five and a half hundredweight per acre. Nothing is said in the report about leaf disease which has ruined so many coffee planters in Ceylon. Should it keep away from Sungei Ujong, growers there will have a good time before them. Appearances go far to bear out the forecast that, what with leaf disease and the abolition of slavery in Brazil, quotations for the berry will rule high in the market ere long. The cocoa trees under experimental cultivation have been less fortunate than coffee. Stricken with blight, they were in a bad way for a long while, but of late, they have recovered sufficiently to hold out hopes of a fair crop this year. Tapioca cultivation does not seem to suit the country, and the trade in the article lessened considerably during the year. So little confidence does this staple product command at present that gambier and pepper find more favour. In the export returns, tapioca makes a brave show. It figures there to the amount of 20,000 piculs; while coffee, gambier, and pepper between them only muster 16,000 piculs. Increase in the yield of pepper in certain coast districts depends upon readier supplies of opium. Both the preparation and sale of the drug there are in the hands of monopolist farmers. The latter charge so highly for the opium they supply, that the excessive price demanded seriously interferes with the progress of settlement. Settlers find that the artificially enhanced rates for the drug, make away, wholly or partially, with the profits on a plantation. The only remedy appears to be the abolition of the Farm, and the substitution of an import duty on opium instead. The only objection to this change lies in the probable increase of smuggling in Malacca, in consequence of any such step. This difficulty can be overcome by authorising the importation of raw opium into Malacca, on payment of duty. The question has been taken into consideration by the Governor, and will need thorough discussion, for any such measure at Malacca would run counter to free trade principles. When matters come to a head, political economy must give way to expediency. Still, as matters now stand, the opium question certainly hampers the development of the tin mining industry. The duty on tin was raised by one dollar a bhara by order of the State Council, which greatly relieved the Chinese miners. They now pay a fixed tax on the metal, instead of squeezes to Malays claiming royalties. Time will show whether this increase of the burdens on the tin mining industry is a wise step in these days of falling prices.—*Straits Times*, July 3rd.

THE ASSAM TEA COMPANY.

The annual general meeting of the shareholders of the above company was held on Monday week at the offices, 5, Laurence Pountney Hill, Cannon Street, E. C., Mr. George Turnbull presiding. The report which was taken as read—stated that the total quantity of tea packed and despatched to London of the 1887 crop, amounted to 2,138,733 lb. which was 200,273 lb. less than that of the preceding year. The average price realised was 1s. 0½d. per lb., or 1d per lb. more than that of the preceding year. This increase of price did not quite counterbalance the diminution in quantity, and the Board were unable to propose a larger dividend than 10 per cent. for the year. The gross proceeds of sales of tea amounted to £113,719 3s. 9d.; the net profit on the crop being £16,121 18s. 1d.

The Chairman, in moving the adoption of the report said the directors were disappointed at not being able to recommend a larger dividend than 10 per cent. The prices realised in the London market for their tea had had not a little to do with that diminished dividend. The diminution in the quantity of tea produced had been considerable, and was due to the fine plucking, and to the cutting down of large quantities of bushes which were half worn out, and

also to taking over about 400 acres of new plantations. Sufficient time had not yet elapsed for the growth of the plants in the new plantations to have produced any tea, and, consequently there had been little or no yield from those 400 acres. Last year they proposed certain changes in the administration of their affairs at Assam, and the packing of the tea in the gardens instead of at Nazerah had been carried out—he hoped with beneficial results. They participated last year in a reduction in the freight from Calcutta and Assam, and they now paid 25s a ton for freight, with a rebate of 5s per ton if all their tea were sent by the liners.—*H. & C. Mail*, July, 6th.

NOTES ON PRODUCE AND FINANCE.

Amongst the new joint-stock companies recently registered are the following:—The Greenwood Tea Company, Limited; capital, £60,000 in £20 shares. Its object is to acquire the estates known as Greenwood, Dinjan, and Blackburn, with the several tea plantations or gardens thereon, situate in the district of Luckimpore and Debrooghur, Assam, to carry on the business of a tea planter in all its branches, and any subsidiary business, and any business, subservient to the company's estates and properties.

The statistics relative to the GREEN TEA TRADE of Ningpo are interesting. About 70 per cent of the total exports of the port are represented by green tea. The export last year up to December 31st amounted to roughly, 17,800,000 lb., as compared with 19,700,000 lb. in 1886. At the end of the year there was, however, a considerable stock on hand, which has, to a large extent, since been shipped to Shanghai for export to foreign countries, thus rendering the season of 1887-88 on the whole a fairly average one as regards quantity. The general quality of the teas produced (according to Mr. Consul Scott) was good, but it seems probable that losses were made among their shipments to New York, the prices in Shanghai being quoted from time to time as higher than the market rates in America. To the exporters from Ningpo the season is said to have been disastrous, and it is estimated that the average loss of the twenty-two Chinese tea-faring establishments there was not less than £1,000 each. Nor is it certain that the season was a prosperous one for the growers even; in the Ping Suey district they lost severely. The price of teas generally, as compared with the season of 1886-87, was higher in the growing districts, but lower in the Shanghai market. The prospects for the present season are stated to be not encouraging. The crop is estimated as likely to be 30 per cent less, and the number of Chinese firms engaged in the trade half of those of the past season.—*H. & C. Mail*, July 6th.

PLANTING IN DELI.

(Translated for the "Straits Times.")

In Upper Langkat, by last advices, this year's tobacco crop bids fair to be of good quality, barring accidents. The weather is as favourable as it can be.

The spread of planting enterprise in the country has thrown fresh light on the origin of that mysterious disease known by the name of beri beri. Experience shows that it breaks out readily among people, who ignorantly settle down on spots where the primeval forest has just been cleared away. Planters who threw precautionary measures to the winds suffered heavy losses in coolies' lives. In Siak, for instance, on a single estate, 14 miles up a river, no less than ninety out of one hundred coolies employed, died. No wonder need be felt at this high death rate, when it is considered that the coolie sheds were set up on newly cleared ground, and the men were quartered there at once. At another place, some soldiers garrisoning a fort thrown up on a jungle clearing, soon came within the grip of the dreaded disease.

Sumatra tobacco has been experimented with for cultivation purposes in Virgipica. The plants look well and yield fifteen leaves each on an average. The outturn is expected to be 300 pounds an acre.

Tobacco growing in Deli, profitable as it is, brings no end of trouble to the planters. They have to count upon incendiarism as an element of danger to guard against. The Battacks who inhabit the inland country take readily to fire raising to pay off any grudge they may against the planters. On the Arnhem estate, recently, this form of revenge has taken such an alarming shape that the neighbouring planters feel uneasy and are preparing for the worst. Fire raising has ever been a formidable weapon in the hands of aggrieved natives.

The shipment of the tobacco crop from Deli has this year been later than ever. Half of last year's outturn had not been shipped by May last. Planters, so it seems object to be first in the market on the ground that low prices may be expected early in the season. Hence they put off forwarding their produce as long as possible.

THE ORIENTAL BANK ESTATES COMPANY, LIMITED.

We have to acknowledge the receipt from Mr. Charles Grant, *pro tem.* agent, of a copy of report and balance sheet of this Company which was to be submitted to a meeting of shareholders on the 25th ultimo. We quote as follows:—

The Directors have much pleasure in submitting to the Shareholders their Second Annual Report, with the audited accounts, showing the continued satisfactory progress of the Company, notwithstanding the severe drought which prevailed in Ceylon during a considerable part of the year.

The net profit for the year to 31st March, 1888, amounts to £25,841 0s 8d, (including £2,191 brought forward), as against £17,398 4s 8d last year. An Interim Dividend on the paid-up capital of the Company at the rate of 7 per cent. per annum on the Preferred and 5 per cent per annum on the Ordinary Shares for the half-year ended 30th September, 1887, was paid in February last, and the Directors now recommend a further dividend at the rate of 7 per cent. per annum on the issued Preferred Shares, and at the rate of 5 per cent. per annum on the Ordinary Shares, in proportion to the capital paid up thereon, for the half-year ended, 31st March, 1888, payable on the 1st August, 1888, at the London Office of the Company's Bankers, the New Oriental Bank Corporation, Limited.

During the past year, besides valuable cocoa estates, a few additional minor estates have been purchased on behalf of the Company, which form important adjuncts, whether for the supply of fuel or otherwise, to the property already acquired. The large tea extensions in Ceylon, already made, are gradually coming into bearing, and the erection and enlargement of factories and equipment of machinery now necessary has been effected. The condition of our Mauritius Estates is reported excellent, the Britannia Estate especially has been materially improved, and the prospects for the coming year are reported to be unusually favourable. Under the provisions of the Company's Articles of Association the Board have appointed two of their number—Mr. Alex. William Crichton and Mr. William Cotton Rohde—to be Managing Directors, feeling that it is desirable that these gentlemen should be in position to continue to give their constant attention to the interests of the Company, and they propose that the remuneration of a Managing Director be fixed at the sum of £500 per annum. As Managing Directors of this Company are not entitled to accept their remuneration as ordinary Directors, this will no longer be charged to the Company, and thus the increase of annual expense from the appointment of Managing Directors will not exceed £500 so long as the Board remains at its present strength.

ESTATES IN CEYLON AND MAURITIUS: THE PROPERTY OF THE COMPANY.

CEYLON.—Bellwood, Oraigie Lea, Dangkande, Darrawella, Delmar, Dene, Dodangalla, Donoughmore, Forest Creek, Glen Devon, Havilland, Haddington, Henegahawelle, Hunugalla, Kondesalle, Kudaoya, Lindupatina, Lonmay, Loolecondura, Mahaberiatenne, Mahawatte, Naranghena, Newmarket, Nilloomally 3-4ths, Sinnappittia, Stelberg, St. Coombs, Summerhill, Waloya, and Wattewella.

Total acreage 12,953 acres, under tea 4,129 acres, under coffee 637 acres, under cocoa 604 acres, under cinchona 1,158 acres, under cardamoms 80 acres, grass, forest, &c. 6,345 acres.

MAURITIUS.—Britannia, Cent Gaulettes, acreage 3,547 acres. The Company is also interested in the following estates:—Beau Sejour, Constance, La Paix, Mon Choix, Mon Songe, Mont Piton, Bon Air, Highlands and Combo, acreage 9,572 acres.

WEATHER IN JAMAICA.—Mr. W. Sabonadière, writing at end of June, says:—“We seem quite to have had your weather: dry from December to middle of April, then had little monsoon; still unsettled now.”

INDIAN TEA COMPANIES.

(From the *Home and Colonial Mail*.)

SCOTTISH ASSAM TEA COMPANY, LIMITED.

The Chairman, in moving the adoption of the report said the Assam Company stood fourth best in the market, in regard to the price obtained for their tea. As to the future price, that was an anxious and difficult matter to say anything about, but he thought their prospects were good. He directed attention to the following paragraph in the report:—"With the view of extending the cultivated area of the gardens, and thus of increasing the resources of the company more rapidly than has hitherto been done by extensions out of revenue, your directors have at present under consideration the expediency of utilising a portion of the unexpended capital of the company, which at present, lies dormant and comparatively unproductive, in forming a special block of extensions of, say, from 150 to 200 acres, and in maintaining the same until it reaches the self-supporting stage." Proceeding, he pointed out that they had about £5,000 which they could use in the manner indicated but then came the question whether, if the gardens were extended, there might not be some difficulty in keeping up the labour force. As it was, there had been a gradual extension of the gardens—88 acres in all in the course of five years.

THE LUCKIMPORE TEA COMPANY OF ASSAM, LIMITED.

The crop amounted to 453,590 lb. of packed tea, showing an increase over that of the preceding year of 111,988 lb., and representing an outturn of 488 lb. per acre of plant over three years old. The average price realised has been 1s 0½d per lb. The estimates of the crop of the current year are, for Mijica Jamb, 180,000 lb. Behallie, 248,000 lb.; or a total of 428,000 lb. on a local expenditure of 4s. 9ps. per lb. equivalent at current rates of exchange to about 91 per lb. laid down in London. The managers have, it will be observed, deemed it prudent to estimate the crop rather under that of last year, but with favourable weather there is no reason why the same amount at least should not be made, and returns up to 31st ultimo show an increase over last year of 3,472 lb. The rates of ocean freight have, after considerable negotiation, been arranged at 20s over those of rough cargo, to be settled monthly, subject to a rebate of 5s per ton; and a new agreement has been concluded with the steamer companies plying on the Brahmapootra for the carriage of tea and stores between Assam and Calcutta at greatly reduced rates of freight.

THE LIMBONG TEA COMPANY, LIMITED.

The cultivated area on the company's gardens on May 1st last was 1,112 acres, the largest we have ever had, and a considerable portion of which, as will be seen by the manager's report, is not yet in full bearing. As mentioned by the chairman at the meeting of shareholders held in November last, a fire unfortunately occurred at Barnesbag Factory in October last, by which 19,528 lb. of tea were destroyed, and the building completely gutted. The value of the tea has been recovered from the underwriters, but the building, being uninsured, the loss in respect thereof, estimated at R4,000 has been charged against the 1887 revenue.

LETTERS FROM JAMAICA. No. 24.

THE "MAY SEASON"—OULETTE AND THE PRESS IN JAMAICA—SLAVE ABOLITION IN BRAZIL—AND PROSPECTS IN AMERICA.

Blue Mountain District, for Packet of 6th June 1888.

To the Editor, "Ceylon Observer."

DEAR SIR,—Our "May Season"—equivalent to the Ceylon little monsoon—was hoped had come to an end, but after a week of cloudy pleasant weather, they appear to have recommenced. It was not unreasonable to expect that after the long drought, which lasted from the end of November to middle of April, that it would be, as is so

often the case, succeeded by heavy rains and floods for commencing with a few days of nice planting weather. The rain came down in real tropical style, and lasted for nearly a week; much damage generally has consequently been done, rivers were flooded and became impassable, landslips were many, mails were detained, people were drowned, and houses washed away in Kingston which is surface-drained, the streets became running rivers, and no business could be transacted for some hours. As much as 25 inches were registered in Kingston for the week; so it is easy to conjecture how much more must have fallen on the Blue Mountain Hills and on the north side celebrated for getting more rain than the rest of Jamaica. On this property, portions of which are very steep like "Glen Alpin," in Badulla, "Gampaha" in Udapussellawa, and many of the Haputale coffee plantations, I have lost or had most seriously damaged by landslips and wash fully three acres of quite young coffee, and I have cause to be grateful, matters were not worse. I can quite imagine that much similar damage has been done on similar lands all over the island, particulars of which have not been published, for our local papers are not a patch on the *Observer*, and do not seem to get the planting news. Here in Jamaica, especially in this district, being cut off from Kingston by unbridged rivers, we are occasionally in danger of being starved out. On the last occasion the local shops ran out of rice, so that the few coolies I have were in a sad plight, and had to fall back on yam if they could get it, and on bananas: these said coolies are *Bengalis* and not as strong or useful as my old friends "Rama Swamy" and "Menatchie." Would I had a good gang of them, and the same easy way as in Ceylon of feeding them, for here the people are mostly dependent upon their provision grounds; everything else has to be carried on mules' backs. Coffee crops in the Blue Mountains have been backward this year, the high coffee specially so, the trees being still well loaded with ripening berries. It is to be hoped this renewed downpour will not be of long duration. We suffer here a good deal more than used to be the case in Ceylon from the ravages of rats and birds. The mongoose has by no means exterminated the former, and now appears to prefer young chickens and eggs, may even fruit and bananas: he will soon become as great a nuisance, as the enemy he was introduced to slay and extirpate. None of the real Blue Mountain coffee had been sold up to latest advices, 101s being the figure so far realized this season, but the next advices should bring us something more like the old figures. And now that the grand news of the Emancipation in Brazil has been received, and is a *fait accompli*, we other coffee planters, all the world over, have great cause for gratitude and rejoicing, that justice has at length been done, not only to the slave, but to coffee growers in general. The fact that slavery has been abolished in Brazil must soon have a favorable effect upon the market, as it cannot be supposed that "Quashie" will act differently in that country than he has done in the West Indies: he will take good care not to overwork himself, he will like his piece of "ground" and cultivate it his own fashion, and will make most of his living thereby and only work to buy such luxuries as fine clothes, rum, tobacco, concertinas, dandy boots and hats, and his "cara sposa" will follow in the same line according to her instincts. We may, therefore, unless the Brazilians can adopt some way of making their old slave, work six days a week for a fair day's wage look for a diminution of the immense pro-

duction of coffee in the Brazils, and this will mean a rise in price in all the European markets; surely it will in one way be better for the Brazilian planter himself to have less coffee at a well paying price, than an overplus wherewith to swamp the market. We must, of course, have a little patience before the full effects of the emancipation in Brazil can be fully realized; meanwhile it will be a good plan for those of my old friends in Ceylon who still have coffee fields to nurse and manure them and do their best to keep them in bearing, and when tea and other growths predominate, perhaps leaf disease and green bug may disappear.

I must now congratulate you, the Uva planters, and the inhabitants generally of the old principality, that the extension of the railway to Haputale is at length sanctioned; certainly the *Observer* has fought the battle most manfully and persistently, I sincerely congratulate you on this happy event, and am sure it will tend to the further restoration of prosperity in the dear old island where I have spent very many happy years. Would that we had such facilities of transport: even a good cart road from here to Gordon Town, our present cart terminus, would be an immense boon, but there is not the least chance of our ever getting it, so we must be content to go on in the old groove: even as they now do about coffee pulpers, using the same old-fashioned machine Laborie had on his estate some 100 years ago. Our own railway scheme of extension is again in abeyance until the Council next meets, but I doubt much whether it will be sanctioned; perhaps it may be commenced in short sections, not but that with a Government guarantee the money would be oversubscribed at 4 per cent interest. Though the railway would do us Blue Mountain coffee planters no good, I should be the last to veto it, as I believe it would indirectly benefit the whole island immensely, and enable our low-country brother planters to compete successfully with other sugar and fruit-growing countries, and also enable "pen" keepers to send their cattle and airy produce to market, and cheapen living generally.

I have read with much interest the letter on Ceylon which appeared in the *London Times* of 3rd March, and also your comments thereupon, and as it alludes to subjects which are now burning topics with our community, such subjects as railway extension, enlargement of elected members of the Council, extension of franchise, import duties, and taxes direct and indirect, I have sent copies to the *Gleaner* and hope they will be published. The late session of our Council as regards the Bill for the re-adjustment of the tariff ended in a *fiasco*: this bill, it was said, was drafted by two of the elected members at the suggestion of Government, all went smoothly at first, new import duties, raising most of them from the present 12½ to 25 per cent, and a temporary law was passed making these new duties at once leviable, so as to prevent people rushing in their rums and other commodities to escape the enhanced tax, the shopkeepers stuck on additional prices on the goods that had paid the old duty, and, as you may well suppose, there was a general outcry at such sharp practice. But not until the vexed question of the land tax came upon the "tapis" did the collapse eventuate. It was proposed to tax all lands held by whites, browns, or blacks at the rate of 1s an acre for the first 100 acres, 6d an acre for the next 400 acres, and 1s 2d an acre for the balance: this would be most unpopular and will never become law, still if the Government must have the money to balance their Budget, and to carry out certain reforms such as

penny postage, increase of schools, extension of railway, bridging dangerous rivers, and other much needed improvements, a moderate and reasonable land tax would not meet with opposition, say one shilling an acre on cultivated land, and 1s 2d an acre on all useless and uncultivated land as at present, a certain rate for pens and pimento properties; it would be as unfair to make "quashie" on his 10 or 20 acres pay one shilling on the whole when, perhaps, he only cultivated two or three, as to make the planter and large proprietor pay 1s an acre on his 1,000 or more, 100 or 200 of which were only cultivated.

Our Governor has gone home on short leave, the senior military officer, Colonel Justice, is acting, not the Colonial Secretary, as in Ceylon.
W. S.

DRUG TRADE REPORT.

London, July 12th.

ANNATTO.—It is very doubtful whether the present prices will induce shippers to send us any further supplies. One parcel of fair Ceylon seed sold at 1d per lb. Brazilian roll neglected; 11d per lb. would now be taken for some lots which have been offered repeatedly.

CARDAMOMS.—Altogether 184 packages were offered for sale today, but the proportion sold was smaller than usual, several holders preferring to keep back their parcels at rates above those now current. Prices were somewhat irregular, as usual, but on the whole very steady, with a tendency upwards.

CINCHONA.—The usual assortment of South American barks was offered today, and showed no special features. Crown bark seemed rather dearer, 10d being paid for fair thin rusty M. O. Z. quill. Ten bales cultivated *Calisaya* in thin flat pieces, rather dark, were bought in at 1s 6d per lb. Several packages ordinary very dusty flat red bark are in the market at 1s 3d to 3s 3d per lb. according to quality. Another parcel of 88 bales flat *Calisaya* bark, very broken, was bought in at 2s 2d per lb., only two damaged lots selling at 1s 9d per lb.

COTO BARK.—Five bales (about ½ ton) true coto, of cinnamon-like odour and pungent taste, recently imported from Bolivia, but rather sea-damaged in transit, were bought in at 1s 9d per lb., no bid being made at auction. There has been none of this bark offered for some time. Some years ago it came into repute as a specific for Asiatic cholera, and the demand for it brought into the market a substitute—para-coto bark—which, however, differs from the true bark in having a much less pungent taste and an odour of nutmeg instead of cinnamon.

OILS (ESSENTIAL).—*Star anise* quiet, and since the recent sale, when 6s 5d per lb. was reported paid, no further business has transpired. Oil from Russian seed is cheap at present, and may possibly advance consequent upon the improvement in the Russian exchange. *Bitter almond* oil is scarce and dear, and higher prices may shortly rule on account of the growing scarcity of the crude material. Good *Cajuput* oil was bought in today at 2s 4d. *Cinnamon* oil quiet. Ordinary quality may be had at 8d per oz., but for fine strong oil 2s per oz. is asked. The Ceylon shipments (including leaf oil) from October 1st to June 14th are: 1887-8, 107,293 oz.; 1886-7, 52,505 oz.; 1886-6, 89,248 oz. *Citronella* neglected at ½d to 15-16th d. for native brands. The Ceylon exports are enormously heavy. *Lavender* is becoming more and more scarce in France. *Lignaleos* (Mexican): 26 10-lb. tins taken out at today's auctions. *Otto of Rose*, the crop has not been quiet so large as last year's as regards quantity, but the quality is said to be fine. Prices have not been fixed yet. *Peppermint.*—Japan quiet. American HGH quoted at 12s 9d, and firm threat. At auction today 40 cases were shown, but bought in, and 9 cases common "Newark, Wayne Co." bulk oil were also bought in at 9s 6d per lb.

PATCHOULY LEAVES.—Considerable quantities have arrived lately, and several lots rather common leaves were offered today's auctions. For one of these of 13 bales greenish leaves, without stalk, but of peculiar appearance, 6d per lb. was suggested.

QUININE.—Early in the week a rather considerable business took place in B. & S. quinine, both on the spot and for August-September delivery, at 1s 5d per oz., and on Monday 1s 5½d per oz. was actually paid, it is said, for a small lot; but there is no backbone in the movement, and it has been a very short-lived one. The market closes much quieter, with sellers of German bulk quinine at 1s 5d per oz., but no buyers at that price. The English makers have not varied their quotations.—*Chemist and Druggist*, July 14th.

THE DUTCH CINCHONA AUCTIONS.

AMSTERDAM, July 12th.

At the periodical auctions of cinchona bark held here today a total of 1,509 packages was offered. Of this quantity 1,486 packages were sold with fairly good competition at a slight advance, the unit averaging 10c. to 11c. per ½ kilo., or 1 4-5th d. to 2d per lb. Druggists' bark in quills, broken quills, and chips fetched from 16c. to 61c. per ½ kilo. (3d to 11d per lb.); ditto root, 21c. per ½ kilo. (3½d per lb.); manufacturers' barks, quills, broken quills, and chips, 9c. to 86c. per ½ kilo. (1½d to 1s 3d per lb.); and manufacturers' root from 25c up to 76c. per ½ kilo. (4½d to 1s 1½d per lb.). The principal buyer was the Auerbach Quinine-Factory, the Amsterdam Quinine-works coming second.—*Chemist and Druggist*.

NOTES ON TEA.

The utilization of waste products has of late attracted much attention. The latest effort in this direction is to extract caffeine, on an industrial scale, from the damaged and inferior tea imported into this country—tea unfit for human consumption, and, of course, not worth paying duty on. Mr. T. Christy, F.R.S., has been engaged in making experiments, under the auspices of the Chemical Trade Section of the London Chamber of Commerce, with a view to ascertaining what can be done in this direction. As the Customs authorities are unwilling to waive the duty on such tea, and also make provision against its entering into consumption without paying the duty to which the revenue is entitled, efforts were made to ascertain a means for "denaturing" the tea in order to make it unfit for human consumption, but at the same time to preserve the constituents from which caffeine may be extracted. A request was made to the Customs to ascertain whether, if the tea were "denatured" by chemical means, it would be allowed to be taken out of bond and treated in a factory for obtaining caffeine. The reply was that unless the tea paid 6d per lb. duty it could not be allowed to pass out. Samples of tea, treated with petroleum, were then presented at the Custom house, and although the tea was "denatured," it was evident this ingredient was unusable, because the wharfingers, for several reasons, would object to petroleum being on the premises. Experiments were then made with tea treated with lime and assafetida, which were approved of. Mr. Christy has subsequently received a letter from the Board of Customs, to the effect that the Lords of the Treasury have sanctioned delivery of tea free of duty for the manufacture of caffeine out of bond, subject, of course, to all necessary precautions, and that the board will at once formulate the needed regulations. On the 3rd inst. the Customs finally decided on the whole of the details, and tea has actually been purchased from the wharfingers in large quantities for treatment.—*H. and C. Mail*.

HOW TO MAKE CEYLON TEAS KEEP.

The advantages of being able to make tea that will keep, that is that will retain its flavour and general characteristics for a long time, are universally conceded. It is asserted that in this respect the matchless teas of India and Ceylon do not equal those of China, but so far no satisfactory reason for this state of things has been advanced. Most tea-makers in Ceylon complain that their tea goes off in the bin and loses its point and flavor, so that complaints made at home

regarding the non-keeping qualities of our tea are only natural. As directly touching this point a suggestion made by Mr. E. M. Hay, an old and experienced tea-maker, is worthy of careful attention. In his opinions the deterioration in quality, too often noticeable in tea, that have remained long in the bins, is due to the moisture absorbed by the tea in the process of sorting—between its first firing and its binning. That tea gains a little in weight in the bin is well-known, and this is due doubtless to its absorption of the moisture in the air during the process of sifting and picking over, and from the coolies themselves, who go out into the fresh air and bring in a certain amount of moisture. To prevent this Mr. Hay adopts the following plan:—When firing-off his tea he does not keep it in the Sirocco long enough to make it very crisp, but just a little so. The tea is then sorted and picked over, and previous to being placed in the bin refined, but very gently, the tea being warmed to about blood heat. Before re-packing the tea is finally fired, so that it thus gets three instead of two firings. This plan is also adopted by Mr. Barber, of Blackstone, we believe, and Mr. Hay alleges he has never had any complaints as to the non-keeping quality of his tea. By firing generally after the tea has been sorted and picked over in the factory all moisture absorbed during the process is driven away and the tea put warm into the bin, as it is into chests when packing. Tea very often is left a month in the bin, a period nearly as lengthy as that which elapses between the date it is packed, and the time it is sold in London. Yet it is considered necessary to re-fire in the one case and not in the other. This is the argument used and suggestion made by Mr. E. M. Hay, and it certainly seems a most sensible one, involving possibly a little extra trouble, but trouble that would be amply and abundantly repaid if it enhanced the keeping qualities of our tea.—Local "Times."

MULBERRY CULTIVATION IN FORMOSA.

The following is from the *Shih Pao*, translated by the *Chinese Times*. We mentioned this proclamation of the Governor of Formosa some time since:—H. E. Liu Ming-chuan, together with Lin, Assistant Commissioner, have issued a joint proclamation exhorting the people to plant the mulberry, with the view of creating a silk industry in Formosa. Their Excellencies state that the soil of Formosa is exceedingly fertile, the crops abundant, and in general, agriculture is much more profitable on the island than on the mainland. But hitherto the cultivation of the mulberry has been neglected, and it behoves the authorities to urgently exhort the people to give their attention to that branch of industry. It is found that in various districts in northern Formosa, and in regions in the interior that have recently been developed, wherever the mulberry has been planted the trees are large and hardy, resembling those grown in Chekiang, and affording excellent food for the silk-worm. Already both Formosans and merchants from the mainland are experimentally rearing silkworms, with great success. The cocoons woven by the worms possess a thick, velvety covering, which yield fibres of a strong and elastic quality. Judging from these experimental operations, the rearing of the silkworm could be made a most extensive and profitable industry in Formosa. The planting of young mulberry trees is an easy matter, as they will grow almost anywhere, by the road-side as well as in gardens and fields. It can be carried on concurrently with farming, as the work of pruning and watering the trees requires but little time. The rearing of silkworms can be entrusted to the women, who outside of the tea season are without any important employment. The profits of the silk industry, if successfully carried on, are far greater than those of the tea trade, or of rice culture. Previously men were sent to the mountains in the interior of the Taiwan district to procure young mulberry trees for distribution among the farming population, and measures were taken to encourage experienced mulberry growers from the interior to come to Formosa and instruct the people in the

principles of mulberry culture. Their Excellency now issue this proclamation, to inform the inhabitants of northern Formosa that the rearing of the silkworm is a matter that concerns their welfare, and that consequently they must take heed to the exhortations herein given; and on the recurrence of every winter and spring they must devote their time and attention to the planting of the mulberry, which in a short time will afford the necessary food for the silkworm. The object of the Governor and Assistant Commissioner in promulgating this proclamation is to promote the interests of the people, and to see them happy and prosperous.

♦

PLANTING IN TRAVANCORE.
To The Editor, "Tropical Agriculturist."

Travancore, 18th July 1888.

DEAR SIR,—In the *T. A.* of April, page 639, appears a letter signed "M." of Travancore, whose object appears to be to take a "rise" out of Mr. John Cox. As however in attempting to do so he has assumed a liberty and shown a contempt for facts, I should like to say a word or two to correct a most erroneous impression expressed by and to be inferred from "M."’s letter. Mr Cox is not, as he honestly avows, the oldest tea planter in Travancore; unless indeed "M." in a facetious mood, referred to Mr. Cox’s own age. Before Mr. Cox planted the 12-acre field, referred to by "M." which I believe was his first tea planted for the purposes of manufacture, tea was being manufactured on an estate not ten miles from Oliver—though not in any way connected with Mr. Cox’s estate; and yield per acre was fully double what "M." states as a liberal estimate for Southern and Central Travancore, and that too in a wretched climate and soil. If in Purmerd 250 lb made tea per acre can be had from tea 3 years old and of a middling jât, in ordinary soil, what is there, may I ask, to prevent similar results being obtained in South and Central Travancore so long as the planting is properly done.

If "M." will be "penny-wise and pound-foolish" and persist in putting his young tea into 8" and 9" pits when the pits are acknowledged to have so great an influence on the subsequent yield of tea, he will have himself to blame if in the end he has to content himself with 100 to 250 lb. made tea per acre.

"M." goes for Mr. Cox on the ground that he produces "hearsay" information. Is "M." aware that all reports and statements must to an extent be hearsay? He can scarcely expect the person compiling a report to personally superintend the operations, a statement of which, with their results, goes to make up the information rendered. If he is so averse to "hearsay information" why does he adduce "hearsay evidence," which of all matters hearsay is to be disallowed, for the purpose of shewing up an ex-Oeylon planter’s representation? Any ordinary planter would have been able to see for himself of what the 800 lb. of leaf per acre consisted without deliberately "pumping" the neighbourhood. "M." has been most liberal with his estimates of produce to be obtained from certain products—not even accepting cacao from which he only expects to get nothing per acre; but he has passed over a product which has been most remunerative in certain parts of Travancore—Mr. Cox refers to it but in a limited manner—I mean cinchona. On Purmerd the succubras, robusta and pubescens, have given most satisfactory results at an early age, in return for very primitive and inexpensive planting and little if any attention afterwards.

In Mr. Cox’s letter of 4th October, should *Kimmylies* not have been substituted for *Belford*? The "Seafield" tea which fetched 1/7 was marked and shipped as *un-assorted*; a most important piece of information which Mr. Cox appears to have overlooked. However thereby hangs a tale. I will proceed no further but subscribe myself, yours truly,
BOG ROY.

♦

THE GERMAN BORNEO COMPANY, the domicile of which is at Hamburg, has no net profits to distribute for 1887. The plantings had a financial result of m.91,517, in addition to which sum an amount of m.160,034 was applied for improvements. The paid-up capital amounted to m.500,000 in addition

to m.203,124 taken up as loans from bankers.—*L. & C. Express*, July 20th.

JUTE.—A paper issued by the Bengal Agricultural Department gives some remarkable statistics regarding the growth of jute cultivation in the Lower Provinces. In the last two years the increase has been about 20 per cent on the normal area, which means an extension of about 200,000 acres; while the expansion in production may be judged from the fact that last year the amount of jute received in Calcutta exceeded the imports of 1884 by over two million maunds.—*Pioneer*, July 16th.

FIBRES FOR PAPER-MAKING.—The *Moulmein Advertiser* draws attention to the fact that Burmah in general and the Moulmein district in particular abounds in plants yielding fibres most suitable for paper-making. The *king grass* was at one time thought likely to take the place of the celebrated *esparto grass*. Experiments tried by the Bally Paper Mills Company (Calcutta) with this grass (which grows in great abundance all over Burmah, proved that it was very suitable for paper, being easily wrought and showing that the loss in the weight is less than that of any other grass experimented with by the Bally Paper Mills. The paper, too, is strong and clean and shows an excellent surface.—*Indian Agriculturist*. [Had the botanical name been given we might be able to identify the "king" grass.—Ed.]

PROSPECTS IN JAVA.—Amsterdam, July 11th.—At the annual meeting of the Netherlands-India Trading Bank the directors presented their report. The report observes that, although the financial result of the preceding year is not satisfactory, there are signs of improvement in the general condition of Java. The coffee crop was small, but prices higher. The cultivation of tea and cinchona bark was much depressed by the constant fall in value. Indigo, and especially spices, realised improving prices. The rice crop was abundant, and large quantities were shipped to Holland.—*L. & C. Express*.

INDIAN FODDER GRASSES.—From Mr. S. M. Tracy, the Director Mississippi Agricultural Experimental Station, U. S. A.:—"The Mississippi Experiment Station is giving special attention to the cultivation of new varieties of grasses and forage plants and desires to procure a few of the most valuable sorts from India. If you send us seeds—even a few of each variety—we shall be glad to receive them. If you should be able to accompany the seeds with dried specimens of the plants, the value will be still greater. The station will be happy to send to your Institution any seeds which you may desire in exchange, so far as we can procure them." The assistance of Mr. Duthie, who has made a special study of the fodder grasses of Northern India, has been asked; and he has kindly sent a supply of seeds which will be supplemented with some from the Society’s own stock, and sent at an early date to Mr. Tracy. A somewhat similar application from Mr. J. W. Lever of Florida, was received some short time back through Mr. W. Coldstream, c. s. Mr. Coldstream some time in 1885 read a Paper before the Edinburgh Botanical Society on the Grasses of Southern Punjab, which was published in the *Gardeners’ Chronicle*. The writer refers to this Paper which he had read with great interest; he says: "In Florida we are compelled to look outside the State and, in fact, outside the United States for a wider range of fodder plants suited to the climate. So far, we have only succeeded in obtaining and acclimatizing the Japan Clover (*Lespedeza striata*), and we annually sow seeds of the Central American Teosinte [*Reana luxurians*]. Mr. Lever goes on to say that he wrote to the Botanical Society who referred him to Mr. Coldstream; and he adds a list of the grasses he wishes to try. Mr. Lever’s wants will be met as far as possible.—*Proceedings of the Agricultural and Horticultural Society of India*.

"ALL ABOUT GOLD."

In view of the present activity in "prospecting" for gold in Ceylon, the latest number received of the "RECORDS OF THE GEOLOGICAL SURVEY OF INDIA VOL. XXI, PART 2, 1888," is of special interest locally. The list of articles in this part is as follows:—

Award of the Wollaston Gold Medal, Geological Society of London, 1881. The Dharwar System, the Chief Auriferous rock series in South India, by R. B. Foote, F. G. S., Superintendent, Geological Survey of India, (with map). Notes on the Igneous rocks of the districts of Raipur and Balaghat, Central Provinces, by Pramatha Nath Bose, B. Sc., F. G. S., Deputy Superintendent, Geological Survey of India, (with a plate). Report on the Sangar Marg and Mehowgala Coalfields, Kashmir, by Tom. D. LaTouche, B. A., Geological Survey of India (with one plate).

The number has for frontispiece a portrait of Mr. Medlicott in the shape of a "photo etching" executed in the office of the Survey of India. Mr. Medlicott joined the Geological Survey of India in 1854 and did good work for a third of a century, in the face of difficulties and hardships. In presenting the medal the President said:—

During the last eleven years you have occupied the important and responsible position of Director of the Indian Survey; and it is to your administrative ability in that position that we owe many of the valuable results obtained by that Survey in recent years; more especially are we indebted to you, and to our Secretary, Dr. Blanford, for that useful Compendium of Indian Geology which has now become indispensable to all students of our science.

It is, however, Mr. Foote's paper on the Dharwar System, the chief auriferous rock series in South India, that is interesting to us here in Ceylon, now that prospecting for gold is exciting special attention. It appears that, as the result of extended examination, the Dharwar rocks have been separated from the gneissic system (the prevalent system in Ceylon) amongst which they were formerly reckoned. Mr. Foote explains the geological reasons:—

The Dharwar rocks form a very well marked series (or system), consisting mainly of Schistose rocks (hornblende, chloritic and argillitic) with associated, more or less hæmatitic quartzites and numerous contemporaneous trap flows. In many parts of the areas occupied by these rocks occur quartz reefs and veins which are auriferous, indeed all the more important auriferous tracts as yet known in South India lie within such areas, and hence the rocks composing them have come to be called the auriferous series. The Kolar gold field unquestionably occurs in an outlying band of the Dharwar system, and so also the Honnabetta, Chicknayakanhalli, Kotemaradi, Honnamaradi, Halekal gudda, Malibennur, Chiranahalli, Honnahatti auriferous tracts and the Honnali gold field (Kudrikonda and Palvanahalli) in Mysore, and the Dambal gold field, in Dharwar District, which occur in one or other of the great bands. The majority, if not all the fifteen outlying auriferous localities, forming the west central group of my Mysore Report are also situated on detached areas or outliers of the Dharwars. The name chosen for this great series of rocks, "the Dharwars," was selected on well recognized principles of geological nomenclature, from the district in which the separation into a distinct and separate system of the Schistose rocks was first recognized. Till then they had been grouped as part of the great South Indian Gneissic system. The necessity for such separation was pointed out by me in my memoir on the South Mahratta country (Memoirs, Geological Survey of India, Vol. XII, 1876), but I waited for further evidence of the stratigraphical relation of the Schistose series to the far more crystalline gneissics, and this was obtained during my traverse across Mysore in 1881, and by an examination of the rocks in the Sandur and Bellary hills in 1884-85. The Schistose rocks are very largely and clearly developed in Dharwar District, and the well known town of Dharwar stands on them. All things

considered, no other local name seemed to have so many points in its favour and the name of Dharwar was therefore given to the schistose, or auriferous rock system.

The occurrence of the Dharwar rocks over the face of the gneissic systems in such remarkable bands, or portions of bands, is a feature which at once arrests the attention and demands explanation. The explanation is that the Dharwars, as now seen, are the remains of a great sedimentary series which covered a very large area in what now forms the peninsula of India. The periods of sedimentary deposition were interrupted by periods of volcanic activity during which great flows of contemporaneous trap were poured out. Many such flows were formed in different parts of the Dharwar area, as in that which now forms the Sandur and Bellary hills, and further to the south-west the hills south of Chitaldrug and the Bababuden mountains. The Dharwar rocks were at a very remote geological period exposed to vast lateral pressure, by which they were crumpled into great folds, which were then exposed to great denuding action, and largely eroded. This took place anterior to the deposition of the Kadapa and Kaladgi basins, which belong to the upper transition group. Both basins were deposited unconformably on the upturned, and greatly contorted and eroded beds of the Dharwar system. The great jaspers hæmatite beds of the Dharwar system furnished the bright coloured jasper pebbles which are so striking a feature in the basement and other conglomerates of the Kadapa system. The force which caused the great crumpling of the Dharwar rocks had, of necessity, also much effect on the underlying gneissic rocks, and in various places induced a parallelism of folds which gives locally great semblance of conformability. The section of the gneiss rocks exposed south of the southern end of the Sandur tract, shows the gneiss to have been affected by an anterior process of crushing from pressure, acting in a more or less east and west direction. This is noteworthy, as it shows that the peninsula was affected at no less than four periods by great, approximately east to west or west to east, thrusts; the two just noted, and two later ones, by which the Kadapa and Karnul rocks were respectively crumpled up into the great foldings they now show. Of these, the last would seem to have been the least energetic.

The auriferous region of Southern India would seem, therefore, to have been exposed, within comparatively recent periods of geologic time, to volcanic disturbances, of which our gneissic rocks, so far as we know, show no traces? But for the settlement of all such questions we ought to have a geological survey of the island.

There is a note on laterite believed to be the result of weathering on the surface portions of the primitive rocks which is interesting to us in Ceylon where so much of our gneiss rock has undergone or is undergoing the process of change:—

NOTE.—A special feature demanding notice in the western half of the Shimoga outlier, and still more striking over the gneissic tract of the Dharwars near Anantapur is the development of lateritic rock which covers the surface almost ubiquitously and to considerable depth, rendering it extremely difficult to find any outcrop of the underlying older rock. I have not attempted to show the laterite on my map separately from the gneiss on which it mainly lies, as my brief visit to this north-west corner of Mysore did not afford me time to determine the relationship between the rocks. I did not see enough of the laterite to feel satisfied as to its being of true detrital origin or merely a product of weathering, as is much of the laterite on the southern parts of the Deccan trap described in my South Mahratta Report (Memoirs, Geological Survey of India, Vol. XII., 1876). The laterite which I am (so far as my observation goes up to the present) inclined to regard as formed by weather action, constitutes a nearly uniform cover to the whole country, whether it be flat or hilly, with a generally pale, reddish, more or less clayey surface which affords but little nourishment to vegetation.

The grasses, especially, seem to thrive very badly and are very coarse in quality, a chief reason probably why cattle and sheep succeed so badly in the Malanaad, as the forest clad, western portion of Mysore is locally designated by the natives.

As many of our readers are aware, much of our Ceylon laterite (cabook), the result of weathered gneiss, is remarkably fertile.

Quotations from Mr. Foote's paper may be useful to prospectors:—

Quartz reefs occur in all parts of the gold-field, but those found in the western part among the chloritic and argillaceous schists adjoining the trap area, are the best defined, and have received most attention from the old miners. They are doubtless the principal source of the gold obtained there. The only reef from which I obtained free gold was one of this set.

The quartz of the Hattikatti reef from which I got the specimen of free gold, and of the majority of the reefs throughout was of the ordinary kind, white or milky in colour, but very largely iron-stained in parts. The group of reefs occurring south of the village of Dhoni on the east side of the Kappatgode differs from all the others in consisting of distinctly bluish, or deep grey, diaphanous quartz, with a few enclosed scales of white or pale mica.

The reefs, excepting that of Hattikatti, and two others a little distance to the S. W., showed no sulphides of any kind, and those three yielded only a very few cubical crystals of iron pyrites. The argillites and chloritic schists, however, show great quantities of cubical crystals of that mineral converted into limonite by pseudomorphism.

A few miles south of Jagalur occurs another auriferous tract that yielded highly promising quantities of gold on washing the sands of two streams rising on the west and east sides respectively of the little hill lying north of Honnamaradi. The hill consists of drab or yellowish gritty schist passing into argillite in parts, on the south-western side of which several medium sized reefs of quartz appear running nearly north and south. Immediately east of the Honnamaradi (golden hill), the gneissic rocks are seen with an apparently faulted boundary in between. On the bank of a small nullah which flows south, a couple of hundred yards to the east of the hills are the remains of some large dumps where the old jalagars had evidently washed the sands for a considerable time. A washing of "dirt" from the bed of the nullah gave a handsome show of gold, of good grain and excellent colour; while a washing from the little rivulet flowing from the western side yielded a rich show of very coarse gold of the highest quality.

No gold was seen *in situ*, but there is every reason to believe it came from the reefs above referred to, as the streams in which the washings were made, especially the western one, have such very short courses that they could not have brought their gold-spluff from any great distance.

The quartzites on the Kotemaradi are of no great thickness, and are locally much altered, nearly converted in many parts into true quartz, and generally permeated by large numbers of small quartz veins. It will be curious to ascertain, as doubtless there will ere long be opportunities of doing, whether this altered quartzite contains any gold. It is certain that the small stream draining the western and northern slope of the Kotemaradi carries down a notable quantity of large gold of excellent colour, and that no reefs of any size or importance show through the extensive talus covering the slopes.

At Chiknayakanhalli we come again upon an auriferous tract which is frequently spoken of as the Chiknayakanhalli gold-field. On Honnebagi hill, a couple of miles south-east of the town, old workings of no great size occur just within the boundary of the Dharwar area. The reefs occurring here are not promising in superficial appearance, being white and hungry-looking; but the quantity of gold obtained by washing in the small streams flowing down the hill is not by any means contemptible, and deeper prospecting might give still more favourable indications.

A little south of the Yadyur bridge an auriferous

tract is encountered close to the village of Kalinganahalli. Here good washings of gold are reported by Mr. Chas. Ogden, M.E., but no reefs of any size could be seen, merely small veins in great numbers traversing the country rock. Numerous dumps thickly scattered about show that the old miners had been busy here washing on a large scale.

The Dharwar rocks seen here are hæmatitic quartzites of no great thickness, but very distinctly marked, with overlying chloritic and hornblende schists, which stretch down south till abreast of Nagamangala. Various good-looking quartz reefs occur in this tract.

A mile and half south by west of Nagamangala town is Honnabetta hill, an outlier of the Dharwar, consisting, so far as examined, of hornblende and chloritic schists, with at least one fine-looking reef at the northern end of the main hill. A good washing was obtained in the stream draining the north-east side of the hill. A mine is being opened at the extreme north end of the Honnabetta outlier on a reef running through chloritic schists, which is traversed closely by a pale green dioritic (?) trap. This is the Girigudda mine. I obtained a very fair result by washing in the little stream draining the east side of Girigudda hill. Chloritic schists form the mass of the small, but rather high spur which diverges from the Shettihalli band and crosses the Lokapavani river some 10 miles S. S. W. of Nagamangala.

It will thus be seen that quartz reefs occurring in chloritic* schist, the quartz itself, perhaps stained red with iron, are the most likely to yield gold in the Dharwar series of rocks, and so probably in our Ceylon rocks.

Quartzite, in some cases forming a "capping" to the hills, is so frequently mentioned as occurring in the auriferous regions, that we feel special attention ought to be directed to the quartzite formations so prevalent on the railway trace as it nears Hapatule and occurring in many parts of Uva.

LATEST REPORT ON CHINA TEA.

(From *Hankow Consular Reports*.)

Mr. Clement F. R. Allen reports on the trade of Hankow for 1887 as follows:—

The trade of Hankow during the year 1887 shows a considerable decrease on the trade of the two previous years, and there is a falling-off in both the exports and the imports.

EXPORTS—TEA.

If the diminished export of tea from Hankow was accounted for by increased export from other ports in China the decline would not be of much importance, but the same reduction has been going on in all the tea-exporting ports. Comparing the season of 1880-81 with that of 1886-87, we find that the decrease in the exportation of China teas was 23,800,000 lb., and the exportation of 1887-1888 was 20,000,000 lb. less even than this. The cause is evident. It is the increased production of better tea in other parts of the world, especially in British India, Ceylon, and Java.

The Peking authorities have felt the matter to be so grave that the Commissioner of Customs here and at the other tea-exporting ports have been directed to make inquiries in order to find out the causes of this decline, and to suggest a remedy. Mr. Bredon, the Commissioner of Customs, has kindly allowed me to see the correspondence on this subject. A masterly and exhaustive letter from Mr. J. M. Ringer, whose judgment in all matters connected with the tea trade is considered unimpeachable, is the document from which I have learnt most. From it and from the other papers I have drawn the following conclusions:—

1st. That Indian and Ceylon tea is better than Chinese, although the Shanghai tea-tasters assert that China tea has naturally the better flavour. In India and

* Chlorite, a soft, olive green mineral, consisting of minute scales, and somewhat soapy to the touch. It is allied to talc, but contains also silice, magnesia, and alumina.—DANA.

Ceylon the tea plants are grown with an amount of care and attention which would strike a Chinese tea-grower as superfluous, if not ridiculous. In China there is an indifference to the selection of proper soil, so that in seasons of drought there is a deficiency of sap. Old tea bushes are rarely replaced. Manuring, removal of undergrowth, and pruning are all done in a happy-go-lucky fashion, with no idea that system and method are all-essential if the growers wish to get as much tea off an acre as is produced in India and Ceylon.

There is the same want of care and system in the manipulation of the tea leaf in China as there is in the growth of the plant. Every operation is done by hand only. Instead of bruising the leaves by rolling them into balls the Chinese half dry them in the sun and then place them in bags, which are trodden until a greenish viscid fluid exudes, which no doubt contains many of the best elements of the tea-leaf. Days may elapse between the time of picking and of fermenting the leaf. It often happens, too, that the grower, instead of picking the leaves when they are fresh and in perfection, will deliberately wait for them to grow larger, in order that their weight may be increased. Mr. Ringer states that in 1887 the late picking made the crop 20 per cent worse than it need have been. Lastly, in China there is not the same care in packing that there is in India. Is it, then, to be wondered at that Indian and Ceylon teas are distinctly better than Chinese?

2nd. That Indian tea is cheaper than Chinese, owing to the heavier taxes, expenses, and charges of the latter.

I am told that the produce of a Darjeeling or Assam tea-garden can be sold in Calcutta at 8d per lb., the equivalent of 14 taels per picul, to show a profit. In Ceylon tea can be purchased at 5d per lb. f. o. b., equivalent to 8.50 taels. The Shanghai Chamber of Commerce gives the average price of Congou in 1877 as 14.50 taels per picul, duty paid. It follows, logically, that inferior tea at 14.50 taels per picul can scarcely compete with superior at 8.50 taels to 14 taels, even leaving out the fact that India and Ceylon are nearer England than China is. The total duty on Chinese teas including *lekin*, is estimated at from 4.10 taels to 5.40 taels, say 35½ per cent of the value of the tea, or 1d to 3d per lb.

Such, is, at present, the unfortunate state of the tea market at Hankow. What are the remedies proposed? They are three:—1st. The reduction of supply. At first the proposal that the Chinese should be ordered by their own authorities to put less tea on the market struck me as rather an audacious interference with the law of supply and demand. But if the officials were to issue proclamations telling the upcountry tea-growers that there is now no demand for inferior tea, and that if any such were sent to Hankow it is certain to bring loss to all concerned, it is quite possible that the good result desired might follow.

2nd. The adoption of a better system of cultivation and preparation.

3rd. The abolition or reduction of taxation.

Another remedy has also been suggested, viz., to drive India tea out of the market by sending a lecturer through England to preach a crusade against it, and to proclaim its unwholesomeness, and the danger of drinking it. The gentleman who suggests this would choose a very fit and proper person to perform this duty, but I cannot myself think that any result would follow.

The Shanghai Chamber of Commerce proposes that the Chinese Government should throw the country open to foreigners, so that these might buy land in the interior and establish tea factories with all the modern improvements, and with machinery. It is scarcely likely that the Chinese Government, or, for the matter of that, so long as exterritoriality is in force, the British Government either, would consent to this. But the following scheme is within the bounds of possibility. Let the Chinese Government appoint a Commission—a mixed one if they wish it—to visit other tea-growing countries, and there learn the best methods of growing and preparing tea. When the members of the Commission have thoroughly made themselves masters of the

question, let them be sent to the Chinese tea districts to start the necessary reforms. To do this with the least chance of success they would have to be armed with an Imperial edict, and backed with the whole force at the command of the provincial authorities, and even then there would be considerable danger of an outbreak.

Next comes the question of the reduction or abolition of duty. When the tariff was made in 1853 tea was supposed to be worth 50 taels per picul, and as the export duty on all articles was calculated at the rate of 5 per cent. on the value, the duty on tea was fixed at 2.50 per taels per picul. Now that the value of tea has gone down to 10 taels it would seem fair that the duty should also be reduced in proportion. Still, if we assert this principle we also infer the justice of raising the duty on other articles which have increased in value, notably silk. Englishmen would, no doubt, willingly consent to have the silk duty raised and the tea duty lowered; but Frenchmen, who buy much silk and no tea, would scarcely view the proposal in the same light. In my remarks on the tea trade I would point out that I have hitherto entirely confined myself to showing how British merchants exclusively are affected; but we must not forget that at the tea ports, especially Hankow, there is a large and rapidly-developing Russian business. No matter how heavy the duty on tea may be now the Russian tea trade seems well able to stand it though to this must be added the Russian import duty of 1s 8d. per lb. I think, then, that we may not unreasonably expect that the Chinese authorities will not care to make experiments with their revenue, but will set the increase in Russian trade against the decrease in British and have things as they are. At the same time I would gladly find myself mistaken.

I know little of the details of the Russian trade in leaf tea as distinct from brick tea. I have already given the amount exported direct to Odessa. Our Russian friends continue to buy the best "chops," and pay the highest prices for them, which, however, does not prevent handsome profits being made in the business, because the trade is large, and in the hands of a limited number of individuals. The trade in Russian brick tea seems to increase "by leaps and bounds." The "bricks" are prepared entirely by steam machinery. The brick-tea factories with their tall chimneys are the most striking buildings in the European settlement.—*L. & C. Express*, July 20th.

A NEW TEA CHEST.

We suppose most of our planter readers have received circulars drawing their attention to the advantages which "the Stanley-Wrightson Patent Indestructible Tea Chest" possesses over those now in use. Messrs. Stanley and Wrightson say:—

"We would incidentally remark, that owing to the rapid development of the tea industry in India and Ceylon, great difficulty is being experienced at the present time in procuring adequate supplies of suitable timber for the manufacture of Tea Chests, and that consequently the local supply has to be supplemented by wood imported from Japan and elsewhere, at extra labour and cost—a matter of considerable importance to the tea grower. But undoubtedly an equally, if not more momentous question, and one which immediately concerns the Tea Trade generally, is, and has been, the hitherto insurmountable difficulty experienced of securing exact uniformity of *Gross and Net Weights*, in consequence of the inequalities of the various woods employed in the manufacture of packages.

"This important consideration," it is asserted, "has been at length met, and in future it will be quite possible to obtain an absolutely accurate and reliable Tare, as the 'S-W' Chests are so constructed to scale, as to permanently ensure any particular size and weight desired, practically incapable of the slightest variation. It is therefore confidently believed that this, coupled with the many other advantages, will obtain for the 'S-W' Chests a most favourable reception by the Tea Trade, the more so when it becomes

known that the manufacturers, owing to there being a demand for these packages, for other goods in England, agree to purchase empty chests and half-chests from the grocer or retail dealer (at prices as stated) on the same being returned to the London factory intact, and free from smell another than that of Tea." It is added that

The packages are on view at Messrs. W. J. & H. Thompson, 38, Mincing Lane; Messrs. Gow, Wilson & Stanton, 13, Rood Lane, and at other offices, where inspection is invited, and where prices and all necessary particulars may be obtained.

Neither is the material described nor the prices stated, but, as it is indicated that the boxes are made neither of wood nor of metal, we suspect our idea expressed many years ago in favour of papier mâché must have been, at length, carried into practice.

Among the advantages for the above chests it is stated, are the following:—

As their name implies they are practically "Indestructible."

They are Cheaper than those now in use.

They require no Lead Canisters, being completely Impervious to damp and moisture.

An important feature is, that these Chests can be made to any required size, always ensuring exact Uniformity of Gross and Net Weights, a thing hitherto found impossible with wooden chests.

Taking an oblong Indian or Ceylon half-chest as an illustration, measuring 19½ by 16 by 15, Tare 18 lb., and holding 49 lb. (net) of Pekoe, it is found that an "S.-W." half-chest of the same dimensions and Tare will contain 61 lb. (net) of similar Leaf, therefore showing of over 20 per cent in Freight to the Importers.

No nails are used in the construction of this package; no leakage is possible, it being unbreakable. For this and other reasons it therefore finds considerable favour with the Bonded Warehouse-keeper.

Unlike the recently introduced metal chests as a substitute for wooden ones, the "S.-W." chests can be scribed in the Bonded Warehouse with ordinary scribing irons, and addressed cards tacked on the lid, and generally worked much more expeditiously.

The manufacturers of these chests agree to purchase the empty packages from Grocers and Tea Dealers, if returned to their factory intact, and free from smell other than that of Tea, at the following prices:—

Half-chests .. One shilling.

Chests .. One shilling and threepence,

and are in a position to do so from the fact of their adaptability for other commercial uses.

The chests will be manufactured at works in London, and packed in somewhat larger cases of the same material, each case containing Six chests, all ready for putting together on the estate, for which purpose ordinary cooly labour alone will be required.

In appearance and shape the "S.-W." package resembles the ordinary Indian and Ceylon chests. The importance to a large class of our readers of the subject induces us to give what is to Messrs. Stanley and Wrightson a gratuitous advertisement. Can any reader state anything from personal knowledge of the new tea chest, its composition and its merits?

After writing the above we found confirmation of our belief as to papier mâché being employed, in the following description of the new tea box given by the London correspondent of the *Indian Planters' Gazette*:—

I went to inspect a new Tea Chest which has just been brought out, to incorporate a description thereof in this letter; as being more interesting than anything likely to occur in the sale-room under the monotonous conditions now ruling.

This new Tea Chest is to be known as "The Stanley-Wrightson," from its two inventors. After a thorough inspection, everybody who has seen it has been very favourably impressed and many are already prepared to back their opinion by ordering numbers at once, without even waiting to see the results of a voyage

upon a trial shipment. This is, perhaps, the best test it could have, short of an actual trial voyage, and says more for its merits than any mere description. It has been approved by several of the leading brokers, who are, moreover, showing it off at their offices. A sample is also on view at the office of the Indian Tea District Association.

Will it surprise you to hear that the sides of this chest are made of paper? or to be strictly accurate, pulp which has been rolled under hydraulic pressure. The corners are of light but strong angle-iron, to which the sides are rivetted (on the factory), and hoop-iron strengthens all the edges and receives the screws for fastening down the lid, the screws also penetrating the pulp to obtain additional grip. The same screws can be used over and over again. This has been arranged for, as this type of box can be used, of any dimensions, to suit other commodities than tea, and should, it is supposed, prove invaluable for export purposes generally. The boxes will be sent out in pieces, and can be very easily put together on the factory. They are well coated with shellac to protect them from damp. I saw two sizes, a chest and a half-chest. They appear to be very strong, and are certainly lighter, handier, more presentable and cheaper than anything yet offered. They can be turned out in any colour, or with any marks already stamped, or stencilled, or painted upon them. The chests as ordinarily turned out are of the yellow colour of the pulp, and the iron angles and hoops frame them with good effect. The full-sized chest measured 24" x 20" x 18", or 5 cubic feet; thus 10 chests go to the ton. Its tare was 24 lb., and the exactness with which this tare can be guaranteed will be a great point in the favour of these chests. The cost of this full sized chest is to be 3s 6d. each, *ex ship* at Calcutta; and the manufacturers undertake to purchase the empty packages from grocers and tea-dealers, if returned to their factory intact, and free from smell other than that of tea, at 1s. 3d. per chest and 1s. per half-chest. The patentees claim that these chests are practically "Indestructible;" that they are cheaper than those now in use; that they require no hooping or lead lining, being completely impervious to damp and moisture; that these chests provide exact uniformity of tare; that they contain 20 per cent. more tea than wooden chests of the same dimensions, and so save 20 per cent. in freight. No nails are used in the construction.

Unlike iron chests, these S.-W. chests can be "scribed" in the Bonded Warehouses with the ordinary "scribing" irons used for wooden chests; and address cards can be tacked on the lid. They are to be sent out in cases of the same material, each case containing six chests, all ready for putting together on the estate, for which purpose ordinary coolie labour alone will be required. It is intended, that eventually these chests should be manufactured in India, from paddy-straw, or other fibrous refuse. The patentees are Messrs. John C. Stanley and Leonard B. Wrightson of St. Olave's Bonded Tea Warehouses, 3 to 7, John Street, Crutched Friars, London, E. C.

Our only fear is that the lac glaze may affect the tea?

A BOYCOTT IN THE TEA TRADE.

"The benefit the dock companies will derive from the present reduction of discount allowed to importers of tea," writes a correspondent to a contemporary, "cannot be described with accuracy as a consequence of the working arrangement authorized by the pending bill for their working union. It is founded on an alliance of a singular character recently formed between the dock companies and most of the private tea wharfingers with the tea dealers. The basis of this re-arrangement is that the warehouse proprietors shall provide a so-called tea clearing house, to which any dealer or firm of dealers shall obtain access on payment of a trifling annual subscription. The real object of this apparently harmless association is found in its rules, one of which binds the warehouse keeping members to allow a discount of 5 per cent on buyers' rent

to any subscribing member, and to give no allowance whatever, directly or indirectly, to any non-subscriber. In exchange for this substantial concession the dealers undertake that no subscriber shall be entitled to warehouse or deposit tea with, or employ in connection with tea, any dock company or tea warehouse keeper who is not a member of the clearing-house, or to purchase or sample any tea from the warehouse of any non-member. The warehouse keepers in order to reimburse the dealers for the assistance the latter afford in boycotting independent warehouse keepers and establishing a close monopoly, present them and them alone with a handsome percentage on that portion of their revenue derived from sold teas. That this doneur must eventually come out of the pockets of the importers is too obvious to need demonstration, and, although, as is rightly said, the cutting policy of the past has been carried to a ridiculous extent, it seems possible that it may be succeeded by a period of rates raised to an undue level by artificial means."—*L. and C. Express*, July 20th.

CEYLON UP-COUNTRY PLANTING REPORT.

A NEW ENEMY OF THE CACAO—POOR OLD COFFEE—
A FEMALE PHILOSOPHER—A QUEER STORY OF A TEA-
CHEST—THE LABOR LAWS AND COOLIES.

6th August 1888.

Cacao, one would think, has already afflictions enough to bear without anything being added; but it would seem not. A new horror, I am told, has appeared, which has a weakness for the cacao pod. It is a beetle which loves the stalk that attaches the young fruit to the tree, and which it rings in a dainty way and leaves it then to die. It is only when the pod is very young that the insect attacks it thus, but it is as likely as not, that the beetle may develop tastes for maturer fruit, and widen the field to play the rogue in. It certainly lessens our chances of crop, having an enemy of this kind, and when you think of this thing nibbling at the stalk, and the Sinhalese villager carrying off for his curry what the beetle has spared, you incline to go in heart and soul with those men who tell you that they never knew such a fraud as tropical agriculture. Just look at the bushels of blossom every cacao tree in the land has decked itself with during the last few months, and the poor results left behind. Who is the man with the bumper crop, I should like to know? And yet, if a quarter of the late blossoms had set, we were all in for bumpers. And then to find this new pest doing its best to make our medium crop somewhat smaller, why, it is about as bad as the burglaries in Colombo, without the relief of an inefficient police force to swear at!

Then, if you turn to coffee, what of it at least is left in this district, there is some food for thought to the man who votes tropical agriculture a fraud. At present it is suffering from such an attack of leaf-disease, that even in the days when this enemy had the whole Central Province to grow rampant in, its like would be difficult to match. And this is the reward for those whose allegiance to the Old King has never wavered, and who have put faith in the conclusions of our local scientists, that the plague was checked, and would likely in time be stayed. It seems to me as if it had taken a fresh lease of life, and had changed its mind about removing to new premises. The only comfort is that things might be worse. We might have been overrun with bug, which is a thing hopeless to fight, whereas the other may in a way be combated. Certainly there is no good getting down in the mouth, or fancying our fate harder than others. There is always the temptation to imagine that elsewhere the

worries would have been fewer, like the wife of the unsuccessful Scotch planter, who maintained when times here got very hard that she "wid rather leeve at hame on a soorack than in the East wi' a' its luxuries." The sequel was that when "hame" was tried there was little else than "sooracks" to be got, alas!

The improved tone of the London tea market has improved the tone of our local brokers. A man who had tea to sell lately was giving me a good illustration of this. He had a break to send away, but the proper number of carts did not turn up. The result was that all his souchong and one box of pekoe was left behind, what went down, was duly reported on, put up for auction and sold. It was an ordinary tea and went with the ruck. When the second lot arrived the one box of pekoe was evidently regarded as something phenomenal and drew forth a phenomenal report. The report classed it as a superior tea to what had recently been sold from the same estate, and this superiority was especially marked in regard to the flavour! When it is remembered that the box was an odd box left behind for want of room, that it was bulked with the rest, and also that the market at home has been firm, and prices advancing, the mystery may be said to be solved. Had the market fallen that phenomenal box of pekoe would likely have earned for itself the character of a reprobate tea, and been valued like a reprobate.

The upsetting of the labour laws continues to have a detrimental influence on the cooly. Many men who have had no trouble for years are having it now, and the cooly is not benefited a bit. In the old days Ramasami was happy enough, was on the whole very fairly treated, and was content. Now we have a lot of men who are regular lawyers, kangani's who have been in many districts and many court's leading a kind of nomadic life among the estates, and who come with their impecunious followers asking for big advances. When they get on to an estate they do a good deal toward upsetting old arrangements, if they can, and the tone they create around them and leave behind them, is bad, and always bad. By the way how is it that the Government, which likes to pose as the coolies' friend, does nothing in the way of restricting the amount of debt between cooly and kangani which may be legally claimed? The indebtedness in many cases is so great, that it amounts in fact to a kind of life-long slavery to work it off, and when you remember how little coolies know about accounts, once he is fairly into the net, and he is always anxious to get there, his chances of shaking himself clear are very few. A kangani will make up his coolies' account, and the total that comes out is astonishing. I had two new people the other day who after working for a month or so were wanted as runaways. Their old kangani's claim amounted to nearly R160, but he was willing to take R100 cash to square. This is but a typical case. It seems to me as if there was a field opened for Governmental tender mercies in fixing a sum above which it would be illegal for a kangani to claim. More real good would result to the Tamil labourer by a law of this kind, than can ever be expected from the muddling of labour ordinances and the hair-splitting of lawyers.

PEPPERCORN.

RING-BARKING IN AUSTRALIA.

An interesting correspondence has taken place in the Melbourne "Argus" regarding the practice of *ring-barking* in Australia, which is extensively followed by gangsters. Dr. Andrew Ross, M. P., in New South Wales, considers ring-barking as a crime against the beast.

terests of the Colony, and though he admits that grass vegetation becomes much more abundant after the trees have been ringed, yet he states that this grass is coarse, rank and indigestible, and deficient in chlorophyll and "other nutritious elements."

The Melbourne "Argus" does not profess to know much about chlorophyll, nor about the laws of physiology and animal economy, but predicts ruin to the man who attempts to live by stock-keeping on 50,000 acres of ordinary unringed forest, while it is confident that, fat sheep and fair clips are tolerably sure when once the trees are killed and the nutriment they might have absorbed is sent on to the grass. It is a pity that the elements of vegetable physiology are not studied by Australian farmers and newspaper editors, and especially that the latter, who hold out the torch of knowledge in such a wealthy and populous city as Melbourne, should trust to their own natural shrewdness rather than to their scientific acquisitions. After the outcry of Professor Huxley in the "Nineteenth Century," and of Mr. Goschen at Aberdeen, it is time for Anglo-Saxons all over the world to give up the system of learning truths merely by suffering from the disastrous consequences of neglecting them, and to endeavour to profit by the wide field of experience of others, which is now so richly offered by science, and in which Germany has taken such a decided lead. But though the Editor of the Melbourne "Argus" may consider that the comparatively deep-rooted Australian trees deprive surface-feeding grass of its proper nutriment, and though Dr. Andrew Ross considers chlorophyll as the green juice of grass, which is much richer and more nutritious under the shade of trees, than in the open; both these gentlemen are actuated by the lofty desire to benefit their country, and their bold display of ignorance of the elementary truths of vegetable physiology in support of their opinions has a certain merit, as there is much to be said for the conclusions arrived at by both of them. Dr. Andrew Ross's real contention is that, forests are essential for the well-being of a country, that, it is inhuman and cruel to condemn stock to live through blazing Australian summers on shadeless wastes, and that, forest destruction affects the rainfall and the discharge of rivers and the permanent timber supply of the country. The Editor of the "Argus" entirely agrees with Dr. Ross on the necessity for the preservation of tracts of forest, such as those on the Otway ranges, which should act as a sponge for absorbing the abundant rainfall and the slow and continuous feeding of several valuable rivers, but he rightly considers that too much shade is prejudicial to grazing grounds, and argues for the destruction of stunted scattered box trees, and the clearing of land encumbered with them for grazing and agriculture. Light is unquestionably essential for the formation of starch in the green parts of plants, and unless these contain plenty of starch, sugar and other nutritious compounds, grazing animals cannot be expected to thrive.

We should by all means allow small groves to remain here and there on grazing grounds, under which cattle can rest during the heat of the day, but the rest of the ground must be cleared of tree growth, if the grass is to be strong and really nutritious. Of late, there have been attempts made by agricultural authorities in India to induce Government to open forest lands much more liberally to grazing, but in our opinion, grazing is best on cleared lands, and the maintenance of forests is incompatible with heavy grazing. Grazing and forest lands should be gradually separated, and in forests intended to be maintained for the production of timber, the regulation of grazing should be left entirely to the Forest officer, whilst in grazing grounds, the sooner the tree growth, with the exception of what is required to shade cattle during the heat of the day, is cleared off, the better will be the grazing afforded.—*In lian Forester.*

EXPERIMENTS WITH EXOTICS IN MADRAS.

From Col. Campbell Walker's special report, we quote as follows:—

Eucalyptus.—The Eucalyptus plants at Palmanér in North Arcot are doing well, while the experiments

in Salem are not satisfactory owing, it is alleged, to want of leisure and attention on the part of Range-officers. A few plants are, however, now thriving in the Námakal, Tirupatúr and Hosúr ranges. In North Coimbatore a few *Eucalyptus citriodora* of those raised at Talamalai from seed sown in 1884, appear healthy and are about 16 feet in height. In Tinnevely the two species, viz., *Eucalyptus rostrata* and *citriodora* continue to do well in the ghát forests at elevations varying from 800 to 3,000 feet. In Malabar (Wynaad) the *Eucalyptus rostrata* has proved a complete failure, all the plants dying out. *Eucalyptus globulus* is unsuited to the climate and elevation (the latter being insufficient) and looks very poor and weedy. The five trees of *Eucalyptus soligna* and *Eucalyptus citriodora* grow well and appear thoroughly adapted to the climate, but unfortunately a beetle has discovered and attacked them in thousands. Mr. Morgan writes: "This small beetle bores a hole 4 inches deep into the trunk and there deposits its ova. A considerable discharge of a highly saccharine and mucilaginous fluid appeared from each hole and the trees looked sickly, but they have recovered." It is hoped that the attack will not be renewed this year. If it is, Mr. Morgan considers the trees must perish.

Fourcroya.—There are 400 plants in the Navinipatti garden in Madura. They have thrown out on an average 20 leaves and attained a height of 3 to 4 feet. 115 of them have been removed and transplanted to both side of the footpath in the garden. All the plants are very healthy and flourishing. They evince greater luxuriance in the shade than in the open.

Giant Bamboos, &c.—Of the four species of bamboos in the botanical garden at Manantoddy in Wynaad, *Dendrocalamus Brandisii* or *Bambusa* has shown the most surprising growth, last year's shoots being over 30 feet in height. *Dendrocalamus Longispachus*, has also grown vigorously and the best clumps, of which there are eight, average 20 feet in height. All the clumps in the nursery were taken up, divided and planted out on the western side of the garden. This has naturally temporarily retarded their growth and they only average some 10 feet in height.

Cephalostachyum Pergracile has been the slowest grower, last year's shoots averaging only 15 feet in height.

30 lb. of *Besha Travancorica* bamboo seeds were obtained from Palghat and put down in the nurseries. All germinated and the plants are now 3 feet in height.

The Burma bamboos in Nilambúr (*Arundinacea Brandisii*, *Dendrocalamus Longispachus*, &c.) are all growing well: The large clump of "yellow bamboos" and the four cuttings raised by Mr. Handfield are doing fairly well. The attempt to grow "Kakao bamboos" both in Nilambúr and Trichinopoly has proved fruitless owing to the worthlessness of the seed which had lost all its vitality.

The District Forest-officer, South Canara, started a small nursery for cuttings of gaint bamboos which proved tolerably successful.

Ipeacuanha (Cephalis).—There are twenty plants now in Nilambúr doing very well. One plant considered as dead in 1885-86 has come up again from the roots.

Kigilia Pinnata.—The District Forest-officer, South Canara, took with him in September last a fruit from the Horticultural Gardens. It gave him several hundred seeds, nearly all of which germinated some after 12 days' sowing, then a few at a time continuously for four months, and one only a few weeks back. The seedlings look hardy, and though they were not always properly attended to, 200 were in a flourishing condition at the close of the year. Some of them measured one foot high.

Lancewood (Orandra virgata).—Twenty-five plants were sent from the Agri-Horticultural Gardens, Madras, to Nilambúr in February last, but they were not planted out during the year. Those similarly sent to Wynaad in pots are reported to be thriving.

Mahogany.—In South Arcot the seedlings raised from seed in 1885-86 and transplanted are doing fairly

well. In Madura there are 70 plants thriving well, besides 185 plants at the Navinipatti garden which also grow very luxuriantly and average 3 feet in height. They are impatient of much shade. In Tinnevely about 1,555 plants have been put out in 6½ acres and are doing well on the whole. Some casualties have, of course, occurred.

In Chingleput 3 lb. of seed were sown during the year, but only a few germinated. The young plants were transplanted into baskets. They were growing well at the close of the year. In Trichinopoly 50 healthy plants were raised during the year from 2 lb of seed and transplanted in pots. They average from 9½ to 12 inches in height. The Padugai (river bank) soil is found exceedingly suitable for these plants. A species of grasshopper caused some damage by destroying the terminal shoots, but the plants since recovered and were doing well at the close of the year.

Of the 350 plants obtained from the Horticultural Gardens, Madras, in May 1886, 299 were doing well and averaged 2½ feet in height at the close of the year.

In Tanjore 25 plants survive out of 71 put out in 1881 and are in a fairly good condition. Of 168 seeds put down at Vettangudi in 1885-86, 84 germinated, of which 9 died and 75 turned out to be vigorous plants; 30 of these were given to the Executive Engineer and the rest planted. Again 1,183 seeds were put down in the Northern Range, but only 48 germinated owing to some defect in the seed.

In Malabar (Wynaad and Palghat) 43 plants were permanently planted out in 1883-84 and 55 in 1885-86. These plants (with the exception of one self-sown, which escaped the borer and is now 20 feet high and 10" in girth) have progressed poorly owing to the constant attacks of the borer.

Two pounds containing 2,400 seeds were put down, one-half at Kanot and other half at the Botanical Garden: 800 seeds germinated at Kanot, but most of the plants were destroyed: 375 germinated at the Botanical Garden, of which 278 are now alive, the rest having been destroyed by *gryllus*. These plants now average 11 inches in height and look healthy.

In Nilambur the largest mahogany tree planted in 1873 measured 70 feet in height, 56 inches at base and 44 inches at 5 feet from base, having grown 1 foot in height, 4 inches incircumference at the base, and 3 inches at 5 feet high during the year. The borer was not so prevalent as in former years and had not attacked the new planting amongst the teak. Mr. Hadfield identifies the grub with that found on the brinjal (*Solanum melongena*).

Mossalla hemp (Musa textilis).—In South Arcot six plants received last year through the Collector are doing fairly well, the largest 13 feet high and stem 20" girth. Three have offsets nearly fit to transplant. In Trichinopoly, of the 50 plants put out in 1885-86, 45 show vigorous growth and average a height of between 8 to 10 feet. In Tinnevely 44 plants show a vigorous and healthy growth out of 60 put out in 1885-86, 16 having died.

In Malabar (Wynaad) the Manilla hemp continues to flourish and throw out suckers plentifully. It has twice fruited. It may be regarded a complete success in Wynaad, the climate of which appears to be very suitable for it. Mr. Morgan considers that thousands of acres might be planted with it in Wynaad, but it is not known whether the fibre produced will be as good as in its native habitat.

Marpale (Erandia Mchafolia).—Half a pound of seed sent by the Conservator in 1885-86 was sown in nursery beds but not a single seed germinated.

Cassia Keropota.—A few seeds were received from the Director of Revenue Settlement and Agriculture at the beginning of the year, but those put down both in North Coimbatore and Tinnevely have failed to germinate.

Pentstemonia ferriana.—In Tanjore 29 seedlings were planted at Méltottam in the Vettangudi forest in 1884, of which 24 look healthy and 7 flowered for the first time during the year.

Pithecolobium saman.—In North Arcot some thousands of plants were raised from seeds gathered from the trees at Vellore. The young plants put down at Tiruvallur and Kilminnel are doing well. In Malabar

(Wynaad) the tree in the swamp has grown very much, especially in girth. Those on the ridge are in a poor and gravelly soil and are bad specimens. There are 142 of them in all.

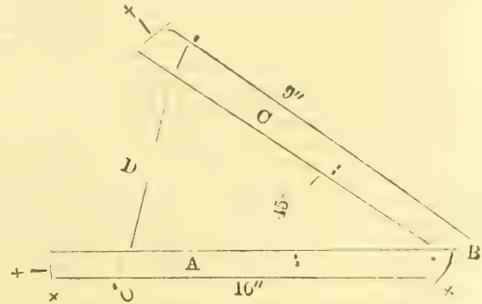

Rubber experiments.—In South Arcot Ceara rubber does not thrive although it bears fruits and yields sap in small quantities. In Malabar (Wynaad) of the three plants of *Hevea Braziliensis* received in 1885-86, from Mr. Ferguson, two are growing rather slowly, but look healthy. The third was bored out and died. The *Castilloa elastica* plant eaten down by stray cattle in the preceding year also died. In Nilambur the *Castilloa*, *Hevea Braziliensis* and *Ceara* are all doing well. Mr. Hadfield had to thin out some of the Cearas during the year. The largest eight trees that he tapped severely both trunks and roots yielded only one pound of rubber which he considers to be a small quantity considering the age of the trees (6 years). The one plant of *Landolphia Florida* was broken off at 12 feet from the ground by the branch of a tree which fell over it, but has thrown out two shoots from where it broke off and that the length of the climber from the ground to the top of the new shoot is now 14½ feet.

The nurseries in the Botanical Gardens at Manantoddy are fully stocked with a valuable and healthy assortment of plants of various kinds.

Many tons of sugar-cane were cut and supplied to the Government elephants from the sugar-cane swamp. Rats do considerable damage to the canes.

HEIGHT MEASURER.

I see Weiss's height measure figured on page 169 of the "Forester" for April, and as I have used for some years a somewhat simpler form, I enclose description of it and sketch.

A is a small bamboo tube with the upper side cut away, and attached by two small pins to another smaller one C at the joint B, so that the tube C can fold down into tube A. D is a non-elastic string knotted outside, as per sketch, and when open these tubes are at an angle of 45°. To measure a tree, peg the ring of a measuring tape in the stem at 3 or 4 feet up, and holding the tape and measurer in left hand, or with both, step slowly back holding A level, and when, looking through both tubes, the upper one is in line with place to be measured, the tape then measures the exact height to that point.—S. E. PEAL.—*India Forester*.

CEYLON TEA IN LONDON.—The news by the mail of July 20th is again cheering as regards our tea, the large quantity offered during the week (10,012 packages) having been sold at a good figure all round, while for finer lots there was eager competition. The top prices were 2s 0½d and 1s 7d for Blackstone, 1s 8d for Elbedde, 1s 7½d for Glenugie, 1s 6½d for Darrowella, 1s 6d for Gerthie, and 1s 5½d for Goatfell. Messrs. Gow, Wilson & Stanton state, however, in their Tea Report:—

Although a few fair liquoring invoices have been catalogued, a large proportion of the tea has been too highly fired. Burnt Ceylon Teas are now becoming very common—a fatal mistake, which is being made upon several Estates.

VANILLA-GROWING IN MEXICO.—Sr. C. B. Pedetro of Mexico, recently when on a visit to the United States, imparted the following items concerning vanilla-cultivation in Mexico to the *Republican* newspaper of St. Louis:—"Vanilla flourishes in two places in Mexico, Papantia, in the State of Vera Cruz, and Misantia; but the first place is the most important. This town, of about 10,000 inhabitants, is in the land of the Toconaco Indians, who are as indolent and improvident as any people on earth. Vanilla is found wild in the forests around Papantia clinging to the trees and bushes for support. When the beans ripen in November or December the natives go out into the forests to gather them. All kinds are put into old sacks together and brought into Papantia to market. Here there are a number of buyers, Spaniards or Americans, and the competition reminds one of what is to be seen in a street where second-hand stores prevail. The old women are generally in the lead, half naked, and with haggard faces begrimed with dirt. Then come the children, equally pitiable in appearance, and finally the old men bring up the rear, their long stiff hair, matted and dirty sometimes, standing out twelve inches, while their beards, filthy and long, lend a finish to the picture that is most revolting. The beans are purchased by middlemen at the rate of 42s. or 50s. per 1,000, taken as they are put up by the natives. One thousand good-sized green vanilla beans will weigh 60 lbs.; the same, when cured, about 10 lb. The first fine morning planks are arranged and covered with quilts on which the beans are laid after being divested of their stems. The sweating process, as it is called, then takes place, and has to be repeated seven times before all the water has evaporated. Then the beans are heated slightly and placed on shelves to dry and air. After this they are assorted in lots of fifty beans, graded according to length. In fine weather the curing process takes three weeks, but such weather rarely prevails, and the curing sometimes takes from four to five months. Last year the beans sold for 58s. per 100, which was about a pound, but owing to a heavy crop this year and the growing competition in the business, the best beans only bring 50s. a pound or 100, and the inferior from 30s. to 42s. The principal markets for vanilla beans are New York, St. Louis, and Chicago. They are bought chiefly by wholesale druggists and fine confectioners, and are becoming an important article of Mexican commerce. Last year, from the vicinity of Papantia alone, 50,000,000 beans were exported."—*Chemist and Druggist*.

ENGLISH TOBACCO.—In the synopsis of the judges upon the manufactured British grown Tobacco, confirming the award of the first prize to us, it is stated that the report about to be furnished by the experts through the agency of the London Chamber of Commerce "will not be favourable to the growth of Tobacco in England, inasmuch as, amongst other objections, there was an excess of moisture in all the samples exhibited, and not a single lot was in really merchantable condition." It is not our desire to champion the subject, but as we have made exhaustive experiments during the past two seasons, at a cost of several hundred pounds, all we ask is that the British-grown Tobacco may have fair consideration; and we venture to say that a mistake has been made, either by the London Chamber of Commerce or by those responsible for fixing the date of the trials, from the fact that it is impossible for Tobacco grown during the summer of 1887, either in the British Isles or in those countries from which our principal supplies are obtained, to be in a merchantable condition in the month of May, 1888. Tobacco grown in the United States has to pass through what is known as the "May sweat," and to bring the British Tobacco into marketable condition it was equally necessary that it should have passed through a similar process, and thus brought into a condition to be fairly compared with Tobacco from other countries. We, therefore, maintain that the competition should have taken place, say, about the month of September next, by which time, as we understand, the first importations of the American

Tobacco crop of 1887 might be expected to reach the manufacturer in England. It is clear from this point of view that the experts have not only committed an error of judgment in submitting the English-grown Tobacco to a final test at the present time, but they have also, upon an unsound basis, compiled a discouraging report, which we think must have the effect of limiting future experiments.—*JAMES CARTER & Co., Gardeners' Chronicle*.

ESSENTIAL OIL IN TEA.—Dr. Hasal, the well-known food analyst, writes as follows regarding the essential oil in tea:—"The volatile oil is not present in fresh tea but is developed in the course of drying and roasting. It is of a lemon colour, readily solidifies, and becomes resinous on exposure to the air. It is to it that the aroma is mainly due. The amount present in tea is stated to be about 1 per cent., a statement we consider to be open to much doubt. For the estimation of the volatile oil, a considerable quantity of tea must be operated upon. This must be distilled with water and the distillate received into a cool receiver. The oil should be found floating upon the water. We may state, however, that, in certain attempts we have made, we have failed to obtain any weighable amount of the oil. The distillate had the odour of tea, but no oil drops were visible." According to Mulder's frequently quoted analysis, green tea contains 79 per cent., and black tea 60 per cent. of essential oil.—*Indian Tea Gazette*.

BLENDED TEA.—Mr. A. Brooke, of the firm of Brooke, Bond & Co., tea merchants of London, was lately in America on a visit of pleasure and information. His firm leads in the selling of blended teas wholesale in the English market. Mr. Brooke has communicated some pertinent facts regarding the trade in blended tea. He says:—"The blend-of-tea idea is of somewhat new growth in England. A variety of causes have contributed to make the system popular. The change in the English taste from the weak growth of China to the more robust product of India, necessitated some system whereby uniformity in strength and flavor became a necessity. China teas are imported in large chops embracing some 400 or 500 half-chests, all of one kind, whereas the India gardens produce smaller parcels of tea at a time, and these vary greatly in character with the changing seasons of the year. "Again, the grocer's business embraces a variety of articles, and how natural it is that he is not able to give that care, attention and time to the blending of tea that its importance demands. What the grocer needs is a uniform standard, reliable blend graded in qualities from fair to fine, even in the leaf, free from dust and stalk, and ready for retailing without trouble on his part. Enterprising grocers in England have taken readily to the idea, and with success and satisfaction. The general tendency all over the United Kingdom is to buy blended teas."—*Indian Tea Gazette*.

LEAF-FUNGUS IN CEYLON.—In Part VII. of his paper on "Timber, and some of its Diseases," in *Nature* of July 19th, Mr. H. Marshall Ward says:—

It should be mentioned here, by the way, that all leaves of all trees are apt to have fungi on them in a wet summer, but many of these are only spreading their mycelia in all directions over the epidermis, in preparation, as it were, for the fall of the leaf: they are saprophytes which feed on the dead fallen leaves but cannot enter into them while yet alive. In some cases, however, this preparation for the fall is strikingly suggestive of adaptation towards becoming parasites. I will quote one instance only in illustration of this. On the leaves of certain trees in Ceylon, there was always to be found in the rainy season the much-branched mycelium of a minute *Sphaeria*: this formed enormous numbers of branches, which on the older leaves were found to stop short over the stomata, and to form eventually a four-celled spore-like body just blocking up each stoma on which it rested. So long as the leaf remained living on the tree, nothing further occurred; but wherever a part of the leaf died, or when the leaf fell moribund on the ground, these spore-like bodies at once began to send hyphae into the dying tissue, and thus obtained an early place in the struggle for existence among the saprophytes which finished the destruction of the cells and tissues of the leaf.

THE MERCHANDIZE MARKS ACT
AND CEYLON TEA

We shall await with much interest and some degree of anxiety the result of the prosecutions under the above Act authorized by the Planters' Association to be undertaken by Mr. Leake. Our anxiety is certainly justified by the uncertain character of the evidence necessary to be tendered to ensure conviction in the case of selling spurious Ceylon tea. Of course, in the instance in which the name of a Ceylon estate has been placed upon the packets sold, which has no existence, that fact alone would justify a verdict favourable to the prosecution. Also, perhaps, in the further instance of a name being assumed, which is a colourable imitation of that of a well-known and famous growth of tea, a conviction might be relied upon. But, when the prosecution is forced to depend entirely upon the evidence of experts, there seems reason to fear that it may be difficult to induce a jury to arrive at such decisive conviction as to induce it to award punishment to the parties prosecuted.

If we may rely upon Mr. Gray's opinion,—and naturally we are most disposed to give it the full weight due to it,—Mr. Leake has only to accuse the parties selling spurious teas, and the onus of defence rests with the latter; that is to say that, unless the sellers can prove that it is Ceylon tea, they become liable to the penalties of the Merchandize Marks Act. Now, this sounds very comforting, no doubt; but what would be the course of the defendants in such a case? They might prove that they *did* buy Ceylon tea in certain quantities in certain markets, and might urge thereupon that the samples complained of were part of such purchases. Against this evidence experts would have to be sworn, that either the tea was not of Ceylon growth in any degree, or else that it was mixed with inferior Indian or China teas. Then it would have to be proved further to ensure conviction that it was the seller who made the admixture, and that it was not the tea as originally purchased by him. Now we all know how liable experts are to disagree, and how easy it will be to dispute the possibility of the possession of a taste fine enough to discriminate, we will say, between pure Ceylon tea and a possible slight admixture of Indian. We believe ourselves that there are palates so trained and of such original delicacy of taste that it is possible for those possessed of them to judge with absolute certainty in such a matter. It will be a different thing, however, to persuade the average British jurymen of the possibility that we can ourselves easily recognize. There is scarcely a limitation to be put upon the sensitiveness of taste which may arise from long practice. We have had a story narrated to us by a personal friend of the parties referred to in it which would almost pass belief were it not vouched for as it was vouched for to our informant. A gentleman had invited Mr. Brooks, the representative of the celebrated firm of wine merchants of London, Messrs. Justerini & Brooks, to dine with him. A connoisseur in wines himself, the host was naturally most anxious that his finest wines should be submitted to the judgment of his guests. He told his butler to serve some of the noted '47 port he possessed, and asked Mr. Brooks on his tasting it what he pronounced it to be. That gentleman replied: "Well, certainly '47 port, and yet I am almost sure I detect in it a flavour of '46 vin-

tage." The butler heard the remark and was overcome by surprize. He said it was the fact that a glass of '46 remaining in the decanter he had used, he thought he would try Mr. Brooks' judgment, and had allowed it to be mixed with the fresh wine.

In the face of such evidence as this story affords who can place a limitation on the power of experts to decide whether teas are of single or of mixed growths? But, as we have above remarked, will a British jury be as readily convinced? If they do not recognize the possession of so marvellous a faculty, it is much to be feared that they will scarcely convict on the evidence of experts, and much advantage that we hope to see, as the result of the action now commencing on behalf of Ceylon teas may possibly be lost if conviction can only be obtained when there is deliberate falsification of a label or trade mark. Neither will it do to shut our eyes to the fact, that, if the prosecution lose its case, it will have to bear not only its own costs, but also those of the parties prosecuted. They may also possibly be themselves sued for damages for giving publicity to reports adverse to the business of their opponents, and we can see, therefore, how necessary it will be for Mr. Leake to move with caution in any case of adulteration, proof of which must rest solely upon the evidence of experts in tea tasting. Such cases must differ widely from the ordinary run of prosecutions under the Adulteration of Foods Act. It is easy enough to demonstrate the presence of so much of sand in sugar or of wood-dust in ground pepper. But no analytical chemist could prove a reliable distinction between Indian and China or Ceylon tea. It is wholly a matter of flavour, and we know how various is the flavour even among genuine Ceylon teas. We have had our attention drawn to this matter by a correspondent who thinks we should urge, that in cases apart from apparent fraudulent marking great caution should be exercised before rushing in for their prosecution. It would be highly desirable, in his opinion, to institute one test case to be thoroughly thrashed out before liabilities may be incurred for which neither our Planters' Association nor the Ceylon Association in London are prepared.

EUCALYPTUS GLOBULUS AND ARUNDO
DONAX.

The following letter has appeared in the *Australasian* :—

Sir,—I wish to make known through your columns the results of experiments I have been making during the last few years with the abovenamed, the first of which is highly valued for its salutary properties, but is dreaded in small areas on account of its rapidly attaining the dimensions of a large tree, and so starving everything near it. I find, however, that it thrives well under the pruning-knife, and, so treated does not prevent the vigorous growth of a hawthorn hedge, &c., close to it. I have allowed the row, now some seven years old, to attain a height of 15ft.; but it might just as well have been kept down to the height of an ordinary hedge. This experiment may have been tried by others, but I have neither heard nor read of it.

For about the same time I have grown (only more extensively) the *Arundo donax*. It is highly ornamental, and very serviceable in a variety of ways, for training vines, light fencing, &c. The plants require no attention when once fairly established, and goes on spreading in a remarkable manner. I measured a cane yesterday and found it 17ft. long. The ripened canes can be cut about August in each year. In a few weeks their places are supplied by vigorous young plants; and if you wish to utilise the old canes for

closehedge purposes you have only to shorten them to about 5ft. from the ground, and they will send out in the spring numerous shoots, graceful in appearance and forming a thick hedge. The giant bamboo is of the same family, and, if it can be grown successfully in Victoria, would be much more valuable than the *Arundo donax*.

In thus writing, I have chiefly in view Mildura and other places to be similarly irrigated. Thanking you in anticipation for inserting the above, I am, &c.,
MARS MILLER.

Miller-street, North Fitzroy, April 23rd.

We may say that, in our own experience, the blue-gum is not by any means so inimical to vegetation in its neighbourhood as other species of eucalyptus. What we take to be *E. amygdalina* is very destructive, while we have blue-gums and seed-bearing tea bushes flourishing side by side. What the writer states about *E. globulus* bearing the pruning knife well reminds us of what the late Director Thwaites advised, and which we and some others carried out to a limited extent. It was to cut off the tops of the blue-gum trees and so render permanent the large dense primary foliage, which is so striking a contrast to the small secondary leaves of this species. The idea was to keep the trees valuable as shelter belts, but the tree when cut down sends up such a multitude of shoots that we can quite believe in its making a good hedge.

The *Arundo donax*, referred to, is the largest of European grasses, popularly known as a reed, and growing to a height of 6 to 12 feet. The hollow, woody stems are an article of commerce, and are used by musical instrument-makers. They are also made into walking-sticks and fishing-rods. We believe this is the reed so commonly grown in Italy to form trellis supports for vines? We think, too, this must be the reed which the late Mr. Corbet introduced, and which some dozen years ago we saw flourishing on several estates. This and other reeds could be cultivated on the banks of streams or swamps, and ought to be valuable for thatch for lines, for mats, tea baskets, &c. We can understand the reed *Arundo donax* making a good fence, but the idea of the gigantic bamboo being a good substitute for it is incongruous. This bamboo is far too valuable as an ornamental and useful plant, to be used for hedges. We have some grand clumps growing at 4,700 to 5,200 feet, stems of which have been utilized as rain and irrigation spouts. A joint, nicely prepared and polished, and on which a lady has painted the arum known as "the lily of the Nile," and the bright scarlet-orange tuft called "the red-hot poker," is much prized and greatly admired. The small China bamboo, of which all the hedges in the Straits are formed, grows well at the altitude of 4,800 feet. But all the bamboos are injurious to adjacent cultivation. So are the aloes.

CHINA TEA.

In a United States Consular Report from Amoy Mr. Wm. S. Crowell writes:—During the closing months of the past tea season the export duty alone was fully 30 per cent. of the market price of Amoy oolongs. This is a short-sighted policy, which will, if persisted in, with other causes bring lasting injury and sure but lingering decay upon the tea trade of China.

Similarly Mr. Wingate writes from Foochow:—The whole tea trade of Foochow is in a most unsatisfactory condition. Merchants see no prospect for the revival of the trade unless measures are taken to put China upon an equality with Indian teas by a reduction in the heavy internal taxation

and export duty, improved methods of preparation and better facilities for internal transportation, But no one here expects the Chinese Government to give up its exactions, or that the other desirable changes will be soon adopted.—*L. & C. Express*, July 20th.

NOTES ON PRODUCE AND FINANCE.

(From the *H. & C. Mail*, July 20th.)

It is now stale news to Indian and Ceylon planters to learn that the tea trade of China is declining rapidly and that Indian and Ceylon are rapidly driving China out of the tea market. The Chinese have at length awakened to the fact that they must do something, but the precise nature of the move has yet to be determined. The adoption of a better system of cultivation and preparation is an obvious remedy, but the Chinese are slow to move. It is remarkable that while the business with England is decreasing so much there is a large and rapidly developing Russian trade, which seems not only able to stand the Chinese duty, but the Russian import duty of 1s 8d per lb. added. While the direct steamers from Hankow for London carried 22,732,221 lb. during the season 1887-8 against 40,528,806 lb. the season before, the direct steamers to Odessa carried 11,146,486 lb. against 9,435,360 lb.

On the Continent gloomy accounts are received as to the prospects of the China tea trade, and sanguine anticipations are formed as to Indian and Ceylon tea. It is supposed that the next season 100,000,000 lb. of tea will be exported to London from India, and 12,000,000 lb. to 15,000,000 lb. from Ceylon.* On the other hand, fine Chinese tea will be very scarce this year, and it is not at all probable that an average quantity of the third and fourth crops will be exported since such low prices are ruling at present in London. China seems to be gradually losing its hold on the European markets.

Devonport writes:—"Considering the enormously increased consumption of Indian teas—due in great measure to the free use of those teas in blending, and not to the self-drinking descriptions,—I think the time has arrived for all Ceylon, Assam, and other plain chested teas to be dated as China teas are (1887-88, &c.), so that the new season's crop may go forth as such, and the old take its place in the rear rank. Much time and labour in sampling would be saved by such an arrangement, besides some disappointment in sometimes getting a 'non-keeping' tea which may be traceable to the fact of its being a year old when bought, so that although liquoring well when purchased, its age tells rapidly upon it. Anyone buying up the clearing lots of old China must have occasionally noticed this peculiarity, but, having bought it with one's eyes open, no notice is taken of it. At present, however, we get old Assams and Ceylons mixed up with the new, and, being undated, 'pigs in pokes' are sometimes bought."

A controversy not very edifying is going on in the *British Medical Journal* about the effect of tea on the teeth. The medical journals must occasionally debate what they call a popular question, and if they can introduce an attack on tea, coffee, or sugar, it serves their purpose for the time being. As the disputants do not appear to have diagnosed dental disease in association with tea drinking, their opinions are not very valuable. The person afflicted with decayed teeth may be a tea drinker, while the dental trouble may arise from other causes. One correspondent has been struck with the apparent connection between tea and teeth decay among factory operatives, but as Dr. Henry Sewill points out, many other things may be found in the regimen of the people to explain the dental phenomena. As a rule they earn good wages and eat a good deal of badly-cooked food, while working in badly ventilated rooms, and they often console themselves with "too much beer and coarse spirit. The conditions under which

* Ceylon is under-estimated by 6 or 7 millions.—
Ed

they live, leaving tea out of the question, tend to produce chronic dyspepsia, and this fact being added to the neglect of the tooth brush, sufficiently explains decay, for the teeth remain from childhood covered with tartar, *débris* of food, epithelium, and secretions—a decomposing mass constantly giving rise to the formation of acid capable of dissolving the enamel. While, as Dr. Norman Kerr points out, a defective staple tea diet is promotive of gastric troubles, it seems to be certain, as declared by Dr. Sewill, that "tea can have no direct effect upon either the teeth or the tissues of the mouth leading to dental disease." The former of these gentlemen directs the attention of other correspondents to the fact that in certain American cities where tea is consumed in much small quantities than in this country, the teeth decay more rapidly than with us. He adds, "The climate, the many indigestible articles of diet, the extreme nervousness of the Americans, and other causes affecting the nerve and general health of that great people tend to induce a dyspeptic condition which always seemed to me to be largely responsible for their premature dental decay."

Last week a tea clearing-house was opened in the city. The new institution is at 21, Mining Lane, and there is a separate office in it for each warehouse proprietor. At present it frequently happens that wholesale dealers are not aware of goods having been stopped until they are informed by the consignees, and a journey of perhaps three miles is then often necessary in order to ascertain the cause of the delay, while a second journey must be made to rectify any error or omission. All this trouble and loss of time will now be overcome, because enquiries may be made at the clearing-house, and any mistake immediately put right. Each dock, wharf, and warehouse will be represented by a responsible clerk, who will make the transaction of business as simple and straightforward as it is at the warehouse; and we believe that, for the further convenience of the wholesale dealers, it is proposed to establish, in the course of time, telephonic communication between the Clearing-House and some of the outlying warehouses, if not all of them. The object of the Clearing-House are—to give facilities to the wholesale trade in tea for the lodgement and transmission of warrants, delivery orders, carding, cording, and other orders to the various docks and warehouses from a central office to provide a central Clearing House or office where all such warrants and orders may be lodged, instead of at the various docks and warehouses and further to provide facilities for the return of warrants and other documents to the trade, and generally to avoid the necessity of the personal attendance of the trade clerks and at the offices of the various docks, warehouses, wharves, &c.; to insure frequent and rapid transaction of documents thus lodged or returned and to provide and afford facilities for answering inquiries and giving information relative to storage, working, or delivery of tea. The annual subscription is one guinea, and no subscriber is entitled to warehouse or deposit tea with, or employ in connection with tea, any dock company or tea warehousekeeper who is not a member of the Clearing-House or to purchase or sample any tea from the warehouse of any non-member.

A TEA GROWERS' COMPANY FOR OPENING AND PROMOTING NEW MARKETS.

Planters will read with the care which the importance of the subject demands Mr. Rutherford's letter. He shows that what is beyond the true functions of the Planters' Association could be done by an associated body of tea planters,—the men specially interested in opening new markets and cultivating and expanding old. We cannot doubt therefore that the scheme which Mr. Rutherford recommends will receive general support. The production of tea in India and Ceylon is increasing at such a rate, that prices have already been affected to a serious extent, and unless consumers

are increased in proportion to production, the limit of profitable cultivation may be soon passed. All possible efforts, therefore, must be made to increase the demand for the product on which the fortunes of the Ceylon planters now depend.

THE PROGRESS OF THE CEYLON TEA ENTERPRISE.

With this issue of the *Tropical Agriculturist* we circulate Messrs. Gow, Wilson & Stanton's illustrated circular, embodying their annual review of the rapidly rising tea enterprise of Ceylon. The document is one which will interest all who are connected with the enterprise, and it deserves to be preserved for purposes of frequent reference. Amongst the illustrations are three green circular balls by means of which the volumes of our tea exported in 1880, 1885, and 1887 are contrasted. While 1880 shows a small pea, 1887 has opposite it a ball a couple of inches in diameter. The amounts in figures which are thus represented are as follows, and they show that from the peculiar circumstances of the case Ceylon took rank amongst the important tea-growing countries of the world with a rapidity utterly unprecedented and not likely to be repeated in the world's history. Taking 1880 as the starting point of appreciable export of tea from our island, the progress in the succeeding seven years has been at the marvellous rate indicated by the following figures:—

	lb.	Average price.
1880	114,845	10½
1881	311,145	11¼
1882	621,068	10½
1883	1,599,687	13½
1884	2,285,294	12¾
1885	4,352,294	13½
1886	7,790,497	17¼
1887	14,082,337	1/1

The figures for 1888 will show the same process of increase by leaps and bounds, and our very success, actual and prospective as growers is the source of anxiety as well as gratulation. The former feeling is founded on the figures for selling prices in the London market. We began the series of years with an average of 10d per lb. and it looks as if in 1888 we should sink to nearly that level. The lessons are that we should practice as much as possible economy in growth and manufacture and energetically support every movement for the opening up of new markets and the expansion of established sources of demand. The mere existence in the United States of so many millions of persons who owe their birth to the British Isles, and whose taste was formed not on Japans or Oolongs but on the class of teas we produce, ought to secure for Ceylon tea a large transatlantic demand, even if the native Americans remain prejudiced in favour of high-fired teas. The question of manufacturing teas of the kinds which find favour with our American cousins is one requiring very full consideration. The first attempt here in this direction was not encouraging. The figures for average prices show that Ceylon teas attained their maxima in the years 1883-85. The progress was upwards for three years; prices remained at a high level for a further three years, and now it looks as if we should have a descending scale for three years. We suppose we must be prepared to face an average of 10d per lb. Anything materially lower would probably shut up many factories in India and Ceylon. Our hopes centre in the tendency amongst large portions of the human race to increase their consumption of the fragrant and cheering leaf or to take to it. Our highest annual average price, it will be observed, was 1/3½, attained in 1883 and again

in 1885. But Messrs. Gow, Wilson & Stanton's diagram, which takes account of "quarters" of years, shows, that, while a descent to 9d was made in the first quarter of 1881, the culminating period for Ceylon teas was reached in the three closing months of 1883 when the figures $1\frac{1}{2}$ were reached. Shall we ever again see such a quarter's average, or $1\frac{1}{3}$ for a year? If the analogy of coffee is observed this is quite possible. Low prices stimulate consumption, and after a time demand outruns supply. If only the 250 millions of India would consume even 1 lb. per caput, the beneficial effect would be great. There is the important fact in the history of our enterprise noted by Messrs. Gow, Wilson & Stanton, that "the consumption of Ceylon tea in Great Britain increased one hundred fold between 1880 and 1887." Such a record is and probably will remain unique. We should like to see deliveries increased in proportion to imports of our teas into Britain, but it is encouraging to find that while in the twelve months of 1886 the total deliveries of Ceylon tea were 9,911,610 lb., the deliveries for six months only in 1888 reached 7,313,302 lb. For the whole year we have no doubt the figures will be considerably more than doubled. In the United States tea, like coffee, is free of duty, and the taste for tea is increasing, seeing that the imports in 1887 exceeded by more than 10 millions of pounds those of 1886. The figures for the latter year are given at 86,864,000 lb. In Canada also tea is duty-free except when imported from the United States, and the imports into that British colony are given at 18,533,000 lb. Here is an aggregate of 105 millions of pounds, and population and wealth in both countries are rapidly increasing. Special and strenuous efforts should be made to obtain a footing for Ceylon tea in such markets as these. Next in importance, perhaps, are the Australian colonies, and in Victoria consumption is certain to be increased by the reduction since the circular was framed of the duty to 1d per lb. The information given as to the total consumption of tea in various countries, the rate per caput and the import duties levied is exceedingly interesting and useful. Russia, it will be observed, comes next after Britain and the United States, with an import of close on 75 millions of pounds in 1887, although the duty ranges from 2d per lb. to 1s 10d. After all, however, the rate per caput in Russia is only 0.61 lb., against such figures as 7.66 in Australia, 4.70 in Great Britain, and 3.69 in Canada. The miserable figures opposite many countries show what scope there is for increase in their own comfort and in the sales of their product by the growers of tea. The population of France consumes only 0.03 per caput and that of Spain 0.01. Even Germany shows only 0.07, and Holland with a tea-growing colony is only up to 1.16. There is room in many directions for largely increased consumption of the article which is now the staple product of Ceylon.

MR. ELWOOD MAY'S PROPOSALS AND THE FUNCTIONS OF THE CEYLON PLANTERS ASSOCIATION.

With reference to Mr. Pineo's letter (page 143), we would remark that no direct attack has been made on Mr. Elwood May's personal character or business standing. But, naturally enough, surprise has been expressed that he should decline the reasonable proposal made by the Tea Fund Committee, that simultaneously with the presentation to him of the 6,000 of tea for gratuitous distribution he should invest in

twice that quantity on his own account. His refusal to risk so small a sum as the cost of 12,000 lb. of tea could not but produce an unfavourable impression, and that impression has certainly not been modified by his demanding of the Ceylon Planters' Association what they have not the power to grant and what, even if they had the power, they ought not to grant. He demands as a condition to his giving Ceylon tea the benefit of his "booming" advertisements and pushing facilities, that he should be appointed the accredited Agent of the Planters' Association, receiving supplies of tea and selling them under the eclat of that position. Now our readers will see at once that such a concession would be unjust to Mr. MacCombie Murray and others who have already been working in America on behalf of Ceylon tea, and would be calculated to deter others from entering the field. But, further, as Mr. Rutherford has pointed out, the Ceylon Planters' Association is not a trading Company, and could not possibly engage to supply Mr. Elwood May with tea of a particular brand in perpetuity or for any appreciable period. The invidious task would fall to the Committee of choosing the teas to be purchased and sent, and the disastrous result to the institution may be imagined. Within the year in which such an arrangement was concluded, the body which has done so much for the planting and general interests of Ceylon would be broken up into "fortuitous atoms," amidst jealousy and strife. Although the Planters' Association is not a trading body, and never can assume the character which Mr. Elwood May seeks to give it, in connection with himself as accredited and he evidently means *sole agent*,—yet it was quite in accordance with its legitimate functions of watching over and promoting the interests of the planting community, to appoint, as a temporary measure, a Tea Committee to further by all possible and proper means, whether by sale of packets, or tea in the cup at Exhibitions, or by gratuitous distribution, a demand for our staple product. That demand once created and new markets opened, it would be the duty as it would be the desire of the Tea Committee to retire and leave the field open to competing private enterprise. Consent to Mr. Elwood May's proposal would involve either the permanent existence of the Tea Committee of the Planters' Association to supply teas of a special brand for sale by a monopolist in America, or the Association itself would have to change its entire constitution and character and become instead of an impartial deliberative assembly, an interested dealer in tea, in partnership with a transatlantic firm! To be plain with Mr. Pineo we must tell him frankly that the impression made on our mind by Mr. Elwood May's proposals and proceedings is, that the promotion of the sale of Ceylon teas in America is with him a very secondary object to the promotion of the interests and the fame of Mr. Elwood May. Had his proposals been accepted and had the result been large sales by him of Ceylon tea in America, so much the better would it be for his interests. But in any case his importance would be enhanced by the fact, of which he would make the most in his circulars and advertisements, that he had been chosen as THE SPECIAL AND ACCREDITED AGENT OF THE PLANTERS' ASSOCIATION OF CEYLON. Individual planters and District Associations, only anxious to see every possible means used to promote the increased consumption of the product on which the fortunes of Ceylon planters depend, and which is reaching the markets in such large volume, have expressed themselves in favour of compliance with Mr. Elwood May's demands *en bloc*. But they will see, on full consideration, that his demand for an appointment

as accredited and sole agent of the Planters' Association for the sale of Ceylon teas, is one which the Association neither can nor ought to grant. Let individual planters and District Associations, if the latter are empowered, send tea to Mr. Elwood May for gratuitous distribution, or for sale, if they like. It may be competent, too, for any member of the Association to propose and carry a resolution that 6,000 lb. or any other quantity of tea be presented to Mr. Elwood May without any condition of his purchasing tea on his own account. But to accredit Mr. Elwood May as the special, sole and permanent agent of the Association for the sale of Ceylon teas, provided and guaranteed by the Association,—all this the Association has no right to do. To use a favourite phrase in legal discussions, such a proceeding would be *ultra vires*, and any dissentient member could, we believe, successfully demand the intervention of the law to set such a resolution aside. The connection of our good friend Mr. Pineo with the "booming" American makes us sorry to be compelled to write as we have done. In the old Ceylon planter full confidence is felt as well as kindly feeling entertained for him, and if Mr. Elwood May declines to take up the cause of Ceylon tea except on his own imperious terms, which are inadmissible, then we trust Mr. Pineo may start "on his own hook" and be very largely patronized by the planters, receiving help in beginning from the T. a Fund Committee. The formation of a Producers' Company, such as Mr. Rutherford has suggested, would relieve the Planters' Association from the embarrassment of dealing with such cases as that which we have been considering. It would be quite competent for such a Company to accredit Mr. Elwood May as their sole agent in the United States, if they deemed such a course judicious and calculated to subserve their interests. But the institution which represents the interests of the whole planting body in Ceylon is precluded by its constitution from considering Mr. May's demands, even if they were not in themselves extravagant and inadmissible.

Let Mr. Elwood May have the 6,000 or more of tea to give away, by all means, if such is the desire of the majority of planters, but further supplies he will have to procure and pay for through Mr. Pineo or some other agent, but not through and as the accredited agent of the Ceylon Planters' Association, which is not a trading Company, but a deliberative body, as we trust it will remain, even if Ceylon tea loses the patronage of Mr. Elwood May.

THE CYCLONE PULVERIZER, the remarkable machine which with nothing but currents of air, set violently in motion in opposite directions, generates a force that grinds into particles the most unyielding articles, by impact, one with another, and not by contact with any foreign element, is opening up unlooked-for possibilities in old, as well as in new, industries. Thus, iron slag, which has hitherto been a useless incumbrance, by the cyclone is reduced to a powder sufficiently soft and smooth to make it the basis of paint. In the grinding of bone, in what is known as its green condition, the pulverizer reduces it at the period when it contains all the ammonia heretofore escaping in the atmosphere by the drying process, and reduces (at the rate of two tons an hour) to a fineness so fine as to serve that, as a fertilizer it easily dissolves and almost immediately becomes operative. In grinding the refuse of slate quarries for making bricks, peroxides of iron for paint, clay for terra cotta, Carolina rock for fertilizer, &c., its wide adaptability is shown.—*Kuhlow's*, July 18th.

CEYLON PRODUCE IN LONDON.—The broker reports received by the mail of July 20th state that there was a good demand for the small supplies of *Coffee* offering, sales being effected at an advance of 1s on the previous week. Of Ceylon marks Mt. Vernon topped the market with 104s.

The *Cacao* market showed no improvement, but good colored Ceylons sold readily, 90s 6d and 90s being paid for Wariapolla.—The supply of *Cinchona Bark* at the week's auctions was the smallest of the year, and the Ceylon lots were of very poor quality, the highest price being 7½d for Albion renewed officinalis, and 7d for Tillicoultry and Katapoola renewed succubra.

PRICES OF AMERICAN QUININE FROM 1823 TO MAY 18TH, 1888.—In a paper which has reached us from the United States and which has been included in our Handbook, figures are given which show the wonderful revolution which the cultivation of the cinchona plants in the East, especially in Ceylon, has effected in that valuable tonic and febrifuge, sulphate of quinine. Sixty-five years ago quinine could not be obtained in the United States for less than \$16 to \$20 per ounce. The price went rapidly down until in 1831 it ranged from \$1.35 to \$1.50. During the period of the Civil War the prices rose from \$1.80 highest in 1861 to \$3.75 in 1864. It then sold at moderate prices until in 1877 it rose to \$4.50. In 1880 quinine was freed from the import duty of 20 per cent, and the price went down to 50 to 56 cents in 1888. The benefit of the lowered prices to the dwellers in the swampy and feverish parts of the United States must be very great.

A PROSPEROUS WEST INDIAN COLONY.—From the official report on Grenada, we learn that the island unlike the majority of the West Indian colonies, is decidedly prosperous. Under almost every head the statistics point to this. Still, the present prosperity is based on the fact that the one staple of the colony, cocoa, is, for the time being, paying the grower a handsome profit on his outlay. Should a heavy fall in prices arrive—and some think it not far off—there is nothing else to rely upon. Sugar has ceased to be cultivated to any appreciable extent, and spices are still but a minor product. It is of the greatest importance that every effort should be made to induce those who own the land to establish in time a cultivation of the many products which would pay well, and for which the soil of the island is admirably adapted. A movement is on foot, which has been started by his Excellency the Governor, to obtain all information which may be of value to those whose enterprise may induce them to lead the way in an endeavour to establish the prosperity of the colony on broader foundations, and to provide them with the means of placing the fruits of their industry speedily and in good condition in the most remunerative markets. Progress in every direction, the report states, has marked the last three years. It may be said that the colony is at the present time spending borrowed money; but after all, the amount expended under the Public Works Loan Ordinance is only £21,000—a sum which, with a very small addition to the public burdens, the colony could pay off with ease in three or four years' time. As it is already—and several years before the law requires that provision for repayment should commence to be made—a sum of £1,500 has been set aside and stands to the credit of the sinking fund. The satisfactory position of Grenada, it is stated, is in the main due to the fact that the land is chiefly in the hands of small proprietors. There are over 4,000 persons who own the fee simple of their holdings, who are resident in the island, and who spend the proceeds of their crops in the place.—*London Times*, July 14th.

Correspondence.

To the Editor.

"PEPPERCORN" AND THE VALUATION
OF TEAS.

Colombo, 9th Aug. 1888.

DEAR SIR,—I have had my attention drawn to "Peppercorn's" remarks (page 133) upon the local tea market. Though your correspondent has been careful not to mention the mark of the tea to which it refers, so making it difficult to reply to his remarks, I have reason to suppose the break in question was a break of Bollagalla tea which I valued. If I am wrong in my supposition no doubt "Peppercorn" will correct me; but if the Bollagalla tea was that referred to, I would call his attention to a misstatement in his article. "Peppercorn" says the break was bulked on the estate, whereas the Bollagalla teas were advised as "packed as soon as made, and therefore of course not bulked;" and the tea in the various packages varied considerably: this will account for the difference in the valuations and the remarks in my report.—Yours faithfully,

HERBERT TARRANT.

THE ELWOOD MAY SCHEME AND THE
PROPOSED TEA COMPANY FOR AMERICA.

SIR,—There is still an undercurrent of feeling among planters that the Tea Fund Committee should have supported Mr. Elwood May out and out. From the correspondence published it is now clear to all that the only thing Mr. May cares about is to be made the *accredited agent* of the Planters' Association in America, and trading under the auspices of the Association it was his hope not only that he would make a good business for himself, but that he would be the means of greatly benefiting Ceylon tea-growers.

At the first glance Mr. May's proposal seems a good one for all. He asks neither money nor tea from us, but simply or good name and offices on which he can trade.

The Planters' Association is not a trading corporation, and does not deal in produce. How can it then constitute anyone its *accredited agent* for the sale of an article in which it does not deal? What possible control could such an Association have over Mr. May's buying agent in Colombo or on the purity of the tea sold by Mr. May in America under the auspices of the Planters' Association? What fantastic tricks might not our *accredited agent* whoever he may be, play with the name of the Planters' Association of Ceylon? a name which has been jealously guarded by its members since its christening day.

Some members of the Association, no doubt, think the time has now arrived when, in this practical age, we should banish the old traditions of the body, or at any rate merely look upon them as memories of the past, and not as guides for the present and the future. That this being a commercial age (and planters hard up) we should not hesitate to sell our birthright to our American cousin, or for that matter to anyone who promises to expend money and energy in pushing Ceylon tea. Those who think thus cannot fail to see vistas of hitherto unthought of fields for the sale of our teas opening out before their astonished eyes. Some members may wish to go further and sell the *patent rights* of the Association's name to the highest bidder in every civilized country!

What wealth we would then cram into the depleted coffers of the Association? The spoil would be so great, that it would necessitate a division among its members.

The members of the Chamber of Commerce would gnash their teeth, because they had not joined in the swim, and the planters of the Association reaping a golden harvest by the disposal of their *patent rights*,—coining untold wealth from the inflated price of their produce by the *push* given to the sale of their teas, would outshine in lavish expenditure and extravagance their elder brethren of the golden era when coffee was king!

This is the dream of the enthusiast in such matters. Before such unlooked for bliss could be attained the present partnership of our Association would have to be dissolved, and a new one formed on a basis that would admit of the commercial element having unlimited scope for carrying out the full bent of its inclinations.

It is perfectly clear we cannot push Ceylon tea *commercially* by means of our Association. We can, and do, assist materially in making Ceylon tea known by the aid of exhibitions, and this is about the only legitimate means the Association can employ for advertizing our teas.

Now I think no one will dispute that the motive power in pushing Ceylon tea must come from within and not from outside the island. The motive power in all commercial transactions is self-interest, and who can be more interested in finding new fields for the sale of their teas than the producers themselves? There are many men among us who are desirous of having Ceylon tea pushed here, there, and everywhere, but their desire is nullified by their anxiety that nobody should make anything out of them in the transaction. It is clear that if nobody is to make a profit in selling Ceylon tea, then Ceylon tea will not be sold. Now, sir, I believe that the proposed Ceylon company for the sale of our teas in America is the best means presented to us of systematically and effectively introducing our teas into that country. If such a Company, as is proposed, be started with tea growers forming its vertebra, superintendents, assistants, merchants, and others interested in the Ceylon tea enterprise forming a large integral part of the company, and with Messrs. Pineo and McCombie Murray as American managers, paid by results, we will then have the machinery being worked by the motive power of self-interest. Therein will lie our strength, for you may as well expect to get work out of a locomotive without fire as to get Ceylon tea sold or pushed in America *without* this incentive. Self-interest is what was the strong point and good feature in Mr. May's proposal, and had the Association been in a position to grant Mr. May's request, the business, no doubt, would have been carried on vigorously and successfully by him.

I hope this Company will be formed, as I believe, if properly constituted and worked, it will prove to be the surest means of introducing our teas in quantity and purity to the people of America.

America and its tea dealers will never come to us and say "Give us of your teas" until we have educated them to their taste. This education will not be one of spontaneity on their part, it will not be an easy one for us to undertake, and must necessarily be of gradual development.

As a little leaven leaveneth the whole lump, and the grain of mustard seed grows into a tree, so in time will the Ceylon Tea Company of America prove the means of having weaned a nation from drinking a spurious and worthless decoction, and lad them into the enjoyment of imbibing a bever-

age which is as "ambrosial nectar" when compared with the "villainous compound" they now indulge in.

Again, let us go shoulder to shoulder as in the "Tea Fund," and give our support to a scheme for a company which, if it benefits one, will benefit all.

H. K. RUTHERFORD.

THE PINEO-MAY AMERICAN TEA AGENCY.

Haldummulla, 11th August 1888.

Sir,—Now that the Dimbula Planters' Association has passed a resolution favorable to supporting Mr. May, there should be no hesitation on the part of the Central Planters' Association in at once making that gentleman its accredited agent in America.

If, however, we are to wait until Mr. May sends certificates of character, business standing, &c. much valuable time will be lost and very little gained.

For years the press of Ceylon has been demanding the opening of new markets for Ceylon tea! Has any real footing been established outside of Great Britain? Has anyone done anything except write to the local press? Does anyone here know really what is the best course to pursue to open up a trade in Ceylon tea in the United States and Canada? Has any real progress been made toward making Ceylon tea known to the American people? Does the planting interest realize that if the United States consumed as much tea per head of its population as Great Britain, 300,000,000 lb. of tea would be required to supply its wants? Are my efforts to receive no recognition beyond covert sneers and faint damning praise? Is it conceivable that I would knowingly and willingly introduce to the notice of the Central Planters' Association any man whose character—both business and private—would not bear the closest investigation? What certificates regarding Mr. May's character will satisfy the planters of Ceylon? If he cannot produce references to leading men in Ceylon, will they be satisfied with any other?

Before concluding negotiations with Mr. May I exhausted every known and recognised channel to ascertain his business standing, probity, means etc. and in every respect my investigation satisfied me that he had the character of being a shrewd, honorable, business man, and his private character was very highly spoken of. Mr. May has his own method of transacting business, and he will not swerve from it. He is an extensive advertiser, and his circulars and reviews go into every quarter of the world. What have I to gain by introducing any man who cannot be trusted? What has the Planters' Association to lose by making Mr. May its accredited agent? Simply nothing. The authority can, at any time, be withdrawn. The tea enterprize has, on the other hand, everything to gain, and with Mr. May at the helm of affairs in America it will gain a very great deal indeed. Mr. May's energy, push, unique methods and means will place our teas before the American people in a way that will astonish and please all who are interested in our great industry.

In Mr. May's Monthly Review he states that "Our bankers are Messrs. Brown Brothers & Co., New York, Messrs. Brown, Shipley & Co., London and Liverpool, and their various branches and correspondents in all the principal cities of the world. Messrs. Brown Bros. & Co.'s connections are the strongest financial institutions in the world."

The permission to use the names of these houses is one of the best possible proofs of Mr. May's standing. It is possible that nine-tenths of the

planters never heard of the old house of Messrs. Brown, Shipley & Co., and I take this opportunity of telling them that the house is known throughout America, Europe, China and Japan as well, and, perhaps better, than those of houses whose names are more familiar to them. Many in Ceylon may possibly be unacquainted with the scope and authentically defined intelligence of the Dun's & Bradstreet's mercantile agencies. In these offices every business man in the United States is thoroughly known, his means, his character, his career, his dishonorable methods or transactions, all are on record, and there is no escaping the vigilance of these agencies, and every particular of a man's business career is there. To both of these agencies I had access, and there Mr. May's character was recorded, and nothing whatever dishonorable was said of it during all the years he had been in business in New York. In a letter dated July 5th, Mr. May writes that an important London tea-house offer him an agency for Ceylon tea, a very handsome discount, free samples and tea on time! He adds:—"You can readily see that unless you can induce the tea planters of Ceylon to make me their accredited agent and show some liberality as to samples of tea that I will be working to a decided disadvantage alongside of the agent that this London house will appoint here. At least planters gain everything by the money we risk and the work we do, as large quantities of Ceylon tea would eventually find its way here through the London market after I had made its sale successful. Upon this they would receive all the benefit. We have decided to name the tea, should we take up its sale, the May Ceylon brand, and what we want is the accredited agency from the Planters' Association and the sole agency for this brand with as many booming letters as possible for advertising purposes." Here you see that a London house has evidently seen Mr. May's name mentioned in the Ceylon papers, and immediately writes asking him to take up the agency for their house. There is no time to be lost if the planters want to secure Mr. May's invaluable aid.

The Dimbula Planters' Association, in the most spirited manner, comes forward and makes a decidedly favorable move, and it now only needs the Central Association to give its verdict one way or the other to have the matter finally disposed of.—Yours faithfully,

R. E. PINEO.

NOTES ON CINCHONA.

BY ANTON KESSLER.

(Translated for the "Tropical Agriculturist" from a reprint from the *Journal of Industry and Agriculture at Batavia* of September 1886, by J. Dent Young.)

If you hang a coffee bean or a tea seed by a thread in a glass vessel, partly filled with distilled water, so that it just touches the surface, keeping the vessel covered with a perforated sheet of glass or card, the seed will in a short time begin to germinate as if it were covered with earth; a young sprout, the future stem, stretches itself upwards vertically from the seed, whilst a well-developed taproot forces itself into the water. This continues for a certain time, until the seed shall have transferred all its contained nutriment to the young plant. After this the development of the little stem and root comes to a standstill, till after a short while the young plant dies for want of nutriment. The root finds nothing in the water that it can use for furthering the growth of the young tree or for its own development,* and the fluid was only of use to the root to protect it from desiccation during the time that the plant was being developed at the cost of the seed to which it owed its origin.

Should you desire to preserve the plant, you will have to remove it into the earth. By this means the young root finds a suitable site for exertion, and rapidly multiplies itself in numberless side rootlets, and more especially in that direction where nourishment is the most abundant.

If on its way it meets a layer of earth rich with nutritive constituents, it penetrates it in all directions with fine capillary rootlets or fibre, whilst a little further it forces its way in long threads almost without any capillary rootlets if it chances to reach a layer of poor soil offering but little suitable nutriment.

Superficially observed it would seem as if the plant sought for food with consciousness and intention, after the manner of an animal. To account for the phenomenon, however, there is not the smallest need of any such hypothesis.

Still it is evident that after the roots have sprouted from the main root, they develop themselves in that direction where they meet the most abundant supply of nutriment and the most favorable conditions whilst the tender rootlets which are sent out by the main root into soil that is unsterile or unsuited to their development must perish, so that

only the bare main root survives. Experimental demonstration of this can be obtained in an interesting manner.

Instead of transferring the seedling into an intimately and amixed mixture of soil, let it be planted in a glass vessel in which poor barren soil and rich mould are so placed as to be kept in clearly distinct portions, although in juxtaposition. After a time let the system of roots be examined by soaking them in water so as to loosen the earth, and gently rinsing it off the roots. Let the roots thus entirely freed from earth be placed in clear water, in the same position as that in which the plant grew; it will be seen that the whole system of roots will arrange itself into the shape which it assumed in the ground—and it is observable that the different portions of earth are more or less interlaced with roots in the ratio in which they are more or less suitable for the nourishment of the plant. Through the barren portions run the bare branchless roots, whilst the fertile divisions of the soil, however they may be placed, whether in horizontal layers, on the surface, along the sides of the vessel, or at the bottom of it, are interwoven with fine white capillary roots.

In this lies the means of obtaining an answer to the question.—What kind of soil or what kind of manuring compost is most suitable to the development of any particular plant to be cultivated? For this purpose let a vessel be divided by vertical partitions into several, say four, compartments. The two partitions are to be placed at right angles with each other, and to be sunk into the bottom, so that the thus formed four compartments may remain perfectly separated from each other. Let a square of from eight to ten centimeters (3 or 4 inches) be cut out of the upper edge of the two partitions at their intersection. Then fill the four divisions of the vessel with the soils to be examined, and form a small cylindrical hole in the earth by means of a wooden plug at the intersection of the partitions where the squares have been cut out.

In this hole filled with ordinary earth, place the plant to be experimented on, cutting off the taproot, so that it shall not reach the bottom of the hole. At the expiration of some months, the earth in the vessel is to be carefully washed away, so that the roots freed from all attached particles become visible. In many cases it will be apparent that the development of the roots in the four compartments has been very different; by cutting off these roots, level with the stump of the taproot, and weighing them, after they shall have been dried in the open air, their relative development in each of the kinds of soil subjected to the experiment can be ascertained. In this way I planted young seedlings of *Succubra* and *Cinchona* in bamboo baskets of about 30 centimeters [12 in. hex. nearly] in diameter and height, and which were divided by vertical tin plates soldered together, into four nearly equal sections. As above described, there remained a small hole formed by cutting squares out of the upper rim of the tin plates, where they were soldered

*The probable small quantity of ammonia and sulphuric acid held in the atmosphere is here left out of consideration.

together, in which the seedling with its shortened taproot was planted after the compartments had been filled as follows:—

a. With vegetable mould, such as is found in the primitive forest on the surface of the ground, and which for brevity I shall here call humus, as it in a great measure consists of more or less decayed vegetation.

b. With two parts of the humus mentioned under a, mixed with two parts of chocolate-colored subsoil;

c. With a mixture of one part of humus (as above) and three parts of subsoil (as above);

d. With unmix'd subsoil.

A few days ago, after the plants had grown for about 8 months, I laid bare the system of roots with the help of water, cut them off, and, after drying them, weighed separately those contained in each compartment. The relative weights in the compartments a, b, c, and d, were, in the case of *Succirubra*, 425, 170, 155, 70; *Officinalis*—not ascertainable, as the plant died during the experiment.

The roots were most fully developed in the forest soil which was the richest in humus, whilst the development diminished in a remarkable degree, as the proportion of subsoil was increased. This phenomenon might almost have been predicted from the nature of the cinchona tree, which only attains its full strength spontaneously in the virgin forests of the Andes, and which especially spreads out its system of roots horizontally and parallel to the surface of the soil, while its weak taproot extends but a little into the subsoil. The experiment places the matter beyond doubt.

I arranged for making similar experiments with regard to composts, but was not successful—for the bamboo baskets became mouldy and decayed to such an extent as to destroy some of the plants, and the rest were so ill-developed, that it was impossible to consider the results as normal. To obviate this for the future, I had some large earthen pots made, in which the before mentioned partitions were formed and baked at the same time. These partitions I rendered impermeable by means of a mixture of Swedish tar and resin, as otherwise, in consequence of osmosis through the porous earthen partitions, an interchange of fluids would have taken place between the adjoining compartments.

These pots were used in the same way as the baskets had been. I hope in a few months, by these means, to obtain results of practical use, with reference to mixtures for manuring purposes.

As the pots have about eight times the capacity of the baskets, the plants for experiments can be allowed to grow for a longer period, which will naturally increase the value of the results. If in this way, it shall be satisfactorily established, what kinds of soil and manure are most advantageous for the development of the tree, it will remain to be ascertained how far a better growth exercises its influence on the formation of the much desired alkaloids in the bark. It is by no means certain that the fertilizer which forwards the abundant growth of wood, leaf and seed will be equally successful in the production of alkaloids.

The elaboration of these alkaloids is not the life-object of the tree as is the seed-forming. Alkaloid appears in the bark, and we desire it to contain the greatest possible quantity; but of what its action in the bark cells may be, we have no certain knowledge—and under these circumstances it is dangerous to pronounce *a priori* positive judgment as to the influence which the formation of this matter in the cells may exercise.

Since the alkaloids are combinations of "organic mucus" or cambium, the presence of this elementary fluid is indispensable for their elaboration.

They further contain cellulose, lignine and the combinations derived therefrom of the same chemical nature, which constitute by far the greater part of the tree, consisting of carbon, hydrogen and oxygen called hydrates of carbon.

From this it might be adduced, that fertilizers containing organic mucus ought above all to excite the formation of alkaloids in the bark, and this assump-

tion finds support in some experiments made by the plant-physiologists Sachs, Ville and others with regard to the influence exercised by the organic mucus on the chemical constitution of plants. Sachs and Ville allowed plants of different kinds, such as beans and wheat to grow in pure air, and also in an atmosphere impregnated with carbonate of ammonia, and found in the latter case that the organic mucus of the plants was remarkably increased.

In some cases a vigorous development of the plant itself is the consequence of the use of manure which is rich in organic mucus; in other instances on the contrary the plants show little return for combinations of organic mucus or cambium, and improve more by being manured with alkalies and phosphates, and this without reference to the quantity of organic mucus elaborated in the full grown plant. Thus cereals and grass grow best in soil manured with nitre, ammoniacal salts, guano or stable manure, whilst clover in particular is best excited to robust vegetation by alkalies and phosphorus. Nevertheless, the produce of a well-grown clover field contains twice or thrice the quantity of organic mucus as does that of a corn field of the same superficial extent.

It is evident that the quantity of organic mucus in the produce does not always define the kind of fertilisers most favourable to its growth. Something similar may also be the case in respect to cinchona, and it is thus desirable that we should be enlightened by experiments carried out for that purpose.

Broughton made experiments by manuring *officinalis*, and thereby arrived at the most favourable and surprising results, since the proportion of quinine from trees to which stable manure had been applied every six months was during five years 7 per cent, whilst the unmanured trees yielded only 2·4 per cent of that alkaloid. (See Moens's *Kinakultuur*, page 173.) Still those experiments were not made with sufficient care to enable conclusive deductions to be derived from the results obtained; hence the necessity of a repetition of experiments of the kind indicated. Such experiments from the nature of the circumstances require a considerable time for their completion, as it will only be after a certain period that the required indications of the constitution of the tree (should they follow), can be expected. I here only make preliminary mention of experiments which I commenced putting into operation a few weeks ago and by which I hope to learn something more with regard to manuring.

I filled several large wooden boxes of about a quarter of a cubic meter in capacity with various kinds of earth and compost in which I planted suckers from the same tree selected as being rich in quinine. In about two years it will be shewn by the analysis of the bark obtained from them, if the manuring has had any influence on the proportion of alkaloids yielded by the bark, and if it has, what has been the nature of such influence. Every one can easily make similar experiments, and by such means data will be multiplied for the solution of this very weighty question.

Analyses of soil, as far as regards the future growth and development of the plant, unconnected with the proportion of alkaloids in the bark, give no indication that can be relied on in the choice of manure, in this respect more is to be expected from empiricism. As cinchona plantations that require manuring from their commencement are rare exceptions, nearly all planters have ample time to institute such experiments as will afford them the means of arriving at a decided opinion based on facts, of which they will stand in such pressing need, when their second or subsequent planting shall necessitate the use of fertilizers.

And not only as regards the growth of the plants and the proportion of alkaloids in the bark, but also with reference to the more or less predisposition to the attacks of the so justly dreaded canker, is it of much importance to know the effects of the manure to be employed.

As every cinchona planter knows, by the term "canker" is signified the root-disease of the cinchona

tree, which causes the bark to rot, gives a mouldy appearance to the roots, and spreads itself at a later stage upwards along the stem in vertical strips, so that the bark dries up over the whole length of each strip, even the underlying wood being affected to some depth. The disease ends inevitably in the death of the tree if it be left to itself. For the purpose of studying the disease, the plan is to cause it artificially, which is not difficult to accomplish. With this object a young cinchona tree is planted a few centimeters too deep, *i. e.*, in such a way that the stem is covered with a layer of earth to the depth of a few centimeters. After a time, shorter or longer according to the less or greater moisture of the soil, &c., the tree assumes a sickly appearance, displayed by a yellowish tint of the leaves, particularly at the top, and by a red leaf here and there amongst the foliage. If at the beginning of the symptoms the tree be examined, the roots will still be sound, but on scraping off the epidermis at the neck of the roots, it will be found that the immediately underlying tissues have acquired a beet-red colour; whilst in health they are of a light green. If the superfluous earth be removed to immediately above the roots, the tree recovers perfectly within a short time. But if left alone the disease increases rapidly, the neck of the root shews a speck of decay, which quickly spreads itself downwards amongst the roots and upwards along the stem.

So long as decay is only partial, for instance, extending to one-half or less of the circumference of the neck of the root, succour is still possible. Let the tree be entirely removed from the earth, wash the roots clean, so that the extent of the disease can be seen, and cut away relentlessly all diseased portions, to the sound layers of wood. It will be found that the ends of the roots are all still healthy, and that the original seat of the disease was the root neck. Diseased roots are best cut off entirely, if they are not much too large, and the surface of the section should be covered with grafting wax.

Severe pruning is now necessary, as the above described operation naturally disturbs the circulation of the sap, and withering is to be feared, should the tree be allowed to retain all its leaves.

Replanted, and this time to a proper depth, the tree generally remains alive, and often grows after its recovery as well as if nothing had happened. In spontaneous appearance of canker in seedlings, I have invariably found similar symptoms, the seat of the evil was always at the neck of the root, whilst the ends of the roots remained the longest uninjured. I conclude from this, that the canker is a simple decay of the bark, which begins at the upper part of the root, and communicates itself to the surrounding portion. As the circulation of the sap is impeded at the seat of decay, the cellular tissues lying vertically above and below the attacked place, will be the first to wither and decay, whilst the mycelium which is found in fine white threads spread over the diseased roots, is probably not a consequence of the disease, but only attaches itself to the decayed parts, as it does to other decaying wood in a damp under-ground position and of this decay at the neck of the roots, I have been able to discover no other cause than that of too much moisture.

This moisture may however proceed from various causes. Too deep planting is one of the principal origins, and one which by close attention can easily be removed. That the stem, which is formed to be above the ground, should decay when buried under damp earth, can surprise no one.

Even though not planted too deep, the neck of the roots may be exposed to too much moisture. The decay of organic matter develops much water, whilst besides this the decaying products themselves are very aqueous. If planting is done in soil too richly supplied with humus, or if too much decaying matter be heaped up round the tree, the consequence will be that the surface of the ground remains constantly surcharged with mois-

ture, of which again decay and canker become the results. Since under these circumstances especially, the diseased parts are speedily overgrown with fungus, of which the germs were already at hand in abundance, it often seems as if the fungus were the cause instead of the consequence of the disease. I am of opinion, however, that this is erroneous.

In an advanced stage of canker a white, tough, fleshy excrescence appears between the decayed bark and the wood, and spreads over the entire surface of the diseased parts. As this fungus is not, however, always found, and only shows itself at an advanced period of the disease, it cannot be looked on as a cause, but only as a symptom of the disease. The withering of the bark and the decay of the tender parenchyma-cells and vessels of the cambium cause an empty space between the rotten bark and the wood, which space is most suitable for the development of fungi, so that we cannot be surprized to meet with them in such a position.

That the so-named canker is nothing else than decay seems to be conclusively proved by another fact.

In the case of young grafts it happens here and there that the starting point of the disease is not the neck of the root, but occurs at the graft joint a few centimeters above the ground. This point is the most vulnerable part of the stem. The outer-edge where the conjoined surfaces of the original stem and the graft grow together protrudes like a callous rim, of which the tissue consists of the youngest formed cells, whilst there is no strong protecting epidermis to secure it from injurious external influences. So that between the grafted slip and the truncated stem of the original tree, should there be anything remaining of the latter, water can readily accumulate which may be forced into the grafted slip, by the bark produced by the growth of the tree. Those who persist in ascribing canker to a particular fungus, of which the germs abound more in one soil than in another, will find it difficult to account for its appearing on grafts situated so far above the soil.

The predisposition of the graft joint to canker indicates an analogous danger to cuttings, at least in so far as concerns those taken from woody twigs and suckers.

CINCHONA CULTIVATION IN BOLIVIA.

Dr. H. H. Rusby, of New York, whose lecture on the home of the coca leaf we reported a few weeks ago, has now also given his experiences in the cinchona districts. Like the swallow of the fable, Dr. Rusby has seen much and remembers much (or, perhaps, even slightly more). Dr. Rusby's statement, that "at the present time no bark, except an occasional bale, reaches the market from South America which is not the product of cultivated trees," is certainly far from accurate, and his description of the dreadful havoc wrought by the felling of trees in the forest to make a clearing for cinchona growing, though picturesque to the ordinary mind, savours of romancing. This is how the Doctor narrates the story:—"The clearing process is not so difficult here (in the mountains) as upon the level ground, owing to the ease with which the trees can be made to fall. It often happens that the trees in falling will carry down immense tracts of forests with them. The place where the trees are planted is very steep. On such a place I have seen a tree weighted down with water go crashing down to a point so far below us that to reach it by the road it would occupy an entire day, whereas the tree reached the bottom in a single instant, carrying with it, not only all the trees and vines in its way, but immense masses of rock and earth, an avalanche of vegetation, blocking up the stream below."

"The trees contain a very great amount of water, and are almost completely covered by parasites. Upon a single tree may be counted sometimes from fifty to one hundred different species of plants growing as parasites, so that the trunk of the tree which might be 3 feet in

diameter becomes 5 feet in diameter. The branches, which themselves are about as thick as a man's leg, become so large with the mass of vines and mosses by which they are covered that a person could very easily make his bed upon one of them, and sleep without danger of falling.

"The stripping of the bark in South America is done by contract, the price paid being from 15c. to 35c. per 100 lb. of green bark. Arriving at the drying-sheds the bark is spread upon long narrow stretchers and exposed to the sun. In a week or ten days it is dry, and is tied with strips of raw hide into bales of from 60 lb. to 65 lb. each. This is the shape in which they are transported. Sixty-five pounds is a load for a man, and two of these bales is a load for a mule. Men, however, usually carry them over the worst stage, because mules are not able to endure the journey. At the repacking centre it is closely packed to go over the summit of the mountains, the transit of which requires eight or ten days, and covers an actual distance of 225 miles, costing from 15c. to 20c. per pound Bolivian currency.

"From the other side of the Andes the bark has to travel another 300 miles to the port of shipment, and Dr. Rusby states that "the entire cost of collecting, drying, and transporting to London, under the most favourable circumstances, is estimated at about 1s per lb."

"I can say too," continued Dr. Rusby, "that from my own estimate I do not see how people can buy bark from Bolivia, bring it to this country, and get from it an amount of quinine which would not pay for the actual cost of the bark laid down in New York, leaving out of account the entire cost of manufacture. I do not see how they can get enough alkaloid from it to pay the cost of the bark itself. It has led me often to wonder whether it is not true that quinine is gradually being manufactured synthetically. I know nothing about it (which we fully believe), but otherwise I am unable to explain the cheapness of quinine at the present time. The appearance of a cinchona plantation is always handsome, owing to the peculiar satiny lustre of the leaves on many of the trees of a rich purple red. When in flower, its appearance is perfectly enchanting. At such times these groves are the resort of myriads of humming-birds. I collected eight species of these birds from a single tree in an hour's time. Besides the bark the natives use the leaves and flowers. The leaves are said to be nearly inert, but infusions of the flowers produce excellent results. They also use the buds, from which they make a gelatinous mass and apply it to fresh wounds, which heal up by first intention."—*Chemist and Druggist*, July 21st.

TEA LIKIN: CHINA SILK.

In the *Peking Gazette* of the 5th instant, a translation of which appears in this number, there is a most excellent, practical, and liberal memorial from the Nanking Viceroy, who, as a first step, has reduced the levy of taxation upon Anhui tea from F.2.08 to F.1.88 per *yin*.

The reduction, though not considerable, shows that the high authorities are becoming alarmed about the future existence of the Chinese tea export trade, now struggling against odds, and threatened by the large and annual increase of the yields of India and Ceylon. But to enable Chinese teas to compete with any chance of success, a reduction of 2 mace per *yin* will be of little use, as all the *likin* and all the export duty will have to be given up ultimately.

In India and Ceylon there are no levies of local taxes, no octroi upon wood for packages or lead for their lining, and the tea pays no export duty. There are also very considerable economies afforded by railways, river steamers, and—as a rule—freight from India to Europe is cheaper than from China. The teas of India and Ceylon also, are of more vigorous and prolific growths; the trees are carefully selected so as to be suitable for the soil of the plantations; the fields are carefully nourished by proper manure; and, in a given number of years varying in different localities and also dependent on the classification of the shrub, old plan-

tations are periodically uprooted, destroyed, and replaced by new trees.* The picking and curing, too, are conducted on sound scientific principles, and the preparation of the leaf for export is not left to the manipulation of coolies but effected entirely by mechanical means. All these new and most successful appliances, costly as they are at the outset, are regarded as investment of capital, and enable the Indian and Ceylon tea growers to cultivate their fields profitably and economically. Thus the weight of leaf per acre in these two countries vastly exceeds the yield of the best Chinese fields, and the various processes, from picking to curing, and from packing to ultimate delivery in the consuming market, the British tea grower has to bear outlays very much smaller than the burdens laid upon Chinese tea from first to last.

This year, owing to abnormal circumstances, which may not recur, the prices given by exporters at Hankow and Foochow for Chinese new teas of the first crops have been higher than were expected. But if the second and succeeding crops are thrown on the markets in average quantity and in average condition, judging by the lowered standards of recent years, the prices are scarcely likely to be profitable to the Chinese producer and middlemen who, also, are now beginning to encounter opposition in places that were formerly monopolized by China. In Russia Ceylon teas now meet with increasing favour, and even the strong and astringent leaves from Assam and the Neilgherries already begin to be agreeable to the sensitive and fastidious Russian palate. In the United States as well, which now take so much tea from Japan, the full aroma and strength of the Indian and Cingales growths are now appreciated. The displacement of China teas by young and vigorous rivals, possessing many natural, artificial, and fiscal advantages, is spreading fast.

Whether by the establishment of botanical gardens, in which experiments may be made by specially qualified botanists and experts, the consequent endeavour to ascertain the true principles of botanical selections for various soils, altitudes, conditions of climate, etc. and the intelligent employment of scientific and mechanical methods of preparation for shipment, the teas of China can be enabled if not to regain their former superiority, or, at any rate, to maintain some sort of equality, is uncertain, and, under present conditions before us, we fear unlikely. No doubt if the Imperial Government, and the provincial Governments concerned went to the expense of founding model plantations, and for the sake of a valuable and important industry favoured the improved methods in vogue in India, some good might be done, and as the experiment will not cost much the outlays would not be wasted. But the stolidity of the Chinese growers the opposition of the coolies and tea firing hong, and the hostility of the middlemen who would see with reluctance the employment of foreigners which would, at first certainly, become necessary are obstacle hard to overcome.

That the attention of high Chinese officials is being given to the matter, a matter in which foreign residents in China are deeply concerned, is satisfactory as far as it goes, and we may hope, as an early result therefrom, there will be some measure of amelioration in conditions, however partial and small.

We trust the Nanking Viceroy will now give his attention to the silk industry, a matter of great importance in his vast government. In the United States, where a large manufacture of silk stuffs has very quickly grown up, and promises ere many years to rival the famous fabrications of Lyons and Italy, Japan silk has almost entirely excluded Chinese silk from the American looms. This need not have been the case, were it not that the shortsighted and over-greedy officials of Soochow and Hangchow, by their oppressive levies of toll, forced the filatures of Shanghai which made the finest silk from cocoons, to close their works, after the native and foreign proprietors had borne much annoyance and loss.

* We are not aware that this has been done even on the oldest estates in India. In Ceylon certainly not: the plants uprooted have been coffee not tea.—ED.

The future prospects for China silk are by no means bright. The improved worm, a mixture of Japanese and European grain, has been firmly established, and France and Italy now produce as much silk as they did before the visitation of the long continued and destructive plague that ravaged the silk nurseries of Lombardy and Southern France, and the new worm, while as prolific as the old race now extinct, is much less delicate. India also produces largely, and an almost boundless new district that produces the finest qualities of silk has been found in Kashmir.

Now in China the mulberry trees, owing to the method in vogue of growing from slips or cuttings instead of from seed, everywhere show signs of fatigue, just as the French vines did before phylloxera, or as the Ceylon coffee plantations did before the leaf disease appeared. The matter, in some respects, is already becoming rather critical, for along with the tree degeneration there is the gradual though not rapid extension of the disease of worms, named *pebrine*.

Thus two important and especially national industries, tea and silk growing, are, to a more or less extent becoming jeopardized, but the evils done by neglect and ignorance in each case can be rectified before the injuries are irreparable. We trust the Imperial Chinese Government will cause investigation to be made as the questions involved are of truly national importance and should not be neglected.—*Chinese Times*, July 14th.

TEA IN CHINA.

Foochow.

The *Foo-how Echo* mentions a rumour that the Chinese teamen at that port are about to form a company for the direct export of tea to London and Australia. Our contemporary discredits the rumour.

We are informed on good authority that the Russian Consul yesterday, in company with the Lekin Taotai and the Haifang-ting, went to the Sun-Cheong tea hong, where several bags of tea were seized, and it is reported that the Chinese Authorities intend to place the hong under seal.

We indeed feel very happy to have occasion to congratulate our tea merchants on the very fortunate result of their shipment per steamer "Glenogle," judging from the reports flying round the settlement, and we sincerely hope that the same happy result will fall to all their shipments during the season.

We hear that a few tea honges have, in consequence of there being no buyers of tea during the last few days, wired to stop buying in the country; as the teamen, who had made good margin in their first crop, have gone mad and made large purchases in the tea districts. It remains to be seen how the matter will end at the close of the season.

OLD-WORLD NOTIONS ON STRONG DRINK AND TEA.

In a reading raid made some time ago and the primary object of which need not be definitely specified, the writer had occasion to examine more or less attentively the whole of the twenty volumes of the *Old Statistical Account of Scotland*, published just about a hundred years ago. The work is one that contains a large amount of interesting information of varied character bearing on the social and industrial condition and habits of the entire population during and toward the close of last century. And thus in going through the work for any given purpose one could hardly avoid now and again stepping a little out of his way to make a note of something in the philo-sophising or moralising of the reverend writers that awakened interest or attracted curiosity.

As was to be expected, not a few of those worthy gentlemen have taken occasion to express their opinions upon the social habits of the people in their respective parishes, and in running through the volumes the writer jotted down a considerable part of their remarks under this head. A brief selection of these, as they bear more immediately upon the question of strong drink, it is proposed to string together for the amusement, if not the instruction, of the reader.

Without any attempt at classification we take up these quaint utterances almost at random, and put them together in the manner of patch-work, simply remarking that having, with hardly an exception, been written by the parish minister, they may be very fairly considered as representing the intelligent public opinion of the time at which they were penned—(A. D. 1782-1793).

The subject of drink manufacture will naturally come first; and under the heading Kinneff (Kincardineshire) we find a breakdown in the local distillery business made the subject of lamentation. "The farmers," says the rev. statish "have for some years past regretted the failure of the Firth distillers, as the great consumers of their bere and barley." His Highland contemporary at Tarland (Aberdeenshire) would have kept the material at home. He says, "It might well be of service to have a public distillery at Tarland, as the county yields a great deal of good bere." This man had a taste for nothing better than whisky. The statish of Kirkmichael (Ayr) would have told him that "whisky, so prevalent in many places, is not esteem'd a genteel drink in this corner." However, other parts of Aberdeenshire loved to encourage "the trade" for, says the statish of Newmachar—"A few years ago they frequently had malt feasts, i. e., farmers from whom the country brewers bought their malt and barley convened when the price of the malt became due, and spent part of it very cheerfully to encourage their customers." And, still in the same shire, we find the virtues of beer as a potent medicine magnified, for in 1771-3 a putrid fever, we are told, cut off many in the parishes of Kinellar and Skene, so many as 33 burials taking place within three weeks. "A stop was put to it (the fever) when it came near the manse, by the minister's sister, who gave a bottle of strong beer warmed, in the beginning. This produced a great perspiration and carried off the fever from all that took it, after several had died who used the bark and other medicines." How far this rev. gentleman would have gone with the folks of Sutherland as pictured by the minister of Golspy we cannot say. "Many in this country," says that gentleman, "think spirituous liquors a cure for almost all diseases, and the poor child in the small-pox is plied hard with whisky in all the stages of the disease, which never cures, but seldom fails to kill." Other people could tell of wonderful cures effected through the agency of intoxicating drink, and we find none more wonderful in its way, nor it may be added, more apocryphal-looking, than one related in a gossipy way by the minister of Tillicoultry (Clackmannanshire), who states that in 1758 a labourer was cured of "the pebrine disease" by "drinking freely of the water of our well." He had been confined to his bed for a year and a half, and his neighbours very kindly came to make merry with him on "Hallowe'en day." Though he could not raise his way to his state of the ale as it went round, and in the end became "much intoxicated." The consequences were, says this credulous chronicler, "that in the use of his limbs next morning, and was able to walk about. He lived more than twenty years

after this, and never had the smallest return of his old complaint!" *Mirabile dictu* we may well exclaim.

The statist of Yester (East Lothian) thus gives expression to his faith in beer:—"The children, in general, are not so stout as they were forty years ago, which must be owing in a great measure to the different manner of living, as the common people now drink a great deal of tea, and not good small beer, which they did fifty years ago." An Edinburgh physician (Dr. W. Nisbet), who reports for Currie (Mid Lothian), thus states his opinions:—"Till within these few years, the people of this parish were sober, industrious, and economical. The vices of the capital, however, are beginning to spread fast among them, and the introduction of those baneful articles to the poor—*tea and whisky*—will soon produce that corruption of morals and debility of constitution which are already so severely felt in many parishes. . . . The introduction of these articles is one bad effect of the present practice of debasing and vitiating malt liquor. Formerly when that liquor was the only beverage in use, excesses from it did not affect the constitution, as it contained a good deal of nourishment. But now since it has been debased it is entirely given up."

Such was the medical wisdom of those days—*tea and whisky* classed together as equally inimical to morality, and good beer pronounced harmless even when taken in excess. We need not wonder then if simple clergymen get a little wild on the subject. The minister of Ayton (Berwick) says:—"The tradesmen and labourers in the village are addicted to the pernicious habit of using tea. Of late also, from the low price of whisky, the execrable custom of dram drinking is gaining ground even among women of the lower classes." Similarly his neighbour of Coldingham (Berwickshire) says:—"The only extravagance they are guilty of is their breakfasting upon tea in place of pottage, the constant morning diet of their more athletic ancestors, which debilitates them. . . . and the immoderate use of whisky, which destroys them. This is owing to the cheapness of these two superfluous and pernicious articles." The minister of Dalmeny (Linlithgowshire), too, says: "The luxuries in which they (the common people) indulge are tea, and, what is worse, whisky." Every one did not, however, consider whisky the worse of the two; for the minister of Gargunock (Stirlingshire) says:—"Tea is universally used. Even the poorest families have it occasionally, and the last cup is qualified with a little whisky, which is supposed to correct all the bad effect of the tea." The minister of Dyke and Moy (Morayshire) remarks that "the use of tea makes rather an alarming progress among many who need a better nourishment at less cost." The minister of Sorbie (Wigtownshire), who held that the effects of the public-houses were most injurious to the morals and industry of the people, especially when little else than whisky was sold in them, gives a very explicit opinion in these words—"A few pence procures as much of this base spirit as is sufficient to make any man mad. The landlords of superfluous petty public-houses generally waste their time and ruin their constitutions by acting like decoys on their silly, half-resolved neighbours. In this shameless business they are flattered by the notion of promoting trade."

One class of curious statisticians give illustrative figures; for example, the report for Muirhouse (Forfarshire) says—"When the present incumbent settled here, which was in the year 1761, there were only two tea kettles in the parish, though now there is scarcely a householder who does not use that luxury." His neighbour of Mains of Pintry (Forfar

also says:—"In 1760 there was only one eight-day clock in the parish, six watches, and one tea kettle. In 1790 there are thirty clocks, above a hundred watches, and at least 160 tea kettles, there being scarce a family but has one, and many that have two." The statist of Benholme (Kincardineshire) informs us that "about 50 years ago the excise officer's family was the only one in Johnshaven that made use of tea. When the kettle was carried to the well to bring in water, numbers of both children and grown people followed it, expressing their wonder, and supposing it to be a beast with a horn!" Rather green this, we should say. Among this class may be reckoned the minister of Hownam (Roxburghshire), who states that "the number of ale-houses (in his parish) are two. The effect they have is rather unfavourable to the morality of the people." The people are, however, "in general piously disposed," and he is evidently more afraid of a meeting house "of the wildest" kind of seceders, whose "principles are not supposed to be very favourable to morals and true piety," than he is of the two ale-houses. It was different in Bourtie (Aberdeenshire), where we read—"The advantages are the sobriety of the inhabitants (not an alehouse being in the parish), and the diligence of the women in knitting stockings." At Keith-hall, a neighbouring parish to the last named, then under the incumbency of Dr. Skene Keith, a man of considerable learning and original genius, and father of the late Dr. Keith, St. Cyrus, well known for his writings on prophecy, the people were in general "industrious, and live plainly, and in such sobriety that since 1788 three different attempts to settle an alehouse among them have proved abortive."

While several of the statisticians look back with fond regret on the good times gone past, others take care to inform us of the improvement exhibited in their own day, while yet a third class have an eye to further reform. The statist for Banff resorts to the use of parallel columns in illustrating the advance of society thus:—

1748.

A joyous company after dinner have been quaffing the wine of a dozen bottles from a single glass.

1798.

A sober party sometimes meet, whose libation consists of a solitary bottle with a dozen glasses.

The minister of Cromarty significantly "hopes" the removal of the coal tax will "supersede the necessity in the people of having recourse so much to what heats them internally, by affording them improved and easy access to comfortable heat of an external nature." His contemporary of Boharm (Banff and Morayshires), in a passage which we have rarely seen exceeded in the way of bombast, utters what he, no doubt, conceived to be a profoundly wise and eloquent deliverance on the subject of needed reform in the drinking habits of the people. He says—"By the nauseous draft of train oil in Lapland, and the more disgusting beverage of Otaheite, it may be inferred that man cannot be satisfied with the simple element alone of water." From the different circumstances "concomitant" on the excise laws in England and in Scotland, he is of opinion that it would be difficult to "investigate why beer has been the prevailing drink among the peasantry of the southern, while ardent spirits have so universally obtained among the same class in the northern, end of the island, to which must be attributed their asperated and contracted features rather than to the influence of the climate." He thinks, however, that it would be easy for the Secretary of State so to model the excise law that beer instead of whisky should in a short time be generally adopted by all the labouring people of Scotland; and "by those means, while he would contribute to maintain in a high

degree the purity of the morals and the soundness of the constitutions of his countrymen, he would at the same time expand their countenances and improve their whole exterior form to the highest elegance of symmetry and beauty."

So much for last-century wisdom on the subject of the cup that cheers and does inebriate, and the cup that cheers and does not.—*Aberdeen Free Press.*

NETHERLANDS INDIA NEWS.

(Translated for the Straits Times.)

Java rice now competes successfully with locally grown rice in the United States. Growers there feel alarmed at the competition, and cry out for a heavy import duty on the Java article. At Savannah, Java rice has almost ousted the local product as in the retail trade, Java rice is not so nutritious the American grain, but looks better, and is cheaper.

In Java, experiments have been made with the Maragopipe coffee, which flourishes in Brazil where it has been attracting attention for planting purposes. In Java, this kind of coffee bears large berries of handsome appearance, and as easy to manipulate and cure as the local variety. So far, it seems easier to prepare for market than the Liberian coffee. At Amsterdam, the Maragopipe coffee in the market equals the best Java, and bids fair to command a higher price on account of the larger size of the berry.

In West Sumatra, the Netherlands Indian Government has begun the construction of a railway from the coast to the Ombilien coal field in the interior. Though the forests in Netherlands India abound with valuable timber for the purpose, they are so unavailable that America has to be drawn upon for supplies.

FLOODS AND FORESTS.

Nearly a century ago it was admitted that climate is sensibly, if slowly, affected by the loss of trees. Later experience has proved that floods and droughts speedily follow upon their disappearance on any large scale; and this they seem to be finding out in the valley of the Mississippi. Though as for that matter, within the last ten years the direct operation of the cause in widely distant countries has been recognized by every Forestry Department that has concerned itself with the inquiry.

The United States Department of Agriculture was one of the first to raise the alarm. The forest area of the States has been over-estimated. It is now officially given as less than 500 millions of acres; while many million acres are annually destroyed by fire or laid bare by the demand for "lumber." Floods and droughts must, we are assured, be the inevitable consequence of such havoc; and that warning given, the havoc proceeds. But the example has not been quite lost upon neighbouring States. The Canadian Government does now give some attention to the matter. The Argentine Republic, in forecasting the prospects of wheat-growing within its borders, declares that "the one thing to be guarded against is the wholesale destruction of forests." Floods and droughts have been traced directly to the same cause in Burma, Afghanistan, and portions of India. Norway has suffered severely from the exhaustion of her spruce and pine forests. The inundation a few years ago in the north of Italy were due to the disforestation of that once well-wooded peninsula, which also is exceptionally visited by avalanches. Nothing so breaks the force of an avalanche as mountain woods; but the slopes on the Italian side of the Alps have been almost completely denuded of timber. Spain also suffers greatly from

inundations caused by the lack of forests; and in Austria-Hungary, and different parts of Germany—well-wooded as upon the whole these countries are—similar local visitations are attributed to the same cause.

The natural chemical processes which ultimately result in "climate" operate more or less obscurely; often through long epochs, and always on a majestic scale. But the mechanical action of forests in arresting floods and preventing drought is simple enough. It is found that when streams are denuded of the trees that grow about their sources the springs that renew them are rapidly diminished. Forests may be said to nurse the rainfall. The canopies of foliage check evaporation, and the roots retain the moisture for a long time in the soil. Finally they yield the unabsorbed redundancy to the springs, thus completing the circle of causation on which natural irrigation depends. On the other hand, large portions of the denuded tracts lose their porosity and become more or less "hide-bound": a state of things frequently ensuing upon forest fires. Like fire, water is an excellent servant but a bad master; and when heavy rains are not detained by trees they are too swiftly carried off the surface of the soil, simultaneously filling the minor creeks and streams, which speedily give dangerous volume to the larger rivers.

The operation of these causes may be made clearer by glancing at the course of events in the great watershed of the Mississippi. One of the most majestic rivers in the world, it stands alone in the number and volume of its tributaries and their affluents. It rises nearly 1,700 ft. above the sea-level, and drains more than half of the whole area of the United States. Less than fifty years ago vast stretches of the eastern watershed were covered with dense forests, not a sixth part of which now remains. By the simplest of natural laws, these forests formed their own system of drainage in a perfect network of streams and rivers all irresistibly impelled towards the Mississippi. But they were regulated currents, being only the surplus water which remained after the normal replenishment of the springs. Then came the pioneers of the "Far West"—with this result: that the whole of the eastern watershed of the Mississippi is now officially spoken of as one immense farm, with only a little clump of woods in its north east corner. The entire cereal product of the United States was, in fact, doubled in the course of the ten years 1870-80; and in the last year of this decade the three States of Illinois, Iowa, and Missouri alone produced over 800 million bushels of corn, or more than the entire yield of the United States in 1870.

Destruction for the purposes of the timber trade followed the destruction of the farmer in making his "clearing;" and it is now feared that even the great pine forests of the north-west will be exhausted before the close of the present century. Commercial instinct naturally leads the lumberman to follow the course of the rivers. The transport of his "saw-logs" is made so much the easier, and from the banks of the stream he penetrates and prostrates the forests on either hand. But, whether the destruction be wrought by farmer or timber-merchant, reprisals will certainly be exacted. The cultivated farm or desolated waste may usurp the place of the forest; but neither can of itself counteract the disturbance of equilibrium which has been brought about. The reserve of water becomes less, and so we have droughts; the influx of water is subject to a too sudden superficial distribution, and hence follow floods.—*St. James's Budget.*

THE FUTURE OF JAPANESE TEA.

(Translated from the *Mainichi Shimbun*.)

By lately published statistics on Japanese tea we observe that the value of the tea exported in 1884 amounted in round numbers to yen 5,819,000. In 1885 the amount reached yen 6,854,000; and the following year yen 7,723,000. The total amount of our exports in 1886 was 47,997,000; of which yen 19,000,000 was realised from the silk trade. We see then we at an important position among our staple products tea holds. Every country has its staple articles of export. England its woolen and cotton cloths, and America its wheat flour, but in no country but Japan do one or two articles constitute more than half of the produce exported. The important position that tea occupies as a source of national revenue demands that great attention should be paid to his cultivation. We are sorry to see that this is lacking. From the statistics supplied by the Tea Association we gather that during the past four years there has been a general falling off in the prices realized for various teas. The subjoined table shows the prices at which teas from principal localities have been selling:—

Quality.	SURUGA, TETŌMI, AND MIKAWA.			
	1885.	1886.	1887.	1888.

This table shows that out of about twenty different varieties of tea some have fallen in price 50 per cent., and that there is not one but has decreased in value more than 10 per cent., and all in the space of four years. We hear also that probably owing to the rapid construction of railways, the wages of the cultivators and pickers of tea have had to be raised during the past year. This is said to have affected some tea districts so seriously as to make it impossible for them to send tea to Yokohama at the current rates of sale. This state of things is something more than a commercial difficulty among a certain class of traders: in that it materially affects the national revenue, it is a great national misfortune. In endeavouring to forecast what will be the future of our tea trade, we are forced to the conclusion that the only chance of success seems to lie in the possibility of our tea taking the place of coffee in western markets, or of its gaining ascendancy over the Indian and Chinese teas. Nether of these things is likely to happen. Hence we cannot but have dark forebodings in reference to the future of the trade. The fall in prices is not to be attributed to deterioration in the quality of the tea produced. The Tea Association organized under Government auspices has paid considerable attention to the

quality of the tea grown and has adopted various rules bearing on the production and preparation of tea. This has, we are assured, been a safeguard against any wide-spread falling off in the quality of the article grown, in fact it has resulted in a decided improvement in this respect. The cause of the decline in prices is to be attributed to over-production. By referring to the various annual reports of the Tea Association, we find that, in the course of ten years, that is between the years 1878 and 1888, the amount produced has doubled itself. Doubtless the same thing has taken place in China and India. The demand for tea in the West has certainly increased during this period, but not at the rate of production and hence the present disparity between supply and demand. It seems to us that the only remedy for this state of things lies in paying closer attention to the taste of foreign consumers, reducing the quantity of the varieties produced, confining our efforts to the production of those teas that are in demand, and endeavouring to reduce the expense of production as much as possible.—*Japan Weekly Mail*, July 21st.

EXPERIMENTS are being carried on in Russia with the view of finding a process, at once practicable as well as desirable on the score of economy and cleanliness, of solidifying the petroleum used as fuel. According to the report made to the Russian Government by Dr. Kauffmann, who has had the principal charge of these experiments, a successful method of accomplishing the desired results consists simply in heating the oil and afterwards adding from 1 to 3 per cent. of soap. The latter dissolves in the oil, and the liquid, on cooling, forms a mass having the appearance of cement and the hardness of compact tallow. The product is hard to light, burns slowly and without smoke, but develops much heat, and leaves about 2 per cent. of a hard, black residuum.—*Indian Engineer*, July 18th. [If it could be deprived of its odour and sold cheaply, we should here have a good tea factory fuel.—Ed.]

TAMIL COOLIES IN SUMATRA.—Says the *Straits Times* of August 1st:—It is reported that the Dutch Government intend, shortly, to take an important preliminary step in connection with the immigration of Tamil Coolies into Deli from India, by appointing a Consul-General at Calcutta. No decision has been come to whether he will be a professional or unpaid consul. The alternative which will suit in this instance is obvious enough, when it is borne in mind that only an official can steer clear of complications of every kind sure to arise from commercial transactions connected with the emigration business. But a paid Consul-General means a heavy outlay. Hence considerations of economy prompt the appointment of an unsalaried holder of the office. With parsimony in the ascendant, efficiency must go to the wall.

MICA mining pays in North Carolina:—100 lb. of block will yield from 10 to 12 lb. of cut mica, that is an average yield; but instances have been known of a yield falling to 5 per cent, while it has risen in some mines to 33 per cent, and once the high tide level of 75 per cent was reached. The highest price realized has been four dollars per pound; the average price is about \$ 1.75. Why is not more attention paid to mica mining in India? Supplies are abundant and obtainable without much difficulty, and, if the enterprise yields handsome profits in a country where labour is dear, as in the Southern State of America, it ought to be still better worth development in places where labour is cheap, as it is in India. Nor is cost of transit likely to be a heavy item of expenditure, the stuff being so extremely light.—*Indian Engineer*. [Beside the large plates for lanterns, pounded mica is largely used as a lubricant in the United States.—Ed.]

THE ORIENTAL BANK ESTATES COMPANY (LIMITED).

The following report, which we take over from the *London and China Express*, gives a very hopeful statement of the position of the Company, a good round sum of money having been obtained as the result of litigation with the Liquidator of the Oriental Bank (old):—

The second annual ordinary general meeting of the Oriental Bank Estates Company was held at the offices of the company, South Sea Chambers, 97 and 98, Bishopsgate-street, in the City of London, at noon, on Wednesday, July 25th, to receive and consider the directors' report and statement of accounts; to consider and declare dividends; to elect a director; to sanction the appointment of managing directors; to fix the special remuneration of directors; to appoint auditors and fix their remuneration, and to transact the other ordinary business of the company.

Mr. Alex. William Crichton presided. In opening the meeting, which was well attended, he said:—Gentlemen, we are happy to welcome you in these new offices, which we hope meet with your approval. They are more commodious than the former ones, and we have obtained the ample space which you see here on reasonable terms. We had felt for some time that the interests of the company required that we should mark the sound and independent position we occupy by securing more suitable and permanent accommodation. But I must proceed to lay before you the report and balance-sheet, which I presume you have all looked at and will take as read. The report shows the continued satisfactory progress and prosperity of the company, notwithstanding the drought which prevailed in Ceylon during the great part of the year in question, and which caused a return of our crops to fall far below the proper estimate. I rejoice to add, however, that the weather has since become normal, and that things are looking well again. A revaluation of our estates lately made shows they have very largely increased in value. In Mauritius we have enjoyed favourable weather for some time past, and prospects of the coming season are reported to be unusually good. The rest of the report deals with matters which, if necessary, will be touched on by others, or presently by myself. Passing now to the consideration of the balance-sheet, you will see that the figures representing payments on share capital remain the same as in our former accounts, except as to the amount of ordinary shares not then fully paid. Almost all the holders of those shares accepted the option which we gave them with your consent and came forward and paid up their shares in full. The amount of capital we thus received was, of course, useful, and the grievance which these shareholders said they had in not being previously allowed to increase their interests in the company was removed. The next heading is that of our liability to sundry creditors, including, first, our acceptances, which, you will see, are rather more than balanced by the whole of our stocks and produce in hand, and secondly, our accounts payable, which are less than the corresponding accounts receivable by us by about £24,000. As to the amount in these accounts payable, you will also find they are less by about £111,000 than was shown in our accounts last year. The explanation of this striking diminution in our indebtedness will be found in the sale—to some extent in the sale—of our claims on the old Oriental Bank Corporation, the proceeds of which we applied in payment of sums of purchase money due from us. It appeared originally as if those claims would form a very remunerative investment to hold, but, when the remaining estates of the Corporation were sold with the sanction of the Court to the Assets Realisation Company, who are only bound to satisfy the claims by payments extending over three years, it became questionable whether it was worth our while to hold the securities longer. After much consideration we determined to realise this asset and to pay off the official liquidator, to whom, as I mentioned last year, there was owing at the date of our last account a

large sum for purchase money on the first contract. I may mention that these claims were very useful to us, inasmuch as they formed a security approved by the court pending the collection of our capital and payment of purchase money—on pledging which with our vendor we were at once let into possession of our estates. Passing now to the other—the asset side of the balance sheet, the sale of the proceeds of these claims accounts for a considerable part of the large sum of £156,255 there mentioned as recovered. These recoveries include too (and the cost of our estate is largely reduced by) the result of our late successful litigation in the Court of Chancery against the Official Liquidator of the Oriental Bank which took place under circumstances which I will presently allude to. Some of the accounts taken in consequence of these proceedings have not yet been completed, but we have already recovered about £11,000, and there is more to come under these accounts. You will remember that we recovered and wrote off last year from our vendor £14,500, so that altogether we have recovered and written off, and the cost of our estates is reduced by no less than £25,000 in two years, which we think extremely creditable. (Applause.) The recoveries also include a sum written off for depreciation of machinery. Then, as to the values of our produce. The produce sold up to the date of these accounts was more than double that sold in the corresponding period of last year, while the produce unsold is about the same. In fact, the produce sold was nearly three times that of the same time last year. I mentioned on a former occasion that the date we were obliged to select for the close of our financial year made it impossible not to have considerable stocks on hand; but that it is being sold quickly is a matter for satisfaction. We had valued them at prudent prices and taken the net values only. As to the accounts receivable by us, they are of the same nature as those described on a former occasion. Then comes the suspense account, which has been increased during the past year by the purchase of the remaining number of warrants necessary. Altogether we have thought that if we paid £2,773 off this account it would be sufficient, considering the extra expense which we are paying out of our income for the benefit of the future. The cash at our bankers was £3,923. And then comes the consideration of the dividend. You will remember that in February last you received interim dividends for six months at the rate of seven and five per cent per annum respectively, on the preference and ordinary shares, and this payment, which absorbed £12,807, added to the balance shown in our profit and loss account, from a total profit of £25,841—this is in addition to the £2,773 written off the suspense account, so that the true profit may be said to be between £28,000 and £29,000. When you consider that a large part of our tea is not in bearing, and that a large half of what is in bearing is not in full bearing, and that we liquidated such a large expense out of income for the up-keep of extensive acreage of plants not yet in bearing, we think you will consider this result highly satisfactory. We recommend payment of further dividends at the rate of seven and five per cent per annum respectively for six months on the preference and ordinary shares, in proportion to the capital paid up as mentioned in our report. Then as to our estates and their condition you will see from the list as compared with the last that we have bought during the year the two large cocoa estates of Mahaberiatunc and Henegabawelle, with the extra estate Dene. The annual return of cocoa from these estates is expected to be, and has already reached 900 cwt.; but it will increase. Dene is chiefly valuable to us for the timber. Then secondly, we bought the estate of Newmarket, chiefly important to us on account of its adjoining Stelenberg which is made more valuable because the two estates can be worked together. Thirdly, we bought some smaller properties useful to us either for timber, fuel, or other purposes, and lastly we bought out Mr. Hedge, till lately a part owner with us in respect of his one-fourth share of the cocoa estate of Kendesalle. By this purchase and by extension of cultivation our tea acreage has reached

4,129 acres; our cocoa has increased from 357 to 604 acres; and our cardamoms to 80 acres. On the other hand the Cinchona shows a slight decline, but this is owing to scattered patches having been dug out on some of the estates to make room for tea. This does not in the least affect our Cinchona property; that is, those acreages where Cinchona flourishes and does well. I mentioned last year that I believed we had a million and a half of cinchona trees. The result of the census taken shows that we have 1,800,000 trees, and, consequently, that I had understated the number of the cinchona trees. During the year additional buildings were constructed, and the necessary machinery purchased and established on the Ceylon estates, and a considerable amount of new machinery was also purchased and established on the Mauritius estate of Britannia. The report of the working of this machinery, which is all of the most approved pattern, is favourable, and the results appear to be very good. All our estates are in excellent order, and we have had maps prepared and drawn to scale, showing the respective acreages of forest and cultivation, and, so divided according to the date of the planting, that we are able to follow upon them the reported progress of our agricultural operations. This is a great advantage because it gives us more control over our properties. You will see some of those maps hanging round the room, and will be able to inspect them and others at the close of the meeting, as no doubt it will interest you to do. I had almost forgotten to mention the circumstances relating to our litigation with the official liquidator of the Oriental Bank; but I will say a few words on the subject, because some shareholders were made nervous by seeing the name of the company figuring on one or two occasions in the Chancery cause list. We did not engage in these proceedings without long and careful consideration. We had rights, for breach of which we felt bound in your interests to obtain redress. In the first place, there was an important difference between the official liquidator and ourselves with regard to the interpretation of a clause in our first agreement with him, and under his construction of which produce to the extent of between R30,000 and R40,000 was withheld from us. Secondly, and what was of more importance, we found on overhauling the accounts relating to our Mauritius estates previous to the date of our purchase that certain sums of money that should have come to us under the agreement had not been paid. We arrived at these conclusions after an inquiry extending over more than a year, and after calling for account sales of many million pounds of sugar, &c., large calculations of much nicety engaging all our attention. The official liquidator entirely denied the soundness of our conclusions, but the result of the legal proceedings was in your favour in both cases. (Applause.) The issue has been, as I have previously stated, that we have recovered already and written off capital £11,000, and there is something more, though not nearly so much, of course to come under the accounts not yet completed. In matters of difficulty and complexity there will always be two opinions, and we do not blame the official liquidator for not having acceded without consent to our demands; but we think we are entitled to the credit of successful management by having engaged in a very arduous task in the face of so formidable and powerful an adversary, and in having brought our dispute to a successful and honourable conclusion with large profit and so little expense to you, because the greater part of the costs were paid by the other side. (Applause.) As to the future, our prospects are bright and full of promise. Our receipts, it is true, have been lessened by exceptional years of drought; but notwithstanding these drawbacks we have been able to give you a good return on your capital, and if this be the case when only one-half of one of our principal products is in bearing—only a quarter in full bearing—and when our revenues are saddled by such large expenses for the upkeep of this, as yet, unproductive part of these products, the conclusion seems to be undeniable that when our estates are in full bearing our profits will not be merely good, but very ample indeed; and

that time seems from every sign to be rapidly approaching. (Cheers.) The Chairman then moved: "That the directors' report and statements of account now submitted be, and are hereby adopted."

Mr. Grant Heatly Tod-Heatly seconded the motion, which was then carried unanimously.

The Chairman proposed, and Mr. Andrew John Macdonald seconded: "That in accordance with the recommendation of the directors a dividend at the rate of 7 per cent per annum upon the issue of preferred capital of the company for the half-year ended March 31st, 1888, and a dividend at the rate of 5 per cent per annum upon the ordinary capital of the company, in proportion to the amount paid up, for the half year ended March 31st, 1888, be, and they are hereby declared, and accordingly, that the sum of 3s 6d per fully paid preferred share sixpence per fully paid ordinary share, and a proportionate sum on the ordinary shares with one shilling paid, be paid on and after the first day of August 1888, upon the shares on the company's register at March 31st, 1888." Carried unanimously.

Mr. Macdonald moved: "That the retiring director, Mr. Alex. Wm. Orichton, be, and is hereby re-elected."

Mr. Tod-Heatly seconded, and the motion was passed.

Mr. Macdonald further moved "That the appointment by the directors of Mr. Alex. William Orichton and Mr. William Otton Rohde as managing directors of the company as from July 26th, 1888, on the terms mentioned in the report be sanctioned."

Mr. Tod-Heatly seconded, and the resolution was carried unanimously.

Mr. Miller moved: "That Messrs. Quilter, Welton and Co., be, and they are hereby appointed, auditors to the company for the financial year ending March 31st, 1889, and that their remuneration be fixed at the sum of fifty guineas."

Mr. Ness seconded, and the motion was carried.

A vote of thanks was accorded the chairman, on the motion of Mr. Nicholson, seconded by General Beville.

This concluded the business of the meeting.

PEPPER CULTURE.

DRUMDUAN, JOHORE, May 2nd, 1888.

The Editor, *Tropical Agriculturist*.

DEAR SIR,—Seeing that some information about planting pepper has been asked for in the above publication, I take the liberty of sending you some notes on the same. I send them with the full knowledge of the *Singapore Free Press*, and trusting they will be of some use, I remain, yours faithfully,

J. R. WATSON.

NOTES ON PEPPER CULTIVATION.

(By a Planter.)

Pepper.—(*Nigrum*). The plant affording black pepper is a perennial climbing shrub, indigenous to the forests of Travancore and Malabar, and cultivated also in Sumatra, Java, Borneo, the Malay Peninsula, Siam, the Philippines and the West Indies.

Cubeb (*Piper Cubeba*; Fr. *Cubèbes*; Ger. *Cubeben*; *Cubeba Officialis*). The fruit of the *Cubeb* is very widely used in the treatment of gonorrhœa. The plant, a member of the *Pepper* family, and a woody climber, is a native of Borneo, Java and Sumatra. The fruit is gathered when full grown, but before it has ripened; and is then dried. It has a strong aromatic and slightly acrid bitter flavour and a pleasant aromatic odour. The great similarity of the fruits of other species of *Piper* renders their confusion with the true drug an easy matter; they are principally *P. Crassipes* of Sumatra, *P. Louong* of Java, *P. Ritesoides*, *P. Caninum* throughout the Malay Archipelago, and extends to *Laurus Cubeba* of S. China.—(From Spon's *Encyclopædia of Manufactures*, etc.

Climate.—A warm, moist climate, with an average rainfall of 80 to 100 inches annually, and evenly distributed, is most suitable for the successful growth of pepper.

lay of Land.—A nice gentle slope, well protected from winds and with an eastern aspect, should be chosen if possible, but as regards aspect I do not consider it an absolute necessity, as I have seen pepper growing with other aspects, and doing exceedingly well.

Soil.—Light sandy soil must be avoided, as pepper likes soil of a retentive nature. The majority of the soil in the Straits is of this description, being composed principally of disintegrated granite and ferruginous clay, with a free subsoil, and on top generally a few inches of vegetable mould. Pepper also grows well in well drained swamps composed almost of pure vegetable matter. I have also seen it growing in magnificent volcanic soil, and the pepper, though very fine, showed clearly, both in wood and crop, that the soil was a little too free, and did not retain sufficient moisture during the hot weather.

Felling and Clearing.—This work if possible should be done on contract. The men commence by cutting down all the undergrowth and small trees and spreading these evenly over the ground. They then commence from the bottom of the clearing and work upwards, cutting all the trees half through. On the top of these they fell a "giant of the forest," and this brings down the trees immediately below and around it, and they in turn bring down the others. The men then proceed over the felled clearing, and lop off all branches, and if these latter are too large, cut them up also, all being spread out so as to cover the ground. When well dry, the clearing is fired. It is best to agree with the contractor to take the risk of the burn, as if it should turn out bad, he has to heap and burn again. Besides if he takes the risk, he will be all the more likely to do the work well.

Digging.—After the burn the clearing should be dug up entirely to the depth of one foot, all roots, twigs, etc., being carefully heaped and all small logs over six feet in length kept for temporary posts; but if labour is abundant, I advise permanent posts being split at once, in which case the small (6 foot) logs can be added to the pile of roots, etc. I will, however, presume that the permanent posts cannot be split in time, so that temporary ones must be used.

Roads should be cut so as to give easy communication to every part of the estate. The gradient should not exceed one foot in twenty (i.e. a rise or fall of one foot in every twenty feet), as then the roads can eventually be turned into cart roads, making transport of manure cheap and easy. The extra outlay will eventually amply repay itself. Breadth of the road not less than 4 feet, and if it is to be eventually widened, the extra bit required for the widening should not be planted. Having chosen the line your road is to take, drive in a small peg (about 8" long) to the level of the ground and beside it drive another peg (about 18" long) so as to show where the level peg is. On the level peg place your tracer, after having adjusted it to the proper gradient. A cooly with the sighting pole should go on ahead about 25 feet or so, and when the gradient is found, a small peg should be driven in to the level. Another sight should be taken to see if all is correct, and another long peg driven in beside the level peg. The tracer is then brought in to the second level peg, and the work proceeds as before. When the road is cut a drain one foot deep and wide should be cut on the inside, and the road should have a slight slope in the direction.

Drains should be traced at the same gradient as the roads, but the level peg is not needed. They should be a chain apart and 18 inches deep and broad. Great care is needed in tracing drains, as if there be any deviation in the trace, the drain is apt to burst during a heavy shower. All drains should be led into the nearest ravine; but if that cannot be done, or the drain be too long, outlet drains should be cut, and care should be taken not to enter the cross drains in pairs, but alternately, and the last few feet should have a steeper gradient, so as to save the sides of the outlet drains.

Lining.—Pegs having been cut 18 inches long, a base line should be run at right angles to the road, pegs being placed seven feet apart. Some plant 8' x 8', but I consider 7' x 7' the right distance. Having run the base line to the end of the clearing, a cross line must be run at right angles to the base line, and the pegs placed the same distance. A rope is then taken about 180' long, and this is measured at regular intervals of 7' and is marked off by a bit of coloured cloth. The rope should be remeasured 3 or 4 times a day, and always after a shower. The two ends are then tied to two sticks, and a cooly takes hold at each end. One man places the end rag on the rope at his end, on the top of the cross line peg nearest the base line. A man at the other end measures with a seven foot stick from and at right angles with the base line, and puts in a peg at the end of the measure. The rope is then pulled straight, and the pegs placed in to correspond with the rags on the rope. The subsequent work is the same. Beyond the look of the thing I see no use in square lining, and a place looks just as well if lined as above. Lining 7' x 7' gives 889 to the acre, 8' x 8' gives 681, a considerable difference.

Holing.—At each peg a small whole should be cut, about a foot deep and large enough to take the temporary post, which should be firmly fixed in it. On the lower side of the post the soil should be dug up to a distance of about 18 inches from it, and about 9 inches deep and in a heart shape, the broader end being near the post. All rootlets, etc., being removed, the earth is piled up along the centre in a ridge leading from the post, leaving a hollow on three sides. It is then ready to receive the cutting.

Nursery.—Cuttings should be bought, or if they are vines, cut two months before they are required for planting. Each cutting should have not less than seven root joints and two branches, but three are preferable. When cut from the vine they should have all the branches cut off the seven joints which are to form roots, the next two or three branches left, and all above the top branch that is left should be cut off about half an inch above the joint, all such cuts being clean ones. Outtings should not be taken from old vines, nor should old bark hardened cuttings be used, as in both cases they grow very slowly and never make good vines. In choosing cuttings, there is one kind which should always be rejected. It is difficult to tell it from a good cutting. It has the roots like the other cuttings, and may look healthy and probably does, but if carefully examined, an eye or even two or three will be seen at the root joints, and all is round and smooth, and the top and eyes will only keep on sending out branch shoots upwards without roots, and in clusters, and no amount of cutting down will change its growth. Having chosen a flat site close to water for your nursery, have it dug up to a depth of 15 to 18 inches, and all roots, etc., removed. Put over this a covering about 5' 6" high, and thoroughly shade. Divide the ground into beds 4 feet broad and any length, having paths between each bed, paths being either on the same level, or even raised above the beds slightly. Begin at one end of a bed, and cut a trench across deep enough to take the cutting as far as the lowest branch. The top side of the trench should have a slight slope, and against this slope the cuttings should be laid roots downwards, and about three inches from each other. The cuttings having been placed in the trench as described, against them a sloping bank of soil, about 4 inches broad, should be laid, and against this bank another layer of cuttings, which are again covered like the first row, the subsequent layers being placed the same way, so that cuttings will be 3' x 4' apart. Immediately after being planted they should be watered, and should have water regularly morning and evening and sufficient to thoroughly sink into the soil. Of good cuttings, about 5% die in the nursery. Care must be taken that the lowest fork formed by the stem and branch of the cutting should not be buried.

Burnt Earth.—It will be noticed that under the heading "Digging" I have recommended all roots, etc., to

be heaped. Before the planting is taken in hand, all remaining timber not wanted lying in the clearing, should be added to these heaps, the latter should be carefully covered with soil and fired. Any green stuff added to the heap would be all the better as it would check too rapid burning. Should the earth be burnt red like a brick it is almost worthless. When the heap is burnt all charcoal and unconsumed wood must be raked or sifted out, and the heap left to cool.

Planting.—The clearing now being ready to receive the plants, directly the rains have well set in this work should begin. The cuttings should be carefully taken from the nursery and carried to the field in covered baskets. Never take too many cuttings at a time. Each man should have a mamotie and from 15 to 20 plants. He begins by opening up the ridge down the centre of the hole and from the post, to a depth of 9 inches or so and at a slope. In this the cutting is placed, roots downwards with the head (which by now should have from 2 to 3 shoots growing) well out of the ground and resting against the temporary post. The plant should be carefully covered, the soil being heaped as originally, and immediately and thoroughly shaded, too much of the latter being preferable to too little.

Application of Burnt Earth (the first).—Directly the plants have well started, about 40 lb. of burnt earth should be applied to each vine. In applying it should be put on the surface (the soil having previously been slightly loosened) and about 6 inches from the post.

Tying.—The shoots which grow from the fork, formed by the branch and stem, should be trained straight up the post. In no case would I allow more than two shoots to grow. The eas as they grow should be tied at every joint, but not too tight, and the material used for tying should be flat. Some allow all the branches to remain on until the vine is "let down." I advise that, with the exception of 4 or 5 branches at the top of each vine, the others should be cut off during the tying process. Care should be taken that, if possible, the three upper branches should have no barren joint between them. My reason for cutting off the branches during growth is that the wound has time to heal, and no risk is run of the plant rotting at one of the freshly cut joints when "let down." In tying, never tie any of the branches, but merely the stem, and below each joint.

Permanent Posts.—Splitting of permanent posts should commence directly after planting, as this is the slowest, hardest, and most expensive work of all. The posts should not exceed 13 feet in length, and should not be less than 6 inches in diameter. The hardest and best timbers should only be used. At the end will be found a list of timbers suitable for this purpose. For the work, each man will require an axe, a wedge-shaped axe, measuring about $12'' \times 3'' \times 2\frac{1}{2}''$, and two iron wedges measuring about $18'' \times 3'' \times 3''$, and a chisel $24''$ by $2''$. Unless used immediately, split posts should be laid flat on a raised scaffolding until required. This will keep white ants off. One good man will cut up and split, on an average, ten posts a day.

Letting Down.—When the vines have reached the top of the temporary post, they should be taken off and buried, otherwise called "let down." This requires great care, and is done as follows:—The man begins first by removing with his mamotie all sand, stones and rubbish within a radius of two feet of the post. He then with a blunt pointed stick digs back on both sides of the part of vine which is in the ground (taking care not to break any of the large lateral roots) until it comes to the end of the original cutting, from which he will find from one to half-a-dozen or what may be called taproots growing. On reaching these latter he stops digging, but releases all the other lateral roots by digging along them until he reaches the end. However, should any of the lateral roots go beyond the radius of two feet I would not follow them to the end. The object in following the lateral roots is to find out in what direction they run, as otherwise they may be cut in two in digging the hole for the vine or permanent post. On no account loosen the tap root or roots. Having laid bare the roots, the vine is next detached from the temporary post and laid flat on the ground, out of harms way. The post is then

pulled out of the ground, and in its place a hole is dug large enough to take a permanent post, and 30 inches deep. The permanent post is then firmly fixed in the hole. I have not tried it myself and do not know if others have; but I do not think it would hurt the vine if the lower end of the post were to be tarred. Having fixed the post the ground should be dug up and the soil pulverised within a circular area of two feet radius from the post, and to the depth of one foot, leaving a space of 4 to 6 inches directly round the post untouched. All bits of wood and rubbish must be carefully removed. The hole, or more properly trench, thus cut must be at the same level as the end of the original cutting from which the tap root starts, and this level must be carried all round. The vine is then laid, roots down, in a circle in the hole, and about 15 inches from the post, and the end where the branches are, must be tied to the post, care being taken that the fork of the lowest branch be not buried. Should there be a double vine, the odd one is carried away from the trench, and the head fixed on to a post placed slantingly in the ground, a stick being placed to mark where the two vines join. The vine or vines are now covered in, the soil being gently pressed down with the hands, and the space levelled. A hollow should not be left as water will collect in it, stagnate and rot the vine. Should any portion of the vine be damaged in letting down, that portion should not be covered, but left exposed until hardened, when it may be covered like the other portion. The portion of the vine above ground should be tied below every joint. The odd vine when well started can be cut off from the main stem and used as a supply which can be let down on a permanent post direct, thus saving at least six months. This latter I advise being done only in wet weather, and the supply thus put down must at once be thoroughly shaded, the shade not to be removed until the vine has got a good start, and even then the removal being only gradually effected. The other work can be done in almost any weather.

Application of Burnt Earth (the second).—While the work of letting down is proceeding, men should be put on to make burnt earth. I advise it being made in jungle this time, as from the mould being added it is richer. As each vine is let down, about 80 lb. of burnt earth should be applied on the surface, and all round the vine, and about six inches away from the post, the soil being first gently loosened.

Pruning, Topping, Tying.—The vine having been let down, it should be allowed to grow about three feet up the post having been tied at each joint as it ascended. It should then be cut down to above the third or fourth branch, thus leaving three or four forks, and the cuttings either sold, should there be a sale for them, or put into the nursery for supplies or extension of cultivation. If cuttings are not wanted for supplies, sale or extension of cultivation, the vine can be topped above the third or fourth branch directly it is let down. From these forks either two, three or four shoots will be thrown out, in some cases, however, there may be only one. In the latter case, let the shoot grow to a foot or so, and again cut it down, when it is certain to throw out two or three other shoots. These shoots should be trained up the post on three sides, or if there be only two shoots, on two sides equidistant from each other. The material used for tying should be passed over the three shoots, provided of course they are all equal in growth and should be tied below the joints. Each shoot, as it grows, will throw out branches alternately. Should however any of the shoots fail to do so, it should be immediately topped below the barren joint, provided cuttings are not required. In the latter case, allow the vine to grow to about two feet, and then top it below the barren joint. If cuttings are required, allow the vine to grow up to about $5\frac{1}{2}$ feet, then cut it down to three feet, but if not wanted it can be topped when it reaches the height of three feet. The object in stopping the growth is to force the sap back, to allow the vine to spread out, and to strengthen it generally, as otherwise it will grow up long and scraggy. Attention to this operation will make a difference of at least 50 per cent in the crop. During its growth the vine will be constantly throwing

out blossoms, which should be nipped off. On a ten feet post, the vine should be topped three times, the third time as it reaches the top, when the shoots composing the vine should be tied together and topped. As the vine is topped every three feet or so, that portion should be tied with some strong material, small unsplit rattan being used in the Straits. All subsequent handling consists in stopping the upward growth of the vine and keeping all suckers and shoots down. The vine should reach the top of the post in between 3 and 4 years, according to soil and cultivation. I would not allow the vine to bear until it has reached the top of the post. The Chinese, however, begin to pick when the vine is from two to two and a half years old, but they allow it to bear gradually from the bottom upwards. A vine is fully matured when 5 years old.

Manuring and Manures.—After letting down, vines should be manured at least once a year. From the time of coming into bearing, always twice a year. Time of manuring—in dry or showery weather. The Chinese use only burnt earth and fish manure, but chiefly the former; and there is no doubt that it has a wonderful effect. Besides the abovenamed manures, liquid cattle manure, applied during dry weather, has also a wonderful effect. Before using bulky manures they should be burnt with the addition of earth mould, the same way as burnt earth; otherwise they will attract whiteants and root-destroying insects of all sorts. I have seen castor-cake applied both to the surface and below the soil. The result in both cases was the death of the vine. In a dry climate or in dry weather, I strongly recommend thatching. Manures should be applied on the surface, but may be lightly covered with soil. Forking should not be done as the risk of injury to the roots is too great. As far as I am aware bones, poonac, lime (pure) or guano have never been tried.

Crop, and Picking and Curing.—There are two crops a year, December—January, and July—August. When the bunches have turned a dark green colour, they are ready to pluck. This is done by nipping off the bunch whole. It is then dried (by the Chinese on mats placed about 6 feet above the gambier furnace) either by fire heat or sun heat, is then separated by rubbing on a rough surface such as a mat and is subsequently put through a fanner, packed in bags and is then ready for dispatch. This is Black Pepper. White Pepper is good by fermenting or, more properly speaking, soaking for several days the berries that have turned or are on the point of turning red. It is then stamped out with the feet to remove the outer skin, washed and dried in the sun. I have no doubt that with a drier, separator and fanner, better work and finer pepper than is obtained at present can be readily turned out. The following may be considered a safe estimate of crop per vine; for the 3rd year, 1 catty; 4th year, 1½ catty; 5th year, 3 to 3½ catties; a catty being 1½ pound.

Buildings.—Should cattle-sheds be built, I strongly advise that the floor should be rendered as watertight as possible so as to lose no urine. Near all coolie lines, too, there should be a covered-in pit, and tubs should be placed along the verandahs to receive waste rice and rice water, etc., as by these means an enormous amount of valuable manure can be collected. Should cattle be kept, I strongly advise a few pigs being kept also. For plans of buildings suitable for an estate I can recommend *The Ceylon Planters' Association's Prize Essay on Buildings*, by Messrs. Owen and Ballardie.

Enemies of the Pepper Vine.—The Pepper Vine, like most other economic plants, is subject to disease and attacks from insects. Its chief enemies are white-ants, black-bug, white-bug, borer, mole-cricket, cinchona-caterpillar and a certain insect belonging, I think, to the *Hemiptera*.

Cures and Preventive Measures.—A strong solution of Tuba root is quite sufficient to keep away white-ants. Tuba root is used by the Malays and Chinese to poison fish in rivers, and is common all over the Straits. Black and white bugs can be got rid of by applying a solution of Tuba root and the juice of common damaged tobacco. In mild cases, ashes, lime or sulphur and lime, applied early in

the morning, will be found sufficient. Borer begins always by attacking the joints of the branches and its presence is known by the light yellowish colour of the bark. I know of no prevention, and provided it has not gone far, it can be easily caught. It always works round the joints, and when it has completed the circle, it commences to bore down the centre of the branch and sometimes, but very seldom, the stem. The mole-cricket goes for the roots, but does the least damage of all. If it has gone too far to dig out, I can only recommend the hole being plugged up as far as possible with clay. The green cinchona-caterpillar attacks the leaves only, but of these it is capable of devouring an enormous quantity. The only way to get rid of it is to send a cooly round to collect and destroy them. The last mentioned insect (*Hemiptera*?) only appears in dry weather and sucks the juice from the young shoots and branches, generally killing the latter. It is to be found at the junction of the branch and stem. I fancy a weak solution of kerosine and water would clear them off, say a wine glass of oil to a bucket of water.

Timbers.—In the Straits I would only recommend the following timbers to be used for permanent posts:—

- Tampenis (*Stactia sideroxyton*). Red, very hard, close grained.
- Krangoe (*Dilum indicum*). Dark red, hard, close-grained.
- Panaga (*Adinandra Danosa*). Bright red, hard, cross-grained.
- Tumbooso (*Fagraea Pergrina*). Very hard, close grained, long fibre.
- Billian. Hard, heavy, close grained. (called Billian Wangy).
- Ballow. Colour dull gray.
- Kulim. Very like Ballow.
- Rassak (*Vatica species*). Red is the best.
- Darreo (*Apodytes species*). White, close grained, agreeable smell.
- Tambaga; Damar Putih; Bawang, light yellow and smells like an onion. Kayu Kuning, I think, is another name for Kulim. Rungas (*Gluta volutinum*) a handsome wood used for furniture making, dark red with black veins. Lasts well. The above timber list is partly taken from the *Tropical Agriculturist*.

ESTIMATE OF EXPENDITURE.

To these rough notes I append an estimate for opening and bringing into bearing 10 acres of pepper. Rate of pay 30 cts. of a \$ per cooly.

	\$
Felling, clearing and burning (contractor taking risk)	70
Digging one foot deep, heaping all roots for burnt earth and keeping trees for posts	100
Lining, cutting pegs, etc.	15
Roads 4 feet	20
Drains 18 inches	20
Temporary posts with carriage	200
Holing, fixing temporary posts	19
Nursery plants \$ 120; cost of nursery and watering \$70	190
Planting and shading	25
Burnt earth	72
Tools, contingencies	150
Weeding for six months at 10 cts. per acre	24
Application 1 pic. burnt earth	30
Tying, one man, 1,500 vines	54
Nursery.—plants 8 1/2. Cooly \$27; vacancies 15	41
supplying and shading	10
Upkeep roads and drains	30
Contingencies	50
Expenditure (Total) Pepper 6 months old	1325

	\$
Permanent posts 889; say 890 to the acre.	360
Letting down.	340
Transport of posts (this depends on distance)	400
2nd application of burnt earth 1 Picul.	
Burning and applying	170
Supplying and nursery	57
Upkeep roads and drains	54
One man tying 1500 vines for 6 months \$ 54	
One man tying 500 vines for 6 months \$182	216
Weeding at 45c. per acre	54
Contingencies, purchase of ladders, etc.	100
Total expenditure pepper 18 months old	3074
Tying, one man, 500 vines	324
3rd application of burnt earth. burning and applying	340
Nursery	54
Supplying, shading	15
Weeding at 50c. per acre	60
Building a small store	300
Purchase of small dryer, fanner	120
Curing and transport of 45 } Piculs Pepper }	45
Contingencies, Tools, Sacking	150
Total for Pepper 2½ years old	4,482
" " (one year) 3½ "	1,000
" " " ") 4½ "	1,200
Total	\$6,682

CROP:—	
Sale of 50,000 rooted cuttings } In 2 years, \$15 per 1000 }	750
Sale of 45 Piculs Pepper off } 2½ year old vines }	675
Sale of 134 Piculs Pepper off } 3½ year old vines at 1½ catt. }	2,010
Sale of 267 Piculs Pepper off } 4½ year old vines at 3 catt. }	4,005
Profit off 10 acres Pepper 4½ } years old }	\$758

I have put down \$15 per picul as value of Pepper. I have further made no allowance or salary, bungalows, lines, etc., nor for purchase of land and interest, as I fancy, beyond my own district, the estimate of expenditure may not be of any great use, owing to cost of labour.

PLANTER.

PROTECTION FRGM LIGHTING.

Professor Oliver Lodge has, during the past spring, been delivering before the Society of Arts a series of lectures on the protection of buildings from lightning. The visitations of lightning in this country are sufficiently frequent and sufficiently serious to constitute the subject one of special interest. In the course of these lectures, the learned Professor has not only suggested numerous improvements in the existing methods of protection, but has, at the same time, given his audience much interesting information about lightning itself and the peculiarities of its behaviour. One hundred and fifty years ago practically nothing was known about the subject, and it was not until 1751, when Benjamin Franklin flew his kite at Philadelphia, that proof was obtained that lightning was, in fact, nothing more than a huge electric spark. No sooner was the nature of lightning thus explained, than the slight electrical knowledge which people then possessed was utilised to protect buildings and ships from its destructive agency, though, from a want of clear perception of its action the protection as then applied was sometimes quite illusory, at others positively harmful. Atmospheric electricity is presumably frictional, occasioned by the friction

of mist against dust and ice particles, in the air. Hence thunderstorms are most frequent when, after a spell of dry weather has filled the air with dust, a damp mist-bearing current mixes with a current of dry air; as for example when the south-west monsoon penetrates into the dry, dust laden atmosphere of Upper India. Electricity is apparently first generated in the upper atmosphere, and so long as there are no clouds it is possible for a very high state of electrification to exist in these regions without any ill-effects following; but clouds act as conductors, and by their means the electricity is brought down into the lower atmospheric strata, until at last it comes to within sparking distance of the earth. When this condition has been established the portion of the earth's surface covered by the cloud, the intervening stratum of air, and the cloud itself, together form a sort of natural Leyden jar, the cloud forming one coating of the jar, the earth the other, and the air acting as the glass or dielectric between them. Now it can be shown by laboratory experiments that if electricity is poured into a Leyden jar, there arrives a time when the tension becomes so great that a discharge between the two metal coatings takes place, the glass is pierced and the tension is relieved. An exactly similar action occurs in nature. By process which need not be explained here, the electrification of the natural Leyden jar at certain times increases with alarming rapidity, the coatings draw together some portion of the cloud covering descending towards the earth, till they reach sparking distance, and then with a crash the discharge takes place. The dielectric (the air) is pierced just as the case with the glass in the Leyden jar, and any opposing obstacles such as men, animals or buildings are not uncommonly destroyed.

For a very considerable period after the discovery of the nature of lightning the erection of lightning rods was strongly opposed by all the religious fraternities. The old idea that the lightning was Heaven's destroying fire clung to them, and it was considered impious to interfere or try to prevent the destruction which, for some wise purpose, was no doubt providentially designed. After a time, however, the heretical rods became fairly common, first in Protestant Germany and subsequently in France and England, and now the only difficulty that Professor Lodge encounters in his advocacy of lightning rods is to induce people to abandon their old ideas and adopt the precautions which recent advances in science have shown to be necessary for proper protection. Numbers of people still believe that a lightning-rod protects a circular area, of which the height of its point from the ground is the radius; others, that a ball at the top of the conductor is the correct arrangement; whilst not a few insist that if the "earth" end of the conductor be connected to a small water-butt, or pool, all the proper precautions have been taken. Each of these ideas is distinctly erroneous. As regards the first, Professor Lodge says all such ideas as areas of protection are perfectly illusory, and of the second, that points to the sky are now recognised as unquestionably correct. To those who firmly believed that once the "earth" end of a conductor is led to water all danger is over, the Professor replies that, as a matter of fact, there is no safety in water unless it form a large, continuous sheet, and most certainly any large flash which was discharged into a water-butt or small pool of water would make a very considerable disturbance when it left the conductor.

The conclusions from these experiments are that,

given a single cloud over a house or building, a sufficient number of points exposed on the roof of the building will take away all the electricity from the cloud and entirely prevent discharge of any sort. There is no necessity for great spikes and tridents, but simply that there should be rows of small points along all the prominent ridges. Such an arrangement will effectually discharge, without the slightest flash or danger, any cloud which is simply hanging over the protected building and quietly assimilating electricity in order to get energy enough to spark. This plan of protection is much the most satisfactory, as it prevents, except in very exceptional cases, the lightning flash occurring at all. Still sometimes it is hopeless to attempt to stop it. One cloud sparks into another which is already keeping the points at their full work in order to exhaust it; and crash it all comes at once. Points are no good under such circumstances: the electricity has no time to choose its route but simply crashes through the air, and it becomes a pure accident where it may strike. To carry sparks of this sort off it is necessary that the roof and indeed all the more projecting portions of the house should be connected up with a good stout iron tape, the end of which should be buried well into the ground and surrounded by a fair supply of coke and salt so as to ensure a certain amount of moisture. Under such conditions a house is supposed to be, and practically is, perfectly safe.—*Pioneer*, August 7th.

VEGETABLE PRODUCTS IN CENTRAL AFRICA.

The following notes on vegetable products in Central Africa are gathered from a recent report furnished to the Foreign Office. Rubber, it is stated, is now found in very small quantities, and, indeed, can scarcely be considered worthy of mention. This is undoubtedly owing to the destructive method adopted by the natives of extracting the juice. Under proper treatment rubber might have become a profitable export. At Mount Zomba *Landolphia florida* was found in large quantities, but the plant is now almost exterminated. Rubber from this species sold in Africa last year for 1s. 6d. per pound. The cultivation of rubber-yielding plants by Europeans appears to be attracting attention, and it is stated that a plant of *Ficus elastica* that had been introduced into a private garden had grown so well that it was intended to propagate it extensively. Indigo grows wild all along the slopes of Mount Zomba. It forms a large bush, and is perennial. Its growth is luxuriant, and its cultivation and manufacture might possibly be undertaken with advantage.

Of the Kombe (*Strophanthus*), which has attracted so much attention in this country of late, it is stated that during last year over 1100 lb. were exported from the districts around Zomba, which realised in the London market 9s. per pound. The following description of the plant and its uses is given:—"Strophanthus is considered the most powerful poison the natives possess. It is found at a low level, and, as far as can be gathered from personal observation and native sources, is not to be had on the high land. The supplies hitherto obtained have been drawn from the right bank of the River Shire below the Murchison Rapids. There is apparently more than one species, or, at least variety, the distinguishing feature being a much smaller pod and fewer seeds. At present information relative to these other varieties is scant. The *Strophanthus* is a strong climbing plant, and is always found in the vicinity of high trees on which it supports itself. The stem varies in diameter, but has an average of a few inches. It lies on the ground in folds, the branches supporting themselves on the nearest trees. The young branches have a red habit, and are in appearance not unlike Elder. The fruit grows in pairs, and has a peculiar appearance, very like a pair of immense

horns hanging to a slender twig. The fruit begins to ripen in July and lasts till the end of September. The natives are quite ignorant of its age, or how old a plant may be before it bears fruit. The native method of preparing the poison is very simple. They first deprive the seeds of their hairy appendages, and then pound them in a mortar until they have reduced them to pulp; a little water is then added. This is done by using the bark of a tree containing a gummy substance, which helps to keep the poison on the arrow in the event of its striking against a bone. The poison thus prepared is spread upon the arrow, and allowed to dry. Game wounded by arrows poisoned with *Strophanthus* dies quickly; the flesh is eaten without evil effect. The only precaution taken is to squeeze the juice of the *Paobab* bark in the wound made by the arrow, and this counteracts the evil effect of the poison. Buffalo and all smaller game are killed by this poison."

Though fibres are much in use amongst the natives, it is said to be doubtful whether those of native preparation would command a profitable sale in the home market. In the highlands of Zomba *Senecioides longiflora* grows abundantly, and *Lakaanga* here is obtained from it. At lower elevations, such as Lake Shirwa; and *Livingstonia*, another species, is found. The fibre which is obtained from the leaf might be used for coarse manufactures, but proper machinery would be required to perfectly crush the leaves and obtain the fibre. The *Buaze* fibre (*Senecioides longipedunculata*) is used by the natives for stringing beads and for making twine; and a fibre known as *Ntingo*, said to be from a *Tiliaceae* plant, is much used by the fishermen on Lake Nyassa for making nets.

On the subject of Coffee culture it is stated that, promising as it seemed to be two years ago, the result hitherto obtained has not realised the expectations of the planters, and though the quality of the Coffee grown at Zomba has been established beyond doubt, still more experience is required before it can with certainty be said whether the cultivation of Coffee in those districts of Africa will be successful or not. The crops grown last year, both in the Mandala and Zomba districts, were, to a great extent rendered unsaleable by the berry becoming diseased just before attaining maturity. The same disease is said to be showing itself again this year, the cause of which is partly attributed to allowing the trees to bear too profusely. In Coffee culture the difficulty of obtaining labour presents a serious obstacle. At the season when the planter requires a large supply of labour to keep down weeds and plant out new ground, the natives are all employed making their own gardens, and will not do other work.

Proprietors of small plantations may, with their few permanent hands, tide over the difficulty till workers can be obtained, but the question of labour forms a serious consideration, and will tell greatly against any foreign enterprise on a large scale being successfully carried out in this country. Another drawback to the prospects of Coffee planters is the heavy transit freights to the coast. Until competition brings about a lower rate of charges, a serious barrier is opposed to the development of European enterprise in these territories.

In favour of the cultivation of Coffee it may be stated, that land with suitable soil can be purchased cheaply. Though unlimited acreage of good soil may not be obtainable, still sufficiently large areas to justify planters in establishing plantations can readily be got. At present about 90 acres of land in the Zomba and Blantyre districts are under Coffee cultivation, a considerable portion being new plantation formed this year. Sugar-cane grows well in the Zomba district, and is rich in saccharine matter. It is successfully cultivated and manufactured by Messrs. Buchanan Brothers, who have created a sugar mill on their estate. At present it would not pay to export sugar from Zomba, and as yet it has only found a local market with the Europeans in these districts. The natives, though very fond of sugar, have not shown any desire to purchase the manufactured article.

A few Tea plants have been introduced, and grow fairly well: but as yet nothing definite can be said of the prospects of Tea plantations. In the highlands it is doubtful whether the cultivation would ever prove successful, and the uncertainty of labour would render it a very precarious undertaking.

Cinchona has been introduced and shows every prospect of its cultivation being a success, from the fact that plants three years' old are now 6 feet high. It remains to be seen whether the quality of the bark will justify the planters' investment of capital, and whether the state of the market will offer encouragement. A small plantation of 1000 plants has been formed this season at Zomba.—*Gardeners' Chronicle*.

THE PLANTAIN TREE A PROTECTION AGAINST MALARIA.—The Hospet Taluk Board has adopted the suggestion of Mr. H. St. A. Goodrich, the Collector of Bellary and President of District Board, who has found from experience that a belt of plantain trees of the ordinary size and thickness planted between irrigated land and crowded towns or villages protected the latter from malaria effectually. The Taluk Board has directed that this be carried out wherever practicable.—*Madras Standard*, Aug. 10th.

LIQUORICE CULTURE IN RUSSIA.—Liquorice root (*Glycyrrhiza glabra*), which is now but little cultivated in this country, the chief supplies coming to us from Spain and Italy, is said to have become of late an important article of cultivation in the neighbourhood of Batoum. A few years ago its existence was scarcely known or heeded. It is now grown in great abundance at Liakha, in the district of Elizavetopol. The quantity exported from this place in 1887 amounted to 1400 tons, and the average price on the spot of production is about £2 per ton, and at the port of Batoum, properly pressed and packed, it realises over £6 per ton.—*Gardeners' Chronicle*.

HIGH-HANDED CONDUCT OF THE CHINESE TEA GUILD AT SHANGHAI.—Our files of China papers are full of discussions regarding the tea trade and tea traders. It is rather surprising, just as we were feeling sympathy with the Chinese on the decadence of their great industry, to be told that very bumptious conduct on the part of the members of the Tea Guild in Shanghai was due to the fact of their having made such large profits at Hankow that they thought and boasted that they could deal as they pleased with the foreign merchants. Accordingly, on mail day, and without one word of warning, a paper was presented to the merchants, to which instant signature was demanded, by which they should be made to agree to a rule that each godownkeeper should give receipts for all tea on its arrival, with no time for examination. The merchants, of course, refused, and the Tea Guild stopped business in tea and everything. The foreign Consular body, on being appealed to, denounced the conduct of the Tea League as illegal, and so represented it to the Taotai, who, as the Guild is amenable to official rule, will bring the bumptious tea dealers to their senses. Meantime, we reserve all our sympathy for the Chinese tea-growers.

ASBESTOS LINING.—The *Citizen* speaks of an excellent adaptation of asbestos for internal use in buildings in the shape of a cardboard, manufactured in sheets five feet by four feet, and produced at the very moderate cost of a minimum of 6d per square yard. At this charge the manufacturer offers a sixteenth of an inch board, and this we found quite sufficient to protect a wooden partition from various flames. Another specimen had been selected to protect the adjacent wood work from an American stove, and on being removed no perceptible deterioration either in fibre or appearance could be detected. The "flatness" obtained by affixing to a wall surface seems to give this substance a distinct advantage, and, although corners of the sheet were

subjected to the action of the flame, the adjacent asbestos seemed to restrict the damage to the portion actually uncovered. It does not seem that with any ordinary care in fixing such positions of attack by fire can be anticipated, but we think it is unlikely that in the case of an accidental fire the minute portions of wood exposed would be subjected to such heat as that offered in the experiment. An additional advantage is that the boards readily lend to decorative purposes, and, indeed, present an excellent surface for the painter.—*Oil, Paint and Drug Reporter*. [Query: suitable for internal covering of the walls of tea stores?—Ed.]

FRUIT WITHOUT SEEDS.—The following will be of much use to such of our readers as take interest in the cultivation of fruit trees. It is well known that high cultivation tends to produce fruit containing fewer seeds, until at last all the powers of the tree or plant are directed to the perfecting of the pulp. In some cases no seed appears. The finest varieties of plantains and bananas, pineapples and bread-fruit have no seeds. Of course, all such trees and plants have to be propagated from shoots or cuttings. It has been a common belief that the life of such could not be prolonged indefinitely. In the case of the apple and the orange this is true. The trees have to be raised from seeds, and the seedless varieties are grafted upon these. Such varieties of fruit could not arise in a state of nature. They are the result of selection by the early races of mankind. It must have been the case that the fruit was abundant, so that people were content only with the best. It must a so have been a favourite, if not a necessary article of food, or men would not have improved it by careful selection. Humboldt thought that some species of the plantain were native to America, but the early discoverers made no mention of finding them there. If we could prove it to be native, it would raise our estimate of the civilization of the people. As the case stands the probability is that these seedless fruits were first produced in the East Indies and from that point have been carried around the world. The name of the banana indicates that it was given in the East, and that the fruit was a leading one in the ancient markets.—*The Indian Tea Gazette*.

ORANGES IN NATAL.—There appeared in the *Agricultural Journal* of May 31st, a letter from Mr. MacOwen, the director of the Botanic Gardens, on the subject of orange trees. The trees were represented as dying from some disease, not scale, which was preceded by large crops of indifferent fruit, scant foliage, and withering of the upper twigs. Mr. MacOwen is of opinion that the trees have suffered at the root, owing to want of care at the time of planting, the ground not having been trenched deeply so that the trees having plenty of good soil around their roots horizontally have sent the leaders through the little that was below into the unbroken subsoil. He recommends transplanting if the tree is not too far gone, and if that cannot be done, the digging of a trench on two sides of the tree carrying it well down into the hard subsoil pan so as to be at least a foot lower than the decaying roots. The trench to be filled two feet deep with the best of the top soil, mixed with an equal bulk of well-rotted manure. As the recently-formed rootlet tips and the root hairs on the youngest parts are the only absorbent portions of the root, no amount of manure dug close to the tree is of any use, except in so far as it is carried away by percolation to the rootlets, a yard away and 20 inches deep. He condemns the custom of drenching the trees with irrigation water; irrigation, without proper, quick drainage below, being almost as bad as drought. "You want," he says, "not only to wet the soil, but to cause the water to slip quickly through its interstices and pull the vital air after it. If I were to write for an hour I could tell you nothing more valuable than that simple, but oft-forgotten, law of cultural necessity."—*Natal Mercury*.

CEYLON UPCOUNTRY PLANTING REPORT :

DRY WEATHER AND ITS EFFECT ON THE LOAFING COOLY—
TEA ESTIMATES AND METEOROLOGICAL FORECASTS—A
PROSPECTIVE RUN ON TEA PLANTS—THE "CYCLONE"
WITHERER.

20th August 1888.

We are all herabouts suffering at present from an enforced idleness. You can hardly call the present style of weather a drought, as every now and again there is a sprinkling of rain; but the showers amount to so very little, that for all practical purposes we might as well be without them. A drought, pure and simple, would not "stick us up" more than we are. You get round your plucking a great deal quicker than you desire, and the average seems daily to get less and less: the ground is too hard and dry, to allow of almost any kind of tillage or manuring: the weeds won't grow, nor the tea flush, and when work gets scarce, and you are at your wit's end how to employ your labour in anything profitable, the muster in the morning grows bigger and bigger, the lines emptying themselves of all the loafers and lazy ones, who have come to add to your discomfiture, and be a burden as usual. Why don't the lazy ones stay in? and why should an attack of all but rainless weather have a moral effect on the Tamil loafer? For the spurt is only temporary. As soon as anything like normal weather returns, and a vista of work is visible, the lazy one absents himself from the parade, and the loafer, if he does turn out, is back again at his lines long ere the sun is high. He falls from his high estate into his old evil ways, frequenting the bazaars, indulging in petty thefts, and steadfastly setting his face against anything like steady work. He often in this way suffers a long eclipse, but when the appointed time again comes round, when the labourers are many, and work is hard to get, he brightens up once more, seizes the opportunity, and tries to re-establish his character for industry. But his case is hopeless, and the knowledge of that is where the shoe pinches us.

Two-thirds of the year are now all but gone, and there will need to be changed times for what remains, if our modest estimates for tea are to be any way reached. I would be ashamed to say how far we are behind; but I did hear of a man who has the privilege of revising his estimate and who thought of reducing it by a fourth, on the understanding that the kind of weather we have been favoured with during the last eight months was to be regarded as a fair sample of what was yet to come. What we want is a good meteorological forecast, more than anything else. Given that, tea estimates could be made safe enough; without it the best is but a guess. The happy guesser is he who puts it low. I suppose that by and bye, if careful records be kept, we will be able to go over the different months of the year, and say that with this given rainfall and that given rainfall the outturns ought to be so and so and so and so; but that day of exact knowledge is considerably ahead of us yet.

This want of scientific knowledge perhaps accounts for the hopefulness which inspires the belief that the leeway will yet be made up. Meanwhile, we wonder when the rain is going to come, and when there will be a suitable display above ground of that abnormal activity below, which we fondly believe the tea bush indulges in in times like these? If it is not doing that, it must have an "uncommon large" quantity of "pure cussedness" in its nature.

When the N.-E. monsoon comes in I expect there should be a considerable run on plants, for

this one has been particularly trying and the numbers lost are very considerable. Especially is this so on old land, where planted even with two hands and a head they haven't half the chances of those put out on new ground say with your foot alone.

There is a chance, I hear, of the new Indian witherer, the "Cyclone," being tried ere long in Ceylon. It has a name for business, does away with withering tats and sheds, withers the leaf during daylight, and allows of its being cured at once. It is a farewell to the worry of wet leaf, if you are able to spend the coin. The cost of a machine to wither fifty maunds of green leaf is R1,300, and one that would do four hundred maunds can be had for R7,000. These figures include charcoal stove fittings, trays and woodwork, but if you fit up your own trays and supply your own woodwork, the respective prices are R1,055 and R4,550. There are other sizes between. It will be interesting to know how the machine will work when tried here, and the comparative prices of tea which has been cured by the "Cyclone." It is just a little late in the field.

PEPPERCORN.

SPRING VALLEY COFFEE COMPANY,
LIMITED.

Directors.—John Brown, Esq. (Managing Director) Edward Conder, Esq.; Leon Famin, Esq., and Henry Hart Potts, Esq.

Report.—To be presented to the Twenty-third Ordinary General Meeting of the Company, on Thursday, the 2nd day of August, 1888, at 12 o'clock noon.

The usual Annual Accounts are now presented to Shareholders, viz., Profit and Loss Account for Season 1886-87, Balance Sheet made up to 31st May, 1888.

The Crop of Coffee secured for Seasons 1886-87 amounted to 3,822 cwt. 0 qr. 3 lb. against an estimate of 3,600 cwt. given in last year's Report. The total value of Coffee sold, including that disposed of in Ceylon, amounted to £17,437 1s 11d.

The first small tea crop was plucked on Spring Valley at the end of season 1886-87, and amounted to 3,347 lb realising £157 15s 8d.

The average selling price of the coffee was 88s 5d per cwt. and the tea sold at an average of 11½d per lb; the total amount realized from sales of produce being £17,594 17s 7d.

The total expenditure in Ceylon and London, including the loss on Oolanakande estate of £382 4s 9d amounted to £11,099 18s 8d, which deducted from the value of produce leaves a profit for the year of £6,494 18s 11d.

A sum of £100 10s 5d is brought forward from last year's account, giving a total available balance at the credit of profit and lost account of £6,595 9s 4d.

On the 7th of January last a dividend of 2½ per cent was paid on the Capital of the Company, amounting to £2,000, and the directors now recommend the distribution of a dividend at a similar rate, making 5 per cent for the year, and leaving a balance of £2,595 9s 4d at the credit of profit and loss account, and for the reasons given below the Board consider it advisable that this sum should be carried forward to next year.

During the above season even the earlier clearings of tea could only be plucked for a very short time owing to the tea plants being so young, and as heavy expenditure had to be incurred on the general upkeep of all the clearings, and also on machinery and conversion of a part of the coffee store on Spring Valley into a tea factory, the profit realised on the coffee is considered very satisfactory.

The following is the acreage now under tea on the Company's properties:—

TEA.

Planted Nov.-Dec., 1884, on Spring Valley..	271 acres,	now 3½ years old.
„ May, 1885, on Oolanakande..	143 acres,	now 3 years old.
„ Nov.-Dec., 1885, on Spring Valley..	230 acres,	now 2½ years old.
„ May, 1886, on Oolanakande...	7 acres,	2 years old.
Total area under tea 651 acres.		

From the above table it will be seen that most of the Tea has now attained an age when a considerable yield of leaf may confidently be looked for, while on the other hand as this yield increases the appliances for treating the leaf will also have to be supplemented.

The Tea is all growing well, and the quality of the present year's crop shows a satisfactory improvement on the first pluckings; the market, however, rules considerably lower.

The importance of manuring Tea which has been planted on land formerly under Coffee, as is the case with the Company's Tea clearings, is every day being more clearly demonstrated both in regard to yield and quality. During the current Season a considerable area has been manured with bulk, and this work will be continued according as circumstances and the results shown by the area already manured may warrant. Reports recently received with regard to the manured area are encouraging.

CROP, 1887-88.

During his recent visit to Spring Valley Mr. Brown was much pleased with the appearance of both Coffee and Tea, and there seemed a possibility of the departure of green bug, 75 per cent of this pest having been killed by the cold wet weather of December last.

Advices since to hand report the rapid increase of green bug, and although in his latest letter the Manager writes more favourably with regard to this pest, the Board fear that the original estimate of 3,140 cwt. from the 990 acres now remaining under Coffee will have to be very considerably reduced.

With this contingency before them, and also the possibility of having to convert into Tea a further portion of the Coffee area if the ravages of green bug continue, the Board consider it highly prudent to retain a substantial part of the balance standing at the credit of Profit and Loss.

The total estimate of Tea for the Season was 30,800 lb., and this will be exceeded, the deficiency of Crop on Oolanakande being more than balanced by the excess of Crop on Spring Valley.

Oolanakande Estate was for some time disappointing as to the yield of Tea leaf, but of late better results have been given, and it is quite possible that in another year's time this estate may be self-supporting.

The Government have decided to carry on the Railway on the present broad gauge, and that only as far as Hapatule, a decision which the Board much regret, as it will condemn the districts of Badulla, Madulsima, and Hewa Eliya, to permanently expensive transport.

This Company is now working a service of bullock carts of their own, by which they cart their produce to the present Railway Station at Nanuoya; by this means the Company effect a saving in cost and secure more regular transport.

From the information given them by Mr. Brown the Board are glad to express their satisfaction with Mr. A. T. Rettie's management of Spring Valley.

Mr. Edward Conder, a Member of the Board, retires on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors also offer themselves for re-election.

By order,

J. ALEC. ROBERTS, Secretary.

July 25th, 1888.

OUVAH COFFEE COMPANY, LIMITED.

CAPITAL £100,000, IN 10,000 SHARES OF £10 EACH.

Directors.—John Brown, Esq. (Managing Director), H. H. Potts, Esq., L. Famin, Esq., and Edward Conder, Esq.

Report to be presented to the Twenty-Fifth Ordinary General Meeting of the Company, to be held at No. 5 Dowgate Hill, London, on Thursday, the 2nd day of August, 1888, at 1 o'clock p.m.

The following Accounts are now presented to Shareholders:—

Profit and Loss Account for Crop 1886-87.

Balance Sheet made up to 31st May, 1888.

The estimate in last year's Report for the Coffee Crop of last Season 1886-87 was 4,000 cwts., and it will be seen that the actual weight sold in London amounted to 3,903 cwts. 2 qrs. 22 lb., and this, together with small sales effected in Ceylon, realised the sum of £18,429 3s 10d.

The quantity of Tea sold in London was 18,528 lb., and, inclusive of a small quantity sold in Ceylon, realised £972 10s 5d.

Cinchona bark was sold in London to the extent of 25,635 lb., realising £480 2s 6d. Cocoa and cardamoms of the value of £34 6s 1d were also sold.

The average gross prices obtained for produce were as follows:—Coffee, 89s 10d per cwt.; tea, 1s 0½d per lb.; cinchona bark, 4½d per lb.; and the total sums realised from the sales of produce amounted to £19,916 2s 10d.

The total expenditure for the year in Ceylon and London, after allowing for profit on Exchange, amounted to £16,069 11s 0d., which deducted from the value of produce sold, leaves a profit of £3,846 11s 10d for the year. To this has to be added the balance of £240 7s 2d brought forward from last year, giving the total sum of £4,086 19s 0d to the credit of profit and loss.

On the 7th January last a dividend of 2½ per cent was paid on the capital of the Company, which absorbed £2,500 of the last named sum, and the Directors now recommend the payment of a further dividend of 1½ per cent, making 4 per cent for the year. To meet the present dividend the sum of £1,500 will be required, leaving a balance of £86 19s 0d to be carried forward to next account.

So far as the actual profit is concerned the result of Season 1886-87 has not come up to the full expectations of the Directors, but they have no reason to be disappointed with the result shown when the work accomplished during the season is taken into consideration. Tea plucking to only a very limited extent was carried out during the season under review, as it will be seen that the only areas from which leaf could be gathered were the 9 acres planted in 1883 and the 317 acres planted in 1884, the latter large area only arriving at plucking age one or two months before the season closed. The total value of leaf secured from these areas, as already stated, amounted to £972 10s 5d, while on the other hand no less a sum than £1,260 11s 3d was paid on account of Tea during the season for machinery, factories, weeding, nurseries, planting, supplying, clearing,

&c. It will thus be seen that but for the large expenditure necessary for bringing Tea into cultivation and for providing the necessary appliances for manufacturing it, the profit on the year's crop would have been very handsome.

Looking to the very uncertain future that exists for Coffee by reason of the pests which are attacking it, it is, however, most satisfactory to know that a very large area of Tea has been planted and brought forward to an age when very considerable and remunerative returns may be expected; and it will be seen from the following table that nearly the whole area of the Tea planted will at an early date be self-supporting, considerable expenditure will, however, still have to be incurred in providing more machinery and factory space as the yield of leaf increases.

The area of tea on the Company's Properties is now as follows:—

		TEA.			
Planted Nov.-Dec..	1883 ..	1884 ..	1885	acres	
Glen Alpin Group..	9 ..	145 ..	272 ..	"	
Narangalla Estate..	..	82 ..	93 ..	"	
Hindagalla Estate..	..	120 ..	85 ..	"	
Total acreage and present age ..	9 4½ yrs.	347 3½ yrs.	450 2½ yrs.		
Planted Nov.-Dec..	1886 ..	1887 ..	Total		
Glen Alpin Group..	26 ..	16 ..	468 acres		
Narangalla Estate..	175 "		
Hindagalla Estate	205 "		
Total acreage and present age ..	26 1½ yrs.	16 6 mo.	848 acres		

The tea is all growing well and the yield of leaf increasing, but it is an established fact that tea planted on old coffee land, as is the case with nearly the whole of the Company's clearings, will have to be liberally manured to produce full and substantial Crops, and the Board are glad to be able to report that facilities and appliances for manuring operations exist in a marked degree on the Company's properties, and they are thus enabled to manure a considerable area of tea cheaply and liberally.

As recent experience has proved that Tea very readily responds to applications of manure, the Board have every reason to expect that a high average yield per acre will be secured, and the Tea already received from the Company's Estates has favourably established the question of quality beyond a doubt.

CROP 1887-88.

The area now under Coffee is 1,231 acres, and the estimated Coffee Crop for the above season was 3,300 cwts., but it is feared that owing to the spread of green bug the Crop will fall considerably short of this amount. The yield of Tea will probably be about 60,000 lb., and it is estimated that about 75,000 lb. of Cinchona Bark will also be harvested. These figures point to only a small profit being realised for the year.

Mr. Brown returned from Ceylon in May, having visited the Company's properties, and a report by him is now handed to Shareholders, dealing fully with the condition and prospects of their Estates, both as regards Coffee and Tea.

The Company used every influence to induce the Government to extend the Railway into the centre of the district of Ouvah, but the Board are sorry to report that the Government have refused to do this, and that they have only sanctioned the extension of the line as far as Haputale, which will practically in no way benefit this Company, and should the present out-let by the roads be neglected, thus forcing the Company to send their produce to the Railway at Haputale, the cost of transport will be somewhat enhanced rather than lessened.

During the past year, with a view to securing more regular transport, the Company have established a service of bullock carts by which means their produce is carried to the Railway Station at Nannoya, and this service is working with regularity and economy.

The Board take this opportunity of protesting against the extravagant expenditure of about £500,000 which the Government contemplate for the short Railway Extension of 25 miles they have authorised, and which will only benefit a particular district, and will condemn the districts of Badulla, Madulima and Hawa

Eliya to a permanently heavy charge for transport, while a narrow gauge railway of 50 miles could have been laid down for an equal sum, and thus have ensured cheap and rapid transport to the whole Province of Ouvah.

Mr. H. H. Potts, a member of the Board, retires on this occasion, and being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

By Order, J. ALEC ROBERTS, Secretary.
25th July, 1888.

BRITISH NORTH BORNEO OR "NEW CEYLON" AS A SOURCE OF TEA BOXES FOR OLD CEYLON.

From Mr. Henry Walker, formerly well-known in Ceylon and now Commissioner of Lands of British North Borneo, a settlement over which Britain has recently assumed a Protectorate, and which, we doubt not, will ere long be ranked amongst the Crown colonies of the Empire, we have received a very interesting map of the Territory, which he certifies has been corrected up to the 23rd of last month. The map appears to have been originally framed to accompany a paper by Mr. Daly, who has been prominent as an explorer of the region in which the protected State is situated. The map purports to have been compiled from the Admiralty Charts and the Surveys and Explorations of Messrs. F. X. Wittig, W. B. Pryer, F. Hatton, H. J. Walker and D. D. Daly; and it gives explanations of the terms (Malay chiefly, we presume) for names of places, which are interesting. They are as follows:—

Bandar	Town	Kwala	Mouth of River
Batu	Rock	Labuan	Anchorage
Besar	Large	Merah	Red
Bukit, Bod	Hill	Pulo	Island
Danau	Lake	Sungei	River
Gunong	Mountain	Tanjung	Point or Cape
Kampong	Village	Telok	Bay
Ketchil	Small	Trusan	Passage or Channel

The territory on the mainland of the great island of Borneo is coloured so as to show the limits of the Provinces, and colour is also applied to Labuan and the numerous other islands scattered off the shores of the settlement. The Provinces have, naturally, been named after the leading founders of the colony, prominent being the name of the gentleman recently knighted. We have the nine Provinces of Dent, Keppel, Aloock, Martin, Culliffe, Elphinstone, Mayne, Nyburgh, and Dewhurst. Attached to the map is a list of "Estates of British North Borneo," some of which are indicated as "applications," and opposite one we find "Timber Leases." Land appears as yet to have been taken or applied for in only five out of the

nine Provinces, preference having been naturally given to the Province of Myburg in which is situated the grand harbour of Sandakan Bay. Here 199,000 acres have been granted or applied for, including "timber leases" to the extent of 12,000 acres of forest on the edge of Sandakan Bay. Most of the land seems destined for tobacco cultivation, although sugar is mentioned in one case and "various" products in others. Blocks of 69,000 and 60,000 have been granted to parties who having purchased at \$1 per acre will doubtless sell portions at a profit, the selling price of land having lately been increased by Government \$2 per acre. Next to Myburg Province comes Martin Province with 80,000 acres and then Alcock with 75,239 acres all of which are destined for tobacco, except 300 acres against which we find Liberian coffee. In Dewhurst Province 69,000 acres have been granted or applied for, and in Mayne Province 52,000. The aggregate is thus 475,239 acres, which is but a small proportion of a territory that we suppose extends over 15 to 20 millions of acres. It is regrettable to notice that most of the land is or is to be devoted to tobacco culture, and that so few of the applicants for land are British subjects. Most of the names are Dutch, such as Teile, Doorn, vander Hoeven, Houthhuysen and so on. "Count G. loes" is a man of large ideas, for we find him down for 26,000 acres in one Province and 10,000 in another. Then there is Baron T. von Amerongen down for 10,000 acres, and Baron A. von Stein for 20,000. We find only three distinctively English names in the list. Mr. Walker, in a letter to our address, very naturally expresses the hope that new and old Ceylon may become more intimately connected than is yet the case, and North Borneo being a country specially rich in timber he throws out the idea of an enterprise similar to that in Japan, by which at present India and Ceylon are so largely supplied with tea boxes. Unless papier mâché, or a combination of paper and other substances, supersedes wood for teaboxes, the idea is a good one and worthy of attention here in Ceylon. On this point and others Mr. Walker's letter is so interesting, that we here quote it:—

"I send you a sketch map of British North Borneo and a list of lands taken up and applied for. Tobacco appears well suited to our climate and rainfall, and the quality of the leaf is said to be quite equal to the best Deli. The price obtained this year will be a great criterion of this, but the small quantities hitherto sent to Amsterdam bear out the statement.

"We expect to be largely connected with old Ceylon shortly by sending you tea chests. We have suitable wood and you want boxes by the million. Your capitalists should put up saw mills here. Our rates for land are low. Timber leases (without cultivation clause) are given at 20¢ an acre rent, and permits to cut timber on Government land have so far been given at a nominal sum. We are offered steam communication with China, Europe, and Australia by three lines, and I expect daily to hear of a settlement of the matter. When the steamers run you can receive tea chests in Colombo direct from the mill in British North Borneo.

"This is a very important matter to your colony and to ours, and I hope to see a very considerable business arise between the two countries. In addition to tea chests, you want oil and coffee casks.

"I say our rates for land are low. Up to the end of July we charge \$1 (one dollar) per acre, but after that date \$2 will be charged for land on the east coast. We do not anticipate it will prevent any one from applying for land."

NOTES FROM UPCOUNTRY.

Kandy, 23rd August.

The Dumbara tobacco fields on the old sugar

* About 40 cents of a rupee. — Ed.

estate and the huge drying sheds for the leaf are most interesting. Cacao, rubber and other products are flourishing on the old tobacco fields, so that the Dumbara soil is not likely to be exhausted.—Grand cacao crop on Pallakelle.—Sunset last night, as witnessed in Dumbara Valley, magnificent; sunrise through the Medamahanuwara Gap this morning a sight to remember!—Rain much wanted in the Dumbara Valley as everywhere else.

Mr. Holloway, the father of the Panwila planting district, is busy over a new estate already fully planted with tea which he is to call Maria galla, and which, through high cultivation, the conservation of rainfall and special attention to scientific agriculture, he is to make a rival to the Mariawatte, in yield of crop. Mr. Holloway is sanguine; he has every possibility, with the high road as a boundary for manuring. We shall see the result.

Messrs. Owen, Bayford and Wetherall have taken up some 500 to 600 acres near Ukuwala for tea and cacao.

Mr. Akbar is opening his Kadugannawa property for tea very carefully; a number of new tea clearings in this old district attract attention.

INDIAN TEA COMPANIES REGISTERED IN LONDON.

The *Home and Colonial Mail* of August 3rd contains the results of the working of the above companies in 1887, and most satisfactory must most of them be to the shareholders. Three only declared no dividend, the Land Mortgage Bank of India, the Upp-r Assam and the Noalcharee Tea Companies, but the profits were £14,458 16s 4d, £16,453 5s 10d and £3,625 19s 3d respectively. The first produced 1,969,120 lb. tea at the rate of 287 lb. per acre from 8,039 acres costing 9½d and selling at 11d per lb. on a capital per acre of £42; the second produced 1,155,644 lb. at the rate of 470 lb. per acre from 2,456 acres, costing 9½ and selling at 1s 1¼ per lb. on a capital per acre of £79; and the last produced 548,765 lb. at 288 lb. per acre from 2,200 acres, costing 11d and selling at 1s 1d on a capital per acre of £31.

The British Indian Tea Company declared a dividend of 1¼ per cent, producing 697,935 lb. at the rate of 401 lb. acre from 2,037 acres, costing 7d and selling at 9d, on the highest capital of £119 per acre. The Scottish Assam and the Dejoo Tea Companies declared a dividend of 5 per cent. each, the former producing 240,016 lb. at the rate of 348 lb. per acre from 765 acres costing 9½d and selling at 1s 2½ per lb. on the second lowest capital per acre of £104, the latter producing 210,260 lb. at 438 lb. per acre from 745 acres costing 10½ and selling at 1s 0½d per lb. on a capital per acre of £59. The Indian Tea Company of Cachar declared a dividend of 6 per cent, having produced 341,680 lb. at 468 lb. per acre from 930 acres, costing 9d and selling at 1s 1½d per lb. on the third largest capital per acre of £101. The Luckimpore Tea Company of Assam declared a dividend of 6½ per cent, producing 453,890 lb. at 488 lb. per acre from 985 acres, costing 9½d and selling at 1s 0½d per lb. on a capital per acre of £78. The Doorns, Darjeeling, and Borelli Tea Companies all declared a dividend of 7 per cent. The Doorns produced 747,578 lb. at 454 lb. per acre from 3,276 acres costing 8d and selling at 10½d per lb. on a capital per acres of £38. The Darjeeling produced 551,097 lb. at 308 lb. per acre from 1,906 acres, costing 9½d and selling at 1s 2d per lb. on a capital of £78. The Morbund Tea Company declared 7½ per cent dividend, on a crop of 28,020 lb. at 509 lb. per acre from 620 acres, costing 9½ and selling at 1s 7½ per lb. on a capital per acre of £66. The Lumbong Tea Company declared 8 per cent. dividend on a crop of 371,303 lb. at 382 lb. per acre from 1,442 acres, costing 10d and selling at 1s 1d per lb. The Doorn Doorn Tea Company declared 8½ per cent dividend on a crop of 942,622 lb. at 382 lb. per acre from 1,685 acres,

costing 8½d and selling at 11d on a capital of £68. The Assam, Jokai Assam), Jhanzi, Panitola, Attaree Khat and Wilton Tea Companies all declared 10 per cent dividends, the Assam Company producing out and away the largest crop of 2,138,733 lb. at 287 lb. per acre from 8,834 acres, costing the high figure of 11½d and selling at only 1s 0¾d per lb. on the low capital per acre of £21. This last item is explained by the fact that the Assam Company got their land for a mere song from those who had tried and failed. The Jokai (Assam) Company produced 791,727 lb. at 456 lb. per acre from 2,130 acres, costing only 8½d and selling at 11½d per lb. on a capital per acre of £31. The Jhanzie Tea Association produced 403,109 lb. at 328 lb. per acre from 1,595 acres, costing 10½d and selling at 1s 1¼d per lb., on a capital per acre of £34. The Panitola Company produced 658,135 lb. at the high rate of 655 lb. per acre from 1,233 acres, costing 9d and selling at 1s 0¼d per lb. on a capital of £53 per acre. The Attaree Khat Tea Company produced 302,554 lb. at 460 lb. per acre from 760 acres, costing 7¾d, and selling at 1s 0¾d, on a capital per acre of £54. The Wilton Company produced 310,752 lb. at 440 lb. per acre from 735 acres, costing 8¾d and selling at 11½d per lb. on a capital per acre of £38. The Tiphook Tea Company declared a dividend of 12 per cent, producing 184,310 lb. at 249 lb. per acre from 830 acres, costing 9½d and selling at 1s 2d, on a capital per acre of £31. The Jorehaut and the Brahmapoetra Tea Companies each declared a very encouraging dividend of 15 per cent, the former producing 1,202,303 lb. at 311 lb. per acre on 4,570 acres costing 9½d and selling at 1s 1¼d per lb. on a capital per acre of only £22; the latter producing 1,118,461 lb. at 502 lb. per acre from 2,695 acres, costing only 8d and selling at 11½d per lb. on a capital of £43 per acre. The Borokai Tea Company finishes, or rather heads, the list with a grand dividend of 16 per cent. The crop was 310,800 lb. at 351 lb. per acre from 1,038 acres, costing 9½d and selling at the very remunerative average of 1s 3¾d on a capital per acre of £40.

The 'profit per mature acre' stands in the following order:—

	£	s.	d.
Panitola Tea Company	...	9	12 4
Indian Do. of Cachar	...	9	12 0
Borokai Do.	...	9	3 9
Attaree Khat Do.	...	9	2 1

British Indian Do.	...	1	19 3

Against the above results of Indian Tea Companies we have those of only one Ceylon, the Ceylon Tea Plantations Company, available for comparison. Full statistics were supplied by Mr. H. K. Rutherford, the Ceylon Manager, which were embodied in the June number of the *Tropical Agriculturist* of the present year. Taking the same items as are mentioned in regard to the Indian Companies, we find that the Ceylon Tea Plantations Company (consisting of Mariawatte, Dunedin, Dewalakanda, Sembawatte, and Mudamana) produced 504,380 lb. at the rate of 403 lb. per bearing acre from 1,267 acres costing 5½d f.o.b. and selling at 1s 1d. The dividend declared was 15 per cent, equal to the second highest dividend declared by the Indian Tea Companies.

IMPORTANT AMALGAMATION OF INDIAN TEA COMPANIES.

We understand that the amalgamation of the Jokai, the Panitola, the Tiphook, and the Kamptie Guallic Tea Companies is accomplished, and that these concerns now form the Jokai Assam Tea Company, with a capital of £250,000 in £10 shares, of which £170,000 is paid up. The result of this amalgamation will be watched with interest. The following is the award of the arbitrators in the union of the Jokai and Panitola Companies, together with a statement of the comparative values. Issued by two eminent authorities on all that concerns tea property, they cannot fail to be interesting.

AWARD.

In arriving at our valuation of the Panitola Tea Company's property, we understand that it is its comparative value to that of the Jokai Company's property as represented by its capital that is wanted, not its actual value, which we would estimate considerably higher, in the same way as the actual value of the Jokai Company's property, as represented by the present market price of its shares, is considerably higher than its capital value.

As it is as a dividend-paying concern that the properties must be viewed, we have based our valuation, as the accompanying figures will show, mainly on the average profits per acre of the tea over five years' old during the last three seasons, but with some modifications which we think reasonable on account of the extent of waste land, the number of contract labourers, and the amount of reserve funds held by each company.

We have thought it unnecessary, and possibly misleading, to make any separate valuation of the younger plant, seeing that its cost in the case of both companies has been defrayed out of revenue, that the proportion of young to mature plant is about the same in each case, and that we have no reliable figures upon which to base any separate valuation.

Regarding the waste lands, we have valued the fee simple lands at considerably less than we should have done a number of years ago, partly because owing to the development of the Assam Coal Fields and improved tea machinery, such large tracts of land are not now required for the supply of firewood and charcoal, and partly that they are not now so saleable as they once were, and that little or no income is derivable from them. For similar reasons and that they add to the annual expenditure in the shape of rent, we have put no capital value at all on leasehold and pottah lands; besides this there is not much difference in the extent of such lands held by the respective companies.

Regarding the allowance in favour of Panitola on account of labour contracts, we think this only fair, because though each concern is supposed to have a fairly efficient supply of both labour and machinery we consider that contract labour, of which Panitola has about 50 per cent. more per acre, is more reliable, and therefore, of more value. In arriving at the amount we have allowed we have given due consideration to the fact of Panitola giving a much larger yield per acre, and therefore requiring a larger staff of coolies per acre for plucking and manufacture, though not for cultivation.

Taking all the foregoing into consideration, and from what we personally know of the two Companies' properties, we are of opinion that taking its paid-up Share Capital of £64,550 as the value of the Jokai Company's property, the relative value of the Panitola Company's property is £56,000.

NEW VEGETABLE PRODUCTS IN SOUTH AUSTRALIA.

Mr. Henry Poett, who has resided in the Northern Territory for over two years as Manager of a coffee and cinchona plantation, and is in Adelaide for a month or two, was examined on September 21. He believes that the guava and lime could be cultivated here. The guava requires a free surface soil, containing lime, and is adapted for the plains. It is first raised from seeds, then planted out, and bears in two and a half years. A fair average crop would be about 25 lb. of fruit per tree. They are planted at 8 feet apart, and reach a height of 12 to 15 feet, being evergreen. About 700 trees would stand upon an acre, and in India the value of the fruit from each would be about eighteenpence. The fruit is chiefly used for making preserves, though it is also a table fruit. Although it will live and bear fruit upon a rainfall of 15 inches it will do better with 30 inches. It likes a hot climate, and the absence of rainfall could be compensated by irrigation.* The fruit ripens about January here. Tea could be grown in South Australia if it were irrigated—it requires heat and moisture. The leaves are picked all the year round, except during cold weather. It would not be profitable, except with cheap labour. The Tamils (Indian coolies) are by far the best men—Chinese are no good. The Tamils are the finest class of labour he ever came across. They spend nearly all the money they earn in the country where they earned it. They do not interfere with labour that Europeans can do. They confine themselves to agriculture, and never rush away to mines or anything of that sort. They take their wives and families with them. They work for 5s. per week and keep themselves, whereas Chinese require 15s. per week. In India the Tamils work for 8d. per day; here you would probably have to pay 1s. per day. The same class of labour is used in Mauritius. In a gang of 100 coolies there would be forty women and fifteen to twenty children, and the rest able-bodied men. The men and children above 7 years of age work in the fields. They generally go back to their own country every two or three years, spend what little money they have saved, and then come back again. The Liberian and Arabian coffee are both grown at the Northern Territory, but the Liberian does the best. It takes three years to realize a first crop.

* Mr. Poett, an old Ceylon planter, ought to know that tea could not possibly pay where irrigation is necessary and labour costly, in competition with that produced where rainfall and labour are both abundant.—Ed.

Mr. Poett was Manager for a year and a half, and does not know whether any crop has been taken yet, though it is time there was one. The place has been abandoned by the Company. There was only 15 acres planted, the labour being Chinese. They lived mostly on rice and salt-fish. If he had been able to use coolie labour he would have made the plantation pay. It made all the difference where a Chinese was paid 15s. per week and a Tamil only 5s. The Chinese would not do as much work, ran away after gold-fields, required to be consulted as to working overtime, and run to cover if a shower of rain came on. The Company owned 3,739 acres, but failed for want of money. The land was bought at 7s. 6d. per acre, and is situated at Rum Jungle, 23 miles from Southport. Coconuts and anything that will grow in a tropical climate can be produced in the Northern Territory. Tobacco also will grow there—the patches of soil for this culture are not plentiful. Tea cannot be grown there, because there is not rain enough. It wants about 100 inches of rain per annum to grow tea.*—*Adelaide Observer*

TOBACCO IN CUBA:

NOTES ON ECONOMIC PLANTS IN HAVANA.

Some interesting notes on Tobacco culture, as well as on the introduction and cultivation of fibrous plants, in Havana, have recently been furnished to the Foreign Office, from which we gather the following facts:—

Regarding Tobacco culture, it seems that the markets are affected by the general demand for light-coloured Tobaccos. This demand is said to cause injury to the plant, which, unless artificial bleaching be had recourse to, must be gathered before maturity, with loss of quality and aroma. There is as much Tobacco grown, and there are as good markets as ever, but the growers and manufacturers, in their race after quick returns, force and spoil the plant in the ground and the curing-house, and ship goods that not only no longer command the market, but are undersold by foreign and inferior, but probably more carefully prepared kinds. There is, as a matter of course, a large amount of exquisite and carefully handled Tobacco exported, but the price of this has become so high that it is above the reach of the middle-class consumer, this, however, ought not to and need not be. Climate, soil, and acreage, are all in favour of a superior and large production that could hold the field against all comers, but the elements to make this a reality—namely, capital labour, and frugal and unfettered administration—are wanting. The social and political state of the island is not of a nature to attract these elements, and prostration and uncertainty are seen everywhere. Although Tobacco grows well all over the island, the soil and climate of the south-west portion produces the finest. This is known as the Vuelta Abajo, and lies along the foot-hills of the Sierra stretching to Cape Antonio and the northern side of the great plain which reaches from sea to sea across the island. The very best land of the Vuelta Abajo lies near to Consolacion and the lomas on the eastern side of the Cayos which overlook the Palm-covered plain.

The planter's house-made cigars, called "vegneros," or "farmers," are celebrated at Consolacion, and possess a delicious aroma, especially when smoked immediately on being made. The leaf is of a very rich, light, coffee-brown, with slight hairy down on it, which is soft and tender. To test the leaf, the vegnero always tries the strength of the material by passing it over his finger in the way one tries the skin of the glove. The "maduro," or the ripest, is considered the very best; but as of late years fashion has ruled in favour of light colours, the Tobacco is dried in such a manner as to get the required shade, but in the opinion of the best judges, to the detriment of the flavour.

The Tobacco seed is sown early in October, after the rains have well soaked the light sandy soil, and

* Here Mr. Poett corrects his previous evidence.—Ed.

cuttings are taken between October and March. Some vegas lying along the arroyos, which are always full of good and abundant water, never fail; others produce only the "tripa," or kind used for working up to form the core of the cigar, the outer leaf being of a finer brand. In this consist most of the frauds which prevail very extensively in the trade.

A company called the Cuban Fibre Company (Limited) has been formed in London for cultivating and extracting the various fibres in Cuba, principally the *Sansevieria*, or *Leuga de Vaca* plant, which give the best fibres of their class. Preliminary arrangements have been made for planting about 1000 acres in different parts of the island; so that next year the export of the fibre will commence, and will, it is expected, be equal to the best Hemp and some kinds of Flax. The cultivation of these hitherto neglected plants is likely to prove a success, for they take up little of the planter's time, and grow readily on the poorest land, leaving him free to attend to more important cultures. In a single month, which may be in the early spring or in the rainy season, hundreds of shoots or cuttings may be planted, giving later a considerable crop. Cuban labourers with families, who are numerous in some districts, will find this new agricultural industry a steady means of gaining a livelihood.—*Gardeners Chronicle*.

TEA CROP IN DARJEELING.—We are sorry to learn that little doubt is now left that the tea crop both in the Terai as well as in the Hills will fall below the estimates even for the gardens in full bearing.—*Indian Tea Gazette*.

A FRIEND OF THE CACAO TREE.—A correspondent writes:—"The insect I herewith send I find amongst cacao. Can you inform me if it is a destructive one? It is to be frequently seen perched on the tip of a dead twig." Our entomological referee reports on the insect as follows:—"An *Asilus*, belonging to the order Diptera, or two-winged flies; feeds on small flies of the same order and other insects, and therefore more likely to do good than harm."

BURNT EARTH.—I can recommend this for general use. The first illustration of its value which came in my way was when engaged in carrying out a new garden a short time ago. I was greatly surprised upon entering the glass-houses to see the luxuriance and beauty of the young stock of plants, especially of *Gloxinias*, *Ferns*, *Palms*, foliage plants, and *Cucumbers*, and on inquiry I was told that, owing to dearth of silver-sand and leaf-mould, burnt earth had been added liberally to the soils. The most delicate-rooted plants luxuriated in what was little else than crude top-spit loam with a liberal admixture of the burnt earth. It may be well to add that only the very finest siftings had been used. It would seem, therefore, that owners of old town gardens, in which the soil has lost its ordinary mechanical properties, may benefit themselves by partially burning and re-mixing the soil.—**WILLIAM EARLY**, Ilford [The value of this material in promoting root-development was shown experimentally by the Editor some years ago.—*ED.*]—*Gardeners' Chronicle*.

CHINA TEAS.—The *Foochow Echo* says:—"Our tea merchants had better note, that sooner or later a company will be formed by some sanguine celestial dealers, to ship teas to London and Australia, in case they cannot obtain the price they want in this market, and we learn that for this purpose a foreign *Chasse* will be or has already been engaged to manage the gigantic company (made of *Ice* we fancy). Now, if this report really becomes a fact, which we doubt very much, it can only have the result of forcing the foreigner to go away from the port and leave the natives to ship their own teas to the London and Australian markets, where perhaps they will or perhaps they will not obtain a better price by shipping on their own account.

This step our celestial friends must have planned either under the influence of *sanshu*, or with the idea of putting other people to trouble, because we do not see the necessity of forming such a company, to protect their interests or to venture their capital in shipments to a foreign country, when they can, without any risk, obtain immense profits at Foochow, if they will only be careful in the manufacture, sell at a reasonable price, and honestly deliver the chops as per musters shown. What we believe to be the real source of this rather funny company, is the idea of benefitting a couple of teamen, who we believe, are unable to stand any longer the losses they have had for years past, and are thus trying to raise the wind, but alas! in a wrong direction. Surely, the teamen must understand, that if foreign buyers, who know teas, and are constantly in communication with the London market, cannot pay the prices they ask, it is absurd for them to believe that they will obtain such prices by shipping on their own account to the same market. Instead of inventing such humbugs, the teamen will do themselves and foreign buyers immense good if they will take vigorous steps to prevent the usual flooding of the market every year with rubbish, which is the real cause of their own losses; the enormous profits they have made on the first crop this season, which was really very good, is a sufficient proof of the fact.—*China Mail*, August 2nd.

INDIAN AND CHINESE TEAS.—Says the *Statesman*:—"It would perhaps be premature for our tea planters to persuade themselves that they have driven Chinese teas from the London Market, but competent judges appear to think that the exclusion of the latter is not far off. The opening of our Indian gardens is almost of yesterday, Assam leading the way. It is little more than fifty years since the tea plant was found growing wild therein, but the yield of the whole province fell short of 300,000 lb. up to 1851. If we glance now, at the statistical returns presented in the annual tea report of the Assam government or last year, the expansion which has taken place in the last 35 years is almost incredible. In 1851 there was but one Company in Assam with a very limited area under cultivation, and a yearly production of about a quarter of a million pounds. In 1887 we find no less than 873 gardens covering an area of nearly a million acres although but one-fifth of that area is actually planted. In place moreover of an outturn of 250,000 lb. of tea, we are told now of an outturn of 70,000,000 lb. The cost of production, which was originally very high, owing to the outlay for skilled labour that had necessarily to be imported from China, greatly of course arrested the progress of the gardens. The pioneers of the enterprise had to buy their knowledge, and success was dear. Today, the whole cost of cultivation does not exceed R54 per acre, while the leaf can be laid down in the Calcutta sale-rooms at 6½ annas per pound, to realize prices varying from 7½ annas to 9 annas, for shipment thereafter and sale in London at an average price of 11d the pound, though on occasion quotations are at as low a figure as 7½d. The aggregate annual outturn from all the gardens of India, is now from 90,000,000 to 100,000,000 lb. a year, of which Assam, as we have said, counts for 70,000,000 lb. This area, however, is almost nothing, when compared with the acreage available for tea cultivation in the hot and moist sub montane tracts along the base of the great hill ranges of our frontiers. Should the cultivation spread in the future, at a rate at all commensurate with its increase in the past, India need have little fear of any competition from new countries like Natal, which have been spoken of in late years in almost glowing terms for their production of the leaf.

INDIAN AGRICULTURE, &c.

"INDIA IN 1887, AS SEEN BY ROBERT WALLACE,
PROFESSOR OF AGRICULTURE AND RURAL ECO-
NOMY IN THE UNIVERSITY OF EDINBURGH."

We have to thank Professor Wallace for a copy of his interesting book, the result of a visit which he paid to India and Ceylon about a year ago, when we had the opportunity of meeting him and admiring his combined shrewdness and enthusiasm. The value of the work is greatly enhanced by the profuse illustrations, most of them from photographs taken by the author. The previous training of the traveller as Professor of Agriculture, first at Cirencester and subsequently at Edinburgh, qualified him to observe carefully and arrive rapidly at conclusions, some of which may be of immense value to a country so largely agricultural as India is, in increasing supplies of good draught cattle and field crops, so enhancing the comfort of the people and tending to avert famine. Professor Wallace has in his book discussed not only the modes and appliances of Indian agriculture, but a vast number of subsidiary circumstances connected with or which affect the success of the tillers of the soil. He is especially strong on the breeds and treatment of cattle, but he does not fail to give his opinion on currency. Forestry is varied by remarks on chemistry, and the Professor speaks of plants, from that important food-yielder the mango to the grasses, which in their quality and luxuriance (and they are too often scanty and innutritious) affect the number and the strength of cattle—zebus and buffaloes—on which the whole fabric of Indian agriculture rests; even irrigating water losing most of its value of the patient and laborious oxen are not available, for every process from the treading of the mud to the treading out of the corn. While doing justice to isolated cases of interesting experiments and valuable results, Professor Wallace is by no means satisfied with the attention which the Indian Government has devoted to the aid and improvement of agriculture. Even in such attempts has been made, he, with his large and special experience, found much to question and criticize, and he thus concludes the introduction to his book:—

"My object in writing an account of my Indian experiences, beyond the personal gratification of doing so, is to induce Government to alter its plans as regarded an Agriculture Department, and to see that ground which has been lost by inexperienced officers is yet capable of being regained by efforts made in the right direction. One of the most hopeful signs that my desires in the matter of an Agriculture Department in India may be realized is the promise of our home Government to create a Minister of Agriculture and a special Department of Agriculture for Great Britain. Arguing in the abstract—if this country, with all its wealth and the greatness and variety of its resources, requires such an organization, what must India require within her narrow grooves of commercial life, with the evils of an over-crowded population at no great distance, and periodical famines staring her in the face?"

What is true on a large scale of Britain and the Indian Empire, is, of course, true in degree of Ceylon, and we trust that until the time for a separate agricultural department in the Civil Service of Ceylon has arrived, the Director of Public Intruc-

tion will not relax his well-directed and in some cases fairly successful experiments. We are pleased while we confess to be somewhat surprised at the, on the whole, very favourable judgment formed by the Professor of our small but wiry indigenous cattle. When well fed and tended (the great point in the case of all cattle of every breed) they are capable of good speed and endurance in labour, and they are for their size, good milk yielders. One of the illustrations represents a "Cinhaliese trotting bullock in native cart," what is so familiar to us in Colombo and other towns as a "hackery." There is also a picture of a "Cinhaliese Bull" and this is what is said about our Ceylon breeds of cattle:—

CINHALESE CATTLE.

Are usually classed in two divisions—(1) The *small native breed* and (2) the *large coast cattle*. The latter are mostly imported from India, and consist largely of Mysore and their crosses.

The local breed first mentioned are the true cattle of Ceylon, and are possessed of beautiful shapes. They are remarkably like Adens; and though small, their *bodies* are extremely well proportioned. Their *heads* and *feet* are both large and clumsy. The head is long, does not expand at the setting on of the horns and taper towards the muzzle as it ought to do to look well. The *ears* are small and sharp, but only moderately well carried. The *horns* are short, thick, and blunt, and point upwards, but do not spring much till the animal is approaching three years old. The *colour* of hair is generally black, with black nose, skin and hoofs. A few are of a deep rich brown, with chocolate skin and points. These are thought to be the more beautiful of the two, but not so hardy. Still fewer have broken colours,—white patches on the prevailing black or brown; and in some rare cases, patches of the brown on the black.

The *legs* are short, and the *bones* fine. The *barrel* is round and substantial. The *hind-quarters* are unusually long for Indian cattle, and carried out square, or on a line with the back to the setting on of the tail. Behind the *shoulder* they are as well filled up as the best of our home breeds. The *hump* is thick and massive, and very often double. The *deu-lap* is prominent, and there is no hanging skin on the belly.

Plate XXIX (a) shows an excellent specimen of a bull, but with the one little defect, which no doubt will disappear with age—want of depth of barrel. He was, at the time the photograph was taken, not quite 3½ years old (but had six teeth), and measured in height 3 feet 5½ inches. He had worked for a year, but being well fed and cared for, he had not suffered, as might have been expected, from going to yoke at such an unusually early age. Good treatment was evident from the number and appearance of his teeth.

Cattle are shod with thin or thick shoes at a cost of 1s or 2s, as the case may be. The nails used have large round heads like great coarse rivets, and a passage is made for each nail through the hoof by a carpenter's brog. In the case of the outer digits, the sharp points of nails are neatly coiled upon themselves and left as ornamentation; the inner ones are cut off and fastened in the usual way. The operation has to be repeated once every two months in the case of animals working on hard roads.

The bullocks of the breed are not noted as quick movers, but they are possessed of great power of endurance and wonderful strength for their size.

The cows of some of the strains upcountry are rather good milkers, and if properly selected and managed, might supply the material from which a good milking herd could be produced.

Branding is more neatly performed, and even more widely practised in Ceylon than in Madras.

There are two points for remark. Had Professor Wallace seen a race between two bullock hackeries, or a hackery bullock put to his speed, as is some-

times come to the danger of the lives of pedestrians and riders on horses or in carriages, he would not have given so qualified an estimate of the power of speed of our little zebus. Many in the chief towns of Europe have been made acquainted with their capabilities in this respect by the hackery races which formed a prominent feature in the exhibition of Mr. Carl Hagenbeck.

Then as to branding: the process must be badly done in the Madras Presidency if it is worse than the system in Ceylon, which so largely, sometimes completely, destroys the value of hides. Occasionally, for fanciful reasons, but mainly to meet the prevalent crime of cattle stealing, branding is performed after a profuse and cruel fashion in Ceylon. With regard to colour, Tennent mentions that white is so rare that cattle of that colour were always reserved for royal use.

In connection with white skins (not by any means coincident with white hair) in cattle, Professor Wallace has discussed the whole question of colour as affected by and in relation to climate. He quotes a letter from Huxley to the following effect:—"The facts you mention are of very great interest as showing a hitherto unsuspected relation between colour and climate." Surely this statement ought to be qualified. The relation of colour to climate has been noticed in the fact that members of the human race inhabiting the hotter regions of the earth are generally dark in colour, while dwellers in cold or temperate countries are as generally white. The puzzle has been to account for the advantage of the black colour of the pigment to those on whom "the sun has looked" with fervid glances. Franklin's celebrated experiment of laying bits of cloth, varying in colour from white to black, on snow, while the sun was shining brightly, conclusively proved that heat rays are absorbed specially by dark colours. The black bit of cloth sank deeper into the snow than any other. A dark-coloured skin, therefore, would seem at the first glance to be disadvantageous instead of beneficial to dwellers beneath a tropic sun. The importance of Professor Wallace's speculations consists in the explanation he gives. His position is that in the dark-skinned man inconvenient increase of temperature is prevented, not by such copious perspiration as is seen on white-skinned persons and the evaporation of which cools them down. In the case of the dark-skinned men, there is, he affirms, a constant cooling down process by the escape of moisture from the skin pores in the form of almost insensible vapour. It now remains for the philosophic world to confirm, qualify or question the Professor's ingenious conclusion. The whole problem of colour in the human race and its relation to climate is surrounded with difficulties. Ancient monuments would seem to show that dark colour appeared early and has remained permanent in large portions of the human race. And if, as Professor Wallace holds, and others have held before him, a white skin betrays inferiority in one of the lower animals, it is anomalous surely that the white-skinned sections of the human race should, as a general rule, be so greatly the superiors of the black, brown, and yellow races: superior in energy and even in intellectual power if not equal to the Asiatic in subtlety. In endurance of the effects of a hot climate, the dark-skinned natives of countries with such a climate have a degree of physical advantage. As a reason why Europeans coming to India and Ceylon should carefully protect their heads against the sun, the custom of the natives in wearing voluminous cloth turbans has been adduced. But natives

who walk about in the sun bare-headed and even with every particle of hair removed from their heads by means of the razor or other depilatory agent (the coolies use a bit of broken bottle),—our own Moormen for example, whose calico skull caps can afford no real protection,—are exempt from sunstroke and other evil effects of exposure to the heat rays of a tropic sun, which affect Europeans so severely. And, curiously enough, the children of European soldiers and of others whose means are limited go about bare-headed in the Indian sun and seem to be none the worse. The skin darkens in the process, however, and we have known old residents in Ceylon who might be mistaken for Asiatics, if the sole test were the colour of the skin. The late Dr. Dickman, too, a shrewd observer, told us that in cases of dysentery he could generally calculate the chances of recovery by the colour of the skin of the patient. In proportion to the darkness of the skin were the recoveries, and so unfavourable an indication was a specially fair skin that when Dr. Dickman's own wife, a lady of Dutch descent, was attacked with the disease, he abandoned all hope of her recovery, the event justifying his fears. As to white skins in the lower animals indicating inferiority, there is a book on horses (perhaps, that by "Stonehenge") the frontispiece to which is a beautiful-looking white horse with pinkish nose, which the writer said was an illustration of all that a good horse ought not to be. Albinos, whether in the human race or amongst the lower animals, are generally defective. Tennent mentions what we have never observed in Ceylon, albino buffaloes with purely white hair and a pink iris. This reminds us of what we have previously mentioned in the *Observer*, the prevalence of pink or flesh-coloured buffaloes in Java. They are not rare but numerous, and our late lamented friend, Mr. Moens, so well and favorably known in the ranks of natural science as the Director of the Java cinchona plantations, assured us that these animals showed none of the defects of albinos, but were regarded as, if anything, stronger and more serviceable than those of the ordinary brown colour. Curiously, too, the flesh-coloured buffaloes of Java are not a distinct variety,—like propagating like. They occur in all herds, alternating with the brown, it being impossible to say beforehand what the colour of a buffalo's calf may be. These were the statements made to us by Mr. Moens, as the results of his observation and experience, and we submit that the subject of the prevalence in Java of what is unknown or exceedingly rare in British India and Ceylon, pink-coloured buffaloes which are either not albinos or differ from albinos generally in showing no defect of vision or strength, but the reverse, is worthy of full investigation in connection with Professor Wallace's interesting theories, which are thus detailed:—

Colour of Hair.—Indian cattle taken as a race, and represented by pure-bred specimens of the different strains are what may be termed "whole" coloured in contradistinction to "broken" coloured. By "whole" coloured is not meant that an animal is all of a uniform colour, but that in the change of colour from that of one part to that of another part there is no distinct break or division line—the colours shade or merge into one another. The most common colour is white or very light grey on the body, and the extremities grey of various shades, the two colours blending harmoniously. The bull of mature years is usually darker than the cow or young bull. Where "broken" or patchy colours appear, they, with few exceptions, indicate cross breeding of more or less recent date. No doubt it is possible in a brede

which has been formed by crossing two distinct breeds many years before, to retain the broken colour as a peculiarity of the new breed, but in that case it is well defined, and tends in some respects to become regular, in such features as a white head, white legs, or even white patches on the body of coloured varieties. The broken colours peculiar to cross cattle are irregular and easily recognised by one who is accustomed to watch carefully Nature's freaks in the matter of cattle reproduction. Few of those animals which are termed white are altogether free from black hairs. There is usually a fringe of black or brown round the hoof-heads, and frequently patches on the joints above the pasterns. The tuft of long hair at the point of the tail is rarely white, and there are often dark markings about the ears, with black hoofs, black muzzles, and black eyes as correlatives. The colour of the skin within the ear, though dark, is often of a lighter shade than the body skin; frequently the tint is orange with dark longitudinal patches through it—one being on the same spot that the dark marking occupies in the inside of the ear of Channel Island cattle.

Report,* No. 1,112, of the Madras Government, dated 21st December 1886, attempts to show a connexion between the colour and certain descriptions of food prevailing in the different districts. *Paddy* straw is supposed to produce small, poor cattle of a red, brown, or black colour; *cholum* straw, large powerful animals, good milkers, with white as the prevailing colour; and *rye*'s raw, compact and useful beasts, generally grey in colour. Though, with the data available in Madras, there does seem to be something in the theory, yet when applied to India as a whole it utterly breaks down. It is much more likely that in the rice districts, where cattle have to work so much in water, that the dark haired cattle belonging to the aboriginal, and in many respects inferior looking breed, were found to possess the hardy constitution suitable, for withstanding the wet; and that consequently the larger light-coloured breeds, that from time to time overrun districts of the country to which they were suited, did not there find favour. Again, land which could grow *cholum* could better afford to bear the cost of the improvement of the cattle by importing than land growing *rye*.

Colour of Skins.—Perhaps the most interesting and remarkable peculiarity connected with Indian cattle is the fact that, however white the hair, all but a very small percentage have jet-black skins underneath. Certain breeds, or members of the same, that will be specially mentioned, have skin, horn, and hoof of a brown or dark chocolate hue. Only a mere fraction of one per cent. have white or light-coloured skins like the most of our own home cattle. Although known to the natives, this fact seems to be unrecognised by the European residents, and consequently the immense importance of it has been overlooked. In Gujarat the name *Kolea* is given to an animal with a white skin and white nose, and it is considered to be soft or weakly. A white muzzle and white skin on the legs and lower part of the body including the dewlap, may exist without the above consequences, if the major portion of the body skin is dark. The white skins in rare specimens of Indian cattle do not entirely correspond to the skins of the white African negroes mentioned by Joseph Thompson, or to the white skins of certain natives of British India, as these are albinos and the white-skinned cattle do not appear to be so. I saw one man, a pure native, a Madrasite with a skin as white as any European. He was reported to be weakly and even less able to withstand heat than one of ourselves.

There is little doubt but that the black skin has much to do with the ability of Indian cattle to work in the sun without suffering as light-skinned cattle do. In this also will be found the best solution of the question as to whether native cattle can be improved by crossing with English bulls. An animal with a white skin in our own country, during

a bright summer becomes tender to the touch, and will shrink from the hand laid on the back; or it even blisters and goes back in condition when exposed to the full force of the sun, under conditions that would not affect darker varieties. One intelligent native pointed out that the difference in the temperature of English and Indian cattle could be recognised by placing one's hand on the skins. Not only is the higher temperature uncomfortable to European cattle at the time, but they, in common with all white-skinned native specimens, are liable to have their skins sunburnt, and possibly, in the end affected with an eruption corresponding to if not identical with a form of leprosy. The hair grows in yellowish patches, giving a peculiarly unnatural and rough appearance to the coat. I have seen cases in various stages of development in most of the important breeds. The constitution in such cases is weakened, and the usefulness of the animal is impaired through its inability to meet the exigencies of the climate. The skins of nearly all the lower animals—sheep, pigs, buffaloes, and horses—under domestication in India are black or dark. It is true that certain breeds of sheep have white wool on their bodies, and most naturally white skin under it, but the head, or most exposed part (covered only with short hair), is frequently black. Sheep, especially the good white-coated varieties in India, are much better protected than other animals from the direct influence of the sun by the wool and the cushion of air which it retains within its interstices, and are thus more independent of the influence of colour. It would appear that the presence of white hair on a black skin is an advantage, being widely prevalent on Arab horses and also on many of the different breeds of cattle. It has always been a marvel that the white skin, which on account of its colour does not absorb heat so quickly as a black skin, should not prevail in the human species within the Tropics; and it becomes even more wonderful now, when it begins to dawn upon us, that the skins of the lower animals follow the same great law of Nature, whatever that law may be.

It would be assuming too much to take for granted that in the colour lay the only advantage in the matter of power to resist the sun's influence, which the skins of animals in India possess over the skins of animals from more temperate climates.* The known difference of quality of surface, thickness, and texture have unquestionably their influence, but it must be left to experiment to determine the relative position of importance occupied by each. I am indebted to Professor Huxley for making me fully aware of the importance of these qualities, which, as he remarks, make the question "immensely complicated." Yet it seems open to us, on theoretical grounds, with the data at our disposal, to look at the direction in which certain influences act, although we may not be able perfectly to point out the limits of their action.

* Various theories exist as to the influence of colour. *Nature*, August 1884, in a paper "Why Tropical Man is Black," says, "Nature having learned in ages past that pigment placed behind a transparent nerve will exalt its vibrations to the highest pitch, now proceeds upon the converse reasoning, and placing the pigment in front of the enlarged nerve reduces its vibrations by so much as the interrupted light would have excited, a quantity which, though apparently trifling, would, when multiplied by the whole area of body-surface, represent a total of nervous action that if continued would soon exhaust the individual and degrade the species." In *Nature*, November 1884, under "The Blackness of Tropical Man," it is said, "In addition to the greater dissipation of heat by black than by white skins, it is to be inferred that the real protection resulting from pigmentary blackness in the human skin consists in there being a few of the invisible solar rays of the spectrum in tropical light injurious to man, which nevertheless possesses unusual penetrative energy . . . but which are intercepted by the contents of the epidermic pigment cells in the African, and in the Hindu."

* The terms "Government Resolution" and "Government Order" are frequently used in place of Report.

The Influence of Black Colouring.*—"It would seem at first sight that the black skin should rather be a disadvantage than otherwise; but in the reality it is not so. The black colour of the skin causes it to absorb more heat than a white skin, but while it is doing so, at the same time and for the same reason it is giving off more heat—its absorbing power and also its radiating power being greater. Therefore, when the sun's rays impinge upon the skin, the heat is rapidly absorbed; but, as the rate of absorption of heat is greater than the rate of radiation, unless the temperature of the skin were lowered by some other influence, the whole surface of the body would become extremely hot.

"To complete the explanation, we must here take into consideration what is known of black-skinned men. Any one who has been in India can see that natives, although they drink water freely, do not appear to perspire so copiously as Europeans, but this is simply because more of the perspiration comes from them in the form of vapour, and less is seen to stand like dew-drops on the surface of the skin. In the evaporation of the moisture exuding from the skin, we have a demand for heat far greater than an ordinary observer might imagine; and by it all the surplus heat which the black skin absorbs over and above what it gives off by radiation can be disposed of. It is a fact which few realize, that the amount of water is small indeed which, by being evaporated could transform into its latent condition all the heat derived from the warming influence of the sun in the hottest climates."

In a communication, which I have received since the above was written, from Professor von Helmholtz, Berlin, he says, "I do not know any physical explanation of it,"—the advantage of the presence of black skin. "An analogous fact, certainly, is what I have often seen in Switzerland, that light coloured men, who do not become brown in the sun, get blistered and become covered with eruption by the reflection of the sun from the snow-fields; while those who become brown bear it much better. The black pigment generally lies in the deeper epithelial layers. Perhaps the nerve ends or other parts of the living tissue are sensitive to the deep piercing rays of the sun, and the violet and ultraviolet rays, which are usually most powerful in all chemical actions, are kept off by the brown pigment. It is known, also, that in frogs and chameleons the shifting black pigment moves to the surface as if the outer layers of the tissues had to be protected."—*Translated.*

While everyone must admit that the above remarks are conclusive of the view expressed by Professor Huxley of the extremely complicated nature of a full solution of this question, yet I cannot see that they are incompatible with my own theory which referred to the part played by absorption, radiation, and evaporation.†

* From a paper communicated by the author to the Royal Society of Edinburgh on 5th December 1887.

† Darwin in *Animals and Plants under Domestication*, chap. xxi., says:—"Light-coloured animals suffer most from insects, in Thuringia the inhabitants do not like grey, white, or pale cattle, because they are much more troubled by various kinds of flies than the brown, red, or black cattle." "In the West Indies it is said that 'the only horned cattle fit for work are those which have a good deal of black in them. The white are terribly tormented by the insects, and they are weak and sluggish in proportion to the amount of white.'" Although nothing is said of the colour of skin, the remarks evidently refer to white-haired animals possessing white skins under the white coat, and most probably belonging to the genus *Bos taurus*. Again, "white pigs suffer from scorching by the sun." Speaking of cattle, he says:—"Cases have been published of cutaneous diseases with much constitutional disturbance (in one instance after exposure to a hot sun), affecting every single point which bore a white hair, but completely passing over other parts of the body. Similar

A NEW ENEMY OF CINCHONA IN JAVA.

A correspondent writes:—"The *Indische Mercur* of 21st July opens with the ominous heading 'Een Nieuwe Plagge der Kina Boomen,'—'A New Plague of the Cinchona Trees.' With their never failing courage and determined perseverance, the resolute de Ruiters and Tromps of cultivation look the evil fairly in the face, and set about their struggle against the new enemy with the same undaunted energy with which they made

'The firm connected bulwark * * *
Spread its long arms amidst the watery wave,
Scoop out an empire, and usurp the shore.'

Kessler's little work shows that there is no diminution of their annual perseverance in the cause of science, and as they were the first to set the example of introducing the healing plant into the East, let us hope that they will now meet with the success they well deserve in the resistance of the new enemy."

LETTERS FROM JAMAICA:—No. 23.

Blue Mountain District, Jamaica,

For packet of 18th July 1888.

DEAR SIR,—My last letter was despatched by the packet of 9th ultimo; this will, I trust, go forward by the "Orinoco," the newest steamer of the Royal Mail Co. She is, I believe, perfect as regards all modern improvements, though not nearly as large as the grand P. & O. steamers which have, I noticed, enabled you to get letters in Colombo in only 15 days from London. The West Indies are still far behind the East; it takes us usually 17 days to get our home letters, as the steamer goes first to Barbadoes, which is certainly a deviation, but if ever the Panama or Nicaragua Canals are opened, our mails will be accelerated.

Our crop season has been unusual in being very backward, and before we have finished with the upper fields, we are likely to have commenced in the lower, for there are fully 2,000 feet difference between the lower and upper portions of this plantation. The coffee in the lower fields appears to be forward, but it will be a small crop generally because of the long drought which lasted from the end of November to the middle of April, and dried up much of the blossom; the settlers consequently will not do as well as last year, both as regards quantity and prices, for those who sold in cherry made money; those who bought largely must have lost a good deal of money. In the Blue Mountains proper we still have a good deal of green coffee on the trees, some of which will not be ripe till

cases have been observed in horses." I have no doubt but that had Darwin been the observer of the details of those cases he records, he would have discovered that the areas affected, though very closely corresponding to the areas coated with white hair, were yet more nearly identical with the areas of white skin. It should be understood that the areas of white hair and of white skin do not exactly correspond in our own cattle. Some British cattle that are mostly white under the white hair have black or brown patches or spots away from coloured hair of any kind, and not noticeable until the hair is turned up. Again, the darker skin prevailing under dark spots, extends often an inch or more under the surrounding white hair. Only a small percentage of cows that are practically white haired have the black skin predominating.

September. The trees are in capital heart, and are likely to do better next year if the seasons are favorable; ripe, and green coffee, as well as a good blossom are now to be seen on the trees, as is often the case in "Udapuscellawa" and "Uva" generally. That Jamaica coffee can and does bear heavily is exemplified by a small field on this property named "Top Mountain;" it must, from all I can learn, be fully 40 years old. We weed it as a job for 2½ acres, and it has yielded 90 tubs of 64 quarts, which at 40 tubs to the tierce is good for 2¼ tierces, say 1,800 lb. marketable coffee, say 16 cwt. or 6½ cwt. an acre. Now as these two-and-a-half acres are such "patch-patch" coffee as not really to be more than one-and-a-half acres of *bona fide* bearing trees, it raises the bearing per acre from 6½ to 10 cwt. per acre, a result I should much have liked to have realized from the 50 acres of *coffee land*, I weed and keep up, but which from crop results must, I am sure, be very much less of *coffee trees*. This result convinces me that Jamaica old coffee generally cannot have much more than 500 trees to the acre, or surely the yield per acre would be more, as individually the trees bear heavily and remind me of the finest coffee in Uva.

Mr. D. Morris, of the Royal Gardens, Kew, has sent me a copy of his address on the "Vegetable Resources of the West Indies," delivered before the London Chamber of Commerce. All he says of the capabilities of the Antilles to grow large and minor products, of the large reserves of virgin land available, and the good climate in all the larger islands is perfectly true, but until these lands are made available by railways or good cart roads, and there is a *reliable* supply of labor to be obtained, things must remain *in statu quo*. I would therefore caution intending investors in Jamaica not to be induced to settle here as coffee planters until they have first come to look and judge for themselves. The land is no doubt "all there" in thousands of acres, but it is mostly very steep and exposed to "Northerners," and being at present so inaccessible and far from labour, he would be a most venturesome man who would sink his capital on our northern slopes. That the estate in which Captain Coxhead, R. A., is interested, has, up to the present, been sufficiently supplied with labor, does not make it by any means certain that if a few more estates were opened in that locality sufficient labour would be forthcoming. Even could this great difficulty of labor be overcome by cooly emigration, or Creoles from the other parishes, large barracks would have to be built, and the trouble of transport would be such that unless Government saw the way to open up these forest reserves it would be madness to open land for coffee, consequently matters are likely to remain as they are, and the cultivation of high grown coffee in Jamaica is not likely to be much extended.

I agree with all the gallant Captain and ex-"A. D. C." says in regard to breeding of horses and stock generally. Pen keeping, with Pimento to back it up, is not an unprofitable occupation, and as to banana growing, figures speak for themselves: even old King Sugar and rum will pay when the Bounty system is swept away, especially if the system of "tines" is adopted as in the French, and even some British colonies; and as to climate it is perfect on the hills, except during the few weeks of the two rainy seasons, and even in the low lands it is fairly healthy, away from mangrove swamps, and I believe with Capt. Coxhead that even labourers of the English class could occupy lands on the lower slopes, and grow various kinds of products on small holdings

of a few acres, much to their comfort and benefit, provided they were temperate, intelligent, and hard-working. In the old days raw run and unhealthy barracks decimated the troops far more than actual ravages of "yellow jack"; yellow fever is now but seldom heard of, and may often be traced to want of common precautions on the part of the sufferer. After all, all countries have their peculiar diseases; England its consumption, scarlet and typhoid fevers; India its various fevers, cholera and dysentery; surely the West Indies cannot be expected to go "scot free," but must have their share of "the ills to which flesh is heir."

Our Governor is away on short leave; a rumour has reached the colony he is not likely to return, as he has been selected for the Governorship of Ceylon, in succession to Sir Arthur Gordon; another rumour is to the effect that Walter Sendlall, formerly in the Ceylon Service, is to be promoted to the Governorship of Trinidad. These may be simply "canards"; the appointments may not be unlikely to follow, but surely Sir Henry Norman will return to complete his five years, as well as to preside over the Council during the forthcoming debate on the revised tariff, and the vexed question of a land-tax, which was to be tackled next session in October. It would doubtless be better to have no land tax at all, as being likely to deter settlers from investing, but as the Government seems to need and *must* have the money, my opinion is a uniform rate of one shilling an acre on all *cultivated* lands would be less onerous and more popular than a tax on the assessed value of properties, of course, the tax should be levied on white, brown, and black alike, and a very small impost placed on the remaining land, which is mostly too rough, too worn out, or too steep to be of any use to the owner. Thus, a property 200 acres in extent of cultivated land would pay £10 per annum, and on the 600,000 acres of land estimated to be under cultivation a sum of £30,000 would be secured, which, in addition to increased tariff charges, would yield the Government sufficient funds to further increase education, make penny postage universal, and yield a sum to pay interest on sums borrowed to extend the railway, and in general better to open up the country.

Nothing has yet been done by the Kingston Municipal Council in regard to street reconstruction, and the drainage of the town, or the building of a dock, and the erection of a quay wall, so as to give Kingston a proper sea front, and do away with the present system of private wharves. The Hotels Company have at last selected a site, and will soon commence the erection of a good "hotel" on the American system.

W. S.

THE NEW INDUSTRIAL ERA IN INDIA.

Sir William Hunter's recent lecture under the above heading, delivered before the Royal Colonial Institute, is fraught with a significance to English farmers and manufacturers which they can ill-afford to despise. The development of India as a food-exporting and manufacturing country, must involve changes in English production, which although bringing their compensation in the end must for a time be attended with suffering and loss. Formerly known as a dealer in curiosities and a retail trader in luxuries, India has developed under British rule into a wholesale producer of staples, doing an enormous export business in goods which feed and the fibres which clothe distant nations. The development has been mainly

regulated by the cost of carriage between this country and Europe, and by the comparative cheapness of production in India. The comparative value of silver in the East and West has also been an important factor. When Indian commodities were conveyed across Asia by caravan, only such articles as would bear a large addition to their cost could be exported and accordingly we find that gems and drugs were the principal if not the only, Indian products which found their way to the markets of the West. In later days, when the journey was made partly by sea by way of the Persian Gulf and afterwards by the Red Sea, the articles exported from India grew in bulk and multiplied in variety. Subsequent to the expedition of Vasco da Gama, the adoption of the Cape route gave a great stimulus to Indian export trade, and the comparative cheapness of this route opened out the hand manufactures of India to Europe. In the present day, the introduction of railways in India, the increased use of steam-shipping, and the cutting of the Suez Canal, have enabled India to appear for the first time in European markets as a producer of raw materials upon an enormous scale. Her old trade in precious hand-made articles has given place to a vast exportation of fibres and food stuffs, and a competition has resulted between Europe and India, which Sir William Hunter describes as "the competition between the productive powers of the tropics and of the temperate zones."

In 1834, the exports from India were valued at 9½ millions sterling, which increased during the following twenty years to an average of 20 millions for the five years ending 1854. During the next twenty years, the introduction of railways, the development of steam-shipping via the Cape, and the opening of the Suez Canal enabled a vast development of Indian export trade to take place, and for the five years ending 1874, we find that the exports of Indian merchandise averaged annually 57 millions sterling. The full influence of Indian railways, of steam navigation, and of the Suez Canal was, however, more fully felt during the following ten years, and in 1884 the exports of merchandise reached the enormous total of 88 millions sterling. The revolution in Indian shipping, caused by the opening of the Suez Canal, has resulted in a considerable decrease in the number of vessels, an enormous increase in their size and carrying-capacity, and a vast expansion in the amount of business done by steam vessels, while there is still enough business of another class to enable sailing ships to hold their own. The increase in shipping could not, however, have taken place had it not been that the development of railways in India enabled staples to be brought to the sea which could never have been brought down by the rivers. The populations along the course of the great navigable channels of India are so dense, that the quantity of food stuffs required for their own consumption leaves but a comparatively small surplus available for exportation; moreover, the great rivers tap but a very small proportion of the Indian provinces: while the railways open up vast tracts of country for which there were previously no outlets for the products of the soil. The introduction of railways into India has, therefore, materially assisted the development of Indian export trade, and the diminishing cost of railway working will tend to further increase that development. In the last fifteen years, the system of Indian railway finance and construction has undergone radical change, and the old guaranteed system of 5 per cent. has given place to the system of State Lines and "Assisted" Lines with a guarantee of not much over 3 per cent. The cost of working has also been largely reduced by

the adoption of Indian coal as fuel where wood or fuel brought from England, was formerly used and at the present time a new fuel seems to be developing in some parts of the Empire. On the Sukkur line experiments made last year showed the average cost of working per 100 miles to be Rs6 with local petroleum as against about Rs5 with coal.

The significance of the reduced cost of working Indian railways is too grave to be lightly dismissed, when its importance as a factor in the cost of transit between India and Europe is considered, and, with further economy in this direction, there can be no doubt that it will be possible to lay down Indian staples in the English market at prices which will defy competition.

The growth of India's export trade has not been unattended with suffering to some portion of her population. When a new food-producing area is opened up by a railway, local prices rise, and the husbandman grows rich but the artisan and the landless labourer have to pay more for their daily food, and until an economic adjustment is effected by a rise of wages, which sooner or later follows the introduction of a railway, a certain amount of suffering is entailed upon these classes. The new industrial era has also impaired or ruined many of the old cities and ancient marts of India, and there has been a growth of new mercantile towns, developed mainly by the growth of railways which have effected a series of displacements in the centres of traffic. We have so far been dwelling upon the cost of transit between India and Europe, and the ways in which reductions of this cost have been effected; but this cost is, however, but one factor in the Indo-European trade. The cost of production is an equally important factor, and, in considering this point, it behoves us to see what commodities India can produce more cheaply than other countries. The first industry that will occur to most minds will be the agricultural industry, for, while Indian cultivators lack the advantages which science and capital bestow upon the British farmer, it must be apparent that in India Nature does very much more for the husbandman than she does in England. An equal amount of human labour produces, with the aid of sun and rainfall, a larger value of saleable produce. The cost of production is less, the cost of living is less, and the rates of wages are naturally and proportionally less. Another point in favour of Indian agriculture is, that the agriculturist enjoys low rents and fixity of tenure, and the result of the latter condition is that the husbandman has what may be called an hereditary knowledge of his fields, and the net result is that the food staples and seed crops of India are produced at a much lower cost than in England. The abolition of internal Customs and the greater facilities of land and sea carriage have largely assisted to swell the growth of the Indian export trade, and we will briefly trace the history of the export of the three great Indian staples—wheat, cotton, and rice. The former export duty on wheat in 1873, the quantity exported was 1½ million cwt., while, since the abolition of the duty, the quantity has increased to 21 million cwt., and, owing to the construction of railways in new grain-producing areas, a considerable increase may be looked for. In fact, the cost of production is so low, that the ultimate dimensions of the Indian wheat trade are chiefly a question of possible reductions in cost of carriage. Up to 1875 the exports of oil-seeds have averaged about 4 million cwt., but in that year they were freed from duty, and, by 1885, the quantity exported had grown to 18 million cwt. The rice trade has not shown such considerable increase as the two former staples, but

is due to the fact that the export duty is still levied upon it, and in this staple India has to compete with the silver-using countries of the East instead of with the gold using countries of the West, as in the case of the wheat and oil-seeds trade. We will deal with another factor in Indo-European trade, and review the development and prospects of India's manufacturing interests in a future issue.—*Indian Engineer*. [The importance of the manufacturing industry is shewn by the statement of Mr. Sutherland, Chairman of the P. & O. Company, that the Corporation has had to build special steamers to convey Indian cotton goods to the far east.—Ed.]

THE PINEO-MAY SCHEME.

Planters' Association of Ceylon, Kandy, 23rd Aug. 1888.
The Editor, "*Ceylon Observer*."

SIR,—I beg to enclose copy of letter received from Mr. J. McCombie Murray, Philadelphia, with reference to the Pineo-Elwood May scheme and his own action in pushing the sale of Ceylon tea throughout America—Yours faithfully, A. PHILIP, Secretary.

Office of the Ceylon Pure Tea and Coffee Co.,
60 North Thirteenth St., Philadelphia, Pa.,
17th July 1888.

To the Secretary of the Planters' Association of Ceylon, Kandy.

Dear Sir,—Referring to Mr. R. E. Pineo's letter of 3rd May, stating conditions on which Mr. S. Elwood May is willing to push the sale of Ceylon tea in the States, I beg to call your attention to the clause which reads as follows:—"That he be permitted to announce himself as the accredited representative agent of the Planters' Association of Ceylon."

Although Mr. Agar refers to my work in America as attacking "only limited markets," I cannot well remain silent, when it would appear there is a possibility of my firm being overlooked when it is proposed that any "accredited agent" is to be officially appointed. Nor do I presume that my interests in the matter will, in the event of such accredited agent being appointed, be overlooked by the Planters' Association of Ceylon. Still in justice to myself I must protect my interests by reminding the members of the Association that any such appointment made in favour of anyone in a special way would be detrimental to my business and the status thereof, so that the question arises who has worked for and deserved the honor of being called the accredited agent of the Planters' Association of Ceylon?

Were the wording an accredited agent I could have no objections, as it would be well for me were there a hundred accredited agents of the Planters' Association of Ceylon in this great country; but as it reads the meaning is very different, and any such appointment would be an injustice to me and my business, the only established business of the kind in America.

I am not writing to flatter myself, but to state my claims upon the Planters' Association as representing the planting interests of Ceylon.

Now Mr. Pineo's scheme supported by Mr. S. Elwood May is of course worthy of every support. In fact it is similar to what I am carrying out myself, the only difference being that Mr. May is said to have capital, while I am only a poor planter. Yet, however poor I may be, I have at least risked everything to make my enterprise a success. Having fought my way single-handed, I am entitled to credit for at any rate whole-hearted service and undivided attention to the interests of Ceylon. Yes, I am poor, and pushing Ceylon tea keeps me poor; but I doubt if Mr. Elwood May will ever do more for Ceylon than I have done and will do, and it will take time as well as money before he can do the business that I am now doing in pure Ceylon tea.

From the day I sent to the editor of the *Ceylon Observer* a letter addressed to the members of the Ceylon Tea Syndicate, dated 23rd July 1886, I have

thrown myself into the work in which I am now engaged, and since that day I have endeavoured to show by results that I was in earnest when I wrote the words "I bind myself to conscientiously serve your interests."

My business, generally known as the "Ceylon Pure Tea and Coffee Co.," is in no way limited to any market, and although extension with limited capital is necessarily slow, it is none the less sure when properly managed.

I have the nucleus of a great business, and my life, if spared, will be devoted to the completion of what I have begun.

Had I no ambition for the future, the subject of this letter would be of little interest.

As it is I am already, through the agency of Messrs. Barclay & Parsons, advertising the "Kootee" brand in New York city, and I am only doing justice to myself when I claim for my firm the first right to any official declaration relative to the representative agency of the Planters' Association of Ceylon.

I trust my meaning is plain in writing this. I will be glad to hear Mr. May has commenced to boom the city of New York, Chicago, or any other city excluding Philadelphia as an accredited agent of the Planters' Association, but not as the or what might be the only accredited agent of that body.

I trust the Association will give careful consideration to my claims in this matter, and not take any steps which might act as a discouragement to one of themselves in a very uphill fight on behalf of their own interests.

My business is day by day putting on the appearance of success, and I am hopeful of being able at no distant date of having the sign of the Ceylon Pure Tea & Coffee Co. prominent in every large city in the States of America.—I am, dear sir, faithfully yours, (Signed) J. McCOMBIE MURRAY.

AGENCIES OF THE CEYLON PURE TEA AND COFFEE COMPANY IN AMERICA.

	Head Office.
Philadelphia	J. M. Murray & Co., Finlay Acker & Co.
New York State.	
General agents	Barclay and Parsons, New York City.
Special Agents in N. Y. State.	
Troy	John Ware
Tarrytown	R. J. Leonard
Whitehall	J. H. Sullivan & Co.
Lake George and Warren County	L. Crosby
Buffalo	W. A. Wallis
Wisconsin.	
Milwaukee	E. K. Morice
California.	
San Francisco	Gen. agent Alex. Souttar
San Diego	W. H. Murray.
So far 12,000 samples of tea have been given away through the above agencies.	
(Signed) J. M. MURRAY & Co.	

IS BRAZIL A FERTILE COUNTRY?

There is a very generally received opinion, in the United States and Europe, that Brazil is a wonderfully fertile region; many persons, well-informed ones too, probably regard it as the richest land in the world. There are plenty of authorities to support this idea. Scores of travellers have described its exuberance in glowing terms; cyclopedias and school-geographies have pictured the undoubted luxuriance of its forests and prairies; it is known to be the great coffee-producing country of the world, and its sugar, cotton and tobacco have long figured in commerce; the Brazilians themselves are thoroughly convinced that the agricultural resources of the empire are boundless, only needing an influx of foreign labor to develop them. In venturing a somewhat diverse opinion I shall be regarded as a heretic, unfriendly to the coun-

try and unworthy of attention. But let us look at the acts.

At present agriculture in Brazil is nearly confined to a comparatively narrow belt extending along the coast from Cape St. Roque southwards. This region is, in the main, very fertile; the decomposition of the gneiss rocks, which form most of the mountains and hills, has given rise to a rich reddish soil, generally deep and affording excellent crops of coffee, cane and other products even with the miserable no-cultivation which is in vogue. There are, however, considerable tracts of stony or badly-watered land, which, collectively, are of great importance, but must practically be subtracted from the agricultural lands of the coast region.

The Amazon valley is a vast steaming forest, generally (in Para at least) with the poorest possible soil; luxuriant as the vegetable growth is, it covers a ground composed of sharp white sand, or at best, of a poor clay, almost devoid of the elements which nourish forests in other parts of the world. Most of the few plantations are on the alluvial iron-bottoms, or tracts of *terra preta* (black land), which was formed centuries ago by the rubbish and rotting palm thatchets of Indian villages. Nevertheless, the Amazon valley is well adapted for certain crops, and with the introduction of improved agricultural implements, it will give good returns to the farmer. The forest is nourished, not from the ground, but by the air, which is always surcharged with moisture; some kinds of trees will flourish for weeks after they are cut. This excess of moisture also tends to support the growth of certain cultivated plants, especially sugar-cane, coffee and tobacco. And if the ground, even this poor clay and sand, were properly prepared to receive the roots of the plants, good crops could be obtained almost everywhere. As it is, comparatively little of the land is regarded as fit for plantations, and these are generally abandoned after a few years.

All the great interior region, comprehending the Brazilian table-land, is covered with *campo*, interrupted here and there by little patches of forest on hillsides and along the banks of streams. Botanists who have travelled through the *sertao* have been struck with the immense variety of families and species to be found among the *campo* plants, and they have naturally fallen into the error of regarding it remarkably adapted for plant growth. The truth is that nearly all the Brazilian tableland is a howling sandy desert with a wonderfully rich desert vegetation. The botanists may find a thousand species of plants on a square league of land; but I doubt if the same land would produce a thousand bushels of corn or potatoes. Much of the country is adapted for pasturage, but only in the wet season; during the dry months cattle must be driven away to the lowlands. The little strip of forest-land can be used for planting and in some places they give good crops; but they form only a small part of the whole. A large district comprising part of Beara, Piahy, Rio Grande do Norte, Pernambuco and Oahia, are subject to periodical droughts, which destroy the cattle and plantations and reduce the entire population to the utmost poverty—often to starvation.

Two elements which go far to determine the fertility of Europe and the United States are almost or quite wanting in Brazil; the winters and the action of earth-worms. Our northern winters are of immense assistance in the formation of vegetable mould. The herbs, grass and forest leaves die away in the autumn and lie in thick beds on the ground, where they are speedily covered with snow; successions of thaws, and finally the spring rains, reduce these leaves to sodden masses; as the sun returns they decay slowly, forming a rick, dark soil, rich with the elements of new plant-growth. In the tropics, the leaves and herbs fall singly, are baked in the sun, broken by the wind, and finally pass away almost entirely in the form of gases, hardly anything being added to the soil. Add to this fact the influence of frost in breaking up and disintegrating of rocks, and the importance of winter cold in the formation of soils will readily be seen.

The elaborate studies of Mr. Darwin have shown that the despised earth-worms are the preservers of our farms and gardens; unseen workers, they are ever bringing up the rich subsoil and strewing it over, the surface; boring the ground in all directions, they keep it loose and soft, and fit it for the roots of even tender plants. Now, earth-worms are by no means common in Brazil; they are altogether wanting in the *campos*, and even in the forest they are rarely seen except along the banks of streams. Probably the sandy soils so prevalent in Brazil are ill adapted to them; very likely, too, they would be of less use in ground which, by its nature, is friable and easily pierced by roots. At all events they are an element, of greater or less importance, which is nearly wanting in Brazil.

I have written all this in no harsh spirit—rather as a friend of Brazil. I wish to point out a mistake which might in the future lead to grave troubles. The first element of success in the individual, or in a new country, is a thorough knowledge of the resources of the weak points which must determine success or failure. Brazil has great resources; it has elements of agricultural wealth which are far from unimportant; but by overrating its own riches it may be tempted to waste them; by resting too securely on agricultural industries it may neglect the no less important ends of manufactures, mining, grazing and commerce. Brazil is far too large and important a country to be content with one element of success. She should seek for all.

HERBERT H. SMITH.

—*Planters' Monthly*.

AGRICULTURAL ITEMS.

(From the *California Florist* for June.)

QUICK WORK.—In Augusta, Ga., a tree felled in early morning, was, before nightfall the same day, converted into paper, and sent out bearing the current news.—*Ex.*

PARCHMENT PAPER.—Mr. A. C. Oelschig, the Savannah, Ga., rose-grower, writes, that so far he has not been able to obtain parchment paper at a price which will justify practical use. It could not be obtained in Europe last season, and the New York factories wanted 25 cents a pound, which is too much. He sends *The Florist* a number of samples of the paper, and promises a full report of his experiments this season. It is safe to predict that this material will soon supplant glass for the protection of plants from both heat and cold in all semitropical countries.

A WEEPING ROSE TREE in a garden at Koosterin, Holland, is so large that thirty performers lately gave a concert under its branches. It is sixty-five feet in circumference, and it has been estimated that it had 10,000 roses at the time of the performance.—*Rural Californian*.

VINEGAR.—A patent has been granted in England for the manufacture of vinegar from tomatoes. The fruit when ripe, or nearly so, is reduced to a pulp and steeped in water for twenty-four hours. The resulting liquor is drawn off, sugar added and the whole allowed to ferment.

MR. PURVIS, of Kukuihaele, Hamakua, has a number of Japanese preparing the ground for a large number of tea plants, which he has successfully raised, and there seems no doubt but what tea-growing will become a profitable industry in the Hawaiian Isles.

SEA-WEED.—California big trees will have to take a second place as botanical giants now that the ocean has undertaken to beat the land in the size of its products. Capt. John Stone, of the ship "Clever," picked up a sea-weed on the Atlantic near the equator, that was 1,500 feet long. It was an alga, and has been identified as a specimen of *macrocepsis pyriferus*.—*Philadelphia Times*.

CINNAMON IN CEYLON.

(Extracted from the "Sandaresa," a native bi-weekly paper.)

It is said that the price of cinnamon is daily decreasing on account of over-production, but there is another cause for the decline of prices, that is, by lessening its demand in the market. Several persons manufacture and export cinnamon leaf oil in consideration of the small remuneration they get through it. In the Negombo district the distillation is not done by the proprietors but by outsiders, who pay a small sum in consideration of the leaves they get. If a distiller were to produce 100 bottles per month (which is the highest average he could attain), and selling these at the rate of one rupee per bottle, he would get barely 15 rupees as profit. On large estates leaves are obtainable during eight months of the year, and if the distiller be very active he will be able to earn R120 per annum. The sum paid to the estate owner for the leaves and fuel is only R5 per month. But it is apparent now that the cinnamon estates suffer much on account of the loss of material carried away in the form of leaves in consideration of such a small sum as five rupees. A great deal of matter which should otherwise fertilize the soil is removed from it. Ceylon exports about 10,000 bottles of cinnamon oil annually. On account of its low price it is used in the manufacture of soap and perfumery. If there is no leaf oil, the manufacturers have to use oil made of bark, and thereby cause a good demand for bark of the lower quality. Instead of 10,000 bottles leaf oil used at present, they should at least use 5,000 bottles of bark oil. To manufacture these 5,000 bottles they require 2,500,000 lb. of coarse bark at the rate of 500 lb. per bottle.

By that means the export of so many pounds of coarse bark would be stopped, and for that the consumers would need at least a little less than 2,500,000 lb. of bark of good quality, and it is for the proprietors to consider how the market would be effected when an additional demand of 25,000 bales of good cinnamon bark is caused in the market. Therefore, it is advisable to leave off the small profits obtained through the distillation of leaves in consideration of the higher demand arising in the market for the bark.—*Cor.*

LOWCOUNTRY NATIVE PRODUCTS.

PADDY AND COCONUT—DIFFICULTIES MET WITH IN THEIR CULTIVATION—THEORIES—USE OF THEORETICAL KNOWLEDGE.

Paddy and coconut are the two principal products cultivated by the lowcountry *goyiyas*. Paddy is usually cultivated in small areas; and as the labour required is great and the results are uncertain, it is usually cultivated by the owners themselves without going to the expenses of having outside labour. In its cultivation the *goyiya* has first to depend upon rain for his supply of water, which is very essential. If he gets more of it, he falls into the danger of not being able to cultivate for the season or to suffer a loss in his crop. He has other difficulties to face besides the supply of water. These are the damages caused by animals, large and small, together with several blights, through fungi, &c. As for larger animals, cattle are always ready to damage the crop if it is not properly guarded throughout. The cultivators are familiar with nine different blights or diseases preying on the paddy plant. Much of the above enumerated evils could be averted if a proper system of cultivation is adopted. With a little knowledge of climatic variations and of principles of engineering, much of the failures could be averted, as the cultivation could be calculated according to the supply of water. By improved systems of cultivation, as through ploughing, transplanting &c., the plants will get healthier and less liable to attacks of blight, &c. Thus, we see a system of implanting the principles of agriculture to village boys, should in the end, lead to a better system of cultivation, and with their knowledge, they would be

able to cope with these evils better than at present, and it is natural enough they would do so. As for the other product, the coconut, it is not so trying a cultivation, and it being a grateful tree, the cultivator with very little trouble could realize his end, but even with that a systematic cultivation with better methods would make it more profitable. Europeans and other intelligent persons who have embarked in its cultivation do it systematically and get higher yields. The *goyiyas* are not without their theories of cultivation; they have deduced those theories by practice, but still they cannot give proper reasons for them. These rules, found out accidentally as it were, they follow blindly without considering the external circumstances. Thus, if a cultivator were questioned on the best method of improving the produce of a coconut garden, he would at once give as his opinion, to establish chekkus (native oil presses) in the place. But in most cases he is at a loss to assign reasons for that improvement. The improvement here is caused by the cattle employed in the work. They drop a deal of dung and urine about the place and thereby fertilize it. There is another cause why the dung and urine should be valuable in this particular instance. Unlike the cattle which they generally have on an estate, which always feed on the grass grown on the soil and then impart as manure only a part of what they have actually taken; cattle employed in chekku work are well fed with straw, cakes, &c., and these droppings are comparatively valuable as manure. And again if we inquire why trees growing near dwelling-houses yield better, the invariable answer would be, that it is on account of the human voice affecting them, though it is caused by the clearing and the placing generally of various sorts of materials which form valuable fertilizers. The above are examples of the theories held at present among the cultivators who have no systematic idea of what they do, but if they can deduce reasons with at least a little knowledge of the principles of Agriculture, things would look better and brighter.—W. A. D. S.

POTATO CULTIVATION IN CEYLON.

We are not aware if the following letter has ever been made public. It is of interest, not merely for its style and contents, but for the evidence it affords that the wife of the Governor of those days discharged semi-official functions on such domestic subjects as the cultivation of Potatoes. The letter is addressed to Mr. J. F. Lorensz, to whom we recently referred as the agricultural Magistrate of Morowa Korale, and who was the first to cultivate potatoes successfully in Ceylon:—

Mount Lavinia, September 28th, 1812.

Sir,—Knowing as I do the deep interest that General Brownrigg takes in the welfare of the inhabitants of this country, and how much he has suffered from the distress he has witnessed in consequence of a scarcity of food, I cannot possibly wait for his return to express to you in my own person how highly gratified I feel at your endeavours to cultivate potatoes being at last crowned with success. Through the Chief Justice I yesterday received the basket you were so good to send to the Governor, and which from knowing its contents I read.

It is with very sincere satisfaction I can say that, although I did not pick out the best, I had three boiled, and they were more highly flavoured and more frumaceous than any that I have seen here either from Bengal or Bombay. I immediately asked my Malabar servant if he would not like that vegetable as well as rice, to which he cordially assented. If any praise of mine could add to the inward satisfaction you must feel in having accomplished so great a blessing to this country, you not only deserve but have them to the fullest extent. To those who have seen the effects of scarcity in a country where so many prejudices are to be combated, your success must indeed give the truest pleasure. In hopes of others attempting the same laudable effort, I have directed a gentleman to make public mention of the result of your experiments in the *Government Gazette*.

Sir Alexander Johnston asks me if I have any of the Bengal potatoes left, with the idea of sending you for seed. I am sorry if it was your wish, but for some time I have not had a potato in my house. When the ships from England arrive, if they have any, particularly from the Cape, I will secure you a few.

I have the honour to be, Sir,

Your obedient, humble servant,

(Signed) SOPHIA BROWNRIGG.

(From the Madras Government Gazette.)

Colombo, 30th September, 1812.

At a moment when the distress of the inhabitants for want of grain is a subject of deep concern to every feeling heart, it must afford general satisfaction to hear that in the very district where scarcity chiefly prevails, the efforts of a gentleman have, at last, succeeded in raising potatoes of a quality superior to those usually imported from the Continent of India, being more dry and farinaceous. We, therefore, are most happy, in this public manner, to express our well-deserved thanks to Mr. Lorenz, Sitting Magistrate of Morowa Korale, for his very laudable and useful exertions, in bringing the culture of so inestimable a vegetable to such perfection.

It cannot be uninteresting to give a detail of the first crop. Ten cuttings were planted on the first of July. The appearance of the plant was for some time not promising, the stem having grown too luxuriantly; but on the 21st instant, being dug up were found to have produced abundantly. One of the plants yielded 70, another 56, and one 52 potatoes of tolerably large size. A few of these Mr. Lorenz has been so good as to send, as a specimen of the produce of Morowa Korale, to Colombo; and being boiled were found to have an excellent flavour, and to be, in every respect of the best quality. This being a vegetable eaten by every caste of Natives, it is earnestly to be hoped that many persons will follow the patriotic example of Mr. Lorenz. General and repeated trials ought in fact to be made to rear this article of food, the culture of which, requiring a dry soil, seems to be of all others the best adapted to avert the possibility of famine in these eastern countries, where excessive drought is so frequently the cause of such calamity.

We had long known that Mr. J. F. Lorenz, senior, was a Prussian Colonist who had been the first to grow Potatoes successfully in the Island when sitting Magistrate of Morowa Korale, but we were not aware that he had interested himself much in other products, or that his agricultural tastes had secured him any official status. A letter from the Matura Kutcherry, bearing the signature of William Granville, Collector—there were no Government Agents in those days, and the new spelling had not given an unfamiliar appearance to well known town—and dated the 17th December 1813, informs Mr. Lorenz that the Governor has been pleased to appoint him "Superintendent of Cultivation in the Morawa Korale," in recognition of the interest he had shown in agriculture. The office was evidently honorary, for we find no mention of any remuneration; but the very elaborate and precise instructions in the latter of appointment show that the acceptance of the office involved the discharge of important duties. The Magistrate was, in fact, to be an Assistant to the Collector in matters agricultural and botanical. We hope to publish the lengthy letter on some future occasion, but note meanwhile the very great interest which the Government at that early date exhibited in Native agriculture. Mr. Green will be interested to hear that the advantages of transplanting paddy were not unknown then; and 75 years ago the Collector of Matura had no suspicion that Coffee would prove such a disastrous failure as it did on the Morawa Korale hills; for he presses on the new Superintendent the need of making experiments with Coffee. It would be interesting to ascertain the results of those early experiments. A

special interest attaches to the inquiry in view of the recent Agri-Horticultural Show and the Southern tour of Sir Noel Walker; and Mr. Baumgartner's industry, if he should hunt through old records, might be rewarded with success, which we should be glad to chronicle. Curiously enough, Cotton too was then pressed on the attention of the people, and it may be that, with the new Spining and Weaving Company just started, the future for Cotton is brighter in the South than the outlook for Coffee ever was. We have, however, now to do with a letter written four years later, in which some of the inquiries of Mr. Granville's successor are answered by the agricultural Magistrate, whose Germanisms do not make his answers the less intelligible or interesting. The letter runs as follows:—

Berlepanatera, 8th August, 1817.

Sir,—I have to apologise for not answering earlier your letter of the 10th ultimo; illness prevented my doing so. I now beg leave to lay before you my answers to your questions.

1. In the short period during which I held the situation in the Morowa Korale, namely from October 1813 till June 1814, I have obtained only a circumscribed knowledge of the nature and extent of all the arable land in the district. However, I ascertained that the extent of Government land appearing in the Kutchery books does not come much short of the truth, at last Mr. Granville thought so. I began a special Registry of Berlepanatera, Ginlye, Urobokke, and Dampah, which was not only to include all the Deewel and Malapala lands, but also the other Paraweny lands with their extent and their present possessions; but was removed from hence before I could complete it. If it be required of me I shall continue with the undertaking.

2. Since my return hither I have not been able to do much; my arrival fell in sowing time; as usual, the general complaint was want of seed grain. The last harvest had fallen out so unpropitious that hardly one person out of ten had any grain at all, and that which there was, was of the worst grain. The consequence was that those who wanted seed grain were obliged to borrow from other people who had any, to be repaid at the ensuing harvest with fifty per cent. Much ground lies therefore waste this year—nor do the fields that have been sown promise fair on account of the bad grain sown. This District lies so far distant from Matura, and is separated from it by mountains almost impassable for passengers, that it is with difficulty the people can obtain relief from the Desave or the Modiar of the District, for no person to whom the distressed cultivators can apply lives in the District; even the Vebede Mohandram who resides at one end of the District, namely at Morawakke, through age and infirmity, seldom stirs this way. Such of the headmen as are able to assist the needy do it, but not without the reward of 50 per cent; this bears exceedingly hard upon the poor cultivator here, and I believe there is hardly any other part of the Matura District to be pointed out where the generality of the people are so extremely needy as here. I shall take the liberty of suggesting to you in the sequel what I think an effectual remedy for this evil.

As to myself, in the short space of time I had before me, I followed up my first plan. I sowed a small plot of Government ground with the best seed I could get, and at the proper season transplanted it. I have now the satisfaction to see (and every person passing by observes it) that my little field produces the tallest and thickest crop in the village. I have taken pains to draw the attention of the people to my plans. I have shown and demonstrated to them, that instead of throwing on the ground four bags of seed grain in order to fill an ammunam's extent, I make use of even less than one bag, and that in this way I obtain a larger crop and better grain than they. I have this time actually convinced them that they are in a wrong opinion that the transplanting of the paddy is so difficult, or would require a greater number of people to work for a number of days which would put them to a great expense in

feeding these people, as is the custom. My paddy was transplanted by the children of the villagers, whom I expressly collected for the purpose, and who did the work cheerfully in the expectation of the promised meal. Further, I have laid out a small potato field, and though I had only a few seed potatoes, yet my little crop promises fair to yield a good quantity of potatoes for next year's trial. I have also a good number of young Sapu plants ready for transplantation, the ground where they are to be put in being cleared by my own people.

3. There are no Tanks in the Morowa Korale. The country being mountainous, and the paddy fields situated in the villages, they are irrigated by innumerable little springs and rivulets led through them in every direction. The tying of the fences to defend the fields from the raids of cattle and wild beasts requires the superintendence of a person in authority to overcome the laziness and indifference of the people.

4. Hemp thrives much better in sandy soil than in clay ground and on hills. I have made no experiments in raising it, but if required, and seed is sent to me I will make the trial. Wheat and Barley I have tried often in different ways and at different times, but with no success. The principal and I may say only requisite to bring this district into a most flourishing state of cultivation, and to relieve the distress of the cultivators, in my opinion, is to provide it with the best sorts of seed paddy that can be obtained, and to issue it on application at moderate interest. This may be done by cultivating a certain quantity of the Government share of the paddy rents in kind. I mean to say, the best kind is to be laid sately up under the responsibility of trustworthy persons to be issued when wanted; if all is not wanted to sell it on account of Government. I am too well assured that Government cannot sustain any loss by this plan, but will be a certain gainer, and the country will be benefited by it; for measuring in and measuring out and laying it carefully up a wastage might be allowed to the person who takes care of it.

5. The Alepe grain never arrived in this District; myself and several other persons who wanted it sustained some loss.

6. The only innovation in paddy cultivation which would be of importance is transplanting, it saves as I said before nearly two-thirds of the grain, and it gives a larger crop and better grain. But among people of the common and lower class in this country, as well as in every part of the world, persuasion on the subject is of little or no effect—whether my example will do any good, time will show. Yet I am of opinion that so desirable a change in the present mode of cultivation might be very much forwarded, if government were to put the holders of Deeval and Mallapalla lands under an additional but light obligation—namely of planting paddy upon one paha's extent on each ammanam of Government land which the holder possesses. Or the obligation might be made to fall on the Vidhan Aratchies and Gameraales in actual service, or the superior headmen of each village might be enjoined to plant one paha's extent every Harvest not on his own but on Government land.

The success which cannot fail to follow these trials must open the eyes of the people that this system is preferable to the old. At the same time, they will become sensible that it is not so difficult to be compassed, as prejudice has made them believe.

I myself intend to make a trial on a small scale in every village in both the Yalla and Maha Seasons.

I shall for the present close this letter in the best hope to receive soon from you such instructions as may enable me to use my best endeavours to forward the improvement of this District, and subscribe myself, with particular respect,

Sir, your most obedient servant,
J. F. LORENZ.

J. G. Forbes, Esq. Collector, Matura.

It will be soon from the interesting glimpse of the past which the letter affords that, in many respects, old conditions and difficulties still exist. The removal

of Officials from one station to another often postpones improvements; the people are still slow to welcome any change in their methods, but, as Mr. Lorenz shrewdly points out, it is the same with the lower and less educated classes everywhere; the Headmen even then were greedy of gain, and as the letter dryly records were willing to help those in need with seed paddy for a reward of 50 per cent. We are not aware that transplanting is practised to any greater extent in the Districts in which Messrs. Granville and Lorenz laboured, than in any other part of the Island; but the suggestion of the latter might well be carried out now, of making transplantation one of the conditions of holding Government land or Government office. The plea now, as it was then, is "too much trouble." Headmen are most able to overcome the trouble, and the drilling their labourers would receive would be useful on their own lands. The old German did not run wild over new products; but knowing the people and their habits by living among them, and with practical acquaintance with the lands with which they had to do, his recommendation was that they should be encouraged to do the best they could with paddy, which yielded their staple food. Mr. Green, as far as we know his views, is of much the same opinion; but in his present position he may be able to secure greater attention to the suggestions for encouraging transplantation than they secured in the second decade of the century. It would be curious if Mr. Green's lieutenant for the practical improvement of Native Agriculture should be Mr. C. Driberg, one of Mr. Lorenz's grandsons, who is pursuing his agricultural studies in Edinburgh, and has, we learn, applied to the Secretary of State for suitable employment in the Island.—Local "Examiner"

THE KEEPING PROPERTIES OF TEA.

Sir,—As all information about the keeping properties of tea is of use, I give you my experience. I make very little tea. I commenced manufacturing in July, and packed all I had made from that date up to end of December. Another estate, as well as the one I am writing from, sent samples for valuation in Colombo. They were valued at the same price. The teas were shipped to England and sold about the commencement of March. My teas were sold for 2½d above the Colombo valuation, while the other estate sold its teas for ½d below valuation. So that there was a difference of exactly 3d in the price of the teas, I must mention that I always fire my teas after softing before putting into the bin, while the other estate does not. You will see from what I have written that some of the tea I made was kept nine months before being sold, instead of deteriorating, and it seems improved by keeping. This I attribute to firing before putting into the bin.—B. E., Matala, July 30th, 1888.—Local "Times."

AGRICULTURAL ITEMS.

(From the *California Florist*.)

THE POET ROGERS once took a lady to visit one of the English gardens. She asked him the names of some of the flowers. He said, "I love flowers too well to call them names."

INSECT PESTS.—Dr. J. A. Lintner, the well-known entomologist of New York, says that there are in the world 320,000 species of insects; 25,000 of those belong to the United States, and about 25,000 prey upon the productions of man; 7,000 or 8,000 of these could be considered as being fruit pests. The future successful fruit grower should study entomology and be acquainted with insects and their habits, so as to be able to tell friends from foes. Prof. Lintner recommends the study of feeding and habits as a guide to the use of insecticides, which should also receive notice. *Scientific American*.

Don't allow anybody to delude you into the belief that it pays to plant anything between the rows

of your orange trees. Perfectly clean culture and a never ending stirring of the ground is the theory that has been adopted here through years of experiment.—*Citrograph.*

The first proposal to grow cinchona in India was made in 1835,* for there seemed to be a danger of the supply from America running short, as no regular cultivation of the tree was carried on. Despite numerous warnings, it was not till 1858 that sanction was accorded to the scheme. A few packets of seeds and six seedlings which were introduced by private individuals failed to germinate, while the first importations under Government auspices were equally barren of results. In 1860, however, success crowned their efforts, and a cinchona plantation was formed in the Nilgheri Hills. By the end of 1870 the three plantations on these hills covered twelve hundred acres the limit fixed by Government. The experiment has been tried in various other parts of India with varying success. In Ceylon, especially, it thrives uncommonly well, for the planters are able to select sites that very nearly resemble its native habitat in South America. The requisites for success seem to be a moist climate, with an equable but comparatively cool temperature, an open sub-soil, a sloping exposure, and other conditions of a perfect drainage.—*Indian Agriculturist.*

WYNAAD PLANTERS' ASSOCIATION.

Proceedings of a general meeting held at the Jubilee Hall, Vayitri, Wednesday, August 4th, 1888.

Present:—Messrs. Abbott, Achard, Atzenwiler, Batty, West, Winterbotham, and Hockin, Honry. Secretary. Mr. Batty, in the chair.

* * *
EXEMPTION OF CINCHONA FROM TAXATION FOR 5 YEARS FROM THE DATE OF PLANTING.—Government are of opinion that this exemption granted by His Excellency Sir M. E. Grant Duff for all plantations planted within 5 years from the date of the order should not be made a permanent one "as the land revenue assessment bears such a small porportion to the working expenses of a cinchona estate that any additional relief that might be afforded by extending the period of exemption on cinchona cultivation from two to five years could not have any appreciable effect on the present depressed condition of the industry which is made the basis of the request contained in the address."

* * *
CINCHONA.—Read extract from Ceylon Planters' Association Report for the year ending February, 1888, stating "as anticipated by the Committee last year the large export of bark has not been maintained and it is unlikely unless there should be a very substantial rise in price to be ever approached in the future. The number of trees now growing in Ceylon can be but a fraction of those calculated on a few years ago. The exports for 1887 were 13,113,067 lb. against 14,675,663 lb. in 1886."

Read letter from W. Hamilton Esq., on cinchona leaf disease. The experience of members present was that it did no material harm to matured trees.

PAPERS ON TABLE.—Proceedings of Wynaad Taluq Board, June 18th 1888. De Indische Mercur.

Ceylon Planters' Association Report for year ending February, 1888. This contains an interesting article on Green Bug giving its life-history, the history of its ravages and its treatment. It also states that it has disappeared from estates and fields of coffee which it once threatened to exterminate; that it has many enemies which will probably in time master it, and that successful experiments for its destruction have been made with diluted phenyle applied at the root of the tree and fifteen per cent carbolic lime applied to the under surfaces of the leaves and branches when wet with dew.

The next meeting will be held on September 5th, at the Jubilee Hall, Vayitri.

(Signed) PERCY BATTY, Chairman.

J. WILLIAMS HOCKIN, Honry. Secy.

INDIAN TEA IN THE AMERICAN MARKET.

The *Indian Planters' Gazette* has been furnished by its London correspondent with the rough draft of a report by the sub-committee appointed by the Indian Tea Districts Association to consider the best means for promoting the sale of Indian tea in America. As something on the same lines may be desirable in Ceylon, we reprint the recommendations as follows:—

1. They are confirmed in the belief that inasmuch as the immediate interests of the trade in America are opposed to forcing any change in the public taste, no material assistance can at present be expected from that quarter, and that accordingly the best way to attain the object in view is to begin by bringing the superior merits of Indian tea before the consumers and thus to gradually educate them to a taste for the article, after which the trade will be forced by self-interest to turn their attention to it.

2. They are of opinion that the most promising plan for carrying the object into effect will be:—(a.) To establish in the large towns retail shops (according to the means provided by the planters) for the sale of blends of Indian tea in packets, and also in cup, on similar lines to the shops that have recently been so successful in London and elsewhere. (b.) To make arrangements with retailers in the smaller towns for the sale of tea in packets. (c.) By judicious advertisements, by handbills, through the news papers and otherwise, as experience may show to be most efficacious.

3. That a Limited Company should be formed, with a Board of Directors composed of gentlemen of business experience who are concerned in the tea growing industry, possessed of the confidence of the subscribers, to whom a free hand should be given in working out the details and in engaging managers and agents.

4. That the Directors should report progress at frequent intervals and call meetings every three months, so as to keep subscribers well informed as to what is being done in the way of carrying out their trust, and to receive suggestions from their constituents.

5. That all tea garden proprietors should be invited to subscribe in one or other of the following ways:—

(a.) In cash, the equivalent of which will be allotted in shares of the Company.

N. B.—It is most essential that all who possibly can should subscribe under this head.

(b.) Parties who do not consider themselves at liberty to take shares in the Company, will be asked to contribute a proportion of their crop, in which case the Directors shall have the option (when they consider the tea delivered unsuited for the American market) of converting it into cash, and using the money as working capital for the purchase of more suitable kinds of tea. The tea thus contributed, whether sold in London or in America, to be accounted for at the end of each season and, subject to the deduction of a proportion of expenses incurred in carrying on the enterprise, in the event of the outlay exceeding the earnings, a certificate of indebtedness to be given to the respective contributors; the Company, however, not to be liable to repay the value in cash until the end of three years. The contributor to have the option of receiving an equivalent in paid up shares.

(c.) Where Companies are not considered competent to hold shares, they would have the option of giving a cash subscription, which could be vested in Trustees and held by them in shares either to be sold and returned after the Company was successfully established, or, returned to them if the Company was liquidated.

If all planters would contribute one per cent. of the value of their crops in one or other of these ways, a

* Shortly after the discovery of tea in Assam.—ED.

working capital of about £10,000 would be provided, which would be ample for the purpose. So small a tax in the first instance is but a very small sacrifice for a great future good, and it is hoped that all will cordially co-operate. At the worst, they can but lose a proportion of their subscriptions, while it is the opinion of persons well qualified to judge that before long good dividends may be looked for.

Applications to represent the Company in America have been received from different quarters with details and estimated costs of working on the lines proposed. But the offers of candidates to give their entire services for a fixed period are conditional on the proposed Company having at its command sufficient capital to guarantee a continuance of the business on a proper scale for a series of years.

Should the Company be formed, it will fall to the Directors to decide on the scale and plan of operations and the details of working proposed by applicants for the post of representative. As, too, the question of the selection of a representative depends to some extent on this decision, the Sub-Committee have not considered it expedient at this stage to commit themselves to any present applicant (especially as they shortly expect to receive further details and information from one of them).

The present seems a specially opportune moment for entering upon the undertaking. The largely increased production of tea in Ceylon, as well as in India, will undoubtedly lead to a further serious fall in prices, unless active steps are taken to open up new markets. America stands open, almost untouched. The instinct of self-preservation will surely lead the Indian planters to make a strong and united effort to carry out this proposal. W. L. Watson, (Chairman). J. B. White, R. B. Magor, R. Rowe, W. H. Verner, A. Thompson, R. R. Waller, G. Seton, Hon. Secretary.

THE LONDON "TIMES" ON THE COLONY OF NATAL.

(FROM A CORRESPONDENT.)

It might be considered exaggeration to say that the colony of Natal is now flourishing, but, at all events, its present condition is one of healthy vitality and progressive development as compared with what it was a few years ago. The town of Durban, with its beautiful suburbs on the well-wooded slopes of the Berea, has all the appearances of prosperity. The one hindrance to its becoming a port of great importance has ever been the shifting bar that frequently blocks the entrance to its extensive and safe harbour. Much money has been sunk in attempts to remedy this defect, and at length the engineers have hit on the right plan, and if the works now in progress can be carried out without let or hindrance it seems certain that the bugbear of the bar will disappear in less than two years and the harbour by dredging will be made capable of sheltering a large number of ships of the deepest draught in all weathers and at all states of the tide.

During the same period we may hope that the railway will be carried forward from Ladismith, its present terminus, to the confines of the colony at Coldstream, tapping the coalfields of Newcastle and Dundee, and as some of the mines already opened, though very imperfectly worked, turn out a coal fit for the furnaces of steamships, there is a reasonable hope of Durban becoming eventually an important coaling station.

There is, unfortunately, no chance of the Transvaal Government carrying on the line northward to the goldfields; but they will doubtless gradually improve the existing abortive roads, and as the development of the short route from Delagoa Bay seems to hang fire from various causes, there is no reason why the Natal route, if properly opened out first, should not always command a fair share of the traffic, which as time goes on will be very considerable.

The sugar plantations in the coast districts are doing better than formerly, as they have found a market for their produce in Australia, and this trade may with care be greatly developed. The cultivation of tea is also said to pay. Great jealousy is felt by the bulk of the colonists of the importation of coolie labour from India. But without it the plantation industries could not be carried on, as the black races of the country have an incurable dislike to continuous labour, and as soon as they learn their work and begin to be useful they return to their homes, leaving their employers in the lurch. On this account it has been found necessary to employ Indians almost exclusively on the railway as pointsmen and so forth.

The objection to the increasing immigration of the class of Asiatic petty traders known by the general, though incorrect name of Arabs is more valid. These men are gradually taking all the trade out of the hands of the white shopkeepers, whom they can easily undersell, as their living, lodging, and clothing cost them next to nothing. They do not enrich the colony, as but little of their profits is spent there, and the goods they supply, though attractive from the cheapness, are, as a rule, of inferior quality.

Farmers with small capital who find it so difficult now to make a living in England might do very well in some parts of Natal. The land rises in terraces as you leave the coast line till an altitude is reached which gives a climate suitable for all kinds of agricultural farming as well as stock raising. The soil in most districts is good. I saw many good fields of roots in Mooi River district and elsewhere, and if stacking hay and aying down silos in the summer-time were resorted to, as well as the growing of roots for winter food, the annual migration of all the stock and sheep from the high veldt to pastures in the lower and bush countries might be avoided.

The cultivation of fast growing timber, gums, firs, &c., would be remunerative. Practically there is no timber in the country fit for building purposes, railway sleepers, mine props, and the like. The demand is large, constant, and increasing, and is supplied at heavy expense by importation from Norway and America. The rapidity of the growth of the extensive plantations in the Pietermaritzburg district shows that both soil and climate are favourable for arboriculture.

MR JOHN HUGHES, THE AGRICULTURAL CHEMIST, ON CEYLON TEA.

The various communications we have from time to time received from Mr. Hughes and published in the *Observer* prove the deep interest he has continued to take in Ceylon since his visit to the island to report on coffee culture and the soils of our estates. His reports and recommendations were searching, intelligent, and practical, and there can be no doubt they would have eventuated in much good, had not the destructive fungus and finally the fatal green bug intervened to annihilate (for that, we fear, will be the end) an enterprise which was once so great and so promising. Mr. Hughes has followed with unflagging interest and with valuable advice the fortunes of our new staple product, and now comes a letter from him indicating his intention to revisit the colony en route to Australia, with the intention of seeing for himself and testing practically the value of the varied and fluctuating opinions which have been given by brokers and others of the quality, and especially the staying quality, of Ceylon tea. We hope individual

planters, as well as the Planters' Association, will be prepared to avail themselves of Mr. Hughes' presence in our midst, by submitting to him for analysis and report specimens of tea, in all stages, from green leaf, to withered, rolled, "fermented," partially roasted and finally fired for packing. Teas from various elevations and different districts ought to be provided, so that the influence of soil and climate can be tested, and we think it would be well if small sample boxes were made up and packed now, to be opened and reported on chemically when Mr. Hughes is amongst us. No man can be better qualified than Mr. Hughes to suggest the treatment which ought to be adopted and the fertilizing substances which ought to be applied to old coffee soils, or soils naturally poor, or in a bad mechanical condition. We need scarcely suggest that in many cases it may be advisable to submit, with specimens of tea, samples of the soil in which it has been grown, with records of temperature and rainfall. Teas made in dry weather and wet, from leaf gathered from old trees and young, and from trees after pruning, ought to be tested. To Mr. Hughes, although the labourer is always worthy of his hire, we feel certain, it will be a labour of love to investigate the characteristics of our now chief product and to render us all the assistance possible in preserving the high position it once enjoyed or in recovering that position if it has really been to any extent lost.

The following is Mr. Hughes' letter to our address.
London, E. C., Aug. 3rd, 1888.

Messrs. A. M. & J. Ferguson, Colombo.

GENTLEMEN,—The recent numbers of the *Overland Observer* have contained numerous references to the supposed falling-off in the quality and keeping properties of Ceylon tea, and only the other day I was visited by a gentleman of experience who asked my opinion as to the cause of this reputed falling-off in quality. I replied that I could give no opinion on the subject at present; but that as I was arranging for a visit to Australia next Nov., I hoped to break my journey at Colombo, and await the following mail which would give me a fortnight for a trip up-country and a personal enquiry into the merits of the alleged falling-off in quality.

Of course there may be a fall in price as the result of overproduction, without there being really any falling-off in the quality of the tea itself.

The most reasonable plan would be to get a full report from the leading brokers, stating in what respect the tea failed, supplemented, if necessary, by careful analysis to show by the aid of figures the extent and in what particulars there was or was not any actual depreciation in the strength or aroma of the tea. Thus, is it the tea made in the dry weather or in the damp weather that is complained of? Is there a falling-off in the strength or in the flavour? Is the proportion of soluble extract greater or less than usual, also what are the proportions of tannin, theine, and essential oil. In other words let us obtain some definite results, and compare them with those already published respecting good tea of previous delivery. It is reasonable to suppose that leaf gathered after a period of drought must be of an inferior quality, to that picked after a few weeks of showery weather during which there would be a rapid growth of fresh tender leaf full of sap, rich in the juices essential to good tea.

I have been informed that the reputed falling-off in quality is chiefly in reference to the older gardens, and that the more recently planted trees have yielded so far a leaf of average quality. If this be so, does it not suggest that the soil is becoming exhausted, and that if the flavour and strength are to be kept up some manure containing the chief fertilizing ingredients of nitrogen, potash, and phosphates of lime should be judiciously applied in moderate quantities.

Certainly, before admitting the genuineness of these complaints respecting quality, some definite facts should

be ascertained, and a careful enquiry into the points suggested should be undertaken.

I have only this week returned from a run through Scotland, during which I was fortunate to get a really fine day for the Glasgow Exhibition—the weather this summer being, as you are aware, unusually wet and quite the opposite to that of last year. The Ceylon Court looked very interesting and seemed to attract much attention among the visitors, while the tea-house must be a great success; for, as early as 1 o'clock in the day, it was full of country people anxious to taste the famous Ceylon tea. The Indian tea-house, though better situated and more luxuriously appointed, was comparatively quite empty at the same time of the day. The well-dressed native servants with their wonderful pearl-like teeth and dark faces, were undoubtedly a great attraction at the little Ceylon tea-house. Their jolly laughing voices as they shouted "All right" on receiving an order for tea, and their civil and obliging manners indicated that they had been carefully selected, and no doubt their presence materially added to the natural attractions of a cup of good Ceylon tea on a summer's afternoon at such an Exhibition.—Yours very truly, JOHN HUGHES.

SILK CULTURE IN COIMBATORE.

[Now that sericulture is again attracting attention in Ceylon, the following article will be perused with interest.—Ed.]

[By Mr. E. B. Havell, Superintendent, School of Arts, Madras.]

The following is a note on Silk Culture in the Kollegal taluk of Coimbatore:—

MODE OF CULTIVATING THE MULBERRY PLANTS.—In the rainy season, immediately after the fall of rain, fields containing black soil or clay are ploughed 4 or 5 times into furrows, and the soil loosened. On another fall of rain, mulberry cuttings, each one foot in length, are planted in small pits a yard apart, in the same manner as sugarcanes are planted. Within two days these cuttings begin to take root and to sprout. At the time the plantation is weeded, and the soil around the plants broken up, and fresh earth mixed therewith. At the end of 4 months the plants grow to perfection.

ABOUT THE REARING OF SILKWORMS.—One seer of cocoons is usually bought for one rupee.—They are laid in large bamboo trays (resembling sieves) which are suspended by ropes for eight days out of the reach of rats and ants. On the 9th day the moths begin to come out of the cocoons. They are at once removed to another bamboo tray in which they are kept for one day. Next day the male moths are taken out and thrown away. Before the evening of that day the female moths lay their eggs, and the next day they are also removed from the trays and thrown away. The trays are then hung about the roof, and covered with thin cloth to protect the eggs from flies, ants, and lizards. On the seventh day after the eggs are laid, the silkworms begin to come out. At this stage the worms are fed with small cuttings of tender leaves of mulberry plants five times in the day and five times in the night. Thus they are fed for seven days. On the eighth day they discontinue feeding and lie down without moving. In this state they are said to be attacked with fever. On the morning of the next day they recover and are fed as before with small cuttings of mulberry leaves. In this way they are fed for four days. Then they are attacked with fever a second time, and discontinue feeding. Next day they are again fed as usual. After the lapse of four more days they are attacked with fever a third time. Next day they recover as usual and are fed with full-grown mulberry leaves for four days longer, when they are attacked a fourth time. At the time of the first fever, the worms in on tray are transferred to two trays. On the second attack the worms in two trays are removed to eight trays, and for the fourth to thirty-two trays. In four days after the fourth attack the worms grow large and change color from white to purple. At this stage they discontinue feeding alto-

gether, and are removed to bamboo tatties called *chendrigan*. Three days afterwards they begin to spin cocoons. During the process the tatties are exposed to the morning sun at sunrise for about half-an-hour and then hung up to the roof inside the house. In two days more the cocoons are collected in bamboo baskets; a sufficient number are laid aside for a fresh propagation, and the rest are subjected to a steaming process to kill the chrysalides. The silk is unwound from the cocoons by putting them in a chatty with boiling water and a few cleaning nuts (Poinmalangal) and attaching the ends of two or more cocoons to a light wheel turned by hand. The cleaning nuts probably serve as solvent for the natural gum secreted by the silkworm for building the walls of his cocoons together. There does not appear to be any specific disease prevalent in the taluk among the silkworms. They are said to be affected in abnormal seasons of heat or rain but not to such an extent as to produce a marked loss in the quantity of silk. The following table shows the average price of raw silk per maund during the last ten years:—

Years.	Average price.
	Rs. A. P.
The price of one maund of raw silk in the year July 1879 to June 1880	130 0 0
The price of one maund of raw silk in the year July 1880 to June 1881	140 0 0
The price of one maund of raw silk in the year July 1881 to June 1882	125 0 0
The price of one maund of raw silk in the year July 1882 to June 1883	120 0 0
The price of one maund of raw silk in the year July 1883 to June 1884	100 0 0
The price of one maund of raw silk in the year July 1884 to June 1885	90 0 0
The price of one maund of raw silk in the year July 1885 to June 1886	110 0 6
The price of one maund of raw silk in the year July 1886 to June 1887	140 0 0
The price of one maund of raw silk in the year July 1887 to February 1888	130 0 0

The price is said to fluctuate according to the increase or decrease in the importations of China, or other silk.—*Indian Agriculturist*.

NOTES ON EAST INDIAN GUMS.

BY J. G. FRENCH, BOMBAY.

During the last few years large quantities of gums, the production of Indian trees, have been exported from Bombay. About three-fourths of these exports go to the United Kingdom, and always I think to London, under the names of "ghati," "amrad," "oomrawutti," etc. In a recent paper on these gums, published in this Journal,* these names and the origin of the gums do not appear to be well understood, hence some notes on these points may be of interest.

"Ghati," an aboriginal or purely Indian word, has the primary meaning of a strait or pass through a mountain. Drugs or vegetables of country or local production are sometimes distinguished as "ghati" from those which are imported from foreign ports or from a distance; thus there is "ghati pitpapa" (*Justicia procumbens*), which is used as a substitute for the true pitpapa (*Panicum affinale*), imported from Persia, and "ghati mirchi" (*Caposium chinense*), country-grown chillies, as distinguished from a variety resembling the West Indian and imported from Goa and known as "gowar-mirchi,"† and lastly "ghati" gum, gum collected on the ghats and hills of the country and called "ghati" in contradistinction to the variety imported from foreign ports.

The best picked "ghati" gum as now exported from Bombay is entirely or almost entirely derived from *Acacia latifolia*‡. I think Dalzell is the

first author who mentions this gum. He says, "the tree produces a very white, hard and valuable gum." The Bombay name is "daura" or "dabria." It is largely used throughout India for calico printing, for which it has a high reputation, and as has been shown by Mander it may with advantage be used in pharmacy in place of the high priced and scarce Kordofan gum. I have obtained the same reactions with this gum as was observed by Mander with a London sample of "ghati" gum hence I conclude that his sample was free from admixture with other gums.

"Oomrawutte" gum derives its name from Oomrawutte, or Amravti, the chief town of the Hyderabad assigned districts known as the Berars, the centre of a prosperous trade and officially described as "the very home of the cotton plant and the heart of the cotton trade in India." It gives its name to a variety of cotton staple, "the Oomrawutties," and such phrases as "good oomras," "good fine oomras," "oomra variety," are to be met with in the Bombay cotton market reports. Oomrawutti gum is considered by the native gum dealers in Bombay to be of two kinds, the "ghati" and the "amrad;" the latter they consider to be derived from the babool tree (*Acacia arabica*). Babool gum is distinguished from all other gums that I have examined by being unaffected by either neutral or basic acetate of lead, and by being more or less darkened, but not gelatinized, by ferric chloride. Samples of babool gum that have hung long on the tree and are of a deep reddish-brown colour give a very dark coloration, almost black, but the pile samples are less affected. The Oomrawutte sample examined by Mander was evidently babool gum. With regard to the name "amrad," I do not think it has any reference to "amra," the native name for the gum derived from *Spondias mangifera*, as this gum has a character more nearly resembling tragacanth than Arabic gum. Forty grains of it form a jelly with about two ounces of water. I thought it might be a corruption of "amravti," but the gum dealers can give no satisfactory explanation of the meaning of the word further than that it is applied to all gums of a reddish tint. It is therefore probably a word imported into India, and as the name is principally applied to Barbary and Egyptian gums it may be a corruption of the Arabic word *hamra*, red, and this thought is supported by a statement I have recently seen that "amrad" is a corruption of "ambara,"* a name applied to a gum derived from an acacia.

Gums are sent to Bombay from all parts of India, but the best come from Amravti. Other centres are Nagpur, Jubbnepur and Cawnpur, and a good deal is collected on the ghats of the Bombay presidency. On arrival in Bombay they are sorted by cooly women and children. Anogeissus gum, possessing well-marked physical characters, is easily separated, and is sent to the London market almost free from admixture, but the dark coloured or amrad gums are generally mixtures of various gums, babool gum pre-eminating. During the last financial year 20,895 cwts. of gum arabic of Indian production were exported from Bombay valued at Rs 743,934.†—*Pharmaceutical Journal*.

CHEMICAL NOTES ON TEA.

BY DR. R. H. PAUL AND A. J. COWLEY.

In the experiments made some time since and recorded in the paper "Chemical Notes on Tea" (*Pharm. Journ.*, [3], xviii., 417), it was found that in the small quantities of tea, merely 5 grams, then operated on, no evidence could be obtained of the presence of theobromine, and we were so far unable to arrive at any definite conclusion as to the opium expressed by Liebig and Zoller, that an alkaloid which they found in a sample of Himalayan tea was none other than theobromine. Shortly after the publication of our paper we were enabled, by the courtesy of Messrs. Gow, Wilson and Stanton, to obtain an authentic sample of Himalayan tea, and were thus

* "Ghatti and other Indian Substitutes for Gum Arabic," *Pharm. Journ.*, April 14, 1888.

† Dymock, 'Materia Medica of Western India.'

‡ I consulted Dr. Dymock on this point, and he is also of opinion that the gum now exported as ghatti is derived as stated.

placed in a position to examine this point more definitely by operating on a much larger quantity of material than is necessary when merely carrying out the determination of the theine in tea. The weight of tea taken for examination was 200 grams, and it was treated in the same way as described by us for the determination of theine.

The hot alcoholic solution gave on cooling a deposit weighing 2.08 grams, but this was found on examination to consist chiefly of wax and chlorophyll with only a trace of theine. It was in such a deposit that Liebig and Zoller found the substance which they considered to be theobromine, but in our examination of tea above mentioned we were unable to obtain any evidence of the presence of that alkaloid.

After the whole of the theine had been extracted from the acidulated solution by frequent agitation with chloroform, in the manner suggested in our previous paper, the solution was made alkaline with potash, and again shaken several times with chloroform. On evaporation of the chloroform solution a very small quantity of a yellow and apparently amorphous alkaloid was obtained that dissolved readily in acid and was reprecipitated by potash. It was almost insoluble in hot water, but readily soluble in ether, and the fact of its ready solubility in ether proved it to be neither theine nor theobromine. The quantity obtained from 200 grams of tea was so very small that we decided to defer any mention of our observation until a further quantity of the same kind of tea could be obtained sufficient for ascertaining the nature of this alkaloid more particularly, and we are now engaged upon this work.

The account which appeared in *Nature* last week of a recent communication made to the Berlin Physiological Society induces us, however, to make known the fact that we had some months ago obtained distinct evidence of the presence in tea of an alkaloid differing from theine. From that account it appears that Professor Kossel has obtained from tea a base to which he has given the name "theophyllin," and that he has been able to ascertain that it is an isomer of theobromine, but differing from the latter by a series of well-marked chemical reactions. No description is yet given of the characters of this base, and it is therefore impossible to say whether or not it is identical with the base we had obtained in the manner above described. The quantity at our disposal was too small to admit of the determination of anything more than the physical characters above mentioned.—Laboratory, 13, Fenchurch Avenue.—*Pharmaceutical Journal*.

SIAM PEPPER GROWING.—The exports of pepper from Bangkok amounted to 1,436 tons (value 74,221*l.*) in 1885, and to 951 tons (value 56,646*l.*) in 1886. The profits of the growers have been increasing, and they have, moreover, been able to get rid, in a great measure, of middlemen. The chief source of the article is the province of Chantabun, on the east coast of the Gulf of Siam. The crop is necessarily a fluctuating one, as it depends upon the rainfall. Many new plantations have been started, and there will shortly be a considerable increase in the annual average output. The price is now nearly double what it was six years ago.—*Chemist and Druggist*.

COFFEE IN JAVA.—Says the *Soerabaya Courant* of 10th Aug.:—"High prices continue to be given for desirable qualities of coffee. We learn for instance from telegrams received today of coffees grown on the Southern Mountains and on Smeroe (south-east and south-west slopes) which realized respectively 53, 54 and 55 cents. A day or two ago a crop of some 5,000 piculs of ordinary coffee was sold here for *f*42½ per picul. The prospects for the coming year are on the whole not bad. Even those lands that have given comparatively large crops this year promise well for the following year also. The trees are recovering nicely, and there is little leaf disease to be seen; very little especially on the topped portions, so far as has been observed."

AUSTRALIAN TILLAGE AND WHEAT.—The Australian Government statistics show that during the year ended on March 1st last there were under tillage in the whole of the Antipodean Continent 2,576,405 acres of land, of which wheat alone occupied just one-half, having increased 180,258 acres over the figures for the previous year. The outturn of grain from this area was 13,328,765 bushels, or an average of about in round numbers, 6½ bushels per acre, which compares very unfavourably with the normal outturn for the whole of India, namely, 10 bushels per acre according to the last report. It is curious to note that the total area of land under tillage in the whole of the Australian Continent is less than that occupied by wheat alone in the Bombay Presidency which comes fifth in point of importance. And yet we have seen Australian flour in the Calcutta market!—*Indian Agriculturist*. [There are only three millions of inhabitants in Australia against 250 millions in India. Hence the surplus of wheat and flour exported.—ED.]

SUGAR BY THE DIFFUSION PROCESS.—Mr. Forsyth, formerly of Glassaugh, Dimbula, sends us a paper from Honolulu with a letter marked in which a Mr. Spalding states:—

"You may make public my opinion that 'Diffusion' will prove a practical success in the manufacture of cane sugar. We have made such decided improvements, and have so effectually overcome the obstacles that at first stood in our way, I am willing to state as my judgment that by diffusion we will gain largely in the percentage of sugar obtained from the cane (say 10 to 15 per cent. in our best mills) at a cost of not to exceed one quarter (¼) of a ton of coal to a ton of sugar, and less than one dollar (\$1.00) per ton for extra labor. We are now running at the rate of over thirty (30) tons of sugar per day of 24 hours, and passing all the diffusion juice (mixed with charcoal or lignite) through our two Kroog Filter Presses. The exhausted chips make very fair fuel, coming from the two roller mill with less than 28 per cent. of moisture in them. But we will do even better by and by."

COST OF TRANSMISSION OF POWER.—The following comparisons of cost of transmission of power by various methods appeared in the *Revue Universelle des Mines*, vol. 15, page 522:—

1. Comparative cost on 10 H. P. transmitted 1,093 yards:		D.
By Cables	...1.77	per effective H. P. per hour.
" Electricity	...2.21	do do
" Hydraulics	...2.90	do do
" Compressed air	...2.98	do do
2. Comparative cost on 50 H. P. transmitted 1,093 yards:		D.
By Cables	...1.35	per effective H.P. per hour.
" Hydraulics	...1.87	do do
" Electricity	...2.07	do do
" Compressed air	...2.27	do do
3. Comparative cost on 10 effective H.P. transmitted 5,465 yards:		D.
By Electricity	...2.64	per effective H. P. per hour.
" Compressed air	...4.66	do do
" Cables	...4.69	do do
" Hydraulics	...5.29	do do
4. Comparative cost on 50 effective H. P. transmitted 5,465 yards:		D.
By Electricity	...2.37	per effective H.P. per hour.
" Cables	...2.65	do do
" Compressed air	...2.99	do do
" Hydraulics	...3.02	do do

Steam was the prime mover used in each of the above instances, and it appears that for long distances electricity takes the lead in economy over all other systems. It has also a great advantage in the facility with which the power may be subdivided, and there appears to be no doubt that, in future coal-mining, electricity will be much used for coal-cutting, tunneling, hauling, pumping, &c., as well as for lighting.—*Indian, Colonial, and Foreign Engineer and Builder*, July 15th.

REPORT TO THE BOARD OF GOVERNORS OF THE ADELAIDE BOTANIC GARDEN.

Botanic Garden, May, 1888.

Gentlemen,—I have to submit for your information my Report upon the Botanic Garden and Park, and the Museum of Economic Botany, for the year 1887.

Since the year 1884 I have not prepared any Report with as much satisfaction as that which I now lay before you. It is seldom that South Australia has been visited with such frequent, abundant, and widely distributed rains as those with which this colony was blessed during the past year. The rainfall registered in Adelaide amounted to 25701 inches. As may be seen in the following table, the heaviest downpour occurred in the months of May and June. Mr. Charles Todd, O.M.C., the Postmaster-General, has been good enough to supply me with the following figures:—

The rainfall recorded was in

January	0.693	inches
February	0.504	"
March	0.317	"
April	2.082	"
May	4.086	"
June	6.021	"
July	2.571	"
August	1.372	"
September	2.517	"
October	2.733	"
November	0.942	"
December	1.863	"
Total	25701	"

The rainfall of the previous year, 1886, was only 1420 inches. A moderate temperature prevailed all through the spring, and during portion of the summer. Indeed hot days were rare, and such hot winds as were experienced were not very severe, and of short duration only. The highest temperature in the shade was 111.2°, and in the sun 164°. February, March, and April were rather dry and warm, especially the latter, the thermometer often reaching as high as 91° in the shade.

The beneficial influence of this genial season has been felt over the whole colony, and the progress of Agricultural and pastoral undertakings has enjoyed a stimulus which had been wanting during several previous years. The wheat crops, with few exceptions, have turned out well, and the average yield throughout the colony has been computed at eight bushels per acre, which is considered to be a fair result in South Australia. There has also been a fair average crop of fruit, which has been of excellent quality, size, and flavor.

In the Botanic Garden the flower parterres, borders, and carpet beds presented a beautiful display of various descriptions of flowers. The summer flowers, such as Zinnias, Tagetes, Portulacas, Verbenas, Amarantus, and, indeed, all the annuals, in the great variety of their forms and colors, surpassed anything that had previously been seen in the garden, and excited the warmest admiration of the numerous visitors who came to the garden.

The roses have seldom been seen to such advantage, and have rarely produced such large and perfect flowers as they did last year. The mild and genial temperature which prevailed in September and October prolonged the flowering considerably beyond the usual time.

The growth of the shrubs and trees of all kinds in the garden and in the park exhibited a rich luxuriance not often witnessed before. The lawns presented a most healthy and verdant appearance. This was brought about, in some measure, by manuring them with sulphate of ammonia, one of the most powerful and beneficial of fertilizers, which can be used for lawns, and which I cannot too strongly recommend.

The Jubilee Exhibition attracted, as was expected, a large number of visitors from the adjoining colonies, and they appeared to be much struck by what they saw, and were loud in their praises of the garden. The Museum of Economic Botany received a large share of attention on account of general utility and instructiveness. Its value in these respects was very generally recognized and acknowledged. It is found that the

garden is not resorted to alone for the amusement it affords, but for the knowledge obtainable from it by those who have a taste for and who practice floriculture in this colony. The number of persons who frequent the garden for instruction is always increasing, and the numerous applications that I receive from visitors for information on floricultural subjects convince me of the great public advantage which this State Horticultural Institution offers in promoting a taste for flower culture. The number of amateur florists, I am glad to say, is extending steadily. This may be seen in the numerous tasteful cottage gardens which are laid out in many parts of the city, and all directions in the suburbs and the general environment of Adelaide. Another proof may be seen in the flower shows which are held from time to time, and in the great improvement which is visible in the cultivation of the plants which are exhibited on those occasions. It is still more gratifying to note the taste for floriculture which prevails to a large extent amongst the working classes. At our shows, under the class of "Cottagers," specimen plants are shown which evidence considerable care, patience, and judgment in the way the plants are selected and cared for.

There are difficulties in the way of my promoting the taste that manifests itself in the ways I have mentioned, and my efforts have not been entirely successful. Some of the colonial nurserymen complain that the public are supplied too freely with plants, seed, and cuttings from the garden, and that in consequence their trade is injured. I do not think that such complaints are well founded. The regulations under which plants, &c., can be spared are offered in exchange for others not in the garden, and which require that no ornamental plants shall be distributed until two years after their introduction, appears to me to afford sufficient protection to the nurserymen. This restriction, however, does not apply to newly introduced plants which have a distinct commercial importance and value, or to medicinal plants which are multiplied and distributed without delay, and to the fullest possible extent. Enthusiastic amateur florists, when they see new flowers in the garden, are not content to wait for two years on the chance of being able to obtain cuttings or seeds from me, but give their orders to nurserymen or seedsmen to procure them from the neighbouring colonies, if obtainable there.

I consider it advisable to give my experiences of some of the plants which were introduced into the gardens in 1885-6 and 1887, viz., the Insect powder plant, the Cheesemaker, Eland's Boontges, and the Kumara.

There is no doubt that the "Insect powder plant" (*Pyrethrum cinerariaefolium* (Trevir), *roseum* and *carneum* (Bibrst.)), have found a congenial climate in South Australia, and, without having the slightest care bestowed upon them, have done uncommonly well in all the different situations and soils in which they have been planted. They also figure well as ornamental plants during their flowering period. The same may be said of the Cheesemaker (*Withania coagulans*, Dun), which continues to thrive well.

Although the growth of the Eland's Boontges (*Elaeagnus Burchellii*, Benth.) is not so vigorous as that of the two former plants, it seems to thrive in the colony. As mentioned on a former occasion, the plant dies down in the winter season, but the fleshy roots, which contain the tannic acid, increase materially in size. The plant itself is decidedly ornamental; its graceful pinnated leaves show it to be an addition to our ordinary flower borders. I have been informed that a box of the roots has been sent to England from the Botanic Garden, Natal, for the purpose of analysis. The report upon the roots is not very favorable; the amount of tannic acid they contained being less than was expected. The roots also contained a coloring matter that is considered to be objectionable. I agree with Mr. Wood, the director of the Botanic Garden, Natal, in the suggestion that the roots should be tested at different seasons of the year, because it is very probable that the amount of tannin may vary considerably at different periods, as it is known to do in wattle bark.

The Kumara (*Ipomœa chrysorrhiza*, Forst).—In the year before last, I left some of the tubers of this esculent in the ground during the winter. That season was a dry one; the roots kept well and produced larger tubers than those which were taken out of the ground in April. I followed the same course last winter, but, that being very wet, the tubers all rotted in the ground. It is clear, therefore, that it will be necessary to take them out of the ground and keep them in a dry place. They should be replanted in August. I fear that the crops of the Kumara, which may be grown upon the plains, will not be prolific, as the tubers produced are small. The plant has not yet been tried in the hills, or rather in the gullies. There, no doubt, they are likely to thrive better, the climate being cooler, and to some extent approaching more nearly to that of New Zealand.

Boussingaultia basseloides (Humb. and Bonpl.).—During the last two years a great deal of notice has been taken of this plant, and it was recommended for extensive cultivation. The tubers are said to be eatable, and are taken readily by cattle and sheep. It has found a suitable climate in South Australia, and is easily cultivated, for the smallest piece of root will grow in any soil, rich or poor. I have not heard whether it has been tried by farmers, or whether the tubers are as useful as has been stated.

The Daira Grape.—When last in London, Sir Samuel Davenport, K.C.M.G., became cognizant of a valuable Spanish grape called Daira, which comes from Almeria in Spain. It is the kind which largely supplies the London market with fresh grapes, and is considered to be the best kind for export, as the bunches do not suffer from either packing or transport. Sir Samuel procured cuttings from Messrs. Jimenez and Sons, Spanish merchants, in London, who kindly sent two lots of the cuttings. The one washed overboard in the Bay of Biscay, the second arrived safely. I have succeeded in growing nearly every one, and I am now able to distribute about a hundred well rooted plants amongst the vinegrowers.

THE PALM HOUSE.—It is to be much regretted that year after year the luxuriant growth of the palms, fern trees, and other plants, causes them to reach the roof of the palm house, and that some of the most vigorous actually break through the glass roof. In consequence of this it became necessary to cut down two splendid specimens of the *Phoenix reclinata* (Jacq.). They were planted in the ground, and consequently could not be removed for replanting. Several others have to be removed. The fine specimen of the *Latania borbonica* in the palm house, which stands in the centre of the dome, grew nearly two feet last year. It is now thirty-three feet high, and the dome itself is only thirty-six feet.

It will be absolutely necessary to raise the roof of the house several feet, but this cannot be done without great expense. Something, however, must be done to save the plants. A number of these have been planted in the ground, and cannot be removed without great injury. The fine fern trees which formed the Fern Tree Gully in the Victorian Court, and specimens of the fine group of New South Wales plants in the New South Wales Court at the Jubilee Exhibition, viz.:—Staghorn and Birdnest ferns, Palms, and Macrozamia—were kindly presented to the garden by the Executive Commissioners of Victoria and New South Wales. Some of the largest and best grown fern-trees, with stems eight or nine feet high, and three to four feet in circumference, are placed in the house, and add materially to its appearance.

The terrace around the palm house presented, all through the year, its customary gay appearance.

Only seven new palms have been added to the collection during the last year, viz.:—*Calamus humilis*, Roxb.; var. *gracilis*, *Geonema gracilis*, Wendl.; *Licuala grandis*, Hort.; *Chamaerops humilis* var. *argentea*, C. canariensis var. *tomentosa*, C. *flexuosa*. This brings up the number of species and varieties in our collection to 180.

Ochna multiflora, Dec.—This is a native of Sierra Leone, and has lately been introduced by Mr. B. Williams into the English market. This is one of the most remarkable plants that deserves a very full des-

cription. It has an elegant growth, and produces bright yellow flowers in great abundance. After a few days the stamens fall off and the calyx immediately begins to grow, and changes in color to a bright strawberry red, and then forms a large fleshy receptacle upon which the seeds form, three or four together. When young these are green, but when ripe they become of a ruby dark plum color. Contrasting as they do with their bright red receptacle, they produce an effect which once seen is not easily forgotten. I find the plant is easy to cultivate, and it retains a showy appearance nearly all through the year, partly on account of its flowers and partly owing to the development of its curious seeds, which grow very profusely.

The number of plants added to the garden during 1887 and possessing an economic as well as an ornamental value—exclusive of florists' flowers—was 220, which is somewhat less than were added in former years. Many of them, however, are specially valuable. The general collection has thus been increased in number from 12,753 species to 12,973.

MUSEUM OF ECONOMIC BOTANY.—Last year 1,795 fresh objects were added to the existing large collection, the addition being occasioned by the Jubilee Exhibition.

The collection of the Sultan of Johore contained a sample of sugar prepared from the coconut. It was not clarified but of intense sweetness. The manufacture of the cocoa is illustrated in six different stages. Samples of the cocoa beans grown in different countries are shown. They come from Trinidad, St. Thomas, Columbia, St. Domingo, Surinam, Bahia, Porto, Castello, and Ceylon. The beans show much difference in size and fulness. There is also an interesting collection of oil cakes, which are much now used in Europe for the purpose of fattening cattle. The percentage of nutritious matter that each contains is worthy of note. Coconut cake, after the oil has been expressed and formed, contains 40.19 per cent.; palm seeds, various 34.52, linseed, 36.8; rape, 32.5; dotter (*Camelina sativa*, Linn.), 31.3; poppy, 25.8; sesamum (hul seed), 24.8; cotton seed 21.7; earthenut, 27.8 per cent.

The museum now contains 8,166 objects of various kinds. It continues to form, as it formed from the time it was instituted, one of the most attractive features of the Botanic Garden. Visitors from other parts of the world are much struck with the objects themselves, as well as their simple but practical arrangement. The descriptions in a short form, and the use to which they may be applied, are sufficiently clear to render the printing of a catalogue now unnecessary.

ANALYSIS OF TEA SOILS.

(From the Proceedings of the Agricultural and Horticultural Society of India.)

In continuation of this subject read following letter from Mr. W. O. Bell Irving—

Calcutta, 17th July 1888.

Dear Sir,—I beg to annex copy of a letter from the Secretary, Indian Tea Association.

At the meeting in question, an unanimous opinion was expressed that Dr Warden's report on Tea Manures and Tea Garden Soils would be likely to prove most instructive and valuable, and as such, sure to be much appreciated by all interested in Tea growing.

On receipt of details as to the manner, &c., in which the samples should be collected, the Tea Association will be only too pleased to do the needful.

It is suggested that samples be sent from 3 or 4 representative Gardens in each District, say Cachar, Sylhet, Assam, and the Doars, and that gardens possessing different descriptions of soil be selected. One garden to send say black peaty bheel soil, another plateau mould, a third stiff soil, and a fourth a specimen of Teelah formation. Some idea should be given as to the amount of earth (surface and subsoil) required as a sample, and the depth at which the latter should be taken, also as to the quantity of oil-cake, bone-dust, cow-manure, &c., necessary for a fair test muster.

Yours sincerely,
W. O. BELL-IRVING.

(Enclosure.)

Calcutta, 10th July 1888.

Dear Sir,—Your letter of the 12th ultimo on the subject of collecting samples of different descriptions of manure for Tea bushes, and specimens of the various kinds of soil upon which Tea is grown in Cachar, Sylhet, Assam, and Doars, was duly considered by the General Committee at their Meeting of the 3rd instant, when it was resolved that this Association would be glad to support the scheme proposed in your letter.

It is understood that at present it is not desired that the Association should take any active steps in procuring the samples of manure or specimens of soils, as this part of the scheme will be undertaken by you after communication with the Agri-Horticultural Society.

Yours faithfully,
G. M. BARTON,
Assistant Secretary.

Mr. Bell Irving mentioned that a firm in Calcutta, interested in the Tea industry, had some time ago been so impressed with the practical advantages of having the information which the Society now propose collecting, that they had spent considerable sums in obtaining analysis of soil, which they sent to an expert in England; and that they had manures expressly prepared in accordance with the requirements of different soils.

BRAZILIAN COFFEE.

The empire of Brazil has attained the supremacy in the production of coffee over every other country of the world. A century-and-a-half of attention to this staple industry has enabled the coffee planters to throw on the markets of the world more than one-half of all the coffee produced. The culture is carried on more or less largely from the River Amazon to the province of San Paulo embracing nearly 20 degrees of latitude. From the coast to the extreme west of the province of Matto Grosso comprises 25 degrees of longitude. Coffee, however, succeeds best generally between the 18th and 25th parallel. Brazil will merit the name of the coffee country *par excellence*, seeing that it produces more than 250,000 tons annually.* Brazilian coffee is divided into eight kinds, which take the names of the districts in which it is cultivated, viz., Rio, Santos, Bahia, Ceara, Minas-Geraes, Andarahy, Pernambuco, and Amazon. Fifty-five per cent. of the coffee exports are shipped from the port of Rio. The total exports from Rio have been in—

	Bags.
1840	1,068,418
1850	1,343,484
1860	2,127,219
1870	2,209,456
1880	3,513,368
1886	4,209,200

The weight of the Brazilian bags of coffee vary, in Rio they are 160 lbs, in Bahia 128 lbs., but the average may be taken at 1½ cwt. The total exports of Brazilian coffee last year were a little over 6,000,000 bags.

What is singular is that in Europe, although half the production goes there, Brazilian coffee is never seen or heard of as sent. It is passed off in trade circles under other names. A prejudice seems to exist against it which leads to this commercial deception, and yet Brazilian coffee has greatly improved of late years both in culture and separation.

In the amount of caffeine it contains it compares favourably with other coffees. The following proportions have been found:—

Yellow coffee of Brazil	1.82
Java	1.79
Mocha	1.26
Cayenno	1.00
St. Domingo	0.89

An analysis made by Prof. Church a few years ago for the Brazilian Government gave 1.18 per cent.

* Now, double this quantity!—Ed.

At the different International Exhibitions in Holland, Belgium, the United States, and Russia, Brazilian coffee has obtained the highest awards, and the Agricultural and Commercial Society of Rio Janiero has taken great pains in the interest of the coffee planters to diffuse useful information, and to obtain justice for their coffee. The principal error appears to be in throwing the produce on the market in too green a state. Unlike tea, which should be used as soon as possible, coffee, like wine, improves with age, and the longer the berry is kept the better, as the moisture is evaporated and the quality is improved. But neither planters nor dealers can afford to store the coffee for any length of time, and incur the loss in weight and expenses—hence the rawness of the coffee, and the objection to its general use, except in the United States.

The Brazilian planters, with the growers in British possessions, are suffering from the gradual fall in prices during the last eight years, and the more general use of tea, in many countries. In England, the consumption of coffee has naturally declined. Ten years ago it was about 1 lb. per head of the population; now it is only 0.86 of a pound, whilst the proportion of tea is 5 lbs. This decline in coffee may arise from adulteration, for 100,000 cwts. of foreign chicory is imported, besides what is grown at home, and cocoa is more popular. If we take the latest year available (1886), the following were the quantities of coffee imported for consumption by different countries, compared with the population, which is given for the years named:—

Countries.	Population.	Coffee Imports in tons.
France, 1886	38,218,903	68,233
Belgium, 1880	5,520,009	26,874
Holland, 1879	4,012,093	81,144
Switzerland, 1880	2,846,102	9,764
Russia in Europe, 1882	87,407,721	7,330
Sweden, 1886	4,717,189	15,453

After the United States, which consumes 10½ lbs. per head, Belgium, Holland, Denmark, the Scandinavian States, and Switzerland are the largest consumers of coffee.—*Journal of the Society of Arts.*

EXPERIMENTAL FRUIT EXPORT FROM AUSTRALIA TO LONDON.—Mr. F. Hannaford, Chain of Ponds, has presented to the Central Agricultural Bureau three cases of stone pippin apples which will be shipped by the mail steamer "Arcadia," leaving on 15th August. The fruit will be packed in special cases in a particular manner, and addressed to Sir Arthur Blyth, our Agent-General, who will be requested to obtain opinions from experts as to the condition in which the fruit arrives, its value on arrival, and estimated value in March to May, at which time such fruit would be in demand in England. If this fruit should reach England in good condition, after being kept so long here, it would be proof that with proper care it could be sent successfully just after ripening.—*Adelaide Observer.*

* Clearly an error for cwt.=118,000 tons.—Ed.

NOTES ON PRODUCE AND FINANCE.

We are glad to see that one of the financial papers has called the attention of its readers to Indian tea companies as investments. The *Statist*, which has been earning golden opinion of late by reason of its exposure of company mongering, says:—"Investors in search of something over 4 per cent. on their money may find some profitable returns from judicious investment in Indian tea company shares." It quotes the following:—

Company.	Dividend per cent. per annum.				Yield at present price on 1887. dividend.
	1884.	1885.	1886.	1887.	
Assam	14	20	10	10	£5 2 6
British Indian	1	1½	5	1½	6 18 9
Darjeeling	7	8	7½	7	6 1 9
Doors		Estab. 1887.		7	6 10 10
Jokai	10	10	10	10	7 11 6
Jorehaut	15	15	18	15	7 2 9
Lebong	9	9	8	8	6 6 0
Luckempore	3½	4	6	6½	9 5 9

Discussing the introduction of Ceylon tea into America, and the remarks made by Mr. J. McCombie Murray as to the advisability of working independently of grocers in the matter, the *Canadian Grocer*, a new trade organ published at Toronto, says:—"We believe it impossible to create a universal or extensive demand for any article of food or drink without the aid of those who are engaged in their general distribution. The retailer is intimately associated with the consumer, and if it is made his interest to talk up the merits of a new article, he will do it in a very effective way. It is a work demanding system, hard and persistent work, and a scheme of co-operative advertising."

By-the-way the *London Grocer* has a good deal of advice to give Ceylon planters. It says:—"In order to secure the constant patronage of consumers generally, the Ceylon planter needs hardly to be reminded that to retain his present hold upon them he must maintain a high standard of quality, so as to attract the greatest number of customers and not disappoint them by afterwards producing an inferior article." If the Ceylon planter is the man of business we take him to be he knows all this and much more.

The *Grocer* also says far greater efforts will have to be made in the direction of opening up new markets in America and Canada if British-grown tea is not to fall still further in price. Considering that the game of opening up new markets has only just begun, and that the active operations hitherto have been practically nil, there is a great deal of truth in what the *Grocer* says.—*H. and C. Mail*, Aug. 10th.

COCONUT PLANTING IN THE WESTERN PROVINCE OF CEYLON.

THE CROP AND DRY WEATHER—A SPLENDID COCONUT DISTRICT IF!—A COCO PALM CANNOT OVERBEAR!
—SOL ENGINEERING THE ROADS—THE CEYLON RAILWAY MANAGEMENT REPELLING TRAFFIC AS NO OTHER RAILWAY IN THE WORLD DOES.

HAPITIGAM KORALE, 11th Aug. 1888.

We had in this district a fair share of the June rains, but since the beginning of July we have been practically without rain, as the two slight showers that fell during the first week of August were hardly enough to lay the dust.

The weather has been rather cloudy, therefore the effects are not so serious as they would have been with hot sun. These effects are, however, bad enough: the pastures are dried up, the lately sown paddy is in the way to be utterly ruined, and the coconut trees, that were promising to take on an unusually large crop, are dropping germs in thousands, and the weaker trees are beginning to hang down their lower leaves. Two dry seasons in the year is rather hard on the coconut planters, and the crops decline in proportion. We have a beggarly account of barren flowers between Christmas and Easter, and just when we began to rejoice in the full swing of heavy bunches in course of forming, this second drought comes to damp our hopes.

The effects of the January-February drought of this year has been less injurious than that of the previous year. The May and July gatherings last year in some cases took over 1,700 nuts to the candy of coppera; the worst heard of this year is under 1,400. What the effect of a second drought in July and August may be has yet to be seen.

Were it not for those long spells of dry weather, to which we are subject, this would be a splendid coconut district; even with this drawback and without any very efficient cultivation, some of the older estates yield annual average crops, up to 60 nuts per tree, which even at the average size and current prices makes each tree good value for R10: Yes, a tree that bears 60 nuts per annum will yield a clear 10 per cent of profit, with a sufficient margin for the usual cost of an improving cultivation; while every cent beyond that expended in manure and manipulation will give a return of at least cent per cent. I have many nine year old trees carrying over 100 nuts, and so far from their seeming oppressed, the only surprise is that such grand trees bear so little.

I have deliberately arrived at the opinion that a coconut tree never overbears. Few thriving trees have less than twenty germs on each flower stem, and some have habitually as many as fifty. As a vigorous young tree opens sixteen flowers in the year, the number of germs at twenty to each flower is 320. Not one tree in 100,000 bears 300 nuts per annum, they necessarily drop germs, and keep dropping them till they carry no more than they can supply with the necessary pabulum; and in the event of an unfavourable season they proceed to drop more advanced nuts, till in very bad cases they have few or none left. That trees do fall out of bearing, that they drop more leaves than they open, and that each leaf produced is shorter than the last, there is no doubt; but over-bearing is not the cause,—that is to be found in the mechanical condition of the soil, in its incapacity of retaining sufficient moisture, in its utter poverty or in an originally feeble plant, to which not the most favourable conditions of soil can impart vigor.

Old Sol, a much more diligent and efficient engineer than any of those belonging to the P. W. D., has been at work on our roads, and has for the time put them into very fair order. Unfortunately his work is not of an enduring character, and as soon as he ceases to operate, we may look out for *glawr* and pitfalls, as nothing else has been done.

There is perhaps, of all the railways in the world, none except the O. G. R. that deliberately repel certain kinds of traffic by excessive charges. This fact was specially brought to my notice the other day in this way. I had a cow and her young calf to send to a friend in Colombo, and on inquiry we found that the railway charge for 30 miles was R7-50, or nearly as much as five third-class passengers. The parcel rates too seem rather anomalous; the P. O. deliver parcels at 5 cents per oz. at the remotest stations; the railway charges 10 cents on any parcel under 10 lb. for any distance under 30 miles and doubles the charge over 30 miles. Our district is especially unfortunate in this particular, as our station is just outside the 30th mile.

BAD NEWS FOR CINCHONA PLANTERS, or rather perhaps exporters, at the present time is contained in the following paragraph from the latest *Chemist and Druggist* to hand:—

"The German Consul at La Paz in Bolivia states that the Bolivian Government, in accordance with the expressed unanimous wish of the cinchona planters, have abolished the export duty of 3 1-5th bolivares per quintal (46 kilos.) on cinchona bark. The Consul adds that for some time the exports will in all probability be enormously heavy, as the planters had caused large supplies to accumulate in anticipation of the abolition of the duty."

On the other hand it is rather strange that the above intelligence and the resulting large exports have had no special effect on the London bark market; perhaps the movement was discounted at the time of the very great depression in bark early in the year?

THE BRITISH INDIAN TEA COMPANY LIMITED.

The annual meeting of this company was held at the offices, 14, St. Mary Axe, E. C., on Thursday week, Mr. A. R. Capel presiding.

The report from which we extract the following, was taken as read:—"The revenue statement shows a balance at credit of £5,791 13s 8d and after deducting from this sum £1,113 1s for debenture interest, £294 4s 8d for new extensions to the cultivation, and £231 17s 5d for income tax, &c., there remains £3,117 7s 7d at credit of profit and loss account. This amount, it will be noticed, exceeds by £2,315 10s 10d the sum available in last year's account, thus bearing out the anticipations of the board that the 1885-86 year's working was exceptionally unfortunate. Out of the above sum the directors recommend the payment of a dividend of 5s per share (free of income tax), leaving £376 2s 7d to be added to the previous balance of £581 6s 3d, thus making an amount of £957 8s 10d at credit of reserve fund. The 1886-87 crop was estimated at 636,000 lb of tea, but the quantity made was 697,935 being an increase of 61,935 lb on the estimate, and of 65,701 lb on the actual produce of 1885-86. It was disposed of in the following manner:—Shipped to London and sold there, 686,716 lb; lost in transit, and value recovered, 2,170 lb.; trade allowance for taring, &c., 9,049 lb. The sales gives the following results:—Chests, 7,613; invoice weight, 697,935 lb.; account sales weight, 688,886 lb.; net proceeds, £22,696 2s 10d; average per lb., gross 9 15d, net 7 9 1d. This results per pound, calculated on the account sales weight, viz., 688 886 lb., should be considered very gratifying, being evidence of a still further reduction in the working expenses. The total cost, including all charges in India and London, with commission to the managers, only amounts to 7 13d per lb., which with a gross average realised for the crop of 9 15d, leaves a profit of 2 0 2d. The out-turn for 1887-88 has been put at 8,550 maunds, or 684,000 lb., for a total Indian expenditure of £221,992, which at 1s 4 1/2 exchange, amounts to £15,262, or 5 3 3/4d per lb., f.o.b. Calcutta, adding to this £1,378 for stores, machinery, &c., and £4,000 for freight, dock dues, sale charges, and London expenses, gives a total of £21,440 lb., or 7 5 1/2d per lb. for all expenditure except commission to managers."—*H. J. C. Mail*, July 27th.

THE PREPARATION OF RHEA.—The Board of Trade have received information through the Foreign Office to the effect that the opening of the competition of machinery and apparatus for the preparation of rhea, which was to have taken place at Paris on the 15th of this month, has been postponed till the 25th prox. The period during which applications for permission to compete will be received has also been extended to the 30th of August.—*London Times*, Aug. 11th.

PLANTAINS IN JAMAICA.—The largest shipment of bananas ever made from this island took place last week, when the following ten steamers were loaded on the North Side of the island and sailed for the northern ports of the United States:—

	Bunches.
"Brixham"	12,500
"Latharna"	12,600
"Ethelbald"	14,000
"Godden"	10,000
"Pomona"	8,000
"Aguan"	16,000
"Dorian"	12,000
"Kong Alf"	12,000
"Kenilworth"	7,000
"Athos"	16,000
Total	120,000

The 120,000 Bunches Bananas shipped are estimated to have cost £12,000—which sum went into circulation in one week. The average shipments

from March til 1st July, for four months, amounted to about 70,000 per week, or £7,000 per week put in circulation. After the 1st July the shipments usually fall off, and do not average over 40,000 bunches per week, but the prospects for this year are better.—*Gleaner*, July 4th.

TEA MACHINERY.—You may have noticed from a late sale of Mr. E. John's that the combined withering and sowing machine, the X-L-ALL at *Banorahally*, has begun to tell during the wet weather—as *Watha Valley* tea (the bought leaf) and *Queenwood* tea both withered and final fired by the X-L-ALL have got the highest average prices in that sale of the teas of 18 estates. Mr. E. Wiggin makes only two classes of tea, so that the novelty of (in Ceylon) making a first-class tea from fresh wet leaf and drying it besides by the same machine deserves some consideration. A small size, the original (the Myth) X-L-ALL from Brown, Rae & Co., goes in a few days to Mr. Hogg, Imbulpitia, and a large size to Mr. Dickson in October, and others shortly."—*Cor.*

CAFFEINE.—The amount of caffeine present in the husk of Liberian coffee, and the pods of cacao and of kola, has been estimated by Messrs. Hecker and Schlagdenhauffen. In kola fruits they found only about one-fortieth of the amount present in the seeds (which contain 2.371 per cent.). From the cocoa pod they obtained only about one-thirtieth of the amount present in the seeds (49 milligrams per 100 grams), Liberian coffee husks yielded only about 6 milligrams per 100 grams. According to these authors the caffeine exists in the free state both in kola and Liberian coffee. The Liberian coffee husk gave off the odour of caffeine when roasted, but the leaves of the coffee plant and those of kola did not afford any caffeine (*Rep. de Pharm.* p. 205).—*Pharmaceutical Journal*.

CHINA GRASS MATTINGS.—We cull the following from an article in the *Carpet Trade and Review*. The making of matting has been known to the Chinese from a very early period. Grasses from which the matting is made grow in great abundance throughout China, but the principal plant, the *Arundo mitis*, is cultivated mostly in the province of Canton. To perfect its growth, the plant requires a great deal of moisture, and this it receives lavishly in the lowlands of Canton, being adjacent to both sea and rivers. The excessive moisture makes the growth so rapid that "hearing the grass grow" is almost a truism. The grass requires little cultivation, and grows from the root instead of from seed. The principal foreign dyes used in the manufacture of these mattings are aniline, but before these were known in China the principal style of carpet was the red and white check. The matting loom simply consists of an upright frame work with cylindrical crosspieces above and below, over which the warp runs, the woof being woven in without a shuttle. A long, flat and smooth piece of bamboo having an eye or split at the point is used to shoot in the single straws, the warp being regulated by the working-beam through which it passes. Each straw is fastened at the right and left hand side alternately by simply twisting the end in and outward around the outer and inner somewhat thicker selvage strings, and then the lay is brought down with sufficient force to give the texture the firmness required. The warp is easily arranged, the necessary number of China grass strings (according to the size of warp desired) being passed over the upper crosspiece and through the holes in the beam and the ends fastened to bamboo sticks, which in turn are secured under the lower crosspiece; when the warp becomes loose it is tightened by driving a wedge between the upright and the crosspiece. Breaking of the warp which is oiled to make it smooth, is of frequent occurrence, but apparently of little importance, as time seems to be somewhat of a drug in the markets of all Eastern countries.—*Kuklow's German Trade Review*.

Correspondence.

To the Editor.

A VEGETABLE CURIOSITY.

Bandaragama, 10th August.

DEAR SIR,—I beg to forward herewith a 'curiosity' which I found inside a pomegranate fruit. If you think it worth to publish something concerning it, please do so. I have never seen or heard any thing about such a fruit as this before. Yours faithfully,

C. M. ANTHONY, Postmaster.

[Dr. Trimen, to whom we submitted the 'curiosity,' kindly writes:—"The specimen sent is clearly one of the divisions (carpels), of which the pomegranate like other fruits is composed, which has grown independently of the rest and has become abortive. All the grains' are seedless. As it has been separated from the fruit of which it formed a part, its precise relationship to the rest (which is the point of interest) cannot now be ascertained. The same 'monstrosity' occasionally occurs in oranges."—Ed.]

THE NUMBER OF CINCHONA TREES IN DIMBULA.

Henfold, Lindula, 15th Aug. 1888.

DEAR SIR,—In a late issue of the *Observer* I note it is stated from observation, that it is estimated there are 6,000,000 cinchona trees in Dimbula.

I think this is an over-estimate, and a serious one, as it may tend to influence the bark market. The bulk of the cinchona in Dimbula is *succirubra* or *robusta*, and 500 of these trees to an acre, when they are 6 years old, make a great cover. I do not know of any land in Dimbula carrying more than 500 of such trees to an acre, and, if there are 6,000,000 trees in the district, then, on this calculation, there are 12,000 acres out of our cultivated acreage of 44,000 acres under cinchona. That this is not so, my intimate knowledge of Dimbula convinces me, and I do not believe that it can show more than 1,000,000 trees of such growth that they are entitled to be considered when estimating the probable yield of bark. Our average death-rate is over 10 per cent yearly, and no planting to speak of has been done since 1833. Much land has also been cleared of cinchona since tea has been planted, not only to help in paying for the cost of planting this new product, but because tea does not yield freely when growing under cinchona.

I may state in conclusion that out of the 140 odd estates in Dimbula under 30 have any claim to be considered as places on which cinchona takes an important position amongst their products.—Yours faithfully,

GEO. BECK.

[Mr. John Ferguson, who made the computation from returns supplied for the Handbook, and felt that personal observation confirmed the accuracy of his estimate, will, no doubt, duly consider Mr. Beck's criticism, when his short holiday is over. See page 201 further on.—Ed.]

MR. PINEO ON A TEA COMPANY AND ON MR. ELLWOOD MAY.

SIR,—In his address the Chairman of the "Dimbula Planters' Association" stated that he could "not advocate the alternative proposal of a Company as we had the example of a similar Company which had been formed in India for the sale of Indian tea in America which had proved to be a failure with a loss of somewhere about £30,000."

Unfortunately, he did not give the reason why that Company had met with failure and loss, and

will, therefore, endeavour to fill up the gap. The Indian Company* selected a gentleman to go to America who was, I believe, in every way competent to fulfil the conditions laid down for his guidance, but those conditions were based on imperfect data and misconception. He visited America and Canada and interviewed those who were more or less directly interested in the China and Japan tea trade, and finally appointed a firm in New York to act as agents. Shipments were made to New York irregularly and Brokers hawked about samples to the trade, but without finding buyers. Eventually the tea found its way to the auction room, and was there sold for what it would fetch. One of the buyers, doing a very large business in New York and Brooklyn, thought he would make a speciality of it, and so packed it up in one pound packets and then tried to get his customers to take it. Some tried it, with the result that it was returned to him, and he finally gave up the packet trade in disgust. He then had a good deal of this Indian tea in his hands, which he could not sell in its pure state, so he used it for blending with, and improving his China and Japan teas. The Indian tea was still being sold at auction, and as there were no competitors, this dealer bought nearly all that was offered at his own price. This attempt resulted:—

1st, in a loss to the Indian Company.

2nd, an improvement in strength and flavor of Japan and China teas; and last

3rd, in not making a single consumer acquainted with Indian tea except the few who had tried and condemned it. The Canadian market was not opened out and the Company retired from the field. The foregoing is not gleaned from hearsay evidence, but was furnished me by the man who brought nearly all the tea that came into the New York market. I had long and frequent interviews with him, and hence it was that I concluded to go direct to the consumer with our teas, believing then, as I now do, that if we can reach him the battle is won. Any Company or individual who may, hereafter, attempt to open out a market in America and Canada, in either Ceylon or Indian tea, through existing channels or on the same lines that the Indian Company pursued, will meet with failure and disaster.

No wholesale business in our tea in America and Canada can at present live.

If the Parent Association decides to make Mr. May its accredited agent, and undertakes to guarantee that he will offer to the American people always, and only, a pure Ceylon tea, then there may seem no need of a local Company being started. I have said all I can honestly say about Mr. May, and so far as I am concerned I can do nothing more. My great desire is to place only reliable data before the planting interest. My experience in America and Canada with tea dealers and consumers (gained by a very considerable expenditure of time and money) is at the disposal of the tea planters of Ceylon. It has been unique because I struck out a path for myself, and varied by reason of having been in close communication with tea-brokers, tea-dealers and consumers of tea.

I will not touch upon the subject of a local Company until the Planters' Association has come to a final decision.—Yours faithfully,

R. E. PINEO.

[We have nothing to add to what we wrote. Let the Planters' Association decide. Whether a Company is formed or not, it is evident that much money and much energy must be spent before a taste for Ceylon tea can be created in the United States. A Company, if formed, would have to postpone dividends for several years.—Ed.]

* It was not a company but the same syndicate which sent teas to the Melbourne Exhibition and employed Mr. Sibthorp to push them.—Ed.

CINCHONA IN TRAVANCORE (NORTH).

August 18th.

SIR,—“To help raise the cloud of depression hanging over the Travancore planter,” as one of your correspondents puts it, Renewed officialis has this year analyzed 1st 5.79 Sulphate Quinine

2nd 6.35 do.
3rd 6.81 do.

Each of the above is the sale analysis taken in each case from about 5,000 lb. and not from picked trees, as our Java friends seem so fond of giving. I may mention that there is little or no bark over 7 years of age, and that the elevation is between 5,500 feet and 6,000 feet.

DEVACOLAM.

THE SUPPLY OF TEA BOXES FOR CEYLON.
Colombo, 29th Aug. 1888.

DEAR SIR,—As no one seems to have thought fit to notice your remarks upon British North Borneo as a possible source of supply for tea boxes in Ceylon, you will allow me to state what is being done in the matter. Some time ago I wrote to my friends in North Borneo about this, and the British Borneo Trading and Planting Company, Limited, when importing their plant for the saw-mills, included in their indent a box-making machine. Some correspondence ensued about size of boxes, mode of slotting, quality of wood, etc. Specimen Japanese boxes were sent by Mr. W. D. Gibbon of Kandy, I believe, and all particulars as to our necessities in regard to tea boxes have been forwarded, specimens of the most likely woods were promised me, but have not been sent as yet. The sawmills were opened on the 30th June last, so that it is not possible as yet to have properly seasoned timber ready for box making. The *British North Borneo Herald* of 1st July gives a long account of the opening ceremonies, and in the advertisement at the end you will find Messrs. D. Edwards & Co., Hatton, amongst the list of agents. The Colombo agency was offered to me, and I signified my willingness to accept it, but have not since heard from Mr. F. Boulbee on the subject. —Yours faithfully, EDMUND WOODHOUSE.

IN DEFENCE OF CACAO AND A GROWL AT “PEPPERCORN.”

SIR,—Your correspondent “Gup from the Highways” betrays much want of experience upon the subject of cacao when he presumes to touch upon it. Inquiry also fails to elicit his authority, beyond a self-constituted one. It is not clear what is the number of trees your correspondent superintends; but it is clear that these same struggle for an existence, under conditions which apparently must be impossible for them, and that the most economical manner of disposing of them would be as fuel for a Sirocco.

Otherwise we should not have it related how that, upon an average of once a week, they attract a new species of pest, and how impossible it is becoming to stand the strain of depredations by the Sinhalese for the purposes of curry of two to three dozen cacao pods per annum. (It takes 700 pods to make one bushel of cacao nibs.)

Let anyone visit at this present any properly constituted cacao estate, and see the enormous crop, remembering also the fearful drought which have been undergone.

No unprejudiced person would otherwise declare than that there was absolutely nothing in Ceylon (and very few things elsewhere) worthy even to touch the latchet of the shoes of cacao; while as for its comparison with tea!—Himmel! as well put aside by side the lustrous merits of Golconda diamonds with those of quartz or the slumness of a tinker's new tin

POTTINGER.

THE KOLA NUT.

SIR,—In *Chambers's Journal* for July, page 362, is an article on “The Kola Nut.”

From this article it seems that the kola nut contains caffeine in greater quantity than coffee; that its paste is more nutritious than chocolate; that it is good for the liver; and that it is the best “pick me up” after being tight.

Surely here is one of the new products planters are in search of; and one sure to be in great demand. Could you therefore kindly inform your readers where the nuts for seed can be got, and a few particulars about climate, soil, and cultivation?—Yours, &c.,

KOLA NUT.

[Our correspondent will find a good deal about the kola nut in past volumes of the *T. A.* As to its value, we quote from the *Chemist and Druggist* of July 28 as follows:—

KOLA.—An article published in a German daily paper on the uses of kola has drawn a commentary from the well-known African traveller, Adolf Krause. Krause is of opinion that there is only a small demand for the drug in Europe, which is not likely to increase, as it would be difficult for a new nutrient beverage to command the field in the presence of such well-established rivals as cocoa, tea, and coffee. Only if it were very cheap would such a result be possible; and this condition he regards as unlikely, as the article is very highly esteemed by the natives—a statement which he supports by quoting various prices at which it is sold. Krause also reminds readers that a German factory had made an attempt to introduce kola chocolate without satisfactory results. The opinion prevalent on the Continent that Europeans eat kola when in Africa is contradicted, it being asserted that they only do so when nothing else is to hand. The traveller says that he himself has tried it in all kinds of preparations, including the fresh dug, and the same when roasted like coffee, but he never derived any great pleasure or benefit from its use.—ED.]

IRRIGATION THE HOPE OF AUSTRALIA.—This was the subject of a lecture delivered by the Rev. M. Wood Green at a meeting of the Chamber of Manufactures on Thursday evening. The President (Sir Samuel Davenport) presided over a good attendance. The lecturer prefaced his remarks by historical references to the knowledge possessed by the ancients as evinced by the ruins of irrigation works. He then urged its importance in South Australia because of the dryness of its climate and the uncertainty of its rainfall. Irrigation in California, the vineyards, orchards and farms, their wonderful production, the preparation of the produce, and the general prosperity entailed were fully and eloquently described. In South Australia much might be done by private enterprise, but there was a great deal to be done by the Government. The profits accruing to Chaffey Brothers from their scheme in this colony would at the least amount to from three to four and a half millions. The Government should undertake irrigation schemes, and if necessary borrow money to do so, charging a fair interest on the outlay and selling the land at reasonable prices. The rev. gentleman gave a calculation based on his observations, which would make South Australia capable of supporting a population of 144,000,000, and concluded with an eloquent peroration on the future of Australia. A discussion followed, in which the lecturer was highly complimented upon his address. It was suggested by Mr. T. Parker that something might be done in the way of establishing an Irrigation League, as in Victoria. The idea was favourably received, and it was decided to continue the discussion at the next meeting, when the Rev. Mr. Green and Mr. Parker promised to attend. A vote of thanks was accorded to the lecturer and the Chairman.—*Adelaide Observer*, Aug. 10th.

WHAT IS AN INDIGENOUS TEA PLANT.

The question "What is an Indigenous Tea Plant?" has been well handled by "Cachari" in the June number (page 817) of your *Tropical Agriculturist*. [Article taken over from *Indian Planters' Gazette*.] He holds that an "Indigenous" and a "China" are the same plant,—no doubt botanically they are,—but so is any *Camellia*:—but I may be in error? The difference is by no means confined to *color* of leaf. What in fact drew my attention to dark-leaved indigenous was the *form* of the leaf being much more round instead of lance-shaped like the ordinary *Singlo*, and the *depth* of the corrugations, forming separate cup-like compartments on the under side of the leaf.

When I was tea planting up there in Cachar 10 years ago, a Naga brought me from his hills among other specimens a branch of this which I at once 'spotted' as most likely to turn out well if trained by cultivation in Ceylon.

"Cachari" is certainly in error when he uses the expression 'dark-leaved' as synonymous with 'small-leaved.' As a matter of fact (and as you saw and commented on in your *T. A.*, Vol. VI., No 9, last year), the large foot-long leaves I sent you were perhaps the darkest green to be found in vegetation; while, far from being brittle, they 'roll' as well as the delicate—too delicate—*Singlo*. As to 'dark-leaved' being a *hybrid* as "Cachari" supposes, its size alone militates against this idea. Another friend of mine up there a Kuki ("Cachari" hit very closely the source of origin when he says Upper Burmah) brought me some light-colored, the leaves of which were as long and narrow as bamboo leaves; this, I have found when planted in Ceylon to be a splendid flusher, and I am now engaged trying to get a cross between it and my 'dark-leaved' (instead of *Singlo*). I was all ready for a big expedition to risk 'jumping' the Burman frontier, and clearing out down the Irrawaddy with a lot of this seed, when my health, as you know, collapsed so suddenly. However, my little game up there was not altogether a fiasco. By-the-bye "*Missing Friends*":—I wonder what has become of "Doodputlee" Weir;—"Heroucherra" Kennedy, and the Noads who were related to the old Ceylon surveyor?

"Cachari" again is perfectly orthodox as regards plants grown in the jungle shade. An *abrupt* change of habitat is trying to any organism, but by the ordinary law of survival, and a gradual training, (tending always to a hardening development), in the nurseries,—after one remove I find they hold their own very fairly as plants with lower jâts in the full open. None of my growths here are under shade. I say as plants; because my experience of seed is that it, the higher jât it is, always has a decidedly greater tendency to 'go off' in retention of vitality compared to the commoner sorts. Also, that if in the capsule on the tree there are three seeds, two only at the outside are worth anything. If there are five (I often have this *lusus* here) only three will germinate, though the whole five may look good.

As to what "Cachari" remarks about isolation for a seed-bearing estate, that is gospel and holds good with any flowering plant. Here, in the Ratnapura district, I am as yet fortunately 10 miles away from what "Cachari" styles "all possible chance of contamination from other plants." In practice I find that "Cachari's" method of alternate rows of 'light and dark' is excessive. My plan is to lay out the estate in 'cadre' or frames each one square chain of 'light,' surrounded by a border of 'dark,'—which is equivalent to one row dark to ten rows light. This gives me just the amount of crossing I desire. Friends have sometimes criticised this way of mine as expensive lining work, but I find that it comes cheap in the long run, checking weeding, &c. (10 squares to the acre); and even in the new clearing as a check on holers, peg contractors, and liners; besides obviating the after-necessity for any professional detailed survey. Time and a 'prismatic' are only required.

Respecting "Cachari's" manuring for seed crop, I for my part don't approve of any forcing of seed bearers whatever; on the contrary I thin off, and as regards cropping seed bearers for leaf: as he says, that cer-

tainly would be madness. *Topping* overgrown trees is a different thing; but I would recommend planters to treat lateral branches with the same sacred respect we showed to the coffee "*Ta-vath*" in the days of our youth under the nurture and admonition of our P.D.'s; and to carefully study "Cachari's" three conclusions, especially No 2. W. G. S.

RUBBER PROSPECTS IN MR. KINGDON'S
MADAGASCAR CONCESSION.

Mr. Abraham Kingdon, who is well known to many of our readers as the original proprietor of this Journal, has, of late, been turning his attention to Madagascar, a country in which he was formerly for some time a resident, and with which he has continued to maintain business relations. His recent visits to the island have resulted in the concession to him (on certain defined terms) of the right to cut and export timber, and to collect and export gums and India-rubber from a district of 1,600 square miles in the North East of Madagascar. The rich virgin forest is intersected by navigable waterways, and a lucrative trade in a great variety of valuable woods, and several other commercial products will, no doubt, be realised by the company which Mr. Kingdon is now forming.

It is, of course, chiefly as a probable addition to the sources of rubber supply that we are interested in the concession referred to. It is chiefly from the north-eastern district of the island that the best Madagascar rubber, that known as "pinkie," and which fetches nearly as good a price as "Para," is obtained. By improving the methods of collection and adopting modern appliances (as the company undoubtedly will do) a really superior article will unquestionably be obtained. Mr. Thomas Christy says of the Madagascar rubber, in reply to a letter from Mr. Kingdon: "If the India-rubber were collected in cans, as it is now in Brazil, and then placed in larger cans, and afterwards poured into water, so as to exclude all extraneous matter, we think that it would fetch a very high price." The India-rubber vines abound in unlimited quantities all over the conceded district, and it seems that the natives of the North-Eastern Madagascar understand how to treat the juice with acid, and prepare it for market. But the quantities hitherto produced by the natives, are of course, as nothing compared to what may be procured by proper organisation and superintendence. There are caoutchouc plants of the *Landolphia* species near the West Coast of Madagascar, but in the north-east districts the caoutchouc is obtained from three varieties of climbing plants (*Vaheca*) belonging to the family of *Apocynaceae*. These climbers yield a really excellent rubber. We have no doubt that Mr. Kingdon will reap the reward he well merits for his recent long journeys and arduous exertions. In spite of the recent troubled state of the island, he has managed to overcome obstacles that would have daunted most men, and those who are now coming forward to aid in working the concession will share in the results of his energy and enterprise. For augmenting the sources of rubber supply, in the manner we anticipate, the thanks of the rubber world will be justly his due.—*Indiarubber and Gutta-percha Journal*.

SHIPS SHEATHED WITH CELLULOID.—Among the various uses of celluloid, it would appear (according to the *Annales Industrielles*) to be a suitable sheathing for ships, in place of copper. A French company now undertakes to supply the substance for this at nine francs per surface-metre and per millimetre of thickness. In experiments by M. Butaine, plates of celluloid applied to various vessels in January last were removed five or six months after, and found quite intact and free from marine vegetation, which was abundant on parts uncovered. The colour of the substance is indelible; the thickness may be reduced to 0.003 metre; and the qualities of elasticity, solidity, impermeability, resistance to chemical action, &c., are all in favour of this use of celluloid.—*Indiarubber and Gutta-percha Journal*.

SOME POPULAR ERRORS ABOUT SNAKES.

The following is the substance of a lecture recently delivered at Trevandrum by Lieut. H. S. Harold Ferguson:—

From the earliest ages snakes have been surrounded by a cloud of myth, and it is only within a very recent period that the cold light of science has been able to dissipate these mists of error. Their habits have readily lent themselves to darken the air of mystery that has always surrounded them; their stealthy gliding motion, their fixed and glittering eyes, the deadly nature of the poison of the venomous kinds, all these attributes have been the subject of remark, and it is not to be wondered at that the primitive man worshipped them as the emblems of death and destruction, and that as civilisation progressed these attributes have become crystallised in the metaphor of the poet and stereotyped, as it were in the proverbs of every nation. All sorts of evil qualities have become associated with the very name of snake, and the innocent have had to suffer with the guilty. An additional and very potent source of prejudice, favourable or otherwise, has been that in almost all the great religious systems of the world, both past and present, snakes have been in some way mixed up, whether for good or evil.

A good deal of misapprehension exists on the subject of a snake's way of moving. The Hebrew King, the wisest of men, says that this is one of the things that is too hard for him to find out. 'There are three things which are too wonderful for me, yea four which I know not,' he says, and the second of these is 'the way of a serpent upon a rock.' Truly it is a wonderful mode of progression, and for many a year it remained to men of science as much a mystery as it was to Solomon. Many people are under the impression that the absence of limbs is a great disadvantage to snakes, but the fact is they have been so wonderfully modified that their ribs take the place of limbs, so that instead of having only two pairs, as other vertebrates have, they have sometimes over two hundred. Aristotle, who, in natural history, was far in advance of his own generation, and, indeed, of many subsequent ones, mixes up fact and fiction very curiously in regard to snakes, and in the matter of ribs he remarks they have as many as there are days in the month, the fact being that the number varies and reaches as many as four hundred in the pythons. The movement of the ribs was first remarked by Sir Joseph Banks, and Mr. afterwards Sir Everard Home, and the latter brought it to notice in a paper on the subject in which he likened the movement of the ribs to that of the legs of a caterpillar. If the vertebra of any snake be examined it will be seen that they are articulated together by a cup and ball point which gives the maximum power of movement in every direction; to the sides of each vertebra a pair of ribs is movably jointed, and these again are fixed at the other extremity by muscles to the sides of the broad ventral scales so that each vertebra supports a pair of ribs which act like a pair of legs having the extremities connected together by a broad plate; the hind part of this plate is free, and when the ribs are moved forward this end is raised so that it takes hold of any roughness or irregularity of the ground. This movement is not rapid, but when progressing in this way a snake moves in a direct line and not with those "indented gides" that are usually seen. When rapid motion is required some portion of the body in front gains a purchase by means of the ventral shields on some projection in the ground, the ribs are drawn together on alternate sides throwing the body into alternate curves, some portion of the hinder part of the body gains a purchase and the fore part is straightened out. One often sees a snake represented as moving forwards in a series of vertical coils; but this is an error. There are, however, wonderful accounts of snakes in Australia which are said to move by extending their bodies to their full length, then bringing up the posterior portion in a loop and so springing forward with amazing rapidity; but this wants confirmation. The old story

of the snake which puts its tail into its mouth and rolls down a hill like a hoop is, of course, a myth. The rapidity with which they move has been much exaggerated, and even such an authority as Professor Owen says of them "They can outleap the Jerboa and suddenly loosing the coils of their crouching spiral, they can spring into the air and seize the bird upon the wing,"—a feat which, I am sure, no one ever saw performed. The fact is we know very little indeed of snakes at liberty in their natural haunts, and I think the exaggerated notion of their rapidity is due to the fact that they can get away easily into where one cannot follow, and so appear to move off with great speed; but if you get a snake in a room or anywhere in the open you will find that it cannot go at all fast. I have followed a fairly large snake down a ditch, and found that I could easily keep up with it at a fastish walk, so that I consider half the accounts one reads of snakes almost flying are gross exaggerations. In Miss Hopley's book on snakes there is an account of a clergyman in Australia who was chased by a snake, and he is described as taking to his heels with all speed, knowing the vicious nature of the creature. "Looking back he saw the reptile pursuing him with strides or bounds, stretching itself to girth full length, then bringing up its tail and springing forward again with terrific vigour. In its excitement it seemed to fly." For "its" here I should rather read "his." A man running away in a fright is hardly likely to be a dispassionate observer of his pursuer's motions, and I should be inclined to class this evidence with that of a native of India who had been an eyewitness of the fall of a large meteorite. He could not give many facts, but on one point he was absolutely certain that the meteorite had chased him for a long way through the jungle.

Having got the snake in motion, imagine him next in search of prey. This is how Pepys, writing about 1661, quotes the description of the way in which the harmless English snake was supposed to catch its prey. "They observe," he says, "when the lark is soared to the highest and do crawl till they come to be just underneath them, and there they place themselves with their mouth uppermost and there as it is conceived they do eject poison upon the bird, for the bird do suddenly come down again in its course of a circle and falls directly into the mouth of the snake." Here the error is obvious. In the first place, the snake has no poison to eject, and, secondly, if it had it certainly could not eject it like a rifle bullet. In this more critical age such a statement would not remain long unchallenged, but those were the days in which they believed in swallows hibernating in the mud, and such like fables. It is easy to see how the error arose. Some one saw a snake in the grass, and a lark soaring in the heavens happened to alight close to the snake who at once seized it. The whole affair was pure chance, but a story is founded on it and false deductions drawn. Now snakes are said to attract their victims within striking or grasping distance by some marvellous power of fascination which they, alone of all the animal kingdom, are supposed to possess. Now, any one who has watched the demeanour of live animals given to snakes in captivity with the hope of seeing this marvellous power exercised must have been grievously disappointed. Chickens, rats, guinea pigs, rabbits, all move about with an utter absence of fear of their deadly enemy, and I have seen a hen make use of a python to roost on. How, then, has this fabled power come to be attributed to snakes? There are several explanations which will fit the several circumstances under which the supposed fascination is described as being exercised. Only the other day, in the columns of the *London Mail*, there was a letter in which the writer described how he had long doubted about fascination, but at last had become convinced from his own observation that the power really existed, and then he went on to say how he had seen a number of birds flying round a snake in a tree, and dashing themselves almost into its face. Now had that same writer seen me on a certain occasion he might very well on the same grounds have

attributed to me the deadly fascination of the serpent's eye. I had killed, or rather wounded a small bird known to ornithologists as the Malabar wood-shrike, which goes about in small flocks keeping up a harsh chattering. No sooner had I picked up the wounded bird than it began to scream, and the whole flock dashed round me almost into my face, chattering and screaming. I could have easily knocked them down had I felt so inclined, so closely did they fly around me, and this went on for two or three minutes, when they flew away. Now this is what probably had happened with the snake the writer saw. It had most likely killed one of a flock, and the rest were mobbing it as one often sees them mobbing an owl or other bird of prey. It is the habit of snakes to wait motionless their for prey, and they make great use of their tongue continually exerting and retracting it. Dr. Stradling noticed on one occasion a hen, which had been put into a cage as a meal for a snake, make a determined peck at the snake's tongue, "sometimes two or three in quick succession, evidently taking the tongue for an insect or worm." He has also seen the same thing done by a frog, so that it may be conjectured that the prey may be attracted in this way to approach the motionless snake. With regard to poisonous snakes it is easy to see how the power has been attributed to them. Sir Hans Sloane writes:—"The whole mystery of charming or enchanting any creature is simply this. When small animals or birds are bitten the poison allows them time to run a little way (as perhaps a bird to fly up in to a tree) where the snakes watch them with great earnestness till they fall down when the snakes swallow them." Any one seeing this might easily be led to attribute some power to the snake's eye of attracting its prey. The apparent fascination then can be accounted for in many ways. It may be the approach of an insectivorous bird or of a mammal in hopes of a meal; it may be the mobbing of the companions of a victim already seized, or of a mother whose nest has been robbed; it may be the effect of poison already injected, or it may be simple curiosity; but fascination as such may be dismissed as purely mythical.

Now, let us suppose the snake has seized his prey that it has been destroyed either by the injection of the deadly poison into its veins, or crushed by the constricting coils. According to the popular idea the next process is what is variously termed the salivering, or the lubrication of the morsel to enable it to be easily swallowed, and this is supposed to be effected by means of the tongue. That the snake is seen to pass its head over and round and about the body, and that the tongue is to be seen continually gliding over it, is perfectly true; but that this is a process of lubrication is quite false. You might just as well expect a man to tar a railing with a camel's hair brush as a snake to cover even a small bird with saliva by means of its tongue. The tongue is bifurcate, as finely pointed as the finest camel's hair brush, and is quite inadequate for such a purpose. What happens is this. As the snake always swallows its prey whole it has to take it in such a way that it will slide down most easily; so it feels all over with the tongue, which is a tactile organ of the greatest delicacy, and ascertains which is the right end to begin on; this done, it proceeds to swallow the morsel, the salivary glands come into immediate activity, and pour their secretions on the part that is in the snake's mouth in quantities thus aiding deglutition "which," says Günther, "but for the quantity of saliva that is discharged over the body of the prey would be a slow process." This is not the only error about the tongue which, from very early times, has been looked on as the serpent's sting. In the book of Job it is said "The viper's tongue shall slay him." In the "Midsummer Night's Dream," Hermia, addressing Demetrius, says "an adder did it, for with doubler tongue than thine, thou serpent, never adder stung." Instances of this sort from Shakespeare could be multiplied, showing that the belief was general in his day in the deadly nature of the snake's tongue. But it is unnecessary. The belief was general then, and it is by no means dead even

now. If, then, the tongue is not used in salivering the prey, and is not a weapon of offence, what is it? It is, as has been before mentioned, a very delicate organ of touch. A snake's eyes are so placed that it cannot see in front or below itself; and as it goes forward it continually puts out its tongue and literally feels its way. It is quite extraordinary how people writing on snakes are carried away by their subject, and attribute all sorts of designs and powers to them. Even a practical naturalist like Frank Buckland, in his "Curiosities of Natural History," writes:—"The tongue is generally protruded in order to intimidate the bystanders." Possibly this is the effect on ignorance, but that the animal possesses such a high degree of intelligence as to be able to divine and play upon human stupidity is obviously absurd."

Among the lower classes of India it is pretty commonly believed that the rat snake is the male cobra. This arises, no doubt, from the fact that in colour they are somewhat alike, but it is, of course, an error as there are male cobras hooded like the female, and there are female rat snakes. It is curious how this error holds its ground, for people are quite aware that the rat snake's bite is not poisonous, but they believe that it uses its tail with deadly effect, and that a blow from it is fatal. Almost every snake in the imagination of the people is more or less poisonous. I remember a curious case of a keeper in the public gardens at Trevandrum. He was bitten by one of the pythons then in captivity, about the year 1876. He was suffering from a kind of leprosy, I believe, which eventually carried him off ten years afterward, but during those ten years whatever ailment he had he put down to the effect of the python bite, and up to the last he attributed his illness and finally his death to the same cause.

Two headed snakes are also believed in, but there may be some ground for this; not that they really exist, but the snake charmers sometimes manipulate some of the blunt tailed sand snakes and so deceive the credulous. But Dr. Vincent Richards, writing to the *Englishman* lately, gives a most curious account of a certain Sergeant Instructor P. as an instance of how the belief may arise without any foundation at all. The Sergeant brought what he said was a two headed snake, but which Dr. Richards at once recognised as a fine specimen of the "Bungarus Fasciatus" which is possessed of an abrupt rounded tail, which the Sergeant declared was the second head and "so great was his delusion that he declared he had seen the tongue protruded at the tail before he killed the brute." The doctor adds "Here was an intelligent and undeniably honest man—for Sergeant P. is both an excellent soldier and a keen and legitimate sportsman—declaring most positively that the reptile under his very nose possessed a physical conformation of which it was utterly devoid."

This is a very good example of how such stories get about; want of observation and a belief that nothing is surprising where snakes are concerned, are at the bottom of all such fables. Of course there are many myths in India about snakes. Dr. Malcolm cites one that he says is current in Malabar by which the origin of shooting stars is explained. "When a cobra finds a pot of gold (the Naga demons are supposed to be the guardians of under-ground treasure) he lies down on it and guards it; the gold shrinks and after many years concentrates itself into dust and forms a single luminous gem of immense value, called the 'Manikkam.' By this time the cobra has also shrunk to a small size; he takes the 'Manikkam' in his mouth and flies away to bathe, his track been shown by the radiance of the gem." Now we come to the greatest error of all, and that is the belief that every snake one meets is not only poisonous, but absolutely deadly. One cannot accept the testimony of one's gardener or other servant, as they are profoundly ignorant on this subject and invariably affirm that every snake is deadly. Now the proportion of poisonous to harmless snakes in India, as regards the number of *genera*, is about one to ten. It is, of course, impossible to say what the proportion of individuals is, but judging from the fact that

many of the harmless species, such as the green tree-snake, the rat-snake, the chameleon-snake, are very common, the proportion, cannot be higher than this, so that the odds are that, out of every eleven snakes you meet, only one would be poisonous. Let us now see if there is not some way of discriminating between harmless and poisonous snakes. The question is more or less a special one, but the facts are easily mastered.

Poisonous snakes may be divided into three classes—(1) sea snakes, (2) viperine snakes, and (3) poisonous colubrine snakes, which more or less resemble the harmless ones. The first class may be left out of consideration; they live entirely in the sea, and are not, therefore, likely often to be met with. They can be readily recognised by the compressed shape of their tails; they are all poisonous. The viperine snakes may be divided into the pit vipers and the true vipers. The latter can be at once recognized by the head being scaled instead of having shields, as in other kinds. The pit vipers have the head more or less imperfectly shielded, but the presence of a deep depression, or pit, between the eye and nostrils distinguishes them. The whole class have flattened triangular heads, very distinctly marked off from the neck, and their general aspect is repulsive. The third class is at first sight hardest to discriminate, but there is one sure sign by which they can be known, and that is the absence of the loreal shield. If the head of a harmless snake be examined, it will be found to be covered by large, flat scales, or plates, of different shapes; these are all known by certain names; that in which the nostril is situated is called the nasal, those touching the orbit and in front of it are called the præorbital, and between them in the harmless snakes there is generally another or sometimes two, called the loreal shields. It is the absence of this shield which at once distinguishes the poisonous colubrine snakes. It is true that the loreal shield is absent in some harmless snakes, but they are not many and can be recognized as harmless by other characteristics. If, however, a snake is met with not possessing a loreal shield it is better to consider it suspicious, and to treat it with caution.

To consider the question more in detail, the poisonous snakes that may be met with in Southern India are not very many. First we have the "ophiophagus elaps" or "Hamairiyad" or snake-eating snake. This is the largest of our poisonous snakes, and being hooded like the cobra it is easily recognizable. It is only found in jungle. The largest recorded is one mentioned by Mr. Phipson, the Secretary of the Bombay Natural History Society. It was killed in the Goanese ghats, and measured fifteen feet five inches. The bite of such a snake would cause death to a man in about three minutes, probably. It is said to be a fierce snake, and has the reputation of attacking any one molesting it, but it is probable that this is only the case when it is breeding. It is not common, however. I have only come across one in the Travancore hills. I was riding with a friend, and as I went round a corner I came on one lying in the path; my pony went over it without touching it, and I turned to warn my friend. But it was too late, and I saw the snake, with hood extended, moving right under his pony. It was a bad moment, for had the snake been touched no doubt it would have struck, but it was not, and glided off the path into the coffee. It was all over in a few seconds, and I was so intent on looking back that I never noticed a branch across the path which caught me on the chin and knocked me over my pony's tail.

The cobra is probably the commonest poisonous snake we have, and nothing need be said of its appearance, as it must be sufficiently familiar to all. It is the snake usually exhibited by the charmers, and is chosen because it is timid and easily managed. It is supposed to be attracted by the musical sound of the pipe, and, you will see the charmer seated in front of the snake tooting away, but always keeping up a side to side movement with the pipe which the snake follows. It is this movement which attracts the snake and not the sound at all. Let the pipe be played behind the snake instead of in front of it

and it will take no notice of the music, for it is almost deaf. Snakes have no external ear, and no drum to their ear, so it is impossible that they can be at all sensitive to sound. The Burmese charmers, it is said, do all their charming without any piping at all, nor do they, as most Indian charmers do, extract the fangs. The next poisonous snake is the "Bungarus" or "Krait." It grows to about four feet, or a little more; it is black above, and white below, with white arches extending over the back. There is a little harmless snake called "Lycodon Aulicus," which is to be found about houses, a dark variety of which is not unlike the "Krait", but it can always be distinguished by the presence of the loreal shield, and by the fact that the vertebrae scales in the "Krait" are considerably enlarged and are hexagonal in shape. Another species of "Bungarus" may be met with, also coloured black and white, but the black bars encircle the body with white between. The bite of both these is fatal. The next genus is "Callophis." The snakes of this genus are not common, and mostly inhabit the hills; their bodies are long and slender; little is known of the effect of their bite, but it is probably not fatal. This ends the poisonous colubrine-snakes of the viperine snakes. There are four species that may be met with, but all in the hills. Two species of "Trimeresurus, Halys Elliotii Peltopelor Macrolepis" and "Hypnale Nepa." They can all be recognised by the presence of the pit, and by their broad flat heads. I have known a case of a European being bitten, I believe by one of these "Trimeresurus," without suffering more than some pain and swelling of the injured member, and of a European planter bitten by "Hypnale Nepa" with the same effect—both cases happening in the Travancore hills. Without doubt the commonest viper is the "Daboia elegans," or "Russell's" viper. It is quite unmistakable; the broad flat head, the absence of shields, and the chain pattern down its back render it easy of identification. When roused it hisses very loudly, and this seems generally to irritate dogs, for I have known two instances in which dogs have attacked, and have, unfortunately, paid the penalty of their temerity. It is a sluggish snake, however, and not easily provoked to bite. The fangs are very long and its bite is fatal. The last of the poisonous snakes is "Echis Carinata," also recognizable by its flat head, covered with numerous small keeled scales; its bite, if not fatal, is certainly dangerous. It is not found in the region of heavy rainfall. This exhausts the list of poisonous snakes to be found in South India.

What result then have we arrived at? There are roughly some twelve distinct species of poisonous snakes to be met with, five of which, the cobra, the two species of Bungarus, the Daboia, and Echis, are to be found in the low country; the rest are confined to the hills. All these are easily recognized and should be destroyed wherever met with. Now to sum up what has been said. Firstly a snake moves by means of its ribs. Secondly, the attribution to snakes of a wonderful power of fascination is an error. Thirdly, they do not lubricate their prey with their tongues before swallowing it. Fourthly, the tongue is not a sting, but only an organ of touch. Fifthly, there are no double-headed snakes; and, lastly, an endeavour has been made to point out means by which poisonous snakes can be discriminated from harmless ones.

—Madras Mail.

HAROLD FERGUSON.

NETHERLANDS INDIA NEWS.

(Translated for the *Straits Times*.)

Though timber of excellent quality abounds in the forests of Netherlands India, the sleepers and other wooden materials required for the Government railway now under construction on the west coast of Sumatra, have to be imported from the United States. The Sourabaya *Courant* ascribes this dependence on a foreign country, to the fact that no systematic efforts have ever been made to open up the forest resources of Nether-

lands India though the valuable kinds of timber available would amply repay the trouble.

The trade in Java tea has not been extending as it ought of late, owing to the little enterprise displayed by the local planters. Their Ceylon rivals leave no stone unturned to get customers. The consequence is that Ceylon tea has distanced the Java product, which indeed lags a long way behind.

The Planters' Association at Padang on the west coast of Sumatra has, along with the Chamber of Commerce there, petitioned the Netherlands India Government in favour of coolie immigration thither from India. The Government is requested to take steps to render the importation of labour from India possible.

DELI NEWS.

(Translated for the *Straits Times*.)

The *Deli Courant* of the 11th August speaks favourably of tobacco prospects in Siak, where planting industry has been going ahead of late. A planter there writes to that journal to say that, so far as he is concerned, the outlook is promising. With him, tobacco growing has been a success.

In Deli, many planters begin to feel uneasy from the diminished inflow of coolies direct from China. Direct immigration has been set on foot in order to balk the coolie brokers in the Straits Settlements. These fellows had been foolish enough to squeeze the Deli planters too much, in fixing the price of coolies. The aggrieved planters could not stand it, and took measures to get labourers straight from the Celestial Empire. The Planters' Association co-operated, and aided in bringing matters to a satisfactory conclusion. That the immigration had not proved more brisk did not arise from any slackness on their part, but from causes beyond their control. It appears that, in the districts around Swatow, which supplies the best labourers to plantations in Deli, a widespread cholera epidemic has broken out. Its ravages resulted in coolie emigration at that port being brought for a time to a standstill. At the end of this month, a steamer laden with coolies from that quarter is expected to arrive in Deli. There is every prospect of regular direct consignments of coolies arriving there regularly in future.

Runaway coolies give the planters no end of trouble. Recently, on one estate, when search was made for absconders from a neighbouring plantation, the coolies on the spot, fell upon the searching party and the manager of the estate with sticks and hoes. The manager and his party had to beat a retreat before overwhelming numbers. The police had eventually to interfere, and arrest the absconders, which they did without opposition. The ringleaders smarted for it before the Magistrate. It turns out that coolies abscond even from estates where they had been kindly treated. Absconding is greatly facilitated by some planters taking absconders into employment, without narrowly scrutinising the antecedents of applicants. Coolies make a regular trade of deserting after receiving advances. By changing masters, they get successive advances within a short time.

Mr. J. W. Van Muyden, agent of the German Borneo Company, has arrived in Deli from British North Borneo. His reports on that company's plantations there have been sent to Europe. It is expected he will receive order to engage suitable persons in Deli for Borneo.

In Ceylon, tobacco planting has been taken up with an enterprise which deserves success. The parties who have taken the venture in hand have secured the services of an experienced planter from Langkat.

MANILA NEWS.

(Translated for the *Straits Times*.)

The Government, by directing that all articles for supplying the Philippine army should be of local manufacture, has taken a step calculated to foster the cultivation and manufacture of cotton in the islands. Formerly, the army clothing used to be of local origin and make. The *Comercio* urges the Go-

vernment to embark upon direct encouragement, by ordering the local authorities to compel the people to plant cotton, whenever the environment suits the cultivation of the plant. That idea had been hit upon by a previous Governor-General in the matter of coffee. By his orders, the provincial authorities left no stone unturned to persuade the natives under their sway, to plant that particular produce article. Millions of coffee trees were planted out in consequence. But when the Governor-General had served his term, the plantations were left to private enterprise, and went to wreck and ruin.

NORTH BORNEO.

Amongst papers put aside for notice at a convenient season, we find a copy of the *North Borneo Herald* with a letter by Mr. W. B. Fryer in which he stated:—

An experienced Ceylon planter, the first one that visited the country, Mr. T. S. Dobree, said that in his opinion the climate and general conditions were so favourable to the successful growth of Liberian Coffee, that he expected to see British North Borneo one of the chief producing countries in the world for it, when once its cultivation was properly started. This opinion was based upon observations made on the Segaliud river. Coffee has lately seen some violent fluctuations, but the price now has apparently settled down at a very much higher rate than it was formerly and one which leaves no doubt of its paying well to the planter, provided no untoward events happen to it: and in the case of Liberian Coffee in this country, nothing untoward is likely to happen as even leaf disease, which almost annihilated Coffee Arabica in Ceylon, and is slowly but surely working havoc in Brazil and Java, is thrown off by Liberian Coffee, not only here, but in the Straits, Johore and Sumatra also I believe.

Several estates I have seen that would have been deserted in Ceylon as destroyed by *Hemileia Vastatrix* have quite recovered, in some cases the cure having been accelerated by the aid of a little cattle dung as manure; while in others, no manure at all has been used. It has no other enemies, is a strong and handsome shrub, bears heavily, and it has been said, by Indian planters, who saw some thousands of plants of it on the Seboga Estate about eight miles away at the back of the town, that it is finer with us at eighteen months old, than in India at three years old.

Another plant that bids fair to have a large share in this country's future prosperity, is the Willoughbeia rubber which grows naturally all over the country, but more particularly about Sandakan Bay; growing under natural forest shade it requires no outlay at all upon felling, clearing, hoiing, and all the other operations which make ordinary planting so expensive; simply put in at the foot of forest trees, it takes care of itself, requiring no weeding to speak of, and when maturity is reached, yields an abundant supply of the valuable "gutta susu" or india-rubber. As to what the yield is, opinions differ, some place the quantity as high as 50 cattie to each creeper, others limit it to 20 cattie, but, in either case, the returns are out of all proportion to the money invested in starting a plantation of it.

The difficulty attending its cultivation hitherto has been the want of seeds from which to start nurseries. It may be safely predicted, that the first person who can get a few creepers of it into bearing, from which to supply seeds, will make a handsome profit, irrespective of the sale of the india-rubber itself. Other plants which seem to promise well to the planter in this country, include pepper, which remains at the very remunerative price of 8½d per lb. and which is not likely to decrease in price, to any marked degree, owing to the still continued struggle in Acheen. When travelling out to the East this spring, I happened to come across a Capitan China from that locality, who informed me that the pepper crops have fallen off, from 75,000 piculs to about 15,000 per year. Gambier is also high in price at the present time, and is likely to still further advance, as it is coming into use for various new

purposes. This plant has never been tried in British North Borneo, but a wild form of it grows freely all over the country in this neighbourhood. Tapioca, not systematically cultivated here, produces tubers of unusual size in the native gardens. In other countries it yields large profits to the growers. Manila hemp, sago, kapok, nutmegs, and many other plants, also promise to repay the cultivator here.

Amongst the many other plants, cotton will probably be numbered. The wealth of North Borneo in good timber is great, and China, which is going in for railways on a great scale, will afford a constant and profitable market. Meantime we are interested in learning whether in the Eastern Archipelago Liberian coffee is really able to resist *Hemileia vastatrix*, which has proved so destructive in Ceylon to both species of cultivated coffee.

THE JAVA GOVERNMENT CINCHONA PLANTATIONS.

The following is a translation of the report, dated Tirtasari, 10th July 1888, of Mr. van Romunde, director of the Government cinchona enterprise in Java, for the second quarter of 1888:—

The weather continued very rainy during the month of April and the greater part of May. In consequence of this, it was possible to carry on planting out uninterruptedly, but, though the wet weather was good for the young plants, the abundant rain was not favorable to the growth of the older and especially the harvestable trees, so that during this year also the same amount of bark will not by a long way be obtained that was collected in a similar period of 1887. The unfavourable state of the weather lasting almost two full months of the previous quarter into erod greatly especially with the regular gathering and drying of the bark. In the first half-year of 1888 a total of some 230,000 half kilograms of bark was gathered, against about 300,000 pounds in the corresponding period of the past year. Of the bark gathered, up to the end of June 155,268 half kilograms had been despatched to Batavia, of which 1,112 pounds were reserved for the local military medical service. At the end of May the long-desired dry weather set in. It is true that it did not last without a break, and during June also there fell more or less heavy showers, but as soon as the dry weather set in the plants began to grow vigorously everywhere, and the regular outthinning crops were also increased, the product of which promises to be very plentiful during the next few months. The plague of caterpillars, mentioned in the first quarter's report of 1888, continued also during the second quarter of this year, and only decreased on the setting in of the dry weather. Not a trace is now to be found of the insect, but the plantations on the Malabar mountains in many places still bear the evident marks thereof. This is especially the case with some gardens of graft plants at Tirtasari, which were lately eaten perfectly bare by caterpillars, but which happily have begun everywhere to recover. The amount of *Helopeltis autumnalis*, which insect appeared everywhere simultaneously with or after the caterpillars, diminished greatly during last month. On 23rd February, 22nd March and 3rd May 1888 sales of cinchona bark of the crop of 1887 were held in Amsterdam. The prices obtained at these sales for manufacturers' bark averaged 52.29, 56.37 and 47.23 cents per half kilogram. For certain lots of pharmaceutical bark remarkably high prices were again paid, such, for instance, as 135 cents per half kilogram for a lot of succirubra in long quills, and 92 cents per pound for a lot of *Calisaya velutina* in long quills, at the sale of 22nd March 1888. But fairly good prices were also paid for certain lots of inferior bark, such as *C. calisaya*, *C. simplicifolia*, *C. elliptica*, &c., and the value of the plantations of these varieties of cinchona has increased considerably. For though lately no more bark of the thinner branches and twigs has been gathered from the plantations, as the harvesting of

these only yielded loss, the harvesting of the bark of roots and of the thicker branches of *C. calisaya* and others, which cannot be gathered in the desired quill form, also resulted in scarcely any profit. It is a necessary factor therefore towards a rational system of cultivation, that the plantations of inferior varieties of cinchona, especially of those which yield no bark either of the desired appearance or of the required form, should continue to be rooted out at a greater rate than has hitherto been the case, in order to make room for the planting of *C. ledgeriana* and *C. succirubra*, which can be carried out now that the nurseries everywhere will yield for the next west monsoon a large supply of seedlings for planting up steadily the plantations to be rooted out. At the end of June three of Davidson's T Siroccos were brought to Bandoeng for the drying of the cinchona bark, which will be speedily erected and set to work as soon as needed.

At the end of the quarter there was in the gardens a grand total of 3,671,500 plants, made up as follows:—In the nurseries: 1,397,000 ledgeriana (including 37,000 grafts), 620,000 succirubra. In the open: 841,000 ledgeriana (including 200,000 cuttings and grafts, but exclusive of the more or less 3,000 original ledgerianas), 11,000 calisaya and hasskarliana, 646,000 succirubra and caloptera, 155,500 officinalis, 1,000 lancifolia.

FRAUDULENT SALES OF CEYLON TEAS.

The view taken by Mr. Leake of the probable effect of the threats of prosecution by him on behalf of the Planters' Association and of its affiliated Society, the Ceylon Association in London, cannot fail to be satisfactory to all those in the island who are in any way concerned either with the growth or with the disposal of Ceylon teas. It is that gentlemen's opinion, as the result of conversation and correspondence had with the several parties to whom letters of admonition and warning have been sent by the solicitors employed, that most will be ready to accept the caution conveyed to them, and that they will take every care, that for the future all teas sold by them as Ceylon teas will really be deserving of that name. The difficulty Mr. Leake apprehends with respect to teas which are openly sold as blended teas we can fully appreciate. The term "blend," indeed, may cover any sort of mixture in which Ceylon tea, in however minute proportions, may have a place. We can estimate that very much of harm to the reputation of Ceylon tea may result from any wide diffusion of sales of this class, but we cannot well see how the evil is to be met and dealt with.

The Merchandise Marks Act only provides for such cases as are evidently of fraudulent intent. To sell as "Pure Ceylon Tea" anything not having that character comes decidedly, and without loophole for escape, therefore under the operation of that Act; but it makes no provision for compelling vendors in any case of the sale by them of blended teas to state upon the packets containing them the various proportions of different growths of which such blends are composed. We should much like to know whether experts in tea-tasting, who are undoubtedly competent, as they claim to be, to decide whether tea is of a pure growth or not, could go so far when estimating their powers as to be able to state even approximately the proportions of different accipitions in any given blend? It is to be feared such a pitch of nice discrimination must be impracticable even to the most experienced and competent of them. It remains, therefore, that, even if the blend was fully described, it would be impossible to test the accuracy of such a description with the exactitude which would be required to constitute evidence upon which a Court of Law could

decide. It is consequently apparent that, to some extent, blenders can work their own sweet wills unchecked by the fear of consequences.

But, after all, it may be that we can—as our London correspondent suggests in the course of his remarks upon this topic—rely upon the educated taste of the Home public to insure that by far the larger demand by them for Ceylon teas will be for the true stuff, unspoil by any blending, however skilfully made, with teas grown in other countries. To satisfy that taste will not in future be difficult. The steps now being adopted must soon insure that the consumer who asks for Ceylon tea, and Ceylon tea alone and unblended, will be certain of being served with the genuine article. Once a palate has become accustomed to the flavour of our teas in their purity, it cannot fail to rapidly detect any foreign admixture; and the retailers will speedily become aware that a continuance to serve blended teas to their customers can only result in their losing them. There is, at best, an element of uncertainty about a successful result to prosecutions under the Merchandise Marks Act, and this must make it a subject for congratulation if the end that it is desired to attain, can be achieved without incurring the risk of pecuniary loss which would attend a failure in any such case of prosecution. Both the Associations we have referred to, therefore, may be well satisfied if one of their primary objects can be secured without involving expenditure beyond the mere cost of sending a lawyer's letter. When the home consumer finds he can be certain of his purchase of pure Ceylon tea, we may predict that the blends will be out of it. They will die of inanition for want of patronage.

THE EFFECTS OF THE DROUGHT IN THE LOWCOUNTRY OF CEYLON:

COCONUTS—PEPPER—&c.

Having just returned from a day's trip into the Siyane Korale, about seven miles to the south of the Henaragoda station, I can endorse the correctness of the account which reached you from Hapitigam Korale of the effect of repeated and prolonged droughts on the coconut palms. Most of our way (three of us travelled grandly from the station each in a bullock hackery) we passed through groves of this tree, most of which have superseded primitive or chena jungle (chiefly the latter) within the past couple of decades, and I could not help attracting the attention of my companions to the signals of distress exhibited by the palms. It would be more correct perhaps to say the proportion of the trees which had "laid down their arms" exhausted in the unequal combat with two successive and severe droughts in little more than six months. One is prepared to see, in due course, a considerable proportion of withered branches hanging point downwards by the sides of the trunks, before their hold on the trees is loosened and they fall to the ground. But what attracted my special attention on this occasion was the very large proportion of green-hued branches which pointed to the earth instead of to the zenith or the horizon. When the weather is normally moist, the sight of half-a-dozen or more green leaves of a coco palm hanging down the side of a trunk reveals the presence of the fatal beetle and its devouring grubs in the soft heart of the tree. But, knowing as we did of the second serious drought of this year through which the unfortunate trees had just passed, the suggestion of beetles was not needed to account for the distress shown by a large minority if not a majority of the trees. It is in very rare cases indeed that the floor of a coconut tope is a model of

tidiness. On one place, it is true, during our journey, we saw heaps of branches, undergrowth and weeds gathered up at intervals and in the process of being burnt. But as a general rule where the branches or rather huge leaves fall from coconut palms there they lie, and where the husks are separated from the nuts there also the accumulated heaps are allowed to pass into decomposition. The effect is better in a manorial than in an æsthetic point of view. No coir seems to be cleaned in this region. During the first half of our journey it seemed to us that the poor soil, some of it approaching "cinnamon sand" in colour, aggravated the effects of the successive droughts on the rather stunted-looking trees. As we approached near the fourth mile southwards from the Henaragoda station, the huge sentinel rock of a series,—the remains, I believe, of a high ridge which once connected Adam's Peak and Negombo,—the tropical gardens being on a portion of it,—there was a marked improvement in the appearance of the soil (decomposed granitic gneiss darkened by humus, or reddened by iron), and a corresponding change for the better in the appearance of the vegetation. But why will so many of the natives persist in a style of cultivation,—200 to 300 coconut palms to an acre, instead of 70 or 80,—which results for many years in the minimum yield of fruit? In a good many gardens very thickly planted with coconuts, areas were still more closely planted between. Here the æsthetic effect was excellent; the tall, slim, perfectly straight-growing areca palms with their crowns of dense foliage contrasting strikingly with the never straight and generally much bent stems of the coconut palms with their wealth of large feathery leaves. A few grand talipot palms interspersed added to the effect, contrasting curiously with the euphorbias and flowering grasses growing on the rocks. The Sinhalese are, as a rule, a shrewd people, and therefore the dense groves which generally occur near dwellings may be a matter of calculation. The natives may deliberately count on the gradual dying out of weakly trees and on a constant succession of palms which bear some nuts, compensating for fewer trees bearing many nuts each? The natives also value the cool shade and perhaps the fallen leaves as firewood? Knowing who your Hapitigam Korale correspondent is, I am somewhat surprised at his even seeming to favour large estimates of nuts per tree per annum. He talks of 60, and no doubt a good many trees in good, well-cultivated soil would bear this number while in their prime. But he and I have often agreed on 30 to 40 and nearer 30 than 40 being a general average for coconut palms as usually grown. Your correspondent alludes to the instinct which leads the coconut palm to discard superfluous germs and even throw off well-grown nuts which the tree finds it cannot, with safety to its own existence, mature. But he might have added that the thinning process is aided and accelerated by external agencies, such as rats, squirrels, &c. It is sorely trying to the owner of a coconut property to see strewed beneath his trees fine nuts in all stages of growth with a hole eaten into each. In one case in our own experience the culprit was taken in *flagrante delicto*, a nut falling down with the snout of the rat in the hole which the thieving rodent had bored and eaten into. That rat can be beheld in the Colombo Museum unto this day, a warning to over-greedy feeders. The shock of the fall was fatal to the arboreal thief. From a very interesting monograph on the coconut palm by Dr. Shortt, retired Surgeon-General, Madras, well illustrated, we extract as follows:—

RODENTS.—The murids or rat family are extremely destructive. In certain localities they infest coconut trees, building their nests in the hollows of the base of the frond and feeding on the tender leaf or young kernels, and also on the mature nut. In the latter they bite a hole on the top, where the nut is attached to the stalk and feed on the kernel. It is difficult to get at these rats; at the Laccadives and the neighbouring islands, people get up rat hunts occasionally; a few men climb up the trees, and the whole of the islanders turn out with sticks and clubs. As soon as the rats on the trees are disturbed they either spring to the ground or rush down the stem, when they are chased and killed. Sometimes over a thousand are killed on such occasions. After witnessing one of these hunts, I suggested smoking the trees. This was not feasible; but a chatty with some damp straw stuffed into it was placed over the opening of each rat hole, and through a small hole bored at the bottom of the chatty, pieces of live coal were forced and blown upon. The smoke was thus sent into the hole, and most of the rats smothered in them. A few, half-smothered, escaped from the counter-openings; these were soon killed. The people were well pleased with this mode. I also suggested that a few good terriers should be kept; after a little training, all the men would have to do would be to turn the rats out of the trees, and the dogs under them would despatch the rats. Unfortunately these islanders were all Muhammadans, and do not care for dogs. I do not remember meeting with a single dog of any kind on any of these islands during my visit to them in February 1873. In the province of Travancore, it is said that the "flying squirrel" or *Pteromyes petaurista* takes up its abode in the coconut groves near woods or forest trees, and attacks the nut at night, doing much damage. The common striped palm squirrel or *Sciurus palmarum*, attacks the blossom chiefly; they are met with in most districts, but the damage they do is small, as they only resort to coconut trees in the absence of other food. The flying fox or *Pteropus Edwardsi* is said to do much damage to the young fruit in Travancore; but this is beyond my personal knowledge. If the fact be so, the damage must be confined to that province. The wood-dog or tree-dog, "mara nai" of the Tamils, and the *Paradoecurus Mustanga* of scientists, the "Toddy cat" of Europeans, does much damage to the young nuts; it gnaws a round hole through the husk at the tenderest part near the stalk, and feeds on the tender albumen which it scoops out with its fore paws. It cleans out the shell of its kernel in the most perfect manner. These animals commit their depredations always at night, and the number of empty shells picked up every morning under the trees shows the amount of damage done.

But it was not coconut cultivation alone which had suffered from the abnormal droughts so as to present sad contrasts to the emerald green rice, peeping above its watery habitat in the irrigated valleys. The tea we went specially to see had suffered. Not only had seedlings perished, while the work of supplying had been stopped, but even bushes had died. In prolonged dry weather we are prepared for the loss of some plants on the edges of drains, but on this occasion trees had died for want of moisture even on spaces between drains. The cause was evidently a "pan" of mechanically hard cabook in lieu of subsoil. Coconuts flourish in cabook soil, and so do tea plants, provided there is moisture sufficient to keep the rock in a suitable mechanical condition. Somewhat more than two years ago I recorded having seen at Awisawella a block of cabook, which had been cut out for transmission to Colombo, in order to show how the taproot of a tea plant had pierced through it. But then the climate of Awisawella has a larger rainfall and one better distributed than the place I have just visited can boast of, and the cabook which was pierced was saturated with moisture. So with the place I am referring to in ordinary years, but in the late severe and

prolonged drought the moisture was, in spots where the bed rock of cabook was near the surface, evaporated from soil and rock, and hence the decrease of a certain number of tea bushes,—a very small percentage, after all, not much more, perhaps, than fall victims to *symplocos* on upcountry estates, but they were regretted nevertheless.* The proportion of hard cabook on the little estate is not great, and over the larger portion, where the soil is deep and free and retentive of moisture, it was a matter of remark how well not only the older bushes but the seedlings (well shaded with ferns) had borne the drought. There are few cultivated plants possessing such tenacity of life as the tea plant, which is specially at home, not merely within fifteen degrees of each side of the equator, like coffee, but has more than twice that range. Scattered over one portion of the place (a ridge rising to about 100 or 150 feet) are scattered blocks and boulders, chiefly of fine red granite, so "confusedly hurled" as to form a very romantic feature, while a beautiful and extensive view is obtained from the top of the ridge. Up the sides of the rocks we are successfully cultivating pepper vines, which rooted in the rich soil at the base of the rocks have well resisted the drought, showing only a few yellow leaves. Rain had fallen a couple of days previously to our visit, and while up amongst the rocks we were glad to be compelled by a smart shower to take refuge in some of the numerous caves, formed by the decomposition of the softer portions. After disappointments with Liberian coffee and cacao (in common with many others), tea is doing well in this locality, while coconut plants, put in at distances which give only 66 to the acre, instead of 150 to 200 in native gardens, are flourishing so as to give good promise for the future. Now that the second drought of 1888 is broken, let us hope that for many years to come abundance of rain well distributed over the months of each year may be the rule, so that the hearts of the cultivators may be made glad.

PEPPER CULTIVATION ON ROCKS.

In our notice of the effects of the recent drought, pepper was mentioned as growing luxuriantly up the faces of rocks on a place to the south of Henaratgoda which we may as well indicate as Eilandhu. Wishing to extend this cultivation we wrote to ask Dr. Trimen as to the advisability of introducing foreign kinds. With his consent we publish his reply, as of general interest:—

"With regard to pepper, experiments in the low-country have shown that it is not a good plan to grow it over rocks, which in hot dry weather become much heated and shrivel up the plants. There are several varieties of black pepper in cultivation by the natives, and one is a superior sort, perhaps as good as any you could get, unless the choicest Travancore or Malabar sorts. The conductor at Henaratgoda garden knows the peppers well, and could supply you with the right sort. We have tried the Singapore sort grown there so largely by the Chinese. It is less of a climber than any of our sorts, and though it does well here at Peradeniya, it did not succeed in the lower country. If you think of trying foreign sorts, I should recommend you to get some from the Malabar Coast.

"Cabooks is another matter. I doubt if you will succeed in obtaining seed of this from anyone, that is seed that will grow. Of course it is easy to go into the bazaar and buy it, but such seed is useless, and that is what is generally sent from Netherlands, India.

* On some places in the Kelani Valley, we learnt, the drought not only stopped flushing but proved fatal to not a few tea trees.

"As with ordinary pepper, cubebis are picked when full-grown, but before they are mature, hence even if fresh-gathered they are incapable of germination.

"Ripe seed is very rare, I imagine, the plant being propagated by slips entirely, and no fruit allowed to ripen."

For the above information we and a good many of our readers will feel indebted to Dr. Trimen. At Eilandhu pepper vines are grown on trees, jak trees specially, besides those trained on rocks, and our observation during our recent visit led to conclusions the reverse of those stated by Dr. Trimen. There were more yellow leaves on the vines which had climbed up the trunks of the trees than on those which had spread over the surface of the rocks. The main reason no doubt was the existence of accumulations of deep rich soil in which the vines were rooted at the base of the rocks, this soil overshadowed by the rocks retaining moisture for a longer period than that in which the trees grew; which latter, moreover was drawn upon to feed the standard trees as well as the adherent vines. There are rocks and rocks too as well as different kinds of pepper, and we are satisfied that the red granite rocks on Eilandhu and the ridge on which it is situated are specially rich in felspar and other fertilizing constituents. The masses which remain of what was in past geologic ages an important range are often deeply striated from the decomposition and washing down of the softer parts, and we specially noticed that it was not on the pepper branches which had fixed to and spread themselves up and over the rocks, that yellow leaves were to be seen, but on branches which had straggled along the surface of the ground. It was not our opinion alone, but that of our two companions, both experienced planters, that the appearance of vegetation and fruit on the rock-borne pepper vines, at the conclusion of a severe drought, formed a full encouragement to extend the cultivation. The rocks, the shapes and arrangement of which in one part have suggested the idea of a "necropolis," look picturesque as they stand, some of them clasped by the long and numerous roots of Indian figs, but they will be still more beautiful when utilized as supporters of pepper vines with the specially luxuriant vegetation of those climbing and spreading planters.

THE AMERICAN MARKET FOR INDIAN TEA.

A well-attended meeting of the General Committee of the Indian Tea Districts' Association was held at the office, 14, St. Mary Axe, on Thursday, July 26th, at which the following gentlemen were present:—Mr. A. Bryans (Buchanan and Co.), Mr. H. Earnshaw (A. Lawrie and Co.), J. M. Holl (Dejoo Tea Company), Mr. R. Lyell (G. Williamson and Co.), Mr. G. H. M. Ricketts, C.B., Mr. R. Rowe (Planters' Stores and Agency Co.), Mr. George Seton (Octavius Steel and Co.), Mr. R. Gordon Shaw, Mr. A. G. Stanton, Mr. J. O. Stenning, Mr. W. L. Watson (J. Finlay and Co.), Mr. J. B. White Jokai and Panitola Co., Mr. R. R. Waller (Octavius Steel and Co., of Calcutta), and Mr. E. Tye, secretary.

Mr. W. L. Watson, chairman of the sub-committee appointed by the association on May 15th last, was called to the chair. The report of the sub-committee, previously circulated to members of the association, and copy of which appears in this issue, was laid on the table. The chairman briefly summed up the proceedings of the sub-committee, referring to the delay which there had been, and to its causes. Several meetings had been held and a good deal of evidence taken. They were confirmed in the belief that, in order to progress at all rapidly

they must go to the consumers, and probably start shops for the sale both of dry tea and tea in cup, extending operations in the different towns by means of agents who would sell the Association's blends of different grades and of uniform quality. They had considered that the joint-stock constitution was, on the whole, better suited to the movement than a Syndicate, but they proposed that the company should hold frequent meetings for the information of its shareholders. To meet the case of companies which did not clearly see their way to hold shares, they proposed the alternative of contributions of tea—to be sold on the market, to produce cash if necessary, and where even this course could not be followed they proposed to invite subscriptions to give which, it appeared to him, practically every company was competent under the usual general clauses in their Memoranda of Association empowering directors to do all such things as are conducive to the attainment of the objects of the company. Their report, it would be found, dealt in detail with the means proposed for giving contributors of tea and others subscribers something to show for their contributions. As regarded the manager or agent to be appointed in America, they had decided to leave over their decision, as explained in the report: that in deciding upon this, no personality must be brought into the matter. He concluded by pressing on the meeting the necessity of this being an absolutely united and universal movement, and he felt sure, if members would only unite and pull together, that they could undoubtedly look forward to making a decided impression on America, and eventually reaping an abundant harvest.

A discussion ensued, on the invitation of the Chairman, in the course of which Mr. Shaw made a suggestion—supported by Mr. White and others—as to young tea being assessed on the basis of its ultimate producing power, but exception was taken by Mr. Rowe to the proposal. The Chairman, however, said that the suggestion seemed a fair enough one, and might easily be given effect to, on the basis, probably, of value of produce with a minimum of four maunds an acre.

After some further discussion, the following resolutions were put to the meeting, and passed unanimously:—

Proposed by the Chairman, and seconded by Mr. White: "That the report be received and adopted."

Proposed by Mr. Lyell, and seconded by Mr. Holl: "That the sub-committee be re-appointed, to take such further steps as they consider necessary for carrying out the scheme, and that they report from time to time to the Association."

The Chairman, in summing up, said that he understood that this sub-committee had the authority of the Association to proceed to do what was initially requisite to carry to a conclusion the proposal made in the report, to obtain more information, and to further elaborate details, with a view to finally formulating the required scheme. That meantime the sub-committee should circulate widely if possible, through companies and agents copies of the report, accompanied by a circular asking for support.—*H. & C. Mail*, Aug. 10th.

OSTRICH FEATHERS:—It has been noticed that of late ostrich feathers have increased in quantity and fallen in price. This is a matter of fashion's caprice. In 1875, the finest white feathers were worth £30 the pound, three years later they sold readily, with an augmented output, at £50, and very superior realised as much as £80. At that palmy time of the industry at the Cape, a chick just clear of the shell sold for £3 10s., and the profits of ostrich farming fully rivalled those of diamond digging. The returns, however, are still considerable. The secretary of the Port Elizabeth Chamber of Commerce has supplied a record of exports from the Cape, from 1858 to 1887, whence it appears that in the first-mentioned year the quantity exported of ostrich feathers was 1,857 lb., worth £12,688; in 1882, the trade reached its high-water mark with 253,954 lb., valued at £1,093,989, and last year fell to an output of 266,832 lb., valued at £365,587.—*Colonies and India*.

OUR CINCHONA PLANTING INDUSTRY.

Remembering how, for many years back, the estimates framed in connection with the Ceylon cinchona industry, whether of planted area, trees available for barking, or of the resulting bark, have been uniformly demonstrated to be far wide of the mark in the sense of being below actual results, it requires some boldness, we consider, in the face of past experience, to come forward after the old fashion and attack Ceylon cinchona statistics as exaggerated. Again and again, in years gone by, has the same story being told to us that the millions of trees given in our Directory must be far above the actual number, as would be shown if that impossible thing—an actual census—were instituted. But how comes it then that the estimates of annual exports, based upon so much bark per tree from such totals, have been uniformly—and in some years so enormously—below the actual figures? It may be said that this has been due not to the harvesting of crop from the growing trees, but to the large mortality and the need of bringing the whole bark of such trees, including root, to account. But apart from the fact that the statistics of root bark do not bear out this view, as Messrs. C. & M. Woodhouse, of London, have shown, who is prepared at this moment to say that our estimates of future exports of bark from Ceylon—based on the total of our Directory returns of trees—are exaggerated? Our contemporary very glibly attacks the totals for all the districts and with a show of wisdom, speaks of the harm done to the enterprise by sending our figures forth to the world. This is rather absurd, considering how exports and export estimates are regarded by men in the bark trade. But, the fact is that our contemporary should be the last to speak; for his *low* estimates of exports—considerably below ours as a rule—have made the “Ceylon cinchona bark estimates” to be utterly distrusted throughout Europe and especially in the City of London. Nor is the current season likely to be an exception to this rule; for with one month still to pass of the season, our shipments are already in excess of the biggest local estimate and 1½ million lb. above our contemporary’s estimate in November last.* It behoves therefore any critic taking the whole country within his purview and endeavouring to make out a case for exaggeration, to speak with bated breath and with the utmost modesty. Somehow or other whatever be our estimates of the acreage or the number of trees of cinchona growing in Ceylon, the export of bark in the following season is always out of proportion, and in excess of such estimates! Generalizing therefore from certain local district experience or from the discovery of a certain amount of error in the returns must be done very cautiously.

At the same time we most fully accept and welcome the criticism of planters, each for his own particular district or neighbourhood. Mr. Geo. Beck has offered one letter of criticism, in which however, he, without entering at all into detail, would reduce the total number of cinchona trees, 2 years old and upwards in the whole Dimbula district, from 6 millions to one million! Now we should like Mr. Beck with our Directory

* The local “Times” estimate of cinchona bark exports in November last was 2,300,000 lb. On October 8th 1887, we wrote in the *Observer*:—“With due reserve we estimate a full to 11 millions in the season on which we have entered;” but in deference to a cry about the cinchona being all gone, led chiefly by Mr. James Sinclair, we reduced our estimate in December to 10,000,000 lb., and yet the actual shipments to 30th ultimo are 11,040,309 lb.

before him to enter a little more into particulars as to the estates from which our returns are manifestly in excess. Of course, for the calculation of trees per acre, where only acreage was returned, we in the *Observer* office are responsible, working as we have done on a certain recognized rule. It is quite possible that our allowance of trees per acre is too liberal; but there is this fact to be explained to the contrary, that for the one district—Udapussellawa—in which the most careful reckoning, we believe, has been made by a local Planters’ Committee, the result came out as given to us by Mr. Naftel, almost identical with our own calculation, based on returns of acreage and trees. But leaving acreage out of view, we have in the case of Dimbula a large number of proprietors or superintendents returning not the “acreage” under cinchona, but the “number of trees” over two years, each for his own place. What are we to do in such cases: accept Mr. Beck’s sweeping condemnation or the individual returns? If our critic will refer to the Dimbula returns he will find a total of over 2½ millions of trees in the entries made by the proprietors, agents or superintendents themselves. This is apart from 996 acres on other properties said to be covered with cinchona only, 4,842 acres covered with coffee and cinchona, and 1,897 acres covered with tea and cinchona. Now even counting 500 trees to the acre for cinchona alone and 250 trees when mixed with coffee and tea, we should get a total for Dimbula of over 4½ million cinchona trees. We cannot possibly see, therefore, how we are to come down to Mr. Beck’s “one million” of trees over two years old for all Dimbula. One rough mode of checking, might be afforded by contrasting Udapussellawa where (as we have said) the return of 3 million trees has been very carefully reckoned. How, we should ask, do these two districts compare in respect of growing cinchona, in appearance? Has Dimbula in all its divisions—the Agrapatana and Lindula especially—fewer trees growing than Udapussellawa? We try not. But we are open to conviction and correction, so soon as it is shown that the individual estate returns of cinchona—for which not we, but the planters themselves are responsible—are much exaggerated.

Very much more to the point than Mr. Beck’s criticism on the Dimbula returns, is that afforded for Pussellawa by Mr. J. A. Roberts, to whom our apology is due for delay in publication. He *does* enter into particulars for a series of estates, and we give his letter prominence as follows:—

“CINCHONA IN PUSSELLAWA.

To the Editor *Ceylon Observer*.

Whyddon, Pussellawa, 20th August 1888.

DEAR SIR,—I am in receipt of your Directory, for which I thank you. I see it contains more information than ever, but I only yet have had time to look up the subject that interests me most, i.e. cinchona.

As your Directory is for two years, namely 1887-88, it is impossible for me to know to what date your figures are compiled. But, if you mean to say that there are at the present moment 35 million cinchona trees in the island over two years old, I am convinced you overstate the number considerably.

For my own district of Pussellawa for instance, I see you put down 2,232,000. Now I am certain from my own observation and conversation with neighbours, that there is not more than one quarter that number of trees in the district.

I enclose a list of the estates which have cinchonas, with the number of trees which I estimate

to be on them and shall be surprised if anyone in the district can increase the numbers there stated. If this letter meets with no contradiction and leads residents in other districts to make similar deductions from their own knowledge of each district, my object in writing will be gained. I am sure you will agree with me that the sooner the true position of cinchona cultivation in the island is known, the better for those who have any left.—Yours faithfully,
J. A. ROBERTS.

CINCHONA TREES TWO YEARS OLD IN PUSSELLAWA.

Estate.	..	Value	Estate.	..	Value
Attabage	..	10,000	Nugawella	..	35,000
Dewatagas	..	15,000	Peak Upper	..	10,000
Beaumont	..	60,000	Rajatalawa	..	20,000
Good-Hope	..	10,000	Riverside	..	15,000
Helbodde	..	15,000	Rosalie	..	5,000
Kalogalla	..	50,000	Rothschild	..	50,000
Lemagastenne	..	176,000	Sanqubar	..	30,000
Kanapediwatte	..	50,000	St. Cuthberts	..	15,000
Melfort	..	120,000	Stellenberg	..	5,000
Moneragalla	..	10,000			
			Total	..	701,000*

This is a valuable contribution to our knowledge, because we are at once able to institute comparisons by estates and see where the errors occur. But, first, even Mr. Roberts is a little rash in his inferences; for he says he is sure not more than one-quarter of our Directory return of trees, exist in Pussellawa: that would actually be 558,000, while he himself shows 701,000 trees. But now we come to comparisons and going over our Directory return *seriatim* we would ask Mr. Roberts how it is we have got an estate "Datry" in his own name with 20 acres cinchona, not in his list? The "170 acres" of "coffee and cinchona" on Black Forest we suppose must have been cleared out of cinchona, though not reported to us, since it does not enter into Mr. Roberts' return? Delta however has 17 acres "coffee and cinchona" not in Mr. Roberts' return; and have Derby, Paragalla, Providence and Grove Hill no cinchona now, though reported? Helbodde was returned to us with 208 acres under cinchona, and yet, for this, only 15,000 trees are credited? On the other hand (and Mr. Beck should note this) for Lemagastenne which has 176 acres under cinchona, Mr. Roberts returns 176,000 trees, and for Melfort also, 1,000 trees per acre over 120 acres. On Upper Peak we have 180 acres cinchona, but Mr. Roberts says there are only 10,000 trees. How about Rothschild however?—our return was 376 acres under cinchona and Mr. Roberts only allows 50,000 trees. Perhaps we may get answers to some of these questions before finally entering Mr. Roberts' figures on our pages. However, on going over the Pussellawa returns again we see a great blunder was made by our corrector of the press in putting down 2½ million trees; the figures as printed only work out 1,562,000 according to the estate returns; while with the corrections for Black Forest and other places patent to us, this would come down to 1½ million. But we do not think Mr. Roberts can generalize from the case of Pussellawa. We do not think it likely any of the Uva districts can show many corrections, and there after all lies the main portion of our planted cinchona now. Meantime this is how we stand:—

CINCHONA TREES ABOVE 2 YEARS OLD IN CEYLON.

Directory as Printed in Table: No. Trees.	Corrections as given above.	By critics.
Badulla ..	3,986,000	
Dikoya ..	1,515,000	
Dimbula ..	6,123,000	4,500,000
		1 million (Mr. Beck)

Haputale ..	3,071,000		
Hewaheta ..	1,206,000		
Madulsima and Hewa Eliya ..	2,568,000		
Pussellawa ..	2,232,000	1,200,000	701,000 (Mr. Roberts)
Udapussellawa..	3,033,000		
All other districts ..	11,421,000		

But after all, as we have said, the men who regulate the bark market look far more to our exports and the probable estimates for the future of bark, than to calculations of the number of growing trees. No doubt the latter may have some bearing on the value of cinchona property here, though even that again must be judged chiefly by the future of the enterprise in Java and Bolivia. What we should like just now to learn (and what we have no doubt cinchona dealers would value much too) is how far our Directory estimates of the future of bark exports from Ceylon can be justified, when we put down 9 million lb. for season 1888-9; 7 millions for 1889-90; and 6 millions for the two succeeding years. Are these figures too large and is there as much chance of a sudden collapse of exports from Ceylon as there was of the totally unexpected large rise from 7½ to nearly 12 million lb. between 1883 and 1884? Of course it is a matter of importance to have the number of growing trees as a guide in estimating the exports; but we do not suppose even with the criticism of Messrs. Beck and Roberts, that the above export figures are likely to be much disturbed. One local mercantile house specially interested, last year put down the two following seasons as likely to give 20 million lb. bark altogether; and if we send 11½ millions this season, that would still leave 8½ millions lb. as likely to go forward between 1st October 1888 and 30th September 1889.

TOBACCO CULTIVATION IN THE DUTCH EAST INDIES.

The *Bulletin du Musée Commercial*, in an article upon the tobacco cultivation in the Dutch East Indies, says that the plant is cultivated in two different manners, according to whether it is intended for exportation or local consumption. The home consumer prefers the long stalk leaf, and cares very little for the ground in which it is grown. When a plot of ground is chosen, either in or out of the *desa*, or village, it is sown after the weeds have been pulled up, and without being even dug up. If there does not happen to be sufficient natural shade for the young plants, they are covered with cocoa leaves. The end of the rainy season is the time usually chosen for sowing. In the morning or afternoon, seed mixed with sand or ashes is spread over the ground; it is then watered and covered with straw, in order to prevent the rain washing the seed away, and to keep the ground fresh in the middle of the day. The seed commences to sprout at the end of fifteen or twenty days. It is then necessary to guard against caterpillars, which have a preference for the shaded plants. At the end of fifty or sixty days, the planter for home consumption considers that the young plants are strong enough to transplant, and then commences to prepare the fields where the tobacco is to be cultivated. A preference is shown, as a rule, to the dry grounds, or *tegals*, as it is believed that tobacco cultivated in these is stronger than that grown in *savahs*, or damp ground. Before taking the young plants from the nursery grounds they are well watered, and the strongest are first transplanted in rows about three feet apart. In this operation the farmer is assisted by his family, and it usually takes place in the afternoon. When the family is not large enough to assist in the work, friends and neighbors are called in to help him. A plantation seldom contains more than 3,000 plants. After planting, the young plants are again watered, and are protected from the rays of the sun by being covered with

large leaves, chiefly those of the *djali*. During the dry weather they are watered every day until the plants having taken root, those which are weakly or dead are pulled up and are replaced by others, in addition the caterpillars are carefully removed. Occasionally the ground is weeded and broken up with a *patjol*, a species of mattock, great care being taken to heap up the soil around the stem. At the end of seventy days, the plants commence to bear buds; these are carefully removed with the fingers or with a small knife. After this operation, the shoots which spring from the stalk and injure the leaves are carefully watched. The highest leaf is considered by the growers as the best of the whole plant, and if it is desired to fully develop it the lower ones are sacrificed, so that in some cases only twelve or fifteen leaves are left on a plant, while those planters who only look to the quantity and not to the quality of their crop only remove from eighteen to twenty of the leaves three months after planting, and when the leaves begin to have a yellowish-green tint the gathering of the crop is commenced. This is done leaf by leaf, and great care is taken to keep separate the higher leaves, the lower leaves, and those growing midway; or again, these are mixed together in a certain proportion, according to the exigencies of the market for which the planter is growing. The crop is covered with leaves of the pisang, *Musa paradisiaca*, and placed upon bamboo tables. After the lapse of twenty-four hours, or when the leaves have become completely yellow, they are removed from the stems, and the principal ribs are taken away; a dozen leaves are rolled up in such a manner as to leave the largest on the outside, and they are then cut up very fine. This is a fatiguing operation, and requires much practice. The tobacco known under the name of "shag"—in Dutch *Apenhaar*—which is sold in European markets, shows to what a degree of perfection the natives have attained in the art of cutting up. The table used for this operation is a simple plank, long rather than broad furnished with two ledges widened toward the top. The rolls of tobacco are placed between these two ledges, and are pushed forward by the hand as the knife cuts off the layers. The knife used is composed of a very long and broad blade in a short handle, and is used only for this purpose. When the planter's family is not sufficient for the cutting, friends and neighbors are called in to assist, and as a rule this assistance is not paid for in money, but the workpeople are well treated and receive a portion of the crop as their reward. For two or three days the tobacco which has been cut up is allowed to remain exposed to the sun, and during the night it is exposed to the air, as it is the opinion of the growers that the dew exercises a favorable effect upon the aroma and the color of the tobacco. As soon as the tobacco is dry and of a brown color, the layers are taken up and folded in two in the form of a square bundle. This operation is usually performed in the morning about nine o'clock, as then the tobacco is supposed to have got rid of the night dews, and has not become so dry as to be difficult to handle. The bundles so formed are wrapped up in banana leaves, and are then heaped up in bamboo baskets, covered in the inside with *pisang*, *djali*, and *alang-alang* leaves. In these baskets the tobacco is subject to a species of fermentation. When the tobacco is not intended for immediate consumption, it is kept in the baskets or in boxes, care being taken to exclude the air and light. The grower for the home market, who thus keeps his cut tobacco (*maljany*) provides himself with capital, for he knows that sooner or later Chinese, Arabs, or the native merchants will visit his village and purchase his surplus crop. Prices vary according to quantity and circumstances, but native tobacco is always very choice, and assures to the grower considerable profit, if he is only careful in choosing his time for selling. Prices generally range from 20 to 80 francs per picul, the picul being equivalent to about 137 lb. avoirdupois. Native tobacco from some parts of the Archipelago, for instance that grown in Baratan, Kudoe, Roedjang, or Palembang, has a very high reputation, and fetches a high price. It is the usual custom of the Javanese to plant his tobacco in the *cauhs*, or watered lands, after the rice harvest, and

in the *tegals*, or dry grounds, after the maize harvest. It is believed that the dry ground grows a stouter and more odoriferous leaf, and the irrigated lands a finer and larger leaf. The *Bulletin du Musée Commercial* states that the information respecting the tobacco industry in the Dutch East Indies has been furnished by the Belgian Consul-General at Batavia, who has also forwarded samples of the native products to the Commercial Museum at Brussels.—*Scientific American*.

THE FUTURE OF MEXICAN COFFEE.

Mexico is by no means sharing as she ought to do in the immense coffee trade of the United States. Last week, basing our statement on the statistics then at hand, we reckoned the annual consumption of coffee in the United States at \$43,000,000 gold. During 1887 the Americans paid for their coffee nearly \$50,000,000 gold, or \$66,000,000 of our currency. Of this vast sum Mexican coffee planters received less than 4 per cent.

The Central American republics sold the Americans more than twice as much coffee as we sent to them. Even Venezuela exported more than three times as much coffee to the United States as did Mexico. These facts prove incontestably that we are annually losing a trade that, under better economical conditions here, should be largely our own. The United States bought coffee in the fiscal year ending June 30, 1887, as follows:—Of Brazil, \$36,401,864 gold; of Venezuela, \$6,770,167 gold; of Central America, \$4,269,867 gold; of Mexico \$1,837,450 gold; of Columbia, \$1,437,177 gold. And, besides, purchased of other countries.

The following presents the contrast between the coffee exportations of Mexico and Central America.

	From Mexico to	
	United States.	
	Val. in gold.	Pounds.
1887	\$ 1,837,450	14,567,005
1886	1,380,756	15,764,902
1885	999,538	10,041,421
1884	1,114,594	9,975,466
1883	809,757	8,578,532
1882	1,817,584	17,020,669
1881	1,730,838	13,911,910
	From Central America to	
	United States.	
	Val. in gold.	Pounds.
1887	\$ 4,269,967	32,734,302
1886	3,091,810	29,867,736
1885	3,833,372	36,811,072
1884	3,288,521	31,827,573
1883	2,475,942	24,715,028
1882	2,512,230	22,449,113
1881	1,989,958	15,858,327

Since we began exporting coffee to our northern neighbors, we have never before, except in two years, exceeded last year's exportation; but what a mere drop in the bucket it is compared to the total value of the coffee bought by the Americans we have seen. Already we have pointed out the imperative need of lessening the local taxation on coffee, if we are to make effective competition with the Brazilians and Central Americans, and of other causes which retard exportation we will treat in a future issue, leaving our readers in the coffee-growing districts to digest the figures we give in this article.—*Mexican Financier*.

The province of Rio Grande do Norte is complaining of drouth, and people are already leaving the interior districts. In Ceará great suffering is reported from various localities. It is generally feared that the north is to experience another devastating *secca*.—*Rio News*.

According to a statistical report of the director of the public gardens at Carityba, Paraná, the export of *heiva matte* from that province last year amounted to 19,403,174 kilogrammes, against 14,783,630 kilos in 1886. The export in 1887 was 12,462,217 kilos.—*Rio News*.

PRACTICAL HINTS ON DISINFECTION.

The following is from "Disease Germs and How to Combat Them," by Lucius Pitkin in the *Century* for July, accompanied by a frontispiece portrait of Pasteur.

First—Corrosive sublimate (mercuric chloride), sulphate of copper, and chloride of lime are among our best disinfectants, the first two being poisonous. At wholesale drug houses in New York single pounds can be obtained, mercuric chloride costing 75 cents, the others 10 cents a pound.

Second—A quarter of a pound of corrosive sublimate and a pound of sulphate of copper in one gallon of water make a concentrated solution to keep in stock. We will refer to it as "solution A."

Third—For ordinary disinfecting solution add half a pint of "solution A" to gallon of water. This, while costing less than 1½ cents per gallon, is a good strength for general use. Use in about equal quantity in disinfecting choleraic or typhoid fever excreta.

Fourth—A 4 per cent. solution of good chloride of lime, or a quarter-pint of "solution A" to ½ a gallon of water, is used to wash woodwork floors and wooden furniture, after fumigation and ventilation.

Fifth—For fumigating with sulphur, three to four pounds should be used to every 1,000 cubic feet air space. Burn in an old tin basin floating in a tub of water; keep room closed twelve hours to allow the fumes to penetrate all cracks. Then open a window from the outside and allow fumes to escape into air.

Sixth—Soak sheets, etc., in chloride of lime solution, wring out and boil.

Seventh—Cesspools, etc., should be well covered on top with a mixture of chloride of lime with ten parts of dry sand.

Eighth—Isolate the patient in an upper room from which curtains, carpets and stuffed furniture have been removed.

Ninth—The solution of mercuric chloride must not be placed in metal vessels, since the mercury would plate them.—*American Grocer*.

A CARD FROM DR. RUSBY.

COLUMBIA COLLEGE, NEW YORK, JAN. 30.

Editor "*Oil, Paint and Drug Reporter*."

In your issue of January 25, page 9, you publish a report of a lecture delivered by me before the Pittsburg College of Pharmacy, in which so many of my statements are reversed or distorted, as to constitute a serious misrepresentation. I beg to present certain portions of your report, and beside them the statements actually read by me from typed manuscript.

1. "The home of the cinchona tree is a belt of 500 acres." I stated that I had ridden 9 Spanish leagues through an almost continuous cinchona plantation, the property of a single individual.

2. "The storm-clouds that sweep constantly over it from the Pacific" I presented the Pacific slope as an almost rainless desert, the clouds all coming from the Atlantic, across the Brazilian silvas.

3. "There is not an ounce of the drug sold today, but what is the result of cultivation." I said "there is only an occasional bale sold which is not the product of cultivated plants."

4. The whole cinchona trade is in the hands of a single Spaniard, of high position, in Chili. My statement: "At the time when cinchona bark brought \$3 and \$4 per pound, the high price was caused, not so much by scarcity, as by the monopoly of the trade, which was wholly in the hands of a single individual."

5. There is a small quantity of the bark cultivated in some parts of India, but it is weak and almost worthless." My statement: "Notwithstanding that the Indian bark is, except as the result of special treatment (I referred to mossaing) somewhat inferior on the average to that produced in its original home, yet it has so cheapened the product as to cause recent shipments of Bolivian bark to be sold in London at a loss to the shipper of about 12 cents per pound." I made the additional clear statement that so far as I could see there was no hope for the South American planter except

in the advent of a European war, or some unexpected destruction of the Indian supply.

At the above point you very naturally comment on the gross ignorance displayed in the statement that you suppose me to have made. I can only assure you that I am familiar with the whole history of the Indian plantations, and of their condition and prospects.

I trust that you will, by publishing this communication, do what you can to correct the wrong impression caused by your report.

Very respectfully,

H. H. RUSBY, M. D.

DRUG TRADE REPORT.

London, August 9th.

ANNATTO, dull. A few barrels fairly good dry Ceylon seed were shown, and for this 2d. per lb. is asked which is about the market price at present.

COBERS.—We received this week consignments of 22 bags per "Telamon" from Singapore, and 6 bags per "Quetta" from Batavia. Our own market remains quiet, but firm, and up to 27½ per cwt. for good genuine berries. None were offered at the sales today.

CINCHONA.—Several parcels of South American bark were offered today, including 101 bales Lima, which sold very cheaply, at 2d to 2½d. per lb. for sound fairly good mossy, and ½d to 2d. per lb. for damaged bark. The whole parcel weighed 9,305 lb. Good grey Huanoco quill brought 1s 4d. per lb. damaged ordinary ditto, 9d per lb. Five bales nondescript bulkings were also disposed of at 3½d per lb.

OILS (ESSENTIAL).—There is very little business doing in this branch, and the alterations reported since last week are small. Today there is a report that Bergamot oil is again dearer in Italy, but we have not confirmed it. Cassia dull; 25 cases unworked bought in at 3s. per lb. nominally. Cinnamon, Cinnamon leaf, and Citronella unchanged but steady. Of Lemon 5 cases were offered at auction, and bought in at 4s to 4s 6d. per lb. Our last report concerning the coming crop of Mitcham Lavender still holds good, although the hot weather of the last few days has slightly improved the prospect. Oil of limes quoted at 3s. Peppermint oil, America HGH, dull at 12s to 12 3d. per lb. Otto of rose unchanged. We hear that the largest Constantinople dealers have not yet bought, as they anticipate lower prices shortly.—*Chemist and Druggist* August 11th.

CEYLON AT THE MELBOURNE EXHIBITION.

We are indebted to the same chatty correspondent who wrote to us some weeks ago, for the following letter dated July 26th from Victoria:—

Shall be glad to send a few notes from time to time, because I feel very strongly that the Ceylon connection with the Exhibition furnishes an excellent opportunity of impressing the great importance of Australia to our tea interests, and because I venture to think that a chatty letter, or quoted remarks by you, are likely to reach those who habitually skip or skim official P. A. reports. I am much pleased with all you say in your last issues of the *Observer* to hand. After the changes being rung by your correspondents on Brussels and Glasgow, Glasgow and Brussels, till those interested in Melbourne might well be jealous, it is comforting to see the lights being turned on the S. Hemisphere at last. Of course you have heard that it is quite settled Mr. Fowkes takes the working charge, and I do not think a better man could have been found. He has secured an office in Collins Street, and is full of activity and enthusiasm, having already grounds for hope of gaining a good footing in the trade, which is everything. He also already supplies one of the coffee palaces, a huge new one, built specially, I believe, for Exhibition time, and I understand the demand for 'Ceylons' showed a distinctly marked improvement at the new season's tea sales just on when I was

down. One of Ceylon's best supporters in this line is Mr. Robt. Walker, the head of a large and old-established firm. Since he met Mr. A. M. Ferguson at the last Exhibition he has always used Ceylon tea himself, and has pushed it continually in his business. There is at least one crumb from the old table.

The space has been allotted at last. Ceylon has also got not one, but two nice little additions to its space, securing thereby a capital "go-down." We are indebted for this to the exceedingly obliging and genial Superintendent of Minor Courts, Mr. Forbes. He would have granted this earlier if he possibly could, and had he done so, we would have been able to increase the width of the verandah, but until the owners of the spaces expressed dissatisfaction he could not move.

Permission was given to the Education Court people to leave a large arched window open between our kiosk and their rooms, as I think the children's competitions would be an attractive feature to ladies who can watch and listen as they have tea. A sketch of the kiosk I hear goes to the P. A. Mr. H. Mackenzie telegraphed at once to Queensland for bamboos, and they are now come. Gas, water, and all such details are arranged, and everything will be ready for opening by the time things arrive from Ceylon. On the whole I really think that, all things considered, Mr. Mackenzie has at last got matters on a very satisfactory footing and that the advertisement will be both popular and pretty. The main building will of course be got ready somehow for the 1st, which they persist in keeping to as opening date, but ten days ago chaos and carpenters reigned supreme; many of the spaces in the Minor Courts bearing still only their chalked numbers, so it does not matter in the least that we are somewhat late. In fact I think it carries advantages.

The German Court was nearly finished and was very handsome indeed. The promise of the entire Show is that it will be worthy of "Marvellous Melbourne." Hotels had already begun to fill, and the streets look more gay. The theatre turning crowds away nightly, among the "rushed" being preeminently that beautiful new theatre, the Princess's, near the Exhibition, where the London Gaiety Company is delighting the colonial "chappies," and everyone who sees their finished, refined and graceful acting and dancing.

CEYLON AT THE PARIS EXHIBITION.

Planters' Association of Ceylon, Kandy, 31st Aug. 1888. To the Editor, "Ceylon Observer."

SIR,—I beg to enclose letter from Mr. J. L. Shand on the subject of the representation of Ceylon tea at the Paris Universal Exhibition 1889.—Yours faithfully,

A. PHILIP, Secretary.

Ceylon Court, International Exhibition, Glasgow, 7th August 1888.

The Secretary, Planters' Association of Ceylon, Kandy. Dear Sir,—I have duly received your letter of 12th ultimo, and I have also to thank you for copy of P. A. proceedings which I read with pleasure and sometimes wish I were on the spot to take a part in.

As regards Paris Exhibition I have had, as I told you before, enough of Exhibitions, but I presume I may take the feeling expressed in your official letter, and in your Chairman's private letter, as a general one, and, as that feeling seems to be endorsed by those interested at home, I feel I should be false to my colors in not coming forward now, and I shall be heartily glad to do all I can to contribute to the success of Ceylon in Paris.

My agreement has been signed, and I will just mention again what it is. The British Empire section hands over to me a space of about 120 square meters with walls and roof, but nothing more, and flooring, &c., &c., has to be done by me, and for this occasion I am to pay £1,200, say £48, for every million visitors to the Exhibition, visitors meaning those who pay at the gate and not including season-ticket-holders for attendants. I have also a large terrace in front, and on the side of the building which will give ample space, altogether I think we shall have selling room for 100 people, which means a very much larger establishment than we have ever

had before. Here we cannot conveniently seat more than sixty, and we are slaves to the greed of Exhibition Councils and the jealousy of rival refreshment contractors.

At the present moment we are parties to a suit for telling our baker he might sell what in an agreement with the Council, we were told we might sell, but we are now told we must not. We have consequently had to make entirely new arrangements from which we may suffer loss, and for which, of course, the Council is responsible, and we have the prospect of a lawsuit before us.

In Paris I am assured no such thing can happen, and, as we have the only tea-room in the British section, we must show ourselves deserving of the monopoly.

As regards a Ceylon Court at Paris Exhibition, it would certainly be a mistake to try it unless there was plenty of money available to do it thoroughly. We should come into contact with the French Colonies which are all straining every nerve to celebrate a great event in the life of their nation, and though on the walls and the corners of our tea-room we might make an effective display in a small way, unless a large sum, say £3,000; could be raised I think it would be a mistake to attempt a Court.

I do not know what arrangements have been made for space for British Colonies. I know the whole space in the British Empire section has been taken up, and I conclude as none of our Colonies are likely to have any official help, none of them are likely to form separate Courts, and the charge for space will probably be heavy.

Again, the circumstances of Paris are entirely different to Glasgow or other Exhibitions. In Glasgow our only chance of not sinking our identity in the Indian Empire, and of not being crushed by an extreme rent, was to provide our attraction in the shape of a Ceylon Court. Moreover there are social reasons (which the members of the Association will appreciate) which make it impossible for me or those associated with me to appear at an Exhibition in this country as mere sellers of Ceylon tea, and even if these reasons did not exist the stand I have all along taken of representing growers and not dealers is far more likely to do good to Ceylon.

In Paris things are entirely different, and my advice to the Association would be to have nothing to do with a separate Court, but to spare no effort in making the tea-room thoroughly attractive, for after all the chief object we have had in view in getting up Ceylon Courts has been to secure a tea-room, and here it is secured without the trouble and expense of a Court. Sir Wm. Gregory writes me very strongly about the necessity of making the tea-room attractive, and congratulates me upon having secured the co-operation of Mr. Smither who has kindly offered me his services, and my desire is to decorate this tea-room as no tea-room has ever been decorated before, making it characteristic of Ceylon and meeting the Parisian love of gaiety and novelty. This will, if properly done, absorb every penny we are likely to get, and I should recommend the Association to confine its efforts to the tea-room. Outlay begins at once. I am called upon to deposit £1,200 as a guarantee, and we shall want all the money we can lay our hands upon, but I am very confident that at the end of the Exhibition I may be able to return to the Association whatever sum it contributes, or at all events part of it.

Glasgow goes on steadily: sales are averaging 5,000 cups per week.—Faithfully yours,

(Signed) J. L. SHAND.

Brazil has abolished slavery. Now let the Argentine Republic do the same. Nominally, it has, but really it has not. There are scattered through the country Indian captives who are to all intents and purposes slaves. They are to be found among "high life" families in the city of Buenos Ayres, the capital of the Republic, and all over the country. They are slaves because in bonds. They work and get no wage. They are not to go and come and go, but are hunted and held as other slaves are held, treated well or abused according to the dispositions of their master. *Buenos Aires Herald.*

TOON TREES AND INSECT PESTS.

Cedrela toona is a special favourite of ours amongst timber trees, as it well deserves to be from its straight clean stem, its peculiarly handsome red-coloured foliage, and the quality of its timber, resembling and not much inferior to mahogany. It grows in time to an enormous girth, and Gamble describes it as generally a quick grower. That is our own experience, as recently recorded, in the case of a grove of young and flourishing trees on a piece of land near the bund at Nuwara Eliya. The rate of growth of the trees here in less than two years has been most satisfactory, while less than half-a-dozen out of several hundreds have suffered in broken tops from wind. They have been attacked neither by insects nor animals, which cannot be said of their companion tree, *Cryptomeria japonica*. The tender tops of these have been eaten off from their infancy onwards. We have blamed rats and hares, but we suspect the chief culprits are stray cattle. The tops of our "red cedar" trees are now almost all beyond the reach of cattle, even if the latter affected them, which they do not. A gentleman for whose opinion generally we have much respect, has recently attempted to shake our faith in toons by asserting that although they grow rapidly when young they subsequently hang fire and that they are liable to attacks from boring beetles. Owing to this latter cause, he stated, Mr. George Beck of Henfold, Dimbula, was extirpating some toons which he had grown: This was the second case we had heard of, the first being in regard to toon trees grown on Looecondera. But this place and Henfold are each fully 1,500 feet lower in altitude than the scene of our experiment, and we have never heard of insects attacking this tree at Darjiling or other parts of the Himalayas, on the Nilgiris or in Java. Balfour and Gamble say not one word about insect attacks, but they notice properties in the wood and bark specially inimical to insects. Accordingly, we are glad to find, on reference to Dr. Trimen (who kindly permits us to publish his reply to our inquiries), that the insects which do occasionally attack toon trees in Ceylon are not timber borers, but merely leaf-eating caterpillars, of little account. Dr. Trimen's interesting statement is in the following terms:—

"The little borer which occasionally attacks the toon is not a very serious pest, and scarcely affords as sufficient reason for cutting down the trees. It is not a beetle-larva, but the little caterpillar of a small moth, and is scarcely deserving of the name of 'borer,' as it does not live in the wood of the tree, but in the extreme twigs when young and green, in fact immediately after they are put forth. It has attacked a few trees in Peradeniya, and I know was troublesome some years ago at Looecondera, but is by no means general or even common. It has nothing whatever to do with the borer of coffee and other trees, and there is no likelihood of its spreading to them. It is, however, very partial to the mahogany, a close relation to the toon, and many of our trees in Peradeniya have been much checked in growth by its annual attacks. The effect is indeed very curious; the repeated destruction of the terminal twigs causes the continuous production of lateral ones on the branchlets below, so that the character of the tree becomes at last quite altered, and a dense, round, much-branched head results, instead of the usual wide-spreading foliage. Probably a somewhat similar change would occur in the toon trees, but that is the worst that would happen."

This is reassuring, and we retain our belief in *Cedrela toona*, the grand "red cedar" of Queensland (whence slabs 8 feet wide have been obtained of fine quality timber), and the whole Himalayan and other elevated regions of India, as one of the most desirable trees to grow at high

altitudes in Ceylon. The trees can be planted very close, can be gradually thinned out, and when mature individuals are finally cut down, they coppice as readily as does that other valuable timber tree, the teak, which ought to receive special attention in the moist lowcountry of Ceylon. In the dry and arid portions of the lowcountry, the satinwood, halmilla, tamarind and palu grow well, and on the banks of the rivers the huge kumbuk. But the tree to be specially cultivated in the dry and arid zones is the palmyra palm, good for fence, thatch and native boat leaves, sugar, fruits and timber.

FLOWERING OF EUCALYPTUS GLOBULUS.—There is now in the garden of Beaconhall House, Exmouth, Devon, a tree of *Eucalyptus globulus*, which in a few days will be a beautiful sight—at present there are some hundreds of flowers open and a large number of buds are about to expand. The height of the tree is about 30 feet, and at 6 feet from the ground, measures 24 inches in circumference. It was planted about seven years ago. Does not such a specimen speak well for our mild climate?—W. J. G.—*Gardeners' Chronicle*.

A NEW SUGAR-MAKING AGENT.—Sugar-growers in Demerara have been much excited of late in consequence of the successful use of coconut oil as a sugar-making agent. The addition to the pan prior to striking, of about a pint of the oil to the ton of sugar produces an enormously increased return of sugar from the masicuite. The sugar made with the oil contains not a trace of the odour peculiar to it. When in addition to this, cheapness of the agent, and the simplicity of its application are taken into account, it seems certain that the new process is bound to come into general use.—*Indian Agriculturist*.

GUTTA PERCHA.—The gutta obtained from the Abyssinian trees, *Mimusops Schimperii* and *M. Kunzei*, Hochst., has been examined by Messrs. Heckel and Schlagdenhauffen, who find that it contains 48.20 per cent. of gutta, 42.80 per cent. of an amorphous resin, produced apparently by the oxidation of albane, and 9.80 per cent. of inorganic salts. The crude article is elastic and adhesive, and owes its glutinous character to the resin. The authors also examined the product of a species of *Paysonia* from the Sunda Isles, which yielded about 30 per cent. of caoutchouc, and a crystalline and an amorphous resin. The authors conclude that neither of these products are available for technical purposes in the pure state, but may be useful for mixing with other varieties of gutta (*Compt. Rend.*, cvii., p. 1625).—*Pharmaceutical Journal*.

FARMING IN WESTERN AUSTRALIA.—Mr. H. Stonehewer Cooper, a well-known writer on the Colonies, writing to the *Sydney Mail*, gives a striking picture of the reckless way in which farming has hitherto been carried on in Western Australia:—

To show your readers what sort of farming has been carried on here in years gone by, I will just give a case:—Not far from this pretty little town of Albany, where I am writing, a man has a farm of about 70 acres, and he has farmed it for 22 years. In all that time he has never put an ounce of manure on his fields, and he has never ploughed more than 4½ in. deep. The average of his wheat return has been 25 to 28 bushels per acre, and of barley 45 to 50 bushels. But the apathetic indolence and indifference to modern ways of doing things surpass all belief. Only a few days ago a correspondent of a Perth paper says that some of the farmers of the rich Greenough Valley refuse manure if offered to them, although they have been pottering on in the same miserable fashion, imported, I fear, from the "distressful country," for some 15 years, are heavily in debt to the storekeepers, and do next to nothing with soil which the ordinary English or Scotch farmer would make a fortune with. These things and many like them make people who wish for the progress of West Australia cry aloud for new blood—men with brains as well as money to turn a land capable of great things to account.

Correspondence.

To the Editor.

PUSHING CEYLON TEA IN AMERICA: MR. MCCOMBIE MURRAY'S EXPERIENCE.
Philadelphia, 18th July 1888.

DEAR SIR,—Perhaps a short account of my experiences in the line of distributing samples of Ceylon tea might be interesting to your readers.

At first sight it may appear a *mighty nice thing*, if I may use the expression, to be the happy recipient of 3,000 lb. of tea, free, gratis, and for nothing. But when it is taken into consideration that this amount of tea is *not* a present to the recipient, but to the public through the medium of said individual, there are two ways of looking at it, as I have found to my cost. When I found that my first three weeks of temporary proprietorship of the tea sent me for distribution, and the labor attached to the work of putting out the same, made me liable for more than \$250, I began to wonder whether I would see my money again. I was the more thoughtful on the subject as there remained a goodly number of tea chests still untouched, which meant that my expenses were by no means at an end, and that I would have to be prepared to put as much again into the work before I got the tea disposed of.

In reading a remark on the subject of pushing Ceylon tea by means of samples made by Mr. J. L. Shand (in your issue of June 11th), I was at first disposed to criticize what appeared to be rather a wholesale imputation of fraud and dishonorable action to all on whose behalf the fund has been instituted, myself included. And indeed it is apparently unwittingly that he made remarks that contained an element of truth. That any man would accept a consignment of tea, on the pretext of wishing to distribute samples free where it could best encourage the drinking of Ceylon tea, and sell it to apply the proceeds to his own personal benefit, I do not believe, as tea would not be so placed at the disposal of anyone whose sense of honor had so forsaken him. But where applicants for samples ought to be very careful is first to count the cost of putting out samples, and then be careful to receive only such amount as he feels he can put out without drawing too much upon his resources.

Given that the tea costs the pioneer of Ceylon tea nothing so far as *buying* it is concerned; it is by no means a cheap, or rather *inexpensive*, style of advertizing, but on the contrary, the most expensive of all ways.

Judiciously carried out, it is equal to any Exhibition, as *there*, there is so much to attract the attention of the sightseer that any *one* article is lost sight of to a great extent in the crowding upon the imagination the interesting features of the whole Exhibition, whereas a well-directed sample comes up on the recipient in his quiet moments at *his own home*. But it is *expensive*, and I would warn anyone who does not feel he can afford to make a pretty good show at an Exhibition, *not* to undertake a general distribution of free samples, as the one course will cost almost as much as the other, even although the tea is given him.

From personal experience I can say that in America a good-sized sample of Ceylon tea (provided it costs nothing to buy) judiciously distributed will pay *in the end* as well as almost any advertisement that I know, but the first expenses are heavy, and although a man may be ever so willing to see the last pound given away, he will not, if he is honorable, give it away *injudiciously*, and, as it is in my own case, he may find it hard

to meet the expenses of putting it out *profitably* all at once.

Having nearly a dozen agents at work in different parts of the country, I have been able to distribute through them, with no cost to myself except packing the samples in boxes and printing and advertizing expenses; but I calculate that in distributing these samples I will pay over \$500 out of my own pocket, or rather out of the resources of my firm, and that without agents established it would have cost half as much again.

The question of whether it has paid me I cannot yet answer. At present I am *very much* out of pocket—so to speak, but in the end it will *pay* me.

Locally my method was in the first place to procure six nice girls to pack in full view of the public. This attracted attention. Secondly, to address envelopes containing my circular and attach to sample package. Then to secure three young fellows nicely dressed and a waggon.

From a book published in Philadelphia called the "Blue Book," we get the addresses of the better class people of the city.

The streets being laid out in regular blocks we could very easily arrange a methodical system of delivery; and before three weeks had passed from date of the arrival of the tea, we had 6,000 samples carefully placed in 6,000 of the best houses in Philadelphia. Personally I supervised the work given me to do, besides which about 5,000 samples have been cast upon the waters, some sent to my agents, some disposed of in other ways, such as to bazaars for charitable purposes, where they were sold at 10 cents each for the benefit of the cause, &c., &c.

With the exception of a few chests *in bulk* (to remain so for a season) all the tea has been put up in sample boxes ready to send to any good channel for profitable distribution. If Mr. Shand could raise an Exhibition here for me at which to boom Ceylon tea, I am sure I would be more than ever indebted to him; but the worst of it is I have no Exhibition, but my own store wherein to indulge in *my* eloquence and eulogize Ceylon tea before the more or less sceptical people of the quaker city.

Down in Cincinnati a Centennial Exhibition has just been opened, and I have done my best to get a man to get up an exhibit there for me, as I cannot leave Philadelphia. So far I have not succeeded, but am now engaged in a correspondence which may end in a representation of some sort. I will exhibit next year at the Pennsylvania State Fair, which, by the way, did me a great deal of good in the end, although it cost money at the time.

I enclose our latest circular for the use of agents in particular. Twelve thousand now received go direct to my agents, so you may judge from that, that my means for reaching the general market are not so very limited as Mr. Agar would have it appear. True, I cannot do in New York or Chicago what I have done in Philadelphia.

Since Mr. Pineo left I have reached the good families of this city on two occasions, once with samples, once with circulars. Through the agency of Messrs. Barclay & Parsons of New York City I hope to do a little in the way of advertizing, and I trust that nothing will occur which will interfere with my right to mention the Planters' Association of Ceylon as the parent body from which I am sprung by the appointment of anyone as the accredited agent and representative of that Association. I am a Ceylon man to the backbone, and I have written to Mr. Philip as Secretary of the Association, reserving any such appointment, as Mr. S. Elwood May, of "New York City," claims for himself in the event of his undertaking to push the sale of Ceylon tea in America.

I do not know Mr. May personally, although I have frequently supplied him with Ceylon tea, but I have no doubt he will do well for Ceylon if he gets encouragement. It would appear he is a man of capital, and if his heart is in the work, let him have full swing. There are very few Americans who will consent to handle Ceylon tea, and if you find the American with money, who will invest his money in the interests of the Ceylon tea enterprise, catch a hold of him and stick to him, but don't forget that there is a Ceylon Planter in America who has done more for Ceylon than Mr. May. I plead guilty to the *weakness*, if it please you to call it so, of wishing my humble efforts to introduce Ceylon tea into America to be appreciated just so far as they have been *faithful* to the interests of Ceylon and *unceasing* since I took the first step in addressing the members of the Ceylon Tea Syndicate through the favor of your columns and those of the "Times of Ceylon" in a letter dated 23rd July 1886. I said in that letter "I bind myself to conscientiously serve your interests," and without a guarantee of any kind I left for America, and none better than Mr. Pineo can tell you that I have kept my word at the risk of utter ruin to my own temporary prospects.

I will say no more; I am not in Ceylon to plead my cause, or to answer any criticism of what I might write, so I must write plainly and openly and let the thing go.

One thing I know, I have fought just so hard for Ceylon, that I am jealous of anyone who would step between me and the first place in the estimation of those for whose interests I have risked everything, and allow him to place even money and power before *my work*, the only reward for which is the appreciation of my brother planters in Ceylon, and a meagre livelihood for myself and family, which is, even now, not out of jeopardy.

I cannot write more on this subject. I have already said perhaps too much, but I must be excused, for I am far away and, as is my usual, in a very anxious frame of mind. If I live and can earn but a bare livelihood in the work I have put my hand to, I am yours in the cause of the Ceylon tea enterprise, whether it be Oolongs, Congous, or any other kind of tea; but I claim what I earn, the first call upon the Planters' Association for their confidence and support.

So far as the manufacture of a Ceylon Oolong tea is concerned, I can only say what I have said before.

If it can be accomplished *satisfactorily*, you can win the Americans over to using Ceylon tea in one-tenth of the time and with just so much less expense, and so long as it can be made to be equally pure and wholesome, why not at least experiment on it, and follow the advice of one of our great soap advertisers, which is "Don't be a clam."

It may not be a successful experiment. The first shipments of Ceylon tea in its present form were not successful as marketable teas. Why expect the first shipments of Ceylon Oolongs to be a great success?

Try it, and if I am well advised *you will succeed*.

For the present I conclude. Your readers are probably tired; I know I am.—Yours very truly,

J. MCCOMBIE MURRAY.

ASHES AND SALT ON POTATOES.—The *American Cultivator* says it is an excellent plan as soon as potatoes are well up to go over the place and throw a handful of a mixture of salt and ashes on each hill. The preparation is soon washed down into the ground by rains. It repels insects makes the potatoes fair and smooth and helps to draw moisture to the potato during a dry time.

PEPPER AND CARDAMOM CULTIVATION.—To give an impetus to the cultivation of pepper and cardamoms in the Wynaad, the Special Assistant Collector of Malabar and the Nilgiris has recommended that the assessment on lands taken up for such cultivation may be remitted for the first three years from date of planting, as the trees take that time to come into bearing.—*Madras Mail*, Aug. 27th.

CEYLON TEA IN AMERICA.—We call attention to the frank outspoken letter addressed to us by Mr. McCombie Murray: we think its appeal will meet with a hearty response from Ceylon planters, and that the Tea Fund and P. A. Committees will be strengthened in their resolve to do nothing to weaken the hands or to derogate from the representative position of Mr. Murray as a Ceylon Tea Agent, in entrusting a similar recognition and Agency to Mr. Elwood May. The more agencies the better, provided there is no partiality shown in nominating anyone in particular as the only Agent recognized by the Planters' Association of Ceylon.

COCOA TREES IN THE SOUTHERN PROVINCE.—It may not be generally known that cocoa trees are found almost wild in the Hinidum Pattu of the Southern Province. The Mudaliyar of the district informed me, some time ago, that trees as large as jak (!) are found in almost every garden, and that the only use made of the pods was for the youngsters to suck the fleshy part of the beans and throw them away. Seeing that I was sceptical, he, in a few days, sent me a gunny-bag full of large pods, but they were unripe and useless or the preparation of chocolate—a preparation often made by me from the produce of some trees in a garden in Labodowe, and highly appreciated by all who partook of it. It is only lately that European planters opened up estates in Udugama. Who, then, planted these trees in the wilds of Hinidum Pattu, and when?—Local "Times."

RHEA FIBRE MACHINES.—Our enquiries in reference to the details of the rhea machines said to have been brought to such perfection in Spain, and to which we referred last week, have thus far resulted in ascertaining that the French Government, impressed with the importance of this very promising industry for the French manufacturers, have issued a decree notifying the holding of an International competition of machines and apparatus for the preparation of rhea in Paris on the 15th of August, offering prizes of various values for those competitors who may be successful. If this competition is held with any approach to fairness as between competitors of different nationalities, there will be every probability that we shall be able to learn which of the various machines for which patents have been taken out, are likely to be suitable for use in India, also as regards their cost. At present the accounts regarding them are somewhat conflicting, and it is especially desirable that the fullest information be obtained, as the practical value of these depends upon turning out a quantity of the fibre in a marketable state within a given time. Without such data the result cannot be considered of practical value. Our readers may probably remember that in the early part of the year 1884, during the currency of the Calcutta Exhibition, we reported the results of trials made with various fibre machines, some of which performed very good work on a small scale, but on being tested on larger quantities were found to be unequal to the task. Since that time a company has been formed to grow rhea in South India, and this part of the undertaking has been actually carried out, considerable quantities of the fibre in the rough or half-prepared state having been sent home for working up. In 1886 the Company had a show case in the Indo-Colonial Exhibition which contained a larger assortment of articles said to have been made from rhea grown on the Company's land. Some of these were beautifully got up and, judging from appearances the success of this Company would seem to have been assured. But it does not appear to have accomplished much, no doubt from the failure of crushing machinery for removing the dried cuticle from the fibre.—*Indian Agriculturist*.

THROUGH MATALE EAST AND LAGGALA.
TEA; TOBACCO; FRUIT; COTTON.

(Continued.)

The Valley of Matale may be said to commence about the Ukuwala station on the railway line and to extend some twenty miles onwards to Kawdupelella, growing wider as the capital is left behind. The cultivation throughout the length and breadth of this valley is more varied and interesting than can perhaps be seen within any other similar area in Ceylon. Long famous for its well-watered rice-fields, presenting just now in their vivid green and long-extended reaches some of the most charming pictures possible, as seen from the hill-sides; famous also for its fruit and vegetable gardens—such delicious plantains and loquats we have nowhere else tasted,—there are besides flourishing groves of the coconut palm more extensive and richer bearing than any to be found between Polgahawala and Batticaloa. Then we have some of the best and most extensive cacao-walks in Ceylon, and if the old staple 'coffee' is fast disappearing (though not a few native gardens still flourish) tea promises to more than make up the deficiency. In addition we have fields covered with the Annattodye shrub: groves of areca palm cultivated by European planters as well as natives; rich and promising expanses of tobacco and a dozen or more of other minor products up and down the Valley all diversifying the prospect and adding to the interest of the visitor. Apart from its proximity to Peradeniya, there is no need for an Experimental Garden in Matale for the very good reason that the whole Valley may be said to be the scene of experimental as well as proved cultivation, with new and old products. Ukuwala station already referred to, as we enter the Valley, is likely to be the centre of a very important tea industry on comparatively virgin (that is chena) land. Accompanying a couple of Missionaries on a visit of inspection, I got out here and, walking along the line for some distance, was able to mark several miniature "Mariawattes" most promising so far as soil and undulating almost flat lay of land went, the only drawback apparent being want of rain. Of course all the country suffers at this time, but even in normal seasons the Matale Valley (with its 75 to 85 inches) is scarcely so well provided as that of Gampola, where Mariawatte gets an average of over 100 inches. Peradeniya tea estate will have the same climate probably as the Ukuwala group and as the still finer Bandarapola tea estate close to Matale town. At Ukuwala, the pioneers include Messrs. T. C. Owen (and partners), J. H. Barber, Kerrs, &c.; while higher up and nearer Wattagama, such fine old places as the Pendleton-Malvern group are doing famously well in tea. Our inspection of the Mission school not far from Ukuwala was exceedingly satisfactory: I could not have believed so many healthy-looking boys could be got together in one school in that quiet place: some 80 on the roll and 50 or 60 in regular attendance, and the examination of different classes showed good intelligent working. This is connected with the Matale division of the Baptist Mission under Mr. Lapham's care, another good school being situated in the village of Rattota. Entering Matale from Ukuwala we came on the far famed cacao and coffee fields of Wariapolla, which present as healthy and vigorous an appearance as any in the island. Far more attractive and refreshing than other tea or coffee fields cultivated in the open, are the shaded cacao walks with their fine large bushes laden with fruit scarlet, pink or white—surmounted by the umbrageous *Erythrina Indica* or Cenà rubber trees, which afford a sense of coolness even

in the hottest hours of the day. We need not allude to the historical interest attaching to Wariapolla, or the unique planting prosperity attending the cultivation of the sister property of Kandanevawara, from which in the palmy coffee days as much as £13,000 clear profit has been made in a single year. Tea is never likely to yield such returns, but it is certain to be remunerative on a uniformly well-cared-for property like the one under notice; and Matale is fortunate to have in the resident "laird" a gentleman of so much intelligence, enterprise and public spirit as Mr. R. S. Fraser.

Though my visit and inspection took place after my return from Laggala, I may here allude to the true "Mariawatte" of the Matale district, in the new BANDARAPOLLA tea property created by the unwearied industry and pluck of Mr. Hugh Fraser. For nine long years was this gentleman engaged in enquiries, negotiations and buying up the various allotments of native property, chiefly chena land, which put together (with the old Godapola places) make up the 930 acres now comprising Bandarapolla. After all had been signed, sealed and paid for, Mr. Fraser's titledeeds and connected papers formed a mass quite equal to an ordinary cooly load; and then to "mak siccar," he very wisely had all passed through the Government Kachcheri, a connected official survey made, and the whole entered in one transfer bearing the official stamp. The contribution in stamps to the revenue for Bandarapola deeds must be something considerable. One thing is certain,—that no thief, even if he got possession, could easily run away with the enormous volume of which we had a glimpse. It will be remembered that a half share of Bandarapolla was sold for R60,000 cash to the late Mr. A. H. Murray-Menzies, a few months before his decease, and a good bargain we consider was made at that price with 300 acres under tea reaching up to five years old, and such tea! It was like taking a stroll in a newly laid out English garden to walk round the knolls and note the successive fields of Bandarapolla, after the ups and downs and almost break-neck paths of Laggala. The roads are cut so as eventually to be rendered fit either for cart or tramway, and most of the tea is planted on undulating flats, in which well selected jats, including a good deal of indigenous, luxuriate. At one end of the property we came on a field of tobacco, the plants (looking like young cabbages) alternately with the young tea which, as the crop is likely to be gathered a few months hence, they are not expected to injure. Some of the tobacco (Havana seed got from Peradeniya) plants intended for seed-bearers show a magnificent growth for the time they have been in the ground. Rain and rain alone was wanted to give a finish to the picture of verdure and vigorous growth which surrounded us on Bandarapolla, and we do not think, with an average of 80 inches pretty fairly distributed, that as a rule the lucky proprietors have much to fear. But one very important addition to this land, secured by Mr. Fraser from the villagers and temple representatives, is the right to a water supply which, after doing its duty by paddy-fields farther up, ran pretty well to waste. There was difficulty of course in arranging for this, and some native objectors carried their pleas to Government. An enquiry was ordered with the result that Mr. Fraser was specially thanked (in place of being censured) for the benefit he had conferred on the native cultivators by blasting out and improving the watercourse between the river and the rice-field in order to increase his own water supply. This water is, of course, primarily required on Bandarapolla to fill a dam and supply

a big water-wheel driving the machinery in a well-furnished Factory. But in connection with his watercourse, Mr. Fraser has very skilfully and wisely carried irrigation channels round the sides of his knolls from which tiny streams run down to the drier flats below, imparting freshness to the thirsty tea at a variety of points when we were there. These irrigating arrangements, in our opinion, render the success of Bandarapolla doubly secure. As to transport, better facilities could not be wished, with a cart-road from the factory door 4 miles to Matale station, while for riding, across the river, the distance is little more than 2 miles. I should not omit to mention the sight of a splendid nursery of tobacco plants, which, as Mr. Fraser said, had cost him for seed no more than R30; while to secure as many tea plants would probably require an outlay of R3,000 in seed! Mr. Fraser is very strong in his belief that tobacco might very freely be cultivated by the Laggala villagers, the leaf being taken to a central factory for sale. Mr. Ingleton (as representing Messrs. Meyer & Co.) should see to this. Meantime, in the lower valley of Matale, there is another product about to claim to attention of the Sinhalese in—COTTON.

(To be continued.)

A LITTLE EASTERN COURT AT GLASGOW AND WHAT IT TEACHES.

[FROM A CORRESPONDENT.]

"Surely we are the most practical people on the face of the earth!" Such were the words I heard spoken by a well-to-do citizen of the northern capital of industry within the exhibition building. I felt inclined to contradict him as regards International Shows. Were it so, there would not be the dense crowds gazing on the show-cases of jewellery and gold and silver, silks and laces from foreign countries; there would be more people occupied in examining those exhibits which instruct and improve. Why is the Indian Court so much thronged, and why is the Ceylon Court so little frequented? In the one is a huge collection of rich and costly curios; in the other is a marvellous gathering of instructive products, showing what industry and application can extract from the earth under the most trying conditions. Yet these things fail to attract as do articles made only for the eye.

The world has heard a good deal of talk about Ceylon tea and of its excellence, but the world knows very little—it may be said next to nothing—about the island in which that tea is grown, nor should I be able to write of it now as I do were it not for the appearance of a compact, prettily-illustrated "Handbook of Ceylon Products and Industries,"—the only one published in the Exhibition, in which a good deal is told in a very brief space. Looking at the diminutive models of Sinhalese villagers engaged in noosing elephants in a kraal, one would not have dreamt that in the remote past, when our ancestors dwelt in mud hovels, the kings of that "utmost Indian Isle" resided in vast palaces of stone, richly carved and ornamented with glittering gems, and that they invaded India with a great army and sacked many cities; nor would it be thought probable that the tanks, and embankments, and palaces, constructed two thousand years ago in that little-known island, were of such magnitude that the labour bestowed upon them if paid for at the current value of such work, would equal in amount the entire capital expended upon all the English railways, viz., £600,000,000, yet so it is, and but for this little handbook, I should not have heard of such things. Strange that Cook with his globe-trotting tourists has not found his way to these

marvellous cities of the dead.

Nor less strange is it that much of what passes current regarding things in Ceylon is without foundation in fact. Even the lady artist whose charming pictures adorn the walls of the Ceylon Court, bright in colouring of tropical scenery, in her description speaks of Buddhist priests, Buddhist worship and Buddhist temples, yet in fact there are no priests, no worship, and no temples! There are Buddhist mendicants, but priest would indicate some form of ritual and worship—which have no existence. At his death, Buddha passed out of existence, and though he left discourses on morality, he left no form of prayer. There is no word in the Sinhalese language for "temple,"—the natives calling the buildings in which figures of their teacher, who was never a God, are kept, "Image-houses." The Dagobas, of which a model is shown in the Court, were often of vast size—one as lofty as our own Cathedral of St. Paul's—but they are not temples, they are simply relie shrines. And when offerings of flowers, and fruit and rice are placed before Buddha's figure, these things are offered not in worship, but simply as an earnest of the votary's desire to live up to the precepts of the great teacher of the eastern world.

More than this, the little handbook tells us that it was on the coast of Ceylon that Sindbad the Sailor was wrecked, as related by him in the Arabian Nights Entertainments; that the identical Valley of Diamonds, whence he brought away much treasure, is still to be found in a particular district, amidst most romantic scenery, as rich as ever in precious stones, rubies, sapphires, amethysts, etc., of which brilliant specimens are shown by Mr. Hayward, who has himself worked in the ruby mines of Sindbad's Island.

And what are the teachings of this bright, this most interesting little Court? We learn from the exhibits and the "handbook" how the glittering things of the remote past have in this modern era of steam and electricity, given place to products and industries more likely to advantage mankind than gems and pearls and spices; and in their place, or, of greater importance, we find tea, coffee, and cocoa for the breakfast table, cinchona for the dispensary, coir for the floor, oil for the soap-maker, perfumes for the toilet, and all these things growing in importance.

It should deeply interest the citizens of the north to know, that the pioneers of the planting industry of Ceylon were Scotchmen, hailing from Banff, Aberdeen, and Crimond. The name of Robert Boyd Tytler, the father of Ceylon planters, was long a household word in the Island, and to this day the Scotch element is strong wherever planting is carried on.

If it were true that we are really a practical people, the fact should be remembered that whilst the Chinaman makes his tea by hand in the rudest fashion, the Ceylon planters employ expensive machinery for every process in tea making, the leaf never being touched by hand after gathering, and that in the purchase of this machinery, large sums of money are expended with Scotch and English firms of manufacturers.

There is yet one other lesson to be learnt by a perusal of the "Ceylon Handbook," a lesson which is curious as it is original, but then in the East we must look for paradoxes in economies as well as in the some other things. In the Court there is a model of a native mill for extracting oil from copra, the dried kernel of the coconut, a very rude affair worked by two bullocks. It works slowly but effectively, and so economically, that, although costly and powerful steam machinery for making the oil has been erected in Ceylon, the little clumsy bullock-mill holds its own, and continues to creak and grind as it creaked and ground half a century ago. In most other countries, Europeans with steam power have killed all native manufactures,

but not so here it seems. The reason is not far to seek. We are told that "when copra is scarce or dear, and oil is not to be made, the pair or bullocks are turned out to graze, costing their owner nothing; but when the large oil factory is compelled to stand idle, the interest on capital invested has to be reckoned, in addition to which an accident to the machinery may involve an outlay of some hundreds of pounds."

There is yet something to be learnt as to why, with the vast tea resources of China being poured upon the market, Ceylon should be able to enter the lists as a competitor, and carrying all before it, drive the older article clean out of its wonted place at the head of the list. It is because whilst the old article fell away in quality, the new leaf deftly prepared and richer in flavour and strength, has shown its undoubted superiority; so much so, that, though selling for more money than China tea, it is really cheaper, as it goes further in the teapot.

Whilst on this subject I have a suggestion to make for the consideration of the tea planters of Ceylon and the Chinese authorities—which it is my belief if acted upon would convert the "irony of fate" into a decided gain to all concerned. Here we have on the one hand Ceylon tea growers complaining that they cannot procure sufficient labourers to gather their crops, and on the other hand the Chinese are unable to employ all the Celestials who are thrown out of work by Ceylon competition, the same Celestials being refused work in Australia. If these round-eyed pig-tailed workmen were despatched from Australian ports to Ceylon, who can doubt their finding ready employment on the tea gardens amongst the Kandyan hills, to the mutual advantage of colonists and Chinamen?

There is yet one more curious little circumstance connected with Ceylon worth jotting down. In one of Miss Gordon Cumming's pretty pictures is a view of the celebrated Adam's Peak mountain nearly 7,000 feet high, rising majestically from the lowland about Sindbad's Valley of Diamonds; on its summit may be seen a remarkable impression reputed by devout Mahomedans to be an imprint of one foot of the Father of Mankind, who, it is said, rested there on his expulsion from Paradise. It is a gigantic print, and what is still more remarkable is, that the measurement of Eve's tomb, near Mecca, pretty nearly coincides in proportion to the size of this reputed footprint of Adam. It is not a little remarkable that the Buddhists of Ceylon believe the footprint to be that of the founder of their faith, notwithstanding that Buddha never visited the island. That however, does not trouble them much.

The reader will, I trust, acknowledge that I have made out a case for the interest attaching to the Indian island, whose Court is to be seen in the Glasgow International Exhibition. It may not be so brilliantly attractive in appearance as some other portions of the "Great Northern Show," but practically, and even artistically and historically, it stands out before most other Courts. Ceylon possesses the oldest Dagoba and the oldest tree in the world of which there is any record; and if more recommendation is needed it produces some of the finest tea in the world. If the reader doubts this statement, let him put it to the test by a visit to the pretty Ceylon Tea house in the grounds.—*Europe*, Aug. 17th.

NOTES ON PRODUCE AND FINANCE.

While the proprietors of Indian tea gardens are deliberating as to the best methods of pushing the sale of Indian tea in America with a minimum of risk to themselves, we learn that an enterprising Calcutta firm has actually started a branch in Canada, their

representative in the Dominion being a smart Sylhet planter. After three months' work, the results are very promising. Agencies have been established in various towns, and the sale of Indian tea is being rapidly and successfully pushed. If the support given to the movement for opening up a market for Indian tea in America, at the out-set, had taken the form of money instead of advice, the campaign in the United States would have been opened long since, and some tangible results would have followed.

Tea is now cultivated in the Fiji Islands. The growers there will find a ready market for it in New Zealand. There is some tea from Fiji shown by Messrs. Pringle and Crichton at the Glasgow Exhibition. It is said to be "well made, of fair liquor, with trace of Java flavour."

There is a market for Indian tea in Morocco. The demand from there at present is chiefly for Hysoa, and the tea is nearly all purchased in England. In 1887 the four chief ports imported tea to the value of £33,553, against £31,519 the previous year.

We know that "all things are not what they seem," and therefore it is not surprising that both Indian and Ceylon teas, especially the latter, are sometimes sold as pure when blends of inferior teas are mixed with them. This is very wrong, but so long as competition is keen, and dishonest practices abound, we fear this form of deceit will continue. A firm of tea dealers call attention to this fraud as follows:—Being large packers of pure Ceylon tea, we are much annoyed by the many brands now offering to the trade described as Ceylon tea, which are practically known to contain both China and Indian tea, or either one of them. We look on this as a most reprehensible matter; it is not honest trading to gull the public into thinking they are buying Ceylon tea when they are only getting somebody's blend of all sorts of teas; and this practice is adopted by some wholesale houses because the retail trade object to pure Ceylon, as they do not show enough profit.—*H. & C. Mail*, Aug. 11th.

SOAPSTONE.

The mineral soapstone, or steatite, is just now coming into prominence by reason of the valuable property it possesses as a pigment for protecting steel vessels against corrosion. This characteristic was recently referred to in our correspondence columns, and it may be interesting to briefly notice this mineral and the many uses to which it is put. Soapstone is a soft magnesian mineral found frequently in small contemporaneous veins, that traverse serpentine in all directions. It is used in the manufacture of porcelain to make the biscuit semi-transparent. It is employed in polishing marble and glass for mirrors, and in numerous other directions in the arts and manufactures. In China, soapstone is used as the material for idols, and other figures which form the household gods of the Celestials. Hence it has been termed figure-stone. Its refractory nature lends itself to the manufacture of gas-burners and for use in furnaces. It is also used in the manufacture of crucibles. Its latest application, however, is that of a paint for protecting the insides of iron and steel ships and other structures, which difficult problem it is stated to have been the means of solving. Besides the purposes to which we have already alluded, soapstone is also largely used in China for preserving structures built of sand-stone and other stones which are liable to disintegrate under atmospheric influence, and we are told that the covering of powdered soapstone in the form of paint on some obelisks in China, which were hewn out of stone liable to suffer under atmospheric influence, has been known to preserve the same intact for hundreds of years. Soapstone may therefore be said to have extraordinary qualities in withstanding atmospheric influence, which have a great deal to do with the corrosion of steel and iron, for the inside of a steamer which, although not exposed to the incessant action of salt water, like the bottom, corrodes much more quickly than the outside. Soapstone has, however, another quality which eminently adapts it as a pigment for protective paints, and that is, the extreme

fineness of its grain, as everyone who has handled this stone is aware. Ground soapstone is one of the finest materials which can be produced, and from the experiments which have been made by Messrs. Holzapfel & Co., of Quayside, Newcastle-on-Tyne, it is found that nothing takes hold of the fibre of iron and steel so easily and firmly as soapstone. It is, moreover, lighter than metallic pigments, and is said to cover a larger surface than either zinc white, red lead, or oxide of iron. The soapstone is mixed by Messrs. Holzapfel & Co. with a quick-drying varnish of great tenacity and hardness, producing a paint of great covering capacity and firmness, presenting an enamel-like surface of a bright red colour. In employing soapstone as a pigment for paint, Messrs. Holzapfel employ practically an imperishable article. Soapstone is neither affected by heat, by atmospheric influences nor by ordinary acids, and will, consequently, be a great improvement on the pigments employed in paints so far. Oxide, lead and zinc mixed with oil, turpentine, and driers are usually employed in painting the insides of vessels, as well as bridges and all iron or steel structures which are liable to corrode. All these pigments undergo a change through being exposed to the atmosphere, and are all easily dissolved in acids, and can, consequently, only last for a limited period. For steel structures, particularly, these oil paints, as a rule, do not offer sufficient adhesive properties to protect the steel against atmospheric influences effectually, on account of the smooth surface and fine grain of the steel. As a strongly adhesive, hard-setting varnish is employed in the present case, soapstone composition may be considered a distinct advance on the present method of painting. The soapstone composition will also preserve woodwork from rotting and sandstone from decay; it will render walls damp-proof, and will be found an efficient substitute for all ordinary paints.—*European Mail*.

[Soapstone paint or varnish would, apparently, be a valuable application to the wood and metal of teahouses. All the notice we can find of this mineral in Ceylon is a reference by Gygax to steatite or "French clay" of an impure nature in Saffragam. Dixon names steatite as occurring at Nuwara Eliya, but gives no hint of its quality. It may be worth while looking after. The beautiful mineral serpentine, with which it is generally associated, does not seem to have been observed in Ceylon.—*Ed.*]

PEPPER AND NUTMEGS IN THE STRAITS SETTLEMENTS.

REPORT OF CONSUL A. G. STUDER AT SINGAPORE.

Black pepper takes the lead in exports, with a vastly increased cultivation on the peninsula of Malacca, in Sumatra, Siam, Borneo, and in localities where formerly little or no pepper was planted. It is now about 85 per cent higher, \$20.50 per picul, than it was during the first years of my residence here, and not so long ago it was up to \$24. For the benefit of the masses of our people who consume more or less of this spice, I would say that, as I understand it, there is in reality no need for such high prices. With due allowance to the plantation laborers for the depreciation of their wages, paid to them in Japanese silver dollars (which allowance they do not receive, but their Chinese "towkay" pockets, when selling his crop), I call this spice, in view of its vastly increased cultivation (like three to four now to one in 1871 to 1875), very dear (not losing sight of the immense stock held by speculators) at \$14 silver per picul (133 1-3 pounds). This wild speculation in pepper originated essentially in Europe.

Pepper, unlike many articles of colonial produce, is one that will keep for a very long time without any discoverable deterioration, if not handled much. The United States' pro rata of population as compared with other countries in Europe, consumes more spices of pepper, nutmegs and mace especially, than any of them, and as to pepper, large quantities of it are used in curing meats on an extensive scale in meat-packing establishments and on the farms in

our Western States in addition to household consumption. This consumption of spices, any kind, pro rata of population by any country, is pretty well known here in the country of production among exporters after long experience, and as most of the latter have branch firms in London chiefly, it is of course well known there as well.

I feel pretty certain that if our Consuls in England, and the continent of Europe, were forbidden to grant their certificates to invoices of this spice (and any other Asiatic produce, for that matter), it would come down from its high horse pretty soon—reduce wild speculation; actual consumption more than speculation would fix the price of it—a reasonable one.

Singapore and Penang are the principal pepper exporting places in the East (Padang, in Sumatra, and Ports in Java export some), and only to satisfy speculation in Europe. I cannot see why not all of it should be exported directly to the United States instead of in this roundabout way by way of ports in England and Europe (keep the profits at home). This would give at the same time more employment to American vessels than they now have at wretched figures (with much loss of time), in view of the immense seafaring competition, steam and sail.

To give a fair idea of the importance of the pepper trade here, in the country of production, and in other countries in 1884 and 1885, I will quote the exports, first from the records of this consulate to the United States, and next from the colonial trade statistics to countries in Europe, taking Singapore first, and giving only the value not the quantity. (The average value per picul for the two years was about \$18, Mexican.)

To the United States from Singapore, as per declared exports in this consulate in 1884, \$554,099; in 1885, \$195,788 as per trade statistics.

Countries.	1884.	1885.
Austria	\$ 159,147	\$ 224,918
France	185,203	149,247
Germany	168,203	249,213
Italy	13,127	274,783
Russia	38,610	55,408
United Kingdom	1,391,566	1,593,358

As to Penang and declared exports thence to the United States, I have not at hand the figures from the consular agency for 1884 and 1885, and only for the years ending September 30, 1885 and 1886 (sent with my first part of this report), and must, therefore, quote from the colonial statistics, which, in this instance, I believe to be approximately correct, viz:

	To	1884.	1885.
United States		\$34,895	\$59,303
Austria	265
France		19,984	33,616
Germany		66,300	75,378
Italy		18,786	8,260
United Kingdom		1,209,199	1,612,352

Holland does not appear in the pepper export statistics, because, no doubt, this spice was exported from her ports in Netherlands India to Holland direct, and I have no means of knowing how much. But the figures above shown speak for themselves. I think that Italy received less pepper in 1884 than she consumed, and much more in 1885, and that some of the latter was probably shipped via Genoa to countries north of Italy. I think that Russia is credited with less than she consumed, and received supplies from British, Dutch, or Hanseatic German ports (as also the Scandinavian states, which are not mentioned at all in the statistics.) Reviewing the exports, as above, to the United States and to the United Kingdom, we find that the former, with a population of about 60,000,000 received only \$844,088.61 worth, while the United Kingdom, with about five-eighths to three-fourths of the former's population, received \$5,811,475 worth for the same period, i.e., 1884 and 1885. Now, I don't believe that one-half of that amount was consumed in the United Kingdom; but supposing it was, the question remains, "what became of the other half?" Granted that some of

the latter was re-exported to different parts of Europe, I firmly believe that the largest portion of it was sold and shipped to the United States, and this belief I base upon what I heard here from reliable sources. For the rest, our own trade statistics of imports from the United Kingdom and other parts of Europe will give decisive information in the premises.

As to white pepper, though its export is much smaller (about one-fourth of the black), because much dearer, the same remarks hold good, and perhaps, with regard to shipments from English ports to our own, were more so. I will only mention the exports of it from this colony in 1884 and 1885 to the United States and the United Kingdom, leaving out countries in Europe and quoting from the same authorities as in black pepper, viz:—

From Singapore to	1884.	1885.
United States.....	\$18,758 65	\$6,666 06
United Kingdom.....	496,068 00	492,670 00
From Penang to		
United States.....	\$3,100 00	\$17,200 00
United Kingdom.....	253,594 00	345,608 00

I would mention here that the trade statistics of Singapore as to this spice do not agree by great odds with those of this consulate based upon declared exports. This, I hardly think, is the fault of the statistician, but of the parties engaged in the said exports by not reporting in accordance with actual facts (deception in trade or strategy arising from trade jealousy among themselves).

My statistics, as above.....	\$18,758 65	\$6,666 06
Port statistics.....	17,865 00	13,644 00

Loss.....	893 65
Over.....	6,974 94

As a merchant exports here on ship to his agent in London, and instructs him to try the markets of England and the United States, to sell in that which pays the most, such discrepancies are easily accounted for, but could not occur if any consul there refused his certificate. At the same time this tends to mislead other exporters here as to actual shipments to America and England. The exports, as actually or not actually intended (a port of destination must be shown, but not under oath or solemn declaration), are reported to the port export office, and by the latter to the Chamber of Commerce, for general information in its market report. The consul has no remedy to prevent such deception, as he can only certify to the invoices presented to him. There his jurisdiction in the premises practically ends. It is only after the publication of the port statistics by the local government that he can discover and expose such deception or "differences."

They are not deceptions, in his commercial report. I have often had inquiries, "Did such a firm ship such goods by such a steamer via London to America?" but I never yet answered them in a single instance, and instead told them to find out at the export office or chamber of commerce. The trade statistics nowhere agree with my own statistics—based upon duly declared exports in this consulate—and no one, before their official publication, ever came to ask me whether they agreed.

As I have been reporting on white pepper, I would briefly say that it is produced from fully ripe berries (light crimson in color and in size about the same as an average currant), from the same tree that yields black pepper, the latter being picked green, before maturity.

NUTMEGS.

This spice, at least, experience only slight fluctuations during the last two years, being at times as low, if not a little lower, than during the first few years of my residence here, and at times a little higher, and now they are again a good normal quotations. The size of the nut has much to do with market quotations, the smaller the nut the lower the price. Between largest and smallest, if in sound condition, there is a margin of from \$15 to \$20 per picul, those of 110 to the English pound being the highest priced. Those exported from Singapore come essentially from the Moluccas (Banla Islands,

Amboyna, and even from New Guinea, where the nutmeg grows wild). Those exported from Penang are the actual product of Penang Island and immediate vicinity on the main land, where the nutmeg tree largely cultivated, with increasing tendency and does well. During my long residence here, I have by close observation and statistics discovered what may not be generally known.

Our country buys and consequently consumes more nutmegs than the whole continent of Europe taken together, and before the repeal by our Government of the 10 per cent. discriminating duty on Eastern good imported from places west of the Cape of Good Hope (referred to in my part), the colonial statistics showed that far fewer nutmegs were exported to the United Kingdom than to our country. Since the repeal of said act, the tables have turned, and judging from the same statistics and my own, which I quote below, it would seem that the British have become enormous nutmeg consumers, beating us badly. But that is not it. I have no doubt that they are shipped from there to our country, the same as pepper, tin, and other Straits produce upon consular invoice certificates obtained there, and I opine that they are a remunerative article of commerce with a margin of 15 to 20 per cent., depending on the sizes of the nuts, with speculation thrown in.

I quote from the same authorities, as in pepper, the exports of nutmegs in 1884 and 1885 from Singapore and Penang to our country and the United Kingdom, viz:

From	To United States.	To United Kingdom.
	1884.	1885.
Singapore	\$150,611 61	\$172,769 19
Penang	43,295 00	49,185 00
Total.....	193,906 61	221,954 17

There was an increase in 1885 to the United States and a decrease to the United Kingdom, but it will be found hereafter that in 1886 the reverse was the case. None of the nutmegs (or any other Straits produce, exported hence to England) were carried in American bottoms and those exported the United States were largely carried by foreign vessels, prominently British Steamers.

The nutmeg cultivation is on the increase not only at Penang but in various parts of the Straits Settlements and adjacent Malay states under British protection.—*Oil, Paint and Drug Reporter.*

INDIAN CAOUTCHOUC.

Though at the present time of writing, stocks are plentiful and visible supplies forthcoming to meet all requirements of consumers, when we reflect that the major portion of the rubber-yielding vines throughout India are located in the mountain districts, inhabited by semi-civilised tribes, utterly incapable of understanding the importance of husbanding resources, and whose cupidity, moreover, is being constantly stimulated by collectors—their lives concerned only with the present—resulting in the merciless tapping of all plants, without the slightest regard to size or age, it is time, we think, attention should be directed to the necessity of taking measures for securing steady, permanent supplies by all such as are chiefly interested in the matter.

We do not wish to pass as alarmists, but a perusal of the annual reports. Reports of those provinces of British India in which the three vines, *Ficus elastica*, *F. religiosa*, and *Clatropassora indica*, are indigenous, tend to show that a marked falling off in output of the above-named products has not tally with the amount exported, we admit, but the cause of the discrepancy is due to the fact that fresh trees, hitherto untouched, are being exploited, and though the yield from these may be expected to increase the output for a year or two, those new fields are being taxed with the same ruthless dis-

regard to future supplies as those to which the official reports are now drawing attention. Facilities for exploration in the more remote districts are being rapidly developed, and though the rubber vine country is extensive, the plants themselves are scattered about in widely distributed groups, chiefly in those valleys that still retain their primeval forests, ranging up from the level of the plains to 6,000 feet above the sea. We may mention that the home of the plants is comprised between the meridians 80° to 110° east longitude, and 22nd 30th parallels of north latitude, though extending down the mountain ranges lying between the 90th and 95th meridians, from the extreme N. E. corner of India through the Malayan peninsula to Singapore. In and around this belt the adjacent countries furnish supplies that are becoming available as our markets are pushed up to our ever-increasing border; but as no attempt is made for conserving the vines from which such supplies are obtained, the matter of exhaustion is but a question of time.

As far as the two former vines are concerned, initial propagation is accomplished by birds, who carry the seeds of the ripe figs from tree top to tree top, where they take parasitical hold, gradually enveloping the tree upon which they have been deposited in their folds until it entirely disappears, the vine assuming the character of a tree, leading the uninitiated to mistake it for one. The gum from the first two vines, when intelligently collected, is hard and firm, and loses but little weight in transit; but in Assam and Burmah, native collectors adulterate it with the juice of the banian, jac, and other similar trees that yield a milky sap. *Chavannessia*, though more abundant and a much quicker grower than either of the others, never loses its character of a creeper, but not only does not yield so prolifically, but its produce, when exposed but to moderate heat, becomes flaccid, sticky, and parts with a considerable amount of moisture; we therefore dismiss it.

Much misconception exists as to the age at which the two first-named vines can safely be tapped, such misconceptions arising from the proceedings of the Indian Forest Department, who, in forming plantations, have in view of the twofold objects of providing tall umbrageous plants for rain attractors to denuded tracts, and prohibiting tapping until the plant had attained a size and strength to yield between 300 and 400 pounds per season. But a little study of the plant (and there are thousands in and around London, at least of *Ficus elastica*), will prove that with care and moderation plants may be tapped at a very much earlier age than is generally supposed. The fact is that, given heat and moisture corresponding to a rainfall of 200 inches, *Ficus* can be bled at the end of its third year from slips, age not being so much the guide in the matter as size and development of mature wood. We have been favoured with the result of some experiments carried out in India at a spot 1,500 feet above the sea. The slips of vine were the thickness of an ordinary middle finger, and eighteen inches in height, when planted; they struck rapidly, and at the end of the third year had attained the height of six feet of matured wood, with a girth, one foot from the ground of from twelve to eighteen inches. Incisions on each side about a foot below the green shoots were made, and each plant yielded four pounds of clean gum the first season, an additional two pounds being taken each succeeding year up to the eight; the deductions from which are, that as an acre planted eight feet by eight feet would contain 676 plants, the yield up to the eighteenth year, when the plants could be tapped from the roots and give its 300 to 400 pounds annually, would be as under:—

3rd year @ 4 pounds per tree =	2,700 lb. per acre.
4th " " 6 " " "	4,000 " "
5th " " 8 " " "	5,300 " "
10th " " 18 " " "	11,900 " "

and so on. *Ficus* will grow on flat land, and with little training can be kept from straggling, and though it might be necessary to thin out the plantation, the yield would not be affected, inasmuch as the necessity for thinning out being begotten of the development of plants, they would have attained sufficient robustness

to make good any deficiency that might be expected to arise from reduction of numbers.

Urceola needs support, and might, as has been suggested, be trained on rocks or allowed to run riot amid the forest though from its more straggling nature it would be difficult to estimate correctly its yield per plant per acre.

The subjoined figures, therefore, are drawn out on the assumption that *Ficus* is the variety to be dealt with, and the expenses spread over three years.

ESSIMATE FOR 100 ACRE PLANTATION OF

<i>Ficus Elastica,</i>	
Clearing at £3 per acre	... £ 300
67,600 slips at 6d.	... 1,700
Planting	... 100
General cultivation	... 9,000
Tapping and gathering	... 3,380
Freight on 120 tons	... 300
Building	... 500
Management, at £ 400	... 1,200
Incidental	... 520
	£ 17,000
PER CONTRA.	
270,400 lb. of gum at 2s.	... £ 27,000
Balance	... 10,000
	£ 17,000

FOURTH YEAR.

Tapping and gathering	... 3,380
Freight on 180 tons	... 450
Management	... 400
Incidental	... 770
	£ 8,000

PER CONTRA.	
400,000 lb. gum, at 2s.	... £ 40,000
Balance	... 32,000
	£ 8,000

Our readers can elaborate these calculations, which will show the advantages of growing direct for their own requirements.—O. W.—*Indiarubber and Gutta-percha Journal*.

[The above article is a surprise to us, as *Ficus elastica* in Ceylon is a large tree and never a parasite or vine. If the account given of its performances can be trusted, it is certainly the plant to cultivate for indiarubber.—ED.]

DAFFODILS.—To show what manuring will do on light soil, Mr. Jenkins (Collins, Gabriel & Co.) has just shown us bulbs of the Tenby Daffodil weighing about a quarter of an ounce, and others from the same original sample increased to 1½ ounce; and parent bulbs of Emperor with four and five off-sets weighing collectively 12¼ ounces. The bulbs are not merely large but of excellent substance and quality. The bulbs in question are grown in light soil to which a good proportion of dried cow-manure is added.—*Gardeners' Chronicle*.

BURNT CEYLON TEAS.—A Ceylon planter now at home, writing about the end of July, says:—"When in Glasgow I tasted some samples of Ceylon teas distinctly burnt. The tea-taster, an experienced man, but otherwise unconnected with Ceylon, told me that during the past twelve months several Ceylon teas had been more or less burnt. General complaint is made of the poor keeping qualities of Ceylon teas; they 'go off' so quickly, and it is suggested that too rapid firing may be the cause. The effect of getting over this difficulty, i.e. of putting our teas on a par with Indian in 'keeping' qualities, would be to add pence per lb. to their value. I have been told that Mr. Davidson, the Sirocco man, refires all his teas in Belfast and increases the value 2d per lb."

TRINIDAD BOTANIC GARDENS.—Mr. Hart's report for 1887 gives a summary of the history and present condition of the garden, its library, and offices. Such a report is specially valuable at home, while the practical details as to the cultivation and preparation of various fibres, food plants, drugs, &c. must be of great importance in the colony itself. The meteorological data also will be of use to home cultivators. The report is in every way creditable to the Superintendent, and affords promise of great future benefit to the colony, as well as to botany and horticulture. In connection with Trinidad we may also mention the publication of a *Bulletin*, of which No. 5 is devoted to Coffee, the report being based upon a treatise of Mr. W. Sabonadière, of Ceylon. Trinidad has the means of producing Coffee equal to that grown in any other part of the world. —*Gardeners' Chronicle*.

ALOE FIBRE has become an important article of export from Mauritius, as the following table will show:—

COMPARATIVE STATEMENT OF SHIPMENTS
From 1st August 1885, 1886 and 1887 to 26th June 1886, 1887 and 1888 respectively.

	1885-86	1886-87	1887-88
	kilos	kilos	kilos
United Kingdom	721,540	1,359,610	1,407,472
France.....	41,500	190,824	610,218
Australasia.....	12,000	4,500	38,000

Surely something might be done with the product in Ceylon?

NOTES FROM PEERMAAD.—In spite of the vile weather, our Coffee is flourishing and fair average crops will be obtained. There is a slight sensation of 'Leaf' here and there, but not enough to cause anxiety. I have just returned from a round of visits, and have seen most of the Tea and Coffee in the District. A small clearing under partial shade, (too much partial and not enough shade to please me) was looking lovely, but then you know, Mr. Editor, that shade coffee is a hobby of mine; and I ride him and love to ride him persistently and it won't be my fault if a good many more acres are not under perfectly partial shade before very long. *Mais nous verrons* as my esteemed friend *Mons. Jean Crapaud* would remark. Tea is flourishing and flushing, flowery Pekoe fluctuating, but factories are full—fortunate foreigners, as our esteemed laborers consider their benevolent masters. But they neither understand financing nor—well my F's are high exalted. Alliteration!—*Con. Madras Times*, Aug. 28th.

BOTANY OF SOCOTRA.—Professor Balfour's detailed account of the botany of Socotra has been published by the Royal Society of Edinburgh, and forms a bulky quarto of 146 pages and 100 lithographed plates. The preface contains a brief history and proceedings of the expedition, which lasted for forty-eight days only, but which was soon followed up by a second exploration by Dr. Roebeck and Dr. Schweinfurth and others. The plants collected by Dr. Schweinfurth on this occasion were generously made over to Professor Balfour for use in the present work. The introductory chapter contains an account of the geographical and geological features of the island. The low ground has approximately the same flora as that of the Sahara and Punjab. In the valleys in the higher ground tropical vegetation occurs. The higher altitudes have a strange and peculiar vegetation of arborescent Composites, aromatic *Ellichrysums*, and other quaint types. The total number of plants is given at 524, of which 573 are flowering plants, no fewer than 208 being endemic. The most showy plants are *Adenium multiflorum*, *Begonia socotrana*, now well known in gardens, and made already the starting point of various hybrids; *Cinnam Balfourii*, *Exacium coruleum*, &c. A *Cucurbitaceous* tree, *Dendrocyon socotrana* is one of the wonders of the island; *Cocculus Balfourii* is also an erect shrub

instead of a loose climber, like most of its congeners. *Punica protopunica* is remarkable for having only one row of carpels, and as being the wild representative of the common Pomegranate. The dragon's blood used in varnish making is the produce of *Draconia cinnabari*, nearly allied to *D. draco*. *Frankincense* and myrrh are also found, while *socotrine aloes* is yielded by *Aloe Perryi*, a species of *Buxus*. *B. Hildebrandi* may prove important as a source of Boxwood. The whole work is a striking proof of what may be accomplished by well-directed energy and instructed zeal in the course of a few weeks' exploration. The exploration and its record, as here given, are alike creditable to British science and to its representative, Professor Balfour. —*Gardeners' Chronicle*.

THE PLANTERS' CEYLON TEA STORES, GLASGOW.—Judging from the numbers who flock to the Tea House of the Ceylon Planters' Association in the International Exhibition of Glasgow, pure Ceylon tea seems to be generally appreciated, and, in order that the public may be supplied with teas similar to those now being dispensed in the Tea House, members of the Planters' Association have opened the Planters' Ceylon Tea Stores at 43 Union Street, where teas are sold in the packet and can be tasted in the cup. The front shop is neatly appointed for the packing and distribution of the tea, which is carefully weighed by Cinghalese and Tamils, specially engaged. The saloon in the rear is decorated in an Oriental fashion, the walls being lined with the orthodox yellow Buddhist cloth and dado of Oriental matting, with most interesting photographs which show the processes of the growth and manufacture of tea from the seed to despatching the chest from Colombo, the principal port of Ceylon. The objects of the Ceylon Planters' Tea Stores Company are purely Ceylon, and they do not mix their tea with Indian, China, or other cheap and inferior tea; but, in order to procure a strong tea having a fine flavour, they blend teas grown at various altitudes, as tea grown in the low country gives strength of infusion, and that of higher altitudes flavour and aroma. A great advantage of purchasing tea in these Stores, is, that it can be sampled and tasted in the cup, and anyone wishing to purchase tea direct from the chest can have a cup of that tea infused in a few minutes. All information regarding the colony of Ceylon, and, in particular, tea cultivation and manufacture, is given gratis by Mr. Roger or Mr. Bett, who represent the Company in Scotland. —*Dunoon Observer*, Aug. 8th.

[No. 4.]

THE CULTIVATION OF NEW PRODUCTS:
THROUGH MATALE EAST AND LAGGALA:
ANNATTO DYE-PLANT AND ARECANUT CULTIVATION—
TWENTY YEARS AGO IN MATALE EAST.*(Continued from page 210.)*

Crystal Hill estate, close to, that is four miles out of, the town of Matale, is one of the most interesting places to the visitor that we know of in the country. We commend it to the notice of the Governor, the Lieut.-Governor, and the Director of the Botanic Gardens. Should His Excellency or His Honor—one or both—visit the approaching Matale Exhibition, the Assistant Agent could scarcely do better than drive his distinguished guests up to Crystal Hill in order to show at a glance an epitome of the intelligent efforts made by European planters in his district, who have passed through the coffee crisis, to cultivate new products other than the one (tea) now universally run after. To Mr. A. G. K. Borron belongs the credit of planting up a comparatively extensive and valuable plantation without a single tea or cinchona, any more than a coffee bush. We find on Crystal Hill a good deal of cacao, some pepper and a variety of experimental products; but the chief features are two products not often seen on a European's plantation in Ceylon. On Crystal Hill, there is a continuous expanse of annatto or arnotto, the famous dye-plant, the handsome leaves of the big bushes, almost trees, contrasting with the bunches of rose-coloured flowers and still more with the reddish-brown, heart-shaped fruit which predominated on the occasion of our visit, so that away up the hillsides there was a show of colour never before equalled in our experience in Ceylon. A cacao "walk" with rich ripe pods no doubt presents a splendid blaze of dark red; but the pods as a rule are hidden under the luxuriant green vegetation, whereas in the case of the arnotto the fruit is borne up aloft and in such clusters as overpower the rest of the bush, and leave the impression of one grand expanse of colour. Single bushes of arnotto in flower and fruit are a familiar sight in Colombo gardens, and from these some idea can be formed—though a very inadequate one—of what a whole hillside covered at regular intervals with such bushes in grand luxuriance and full crop, should look like. To acquaint our readers more clearly with the plant we speak of, we quote from the "Dictionary of Botany" as follows:—

"BIXA. A name applied by the Indians of Darien to the plant producing the Arnotta of commerce, and adopted by botanists for the genus *Flacourtiaceæ*, to which it belongs. There are four species known, all of them natives of tropical America, and forming small trees, with entire leaves marked with numerous pellucid dots. Their flowers are produced in large bunches at the ends of the young branches; and have a calyx consisting of five sepals, which alternate with five wart-like swellings on the stalk, and likewise with the five petals; numerous long free stamens, and a long style terminating in a two-lobed stigma. Their fruit has a dry prickly husk, which splits into two pieces, each bearing numerous seeds attached in a perpendicular row on their inside.

"*B. Orellana* is a small tree growing about twenty or thirty feet high, having broad heart-shaped pointed leaves, and bunches of rose-coloured flowers. Its fruit is heart-shaped, rather more than an inch long, of a reddish-brown colour, and covered with stiff prickles. The seeds have a thin coating of red waxy pulp, which forms the substance called Arnotta; it is separated by throwing the freshly-gathered seeds into a tub of water, and stirring them until the red matter is detached, when it is strained off and evaporated to the consistency of putty. In this state it is made up into rolls and wrapped in leaves, and is then known as flag or roll arnotta; but when more thoroughly dried, it is made into cakes and called cake arnotta. In South America arnotta is greatly used by the Caribs and other tribes of Indians for painting their bodies; paint being almost their only article of clothing. In this country it is used for colouring cheese, inferior chocolates, &c.; and by the Dutch for colouring butter. It is also used by the silk-dyers; and by varnish-makers for imparting a rich orange tint to some kind of varnish."

The crop of bright red seed from the pods, which are opened by women and children in the field, is not a bulky one, nor is the value large in proportion to weight as compared with other and more popular products. But Mr. Borron (with his intelligent Superintendent, Mr. Van Starrex) has given special attention to the preparation and finds encouragement to go on; although one cannot help thinking that as in the case of "croton oil seed," a few more plantations of the size of Crystal Hill would effectually swamp the arnotto market with their crops. Meantime the cultivation on Crystal Hill is a picture in itself and well-worthy of official notice. The total export from Ceylon in 1887 of "arnotto seed" is given in our Handbook at 349½ cwt. and of Bixa Dye 17½ cwt. From French Guiana, the annual exports are said to equal 10,000 cwt.; from Guadeloupe 15,000 cwt. and from Jamaica 3,000 cwt.

The other feature on Crystal Hill which at once arrests attention are the rows of well-grown araca-palms, some of them 5 to 9 years old, graceful in form,

vigorous in vegetation though not yet bearing and contrasting well with the arnotto which is not at all affected—unless it be beneficially—by their shade. Mr. Borrón returns in the Directory, we find:—50 acres cacao, 30 acres arecanut, and 160 acres arnotto on Crystal Hill; but he is extending both arecas and arnotto in new fields. Some of his native neighbours are copying his example, and in Laggala there are also several clearings of arnotto, the crop having an advantage in its small bulk for transport over long distance. As regards arecas, the only fear in the neighbourhood of Matale is of the rainfall not being sufficient, the home *par excellence* of the areca in Ceylon being the wet south-western slopes of the hills in the Kegalla and Awisawella districts. But very probably careful cultivation may more than atone for any such deficiency.

Along the Matale-Rattota road there is every sign of comparative comfort if not prosperity among the natives. The rice-fields on the river valley from Elkaduwa downwards and away towards North Matale are specially luxuriant and after leaving Rattota village—where the school located in the old Baptist Mission Chapel is a prominent object—I have pointed to me the location of the 700 acres of land applied for by the Tobacco Syndicate, undulating chena not far from the river, at present waste and likely to remain on account of drought so far as tea is concerned, but very possibly well fitted for tobacco. However, there is no sign of this block being taken up this year and perhaps Mr. Ingleton's principals are satisfied for the present with the rich fields planted on their account in the Kurunegala district.

I ought to have referred in passing to the Suduganga property which like so many old places is, under tea, taking a new lease of life. Here I first spent an evening twenty years ago with Mr. Peter Moir when he was hard at work renovating a property which in its day, had borne some of the heaviest coffee crops known in the island. One of the biggest was, however, almost completely ruined through inability to overtake its preparation and despatch during persistently wet weather, all the cherry ripening at once. So grievous and absolute was the loss that the young planter then in charge—this must have been early in the "fifties,"—began burying the rotting beans in holes in the estate, the coolies being hard at work in this fashion when the proprietor turned up: tableau! Finally, a good deal of the crop when it reached London had to be thrown into the Thames as unfit for food,—so that the biggest crop Suduganga ever gave left the proprietors less profit than the succeeding very short one. Next, coming into Mr. Borrón's hands, we all remember his young clearing with 20 to 25 cwt. of coffee per acre on the trees, and how visitors from the higher districts flocked to see the sight, among the rest Mr. Phipson from Maskeliya who negotiated the purchase for the present proprietors at what was deemed a fancy price, but which in reality did not leave much over to the seller. Higher up on our route, I might fix on Opalgalla as the crack estate of the Northern division of Matale East in the days of old. Here I saw that model Manager, Mr. R. J. Chippindall, when the model estate was in its prime in '69—a cartroad made especially for its use (and that of the Gammadua group) from Rattota, while a plantation better supplied with every facility for economising labour, expediting work, saving soil and applying manure did not exist in Ceylon. Mr. George Wall gave much of his attention to Matale East, and probably no one outside the district made so many weary journeys over and along both sides of this steep Laggala rang

in years long gone bye as this well-known leader among merchants and planters. On Opalgalla hill the foundation of a small fort can be traced, the construction of which vague tradition as usual ascribes to "Yakkas," the alleged architects of so many ruins in Ceylon. But my route lay in the other direction by bridlepath up the steep ascent to Dangkande and Laggala, a route which has been used by the Sinhalese as the means of communication between the two sides of the country from a date, I suppose, long anterior to the advent of planters in the country and which I fancy has scarcely if at all been improved since it was passed over by Major Forbes perhaps sixty years ago. The wonder is that so little life has been lost on these Matale East breakneck, rocky paths and dangerous fords. One young friend, Willie Allen, just as he had attained to the top of his ambition as a pukka full-blown Manager, lost his life riding home from Matale in crossing a swollen stream—swept from his horse and drowned—but that was farther to the west, on the river below Elgalla. The Dangkande path, however, is not without its dangers as Major Forbes found in one of his official tours when he records:—

"Nearly clear of the forests of Dankande, and already looking down on the Matale valley, we were congratulating ourselves that the horses had passed without accident: when we came to a narrow platform, supported along the face of a sloping rock, my pony passed without hesitation; but, in the middle, Mr. S———'s horse, feeling the spurs bending, got frightened, started, and fell. Hearing the clattering of his hoofs as he rolled over and over, we expected to find the animal killed or disabled; but, on clearing a path obliquely down to the bottom of the rock, we perceived the horse quietly grazing and perfectly unhurt; so effectually had the thick brushwood, matted with creeping-plants, which spread over the lower part of the rock, broken the force of his rolling fall."

The blessing that 10 or 15 miles of cart road would confer on the Laggala district cannot be overestimated; and of this we shall have numerous illustrations afforded as we pass on.

CEYLON UPCOUNTRY PLANTING REPORT.

"FERGUSON'S CEYLON HANDBOOK AND DIRECTORY": THE BEGINNING, MIDDLE AND END OF THE BIG VOLUME.

3rd September 1888.

There are some few things which it is impossible to conceive our colony without, and *Ferguson's Handbook and Directory* is especially one of such. Before it is issued, it is one of the mild excitements of Ceylon life looking forward to its appearance, and when after many delays it has reached the hands of its subscribers, it is as good as a gossip with the best-informed men in the country as to "who is who" and "what is what" just to go lazily through its pages. But the book is a very great deal more than this; for, as a standard work of reference in regard to all things related or relating to Ceylon, where can you find its equal? If a man is in a fix about anything; if for instance he wants to know the amount of rupees which the Inspector-General of Police absorbs in return for those services, and that personal knowledge of everybody so pathetically referred to at the indignation meeting by his ex-inspector; if he wants the height of Mutton-Button, the amount of the arrack and toddy farms, the strength of the Salvation Army in the island, or ten thousand and ten as diversified things, where can his wants be better supplied, or his enquiries more fully satisfied, than in the *Handbook and Directory*?

What a queer position the island would be in, through the working of some occult cause, every existing copy of the *Directory* were to disappear, and we were left without this *vade-mecum* to refer to? We all depend upon it a great deal more than we think, and if a reference to its pages results in a barren return, the compilers and publishers are only too pleased to learn where the work has failed so as to meet the want in future volumes. The new volume which is just being issued is as sturdy as the facts it holds and is divided into three parts:—The Planting and Agricultural Review, the Handbook and Compendium of useful knowledge, and the Directories.

In the first division of the work, all the Ceylon products, major and minor, have due attention paid to them. It is a history of the past as well as of the present, and it is pleasing to notice how well the information is brought up to date. The articles on Tea and Cinchona are especially full. They contain a store of information, which it would be hard to get elsewhere, and to which planters and others may want to refer from time to time. As to the statistics, well if the *Directory* is not strong on that point, it is strong nowhere. Men fond of figures—I am not one of them—here can revel to their heart's content, and having gone away saturated, may return again and again for renewed feasting. If the Planting and Agricultural Review were published in a small volume by itself, it would make a valuable and handy book, and might find a public outside of the island, which is not likely to be reached through the dearer *Directory*.

In the middle portion of the work, the "Handbook and Compendium of Useful Information," the labour of the compiler and the statistician here assumes its fullest proportions, and this part is perhaps the most valuable to the local public, or the outsider who desires to be fully informed in reference to Ceylon affairs. It is not like the directories. In the nature of things, some names are out of date in that section before the book has even seen the light. Their owners may be dead; have changed their residence, or occupation; or it may be, left the country; so rapidly does the directory public of Ceylon alter in a short space of time. But what has been written in the "Compendium" has an enduring interest for almost every class of the community. It is difficult to dip into any part of it, without having the horizon of your knowledge enlarged, and the vague information which floats about in the minds of many is there crystallized and condensed into handy figures. The ground it covers is co-extensive with the whole interests of the colony; and the fulness and completeness of the information offered, has but to be studied to be properly appreciated.

As to the "Directories," they are as full as ever, and the many subdivisions make a special reference easy enough. The details given in connection with the different estates are replete with interest, and the tabulated information gathered therefrom, is the most accurate source one can go to who desires to learn aught that is trustworthy regarding the position of the agricultural interests of the colony. The labour entailed in getting together this widely scattered knowledge must have been very considerable, and called for patience, tact, and perseverance.

Of course a voluminous work of this kind is hardly to be expected to be free from misprints and other minor mistakes. But the wonder is not that they are there, but that their numbers should be so few.

The editors and compilers of *Ferguson's Handbook and Directory, 1887-8*, are entitled to feel con-

able pride in their work, and the general public may be congratulated that they have such a book to refer to. It is a worthy successor to the Directories which in former years have been edited by the same hands and issued from the same press, and in saying so I feel that a higher compliment to the volume can hardly be paid.

PEPPERCORN.

As "Peppercorn" has started the ball, we are tempted to dispose of a few more complimentary references lying by us in regard to the big volume.

His Excellency the Governor, in acknowledging his copy, was good enough to express the opinion after a first glance, that it was fuller in information than any of its predecessors.

The Lieut. Governor and Colonial Secretary has very considerably favoured us with the following communication in acknowledgement of an early copy:—

4th August 1888.

Dear Sir,—I thank you for the advance copy of your "Handbook and Directory for 1887-88." I can well appreciate the amount of labour and time it has cost you, and I congratulate you on having reached its publication. My official necessities and daily search for information in my strangeness to everything here perhaps constitute me a good judge of the practical value and use of your publication, and I rarely turn to it for assistance without success. I can pay it no better tribute than in saying so. The earlier issue was the first book on Ceylon which I obtained at home on my appointment here. I shall be glad to be enrolled as a registered subscriber to the publication, not so much in a commercial spirit as in the desire to record my appreciation of a useful and most meritorious public service, and I shall always be pleased if I can in any way in my official capacity or personally assist you in further prosecuting the work.—Yours faithfully,
E. NOEL WALKER.

Other gentlemen who received early copies—old and leading members of the planting community—write as follows:—

"Your Handbook and Directory for 1887-88 keeps up its reputation for thoroughness and indispensability, and, if it be possible, exceeds its predecessors in usefulness and finish. It keeps its possessor up to and abreast with the times; and, judging from its bulk and index, omits absolutely nothing worth recording. On the contrary, ALL Ceylon matters,—political, legal, religious, agricultural, sanitary, &c., &c.,—are exhaustively dealt with; while the Directories of properties and institutions, and of persons—everybody who is anybody being included with name and address,—make it the only reliable guide to find 'who's who,' and WHERE and WHAT 'who' is."

"Many thanks for new Directory just received. Ceylon is certainly the first Crown Colony yet, and in spite of our losses in coffee we may yet hope for much good. I take your new Directory as *aspiciam melioris ari*."

Kandy, 25th August 1888.

Messrs. A. M. & J. Ferguson, *Ceylon Observer*, Colombo.

Sirs,—I duly received the copy of your valuable Handbook and Directory, and at the recent general meeting of the Association, the Chairman, in inviting special attention to it moved that an expression of the cordial thanks of the Association be conveyed to you for the volume. On behalf of the Planters' Association I beg to transmit this acknowledgment of your courtesy and need hardly add that motion was carried unanimously.—I am, sirs, yours faithfully.

A. PHILIP, Secy.

On the other hand it was not to be expected in a voluminous work dealing with so great a

variety of topics, perfection could possibly be attained. Our columns bear witness to the objections raised about certain cinchona statistics. In addition, a number of corrections have reached us on different portions of the Directory: most of which will be embodied in Errata for the rest of our edition. The error we most regret is giving "Deltotta" in place of "Hewahetta" as the post station for Rookwood, Hope, Katukelle, Amunamulla, Columbia and Eastland estates. This should be noted both in the Estates and General directory by readers.

On page 293 of our Handbook, it is stated that the N.-G. Lloyd's Steam Co. have a subsidy of £10,000 per mile, which is a mistake, as the total paid is only £220,000, and this is coupled with onerous conditions as to reductions in passage rates to civil servants and military. Of course the German Government pays nothing for the carrying of mails.

At page 536 the market price of Lanka Company's shares is given by mistake at 10s, whereas they have never been below £5. The capital of Mariawatte, Dunedin Co. is given by mistake at R75,000 in place of £75,000.

MAZAWATTEE TEAS AGAIN.

[I herewith enclose you a circular that was sent out to me from my sister, to whom it had been sent. It speaks for itself as to what is doing in provincial towns in Scotland as well as England with the name of Ceylon.—*Cor.*]

High Street, N. B., July 1888.

Madam,—I have made arrangements for the sale of the celebrated Mazawattee Ceylon teas, which are now generally acknowledged to be the finest in the world.

Connoisseurs and those who really appreciate fine teas, can scarcely realize the revolution caused by the successful cultivation of tea in Ceylon.

To find a parallel in quality for the finest blends of Ceylon teas, one would have to recall the delicious China teas of thirty years ago.

The prices are 3s, 2s 6d and 2s per lb., and they are now packed in any size of packages. I shall be pleased to send sample $\frac{1}{2}$ lb packets on receipt of stamps or order.—I am, Madam, yours obediently,

COCONUT PLANTING IN THE WESTERN PROVINCE.

FIBRE-REFUSE—MULCHING—SALT—HEAVY BEARING COCONUT PALMS—WEATHER.

SIYANE KORALE, Aug. 1888.

The extract you recently gave from the *Planters' Monthly*, I believe it was, on the value of fibre-refuse as a top-dressing affords evidence from an independent and unbiased source, of the soundness of the position I always held against Messrs. Symons and Shand. I wonder whether it is instinct or intelligence, surely the latter, which leads the natives in the Cinnamon Gardens to largely use fibre-refuse to improve the texture and mechanical condition of their hungry soils. If the mill-owners in Colombo who find this stuff a nuisance were to press it into conveniently sized bales, I am sure it will be largely used in coconut cultivation.

Mulching with maana grass was practised to some extent on estates adjoining patanas in the hey-day of the coffee enterprise. In damp situations it was supposed to warm the soil, and in low-lying districts to afford the soil the needful shade, wash was entirely stopped by it, and weeding became unnecessary where it was practised. Finally when decayed if it was worked into the soil with lime, it proved a very acceptable top-dressing. The objection that mulching draws the roots to the surface is unfounded for what is drawn to the surface are the root-hairs

or feeding rootlets, and these are produced as occasion requires. Cinnamon planters unconsciously practise mulching round their peeling sheds with the scrapings, which are the epidermis or outer corky covering of the bark. This is possibly as poor a substance* (as one can come across manurially), yet the bushes that are so treated seem to grow perceptibly and produce fine, succulent, well-grown sticks that yield fine bark. Why is this, but in gratitude for the protection their roots receive from a substance which is as retentive of moisture and as impervious to the rays of the sun as fibre dust itself.

In the *Tropical Agriculturist* for June, an Indian planter grows enthusiastic over the virtues of salt agriculturally. Chlorine plays a very unimportant part in the economy of nature and is placed last in the order of importance of the mineral constituents of plants. Yet, as common salt, it is said to occur pretty freely in vegetation in the earlier periods of its growth. Salt though not of much value as a direct food of plants is valuable as a "digester" of food, for it has the property of rendering available the valuable plant food contained in the soil. Whenever its use has increased the crop of cereals, the increase is attributed more to the property it has of stiffening straws and enabling them to bear the weight of their ears and not allowing them to lie prone and be destroyed, rather than to having acted directly as a manure.† Its chief value, however, lies in its affinity for moisture. I have so far spoken of the value of salt generally, but in coconut cultivation salt has an especial value, for it is found in the mineral constituents of the tree from the fronds down to the roots. The salt-saturated soil of the sea-shore is the first and natural home of the coconut tree, at least as far as this island is concerned. An excess of salt seems to act beneficially rather than otherwise from its earliest stages of growth. If plants before being put out are steeped in salt water, they withstand the ravages of white-ants and receive a favourable start as well. If a handful of salt be sprinkled in the holes at planting, not only are the ravages of white-ants averted, but the plants are enabled to pull through a dry season as well.

This affinity for moisture ought to render salt invaluable in coconut cultivation, especially in localities severely affected by drought. No better and simpler illustration of the affinity of salt for moisture can be obtained than by exposing in the open a sack used for salt. The sun will bleach it and render it perfectly dry, while in the morning it will be found reeking with the moisture it has attracted from the atmosphere. Will not some of the intelligent and spirited planters and proprietors in the Mahaoya Valley, also known as the Happy Valley, experiment with salt on an acre or two of their lands most affected by drought, and give it a crucial test, now that its properties have been prominently brought under notice. It can be applied broadcast, after the soil has been turned with plough or matmotie, with the last rains of the N.-E. monsoon. No fear need be entertained that the salt will be washed out of the soil, for clays have the valuable property of retaining the too soluble salts. To give the experiment a fair test, I suppose it will be necessary to apply salt liberally, say half a ton the acre. At 75 lb. to the bushel this will be about 15 bushels to the acre. It is not too much to expect Government to aid in the experiment by supplying the salt at the price it is supplied for export viz. R2.25 per ton. The cost per acre will then not much exceed R10, say R15 inclusive of everything, and that sum is not beyond the means of the happy proprietors of this fruitful valley. Government ought to encourage the free use of salt by supplying it for agricultural purposes at

* We have watched the heaps of scrapings at Mr. De Soysa's store pass into mould which could not be distinguished from good soil.—Ed.

† This is curious, if reliable. We have always understood the stiffness of straw, to depend on the amount of soluble silicious matter in the soil. Probably the action of salt renders quartz soluble.—Ed.

about double of what it costs them. Surely the chemists in our midst could suggest something to mix with it to render it unfit for food. I would suggest pou-drette as this will encourage a new industry, otherwise some offensive smelling stuff like steamed bones or superphosphate of lime. I lately had occasion to use the former and could with difficulty induce my men to even carry the bags containing it. I doubt whether I convinced them effectually that the offensive smelling stuff was harmless bones, even though I handled it freely. The mixture could be made under the supervision of a Government official and at the expense of the buyer, with the stuff for mixing supplied by him.

On every estate there is a certain proportion of trees that seem unable to support their bunches and branches. The reason for this has so far as I am aware been only laziness. They are supposed to be the result of immature seed nuts or seed nuts from immature trees. Whatever the cause for them, they present an unsightly appearance, and it should be the aim of planters to cure them if possible of this pernicious habit. I have before said that to salt is attributed the property of being able to stiffen the straw of wheat. Is it unreasonable to suppose it will possess the same stiffening properties when applied to coconuts and will enable the trees I have referred to, to carry their fronds at the proper angle, and thus support the bunches that look for support to them? Any way the experiment is worth a trial.

This has been an extraordinary July with only 1.64 inch of rain. Following as it does an exceptionally mild "burst," the effect on the cinnamon stools I transplanted is not of the pleasantest. Even what I planted towards the latter end of May, before the rains began are evidently succumbing to the combined effects of a fierce sun and a scorching wind. But this has been a glorious peeling season. I never knew cinnamon being cut cleaner. Hardly a coarse stick went to waste, when in previous years they were cut and thrown away as unpeelable and cumbering the bushes. Since the middle of the month we have an abortive bud, now called "flush" I see, to complete I suppose the similarity you and a correspondent of yours maintained exists in the treatment of the cinnamon and tea bush. The bud is rendered abortive from want of rain, but in spite of the bud it peels very fairly with me.

ROUGHING IT IN AUSTRALASIA.

An ex-Travancore coffee planter, who passed through Colombo for Fiji some eight or nine years ago, in writing to us from Northern Queensland by last mail says:—

I have been in Queensland ever since leaving Fiji and have had a very fair all round colonial experience I can tell you. I was for a long time assisting in pioneering in the north among the Myall blacks and the alligators. It was poor fare, poor pay, and generally a poor life, though it had its redeeming features. I had intentions once of getting a selection suitable for sugar, coffee or other tropical products, but after a time I decided that the game was not worth the candle. I was for a long time employed by surveyors north and west, and actually studied the business up so that I was master of most of their formulae. I could not, however, pass as a surveyor without serving an indenture, and this I was too old to do. I therefore gave that life up. I once worked alongside of a Ceylon planter in the bush. I forget his name just now. He got drunk one day when we were camped near a publichouse, and we had to leave him behind, and I have neither seen nor heard of him since. For the past three years I have been employed in clerical work chiefly in Brisbane upon a microscopic salary, but it was more congenial than the bush, as I could choose my associates and I had good opportunities for study.

SAMPLES OF TEA FROM AMERICA.

Five samples of tea have been sent to us by Mr. McCombie Murray to illustrate the descriptions appended in America. For the benefit of local plan-

ters looking to the United States for a market, Messrs. Somerville & Co. have been good enough to report on these samples as follows:—

Sample No.	Description.	Present London value.	Colombo Equivalent to exch. 1s 4½d. R. c.
1	Oolong	1s 7d to 1s 8d	1 06 a
2	Do.	1s 5d to 1s 6d	0 94 b
3	Do.	1s 3d to 1s 4d	0 82 c
4	Hyson	1s 10d to 2s	1 27 d
5	Gunpowder	1s 3d to 1s 4d	0 82 c

REMARKS.

a Leaf blackish, greyish, rather irregular twisted. Liqueur sharp flavory, good quality; pale straw colour.

b Leaf same as above. Liqueur pale straw colour; little thin; fair flavor and quality.

c Leaf greyish, blackish, even choppy, few ends. Liqueur dark, fair strength.

d Leaf even well twisted; good even colour.

Liqueur pale straw colour; pungent, flavory, good quality.

e Leaf even shotty appearance.

Liqueur pale straw colour; fresh, pungent.

pp. SOMERVILLE & Co.,

Sept. 6th. A. H. THOMPSON.

It is impossible to give a correct value for these teas, as there are no standards to work by and no market for this class of tea locally. pp. S. & Co. A. H. T.

The samples can be seen at the Observer office by anyone interested.

PLANTING NOTES.

Mr. G. Klomp from Amsterdam arrived in the "Will o' the Wisp" on the 24th July. Mr. Klomp intends to reside some few weeks, (or months if necessary) in North Borneo and prospect for tobacco land.

Mr. S. P. J. Netscher arrived at Kudat by the S.S. "Paknam" on the 15th July, to open the land originally conceded to Mr. H. van Son in the name of the Marudu Bay Company. Mr. Netscher brought a steam launch in tow from Singapore which will be a great boon to the planters at that end of Marudu Bay. We hear that Count Geloos also intends to obtain a launch.

Messrs. Jan C. Teves and A. P. B. van Delden, left Sandakan in the S. S. "Paknam" on the 17th July. Mr. Teves has acquired some concessions of Land for himself and his friends and, in addition, Mr. Teves has bought a Suburban lot. We hope the time will come when he will take up his residency in Sandakan. Mr. van Delden has obtained a concession of land on the Kinabatangan.

Mr. P. Persyn was a passenger from Kudat to Sandakan in the S. S. "Paknam," arriving on the 16th July, and left the next morning for the Belacking River to inspect a concession of land applied for by Count Geloos. Mr. Persyn informs us that his crop of Tobacco from Ranow estate of 442 piculs (not Bales as printed by us in July number) was obtained from 42 fields, each field being 54,000 square feet, or about 1¼ acre.

As the Tobacco only left Singapore in July it is not likely it will be auctioned before October and the price to be obtained is looked forward to with great interest.

Alterations in Land Rules are never satisfactory to all the public and just now a good deal of critical comment is made upon the regulation just issued, viz. that no one interest shall receive more than 5,000 acres. A reference to the Estates Directory of Sumatra will show that the average acreage of the 160 estates is 4,362 acres and a

some of these are for as much as 17,500 acres (10,000 Bows) it follows that others are much below the above average. Looking at the facility with which some concessions of 4,000 acres have changed hands we think it quite reasonable to suppose that acreage is sufficient for a Company and that 5,000 acres is a sufficiently liberal allowance.

Arrivals by the S.S. "Paknam," 16th July. Messrs. H. N. J. Lugt, V. W. van Gogh, T. F. W. Kehrer and Aug. Koch. These gentlemen are all connected with planting and their object in visiting British North Borneo is to select land suitable for Tobacco planting. They proceeded the following day to Lahad Datu to visit Baron von Stein's Tobacco Estate the soil of which they report as being very suitable for Tobacco. After their return to Sandakan they proceeded up the Kinabatangan in the S. S. "Normanhurst" as far as Bilit and continued up stream in the "Thistle" with their men and boats in tow, to prospect the Lokan and upper Kinabatangan. We are glad to see these gentlemen among us and hope they may meet with success.

A PROLIFEROUS STRAWBERRY.

Horticultural editors are often appealed to to interpret the conditions in the schedules of flower shows. A frequent inquiry is as to whether Rhubarb is to be considered as a fruit or a vegetable—using the latter word in a culinary sense. A similar question is often put with reference to the Tomato. No such enquiry has ever reached us as to the Strawberry; every one seems quite satisfied that should be called a fruit, and not only a fruit, but that particular fruit called a berry. It may be read that the Almighty might have created a better "berry," but that He did not. What then, if the so-called Strawberry be not a berry at all, and, except in a very loose sense, not even a fruit? In point of fact, the true fruits in the Strawberry are the little dry pips commonly, but erroneously called seeds, and which spring from and are more or less imbedded in the fleshy end of the flower-stalk. Usually the flower-stalk or axis, after having given origin to the several parts of the flower, ceases to grow, and disappears from sight; but in the Strawberry it swells out into that delicious succulent mass which is so nice that the partaker heeds not for a moment the botanical pedant who tells him it is not and could not be a berry. That it is really the dilated top of the flower-stalk is, however, shown on various grounds which it is unnecessary to discuss. Suffice it to say it is the office of a stalk to produce leaves, leaf-buds, shoots, or flowers, or all of them, as the case may be; and in the Strawberry before us we have three or four such buds springing from the sides of the berry, and one of them so perfectly organised as to have not only leaves (A) but adventitious roots, the commencement of a runner, (C), and a terminal flower.—*Gardeners' Chronicle*.

MATERIALS USED IN THE MANUFACTURE OF SOAP.

Under this heading we find the following information in the *Indian Engineer*:—

Palm oil may be considered next in importance to olive oil in the fabrication of soap, for which purpose it is consumed in vast quantities, in England especially, where it was first used. It enters into nearly all their best rosin soaps, and this admixture has given both character and popularity to English yellow soaps. It is also used advantageously in many soaps for toilet purposes. It is obtained from the fruit of a species of palm, the *Avoira Elais* or *Elais Guianensis*; according to others, however, from *Cocos Butyracea*, as well as from an *Areca* species. It is, however, not improbable that all these plants

produce similar vegetable oils. Palm oil is a product of the soil of tropical Africa and South America (Guiana), the Canary Islands, India and also of some other regions. The largest consumption of palm oil is in England, which country, in 1879, imported 147,993,216 lb., but the consumption of it is also very great in Germany, France and the United States. The different kinds in the market have various names; the *prima lagos* and *seconda lagos* being the most excellent; the former can be more easily bleached than the latter.

Palm Kernel oil—Has recently made its appearance in the market, and it is but a short time since it found application in the manufacture of soap. It is obtained by crushing and pressing the stony kernels which are obtained in the fruit of the *Avoira Elais*. In the raw state it has almost a coffee brown color and a peculiar cocoa-like fragrance. Before its application to the making of soap it must be bleached. To do this, the following recipe will answer:—50 kilogrammes (110 lb.) of fat are well stirred with a rake in a sub-lye or a solution of culinary salt of 26° B, at a temperature of 100°C. (212°F.); after this it is left to settle a while, during which time the fat, which has already lost considerable of its color, rises to the surface. It is then scooped off, warmed to 35°C. (95°F.), mixed with 1 kilogramme (2½ lb.) of crude muriatic acid and a solution of ¼ kilogramme (8½ oz.) bichromate of potash in water and well stirred. On the following day the oil is re-heated to 35°C. (95°F.), and again ¼ kilogramme bichromate of potash and 1 kilogramme muriatic acid are added. The oil thus bleached, called in commerce palmitin oil, has a faint reddish tint and an agreeable smell similar to that of a mixture of palm oil and cocoa-nut oil, and in consequence thereof it may be used with good results for making the so-called Swiss soaps, also for colored toilet soap, which in this case is not subject to that disagreeable odour which cocoa-nut oil soda soap possesses.

Cocoa-nut oil.—Of this valuable oil several kinds are at present known in commerce, Ceylon, Sidney, Malabar, Goa, and Cochin-China oils,—the latter being considered much the best—whether from a different species of palm or the care in its preparation is not known. These oils are obtained by boiling* the ground or crushed kernels of the nuts of the *Cocos Nucifera*, the *Cocos Butyracea*, and perhaps other species. Cocoa-nut oil is a white usually rancid fat of the consistency of lard, with an unpleasant taste and smell; it melts at 20° to 22°C. (68° to 71.6°F.) and congeals at 18°C. (64.4°F.). Tyndall made some experiments, and obtained by the operation from 210 kilogrammes (462 lb.) dividing the cocoa-nut kernels into portions of 3½ kilogrammes (7.33 lb.) in pressing bags made of the best mats, various sorts of oils of steadily increasing melting points, after having five times increased the temperature of the masses which were prepared for pressing.

Sesame oil.—This valuable oil, from the seeds of the *Sesamum Orientale*, † has many good properties for forming a superior soap especially adapted for the toilet, but generally in combination with other oils or fats. The plant, originally indigenous to India, however, generally thrives in hot climates, and is frequently cultivated as an oil plant. In India three varieties are said to be known, viz., with white seed, with partly colored, and with brownish-black seed grains; the latter furnishing the oil of commerce, and containing 40 to 50 per cent of oil. The Sesame seed is exported in large quantities from India and Africa to Europe, France, Germany and England, where, by pressing, the oil is obtained. It is yellowish in color, and, in a pure state, odourless and tasteless. When first pressed, it tastes somewhat sharp, but this taste is soon entirely lost. If exposed to the air for some

* Certainly not: it is expressed by both natives and Europeans, the latter using powerful hydraulic presses. Boiling is resorted to only when oil is wanted for culinary purposes.—Ed.

† Gingly.—Ed.

time it attains a hemp-like smell. The oil has a specific gravity of 0.923 at 15° C. (59° F.); at 5° C. (45° F.) it congeals and assumes a consistency like a palm oil; heated to 150° to 200° C. (302° to 392° F.) it becomes somewhat lighter in color. Sesame oil finds a very extensive application as table oil, illuminating oil, and especially for soap-making. It is used in a similar manner to Olive oil, and serves frequently for adulterating it. According to Pohl, Sesame oil, mixed with sulphuric acid, turns quickly to a brownish-red color, while Olive oil attains a greenish-yellow or brownish-yellow hue; according to others the presence of Sesame oil in another oil is perceivable by a stronger foaming, which becomes visible when the oil is left to descend in a thin stream from a height of 1-2 to 1.5 metres (47 to 59 inches). What influence the state of the seed, the age of the seed, and the manner of pressing have on the properties of the oil, has not yet been ascertained. Soda soap made from Sesame oil always remains somewhat soft, and hence it is best applied for making soft soap, or added to fats making a hard soap.

Ben oil.—Is obtained from the seeds of the *Galundiga moringa*, and is very well adapted for use in perfumery, it having the property of resisting rancidity better than almost all known oils. For this reason it is used in oiling clocks. The more solid parts are extracted by congealing the oil, and the limpid oil used for this purpose. For soaps this oil has no advantages over Sesame and some other oils, while it is usually much higher in price.

HOW TO GROW TOBACCO.

In our May number we referred to the importance of pushing the cultivation of tobacco in Ceylon, and we are now able to give below an essay published in *Tobacco culture*, which contains thirteen other essays (selected by a committee out of eighty articles sent to compete for the prize) by experienced cultivators resident in different parts of the United States, including the prize essay, which originally appeared in the *American Agriculturist*. Four experienced growers attested to the correctness of the process described in this essay.

ESSAY BY MR. JOHN PURSLEY, FRANKLIN COUNTY, MO.
I have grown this plant for over ten years, and have tried many different modes of cultivating it. There are more than twenty distinct varieties, of which I will only mention the most valuable.

The Yellow Prior, Blue Prior, Orinoco, Little Frederic, Big Frederic, Cuba, and Spanish tobacco. These are considered the most valuable in this State. The Yellow Prior and Orinoco are the most profitable.

I prefer the Yellow Prior, as it is the easiest cultivated and is the most fine and smooth of the many varieties. Some growers prefer the Orinoco, on account of it being the heaviest. I do not for various reasons: it has large stiff fibres and pulled stalks, which afford hiding-places for insects; it molds easier, is harder to cure, and generally does not bring as good a price as the Yellow Prior.

Selecting Seed.—In gathering seed, the largest and ripest bolls should be selected and put away in a dry place. When procuring seed, at a seed-store, always be careful to get new seed. When it is new it is of a dark brown; when old it is lighter in colour. The seed should be sown *early*, from the 1st of February till the 10th of March; but I have known it to be sown as late as the 25th of March and do well.

The seed bed should be made on a south hill-side, in new loamy ground, not too dry. Cut off the timber, and separate the stumps from the coarse wood; then rake off the leaves and brush, leaving the ground perfectly bare so as to admit the heat of the sun. Then put the brush on four or five feet thick; then put on a thick layer of the coarse wood, and then set fire to it. This should be done when the ground is in good working order. After the bed is burnt, the ashes should be run till the ground is cool, then the brands should be raked off, and the ground dug up five or six inches deep; this is best done with a grub-hoe; rake and pick all the roots out, making it loose and mellow. Level the

surface of the bed, and it is ready to be sown. Mix the seed with dry ashes, so as to sow them regularly. One table-spoonful of good seed will sow a best 25 feet square, and will raise enough plants to set five or six acres. After sowing as regularly as possible, the bed should be rolled or tramped with the feet until it is solid and level; then cover it up with brush till spring opens; then the brush should be removed to admit the rays of the sun, which will soon bring the plants; keep the weeds and grass out of the bed till the plants are large enough to transplant. They are handiest to transplant when their largest leaf is three or four inches long.

SOIL AND PLANTING.—Tobacco can be raised on most qualities of soil; but the best is new first year's land; white oak, hickory, hazel, or pawpaw land is preferable. After plowing, the ground should be harrowed thoroughly, making it as mellow as possible. Checker it off with a shovel-plough, so as to form the hills about three feet apart; make up small flat mellow hills. This should be done by the time the plants are large enough to transplant. Transplanting is usually done with a peg, sharp at one end, making a hole sufficiently large to admit the plant; press the earth closely around the roots, in the same manner that cabbage is transplanted.

We generally commence setting out tobacco about the 1st of June and continue till the 25th; if set out after this, it is not apt to get ripe before frost.

CULTURE.—As soon as the tobacco is set out there is a great destroyer lays hold of the plant, and often cutting the stem off, thereby ruining it. It is a species of black ground-worm, usually known as the cutworm. These must be looked after every morning, for they do their mischief in the night, consequently their sign is easier detected in the morning, and they have not entered deep into the ground. When the plant makes a start to grow it soon gets out of the reach of the cut-worm; then all the vacant hills should be replanted.

As soon as the weeds and grass start to grow, the hills should be scraped down with a hoe, not disturbing the roots of the plant. By the time the grass makes its appearance the second time, the tobacco is large enough to admit the plough. A narrow shovel-plough does the neatest work; run three furrows to the row, not close enough to fracture the tobacco, then work it over thoroughly with the hoe, putting a small mellow hill to each plant.

WORMS.—By this time you will observe the work of the green tobacco-worms. They must be looked after at least once a week. There are two different species of this worm—the red-horned and the blue-horned, each equally destructive. One of these worms will soon destroy a plant. When it has finished its work, it enters the ground to come up next spring, in the form of a fly. This fly lays her eggs on the tobacco, which hatch out young worms. The egg is hardly as large as a mustard-seed and of a yellowish colour. Many of these may be caught about Jamestown weeds and destroyed. They may be seen of evenings sucking the Jamestown blooms. Keep all destroying insects off of the tobacco while it stands in the field. The cut-worm was very destructive in the years 1869—72; it works in the bud of the plant, making great havoc with the young leaves.

When the tobacco is about a foot-and-a-half high, it should get its last ploughing and hoeing, and should have a large flat hill put around it.

PRIMING AND TOPPING.—When the buds that contain the blooms make their appearance, it should be primed and topped. Priming is done by pulling off the bottom leaves, so that those remaining will not reach the ground; then pluck out the buds, leaving twelve or fourteen leaves on a stalk.

We generally go over the field three or four times, topping and priming. First topping that which is large enough, and letting the smaller remain till the next week, and so on till it is necessary all should be topped, to except the first. We generally finish topping by the 20th of August.

If the transplanting is finished by the 20th, or June, which it should be, the tobacco will be amply

large enough to top by the 20th of August, which will give it time to ripen by the 20th of September.

Some seasons tobacco may be planted later, but it is unsafe in this locality, for the frost may come and lay waste a summer's labour.

SEED-PLANTS.—The earliest plants should be left for seed; do not top them, but trim the leaves off at the top, to about ten to a plant.

Four flourishing plants will yield one half-pint of good seed. The bud-worm should be kept from the seed-plants, as they will enter the pods and eat the seed. I have caught as many as twenty bud-worms on one neglected seed-plant.

SUCKERING.—After the tobacco has been topped about a week, there will be little sprouts or suckers put forth on the stalk, at the but of every leaf. If they are neglected, they will grow up and go to seed, and take all the nourishment from the stalk, giving the plant a haggard appearance, and literally ruining the tobacco. These suckers must be strictly attended to; they should be pulled off as soon as they have grown long enough to be conveniently taken hold of by the fingers.

There are generally three sets of suckers, sometimes four. After one set is pulled off, in a week or so there will be another set put forth, in the same place, and so on until the tobacco is ripe.

The better the worms and suckers are kept off, the better the tobacco will be.

HARVESTING AND CURING.—When the tobacco is ripe it has a yellow faded colour, and becomes brittle; the surface of the leaf is rough and ridged. By bending the leaf short between the fingers, it will break before it will double.

The sticks to hang it on should be in readiness. The best mode of hanging or stringing, is with a V-shaped spear, made of iron or steel. The spear has a socket, large to admit the end of the stick. The sticks should be sharpened at one end to fit the socket; should be four feet six inches in length, two inches wide, and one inch thick. A stick of these dimensions will hold eight plants.

The tobacco should be cut off just below the bottom leaf, then turn the plant upside down, and let it remain so till the sun wilts it. When it is wilted it can be handled without breaking; then it should be taken up and laid in piles of eight stalks each, placing the butts of the stalks towards the sun, to prevent it from sun-burning. When it is sun-burnt it turns black, and it cannot be cured any other colour than black, which ruins its sale.

The sticks should be strewed along, one stick to a pile; place the spear on the end of the stick, and set the stick upright; then take up the tobacco, one stalk at a time, and thrust it on the stick, letting the spear pass through the stalk, about six inches from the butend; then take the spear off and take up the stick, and shake the tobacco out straight, and set the stick up with the butts towards the sun.

Some tobacco-growers prefer splitting the stalk from the top down to within about six inches of the but then hang it on the sticks. But I cannot agree with them, for it is more difficult to handle, and is apt to slip off of the stick, when moving it; besides, the tobacco cured in this manner is not so heavy as if it was speared. It dries out quicker by being split, but the substance evaporates instead of remaining in the leaf. I am not certain that it injures the taste of the tobacco, but I am certain that split tobacco is lighter than that which is speared.

Some prefer hanging the tobacco on scaffolds in the field until it is ready to be put in the barn and cured by fire. But it is the safest to house it as soon as it is strung on the sticks.

Scaffolding is done by placing poles on forks, about four feet apart, and four or five feet from the ground; then hang the tobacco between the poles, letting the ends of the sticks rest on the poles. This procedure is unsafe, for the rain may come and saturate the tobacco and wash off the gum, thus making it light and chaffy.

Tobacco should not be exposed to the weather after it is cut. It should be immediately conveyed to the

barn and hung up. As soon as it gets about half yellowed, a slow fire should be started under it; if made too hot at first, the tobacco will turn black. About the second day the ends of the leaves will begin to curl up; then the fire should be gradually increased, till it heats the tobacco blood warm; it should be kept up so till the leaf is thoroughly cured.

If this rule be strictly adhered to, the tobacco will be cured bright. The brighter it is cured the better it sells.

Our barns, in this State, are generally built of logs, some have frames. The barn should be made tight up to the tobacco, which should hang about eight feet from the ground; above this leave cracks or air-holes sufficient for free ventilation.

A barn to hold two-and-a-half acres of tobacco, which is as much as one man can attend to, should be twenty-four feet square. It should have five tiers of poles, the lowest about six feet from the ground; these should extend across the barn, and be fastened at each end into the walls. The poles should be four feet apart, and the tiers directly one above another.

The sticks which contain the tobacco should be placed within eight inches of each other, on all the poles except the bottom ones, which should be left vacant directly over the fire. When tobacco is nearly cured, it very readily catches fire.

If there be a wet spell of weather before the stalks are thoroughly dry, build a fire under the tobacco sufficiently hot to keep it dry. It should not get damp and plient until the stalks are dry, then it may be allowed to get damp.

STRIPPING will be the farmer's labour during damp weather, until his tobacco is stripped and ready for market.

The lugs, shipping, and manufacturing, which are worst, medium, and best qualities, should be separated at stripping. The *lugs*, or worst quality, are found at the bottom of the plant; they are chaffy and light leaves, and should be stripped from the stalk and tied in bundles by themselves with all of the ragged black, and injured leaves.

The second quality, or *shipping tobacco*, is a grade above the lugs; it is the red or brown tobacco; this should also be tied in separate bundles.

The best, or *manufacturing*, is the finest and brightest leaves, and should be put in bundles by itself.

In stripping, the stems of the leaves should be broken off as close as possible to the stalk; this adds to the weight of the tobacco.

In forming a bundle the butts of the leaves should be placed evenly and closely together and pressed tightly in the hand; then a leaf should be folded to form a wrapper two inches in width; then wrap it tightly and smoothly around the butts of the leaves, winding it from the end down, about two inches and a-half; then open the bundle in the middle and tuck the wrapper leaf through the opening and draw it snug, so that when the opening is closed the wrapper leaf will remain; this forms a bundle which we call a "hand of tobacco."

The hands should be strung on sticks and hoisted up in the barn on the tier-poles; eighteen or twenty hands may be put on each stick, at equal distances apart.

BUCKING AND PACKING.—Let the tobacco hang in the barn until within a week or two of hogheading, take it down, remove it from the sticks, and put it in a bulk. This is done by making a platform, and covering with straw or hay; then lay the hands of tobacco side by side, in layers around, with the butts outward, in the same manner as wheat or oats are stacked.

If the atmosphere is dry, the bulk should be covered up closely, so that the tobacco will retain its moisture. It should not be too damp, for there is danger of its molding in the bulk.

If it should mold, hang it up again in the barn, and put fire under it. The mold that it gets in the bulk is generally the yellow mold, which is the most fatal. It sometimes gets a white mold on it, while hanging in the barn, when the atmosphere is very damp and warm, but this does not materially injure it, for it will rub off while drawing the tobacco through the hands, it should be drawn through the hands every time it is handled, to keep it straight, and to give it a silky texture, which adds to its price.

We generally send tobacco to market in hog-heads, and sometimes in boxes. A hog-head four feet in length, and three feet in diameter, is the medium size. One thousand pounds is considered a full hog-head; but one of the above dimensions can hold one thousand five hundred pounds, by hard pressing; but this blackens the tobacco, and injures the sale of it. Packing in the hog-head is done by first laying a course or layer of bundles straight across the bottom, keeping the butts even and close together, then fill up on each side of the centre course, placing the butts against the staves; then the butts of the hands that lie against the hog-head should be covered up with two or three others, pressed closely down. The next centre course should be laid across the first, and done in the same manner as before, and so on, crossing each course in succession, until the hog-head is two-thirds full; when the press should be applied till the tobacco is pressed down to within a foot-and-a-half of the bottom of the hog-head.

The press should remain on an hour or more, in order that the tobacco may settle together; then the press should be raised, and the packing resumed as before, till the tobacco is within a foot-and-a-half of the top; then the press should again be applied till the tobacco is pressed half way down the hog-head; the same proportion should be observed until the hog-head is full. Then put the head in, and it is ready for market.—“Ceylon Advertiser.”

TOBACCO GROWING.

It is now beyond doubt that tobacco growing in England cannot be made to pay. Tobacco can be made to grow, and where money is lavished upon it to grow in abundance, but the crop is not worth much at the best, and the average specimens are unsaleable. This is the verdict of the judges on whom it devolved to pronounce upon the relative merits of certain crops in the competition for a prize of fifty guineas offered to the producer of the best tobacco leaf. The prize has been awarded, but the judges thought fit to make an addendum to their award. Not one of the four samples, they say, eligible for the prize, is in any respect valuable for trade purposes. “With regard to the prospects of tobacco growing in England,” the judges add, “we share the opinion that, even under the most favourable conditions possible, such a crop cannot be made to pay, and that in most seasons it must be an absolute failure and heavy loss.” So then this source of revenue is closed against English agriculturists, together with other sources in which their hope was for some time fixed. With the decline in the price of the staple of English farming—wheat—pasturage was thought to be a better paying alternative, but the large importation of frozen meat from abroad speedily dissolved this hope, and various other remedies for the depression, such as fruit farming, were in their turn recommended and found wanting. The idea of jam making, which found its origin in the fertile brain of Mr. Gladstone, proved no better specific. The resources of jam, eggs, butter, meat, and grain have been inadequate to arrest the decline in farming, and now tobacco growing is shown to be the most delusive hope of all. But the report of the judges will contain no great disappointment, for few ever believed that the soil or the climate of England rendered it possible to cultivate the tobacco plant to any good purpose. Even the most daring enthusiasts could hardly entertain the idea that by tobaccos produced at home could rival in flavour and perfume the produce of Virginia or of Egypt. But now even the most moderate expectations have been shown to be extravagant. The fifty-guinea prize tobacco is flavourless and insipid in comparison to ordinarily good samples of the imported article. Pity 'tis true, but it is as well to know exactly how we stand.

We shall have to go back to old-fashioned farming and make the most out of it. This is exactly where in the hope of the future rests—in making the most out of what growing, stock producing, etc.—and it is not unlikely that, if schools for agriculture were more general, and the science of farming as well as its practice

better understood, we shall yet be able to hold our own with the competition from abroad.—*Chemical Trade Journal.*

CHINA TEA TRADE.

There is no need to dwell on the section in Mr. Hughes' report devoted to the tea trade, for there is nothing new to be said on the subject of the tea trade between China and England. He makes a good point of the fact that the brick tea shipped in such large quantities to Siberia only pays an export duty of Tls. 0.60 per picul, and is exempt from transit duty, while the coarse leaf and dust, of which it is made, pays Tls. 2.50 per picul, if shipped to England. He concludes:—“The trade has never been in our hands, and we have no reason to grudge our Russian friends their success, but attention may fairly be drawn to its flourishing condition in support of the contention of our merchants that the export duty on tea should be largely diminished or altogether abolished.” As we have before remarked, the Chinese government may reply that their interest in the tea trade is in the duty they extract from it, and that it is unreasonable to ask them to abolish that duty; though they may be persuaded to relax the duty, when the tariff is revised, as the local officials this year have in certain places relaxed the inland taxation on the leaf.—*North-China Herald*, Aug. 24th.

MEDICAL HINTS FOR THE HILLS.

[Dr. Bishop, a couple of years ago, published a curious picture of planter and cooly life in Assam, more amusing to outsiders than to the planters depicted. Now he seems to have issued a graver book, a notice of which we reproduce from the *Indian Planters' Gazette*.—ED.]

Doctor Bishop's “Medical Hints for the Hills”* is a little unpretentious book that one can easily carry in the pocket. It deals with topics which, so far as we are aware, have not hitherto obtained that attention which their importance demands. How often does it happen that invalids going to the hills are little the better for the change; and in some instances sink under the new conditions of climatic surroundings. There is no doubt that many valuable lives are lost owing to insufficient care on the arrival in the new station. “I have often noticed,” says Doctor Bishop, “after arrival in a hill station from the plains, that visitors, more especially those who come on account of their health, suffer from various indispositions; and it is my aim in these notes to try and point out a few of the most common incidental to the change of climate. From my own experience I am confident if more care were taken, and more prudence exercised, in a great measure a good deal of unnecessary sickness could be avoided. We must bear in mind the additional strain there is thrown on the constitution, which is not altogether compensated for by a hill trip. After a prolonged residence in the plains, the large organs of the body are generally debilitated and unable to bear the extra work which is thrown on them; therefore it behoves all new arrivals to use some discretion, and to gradually adopt the system to the change.

“The heart, the liver, the lungs, the stomach and kidneys all have their work increased.”

These organs and their diseases, as they appear in the hills, are dealt with in a very able and exhaustive manner. Fever, hill climates; sleeplessness,

* “Medical Hints for the Hills.” By Doctor S. O. Bishop. Printed by N. L. Ray at Lachna, at Darjeeling, in the Scotch Mission Orphanage Press, and Messrs. Newman & Co., Calcutta.

and sanitation are all treated more or less exhaustively and free from technicalities. The author's address to planters should be in the hands of every planter in India. Doctor Bishop says:—

A planter's life is one of continued risk and exposure, only those who have lived and worked amongst them can realize the risks they run. Year by year the already heavy list is steadily increased by those who pass over to join the great majority, victims of the climate. Young men who arrive from home strong and healthy, full of life and vigour, succumb to that deadly curse, malaria. Often situated away from European medical advice, sufficient attention is not paid to the health of the planter; he probably goes on getting slight attacks of fever which he treats as best he can, finally drifting into a debilitated state of health, and is carried off by the first sharp attack of malaria; his system not rallying sufficiently to throw off the poison. Planters, as a rule, are a happy-go-lucky sort, and pay little attention to attacks of malaria. With the great responsibility of large concerns on their hands they have no time to lay up, often going to their daily work with fever, trusting to a few doses of quinine to pull them through; so it goes on until the liver and spleen become affected and the constitution ruined. More attention should be directed to this, and every planter ought to be overhauled occasionally. He may not be ill, but at the same time some advice is useful, and an experienced eye can detect a flaw when least expected—it may be only a trivial ailment, but still require seeing to. Planters are somewhat careless about their health, being so wrapped up in the interests of their gardens that if medical advice is not handy, they seek it when too late, and irretrievable mischief is done. It is useless to expect a planter to ride miles and miles in a blazing sun to obtain a medical opinion. It must be at hand. A monthly visit from the doctor is little enough, a friendly chat sometimes disclosing symptoms which otherwise would never have been noticed. To those proprietors interested in tea properties, I would most earnestly impress on them the necessity of seeing that their managers and assistants have furlough in due season; many a valuable life has been sacrificed for want of a timely trip to sea. The planter, sooner than risk a refusal, will go on working till he drops, and the change comes too late. A trip to England every five years is absolutely requisite for those engaged in the plains and malarious districts, and in many cases oftener. Longer subjection to malarious influence means the constitutions becoming so imbued with malaria that sooner or later it tells on the frame, and it is no easy work to repair the mischief done, numbers only going when dire necessity compels them, arriving home in such a state that their health never recovers sufficiently to allow them to return to their duties. A change being only beneficial when taken at an early stage. In my opinion, if change of air were ordered more frequently, less lives would be lost. Planters whose lot is cast in the Terai, the Dooars, parts of Assam, Cachar and Sylhet, all more or less suffer from malaria from time to time varying in severity. Perhaps, mostly in the Terai. The earth of this district is immensely rich and covered with dense forests, which being shut in by the vast mountain ranges, make free perfusion of air impossible. This, at particular seasons of the year, causes it to be very unhealthy. Even those who live above the plains at a higher elevation are not always safe from the baneful poison, for malaria has been known to attack residents who thought themselves so elevated as to be out of harm's way. The malaria has been carried along by winds

sufficiently strong enough to do so, yet not to dispel it. Currents of heated air will cause it to ascend far above its origin. Bungalows built above a malarious plain are often more under its influence than those below. Malaria, if helped by gorges and hot air currents, has been known to invade mountains at various heights. It is not wise to place bungalows on the edges of ravines supposed to be above fever level. A good belt of forest intervening between a malarious swamp and a bungalow is a great protection. Water acts in a similar way by its absorbing powers. As long as the earth is protected from the sun by forest, it is not so bad; however, after clearing the forest, and before the land is brought into cultivation, is the time when the malaria seems at its worst.

I do not think planters exercise sufficient discretion in their living, and to this I wish to draw attention; likewise to the pernicious habit of taking stimulants between meals; not that this is done to excess. Still planters do get into the habit; returning from the morning's work tired and exhausted a peg is taken; most probably he will find this freshens him up. So without knowing or thinking about any harm that might result from this, he gets into the way of having intermediate nips between meals. These are bad, very bad. Habershon, in his excellent work, says, 'From the free use even of wine and malt liquor we often find a state of subacute inflammation of the stomach produced. Congestion of the liver and enlargement follows. This state gives place to chronic dyspepsia, very frequently to the vomiting of blood and to a disordered state of the whole abdominal viscera. Organic degeneration of the liver and kidneys often succeeds, or chronic ulcer of the stomach with its attendant miseries; an atheromatous condition of the arteries is another consequence of alcoholic imbibition, and this again becomes the cause of valvular disease of the heart, and may endanger life from apoplectic effusions into the brain. Alcohol may be a most valuable medicine, but the abuse of it entails innumerable miseries, and that which may be of temporary benefit becomes direct injury when unnecessarily continued; the temporary requirements of disease and of a failing circulation are never meant to be the guide of normal health; and if large doses of stimulant be continued, organic disease will almost invariably follow.' A planter's life is necessarily a very hard one, and it is of the uttermost importance that he should keep himself in good health to be able to go through his arduous duties, and to avoid the risk of malarious poisoning: with this aim he must live well and have regularity in his meals. A sufficiently substantial meal is not always taken in the morning, to carry on till breakfast, usually at midday. The result being that nature becomes exhausted long before breakfast, and a peg is indulged in sometimes to help along, without a biscuit or anything to eat at the same time, which materially decreases the harm. In my opinion, planters, from the robust life they lead, and living often in a malarious climate, are none the worse for some stimulant, providing it is taken at the right time with meals. What I wish to point out is the irreparable mischief done to the great organs of the body, viz., the heart, the liver, stomach and kidneys by the habit of nipping between meals. The mischief comes on insidiously, one of the most frequent outcomings of this habit being chronic catarrh of the stomach, resulting in an accumulation of phlegm in the throat on rising, efforts to dislodge which cause vomiting. This is simply an inflamed condition of the coats of the stomach, due in some cases to cold, but more

often caused by taking spirits on an empty stomach. At the midday meal light beer, as Pilsener, or claret and soda, are the most harmless kinds of stimulants suitable to a planter's avocation. Bass's beer and pegs are rather heavy at this time of day. At dinner a glass of beer, or claret, or whiskey and soda, might be taken if required. I likewise do not see the harm of a mild peg after the work of the day is over and the sun well down but this is, often replaced with benefit by a glass of dry sherry and bitters. It is a bad symptom when one cannot face breakfast in the morning before going out, it means something wrong and is not natural. The interval between the meals is a long one, during which time all the hardest work of the day is done. It is a most deleterious habit to go out round the work, if the stomach is not well fortified; with an empty one the system is much more susceptible to malarious influences. In the plains many indulge in an afternoon nap, this has been blamed by some. I myself think the secret is not to go to sleep too soon after your food; then I do not see the harm of indulging in half an hour's rest; provided you wake up refreshed and not heavy with a nasty taste in your mouth. Gentlemen, a good deal rests with yourselves, though you are exposed to great vicissitudes of climate, yet with ordinary care in your mode of living, taking change in time and not being too indulgent, you ought to enjoy good health. Take note of attacks of fever. If you find they are coming too frequently, seek advice in time and do not go on doctoring yourselves.

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

The *Java Bode* hails with satisfaction, the extension of a British protectorate over North Borneo, Brunei, and Sarawak. A British occupation, in its opinion, will prevent any difficulties like the Acheen one from arising. Holland cannot do anything in the direction of a protectorate. The trouble and burden of it will now be borne by another power, which is sure to make life and property there safe enough to admit of Netherlanders settling down to grow tobacco, or look out for some other means of gaining a fortune. Holland has too many irons in the fire to admit of her managing effectively the Colonial possessions she holds. In the Netherlands portion of New Guinea, the Government officials do nothing more than every now and then, giving a look round to see whether the natives are content and in good case. They are never otherwise, interfered with.

Many of the islands under the Netherlands Indian Government are little known to the scientific world. To meet this want of knowledge, Dr. Baseler, a young and wealthy German scientist, who has travelled through Egypt and Hither India as well as Ceylon and Further India, is now pursuing investigation and research in them. After visiting Java, he went his way to the Moluccas, and New Guinea. There, he was carrying on explorations by last accounts. Dr. Baseler is provided with the choicest of instruments, and is chiefly making ethnographical and anthropological inquiries, with the aid of an excellent photographic apparatus. Being furnished with credentials by Professors Virchow and Bassem, and letters of recommendation from the Governor General, he has met with every aid and help from the local officials.

A correspondent writing to the *Surabaya Courant* from Baling, the chief port in Bali, reports that the coffee trade there is steadily on the increase. That article takes a prominent place among what is

known as Straits Produce. The export of the berry has taken promising dimensions. The Chinese-owned steamers frequenting the port, profit the most by the opportunity. They usually leave it with full cargoes of that produce article. The steamers of the Netherlands India Steam Navigation Co. cannot compete with them, and often have to depart from Baling with hardly any local cargo on board. The Chinese-owned-steamers manage to fill up with coffee, all the same. Tact and enterprise on the part of the latter's agents, largely contribute to their success.

DOMESTIC COCONUT OIL.

What is known as "Cuban" coconut oil is seldom seen in the American markets, but an article of domestic manufacture has taken its place and sells at a fraction under the price of Ceylon oil. Coconuts unfit for other purposes are taken to New Jersey and converted into soap stock and fertilizing materials. The production of oil from this one source is claimed to average seventy-five tons per month, but it is questionable about rejected nuts being exclusively used, as the damaged exportations must be very extensive to produce such a quantity of soap stock. For some years, coconut oil has been made in Philadelphia and on the Pacific coast but the domestic article has not been an important factor in the market and never will be on account of the superior quality of Ceylon and Cochin oils. The total production here is only a drop in the bucket compared to the importations, and consequently, is not a disturbing element.

Strange as it may seem, American oil has been sent to Marseilles to be used as a component part of French soaps, and operators are at a loss to account for it when the foreign consumers are more favourably situated in regard to Indian supplies of raw materials. There can be no inducement from extremely low prices, as home manufacturers can dispose of their entire output at a good figure in this vicinity and no necessity exists for shipping abroad. The cause is probably to be found in the fact that a surplus was allowed to accumulate a few months since when stocks of foreign oil were large at this port and the movement slow. Holders no doubt concluded to send their supplies out of the country at an important concession rather than pay storage and bear the market with their presence, but the shipments are not of recent date.

The traffic in American oil is the result of efforts to utilize a waste material. It can never be made an industry of importance, the oil being merely a by-product in the manufacture of bakers' coconut or extracted from damaged nuts which would otherwise be worthless.—*Oil, Paint and Drug Reporter*.

[Coconuts are very largely used in the United States by cooks and confectioners to produce dainty dishes, cakes, &c.—*Ed.*]

CEYLON VS. CHINA AND INDIAN TEAS IN GLASGOW.

In sending us the following communication, a well-known Ceylon planter writes:—

"Here are a few remarks by a professional tea-taster, and perhaps you may think them worthy of printing. He sees my *Overland Observer*, and hence his remarks. Privately his opinion is that we have still a deal to learn with regard to manufacture. But he admits that we have a decided speciality in flavour in our Ceylon teas, and if our manufacture was up to India's standard, we would have no difficulty in topping Indian teas. I have repeatedly explained to him that a great many of our plantations are at that stage, that it is almost impossible to do justice to curing. He very properly says that is nothing to the trade. Our tea is put against India, China and Java teas, and which ever comes out best in the liquor is the best value. I only wish planters could see the awful rubbish I see sometimes of a morning, and have no doubt they would at once admit what my friend says that they have still a lot to learn as to curing."

(By a Professional Tea Taster.)

During the past nine months I have been a constant reader of the *Overland Ceylon Observer* lent to me by a planter friend now sojourning here, and I notice from time to time letters and arguments *re* the ups and downs of prices of Ceylon teas. From my point of view and speaking as a practical tea taster of 18 years' experience, I think Ceylon in general has nothing to grumble at as regards tea. What could be more rapid than the growth in public estimation of Ceylon tea? For the last 10 years I have been selling tea to the wholesale and retail trade in Scotland. Speaking of Glasgow in particular, ten years ago blends were composed of 2-3rds China, 1-3rd Indian. As time went on Indian was used more freely. Three years ago Ceylon planters began to assert themselves, but lost favor again slightly, because they went "dead" after keeping a while. At the present time they are greatly in favor, and there is hardly a tea dealer or grocer in Glasgow who does not use Ceylons either pure or blended. The tables are quite turned on China teas: now, the proportion of China used is only about 1-7th to 1-10th, and I anticipate that (in Glasgow certainly) they will disappear altogether except the very lowest priced teas for the low retail out. This season's import of China teas will give a great lift to Indian and Ceylon teas. The China Monings are all or nearly all, so far, tarry or smoky and most undesirable. The red leaf Kaisow teas are even worse than the Monings, the Soomoo kinds, which is by far the largest assortment of the Kaisow crop, are simply rotten.

I notice a great deal of squabbling (in your issue, 3rd July) amongst your planters and brokers. After reading all letters and remarks carefully, I quite agree with the Colombo brokers. The reports they gave in the circulars quoted were quite justified by the outturn of the teas arriving here in May and June: a more sapless and insipid lot of teas could not be wished for by the greatest anti-Ceylonist. We had good liquoring Assams and Chinas at the time, so could afford to pass over all undesirable sorts, hence the low quotations. At the end of June and beginning of July the quality improved considerably, but we were then in the throes of the arrivals of new China's which diverted the attention of the trade for a week or two till we had seen a few shipments, and discovered what a miserable lot of stuff China had sent us. The whole trade to a man turned their attention to Ceylon's resulting in an immediate rise in prices, which has since been maintained and is likely to be till we get a larger supply from India. Ceylon has nothing to fear from China; keep your eye on Indian teas and imitate their make as far as possible, avoiding the harshness of some Indian teas. Avoid burning the Ceylon teas as far as possible, but on the other hand don't send us the thick, soft, bitter almond-flavored sorts: they won't take anywhere, and in a month or two go off as dull as ditch water and do more harm to the interests of Ceylon tea than all the brokers' reports that could be written from now till Doomsday; as these reports are not seen by the British public in general. Brokers are like a certain garment; they are indispensable. Speaking of London brokers, they are expected to send out a circular, the tone of which in nine cases out of ten depends on the "luck" they have had during the week. London brokers should not write circulars: they have no idea of the wants of the country in general. They get teas put into their hands to sell either by public or private sale; in many cases they have not a shadow of an idea of the value of the tea they are offering, trusting to the dealer to make a respectable bid. The bid made, the broker goes to the merchant entrusted with the

tea, pulls a long face, and says this is the best he can do, better sell; result, planter robbed; buyer chuckles at his bargain. To get a really honest report of the British wants, go to a first-class dealer (I mean London wholesale dealer) who has his or their agents or representatives established in all the best districts in the Kingdom, who are supposed,—and do in all well-regulated houses,—write daily letters stating the wants of the trade and get samples accordingly. A great deal is said about subsidies; why not subsidize all tea agents of London-houses who make a point of pushing Ceylon tea? Why send your subsidies to America? You get no return. Here you have it guaranteed, provided you give us teas well cured.

I have seen a number of Ceylon planters during this 12 months, and I find they have a lot to learn as regards the proper liquor for the British market; many say they don't know how to liquor teas, *i. e.* taste as we do.

FISH IN AUSTRALIA:

SIR THOMAS BRADY ON TROUT BREEDING.

Within 70 to 100 miles of Melbourne is a magnificent region of mountains, rivers and lakes, the latter having communication with the sea, known as Gippsland after a former Governor, Sir George Gipps. Melbourne is largely supplied with sea fish from the lakes, and, naturally enough, the idea of stocking the rivers with salmon and trout has been entertained, and we are only surprised it has not yet been carried out. The railway now extends via Sale to Bairnsdale, the centre formerly and probably still of extensive hop culture on the alluvial soil which forms the banks of the beautiful Mitchell river. Its sides were blazing with sweet-odoured "golden wattles" when we steamed down its course into the Lakes. These Lakes are the very home of the black swans and other aquatic birds of Australia, which are now, we are glad to say, protected. Amongst the Gippsland snow-capped mountains, whence numerous fine rivers pour down, are many gold mines, including one of the richest in the world, the "Walhalla." But plentiful supplies of food are more important to human beings than any quantity of gold, and so Sir Thos. Brady, an Irish visitor (Inspector of Irish Fisheries), has been prospecting for fish existing and for conditions favourable for additions to the kinds now bred and caught in the brackish lakes and the fresh-water streams. In the latter the nearest approach to trout is the "black fish" to which visitors to Fernshaw are treated. From a notice in the *Australasian* of Sir Thos. Brady's visit, we take a few extracts, having a bearing on the praiseworthy efforts of Mr. Le Mesurier to naturalize trout in Ceylon. The recorder of the events of the trip writes:—

We set out, first to take a look at the upper, or rather the running, waters of the Mitchell, and secondly to run down through Lake King and Reeves River to the Heads, or, more correctly, the present opening to the sea. The Mitchell is a beautiful stream by Bairnsdale, deep, clear, broad, and still. For seven miles below and three miles above the town it has no perceptible current. "As fine an estuary," said Sir Thomas, "as salmon could desire." Our immediate object was to ascertain the possibility of the successful introduction of salmon to the Gippsland rivers, and to ascertain this it was necessary to inquire into three distinct matters. First as to the upper or running waters. A clear stream running over a gravelly bed was essential. A lake at the head waters was also desirable. We could discover by inquiry that there was no lake, but as to the stream, rumour reported many things, and the only

way of discovering the truth was by personal investigation. The river ran clear, we were told, and over a visible bed at Mr. Hill's station, seven miles out of town and therefore at early morning to Mr. Hill's station we set forth. The morning was cold and frosty—enough winter about it, one would imagine, to satisfy any salmon; but the journey was short and the roads good, and at 9 o'clock we were down on the bank of the river immediately below the homestead.

We are tumbling down a steep bank, and walking through rank grass and various vegetable growths to the river's bank. Satin birds fly along before us, and red and blue loons lit from bough to bough. We come right to the edge, and look down on the river. The bed here is of sand, silt, gravel, and snags. The water is a pale bluish green, tolerably clear, but not transparent; the bank of loose silt, fine, almost as wheaten flour, washed down from the hills and spread over the flats by the rains and floods of ages. A very brief inspection suffices. "Trout," says Sir Thomas, "but not salmon. That is not a salmon stream." "Did you ever try trout here?" "Yes, we have put trout in the stream." "How many?" "A few hundreds." "Put in a few tens of thousands, and you would have a better chance of success." Sir Thomas holds strongly, and, as one cannot doubt, rightly, that this business of introducing new fish must be gone into in a wholesale fashion; to put a handful of foreign fish into a river is like scattering a handful of strange seeds in a forest. The four hundred thousand young fish which will shortly be released in Tasmanian waters are not by any means an extravagant number. "It will be four years before they begin the work of reproduction, remember, and think of all the enemies that will assail them during that period." But is the game worth all this mighty expenditure of candle? Well, yes, taking, as in all other instances, the commercial aspect first. The salmon exported from Ireland return on an average £600,000 annually, and probably £100,000 worth go into home consumption. And to this must be added that unknown quantity—the value of the sport. If that be so, we must really endeavour to find a true salmon stream in Gippsland, and where shall we look for it? "The Snowy," says one, and another "The Snowy is as fine a stream as could be found in the world." I myself have seen and heard the Snowy brawling over the granite boulders at Buckley's Crossing, in the Manaro Mountains, and join in the general chorus of advice that the Snowy should be visited.

We attract attention to the statement that Sir Thos. Brady did not expect the trout to breed under four years. Has not Mr. Le Mesurier therefore been expecting results at too early a date from his fish? But to continue our extracts:—

We pass on, and an hour after noon steam through the broad channel which skirts the long, flat narrow cape into Lake King. The luminous home of waters and of fish opens broad before us, and as we steam out the far away blue mountains rise beyond the dark, low timbered hills. There are streaks of snow in the clefts of Mount Wellington, but every other height is far faint cobalt. The lake is smooth as glass, and ten thousand swans and a hundred thousand ducks are sailing or resting on its broad surface.

The account is to be continued, and in due time we shall doubtless learn Sir Thos. Brady's opinions regarding the Snowy River, the Avon, the Mac Allister and other noble mountain streams, which flow through the majestic forests and rich soil of Gippsland. Meantime, might it not be well if efforts were made to obtain ova from the trout (whatever may be said of the salmon) which have flourished so wonderfully in the grand Derwent river of Tasmania. It seems probable that the progeny of trout naturalized in the climate of an island so much more alike in conditions to those of the hill country of Ceylon than any part of Europe could be would be more likely to thrive in our streams than that brought direct from regions so much colder for a large portion of the year.

Advantage might be taken of the presence in Australia of Mr. Arthur Sinclair, a former Ceylon planter, and still retaining a deep interest in the welfare of our island, to obtain supplies of fish ova, which we feel sure the P. & O. Company would be glad to convey hither in water cooled by ice. We submit the suggestion for the consideration of those interested in the experiment.

PLANTING IN MATALE EAST AND LAGGALA.

(Continued from page 218.)

LAGGALA GAP AND THE TRAFFIC BETWEEN EAST AND WEST—RAMA'S ARROWS—A NEW WORLD; THE COUNTRY OF THE SEA OF PIKRAMA—A LAGGALA BURGLAR AND AN ARACHCHI AFTER A LICENSE TO SHOOT HIM—THE STORY OF 3 TREES VALUED OFFICIALLY AT R768—A PLANTERS' MODEL BRIDGE ON THE TELGAMA-GANGA. Of all the "Gaps"—and there are some half-dozen altogether—leading across the mountain range from Matale East to Laggala, that belonging to the path from Rattota village through Dangkande and Laggala estates seems to have been longest in use. Indeed it belongs to the ancient village path traversed by the Sinhalese for generations if not centuries before the Kandyan forests were invaded by European planters. And to this day, as we had evidence at almost every turn of the road, there is a very considerable native traffic between the large native district on the East of the range and Rattota and Matale towns. A good deal is done with the aid of tavalam bullocks, chiefly owned by Moormen, but still more by Sinhalese men carrying each his own burden, chiefly small bags of paddy or kurakkan, slung over the shoulder, brought across to sell or barter for curry stuffs, cloths, &c. in the Matale bazaars. It quite surprised me in a couple of days' journey to see the number of men engaged in this traffic, and the large quantity of grain that must in this way be supplied from the eastern districts. The Laggala route through the forest being so well-known it was no wonder perhaps that hereabouts some of the earliest coffee pioneers commenced work. The neighbourhood is redolent of the names of Tytler, Strachan, Mackay, Jolly, Duncan, and many more of the early days. The grand Dangkande rock and mysterious Laggala Gap—cut, according to Indian tradition, by a stroke from the shaft of Rama while engaged in the search for his lost bride Sita,—have ever been objects of more than ordinary interest. Splendid crops of coffee were grown on Dangkande as on the neighbouring Cattaratenne estate in bygone days, and now both are gradually but surely being covered with a green mantle of tea, fresh and vigorous-looking. The carefully planted young tea-fields on Cattaratenne are especially a sight to see in their promise of good things to come. So far, Mr. Watson on Dangkande has the only regular tea factory in the locality and it receives the leaf from a good many other plantations, including Moncrief which is ten miles distant on the outermost shelf of the North Laggala range. This is, I suppose, about the greatest distance tea leaf is carried by coolies in Ceylon and yet, I did not hear that there was appreciable damage. The journey is made easy for the coolies by relays from the Dangkande end, meeting them half-way, so dividing the trip. Of course the arrangement is only temporary, hectore on the other side being only a question of time. Indeed Laggala estate proper, with 500 acres under tea of its own, will want a very considerable factory, already planned, and a steam engine which will cost a pretty penny to

get carried up in parts, no matter how divided, from the end of the present cart-road. Twenty or twenty-five per cent of the cost is likely, we believe, to be swallowed up in transport! and the present path will have to be widened and strengthened so that elephants may be employed to drag up cylinder, boiler, &c. "Oh! for a cart-road," Mr. Reith may well exclaim, or better still the Lartigue railway if it could only ensure the economical carriage of heavy pieces of machinery. The course proposed for the Lartigue was pointed out to me from time to time in crossing the valley and ascending the hill-sides; but I could not help expressing the opinion—shared in the district I found—that it would be much more advantageous to the traffic of Matale East and Laggala, if this line were first projected from the end of the existing cart-road at Rattota, in place of from Matale town! The question of solving the transport difficulties of the several divisions of this part of the country is not an easy one to face, but some relief is certainly very urgently called for. Dangkande (once the property of Tytler and Strachan) was the scene, on a piece of flat, when held by Mr. Borron, of a rather extensive experiment with arrowroot, but as in so many other trials of minor products, the result was not financially satisfactory. The climb of a thousand or 1,200 feet from Dangkande to the Gap is as steep a bit of riding as any in the island; but on a clear day, the view backward over the wide extending Matale valleys, across to the Matale West and Kurunegala hills, and to the circle of higher ranges to the south-west, well repays the traveller. Alagala presented a new side and shape so as to be scarcely recognisable; while Yakkessagala indicated the site of the capital of Seven Korales. On the way up, a big cavern under a great mass of rock is passed, and here we are told an ambuscade of rebels took up their position during the troublous times of 1847-48. A headman on the Laggala side was one of the most determined foes of the British, and the Matale East estates of that day were nearly all taken possession of in the name of the upstart "king." The exception was that in which a surdy Scotch Superintendent objected to give up charge to a native rabble, saying he would just remain and look after the place for the "King" himself, and in another where though the "durai" had bolted into Kandy, the bungalow servants dressed up a figure in master's clothes, sticking a newspaper in its hands, and so assured "the rebels" that their Mahatmaya was deeply engaged reading in his verandah, and that he was such an angry man as to shoot anybody who disturbed him while so engaged! This made a sufficient impression; for finding that their coughs at a respectful distance had no effect in attracting the irascible Mahatmaya, the rabble (whose only object was loot) went away without entering the bungalow at all! So much for the so-called rebels.

Poor Watson Duncan with his hearty honest genial ways, how he would have rejoiced in this lot, after all his struggles with coffee and cinchonas on his Laggala property. Cinchona flourished here for a long time as it did on few other places, Duncan complaining of his 14 years old trees never giving him any seed; but they have long ago been cut and the bark utilised, and now tea covers the fields on both sides of the range. But if the look westward and southward from the Laggala Gap at 3,500 feet (?) satisfies the visitor, what shall we say of the new world revealed by the very few steps which carry one over the ridge? Looking down from this proud eminence over the cultivated tea fields of Laggala interspersed in the most picturesque way with grassy downs, and

clumps of forest, the eye passes on over a wide extent of diversified patana, rolling grassy slopes, sholas of forest and isolated hills to the grand expanse—a continuous wilderness—of forest which runs away to the sea margin on the far East. As Tennyson puts it, from Laggala eastwards we viewed,—

A land where all things always seem the same!

Looking to the north-west, the region of the ancient sea of Prakrama is before us. Glints of silvery brightness in the wilderness indeed mark the course of the waters of the Mahaweliganga, and by-and-by a big patch of brightness reveals Minneri, while certain landmarks define the site of Polonnaruwa. The change within a few seconds from the West to the East is indeed startling, and the diversity of views as we proceed along the range, unequalled. I could quite understand however, how, in the full fury of the south-west monsoon, the wind must tear down the several ravines and steep slopes on its way to fill the vacuum in the hot lowcountry. But fortunately the damage to tea is far less in every way than to coffee—at the most affording only such a rest to the shrub for a month or so, as might be given by a light pruning. Passing on through Mousaheria, Pittawelloya, Hattanwella and afterwards Marnagalla and the Telgamas, I saw where wind had done its worst in the coffee era to the destruction of the hopes and purses of Hope, Wingate, Beckett, Cato and others. Wingate's nice avenues of oleanders still flourish—though the shrub is an objectionable one on a plantation—but, alas, for the poor patches which remain of what was once the staple of cultivation. Looking back to far distant Monerief, I am reminded of the warning given to Mr. James Wright on his way to explore the jungle by a companion who learned that ironstone prevailed on the Laggala side. They met several natives carrying blocks to be smelted in the Matale valley and the visitor decided that an iron country was not the place to grow coffee! For tea however, we know from experience in Ambagamuwa, Balangoda and other districts how compatible a ferruginous soil may be with heavy crops of leaf, yielding a desirable liquor. The present laird of Hattanwella (who has acquired so high a reputation on Hooloo as a tea-maker) is opening quite a number of clearings, and he would treble his acreage if only the cart-road were extended; but it will be hard for him to open any new clearing to beat his present little field on the flat with its vigorous growth of bush.

Spending a night at Hattanwella with the intelligent Superintendent, it was amusing to learn that the epidemic of burglaries which has so long infested the capital, has its counterpart amidst the sequestered, peaceful villages and plantations on the Laggala side. Laggala residents were unanimous in holding that a better behaved, more virtuous people than the Sinhalese below them in the valleys could not be found in Ceylon. When robberies from bungalows, stores or coffee-fields took place, the culprits were invariably traced to the other, the Rattota side of the range. They used in the time of coffee crops to make raids over the hills especially on moonlight nights. But of late, one particular rogue had developed among the Laggala villagers themselves. He must have got his training and villainy from the "civilized" side of the country; but he chose to carry them back and exercise them on his own people. The result was a whole series of depredations and disturbances and yet though every village was annoyed, the simple folk would neither arrest, nor give proper information to lead to the capture of the robber, and the Arachchi of the neighbourhood was

at his wits' end. He had come to consult Mr. Burnet as to what was to be done? The whole country side could not have its peace, and properly risked for one man. The Hattanwella "mahatmays," no doubt with a twinkle in his eye, suggested as the only sufficient (and legal) remedy, that the Arachchi should proceed to Matala and apply to the Agent, Mr. Burrows, for "a license to shoot" the rogue "Mudiyanse," who was certainly a greater public nuisance than any wild trespassing buffalo in the district. The Arachchi took the counsel quite gravely; it met with his full approval; it looked a legal as well as equitable course of procedure and he made up his mind to visit Matala—with what result we have yet to learn. The general opinion was that the face of the Assistant Agent would be worth photographing when he received the application of his worthy headman!

But if planters can get a little fun out of headmen, they certainly get a *quid pro quo* sometimes. On my way up to Dangkande, I passed, on a piece of Crown patana, three stately but solitary trees of goodly appearance, about which there hangs a tale unprecedented perhaps in the annals of timber, red-tape and Kachcheri business in Ceylon. Mr. D. Watson, the manager, being in want of timber, in place of cutting down stray trees which could scarcely ever be missed, did the honest thing in a formal application to purchase these three particular trees; it was referred to the headman for report as usual, passed on to the Kandy Kachcheri and from thence came the required permission on payment of 768 rupees as the appraised value of the said three trees. Anything more provocative of fun among practical men at the expense of dry-as-dust officials could scarcely be imagined. The headman, no doubt, was a clever fellow in his way, but that there was not sufficient humour at the Kandy headquarters to understand the joke of valuing three trees away up on the side of the Lagala range at R250 a piece, is passing strange. Had Mr. Watson sent ten rupees for each tree with his application, he would certainly have done handsomely by the Crown and general revenue.

(To be Continued.)

WHAT IS A THOROUGHBRED ARAB?

By the Editor of the Quarterly.

Sir, It is a curious fact that in the Bible no mention is made of horses in connection with Arabia. When the Israelites came in contact with the tribes of the desert, as the Midianites, we find that such tribes had plenty of camels, asses, oxen, and sheep; but no horses are spoken of. At a later period, when the Midianites made hostile forays upon Palestine, "their camels were past numbering," and even their chiefs rode only upon camels (Judges vi. and viii.). In the days of King Saul, when the Jewish tribes beyond Jordan fought for the pasture grounds with the Arabian nations, the victorious Hebrews took 50,000 camels, 500,000 sheep, 2,000 asses, and 100,000 oxen; but still no horses are mentioned (I. Chron., v. 10, 20, 22). When Solomon was forming a body of cavalry it was from Egypt that they were recruited (as the writer of the paragraph in the *Quarterly* remarks), although naturalists have often supposed that Arabia was the native country of horses. The Arabs themselves say that their best breeds are descended from the stall of Solomon, a tradition without any solid foundation but it seems at least to involve an admission that horses were used in Palestine earlier than in Arabia. Strabo, the geographer, who wrote some 100 years after Christ, was expressly stated that in Arabia there were no horses in his time, camels supplying their place. I am sorry I cannot give a direct reference to the passage in Strabo where he makes this state-

ment, but I am quite certain he does make it; and in all cases where he had personal experience he is thoroughly reliable. If, then, Strabo's statement be true, it entirely upsets the theory that "the Khamsa is descended from one of the five mares of King Solomon." When the Arabians began to pay attention to the breeding of horses, ever has been, is, and probably ever will remain a mystery but it is certain that horses, wherever they came from, were numerous and highly valued in that country in the time of Mohammed (*vide* Dr. Kitto). Yet it is singular that the Patriarch Job gives a glowing description of the horse as used in war: "He paweth in the valley, and rejoiceth in his strength; he goeth forth to meet the armed men. He mocketh at fear, and is not affrighted; neither turneth he back from the sword. The quiver rattleth against him, the glittering spear and the shield. He swalloweth the ground with fierceness and rage; neither believeth he that it is the sound of the trumpet. He saith among the trumpets, Ha, ha; and he smelleth the battle afar off, the thundering of the captains, and the shouting." (Job, xxxix. 19-25). (I have quoted this passage at length not only for its great beauty but also because it goes far to confirm the opinion of those who place the scenes of this ancient Book in the deserts towards Mesopotamia.)

Bacon knew nothing about horses, Shakspeare did. At the present time when such strenuous efforts are being made to tear the laurel wreath of Genius from the brow of Shakspeare and plant it on Bacon's head, which already is adorned with quite as many as it deserves, I feel sure you will excuse my endeavour to enlist the sympathy of our very horsey fellow-colonists for Shakspeare, by concluding this letter with his opinion of what are the qualifications of a good all round horse, though the quotation be somewhat irrelevant to the subject matter in hand:

Round hooped, short jointed, fetlocks shag and long;

Broad breast, full eyes, small head, and nostrils wide;

High crest, short ears, straight legs, and passing strong;

Thin main, thick tail, broad buttock, tender hide.

—I am sir, &c.,

JOHN NELSON.

Hillsborough station, 26th July.

INDIAN TRADE IN 1886-7.

FROM A PLANTER'S POINT OF VIEW.

The Indian Administration reports for the 1886-7, which, having just come to hand, are not very fresh or very light reading. People have almost forgotten the period with which they deal. Nevertheless, in some respects, they are instructive, and if they have taken a long time to compile, the reason is that the mass of statistics with which they deal is not easily ascertained or quickly arranged. Under the head of manufactures, mines, and industries, we observe that the export of indigo showed an increase of 15½ per cent., but prices fell heavily, except in the descriptions suited for the American market. The increasing production of Java indigo, the quality of which is said to rival the best produce of Tirhoot, has seriously affected the Indian trade, except in the exports to the United States, which showed the largest figures on record. Of course tea developed largely in the period referred to, and the statistics on the subject are ancient history. The Assam reports show a total production in that province of 61,719,678 lb. during the year 1886-7. This, added to the 16,500,000 lb. from the British territories, makes a grand total of over 78,000,000 lb., as against about 15,000,000 lb. in 1872—an actual and development of production. Chinese tea cultivation sprung seriously from a hardship in Darjeeling, when some and buried 300,000 trees, including some of the best on the estate. In the earlier part of the century 25,000 promising young trees were destroyed by a hailstorm. Taken at from a purely commercial point of view, the year has been a bad

one for the producer, the price of quinine, and consequently of all cinchona products, having fallen to the lowest known limits. The increase in the crop from Ceylon, where the growers were preparing to plant tea, is held unaccountable.

The decline of the sugar industry in British colonies continued to hamper the emigration agencies working in Calcutta. Only three British colonies, Demerara, Trinidad, and Fiji and the Dutch colony of Surinam indentured for labourers in the past year. In Jamaica immigration has been entirely suspended; the prospects of sugar manufacture in Natal show no sign of improvement, and in St. Lucia were so bad that some of the central factories will be forced to abandon operations. In the latter colony the Indian coolies suffered severely from malarial diseases and want of work but the authorities refused to sanction the departure of labourers no longer under indenture to Panama where high wages, which have attracted large numbers of immigrants from Jamaica, are paid on the canal work.

For railways the year was one of consolidation and completion rather than of new work, only 62 miles of new line having been opened for traffic, principally on the Assam, Behar, and Tirhoot system.—*H. & C. Mail.*

ASSAM AND ITS TEA GARDENS.

The report of the administration of Assam for the past year illustrates the theory of the survival of the fittest. While the amount of land under tea cultivation is increasing the number of gardens is decreasing, owing to amalgamation and other influences. The average size of the Assam gardens is increasing year by year, showing combination among owners or more capital, and the small cultivators are disappearing. There were 883 gardens in 1886 and 873 in 1887, although new gardens were opened during the latter year. Even more was done in previous years to amalgamate gardens with a view to economy and convenience of working. The total area under tea cultivation in 1887 was 950,171 acres—an increase of 16,037 acres over 1886. In 1882 the area of the gardens was 783,362 acres. These figures represent the areas held by the tea planters, and either not yet worked at all, or in one or other of the various stages between jungle and productive and saying tea garden. The area under mature plants last year was 177,900 acres, and under immature 33,179. The area under mature plants increases steadily in Assam; in 1882 it was 156,707 acres, 1885 159,876. The total tea production of the province for 1887 is given at 68,451,130 lb. an increase of 6,731,502 lb. or 10.91 per cent. over 1886, and more than double the production of 1885. According to the figures of the Indian Tea Association, Assam produced 74.89 per cent. of the whole crop of Indian tea in 1887. The yield per acre for the whole province was 335 lb. for the year, as compared with 363 lb. in 1886. The tendency of the cost of production is to decrease with the improved communications and methods of cultivation and manufacture. More is obtained from the soil at less cost, it is handled more cheaply and effectually, and reaches the consumer by more economical communications. The price is now lower than it ever was before, yet the planters are doing fairly well as regards profits. The explanation is that the tea can now be turned out for less than was possible a few years ago. The use of machinery of an improved character is now largely extended, while freight and cost of transport are much less. The coolies are growing older and more skilled in their work, and can do more, and far better, than they could when raw hands. The Indian Tea Association estimate that Assam will produce 70,975,884 lb. this year, out of a total Indian crop of 95,829,312 lb.

THE GOVERNMENT JAVA COFFEE CROP, this year, is estimated at 545,000 piculs. Most of it has already been garnered. This result is an agreeable surprise. The contrary had been counted upon.—*Straits Times*, Sept. 5th.

THE IMPORTATION of coffee plants into Tonquin has been prohibited, the object of this measure being to prevent the introduction of the coffee plant disease.—*Hongkong Daily Press*, Aug. 30th.

TOBACCO.—It is interesting to note the gradually extending field of selection of Tobacco lands in British North Borneo. At first Sandakan and Marudu Bay, then the Sugut and Labuk Rivers and Darvel Bay, followed by the Segama and now the Kinabatangan. The last, the largest river in the territory, must have a large extent of suitable land for Tobacco on its banks and the means of transport afforded by its broad stream will be a strong point in favour of an inspection and possible selection. All these districts belong to the East Coast. Who will pioneer the way for selections on the West Coast? Prices for Tobacco have, so far, ruled somewhat low but already a rise has been noted and the reason alleged for the previous low rates is said to be owing to want of competition from American buyers. The crop of Tobacco for 1888 from Sumatra is estimated at 200,000 bales as against 180,000 bales in 1887.—We hear that Mr. J. van Gogh who applied for a concession of 10,000 acres of land on the Segaliud River on the 6th March last has since sold his concession to a Company for 115,000 guilders, say over \$50,000. In other words Mr. van Gogh has made a profit of over \$40,000 in less than five months. The choice of the land was due to the making of a road trace from the Segaliud to Kinabatangan which enabled the Commissioner of Lands to take Mr. van Gogh and his skilled Tobacco planter, Mr. Merchistein of Deli, straight to the block and Mr. Merchistein promptly made the selection which has already been attended with such happy results to the lucky purchaser. We learn that Mr. van der Hoeven has already formed a Company to take up his concessions of land on the Labuk River and has received a sum of 60,000 guilders in cash and 120,000 guilders in shares. This is good business. Mr. van der Hoeven is expected out shortly to commence planting operations.—*British North Borneo Herald*, Aug. 1st.

TOBACCO PROSPECTS.—The following report is of interest to Ceylon tobacco planters. It is from Consul Robinson, Amsterdam, to the Marquis of Salisbury.—“The tobacco trade during 1887 was large, brisk, and profitable. Our market has become more and more the principal one in Europe, in consequence of the excellent quality of the Sumatra tobacco, which is sought for here by buyers from all parts of the world, and especially by the American cigar manufacturers, and of the large amounts of Dutch capital invested in the plantations of Sumatra, Java, and Borneo, the extent of which is daily increasing. The crop of 1886 was the largest hitherto known. Sumatra sent to Holland in 1887 138,000 bales, value £2,660,000, as compared with 125,000 bales, value £2,300,000, in 1886. North America alone purchased for £1,160,000. Prices slightly improved, partly in consequence of the demand for the finer qualities for cigar-making, for which extra rates, were paid. The measure taken by the English Government, fixing 35 per cent. as the limit of water to be added by the tobacco manufacturers, was a severe blow to the sale to England of Java tobacco, the absorptive power of which is very great. Borneo is now beginning to send some tobacco of excellent quality, and the produce of British North Borneo is now looked forward to with much interest. The dividends of the more important Sumatra tobacco companies were again very high—the Deli Company 109 per cent. per annum, and the Arendsburg Company 169 per cent.”

CACAO (COCOA) PLANTING IN CEYLON.

A LECTURE DELIVERED AT MATALE ON THE 30TH JUNE 1888, BY MR. J. H. BARBER.

It is not my intention to devote this paper to the consideration merely of such cultural details connected with cacao planting as may be readily gleaned by reference to that most valuable publication, the *Tropical Agriculturist*, or any manual treating on cacao cultivation generally, but to raise for future discussion at our Agricultural Association, as far as the limited scope of this paper will permit me to-night, some of the vexed questions connected with the cultivation of this product, on which it would be desirable to have the experience of planters—facts that should be more generally known and more generally discussed: although they may be within the knowledge and experience of managers of the older and leading estates of the Island. Indeed this want is one that can be easily supplied by an institution such as the Matale Agricultural Association, with the experience that its members have already gained in cacao cultivation. By meeting here frequently, and discussing agricultural matters, not only will benefit accrue to us individually and directly; but in the end it will follow that we shall, by promoting the cultural industries of Matale, help materially to the prosperity of a part of the Island which holds great potentialities, and is waiting only for enterprise and capital to develop its resources. With its rich soil and forcing climate, there is no tropical plant that cannot be cultivated here. Cacao, tea and coffee as articles of diet; pepper, cloves and nutmegs as spices; and even the costly tobacco and the rare vanilla had a home here, while the graceful areca palm, shading the humble homestead of the poor villager, flourishes here with a luxuriance that is matchless.

In such a district as this, at a happy moment the idea appears to have suggested itself to the promoters of the Agricultural Association to call it into existence. And it is now left with us to make it really useful, and subservient to our best interests, by making the fullest use of our opportunities.

We can also, I think, always rely on the ready support of the Government, and of those who will, from time to time, be connected with our Royal Botanic Department. The desire to support the planters in the colonies is a feeling not merely confined to the incumbents of our local garden in the Island, but one that emanates from higher quarters; in fact, from the very fountain-head at Kew.

In a letter addressed to the Colonial Secretary of Jamaica by the Director of the Botanical Department there, dated 28th October 1881, I had embodied the views of the Director at Kew as regards the West India Islands, which have more than a local bearing, and which convey encouragement to all colonists alike; showing how keenly alive he is to the necessity of publishing information and of promoting new industries.* These are his suggestions:—"In addition to distributing plants, there might be encouraged at the Central Institution a regular system of botanical bulletins, containing practical hints as to the treatment of economic plants, and the conditions under which they might best be utilized as objects of remunerative industry."

"There is no doubt a great want felt in the West Indies for reliable information on the culture of new economic plants; and to ensure success it will be necessary not only to supply seeds and plants, but also careful, compiled and plain practical hints as to

the means to be employed for rendering them of the greatest value."[†]

These are the views of Mr. Thiselton Dyer, now Director. We in Ceylon cannot say that this want is not felt by us here also at times: and that the Botanical literature of the Colony, although extensive and varied, is all-sufficient for our wants. There are occasions, indeed, when we do wish for more information and more help. It was only last week that I was travelling with a Matale planter who, speaking of tobacco culture, told me that he intended going all the way to Sumatra, for want of sufficient information here. I daresay the Director of the Royal Botanic Gardens, who has given this subject his attention already, will feel it his duty to give it fuller attention now, and also to afford us hints regarding the curing of the leaf. I will refer to another instance. How many planters are there in Ceylon who cultivate cubebs (*Piper cubeba*)? We all grow pepper here at Matale, and there is no better district for it than this; and cubebs grow where pepper grows.

In 1855 the price averaged for cubebs was 77/6 per cwt.; then it came down for a while, and in 1880 it went up again. Since 1880 the price has steadily gone up, and good genuine cubebs in 1886 realised £20 to £22 per cwt. But who grows it? you ask. In Java small plantations are specially devoted to cubebs. They have also been latterly cultivated by European planters on coffee estates.† But I fear our getting this variety of pepper is a difficult matter. Dr. Trimen was written to by me for this plant about a year ago. He had not then the plant to give me, and his reply was not by any means calculated to encourage me as regards its cultivation, owing to the fluctuations in price. Here it ended, although I was prepared to give anything in reason for seed or plants, to start it in Matale.

The next reference to it that I find is in his report, which I shall read to you:—

"It is by no means easy to obtain the true *P. cubeba*, which is a plant very little known and indeed very imperfectly understood, even by botanists. Several other plants approach it very closely, and even at Kew the cultivated plant hitherto believed to be *P. cubeba* and figured by me under that name in 1877 has since been determined to be another species." And so it has. It has been proved to be *Piper chaba*, Hunter, or *Chavica officinarum*, Miquel, belonging to the long pepper group.‡

The learned Doctor, however, gives us the comforting assurance that he is now endeavouring to obtain seed from Java, stating that hitherto the difficulty was due to the cultivation being in the hands of the natives. I shall give you his very words:—"I am now attempting to get ripe seed from Java. But it appears to be difficult to obtain this from the natives."

It will be found that much of the information contained in this part of the report of Dr. Trimen is drawn from the Kew Gardens Bulletin for Dec. 1887, from which I have just read to you, and from this you will perceive, if the bulletin be correct, that the cultivation is not now entirely in native hands. And we may now be said to be in a fair way towards getting this much-prized variety of pepper, in, say, another eighteen months or so. It is matter for great satisfaction and rejoicing to know that we shall shortly be in the running with our luckier neighbours at Java; although the full period of ten years will have elapsed, when we begin growing this pepper, from the date at which cubebs began "going up in price steadily" (1880). And one is casually reminded of the time consumed in the siege of Troy; in the early history of warfare, before the invention of gunpowder, and the knowledge of steam and electricity. This merely as a coincidence.

I have referred to these facts to show you how necessary it is for us to devise means, by concerted action, to help each other, and the Government ultimately, in developing the resources of our Island.

* Italics are mine.

† Kew Bulletin, Dec. 1887. Italics are mine.

‡ Kew Bulletin, Dec. 1887.

* Kew Bulletin for June 1887. Botanical Stations in the West Indies, p. 7.

With these preliminary remarks I shall proceed to the subject I have chosen for discussion today.

We need not wait to inquire where cacao will grow in Ceylon, and where it will not.

Everyone knows that it will not grow in Nuwara Eliya; and that it does grow in Uva on the one side; and on the other side from Dolosbage down to sea-level, embracing Peradeniya, Dumbara, Matale, Kadugannawa, Rambukkana, Polgahawela, Kegalla, Veyangoda and so on down to Colombo, and even Negombo. I obtained some pods from that district, not long ago, sent to me by Mr. F. Driberg, which were remarkably fine of their kind. But it may not be generally known that about thirty or thirty-five years ago there were cacao trees flourishing in Colombo. I remember, among my earlier recollections, seeing two trees growing in Small Pass, Colombo, bearing freely and flourishing for a long time. This was in a property owned by Mr. John Van Dort of the Surveyor General's Office, father of the Artist and of the Doctor, both so well known in Ceylon. I also remember a tree in Kalutara, standing not far from the Post Office. This tree has stood there for many years, yielding heavy crops.* And all these, as far as my recollection serves me, were of the original type that was long after shipped to London from Rajawelle and Pallekelly. Indeed, if it were otherwise, it would have been noticed earlier.

A question that very naturally presents itself to the cocoa planter, at the very threshold, is one regarding the selection of seed for planting [his estate with]; as the commercial value of the future crop and the profits accruing to the enterprising planter will be determined by the variety selected by him.

We have of late all taken up the cry of "*Forestero*" neglecting the much-prized so-called *Caracas*, which gave Ceylon cacao such a reputation, as soon as it went to the London market. How far we shall suffer hereafter when all Ceylon estates take to shipping the coarser variety in large quantities can be only a matter of conjecture just now; but this much is clear, that we seem to be actuated by the idea that cocoa being such a paying concern, we can afford to be content with even less for our crops, so long as we can grow some sort of cacao with a little more success, and with a little less risk than heretofore. Indeed, we could be quite content with the old red pod that was universally planted in Ceylon at first, but for its extremely delicate habit, and the difficulties attending its successful cultivation.

We have, after years of experience, thought it desirable to neglect this variety for the *Foresteros*, just as the West Indian planters, in their day, went from the one to the other for the same reasons.

With what material advantage to individuals and to the Colony we are adopting this sweeping change time alone can show, with heavier shipments of the *Forestero* from our quay; though I suspect there are many here who would still prefer the neglected old red pod, if they only had the choice of land. But much of our best land is in the hands of the Sinhalese villagers as gardens, or has been ruined by chena cultivation. Talking of chena cultivation and the ruin to land, let me pause here to remark *en passant* that I fear this will be the fate in reserve for the lands taken up extensively for tobacco cultivation: if it is cultivated here as in Sumatra; and if timely measures are not adopted by the Foresters and the Legislative Council to conserve our forests for more permanent cultivation. The native tobacco planter in Jaffna, † Negombo, and other places, with the aid of heavy manuring, keeps his land always cultivated. But the planter who asks Government for a 1000 acres is likely to take the cream of the land from, say, a 50-acre block at a time, and pass on to the next block of 50 acres or more, and so on, abandoning the previous clearing; and well he may, after paying Government a nominal R10 per acre, and netting the splendid profits that tobacco is said to return.

* I have been told that it is still there now, and it is said to be over 50 years old.

† In Jaffna sheep are penned and fed on land cultivated with tobacco.—Ed.

But while we congratulate the individual who makes the most of his bargain in the shortest space of time, no one can regard such a system of cultivation as an unmixed blessing to the Colony; which has not after all an unlimited extent of land suitable for cultivation.

A system such as this, while it blesses the receiver, who flourishes on the accumulated wealth of the forest, hoarded up for him for centuries past, can hardly be said to bless the giver—the Colony, should acre after acre, tract after tract, and district after district be opened up, harvested and abandoned, as the chena cultivators did before. The absence of that permanence in the cultivation of each and every acre of land in the Island that is opened out, which is a condition essential to its continued well-being, cannot fail to tell on its prosperity ultimately. Every such clearing will be a blow at the root and foundation of its agricultural permanence.

To return to the subject in hand, with good cultivation and abundance of shade, the so-called *Caracas*, or red pod variety, continues to flourish in many places that I know of, and in one little place that I own myself, paying very fair returns and bringing high prices for their crops.

One argument advanced in favor of the new varieties is that the attacks of *helopeltis* can be better resisted by the *Forestero*, with its thick pericarp or husk to protect it. But I have seen this fastidious bug, which evinces such partiality for the food of gods, quite indiscriminating in its attentions, when it narrows down to a question of variety only.

You will all remember how this bugbear created a panic among planters a few years back; and the report by Mr. J. R. Martin of Yatewatte, to the Planters' Association in 1885, where he stated his conviction that "the scare which was raised by the discovery of its devastations was altogether unjustifiable." About that time I visited an estate at Kadugannawa, fully planted with *Foresteros*, belonging to Mr. Ferdinandus of the Royal Botanical Gardens, Peradeniya, a Sinhalese gentleman of much botanical experience, from his long connection with the gardens, and withal a practical planter.

When I went there, his coolies and conductor were employed in burying his entire season's crop for manure, under the very trees that bore it: so virulent was the attack. But it has all blown over now, and no one speaks of the mosquito bug seriously.

Now, the question is: if it is essential to our safety that we should grow *Forestero* and not *Caracas* (I will call this variety *Caracas* for distinction), is there any particular variety, or more than one, out of the many we have, that can take the place of this so-called Ceylon *Caracas*, of such unquestioned excellence? Now the *Foresteros* are admittedly a coarse variety; and their beans cure darker than the *Caracas*. They cannot be said to have the same commercial value.

I know, for a fact, that of the many West Indian samples that were sent to me from "Mincing Lane," by my agents some years ago, of cocoas that had just then passed the hammer, the *Caracas* stood away from the rest in price. And this was a bright small bean like ours.

Further proof of the superiority of our red pod appeared in a report from Messrs. Rucker & Ben-craft as far back as 1881, when shipments from Ceylon were beginning to attract attention in the Lane. The *Observer* noticed it specially, and gave it prominence at the time.

"One little parcel of Ceylon marks Amba and Palli fetched the fancy prices of 100s to 100s 6d. This cocoa is much liked; it has the true rose color, and the husks are light and fragils."

So that if the common red of Ceylon is not the true *Caracas* botanically, it still ranks in commerce as its equivalent from Ceylon.

If we can now only obtain such a variety of cacao as will combine the excellence of the *Caracas* with the hardy habit of the *Forestero*, this will be the variety to be fixed upon for general cultivation. It is well known that we owe our best flowers and vegetables to the skill and care of seedmen, who

devote their closest attention to hybridisation—a study that has for a long time engaged the attention of the naturalist, and one now systematically practised by the gardener as a means of plant improvement. We are told that “the first apples planted in America by the earlier colonists retrograded, until the fruits were no better than ‘crabs.’ Now their apples are equal to any in the world.” (Paper read by Mr. Pink of the Botanic Gardens on the hybridisation of plants, before the Royal Society. See *Tropical Agriculturist*, April 1885.)

At the last Autumnal Show of the Royal Horticultural Society, there were exhibited no less than 125 sorts of that homely vegetable, the potato; of these, 47 were produced by one firm alone, of which 27 were already introduced by them among their constituents. I daresay you are aware that a tomato has now been produced by Sutton & Sons which can be grown in the open, in England, as it is grown here. (Sutton's Catalogue for 1888.)

But just in the same way that we have obtained by chance hybridisation valuable varieties of cinchona and tea, it is possible that later on we may obtain varieties of cacao, better than those we have; though I am inclined to think that we have already certainly one variety (although there may be more) of great value for future general cultivation. The *Forestero*, known commonly as the pink *Forestero* is, I think, undoubtedly a hybrid. It is a noteworthy fact that while some of its seed share with the *Forestero* in color, there are others quite white, like the Ceylon common red (so-called *Caracas*)—others again are neither quite purple nor white, but shaded pink or violet. This diversity exists sometimes in the same pod.

I remember shewing this singular phenomenon to some brother planters, at the last Matale Exhibition, who had not noticed it before.

You will all remember the magnificent pods that came from “Gonambill” estate; it was there among them. I think it worth our while collecting information on this subject. If a separate sample of this can be cured by those who have enough of it, and have the same valued, it would add to our information, materially.

A Matale planter, Mr. Purdon, writing to me the other day on cacao, also makes reference to a variety that he has, as one which he considers to be a superior sort of *Forestero* or a variety of *Caracas*. From what appears in the letter, I presume it to be a hybrid of much value, whether it is the same that I am talking of or not.

Here is his letter, which I think will be of interest in our investigation, as fresh evidence from an unexpected source on the same question:—

“The pods are not *Forestero*—so says Dr. Trimmen—but pink or yellow (I forget which) *Caracas*. The former is, naturally, purple in the bean, but these ones are, or were, all white when cut across. Many, once white, are now purple, having hybridized, but that does not seem to have affected their commercial value, because they retain the bright golden color outside, when cured. The ordinary *Forestero* usually cures dark.”

Talking of this pink *Forestero* variety as a specially fine one: about 18 months ago, when I was collecting seed for the “Ukuwela” nurseries, I was strongly urged by a friend of mine, who was an advocate for another variety, to come over to the plantation under his management,—which was one of our older plantations—and see how well his own favourite variety did. He had been all along supplying me with the pink *Forestero* (which I shall, for the sake of distinction, here call the hybrid variety). Well, I drove down to the plantation one morning, and after we had examined carefully the two varieties, it appeared to me that the hybrid had another advantage, quite apart from the question of quality, over the favourite variety of my host, which was the Maravilla or green long pod. By way of test I took a number of average-sized pods of each variety, and proceeding to the office, took out the seeds of the respective pods and weighed them separately. We also weighed the husks, and it was then found that

relatively, in proportion to the weight of husk, there was a preponderating weight of seed in the hybrid over the Maravilla. In respect to the seed contained in each pod also, we found that the hybrid weighed more than the Maravilla. The Maravilla contained the larger number of seed; which again gave the advantage to the hybrid in size of bean, which enhanced its commercial value.

Now this variety that I am talking about, it may be of importance to know, is not to be found in the group of *Foresteros* at the Peradeniya Botanic Gardens. These came into the Gardens from Kew in November 1880, and I have watched them ever since with the greatest interest.

It must also be mentioned that the pink *Forestero* hybrid I am speaking of was then with me, at my little property in Dumbara. This was a plant obtained by me from Mr. Ferdinandus from his own garden. He, in the year 1875, received from Mr. Wm. Rollo, the visiting agent, and for sometime manager of the Ceylon Company, Limited, one of two cases of plants that were brought out from Trinidad. A dozen plants were successfully brought to bearing by Mr. Ferdinandus, all foreign, and different from the common red cacao, and one of these turned out to be the cacao known to many of us now as the pink *Forestero*, and which I conclude to be a hybrid between a *Forestero* and a true *Caracas*. Pods from this tree were sold by Mr. Ferdinandus ever since, year after year, to many planters. And I believe Wariapola, as well as the Dumbara estates, obtained this variety from him, as I did myself afterwards.

I now come to the details of the nursery. There are various ways of making nurseries, but I have found the following mode the safest, and the cheapest in the end. Two ordinary half round tiles, tied together with a bit of coir rope. These make a pot fully a foot long, giving both taproot and laterals ample scope to establish themselves. But the principal advantage is that in the transplanting, the plant can be placed in its future home, without the slightest molestation. The tiles are withdrawn one after the other, and sent away to cover your bungalow or store, or extensions in your coolly lines. Thus your pots cost you nothing in the end. I planted about 75 acres last year, and over a 100 this year in this way, and not a single plant was lost, except what was chargeable to the omnivorous white ant, and he is one of the most formidable enemies that the cacao planter has to contend with. If he is omnivorous, he may be said to be also ubiquitous; and his working hours spread over the entire day, and the night as well. He works with an unflinching industry; and his name is Legion. To destroy or to circumvent this unrelenting foe, has been the fondest wish and prayer of every cacao planter that I ever met. But to no purpose; you may clear the ground of all the twigs and branchlets; you may even sift your soil, as I did for the nursery; but you will not exclude his presence. He attacks your plants when he has no twigs to fall upon; and where the ground is strewn with a plentiful supply of rubbish, he then seems to turn in a spirit of mischief, or from sheer fastidiousness, to your much-prized plants of *Forestero* (from pods purchased at R25 per 100!)

The white-ant has no doubt his own special mission on earth: that perhaps of speedily converting twigs and rootlets and waste and dead matter into soil for the agriculturist; just as Darwin tells us the humble earthworm supplies us with so many tons of mould per acre per annum.

But all the same it is terrible to see, after your best endeavours to destroy this enemy, or to beat him off for a time, how he returns to the charge; rising superior to all your devices, and getting back to his mission, with a sense of duty, that is quite exemplary. Only that he is out of his legitimate sphere of usefulness when he attacks living matter.

Now there are one or two things which do not seem to possess special attractions for the white ant, and the neighbourhood of which he appears to avoid. One of these is said to be koroume; and koroume and water is used in some places regularly

But as the oil and water can only be said to mix mechanically, it is likely to follow, when the mixture is poured round the plant in a circle, that the water will gradually filter into the soil, leaving the oil globules more or less on the surface. As the white ant works down to six or eight inches below the surface, very often, it is doubtful whether this will answer as well as it is expected to. Information on this subject from those who have tried it may be of value.

A very good thing is found to be phenyle; a tar product which has the quality of being thoroughly soluble in water, and is a reliable insecticide. It can be mixed safely in a hundred parts of water, and applied at the rate of about three oz. to the plant. Its cost is about six rupees per gallon, and the cost of application per acre including phenyle may be said to be about 50 cents.

The poonac of the "kekuna" seed is another cheap remedy; and it is plentiful in the villages. Its odour is strikingly offensive; and white-ants keep clear of it.*

The saw dust of jak wood, mixed with the soil, round about the roots, has also been known to protect the plant; but with all these appliances one has to watch the plantation for the first two years with the closest attention and care.

The next important question is the one regarding shade. Now, although cacao can only be grown here successfully under shade, yet there is a period up to which it is found best to grow it in the open. They not only grow quicker; but with sunshine and light they grow more robust. There are times, however, during long droughts, early in the year especially, just after the N. E. monsoon rains have passed away, when one feels anxious. But it is worthy of notice that at "Ukuwele" my plants in the open survived the last drought without trouble, while plants near about trees that had been spared in the clearing needed all the attention we could give, to save them. The explanation may be that large trees absorb so much moisture themselves, that the little plants suffer more under them and near their roots, than elsewhere, from drought alone. But where there is dense shade from trees, all over a plantation, this is not the case; as the thick carpet or covering of decaying and fallen leaves preserves the moisture in the ground, while the exclusion of sunshine checks its rapid evaporation. But under dense shade, little plants take a very long time to attain maturity, and then they are attenuated and spindly in habit. It is therefore best to clear your ground entirely, and after planting your cacao, to plant your shade.

A tree we all know to be used in the West Indies for this purpose is the *Erythrina umbrosa* or "Immortelle." But we have our Ceylon variety; the *Erythrina indica*, or "*Eradadu*," which is at our doors, and seed of which the village boys will collect for you for a few cents. This I found to grow at "Ukuwele" quite nine feet in one year, at some places. Dr. Trimen strongly recommended me this variety, when first the question of shade was being discussed. The *Erythrina lithosperma* or "dadap" is also said to be a very useful variety, and seed of it can now be obtained in Ceylon. But I must not omit to notice a reference to this variety by the editor of the *Tropical Agriculturist* in May 1885:—"Nothing which I saw of the 'dadap' in Java impressed me favorably—quite the reverse indeed—and when I was in the Dutch Island at the latter end of 1881, the planters had transferred their love for it as a shade tree to the luxuriant but brittle *Albizzia moluccana*."

In the meantime, at distances of say about 36 feet apart, where we plant cocoa 12 feet apart, it will be found convenient to put in jak for shade. There are many advocates in this and other districts who stand by the jak; although there are some who do not like it. In 1881, Mr. John Drummond, writing

from Gangwarly, said: "I find the jak tree answer capitally." And many other cocoa cultivators, including Mr. Ross of Kawudupelle, have proved it a fact. We have also recently introduced into Ceylon the *Albizzia moluccana*. And I planted it in Ukuwele last year among my cacao. But this year when I went there to supply my last year's failures, I found that the *moluccana* had taken entire possession of the field, and was master of the situation. The cocoa holes in its neighbourhood, to an appreciable distance, were so completely filled with its roots, that the new plants of this year would not have had a chance, while those of last year, close by, appeared to be languishing and holding back; so the edict went forth, and they were all ruthlessly cut down, to make room for the generous shade of the *Madre de cacao*—*Erythrina*—a foster mother truly, under whose spreading arms cacao flourishes best.

I have been asked what I thought of the plantain (*Musa Sapientum*) as a shade, in the early years of cacao. The banana, we are told, is used for this purpose in the West Indies; and in Ceylon, in one or two places, the plantain has been tried with advantage to the cacao. But where there is other shade, that can be quickly grown, I would not employ the plantain. The one argument that is advanced in its favor is that it is not a profitless cultivation; inasmuch as its fruit may bring in returns for a couple of years. But against this there is, *per contra* in your account, the exhaustion of good soil which should be saved on your estate, as much as possible, for the product that is going to be a permanence; and which, when it is fifty years old, may be said to be still in its prime. Besides, when after a few crops of plantain, you decide on rooting the bushes up, and set about it, you will find the cost a far heavier item than you reckoned at first, as the bulbs will keep growing for ever if you do not get rid of every particle.

It has been pointed out that the plantain fibre may have a sufficient market value to justify looking more closely into the question.

I have considered this matter too, and fear it does not offer a sufficient inducement just now; unless indeed a paper mill is started in Ceylon.

The fibre industry has had some attention paid to it in the West Indies; and it was found that the plantain yielded in one place 1.81 per cent, and at another 2.25 per cent of fibre on the gross weight; and the fibre may be said to be worth about £15 per ton. There is a plantain (*Musa textilis*) out of which the manilla hemp is obtained, which is worth about £40 per ton. Regarding the plantain being used for paper making, Dr. King, Superintendent of the Royal Botanic Gardens, Calcutta, says: "I have ascertained by reference to a large English paper-maker that if it can be delivered cheap enough, fibre would be readily bought for paper making." (Kew Bulletin, April 1887.)

But we need not wait to inquire into this question further just now. The plantain, suffice it to say, is not only known to exhaust the soil, but I have heard from a high authority that its roots leave in the soil certain acid matter, positively injurious to vegetation.

So while we copy the example of the West India planters in some matters, it may be well for us to exercise our own judgment in others, and to be guided by that best of masters, one's own dearly-bought experience.

I must leave the subject here for the present, as the paper has been, I fear, longer than I intended it at first.

RUSSIAN AND AMERICAN PETROLEUM.

[Petroleum is becoming an article of so much importance in our market as a light-yielding material and a probable source of fuel, that we think it right to lay before our readers the following extract from a very elaborate paper on the substance as exported from the United States andussia respectively.—Ed.]

* Mr. Barber has told us in conversation recently that this is by far the best remedy. The *Kekuna* is a tree with beautiful silvery leaves cultivated near native houses for the sake of the oil-yielding nuts. Thwaites gave its botanical name as *Canarium Zeylanicum*.—Ed.

BY SAMUEL P. SADTLER, PH.D. *

American petroleum, or, more exactly, Pennsylvania petroleum, has, I am aware, been taken as a subject for lectures before this institution on several occasions already, notably in recent years by Mr. Chas. A. Ashburner, of the Second Geological Survey of Pennsylvania, and its geology and conditions of production as well as its refining and varied utilizations have been ably described. I am not aware, however, that it has been discussed in comparison with that equally wonderful and more recent production, Russian petroleum. It is my purpose then to describe briefly the conditions of occurrence of these two most important natural products, to note the chemical differences between the two "crudes," the differences of treatment made necessary in consequence, the characters of the respective products, and lastly the present and prospective commercial values of these two gifts of Nature. In speaking of the American field I shall speak, of course, essentially of the Pennsylvania production, for although we have Canadian oil, West Virginia oil, California oil and, prospectively of still greater importance, Ohio oil, the great bulk of the crude oil which is refined for illuminating and lubricating purposes, comes from what is called the Pennsylvania field.

None of these Pennsylvania and New York oils contain any appreciable amount of sulphur or other impurity which would require a modification of the general refining methods. The heavy oils of Franklin and Smith's Ferry, Pa., and some few other localities, are so valuable for the manufacture of lubricating oils that they are collected and worked separately. The Pennsylvania crude oils has in general a dark greenish-black color, appearing chert-red by transmitted light, and varies ordinarily in specific gravity from 0.782 to 0.850 or as it is frequently expressed, from 49 deg. B. to 34 deg. B. Exceptions to this general statement are the Washington county amber oil, the light colored oil of Smith's Ferry and some other natural yellow or amber oils. In chemical composition it is essentially composed of hydrocarbons of the paraffin series C_nH_{2n+2} , the gaseous and the solid members of the series being alike held dissolved in the liquid ones, and smaller amounts of the olefine series C_nH_{2n} and the benzene C_nH_{2n-6} . According to Markownikow, as confirmed by Kramer, Pennsylvania petroleum also contains hydrocarbons of a series C_nH_{2n} , which he terms "naphthenes."

The crude oil of the Pennsylvania field is mostly refined in the three large cities of Pittsburg Pa., Cleveland, O., and Buffalo, N. Y., or on the Atlantic seaboard, in close proximity to the ports of shipment. The transportation of the oil to these points, at first effected exclusively by railway tank cars, is now very largely effected by means of pipe lines. Most of these are now controlled by the National Transit Company. * * *

If we turn now to the question of foreign petroleum production, we will find that only one locality deserves to be mentioned in comparison with our Pennsylvania production, viz.: Baku, on the Caspian, in the Russian province of the Caucasus. The map (projected on the screen) will show the several known petroleum deposits of Europe and their geographical relation to each other, and to some extent the transportation facilities, as far as illustrated by the railway connections. The second or special map of the immediate Baku district will show the producing points and the refining center on the outskirts of the town of Baku. As seen on this last map, there are two great groups of wells, the Surakhani and the Balukhan groups. The former exists on the site of the old fire worshippers' temple, where the petroleum gas has been issuing from the ground from the prehistoric period, 2,500 years ago, to the present. Only two or three companies carry on operations here. The majority are gathered at Balukhan, as a more copious supply was discovered here, and drilling operations were found to be more easily carried on.

The geology of this Baku district is not very deti-

nately known. Vasilieff, in an article in the Russian *Mining Journal* of September, 1886, states that the petroleum-bearing strata of the Caucasus belong to the Lower Miocene series of the Tertiary epoch, the deposits extending in a north-easterly to south-westerly direction, and the dip ranging apparently between 20 and 400. The petroleum bearing beds are composed of sand, calcareous clays, marls and, in places, compact sandstones, often of great thickness, penetrated by bands of pyrites. The theory of Ludwig Nobel, based on numerous oil well records made by his company, is that "the oil bearing strata, originally running regularly in an almost diagonal direction, became dislocated and thrust hither and thither horizontally during some volcanic disturbance, and a sort of irregular cellular character given to the petroleum deposits." The peninsula of Apsheron is probably honeycombed with thousands of these oil cells, which seem to be for the greater part independent of each other. They are found at all depths down to 825 feet, the extreme depth yet reached. The great Droobja oil fountain, which in six months of 1883, poured forth about 55,000,000 gallons of oil, had reached a depth of 574 feet only, and while this was flowing at the rate of 2,000,000 gallons per diem, wells a stone's throw off and of lesser depth, were giving their daily supply of petroleum totally unaffected by it. Many of my audience have, perhaps, read newspaper items with regard to the terrific power and prolific character of some of these Baku oil wells, and may have put down much of the account to exaggeration. But numerous reliable and unbiased witnesses have united in giving figures that we must therefore accept. The largest flowing well we have had in Pennsylvania (the Armstrong No. 2) flowed for a time at the rate of over 6,000 barrels (or 260,000 gallons) per twenty-four hours. When Boverton Redwood, the secretary of the British Petroleum Association, visited Baku in the fall of 1884, one of Nobel's capped fountains was opened for his benefit. A solid column of oil, more than a foot in diameter, shot up to a height exceeding 100 feet, and continued to flow without diminution of violence as long as the valve remained open, forming a lake of oil to leeward of the well. The derrick was seventy feet high, and the oil column occasionally rose to at least double this height. This well (Nobel's No. 18) yields at the rate of 1,125,000 gallons per twenty-four hours whenever opened. It was, however, exceeded by the Droobja well before referred to, and Nobel's No. 9, each of which for a time having yielded double that quantity, or over 2,000,000 gallons per twenty-four hours, about eight times the amount yielded by the strongest Pennsylvania oil well known. The Nobel No. 9 was promptly capped, 1,000,000 gallons of oil being the total loss, but the Droobja well could not be gotten under control for over four months, and it is supposed that 100,000,000 gallons of oil were lost during this period. Not only this, however, but this Droobja fountain, which was from 200 to 300 feet high, threw out so much sand that neighbouring engine houses and derricks were partly buried by it. The company owning it not only lost their oil, but were ruined by the damages they had to pay the surrounding well owners for flooding them with sand and oil. The maximum pressure previous to the discovery of these two fountains, had been four atmospheres, but in the case of Nobel's No. 9 and the Droobja wells the pressure exceeded thirteen atmospheres, or nearly 200 pounds pressure to the square inch. Of the 400 wells in the Baku district, only about 100 are producing at present, and of these 100 some twenty are flowing wells. These twenty, however, would for a time yield more than enough crude oil to suffice for the manufacture of the 2,000,000 gallons of refined petroleum that the world consumes daily. Nobel Brothers had, moreover, at a recent date, fourteen oil fountains plugged up and held as a reserve.

Wells in the Baku district which do not flow, cannot be pumped in the ordinary way, in consequence of the large quantity of the sand present (sometimes as much as thirty to forty per cent.) and the oil is raised to

* A lecture delivered before the Franklin Institute.

the surface in cylinders resembling the sand pump. About two minutes are required to lower and lift the tubes, which bring about fifty gallons of oil to the surface each stroke. "Torpedoing" is so far unknown as a well requires only to be bored a little deeper in order to bring fresh quantities of oil. The oil on issuing from the well is always allowed to stand for a time in reservoirs (which are frequently only shallow ponds in the surrounding soil) in order to deposit the sand, and is then pumped through the pipe lines to the refineries at the Blacktown on the coast some eight miles off.

The Baku petroleum has a higher gravity than the American, averaging 0.873, or 810 B., and has been found to be entirely different in its chemical composition, consisting for the most part of hydrocarbons of the series C_nH_{2n} , isomeric with the olfine series and called "naphthenes." As will be seen later, this difference in chemical composition involves a difference in the refining methods and results.

The processes of distilling Pennsylvania petroleum are in a general way at least familiar to most of my audience, so I shall not take the time to go over them in detail. It is sufficient to say that although a normally conducted fractional distillation would give from thirty-five to fifty-five per cent only of illuminating oil, by the process of "cracking," or destructive distillation, the percentage of illuminating oil may be increased to seventy-five to eighty per cent, the benzene fraction being from ten to fifteen, and the residuum from five to ten per cent. On the other hand, the Russian petroleum does not yield over about twenty-seven to thirty per cent of illuminating oil of satisfactory quality, but will yield fifty per cent. of a very superior lubricating oil. Nobel Brothers, who are by far the most scientific and progressive in their methods, obtain about the following result: Benzine, 1 per cent; gasoline, 3 per cent; illuminating oil (32 deg. C. or 89 deg. F. Abel flash point), 37 per cent; Soliarovi lubricating oil, sp. gr. 0.87, 12 per cent; Vereguni lubricating oil, sp. gr. 0.89, 10 per cent; lubricating oil, sp. gr. 0.905, 17 per cent; cylinder lubricating oil, sp. gr. 0.915, 5 per cent., vaseline, sp. gr. 0.925, 1 per cent; liquid fuel, 14 per cent, and loss, 10 per cent; total, 100.

It is true that more illuminating oil than this twenty-seven per cent is sometimes gotten by some of the Baku refiners, but it is of lower flash test. Prof. Beilstein, of St. Petersburg, has also proposed a method of cracking by which the yield of illuminating oil can be raised to fifty per cent, but it is not adopted as yet to any considerable extent. With regard to the character of the best Russian illuminating oil as compared with the American oil, it is claimed by English and German experimenters that, while the Russian oil gives less light at the beginning of the burning when the lamp is full of oil and freshly trimmed, it affords a flame of somewhat greater permanence as the level of oil in the reservoir becomes lower, the difference being supposed to be due to the greater power which the Russian oil has of ascending the wick. In a comparison of the lubricating oils, there seems but little doubt that the Russian product has a distinct advantage. These lubricating oils from Baku petroleum contain little or no solid hydrocarbons, the greatest quantity obtainable amounting to only a quarter of one per cent of the crude oil. They will show, therefore exceptionally low cold tests. At the same time they have a remarkably high viscosity in relation to their specific gravity. This characteristic is exhibited in the following tabular statement prepared by Boverton Redwood:—

	Viscosity at 70 F.	Viscosity at 120 F.	Less per cent in Viscosity
Russian oil (sp. gr. 0.913.)	1400	166	88
American oil (sp. gr. 0.914)	231	66	71
Russian oil (sp. gr. 0.907)	649	135	79
American oil (sp. gr. 0.907)	171	58	66
Russian oil (sp. gr. 0.898)	173	56	67
American oil (sp. gr. 0.891)	81	40	50
Refined rape oil (for comparison)	321	112	65

It is true that the disproportion is chiefly at lower temperatures, the Russian oil losing its body relatively faster than the less viscous American oil. One distinctive feature of the Baku refining is the successful use they make of continuous distillation processes which are especially suited to Baku petroleum, as the quantity of burning oil separated being comparatively small the residuum is not very much less fluid than the crude oil. The stills, each of the capacity of 4,400 gallons, are arranged in groups or series of not more than twenty-five, and a stream of oil is kept continuously flowing through the entire number. The crude oil entering the first still parts with its most volatile constituents, passing into the next still has rather less volatile hydrocarbons distilled from it, and finally flows from the last still in the condition of residuum, which in Russia is termed *astatki*, or *masut*. The several stills are maintained at temperatures corresponding with the boiling points of the products to be volatilized. Superheated steam is used for all the stills, the steam being delivered partly under the oil and partly above the level of the oil; that is, in the vapour space above. The fuel used under all the stills in Baku is petroleum residuum or "*astatki*." At many of the smaller works, the liquid fuel is simply allowed to flow upon the hearth of the furnace, and in thus using it, a very dense black smoke is evolved, whence the refining suburb of Baku has come to be known as the Blacktown. At Nobel's refinery, however, arrangements are adopted for burning the fuel with a proper admixture of air, and smokeless combustion is thus obtained. The part the *astatki*, or liquid fuel, now plays in the Caucasian district and in Russia is something not to be overlooked. It is the only fuel for locomotives, steamers and factory engines throughout this part of Russia. It has replaced wood and coal, and the use of it is now extending as far as Moscow to the north, Teheran to the south, Merv and Khiva to the East and Batoum to the west. In 1883, the aggregate export of *astatki* to Russia by all the Baku firms was 281,000 tons. On the other hand, the production was estimated as exceeding 500,000 tons, leaving, after making allowance for consumption in refineries, perhaps as much as 200,000 tons, or 50,000,000 gallons undisposed of. Enormous quantities are therefore allowed to go to waste. It is found in practice that with a good hydrocarbon furnace one ton of *astatki* goes as far as three tons of mineral fuel.* Nobel Brothers alone are now turning out 450,000 tons of this fuel per year.

It remains now to glance at the methods of transportation and commercial development of Russian petroleum fields as compared with those of America. Our American system of pipe lines, extending to the seaboard, has already been illustrated. With the oil once at the Atlantic seaboard, its shipment either as crude or as refined is readily effected to any part of the habitable globe. Here, the Russians are at a disadvantage. Baku is on the Caspian Sea, on the border line between Europe and Asia, but with very imperfect means of communication. What there is may be said to have grown principally out of the energy and engineering ability of one man, Ludwig Nobel, a Swede by birth, although resident in Russia since his twelfth year. In 1875, his elder brother, Robert Nobel, began refining at Baku in a small way, with capital furnished by Ludwig, who had extensive engineering works at St. Petersburg. The Nobel Brothers found all the oil that was refined at Blacktown transported from Balakhani in barrels slung in two-wheeled Persian carts, termed "*arbas*." They laid down a pipe line eight miles long and it paid its expenses the first season. The imported American oil-well borers revolutionized the method of sinking wells. Then it was that, finding the transportation facilities too limited to allow them to ship their oil, Ludwig Nobel, the engineer, designed and had built the first of the oil-tank steamers that allowed him to ship his oil on the Caspian from Baku to the mouth of the Volga, a distance of 460 miles. This first liquid transport, or "*cisterna steamer*," appeared on the Caspian in 1879. There is now a fleet of forty of them, the Nobels owning twelve, carrying

* N. B.—Ed.

about 5,500 barrels apiece each trip. As the Volga at its wide mouth is very shallow, the tank steamers can proceed no farther than a locality known as "nine-feet sounding," about twenty miles from land, when the oil is transferred to oil barges, in which it is conveyed to Tsaritzin, the first railway point on the river Volga, 400 miles distant, where Nobel Brothers have established one of their great distributing centers for Russia. They have twenty barges on the Volga, and from Tsaritzin they distribute the oil by trains of oil-tank wagons. Of these, the Nobels own 1,500 holding 2,500 gallons, or about ten tons of refined oil each. These are made up into trains of twenty-five wagons, so that the firm runs sixty such trains continuously in their distributing work. The accompanying map shows the network of storage depots and distributing stations that the Nobels have established throughout Russia and the adjacent countries. This system of storage depots is not merely a matter of convenience to them, but is to a large degree a matter of necessity. During at least four months in the year, the Volga is frozen over solidly, so that the oil needed for consumption during this winter term has to be accumulated at points accessible by rail connection. The oil trains of the Nobels, therefore, are occupied during part of the year in collecting the oil in their storage depots, and during the winter in distributing it for consumption. This work is directed from St. Petersburg, where Ludwig Nobel, the president of the company, resides. They are beginning also to ship their oil by tank steamers from Libau on the Baltic, where they bring it by tank cars, to Stettin, Hamburg and even to London. At Stettin, they have begun to erect storage tanks for the supply of the German trade.

In 1883 the Trans-Caucasian Railroad was finished and oil is now shipped from Batoum on the Black Sea in quite considerable amounts to Mediterranean ports. A pipe line from Baku to Batoum has also been surveyed, and the government concession having been obtained, it will likely be built in the near future.

The successful introduction of transportation of oil in bulk by means of oil-tank steamers on the Caspian, of course, led oil shippers to consider the question of usings similar tank steamers for the transportation of oil in bulk to Europe. Indeed some slight experimenting in this line had preceded the adoption of the tank steamers on the Caspian, but the engineering difficulties connected with the shipment of oil in bulk for the voyage across the Atlantic were far greater, and hence greater precautions against danger had to be devised. Two large tank steamers, however, have been running this last year successfully, the "Crusader" and the "Andromeda" the former to London and the latter to Bremen. The most important feature of their construction is the provision of auxiliary tanks above the level of the storage tanks and in communication with them. The storage tanks can thus always be kept quite full of oil, the auxiliary tanks serving to hold the surplus when the storage tanks become expanded by heat and supplying the deficiency when contraction takes place. The "Crusader" is provided with forty-five tanks, with an average capacity of 125 barrels each, the "Andromeda" with seventy-two tanks, and carried in its first trip to Bremen 681,641 gallons of refined oil.

The statistics of production of both American and Russian oil and of exportations of the two, as far as statistics are attainable, are given in the tables in the appendix.

APPENDIX.

TABLE I.

Annual production and value of petroleum in the United States, according to the Bureau* of Mining Statistics, U. S. Department of the Interior:

	Production.	
	Bbls.	Valued at
1882 ...	30,053,500	\$23,705,698
1883 ...	23,400,229	25,746,352
1884 ...	24,089,758	20,476,294
1885 ...	21,842,041	19,193,691
1886 ...	28,110,115	20,028,457

* N. B.—Ed. † Barrels.—Ed.

TABLE II.
Annual production of crude oil in the Baku district according to Engler:

1881...	4,900,000	hundred kilos, or	3,500,000	bbls.
1882...	6,800,000	"	4,857,143	"
1883...	8,000,000	"	5,714,286	"
1884...	11,300,000	"	8,071,428	"
1885...	16,360,000	"	11,685,714	"

TABLE III.

Exports of crude and refined petroleum from the United States during the years 1884-85 and '86 according to the U. S. Bureau of Statistics:

	1884.	1885.	1886.

TABLE IV.

The shipments of Baku petroleum for the years 1885 and 1886 are thus given in the U. S. Consular Reports.

(1) From Batoum via Trans-Caucasian Railway:

	1885.	1886.
	Gallons.	Gallons.
Illuminating oils.....	26,865,325	39,321,005
Crude, lubricating and residuums	4,774,600	14,965,315
Total.....	31,639,925	54,286,320

(2) Via Astrachan on the Caspian Sea:

	First six months of 1886.	
	Gallons.	
Illuminating oil.....	44,428,335	
Crude, naphthas and residuums.....	79,866,200	
Other products.....	8,851,960	
Total.....	133,146,405	

—Oil, Paint and Drug Reporter.

INDIA IN 1887.*

This title is so comprehensive, that, it might mislead, were it not followed by the frank limitation that the India referred to is bounded by the vision of the professional agriculturist. It is desirable also to state that Mr. Wallace landed in Bombay on May 10th, and embarked from the gate of Western India on September 13th, 1887, during which period he "travelled by rail over thirteen thousand miles," including a flying visit to Ceylon. It cannot be said that he did not make the most of his time; for he reached Simla and Lahore through the Aravulli route by Ajmere, ran down to Calcutta and up to Darjeeling, flitted back to the Western coast, and thence descended on Southern India, whence, after a trip to Kandy, he returned to Bombay. Four months' travel in the hot season implies great energy, and, to profit by it, close attention to the special objects for which the journey was unpertaken; and, so far as the contents of his volume warrant an opinion, he kept steadily to his purpose throughout his rapid tour. He wished, primarily, to ascertain what had become of certain British and native students whom he had taught at Cirencester, next to press on the Indian Government the necessity of establishing an Agricultural Department, and also to extend his own knowledge. We are bound to say that, although he was so short a time in the country, the result of his toil is not an example of

* In 1887, written by Robert Wallace, Professor of Agriculture and Rural Economy in the University of Edinburgh. Edinburgh: Oliver and Boyd, London: Simpkin Marshall and Co.

book-making, but a genuine contribution to the description of matters of great importance; and the reason is that he carried to India a large fund of knowledge derived from experience and study, and a sincere desire to promote the welfare of that vast dominion. His pages contain many photographs of cattle, the value of which is diminished by their imperfections, due to the fact that the author only began to learn the photographic art 15 days before he embarked.

If he failed in photography, he made a remarkable discovery in regard to cattle, alighting on a fact which apparently, though not unobserved by the natives, is new to the physiologists. He found that all the Indian cattle, a small percentage excepted, however white the hair, have jet-black skins. The native farmers attribute weakness to those having white skins, and the inference he draws is that the black skins may help the cattle to bear the sun. Nor is it confined to them; for the same peculiarity exists in sheep, pigs, and horses. Mr. Huxley, in a letter to the author, says that the fact he mentions "is of very great interest, as showing a hitherto unsuspected relation between colour and climate." Professor Helmholtz cannot furnish any explanation of the phenomenon. Mr. Wallace, however, has a theory of his own. He thinks that while black absorbs heat in a greater degree than lighter colours, the black body is relieved by the moisture escaping in the form of vapour, which carries off "the surplus heat which the black skin absorbs over and above what it gives off by radiation." The question is one requiring a closer examination; but, apart from its scientific interest, it is held to have some bearing on the attempts to improve Indian by an admixture of English cattle, which find no favour in the eyes of Mr. Wallace. Indeed, the kernel of his doctrine is that Indian agriculture can only be improved by applying English knowledge and thoroughness to Indian methods. "It is not difficult to see," he writes, "and no practical man will wonder at it, that climate and general surroundings being so vastly different in India from those at home, British and American practices must be unsuited to Indian conditions." Therefore he is of opinion that "the first step to be taken is the study of native agricultural practices," not to subvert, but to make them more effective; and that is why he wants an Agricultural Department, which should deal with the whole subject. The thing has been tried and has failed, so far; yet he would persevere, believing that a choice of competent men who went to work on the lines he has indicated would bring success. His scheme, however, is very large, and might be expensive; yet it is based on the correct principle that Indian methods, as a rule, form still the best basis of any system or systems which should give the Indian farmers and breeders the benefit of Western science so far as it may be applicable or adaptable to the conditions of the East. At the same time, the demands on the Government are endless, the expert is not infallible, and the problem is so difficult that even more money may be wasted. One thing is encouraging. It is that the natives will readily adopt real improvements. A sugar-cane crusher is widely used; the native tailor has taken kindly to the sewing-machine; and a Hungarian has successfully secured a considerable European market for cigars and tobacco, not by substituting European for native practices, but by "improving native methods of growing, curing, and manufacture by the light of his superior and more extensive knowledge." So it is with machinery; it must be such as will suit the soil and climate, or it will be useless. The fact is that the various peoples of India do know something

considerable about rearing and tending cattle and other creatures, and about cultivating and manuring land, because they have been so engaged for some thousands of years; and the help we can supply, if at all, is by infusing into agriculture the spirit which pervades the British administration, thoroughness, and bringing to bear the advantages derived from science, guided by that wise caution which a scientific education is supposed to impart. It is even possible that a long and minute personal acquaintance with India might modify some of the strong opinions held by Mr. Wallace and other experts, and make them more keenly alive to the difficulties which beset the Indian Government.

Not the least interesting chapter is that dealing with the wheat trade. There has been some apprehension that the Indian ryot would supplant the British farmer. Mr. Wallace, examining the question on the spot, does not deny that Indian wheat will remain as a substantial item in our imports; but he gives many solid reasons to show that the supply will not be boundless. Drought, diseases peculiar to the grain, frost, fogs, locusts, rats, and weevils plague the grower. "We must not forget," he says, "the likelihood of the yield decreasing and the quality degenerating by too frequent growth on the same land." The natives have already observed that wheat causes the soil to deteriorate, if not manured; and, therefore, they cling to their system of rotation. In Russia and America the same law holds. In the latter country, "the line bounding the best wheat area has steadily moved westward," and left, as a record of its course, the ruins of disused and deserted mills." In Southern Russia failure followed on an attempt to extract continuous crops of wheat from the same area. Then in India, as elsewhere, a deficient harvest reduces exports, and obviously a rise in freights has a similar effect even in years of plenty. Still, the power of sending forth wheat, the result of improved oceanic communication, is a boon to the Indian farmer. He may find another in the adoption of ensilage. On that point Mr. Wallace writes in a confident strain:—

"If silage," he says, "is ever to be effectually established on a large scale for the benefit of a great community, it will be in India. Although I am no advocate of the general adoption, under all circumstances, of systems of ensilage in this country, yet I believe the adverse climatic conditions met with in our Eastern Empire are such as could be overcome in a marked degree by making silage on an extensive scale. Modern invention and recent experience have produced methods by which ensilage can now be practised at a merely nominal expenditure of capital. It is not necessary to build an expensive house or silo. It is even unnecessary to dig a hole in the ground to contain it. All that is required is to build the grass into a good large stack on the surface of the earth, and tie it down tightly with galvanised steel-wire rope. Some who pretend to have a special gift in the matter of reading the native character, say that a native will never come to bury good food for cattle in a hole in the ground. Surely they can have no objection to build it in a heap, where they can always have an eye upon it."

He admits that bad results have followed from the use of silage in some instances, and that the soldiers are against it as horse provender; but he still contends that sufficient success has been attained to warrant the belief that this mode of economising grass-crops will be adopted in the end, and not only mitigate famines, but avert, or help to avert, "the impending evil of an over-crowded population." The book, indeed, is full of suggestions; and, on the whole, Mr. Wallace's report looks decidedly favourable to the future agricultural prospects of India,—all the more because the produce, animate and inanimate, is as vast and varied as the enormous dominion itself.—*Spectator*.

THE CINCHONA BARK TRADE OF BRITAIN

is this subject of an interesting article with statistics from the *Chemist and Druggist* given below. It is shown that the average annual value of the Ceylon bark imported into Britain for five years* has been £541,000 out of an average value for the whole of the imports of only £733,600. Low as the price of bark has fallen, we should have thought these figures below the mark. Interesting information is given respecting the exports of bark from London to the Continent of Europe, but these do not afford a proper idea of the actual manufacture of bark and consumption of quinine in each country. This has been summed up in our "Planting Review" (in the "Ceylon Handbook and Directory") with the aid of every authority within reach, and we commend to the notice of our London contemporary the following results arrived at by us after prolonged examination of all statistics within our reach:—

IMPORTS AND CONSUMPTION OF CINCHONA BARK.	
United Kingdom (and British Colonies) import about 17 millions lb., but manufacture or consume only	6,000,000
India (manufactures from local growth apart from 250,000 oz. of quinine &c., imported)	350,000
Europe, Continent of (imported through France, Holland and Italy) — Italy 3 millions; Germany 7 millions; France 4 millions; Holland and Belgium 1½ million; Russia ½ million; other countries ½ million... ..	16,500,000
United States (besides 2¼ million ounces of quinine)	5,000,000
Other countries (Brazil, Africa and rest of Asia)	650,000
Total Bark:—28,500,000	

QUININE MANUFACTURED BY		lb.
United States, 4 Manufacturers		80,000
Germany, 6 "		180,000
Italy, 2 "		70,000
France, 3 "		80,000
Holland, 1 "		10,000
England, 2 "		40,000
India, 1 "		8,000
		468,000

QUININE, CONSUMPTION OF:		lb.
United States		200,000
Germany, Austria, Holland and Belgium... ..		51,000
Italy,		35,000
France,		30,000
Russia, Turkey & Greece		80,000
Spain,		15,000
India,		25,000
Other countries, Japan, China, Brazil and Africa		15,000
United Kingdom & Colonies		15,000
		468,000

Probably in 12 months, 1888-9, the manufacture and consumption of quinine will not be much under 470,000 lb. (7,520,000 ounces) per annum, apart from a limited quantity of inferior alkaloids and bark used up by druggists, brewers, &c.

What our London contemporary says about the virtual abandonment of bark harvesting in many districts of Ecuador and Columbia, and the difficulties attending export from Bolivia, is full of interest. We have yet to see what effect the abolition of the export duty in Bolivia will produce.

* The total value of Ceylon bark for the 5 years imported into London is given at £2,705,510.

THE BRITISH TRADE IN CINCHONA BARK.

(From the *Chemist and Druggist*, Aug. 18th.)

In our market report we publish this week an interesting table giving the weight and value of cinchona bark imported into and re-shipped from the United Kingdom during the last five years, from and to the principal countries with which we deal in that commodity. These statistics show that from 1883 to 1887 inclusive we have imported into the United Kingdom 639,360 cwts. of cinchona, and re-exported 534,127 cwts., leaving for our own consumption 105,233 cwts. in five years' time, or, say, about one-sixth of our entire imports. If we take into account the fact that we entered upon the year 1883 with the stock of 3,500 casks and casks and 67,176 serons cinchona, or, say, an aggregate of 74,176 cwts., and were left at the end of 1887 with a supply, in the first hand, of 11,333 cases and casks and 48,286 serons, or about 70,952 cwt. altogether, we find that we must add about 3,224 cwt. for the decrease in our stock to the balance of 105,233 cwts. excess of imports over re-exports to arrive at the nearest possible estimate of our actual consumption of cinchona for all purposes. This, upon the above-named basis, has averaged about 21,691 cwts. per annum since 1883, less, of course, than we export to Germany alone, directly and via Holland but still a respectable enough quantity. Looking at our cinchona imports, we find that their aggregate value has been steadily declining since 1883, though in weight they show an almost equally uninterrupted growth. The cinchona imports from British India are expanding considerably, although even yet they weigh scarcely one-tenth part as heavy as the supplies from Ceylon. France (Holland not being specially named in the returns) is the only European country from which we receive any cinchona supplies of importance, and even she does not furnish us with much more than 1 per cent of our entire imports. We receive from France principally South American barks of the cuprea and Maracaibo varieties, which are brought to Havre by the steamers running from that port to Venezuela, Colombia, and Central America. Of South American countries, Ecuador has almost ceased to send us any bark at all, notwithstanding that the Guayaquil, Ibanaco, and Loja cinchonas, which are usually imported from that country, have suffered proportionately less depreciation than most other varieties. But Ecuador in 1886 and 1887 passed through some political squalls of more than usual severity, and this may, partly at least, account for the hiatus in the supply from that quarter, while, moreover, the forests easiest to reach have been quite denuded of bark, and the present prices do not make it profitable to collect it in out-of-the-way places. The imports from Colombia are also dwindling, but most of the bark shipped from the ports in that country, Carthagena, and Maracaibo, is sent to the United States. The forests in the State of Santander, however, where the oak called, from its copper-like colour, "Cuprea" was discovered about thirty years ago, are now partly exhausted, and the depreciation of this bark, which was worth up to 2s 6d per lb. in 1880 and now fetches only about 3½d per lb., does not encourage the bark-hunters to take any very great pains in procuring fresh supplies. Bolivia is not specially mentioned in the returns which we have compiled. The country is completely cut off from the sea since the Chilean war, and therefore, although no doubt the largest producer of cinchona in America, the Bolivian barks figure, without exception, in the returns from her neighbours, Chili, Columbia, and the Argentine Republic. The Bolivian plantations, which now furnish such excellent yellow bark, are situated in the neighbourhood of Cochabamba, on the eastern slope of the Andes, and the cultivators find it cheaper to ship their goods by the comparatively easy, though long, water-way along the Beni-mayo and Beni rivers to Buenos Ayres or Montevideo on the River Plate, than to send the bark by a much shorter route across the difficult mountain passes. In a like manner the red Colchaca bark, procured from the wild trees found in out-of-the-way forests, are mostly despatched by river through Brazil or the Argentine Republic. But it,

as is probable, the exports of cinchona from Bolivia should assume abnormal proportions this year in consequence of the abolition of the export duty, we shall probably be able next season to publish statistical information concerning the shipments from that country. The sudden doubling of the value of cinchona received from various less important countries is probably owing to the increased shipments from Jamaica and Africa, and to the fact that more Java bark has been sent to London for sale, either direct or via Holland. As regards our export trade in cinchona, the returns are valuable as showing at a glance that our re-shipments are drifting more and more towards Germany and America. France, which is our best customer for South American cinchonas, takes an average of about 12,000 cwt. per annum, and the amount of her purchases varies very little, but our shipments to Germany (including Holland and Belgium), which were only 40,675 cwt. in 1883, have gradually expanded to 70,692 cwt. in 1884, 67,650 cwt. in 1885, 74,481 cwt. in 1886, and 74,360 cwt. in 1887. We must add to this the increasing quantities bought every year by Germany at the Amsterdam auctions, and the figures, therefore, go a long way to prove that in spite of the low quinine prices there must still be a margin for the manufacturers to work the bark, since it cannot be supposed that the stock of a depreciating article is merely left to accumulate in Germany. Of course, we do not claim for our figures that they absolutely prove this contention, but still, taken in conjunction with other available statistics, they unmistakably point in that direction. Next to Germany the United States are our best customers for cinchona, and to this country also a very large increase in the shipments is shown, the excess of quinine thus shipped in the bark fully counterbalancing the decrease in the imports of prepared quinine into the States. Italy also buys more and more bark every year, the fall in the shipments in 1885, consequent upon the failure of the Milan quinine works, being the only exception.

London, Aug. 16.

CINCHONA.—The total quantity offered for public sale on Tuesday was somewhat smaller than that catalogued for the preceding auctions (3,779 against 4,179 packages), but on Tuesday more Eastern barks, forming on the whole a very good assortment, were shown, the catalogues consisting of 1,907 packages, Ceylon, including a large quantity of Hybrid bark, but little Officialis. For Ceylon bark there was a fair, though by no means excessive, competition, and three-fourths of the supply offered sold at fully last auction's rates, and in some cases at about 5 per cent advance. Of Indian barks, 442 packages were offered, mostly from Southern India (Nilgiri Hills), but the demand was rather slack. Java cinchona was in better supply than usual, 190 packages Ledgeriana, including no particularly fine lots, being offered and sold. *South American* cinchonas, finally, were represented by 1,240 packages, mostly *Ouprea* (506 packages), which is at present a veritable drug in the market, and of which parcels imported several years ago are being constantly offered for sale. Of Bolivian *Calisaya* bark there were 427 packages, and the rest was made up of 189 packages *Pitaya* and 118 soft *Columbia*. A few lots were disposed of. The unit is generally estimated at 2d to 2½d, or very slightly in excess of the preceding auctions, and the principal buyers were the agents for the Mannheim and other German factories. The prices realised were as follows:—*Ceylon Cinchona*.—*Succirubra*—Dust 3d; ordinary and branch to fair stem chips, 1½d to 4d; good strong chips, 4½ to 5½d; spoke shavings, common to fine, 2½d to 5½d; root, including "renewed" lots, 2d to 5d; quill, fair to good stout silvery druggist's 6d to 9d; renewed, medium to fine, mostly shavings, 4½d to 8d. *Officialis*—Chips, small branchy to fine bold stout stem, 3d to 6½d; root, 4½d to 8½d. *Hybrid, &c.*—Chips, weak to fine Ledger, 2½d to 7d; root, 4d to 4½d; quill, bright 9d. A few packages very fine bright natural Ledger spoke shavings, 1s 5d per lb. *Indian Cinchona*.—*Succirubra*—Siftings, 1d to 2nd; ordinary to fine stem chips, 2½d to 6½d. *Officialis*—Branch, 1d; shavings, 4½d to 5d; root, including renewed,

6d to 11d, *Hybrid*—Branch, 2½d to 5d; chips, 4d to 5½d; root, 10½d; thin weak quill, 2½d per lb. *Java, Cinchona*.—*Ledgeriana*—Chips, young to fair quilly, 3d to 6d; good stout strong, 7d to 9d; root, 9d to 11d; branch and siftings 2d to 3d per lb.

SOUTH AMERICAN CINCHONA.—*Calisaya* from the Bolivian plantations, in quills, fairly good to strong and of fine appearance, 8d to 10d.; old *Cuprea*, 3½d.; and common *Pitaya* at ½d to 1d. per lb. The imports of cinchona into Germany during the first half-year of 1888 were 1,843,100 kilos., against 2,359,600 kilos. during the first half-year of 1887. The re-exports of cinchona from Germany were respectively 12,200 and 10,800 kilos. The exports of cinchona bark from private plantations in Java for the first four months of the year has been:—

TRADE IN FLAVORING BEANS.

To the report of the Committee on Statistics, made at the late annual convention of dealers in drugs, we are indebted for the following statement of the trade in Vanilla beans:—

The reports in circulation for the last year or two about a great falling off in the crop of Vanilla beans in Mexico are not borne out by the statistics of imports for the past three years, which are as follows:—

	Lbs
1885...	97,095
1886...	99,529
1887...	137,479

The average imports for the four years previous to 1886 being 90,000 lbs per year. It would appear, therefore, that not to shortage of the crop, but to largely increased consumption and competition among importers, vying with each other in buying in Mexico, is due to the advance in price. In 1886 the total imports were valued at \$422,831, or \$425 per lb. To June 30, 1887, the value entered was \$775,423, or \$5 65 per lb. Within the last twelve months considerable arrivals of Bourbon beans were offered in the New York market. With the price about half that of Mexican, it is thought they may in time prove a serious competitor, even although it is generally admitted the flavour is not nearly so fine as Mexican. The price of Mexican in July, 1886, ran from \$5 50 to \$10, according to quality; in September, \$7 to \$15 was established, closing lower, viz., \$6 50 to \$12. Bourbon beans ranged from \$4 50 to \$5 during same period.

The export demand for Mexican Vanilloes is small. Shipments to June 30 in each year were:—

Year	Value
1886	9,355
1887	1,568
1886	43,174
1887	11,058

France being the only buyer. The cultivation of the Vanilla plant appears to be progressing very satisfactorily in Ceylon. Vanilla beans would have been higher if it had not been for the introduction of the artificially prepared vanilline, which takes its place to a considerable extent, as proved by its increasing importation.

In Tonga beans the stock of Angostura being well under control, the price has not varied much during the past twelve months. In December last a reduction of 10 cents to 20 cents per lb was made on large lots. The jobbing price at present is \$1 25 to \$1 40, according to quality, against \$1 35 to \$1 65, same period in 1886. The beans grow wild in the forests of Venezuela, and it is said almost unlimited supplies can be collected but since 1883 the collection has become a monopoly, with an export duty of 10 cents per lb levied by the Government. The crop of 1886 was the largest for a great number of years, being said to be over 350,000 lb. The following were the shipments from the port of Ciudad Bolivar alone for

Year	Gross weight, Lbs.
1882... ..	89,985
1883... ..	153,138
1884... ..	150,681
1885... ..	35,325
1886... ..	298,000

Imports to the United States of all kinds were:
 1886 315,000
 To July 1, 1887 5,000
 —American Grocer.

THE KALUPAHANA VALLEY, LAGGALA.

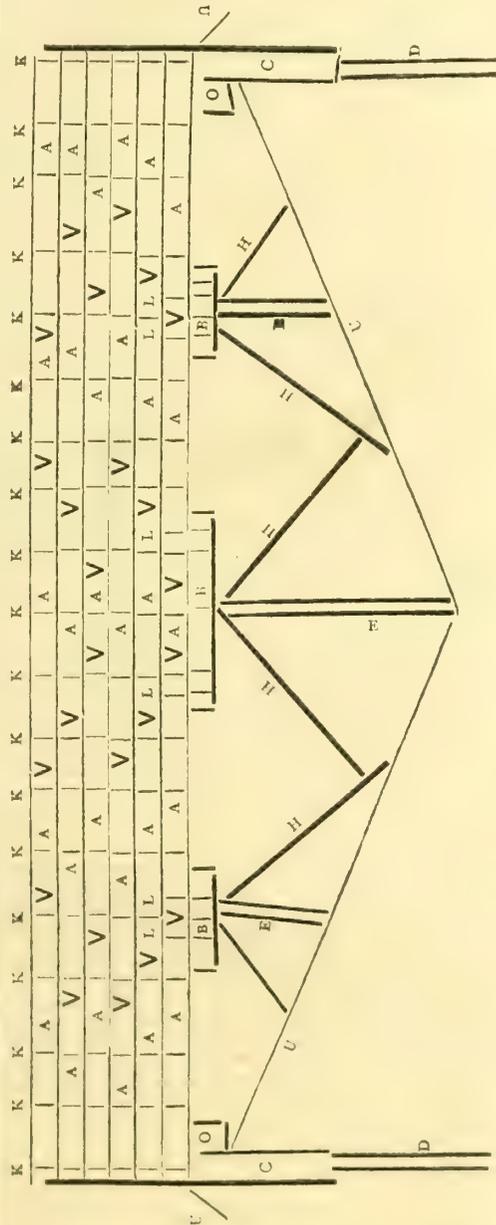

TELGAMA-GANGA BRIDGE 62 BY 14 FEET COSTING R150
 —EN ROUTE TO KALUPAHANA VALLEY—THE TELGAMA VALLEY: WESLEYAN MISSION AND SCHOOL—THE GREAT NEED OF A MEDICAL DISPENSARY—MAJOR FORBES ON THE LAGGALA DISTRICT—THE RICHEST PASTURE FOR GOOD MILK AND FATTENING CATTLE IN CEYLON—COCONUTS AT A HIGH ELEVATION—THE KALUPAHANA AMPHITHEATRE.

Leaving Hattanwella to visit the Kalupahana Valley some ten to twelve miles farther out from the Laggala range, the early morning walk down to the side of the Telgama river was a caution in its steep roughness, but to cross the stream we had the advantage of a capital bridge erected by Mr. Burnet at a very moderate cost which might well be taken by planters and minor road officers, as a model to be copied in many other parts of the country. Its superiority to the very best wire suspension bridge cannot be questioned. At my request, Mr. Burnet kindly furnished a sketch and few notes on TELGAMA-GANGA BRIDGE, which the printer has endeavoured to reproduce with his type as follows:—

Sketch of 1 Beam with Supports and Tension Rod of a Tavalam bridge over the Telgama-ganga at

Managalla in the Laggala district showing details of construction.

FIFTY FEET IN LENGTH, BY 3 (?) IN WIDTH.

AA Planks with bevelled ends of which the beam is built, held together by 19 pairs of bolts xx.

BBB Cleats fixed at the points of lowest plank in beam and held in place by 6 pairs of coach screws LL.

CC Beams (resting on posts DD) on which the beam lies and through channels out in top of which pass the iron chains UU which are secured to holdfasts at each end.

OO Cleats nailed to lower surface of beam resting against CC and preventing them from being pulled inwards in straining the chain.

EEE Straining posts kept in position by struts HH.

"NOTES ON A TAVALAM BRIDGE OVER THE
TELGAMA GANGA AT MANAGALA IN
LAGGALA.

"This river being subject to very high and violent floods, it was necessary to have a bridge which would stand as well clear of the water and offer as little obstruction to the current as possible. Accordingly a site was chosen at the foot of a fall on a spot where a rocky bank shelves steeply down with occasional ledges on one side of the river; while a huge boulder projects some distance into it on the other, standing some ten or twelve feet above the ordinary level of the water. On the top of this boulder two holes were drilled one foot deep, three feet apart, for the reception of a pair of iron bars (D in sketch) four inches in diameter and projecting five feet above the level of the rock. Another similar pair of bars were fixed in a ledge at about the same level on the opposite side of the river—a distance of fifty feet. On the top of each pair of bars was fixed a beam (C in sketch) by boring holes half through into which the heads of the bars fitted: these beams were one foot square and four-and-a-half feet long. Exactly over each bar on the upper surfaces of the beams, channels were cut an inch and a half deep through which pass the chains (M in sketch) which were drawn as tight as could be managed and made fast. Some of the battens which were to form the roadway of the bridge were then tied on the chains cross-wise at distances of six or eight inches to form the scaffolding. The beams which had been previously built up ashore of planks six inches by two and lengths as shown in the sketch were then taken to pieces again, and the bottom layer only of each beam fixed together again by the help of the cleats B B B, and coach screws L L. The straining rods E E E were then fixed and the struts H H H put in position, the straining rods being so proportioned that they raised the centre of the beam a very little above the level. The two small cleats O O were now fixed to prevent the bars D and beams C being pulled inwards by the chain when the full weight came on it and then the remainder of the beams was built up again and the bolts screwed tight when the extra weight brought the centre of the beams down to the level of the ends. The battens (four-and-a-half feet by three inches by two) were then nailed on—a short span made with ordinary beams to connect the main span with the sere at the boulder end—handrail erected and the bridge declared open.

"Annexed is memo. of the whole cost of the bridge:—62 feet long in two spans of 50 and 12 feet by 4½ feet wide—six chains of approach road and reopening half-a-mile of abandoned road. Iron bars and chains were used because they were there already—parts of an old bridge a little farther up—but wooden posts and bits of an old wire shoot would do equally well. The money spent on making the roads however would have covered their cost. Taking into consideration the mistakes made and round-about methods of doing things adopted owing to want of experience on the part of both architect (!) and artisan there can be little doubt that it could be done over again for R150,

	R.	c.
Walker's account—Nuts, bolts and railfare and nails	29	39
Sawyer's account—960 feet timber	37	60
39½ days carpenters	32	87
122½ " labour	46	27
82 " " at approaches	31	27
Sharpening jumpers	2	00

R179 40"

The whole cost of construction was not above R150, some of the material, chains, &c., coming from an old bridge. It was not possible to print the sketch to scale; but we have no doubt, anyone interested can have the exact details from the constructor (Mr. C. G. Burnet, Hattanwella, Rattota). It struck us as one of the most serviceable bridges we had ever seen thrown by a planter across a mountain stream;—a stream too which at all times with a good deal of water, can become

a raging torrent, flooded from bank to bank and of great depth during the monsoon seasons.

The Kalupahani valley beyond Laggala lies at the back of the Knuckles range, the most direct route into it, if practicable, being across from about the middle of the Knuckles district. South of Kalupahani divided by a high ridge, is the Nitre Cave district which lies at the back of Rangala. The upland rice valleys and rolling patanas of Laggala leading to Kalupahani, and before falling into the wilderness of jungle covering the lowcountry, present a very pleasing and diversified aspect. Some of the most prosperous of rice fields are to be found in successive valleys having a never failing supply of water from the Telgama and other streams. In the first valley below the Laggala plantations is found the mission station and school established by the Wesleyan body, and to the success of which I found ready testimony both official and otherwise. One great want of this remote district is a Dispensary and more especially in the interests of the Sinhalese who at present, to a great extent, are dependent on their planting neighbours for fever powders and other treatment. The planters, too, find it very inconvenient for their coolies to have to go all the way to Kelebobka, and, therefore, if a Dispensary were granted in the Telgama valley it would suit both Sinhalese and Tamils, and estate proprietors would be ready to bear part of the cost. We trust a goodly addition to the number of Outdoor Dispensaries in different parts of the country—and especially in the remote divisions of Matala—will prove a feature of the Supply Bill for 1889. If not, a strong stand ought to be made by the unofficial members on behalf of such absolutely needful and truly humane expenditure, as against votes for what must comparatively be "luxuries" in more favored divisions. Any large populous district without a road, a dispensary or a school at this time of day, has a special claim for attention on the Central Government, and the native unofficial representatives especially, should take cognizance of such claims.

Leaving Managalla, *en route* to Kalupahane, we pass away from the main range well out into a country from 2,500 to 1,300 feet above sea-level, the most striking feature of which is presented in great detached masses of rocky hills, rising from the patanas covered with grass on all but one precipitous side where the gneiss in clearly defined layers is fully exposed. These layers of stratified rock have been so affected by weathering and successive monsoon storms as in many cases to become very loose in the hill-side: indeed the valleys give evidence by the number of fallen masses or boulders that the sides of the hills often give way altogether. Forbes well heads his chapter describing a visit "to the mountain of Lakagalla" with the lines:—

*** Pale grey crags that frown above us;

Which seem like records pointing us to read
Of desolation past,

Forbes travelled to Lakagalla by a different route, round the North end of the range, although he must have returned through the Laggala Gap and Dangkande forest and it is of interest therefore to see what he has to say about this part of the country:—

"An opening caused by the falling of some decayed trees on the top of this rocky range of hills enabled us at last to extend our view beyond the surrounding jungle to the forest-encumbered valleys of Lagalla, over which grassy slopes and wooded summits of mountains rose to a height of six thousand feet. Advanced from these the rocky pinnacles of Lakagalla attracted our attention, and we perceived its precipices beetling over the artificial-looking crags called the Brahmim Rocks Having descended to the village of Pallegamm.

on the banks of the Kaluganga, we there rested during the heat of the forenoon, and then proceeded by a rocky path, through several small but prettily situated villages, to Narrangamma. This is a large village; and from its proximity to the mountains, as well as its elevation above the sea, combines the advantages of a pleasant climate and picturesque situation. Amidst its bright green rice fields several masses of rock were surmounted by watch huts; around the margin of the cultivated lands a few of the houses might be distinguished; and the presence of the coconut trees showed the position of the remainder of the village scattered near the base of Lakagalla. In the morning we commenced ascending the mountain, and, after passing the cool clear stream which flows from it, entered a small level plain covered with rick black mould. This place preserves the name of Uyangamma-tenna-wewa (lake of the garden-flat); and here the growth of underwood is prevented by the thick shade of forest trees, and by the circumstance of the ground being occasionally inundated. Into this rock-encircled basin huge masses of stone, which occasionally detach themselves from the Matale peak, plunge with a tremendous crash; and the natives believe such occurrences are the forerunners of domestic troubles in the country. Under this impression, the descent of one of these crags, and even the distance to which the sound of its fall extended, were officially communicated to me by the principal native in the district. From various names of neighbouring places, and for other reasons, I believe the Yakka town of Lankapoor* was situated around this mountain; and this circumstance, conjoined with still more ancient traditions, has obtained from native superstition a belief that its formation was miraculous, and that the sounds of its falling rocks are mysterious prognostics of public misfortune. If the narrow gap through which we entered into the Uyangammatenna were filled up, even to the height of four feet, the peaks of Lakagalla might again be reflected in its embosomed lake.

"In ascending, we found several springs of the purest water; and breakfasted, at an elevation of three thousand three hundred feet above the sea, on a spot from which we saw into the valley of Meemoorra on one side, and on the other our view extended over the districts through which we had passed to the plains on the north and east of the Kandian territory. Through these levels we could discern the course and occasionally saw the silver light of the Mahaweli-ganga, where it flowed near the isolated mountain of Dimbulugala in the direction of Trinkomalee. The upper part of Lakagalla is covered with coarse grass, which spreads in patches over the moist mass of solid rock that forms the summits of the mountains; trees and thickets occupy the sheltered ravines; and, near its base, the new forms a dark disagreeable jungle.

"My guide this day was an old Kapua, who said the was a priest and worshipper of the Ganga Bandera (river prince): from his recitation I obtained some verses, which he repeated to prove that the very spot where I stood was hallowed by legends of the olden time:

(Translation.)

Through the vale of Meemoorra † while sweeps the wild storm,

* Although in the Pali account of the Yakkas it is called Lankapoorra, the Ehi (Sinhalese) history mentions Laggala.

† Meemoorra is a deep narrow valley beyond Lakagalla; and in the mountains which form the opposite side is a nitre-cave, the most productive in the Kandian country, although the quantity it yielded was so trifling that it is not now worth working.

The red thunderbolts gleam shows Lak'galla's rude form.
Hallow'd region of spirits! * when tempests rush by,
Frowning o'er their dark course, thy scathed peaks †
shoot on high.

Here stern Rawan was vanquish'd, and in that dread hour,

Lakagalla was rent by the conqueror's power;
It was Rama's keen shaft chid the mountain in twain,
And Lak'galla's bright lake made a desolate plain.

"The malignant spirit called Ganga Bandera, Oya Bandera, Oya Yakka, † &c. is properly an object of terror, not of worship; and under very many different appellations the identity is easily perceived: he is the representative or personification of those severe fevers to which, from some occult causes, the banks of all Ceylon rivers are peculiarly liable. The manner of making offerings to the Ganga Bandera is by forming a miniature double canoe, ornamented with coconut leaves so as to form a canopy: under this are placed betel, rice, flowers, and such like articles of small value to the donor, as he flatters himself may be acceptable to the fiend, and induce him to spare those who acknowledged his power. After performing certain ceremonies, this propitiatory float is launched upon the nearest river: in a sickly season I have seen many of these delicate arks whirling down the streams, or aground on the sandbanks and fords of the Ambanganga. The ceremony with which the ashes of Cingalese Kings were consigned to supposed annihilation in the waters of the Mahaweli-ganga seems to have been derived from these rites; and was admirably adapted to perpetuate the feelings of mystery and awe which it was the policy of Ceylon monarchs to maintain when alive, and after death to transmit to their successors.

"In the legends regarding Lakagalla, we pass from the era of Ramachandra, and the wars of Rawana, to the time of Vijeya, a Hindu conqueror, who landed B.C. 543, and afterwards established his power over the various tribes which then occupied the country. It was at the marriage festivities of a chief of Lakagalla that Vijeya surprised and massacred a multitude of Yakkas, and thus secured that ascendancy in Lanka which enabled him to found a dynasty whose patronymic became the name of the island, and, after enduring through twenty-three centuries, only fell before the British power in A.D. 1815, when the last of one hundred and sixty-five Sinhalese kings passed from the Kandian throne to a British prison.

"From Matale to Narrangamma, by the way we had come, was nearly double the distance of a jungle-path leading over the range of mountains which we had doubled by passing round its extremity at the Ambanganga. I had directed a large body of people to make this short line passable for a horse, and to clear the jungle on each side; as afterwards, by this route, the inhabitants of Lakagalla might reach the court-house in half the time that the journey now occupied. Departing for Puackpitia, we passed at a considerable elevation across successive ridges of hills, in most places free of jungle: the higher parts of these open grounds were covered with illuk and common lemon-grass, herbage too coarse for the pasture of any animals except buffaloes, but useful for thatching houses or forming temporary huts.

* Some legends say it was the birth-place, at least a chosen haunt, of Kartikeya (Nars).

† From one side Lakagalla shows three peaks, one of them is so sharp, pointed, and narrow, as to resemble a steepie of surpassing height; all of them are of solid rock:

‡ The river king, prince, or devil, the washerman's fiend, the water-fiend, are some of the names given to the visible signs of sickness that sometimes follow the course of running water in Ceylon.

"The lower slopes produced, in immense quantities, the finest grass I had seen in the island; thus it is which has rendered proverbial amongst Kandians the milk of Lagalla and the fatness of its cattle. The people of the neighbouring districts profit by its rich grazing grounds, and drive bullocks and buffaloes in thousands (when their services in cultivation, or as beasts of burthen, can be spared) to fatten in these luxuriant pastures: neither can the proprietors prevent this intrusion, as by Kandian custom all pasturage is common, unless fenced in by the proprietor; that is to say, he has the right of property, but, when left unenclosed, cannot obtain compensation for a trespass.

"In the wooded valleys that intervene between the successive ridges over which we crossed the cinnamon-bushes were abundant; and a few trees of this spice were pointed out with stems about eighteen inches in diameter, and of height proportioned to their size. The barks of these large trees had a strong flavour, but when chewed felt coarse and gritty.

"Near the Batandua pass, an elephant, in attempting to reach the leaves of a bo-tree, a food of which they are remarkably fond, had tumbled headlong from a precipice; and, falling on his thick, straight, short tusks, had shivered them to the extremity of their sockets. The animal was killed by the shock; and a Kandian, who passed soon after, secured the shattered ivory, which he produced to me, and pointed out the rock from which the animal had fallen."

The goodness of the Laggala pasturage continues to be widely appreciated by the Kandians on both sides of the mountains and one of the troubles of the planters is to keep buffaloes driven across to the patanas to graze, out of their clearings, wide ditches as well as fences being in many cases provided. Forbes refers to the coconut palm in the Laggala uplands as well as valleys. We were much struck with one prosperous grove near a Kandyan village at the back of the Knuckles range, before reaching Kalupahana; quite 2,000, to 2,500 feet above sea-level. There resides a headman who for rather more than sympathy with the would-be Rebels of '47-8, was deprived of his office and has ever since been under a cloud. His village home with its groves of fruit trees and surrounding upland rice-fields is a most picturesque one, and from this point, the Kalupahani valley with its fine expanse of forest—running from the riverside up to the top of an encircling amphitheatre of mountains,—lies like a map at our feet.

(To be continued.)

NOTES ON FUEL FOR PROPULSION AND TEA FACTORIES, AND ON TRAMWAYS, BY AN ENGINEER.

"M. I. C. E." writes:—"I enclose a page of 'The Machinery Market.' There are one or two notices that I think might be interesting to your readers who have not seen this paper, especially 'Petroleum Fuel for Locomotion.' As in India so eventually here, the 'cost of wood fuel is increasing yearly owing to its scarcity.'

"In the same paper there is an interesting article on 'Yarrow's Zephyr System of Propulsion for Launches.' 'The material used for burning is the ordinary paraffin or kerosine oil, $\frac{1}{4}$ a gallon of oil per hour for a 4-horse power engine, no skilled labour required.' In view of the increase of

railways, the daily erection of tea stores and the probable scarcity of wood fuel in a few years every attention should be given to all new motive powers for working machinery of every description.

"P.S.—Since writing the foregoing I have been reading over some notes made from time to time, and I think the following suggestion for the benefit of the island in view of a future want should be adopted. Of course, you are the man to lead everything. Consequently, I think allowing that the cost and therefore the scarcity of wood fuel will before long prevail, you should call a meeting of engineers and leading planters (I should include Government engineers that know an engine from a Coast bullock), to appoint a Committee who should read up and write papers from time to time on all new improvements on the new phase in the history of motive power, which undoubtedly we are now entering upon. So that not only the junior but many of the senior planters should be fully acquainted with what they purchase and what is best to purchase for their individual requirements. This may at first sight seem to be very rough on any agent for any particular machine. Whatever motive is eventually thought best at one time, it will be sure to be improved on in this world of progress in a few years. So the sooner their firms adopt or improve, the better for them.

"The tramway in Colombo should have been taken up long ago. Kingston, Jamaica, is in the hands of 3 or 4 individuals, and although they are always calling out 'wolf,' I know it pays well, and not over flat ground like Colombo where you could drive one of Barrell & Sons tramway cars with his new compound tramway locomotive at any pace. In Kingston they use mules. I am afraid to say how many mules die in the year, but their Half Way Tree line of over 3 miles by a couple of chains or so has a rise of an average of from 1 in 170 to 1 in 150 3 mules up and 2 mules down. Mules cost from £15 to £20 each."

On which we have to remark that the fuel question is literally as well as metaphorically a "burning" one. We were just stating suggestions for inquiries respecting Indian coal from the Warora mine, when the above letter reached us:—

INDIAN COAL TO CEYLON.—Noticing that portion of Col. Conway Gordon's railway report on Indian railways which deals with the question of fuel, the *Indian Engineer* states:—

The outturn of coal at the Warora Colliery, during the year under review, was 113,073 tons, and a profit of 6-83 per cent, on the capital cost of the colliery was made. There is every probability that a large field of virgin coal exists, and the Great Indian Peninsula Railway Company have made arrangements to take 72,000 tons annually at the reduced rate of R4-4-0 per ton.

Here it will be seen that the best coal as yet found in India can be obtained by the Great Indian Peninsula railway for R4-25 per ton. Might it not be worth while for our railway authorities, or an enterprising private individual, like Mr. Grilinton, inquiring at what rate coal from the Warora mine could be delivered on board a sailing vessel in Bombay for transmission to Colombo? With the prospect of establishing an appreciable trade, both the Mining and Railway Companies would probably concede favourable terms. If even the contract rate of the Indian Railway Company were trebled by the time the coal was landed in Colombo, or brought up, say, to R12 per ton, there would be, we suppose, a saving of 25 to 30 per cent on the rate at which English coal is supplied. In that case the remaining question would be one of quality. We have not heard anything further of the lignite of Siam, which our good friend Mr.

MacGregor, Mining Engineer, was of opinion could be conveyed to Colombo at a cost of Rs per ton. The establishment of a cotton mill at Colombo will give new emphasis to a fuel difficulty. We cannot help feeling that India, so near at hand, will be able, ultimately, to help us besides supplying her own wants from coal deposits, which are constantly being discovered, of varying quality, but generally improving as greater depths from the surface are attained. The use of paraffin or kerosene oils is advancing and bound to advance at an accelerated rate, but the sources of this fuel are distant from us, and the odour, unless it can be dispelled, would be fatal to the use of this substance in tea factories.—Our correspondent exaggerates our "leading" powers, as much as he seems to under-rate the ability of Government railway engineers to discriminate between an engine and the animal which old George Stephenson called a "coo." Engineers are professional men, entitled to put a money value on their opinions. So, for that matter, are "senior" planters, many of whom are specially employed to give advice as visiting agents. Neither class would be likely to respond to an invitation to form themselves into a society for giving advice gratis, although both have shown a creditable readiness to discuss economical questions of public interest. Mr. Rutherford, for instance, has published the results of his experience, in his dual capacity of planter and engineer. We can trust him and others, in the future as in the past, voluntarily to give their opinions on subjects of public interest. We need scarcely say that we should gladly see tramways at work in Colombo, but if animal traction is to be resorted to we should think good, strong Indian bullocks would be preferable to mules, on the score of expense. Mules have never been an institution of any consequence in Ceylon, while the planting and farming literature of the West Indies is full of these hybrid animals. We suppose their large employment was due to the proximity of the western British colonies to South and Central America, where horses and asses are so plentiful and the breeding of mules is reduced to a system. Here the Indian bullock holds the place of the mule, and we suppose oxen will be less likely to injure themselves by violent pulls at each successive start than horses or mules.

From the extracts marked by our correspondent we quote as follows:—

Petroleum Fuel for Locomotives.—Experiments have been made, both in India and the United States, with petroleum as fuel for locomotives. In the former country the experiments were made on the North Western Railway, two engines being run on the main line between Sukkur and Radham, a distance of seventy-nine miles. The results were most satisfactory. It was found that the cost per 100 miles, worked for various kinds of fuel, was as follows:—Patent fuel, 51.23rs.; coal, 51.14 to 57.4rs.; petroleum, 36.8rs.; wood, 15.8 to 30rs. The average evaporative power of petroleum was found to be 382 lb. of water per lb. of fuel, as compared with—Patent fuel, 771 lb.; coal, 691 lb. Petroleum is, therefore, cheaper than coal or patent fuel, but more costly than wood. The cost of wood fuel, however, is increasing yearly, owing to its scarcity. On the Sind-Pishin section, where wood fuel is not obtainable, petroleum would be invaluable. The average consumption of petroleum, according to the experiments made, was 28 lb. per train mile, one gallon of oil weighing 8½ lb. nearly. The oil is very thick in its crude state, and contains earth, water, and sulphuric acid, so much so that, in order to get it to burn, it was found necessary to strain it to get rid of the earth, and to boil it in the tank of the engine tender to clear it of the sulphuric acid and water. Although the fuel

was a novelty to the drivers, the engines were worked without a hitch. The experiments in America were made on the elevated roads of New York with petroleum refuse. This fuel is said to have proved a success, and engines can be run with it cheaper than with coal. But it is in Russia, naturally enough, the substance being so abundant, that the chief and most successful experiments have been made with mineral oil as a motive power. A very elaborate paper on Petroleum as exported from the United States and Russia respectively, from the *Oil Trade Review*, is of too great length and too much technicality for our daily issue, but we are reprinting it in our monthly periodical (*Tropical Agriculturist*) and it ought to be read by all interested—and who is not?—in the future of a material which is daily growing in importance for its light-yielding and fuel properties.

THE MELBOURNE EXHIBITION.

(From an ex-Ceylon Planter.)

The Exhibition, to celebrate the Centenary of the occupation of Australia by the white man, was opened in Melbourne on the 1st August with great pomp and ceremony; a huge procession, comprising all the military, navy, and trades unions of Victoria, marching through the main street, Collins Street, which is a mile long, accompanied by numerous bands, together with representatives of all the Benefit Societies, mayors by the dozen, and town councillors innumerable, processed to the building in the early morning, where the "upper crust" of all the colonies, together with the public who cared to pay a guinea for the privilege of being present to witness the ceremony, assembled waiting the arrival of the viceregal party which reached the building about 12 o'clock. This consisted probably of the largest number of H. M.'s representatives ever met together to assist in any ceremony, there being no less than six Governors present, each with his suite: these were escorted through the streets by a business-looking squadron of Victorian mounted rifles, the streets being lined by a vast crowd, the numbers of which it is simply impossible to estimate. The crowd though made up of all classes of society was well-dressed and orderly, but no signs of their patronizing vice-royalty were apparent with the exception of the faintest cheer at very long distances apart, and perhaps about one individual in 1,000 taking the trouble to doff his hat. [The Australians, as a rule, will not appreciate the value of a home representative amongst them, until they get a foreign fleet thundering at their gates, when they will anxiously look out for the fleet of the mother country, and until something of that kind occurs all ideas of imperial federation may be dropped; however this by the way.]

The ceremony, with the usual concomitants in such grand functions, passed off with success, a telegram—advising the same—being despatched from the building to the Queen, which reached London in 36 minutes: an answer appearing in all the Melbourne papers the next morning.

The attendance at the Exhibition so far has been disappointing: this is probably caused by the weather, which is very cold, the building itself being exceedingly cold and drafty; however the almond trees being in full blossom show summer to be near at hand, when a larger attendance may be expected.

CEYLON TEA AT HOME.

I was amused at a shop close to us, to see a tin with label

"Spring Blossom

"Ceylon Tea.

("Being the choicest spring pickings of Ceylon, India, and China teas.") It is called "The Spring Blossom Brand," and the label gives this quotation from the *Living Telegraph* of June 24th, 1886:—"The Ceylon tea is not

a mere fancy article; it is good sterling stuff, commanding a high price in open markets of recognized strength, cured with the best knowledge of modern times." The canister ($\frac{1}{2}$ lb. and 1 lb.) both 2s and 2s 6d tea has tin lid and bottom, but the body of it is of cardboard blocked into a round shape. There are 15 or 20 shops in this town where Ceylon tea is sold.—*Home Cor.*

INDIAN WOODS SUITABLE FOR ENGINEERING PURPOSES.*

BY THE LATE-KUNHYA LALL (RAI BAHADUR), M. INST. O. E.
The Principal Indian woods suitable for engineering purposes are:—1. Bamboo; 2. Babul, or Keeker; 3. Deodar; 4. Ebony; 5. Sal; 6. Teak; 7. Toon; 8. Tamarind, or Imli; 9. Shishan.

1. The Bamboo (*Bambusa arundinacea*) is the most generally useful of all the vegetable productions of India. It forms the war lance of the cavalry, and the deadly bow of the Bheel, as well as the pole of the dooli which carries the wounded soldier out of action. It is used for boat-oars, clubs, walking-sticks, and for scaffolding. It also forms a principal material in thatched roofs of houses, in which it is employed for the net-like frame-work that supports the thatch. It is an ornamental as well as a useful garden-tree. The bamboo is of two distinct kinds, the small, hard, close-grained variety, and the large hollow one, generally used for the uprights in scaffolding. The bamboo is very tough, and is stronger than any of the Indian woods.

2. The Babul (*Acacia Arabica*) is found on sandy and clayey plains and waste-lands. It thrives best on the poorer soils, as it is generally found on all the uncultivable lands around Indian villages. The tree seldom attains a greater height than 30 or 35 feet, or a greater thickness than 2 feet. The heart-wood is of a light red colour, close-grained, hard, tough, and of great durability. It is preferred for cart-wheels and ploughs; also for the beams of sugar-mills, and for roofing purposes. It is in general request for the manufacture of tent-pins, for which it is admirably adapted by its toughness and hardness, combined with lightness, which is a point of greatest importance to the traveller. The bark of the wood is extensively used as tan.

3. The Deodar (*Cedrus deodara*) is generally supposed to be a variety of the Cedar of Lebanon, used in the building of Solomon's temple. It has great stiffness, strength, hardness, and durability, and on this account is well adapted for engineering purposes. It grows in large quantities in the Himalayan forests, and is brought down to the plains by river. It comes down the Ravi, Jhelum, and Chenab, in large logs, varying from 20 to 60 feet in length, and from 2 to 12 feet in girth. It takes a long time to season, and is never well-seasoned for joiners' work under eight or ten years. For engineering purposes it is said to season sufficiently in three years.

4. The Indian Ebony (*Diospyros ebenaster*) is of a small size, not more than 8 to 12 inches in thickness. The natives use it for axles of carts, for which purpose it is admirably fitted by its extreme hardness, toughness, and strength. The sap-wood is much used for door-frames and for wheels; but the heart-wood alone is used for furniture. It is the heaviest Indian wood yet known, being superior to Sál in this respect. The heart-wood is of a very dark colour, approaching to black, and takes a good polish. On this account it is used for ornamenting furniture, for wood carvings, and for ornamental ceilings.

5. Sál-wood is obtained from the principal forests along the Terai, at the foot of the Himalayan Mountains and the Vindhyan Hills near Gaya. The sál (*Vatica robusta*), one of the most celebrated of the Indian trees, as well as one of the most useful, is close-grained and of straight fibre, possessing great stiffness, hardness, strength, and durability, and is the chief building timber in the North West Provinces of India. It is the heaviest Indian wood

except ebony. It can be obtained from 40 to 50 feet in length, and from 1 foot to 5 feet in thickness. The logs are almost straight, without any knots, flaws, and cracks; but the wood dries so slowly that it continues to shrink for several years after other woods would have become quite dry. Small scantlings and planks are very liable to warp in drying, unless some means are employed to prevent it. Sál-wood is very heavy and coarse-grained, and is particularly straight and even in fibre. It is superior to almost all woods in strength, and is well adapted for engineering purposes.

6. Teak (*Tectona grandis*) is not procurable in the Punjab, nor in the North-West Provinces, but is obtained from Burmah, Bombay, and from the Central Provinces. The tree does not reach any great size; the largest timbers not being more than 16 feet long by 12 inches in breadth. It is used in small scantlings for railway-carriages and for flooring. Beams for roofs are seldom obtained exceeding 20 feet in length. Indian teak is much superior to Burmese teak in strength and beauty. The weight is about the same; but the deeply-marked, and wavy irregular veins of the Indian tree afford a much handsomer cabinet wood than the straight-grained and faintly-marked timber of the Burmese variety. It is almost straight, close-grained, and of even fibre, and is on that account well fitted for engineering purposes. Doors and windows are also made of it.

7. The Toon (*Cedrela Toona*) is another of the more useful Indian woods. It resembles mahogany, and has been brought into general use by Europeans. It is a very excellent substitute for mahogany for making tables, chairs, book-cases, frames, and furniture of all kinds. It is also used for doors and windows of houses, but not for beams and joists of roofs, as it is not strong enough, and is also costly. It becomes rapidly brown with age, unless it is kept well waxed. The toon tree is grown in most gardens, of which it forms an elegant ornament.

8. The Tamarind (*Tamarindus*) is found chiefly on hard dry soils, occasionally also on black soils, but never on hilly or rocky ground. A full-grown tamarind presents the finest appearance among Indian trees both for size and beauty. The young tamarind, of from twenty to fifty years' growth, is much used for door-frames, but is subject to the attacks of worms unless well seasoned. The wood is of a crooked grain, and is therefore not fitted for roofs. It affords a profusion of fruit.

9. The Shishan (*Dalbergia latifolia*) is another popular Indian wood, but is never obtained in long lengths, and is therefore not fitted for roofs except for small spans. It is used for furniture of all kinds, being very hard and tough, and taking a good polish. It is found all over the plains of India. The heart-wood is heavy and of a reddish colour, and is employed for structures where hard wood is required. It is in general use by the natives as well as Europeans. It is the only wood adopted for furniture in the Punjab.

Of the above nine kinds of woods, the most useful for engineering purposes, are Deodar, Sál, and Teak, as they possess great strength, hardness, stiffness, and durability. These qualities are generally found in timbers which are free from large and loose knots, and straight-grained, and which are least affected by being soaked in water.—*Indian Engineer.*

[On the above we would remark that there are a great many more species of bamboo than two; that the *babul* might well be grown in the drier parts of Northern and Eastern Ceylon; that we need scarcely regret the absence of the deodar from Ceylon, seeing it is so slow of growth and requires so many years to season; that the Ceylon ebony is evidently superior to the Indian; that the sál would be a real acquisition in Ceylon, if the seeds could be got to retain their vitality; that special attention should be given to teak at low elevations and to toon at high altitudes (it grows readily in Nuwara Eliya); that tamarind also should receive attention as a useful and ornamental wood, and that *Dalbergia latifolia* would be valuable, as would also *Dalbergia sissoo* if they could be naturalized in Ceylon.—Ed.]

* Other Selected Papers. Trans. Inst. O. E.

PROGRESS IN TRAVANCORE.

CARDAMOMS—COFFEE—COPRA—FORESTS—RAINFALL—REVENUE.

From the Report on this Native State for 1887-88, we take a few extracts:—

CUSTOMS.—There was a falling off in the year in the export trade of all the chief dutiable articles, viz., copra, coir, areca-nuts, &c. The duty on pepper, on the other hand, yielded a higher revenue.

CARDAMOM AND OTHER GOODS.—The outturn of the cardamom crop in the year proved very disappointing, having been much less than was anticipated. This is a very fluctuating and precarious source of revenue.

The available revenue for the year amounted to R12,175,872, which, however, included a balance from the previous year to the outrageous amount of R5,819,445. On such a reserve the Madras Government commented adversely. From the estimates for the following year we quote an follows:—

CARDAMOM AND OTHER GOODS.—From accounts of the condition of the cardamom crops received, the prospect this year appears to be promising and justifies an estimate at over a lakh in advance of the actuals of the previous year.

From the report of the Resident we quote thus:—

LAND REVENUE.—The table of rainfall in the State given by the Diwan is interesting, showing the gradual increase of rainfall from 8·8 inches in the south (at Cape Comorin) to 118·9 inches in the extreme north of the State (at Poravoor). Owing to deficient rainfall during the year, there was a slight failure of the later crops in the south; increased imports, however, prevented any rise of prices. The total revenue demand amounted to R18,02,883, of which R17,35,646 was collected. Of old arrears no less than R5,43,291 are still outstanding, and special arrangements have been made to collect the amount. Such an amount of arrears shows a bad system of accounts. The management of the Puniath Chief's estate has been continued by the Sirkar with the favorable result of a balance of R13,942 to the Chief's credit. A change was introduced in regard to the assessment of hill cultivation of a temporary character. Instead of taxing the produce, the tax is now levied in money on the area cultivated. This is a more equitable method. The system of dealing with applications for waste lands was dealt with during the year; and power was given to the Division Peishkars to deal with such applications, with the result that the quantity of land taken up has increased and the revenue proportionately benefited. The Administration has been actively working for the benefit of the people:—

(1) In placing more power in the hands of the Peishkars to enable them to deal more promptly with applications for waste lands;

(2) In endeavouring to introduce better systems of agriculture in the country;

(3) In assisting in the construction and repair of embankments and channel banks;

(4) In encouraging improved agriculture and stock-breeding by the introduction of exhibitions.

FORESTS.—The net revenue derived from forests was R1,97,298. A Forest Act is being introduced, which will tend to the better conservation of forests. The prices realised for cardamoms was considerably below the average, and the crop was a very poor one. The Ceylon cardamom production affects the Travancore monopoly selling prices.

The financial condition of the State is prosperous and the general administration appears to me to be sound and progressive.

The Government Order states:—

TRADE.—Exclusive of Government transactions and internal trade, there was a slight decrease (1½ per cent.) observable in the trade of the State. The amount carried by the backward for importation was less than that in the year before by 25 per cent. The depression in the coffee industry, which has been felt for a long series of years, showed no signs of departure. The value of the total exports, R2,21,000 in 1861, was only a lakh of rupees this year. Of

the exports, copra (25·4), coir (20·7) and miscellaneous goods (14·3) again bore the best proportion to the total value, and pepper rose to 9·2 per cent. Under imports the best results were shown by tobacco (29·5), miscellaneous goods (19·7), rice (16·7), thread (12·1) and piece-goods (11·0). Nearly 85 per cent of the trade was in the direction of British India; that towards the United Kingdom fell from almost 3 to below 1 per cent; and that towards Ceylon rose from 9 to 10.

A SUMATRA TOBACCO PLANTER.

We have to welcome back Mr. Melville Bell of the Kelani Valley looking all the better for his short trip to the old country, where, however, he found even "summer" weather far too cold—bitterly cold—to suit a Ceylon wallah. The Red Sea on the return trip made, however, ample amends: 98° in the saloon must have been a contrast to the "bitterly cold" of Edinburgh a fortnight earlier!

A fellow passenger of Mr. Bell interested in Ceylon was Mr. Harrison of Deli, Sumatra, who is engaged in a large way like so many residents there in tobacco. Mr. Harrison, beginning life as a surveyor some twenty years ago, must have been one of the earliest among tobacco planters, and he is evidently well up in all the "mysteries" connected with tobacco curing. Some years ago he tried as a diversion some 50 acres of cacao, but dropped it on learning that Ceylon had begun to plant that product, because, as an adviser said, "whatever Ceylon touches is overdone"! Mr. Harrison was enlightened on learning that both in cacao and tobacco Ceylon can never lead the way as she did with coffee, cinchona, cardamoms and may do with tea and now does with cinnamon and coconut oil. On our remarking that cacao wants not only good deep soil but shelter, Mr. Harrison made the characteristic remark that they should never have grown tobacco in Sumatra if exposed in any way to wind, or to drought such as Colombo is suffering from, he added, to judge by the burnt-up Galle Face! Moisture and shelter (or absence of wind) are therefore wanted for tobacco, and yet how about dry Kurungala and Dumbara? Mr. Harrison, we are glad to say, is likely to give us farther information about tobacco, and he may be back here on a visit to our hillcountry a few months hence.

NOTES ON PRODUCE AND FINANCE.

(H. & C. Mail, Aug. 24th.)

This is the season when, as poor Harry Leigh said:—

"My Brown has gone away to Greece,

My Robinson to Rome;

My Jones was off today for Nice,

And I am still at home.

One friend is on the Tiber,

Another on the Rhone,

The third a *bock*-imbiber—

And I am all alone."

Tea, like time and tide, wait for no man, and the chests continue to arrive, irrespective of Tomkins, who is in Venice, and Smith who is at Margato.

The question of the quality of Ceylon tea and the remarks thereon that have appeared in some brokers' circulars, are the subject of comment in the *Lane*. In a circular issued in June by Messrs. J. A. Rucker and Bencraft the following remarks occur:—"Every halfpenny lower brings Ceylon tea into competition with cheap China tea, and if the element of quality is to be eliminated, and more and more low class tea sent forward, it will not be long before planters find themselves at a level were the greater the output the greater the loss—net profit. We constantly read statistics to show how Ceylon tea is ousting China tea from consumption, but if Ceylon tea is going to interfere with 3½d. China congenues, there will be a little profit to the planter, and precious little pleasure to the consumer."

Mr. Alfred Seovell thereupon wrote to the *Ceylon Observer*, asking why it should be the fashion amongst numerous firms in the tea trade to continually damu with faint praise and to do all they can to prevent Ceylon increasing its output, points to the one conclusion, that these firms must be largely interested in China tea, and unable to shake off their Hankow connections. The prayer of the whole circular is,—For goodness' sake don't interfere with our 3½d congous, or, if you do, the greater output will be the greater loss—not profit. If you oust our 3½d congous, "there will be little profit to the planter, and precious little pleasure to the consumer." This is one admission that the present China congous afford precious little pleasure to the consumer. So far so good; and the sooner these fifty millions per annum of Congou rubbish are ousted, the better. From beginning to end the circular is dead against quantity from Ceylon, and the conclusion is that the above-named firm must have a big thing in China Congous, which are admitted by them to be next door to rubbish.

The *Grocer* commenting upon this says:—"While making every allowance for parties living at a considerable distance from the home markets, it must be evident to most persons who peruse this letter that the author of the letter could not have been very well acquainted with the position and standing of the London house on whom he tries to throw the greatest discredit." A correspondent of that paper in the same issue says:—"We would suggest that it would be greatly to the interest of the pure Ceylon tea trade if you could form a jury of (say) the five leading Ceylon brokers, to whom, through you; samples of the various brands of teas offered as Ceylon could be submitted; and if the reports of this jury were published in your paper, we think a very serious check would be given to what we would call the spurious Ceylon trade.

The rice planters of Louisiana are considerably disturbed in consequence of the formation of the American rice millers' "trust." It is urged that, under cover of protective duties the Louisiana rice planting industry is being extended very rapidly, and bids fair not only to rival the local sugar industry, but to produce sufficient to permit of a surplus for export. The rice millers, however, have now combined to maintain a fixed price for cleaning rice on account of the planters, and to dictate their own price for rice bought on their own account. This latter they are enabled to do by refusing to buy except through one appointed agent, who is thus made the sole customer to whom the planters can sell. The planters apparently fail to realise that, under the protective system, being as yet unable to produce sufficient rice to supply fully the home consumption, they themselves practically constitute a combination which has hitherto had both consumers and millers at its mercy. Were the protective duties abolished, millers as well as planters would find such combinations impossible, as they would be compelled by foreign competition to allow prices to take their natural course. The millers' combination for the purpose of "squeezing" the planters is essentially the same in principle as the protectionist combination for the purpose of "squeezing" the consumers.

The French Government is very ingenious in its diplomacy. Just now it is making a difficulty in the sugar bounties question in regard to the new English invention—saccharine, which it declares will undo all that the proposed Convention will assert. As a result, the British excise authorities are maintaining a very strong attitude towards the product of tar which sweetens so powerfully, and are prohibiting its use wherever possible.

Baron De Worms is quite sanguine as to the result of his labour in connection with the sugar counties. Writing to the Burton Trades Council, he says:—"Your meeting appears to have been so unanimous that the bounties were unfair and unjust to British workmen, that I need hardly add a word to emphasise the obnoxious character of this system; but I should like very briefly to ask of you to keep well in view two special phases of this subject, viz., that in seeking to terminate the

bounty system, we are aiding the removal of a serious impediment to free trade principles; which of course do not admit of bounties. In the next place, it is important to remember that foreign governments do not give these bounties out of philanthropic regard to the English consumer, or to make his sugar cheaper. We would be lamentably shortsighted if we acted on this assumption. The bounties are paid to establish in the several countries a sugar industry, and by so doing to crush out of existence the British branch of this industry. If that should be accomplished, the foreign producer assuredly would raise the price of sugar. But I am hopeful we may avoid the calamity by a general agreement to abolish bounties in the interests of all concerned."

LIBERIAN COFFEE CULTIVATION.

(*British North Borneo Herald*, August 1.)

The following reliable Estimates for a Liberian Coffee Estate have been kindly furnished us by our Ceylon Agent, Mr. W. D. Gibben, and which cannot fail to be of use to intending Planters in North Borneo. It should be noted the estimates are calculated in rupees, the currency of Ceylon.

ESTIMATE FOR OPENING A LIBERIAN COFFEE ESTATE OF 100 ACRES EXCLUSIVE OF COST OF LAND.

	52,000.00				
	R1,987.12				

Dr. Balance end of 7th year.

Subsequently stores improved and manuring required a liberal allowance for cultivation would be Rs9 per annum, say Rs,000 expenditure annually, while crops could be averaged probably over 400 cwts = 1.400 crop.

Leaving profit of Rs,000 annually.

ELECTRIC LIGHTING ON SUGAR ESTATES.—We (*Mauritius Gazette*) understand that several estates have adopted electric lighting for their mills. "Alma" and "Midlands" have just commenced crushing and have been lighted with about fifty incandescent lamps of thirty-five candle power each and one arc light of about 1,000 candle power for the yard. These installations are worked by a Gramme dynamo of the latest improvements.

MR. THOMAS CHRISTY, who was chiefly instrumental in obtaining from the Board of Customs permission to use refuse tea for the manufacture of caffeine in this country, sends us a sample of the chemical manufactured, we understand, by Messrs. Howards & Sons. We also notice from an advertisement published by Mr. Whiffen, of Battersea, who has likewise commenced the manufacture under similar conditions, that he is now prepared to supply the alkaloid.—*Chemist and Druggist*, Aug. 25th.

CALIFORNIA.—Rev. Dr. John Hannon in a letter to the Richmond "Christian Advocate" speaks of California, to which land he was exiled:—*In the Superlative Degree*:—The biggest 'milk dairy' in the world, the largest butter dairy in the world, the largest almond orchard in the world, the largest orange orchard in the world, the largest vineyard in the world, the most productive gold quartz mine in the world, the largest hotel in the world, the largest grape vine in the world, the corporation which has built the most miles of railroad in the world, the largest telescope in the world (I think perhaps), the biggest vessels in the world: these are some of the things that California glories in.—*Southern Planter*.

COTTON GROWING IN CEYLON: NEW GINNING MACHINES IN CHINA.—Mr. Consul Scott, of Ningpo, describes a new cotton ginning machine now used in China, which is imported from Japan, and which is said to have two great advantages over American methods: (1) the staple is less cut and injured; (2) the seeds are apparently better cleaned. It seems probable that in a few years the smaller machines must come into general use throughout the cotton-growing districts of China, and a very large demand for them must arise—a demand that, if the principle is really of the excellence suggested, will not be confined to China, but will extend in America, India, Egypt, and all cotton-growing countries. It would seem that the invention is one worthy the immediate attention of British machinery manufacturers.—*Chamber of Commerce Journal*, Aug. 6th.

THE PEARL FISHERY OF MOZAMBIQUE.—The Belgian Consul-General at Zanzibar, in a recent report, makes the following reference to the pearl fishery of Mozambique:—"There exist on the coast reefs of pearl oysters, of which the most important is situated to the south of Chiloane, in the Bazaruto archipelago. The greater portion of this reef is within enclosed waters, and as it has never been regularly worked, the pearls which would be found there ought certainly to be of very considerable dimensions. At Mozambique and Ibo, similar but less important reefs are met with. In the latter locality the negroes, who devote themselves to the oyster fishery, often find black pearls of great beauty, but their value is absolutely destroyed in consequence of the method employed in extracting them from the shells. This method consists in placing the oyster in the fire. The working of the pearl oysters has hitherto been unfettered by legislation."—*Morning Post*. [What a chance for some enterprising Ceylonese capitalists—Messrs. De Soysa, Muttiah, Jeronis Pieris & Co.—to charter a steamer and despatch trustworthy agents with a select number of our Pearl Fishery divers?!—Ed.]

LOSS TO PRODUCTIVE INDUSTRIES IN UNITED STATES.—The annual loss to productive industries in the United States caused by insects is estimated at 150,000,000 dols. The loss to the cotton crop is estimated at 15,000,000 dols. a year, while that to the apple crop is not much less, and that to the potato crop at least one-half as much.—*Indian Agriculturist*, Aug. 25th.

TEA IN FIJI.—The *Fiji Times* thus notices a sample of tea grown on the estate with which Mr. Arthur Stephens is connected:—"We have received from Alpha estate a sample of Pekoe of excellent quality. This description of tea always fetches a high price when it attains anything like its proper sapidity, and the small lot inspected, should certainly be spoken well of in the market. There can be no doubt as to its suitability for the purpose to which it is chiefly applied—that of giving an extra flavour to ordinary teas. It is remarkably well cured and merits all the commendation which can be bestowed upon it."

HIGH-PRICED TEA IN IRELAND.—In the latest book on Ireland by Mr. Hurlbert, there is a curious reference to tea. The *Spectator* review says:—"Mr. Hurlbert was told repeatedly in the Gweedore district that the people there constantly bought tea at 4s or 4s 6d per pound, which they stewed and drank continually,—the teas offered at any cheaper rate being despised, though the flavour of the tea cannot possibly be discerned by people who use tea after this cruel fashion. They buy these extravagant priced teas on credit, always being more or less in debt to the dealers."

THE SEASON seems to have been extraordinary all over India: drought in some places and drowning in others. A Chittagong planter sends to the *Indian Planters' Gazette* a record showing incessant rain from 15th July to 24th August, rising on one particular day, August 15th, to 10.54 inches, followed by 4 next day. In the 40 days 54.47 inches fell. To quote:—

"Swamped Out" writes us from Chittagong:—"We have had the most extraordinary weather here since the 15th ultimo. I append below an extract from my rainfall register. The fall in 41 days raised my rainfall from 37.23 to 92.65 and, as during all this time we have had no sunshine, you can imagine the planter community have had anything but a cheerful time of it. The rice crops, I am given to understand, have suffered very severely, no less than three separate consecutive sowings having been destroyed. While I write the heavens continue overcast and we seem in for some more of it."

CEYLON TEA IN AUSTRALIA.—There is a very common opinion amongst planters here that people in Australia do not care for really good first-class teas, for which they have to pay a decent price. We have just received an elaborately got up circular from Messrs. James Inglis & Co., of Sydney, evidently a big firm, and in speaking of their imports they say:—

With regard to our own imports, in addition to the finest Panyong, Souchong, Saryune, and Yung How procurable, we are this year bringing down from Hankow a chop of the very finest Ning Chow Congou such as now invariably goes to Russia, and though this is, of course, an experiment, we believe that consumers in New South Wales are quite willing to pay value for really fine Tea, if it be offered to them.

Having this object in view, we recently imported by far the finest Ceylon Pekoe that has ever come to Sydney, and we have so perfected our arrangements that we shall, in future, be in regular receipt of varied and well-selected shipments from both the Northern and Southern ports of China, and from India, Ceylon, Japan, Java and Fiji. It is to be hoped that if the taste for good tea is thus cultivated Ceylon will be able to hold her own.

ROYAL GARDENS, K&W.

(From the Bulletin of Miscellaneous Information.

August 1888.)

COLONIAL FRUIT.—In the *Kew Bulletin* for the months of November 1887 and January 1888 information, derived from official sources, was supplied, respecting the capabilities of certain Colonies for the production of fruits. The *Bulletin* for November 1887 was wholly devoted to a comprehensive report on the fruits of Canada. The *Bulletin* for January 1888 was devoted to reports furnished by their respective Governments on the fruits of Victoria, South Australia, Western Australia, Tasmania, New Zealand, Cape Colony, and Mauritius. In the present *Bulletin* it is proposed to continue the publication of such reports, and we now present a summary of information relating to the fruit productions and fruit sources of the West Indian colonies:—Jamaica, Bahamas Islands, Barbados, St. Lucia St. Vincent, Grenada, Tobago, Trinidad, and British Guiana.

The list of questions to which answers are now furnished was published in the *Bulletin* for November 1887, pp. 2–4. This list, if consulted, will afford a key to the arrangement of the reports and furnish those interested with the special points to which the inquiry has been directed.

JAMAICA.

The chief fruit interest in the West Indies is connected with Jamaica. The exports of fruits from this island are of the annual value of a quarter of a million sterling. The following Report was prepared by Mr. J. H. Hart before his transfer to the charge of the Botanical Gardens at Trinidad:—

The chief fruits of the Island of Jamaica are Cocoa-nut (*Cocos nucifera*), Banana (*Musa sapientum*), Orange (*Citrus Aurantium*), Pineapple (*Ananas sativa*), Lime (*Citrus Medica*, var. *acida*), French Lime (*Citrus Medica*, var. *Limetta*), Mango (*Mangifera indica*), Citron (*Citrus Medica*), Lemon (*Citrus Medica*, var. *Limonum*), Shaddock (*Citrus decumana*), Forbidden Fruit (*Citrus decumana*, var.), Avocado Pear (*Persea gratissima*), Bread Fruit (*Artocarpus incisa*), Neesberry (*Achras Sapota*), Bilberry (*Vaccinium meridionale*), Strawberry (*Fragaria vesca*), Star Apple (*Chrysophyllum Cainito*), Guava (*Psidium Guava*), Pome d'or (*Passiflora laurifolia*), Granadilla (*Passiflora macrocarpa*), Nutmeg (*Myristica fragrans*), Otaheite Apple (*Eugenia malaccensis*), Rose Apple (*Eugenia Jambos*), Otaheite Gooseberry (*Cicca disticha*), Cashew (*Anacardium occidentale*), Grapes (*Vitis vinifera*), Cherimoyer (*Annona Cherimolia*), Sour Sop (*Annona muricata*), Custard Apple (*Annona reticulata*), Sweet Sop (*Annona squamosa*), Genip (*Melastoma bijuga*), Tree Tomato (*Cyphomandra betacea*).

Cocoa-nut (*Cocos nucifera*).—This is placed first on the list on account of its being a fruit which is likely to become in the future of more permanent value than any other (1) on account of its keeping qualities, (2) for its economic value, (3) for certainty of crop, (4) for permanence of crop, (5) by reason of its requiring little or no cultivation, and (6) by its being adapted to many kinds of soil.

Banana (*Musa sapientum*).—Obtainable throughout the year, but most plentiful during August and following months. Supply good, except after hurricanes; cultivation might be largely extended.

Orange (*Citrus Aurantium*). In full season during the closing months of the year. Supply very good, capable of being largely extended.

Pineapple (*Ananas sativa*).—In season June, July, and August in large quantities: all the year round in fair numbers. Could be grown in large quantities if demand arose.

Lime (*Citrus Medica*, var. *acida*).—In season all the round. If the paying demand arose the supply could in three or four years be made unlimited.

French Lime (*Citrus Medica*, var. *Limetta*).—This possesses more pice; is larger, with skin resembling an orange; it is a very fine fruit. The supply is small, but worthy of extensive cultivation. [Have we got it in Ceylon?—Ed.]

Mango (*Mangifera indica*).—Throughout the island the supply is now practically unlimited, but were an export demand to arise, better varieties would be planted and the value increased. In season June, August.

Citron (*Citrus Medica*).—Supply small all the year round. Capable of being extensively grown at lower elevations of excellent quality.

Lemon (*Citrus Medica*, var. *Limonum*).—Supply small, but of excellent quality; could be extensively grown. Shaddock (*Citrus decumana*).—See Lemon.

Avocado Pear (*Persea gratissima*).—Supply very good. In season from June to September at different elevations. Supply could be very largely extended in a few years.

Bread Fruit (*Artocarpus incisa*).—Supply small comparatively, except in moist districts; in season during most months of the year. If cooked by baking will keep well for two or three weeks. [We have never heard of it being so kept in Ceylon?—Ed. T. A.]

Neesberry (*Achras Sapota*).—One of the most delicately flavoured and wholesome fruits grown. Gathered when "full," it will stand transport well. In season June to November.

Bilberry (*Vaccinium meridionale*).—A wild mountain fruit which could be readily cultivated; makes a fine coloured natural jelly, a good wine, and is excellent for tarts. June and August. [Has the bilberry ever been tried in Ceylon?—Ed. T. A.]

Strawberry (*Fragaria vesca*).—A small variety resembling the Alpine species. In season on the mountains at 4,000 feet during nine months of the year, wild.

Star Apple (*Chrysophyllum Cainito*).—In season June to September. A fruit difficult to transport.

Guava (*Psidium Guava*).—Supply limited. Wild; no good varieties cultivated though present. June and July.

Pome d'or (*Passiflora laurifolia*) and **Granadilla** (*P. macrocarpa*).—Could be cultivated in quantities for export. July September. [Was at one time (forty years ago) largely cultivated in Ceylon and ought to be so still.—Ed. T. A.]

Nutmeg (*Myristica fragrans*).—Mentioned here for sake of its pericarp or outer fleshy envelope which is succulent and possesses a fine mild spicy flavour; makes an excellent and rare preserve, which only waits to become known to encourage a large demand.

Otaheite Apple (*Eugenia malaccensis*) and **Rose Apple** (*Eugenia Jambos*).—Make excellent preserves, and are in season from June to October. They possess a flavour which reminds of the smell of rose, the latter especially.

Otaheite Gooseberry (*Cicca disticha*).—An acid fruit. Might be bottled as gooseberries.

Cashew (*Anacardium occidentale*).—Make an excellent preserve; will not stand transport. Nuts, when roasted, are a choice dish for dessert.

Grapes (*Vitis vinifera*).—Grown in small quantities in the neighbourhood of Kingston, chiefly the Muscat varieties, but never likely to become a reliable crop, all the year round.

Cherimoyer (*Annona Cherimolia*).—A mountain fruit of great delicacy, but difficult to transport. July to September.

Sour Sop (*Annona muricata*), **Custard Apple** (*A. reticulata*), **Sweet Sop** (*A. squamosa*), and **Genip** (*Melastoma bijuga*).—Tropical fruits of ordinary value. June to October.

Tree Tomato (*Cyphomandra betacea*).—A tree bearing a fruit of excellent quality, which when preserved, somewhat resembles in colour and flavour the Apricot of Europe. Will only grow at elevation of 2,000 ft. and upwards in a temperate of 63° mean annual. The tree fruits all the year round; is easily cultivated, and the supply could be increased to any extent in two or three years.*

Of the fruits most capable of being produced in larger quantities the first 14 mentioned are most deserving of notice, for they could be extended to

* It is equally successful in Ceylon. This fruit and the vegetable cho-cho are valuable ac positions, due to the enterprise of Mr. Neek of the Hakgalla Gardens.

an enormous degree if proper facilities were afforded for placing them in suitable markets. The production of the other fruits mentioned could be increased to a very large degree if any profitable demand were to arise.

The steps necessary to develop the fruit trade are:—

1. Suitable and speedy transport.
2. Certain markets.
3. The institution of a system of brands at port of export so that fruit of a certain brand should be of uniform quality; in a similar manner to the governmental inspection of fish stuffs in the province of Nova Scotia, which does not permit an inferior article to be exported.
4. A better system of packing, methods for which might be introduced under Government control for a time to show cultivators that higher prices would surely accrue from well-packed fruit.
5. To introduce a syndicate for packing, delivery, and sale of fruit produce in the best markets, instead of trusting to brokers and irresponsible agents.
6. Telegraphic communication from responsible agents to enable sellers to place their produce at ports where there is the best demand from time to time.
7. And not least, money at easy rates to assist cultivators or an agricultural loan bank.

As to preserved fruits, the local methods hitherto in vogue are too expensive. What is required is to institute the modern English and American methods, which should be done by someone conversant with the extensive plant required in a preserved fruit factory. The price of locally preserved fruits is prohibitory to their extensive sale, and as a rule the taste of buyers is not consulted. An article suitable for the West Indies does not as a rule suit the European palate.

The quality of Pine-apples, Bananas, Oranges, Lemons, Mangoes and Neesberries grown in Jamaica is of such a high character, that if suitable transport were provided they would obtain a ready sale in almost any market in their fresh state.

[Why should not fruits be grown in Ceylon for export to India at least if not ultimately to Australia?—Ed. T. A.]

BAHAMA ISLANDS.

The principal fruits of the Bahamas are Pine-Apple, Sweet Orange, Banana, Grape Fruit,* Coconut, Plantain, Limes, Mango, Sapodilla, Tomato, Water-melon, Pumpkin, Alligator or Avocado Pear, Guava, Tamarind, Lemon, Sour or Seville Orange, Shaddock, Sour Sop, Sugar Apple, Ground or Pea-nut, Mammee, Cucumber, Rose Apple, Bread Fruit, Egg Plant, Cashew Nut.

The Pine Apple is obtainable from the latter part of May to end of July. Crop amounts to about 6,000,000 fruit. The wholesale local prices are 2s. per dozen for the first cuttings, or pick of the fields, 1s. 3d. to 1s. 6d. per dozen for the second cuttings, and 9d. to 1s. per dozen for the third cuttings.

The Sweet Orange, Grape Fruit, Lime, Lemon, Shaddock and Sour Orange are in season from October to January. The Sweet Orange yield is fully 4,000,000. The wholesale local price is 1l. per thousand. The Grape fruit crop amounts to about 150,000. Wholesale local price 2s. per hundred. Of the Lime, Lemon, and Sour Orange no estimate can be given. Only a small quantity of each is available. At the present time they are grown chiefly for local consumption. The wholesale prices are respectively 9d. to 1s. per hundred, 15s. per thousand and 10s. per thousand. The cultivation of the Shaddock having materially declined within the past 15 years, the crop does not now amount to more than 4,000 to 5,000 fruit. The wholesale price is 4s. per hundred.

The Banana, Plantain, and Coconut can be obtained throughout the year. The annual yield of the Banana must be fully 400,000 bunches, by far the greater part of which is locally consumed. The quantity available for export at any one time does not exceed more than

2,000 bunches, and these would have to be collected at different points. Wholesale price is from 1s. to 2s. 6d. per bunch.

The Plantain is extensively grown, but being an important article of food, nearly the entire crop is consumed in the Colony. The annual yield is nearly equal to that of the Banana.* The quantity available for export, however, is much less, and does not exceed at any one time more than 300 to 400 bunches. Wholesale price is from 1s. 6d. to 4s. per bunch.

The Coconut is also extensively consumed at home. The annual crop is about 1,000,000 nuts, of which from 8,000 to 10,000 can be obtained any month for export. Wholesale price £4 per thousand. In a short period the crop of this fruit ought to be double that of the present time. A few years ago large numbers of trees were planted throughout the Colony, which will soon commence to bear.

The Tomato is obtainable from December to March. It is raised both for home consumption and for export. The quantity annually exported is about 2,000 bushels. Wholesale price average 4s. per bushel.

The Mango is in season from June to August. No reliable estimate of the extent of the crop can be given. It is never less, however, than 1,000,000 fruit, nearly all of which are locally consumed. Owing to the rapid ripening and decay of this fruit after being plucked it is almost impossible to export it with any prospect of success. It will not stand a sea-voyage of over a few days' duration. The foreign trade is therefore exceedingly small, and is almost entirely confined to the near port of Key West.

The above remarks also apply to the Avocado Pear, the Sapodilla, the Sour Soap, and the Sugar Apple.

The Avocado Pear is obtained in August, September, and October. Wholesale prices 4s. to 6s. per hundred.

The Sapodilla, first crop, is in season in February and March, and the second crop in August and September. The tree grows without cultivation and in the greatest abundance. The annual yield is immense, being several millions, only a proportion of which is utilized. Wholesale price 9d. per hundred.

The Sugar Apple is not available for export, and the Sour Soap in a limited quantity only (not over 1,000). The wholesale price of the latter is about 15s. per hundred.

The Water Melon is obtainable in quantity for export from May to September. The crop is about 10,000 only, about one-third of which is exported. Wholesale price average £1. 5s. per hundred.

The Pumpkin can be obtained throughout the year, but principally during the summer and autumn months. Annual yield about the same as that of the Water Melon. Wholesale price also about the same.

The Guava is in season from August to October. Crop large, and is almost entirely used in the manufacture of preserves. There is no foreign trade in the raw fruit. Wholesale price about 2s. per bushel.

There can be no doubt that the fruit can be improved by higher cultivation. Manures and fertilizers should be more generally and freely used. The fields and orchards should be kept clear of weeds. The Orange and other fruit trees should be regularly and carefully pruned and scraped.

BARBADOS.

The chief fruits grown in Barbados are Bananas, Oranges, Shaddocks, Tamarinds, Mangoes, Star Apples, Golden Apples, Avocado Pears, Guavas, Grapes, Cashews, Sapodillas, Pine Apples, Chili Plums, Pomegranates, Mammee Apples, and Papaws.

2. (a) What little fruit there is chiefly obtainable from September to March. (b) The only fruit available for export are Tamarinds. (c) The wholesale price of Tamarinds varies from three shillings to five shillings per hundred pounds.

* The distinction between bananas and plantains is unknown in Ceylon.—Ed. T. A.

† With special care mangoes have reached Vienna from Bombay in good condition.—Ed. T. A.

* A variety of the Shaddock or the Pumelow.

3. (a) No fruit is exported in a fresh state. (b) Tamarinds are exported preserved in treacle: the value of which for five years ending 31st December 1885 is as follows, viz. :—

	£.	s.	d.
1881	1,307	10	0
1882	1,122	7	6
1883	1,139	10	0
1885	2,407	7	6

(c) All of the above was shipped to Great Britain with the exception of small quantities sent to British North America in 1882, 1884 and 1885, the value of which amounted in the aggregate to one hundred and forty-three pounds ten shillings.

BRITISH GUIANA.

Remarks on the Principal Fruits of Colony.

Plantains.—These being the principal article of food of the negro peasantry, their production comes next to sugar (though insignificant in relation) as one of the staple industries of the colony. They are gathered green before maturity, and used as a vegetable, boiled or roasted. Cut when full grown, but while still green, they are used by colonists roasted in ashes. At this period they have a soft mellow, somewhat cheese-like substance. If kept for a week or ten days in store when thus gathered they ripen and turn yellow, acquiring a fruity character. They are then prepared for table by baking in the oven, whole, the skins having first been removed, or are sliced, lengthwise, and fried. In this state they resemble ordinary baked apple, but are sweeter, with a much firmer substance. Were these qualities of this fruit known in temperate countries, I think a demand would arise for it, and it might be made an article of export from the Colony. For this purpose it would have the advantage of the greater hardness it possesses in handling over the Banana. The quantity of fruit produced and consumed in the country must be very great, but there is hardly any means of estimating it. The average number of bunches annually exported is about eight thousand, valued at one thousand three hundred dollars, which are sent to neighbouring countries.

Bananas.—The cultivation is almost confined to supplying the demand for local consumption, but it might be increased to any extent. Several varieties are grown, the smaller kinds, called Figs, being chiefly in demand among the better-to-do classes. The kind apparently in most favour with cultivators and the working classes being the dwarf Chinese; this produces large bunches and is one of the best in keeping, but in quality is not so good as several of the taller growing kinds. I am quite unable to estimate the quantity or value of that locally consumed. That exported I estimate at from 10,000 to 12,000 bunches a year, and in value from \$2,000 to \$2,500. For full information on the subject of this fruit as an article of export see the paper attached entitled "Regarding an Export Fruit Trade."

Mangoes.—There is no cultivation in the proper sense of the term of this fruit. From its first introduction to the Colony it was planted on the "Dams" of sugar estates, and the greater part of the trees now growing in the country occupy these situations; and the want of drainage prevents its spreading spontaneously. Fewer trees are in existence now than formerly, for an abundance of Mangoes tends to sustain idleness among the labouring classes; and partly as a consequence of this "fruit walks," as the avemies of fruit trees on the dams were called, are not kept upon many estates now. The mango in Guiana fruits precariously, a very dry year yields usually a heavy crop, but in ordinary seasons the yield is light. At the former old settlements on the rivers very fine trees are in many places found, but they rarely fruit,—the present occupiers say only about once in seven years, and then only in an exceptionally dry season. This tendency is characteristic of the Mango in all countries to which my experience has extended. The kinds grown here are generally poor, and there is no first-class fruit among them. The Botanic Gardens are endeavouring to remedy

this by propagating only good and first-class kinds by grafting (in-arching) and offering them for public sale at a cost to cover expenses. In good mango seasons all classes have an abundance of the fruit. At such times it has hardly any value in country districts where trees are plentiful, and after transport to town, is sold at from one dozen to two dozen for a penny. In less favourable seasons it sells at twice to four times this rate. None is exported. First-class fruit would be worth exporting, but a refrigerator would be required for its safe conveyance. No attempt, however, should be made to export the fruit now available, as its quality is so poor it would only prejudice the market. The difference between poor and good Mangoes is as great as that between crab-apples, and the choicest cultivated kinds of that fruit.

Oranges.—Of this fruit there is hardly any real cultivation, nor are trees abundant. The soil and climate appear very favourable, and good crops are generally produced. Trees suffer from the orange scale pest, and individuals often succumb to its ravages. The kinds grown are not all of equal merit, but some are very good. The cultivation might be carried to an indefinite extent. There is no export, and small quantities are sometimes imported from the West Indies.

Limes.—These are not grown largely, but more than sufficient for local demand. In some places dams are planted; and there the fruit is allowed to a large extent to perish on the ground, as there is little demand for it in the local market, and the price realised does not pay carriage to town. A small quantity was exported on trial a short time ago to the United States, fresh, in barrels, upon which, compared to the quantity, there was a considerable loss. Lime-trees seem to suffer much more from the orange scale than Orange-trees do, and many from time to time are killed from its attacks. Apart from this pest, the conditions here are favourable, and the cultivation might be multiplied indefinitely. Two or three varieties are grown, one or two of which are very fine fruit.

Pine Apples.—The land of the coast region, a stiff clay, is not suitable for the best growth of this plant. Still a good many fruit are grown on the dams of sugar estates and elsewhere. Some of the best of the English kinds are among these. The sandy land of the interior, where, by the way, the Pine Apple is plentifully indigenous, is specially adapted to the cultivation. There the Indians grow this fruit more or less plentifully in their provision fields. The area of land, within reasonable distance of the ports of shipment, most thoroughly adapted for the culture of this fruit is very large. None is exported.

Guavas.—These are naturalised in pastures and other places, and consequently are not much cultivated. The greater part of the fruit wastes on the ground or is eaten by animals, but some is made into jelly for local use or for export. The entire quantity used is not however of much consideration. There are three or four varieties, all of which thrive freely on both the coast and interior lands, and might be multiplied indefinitely.

Avocado Pear.—This tree does not thrive so well here as in the West India Islands, and the fruit is, as a rule, expensive. Fine fruit is, however, produced in some places, but is chiefly consumed by the owners, and that which reaches the market is little in quantity and of inferior size and quality. In the principal season there is a small importation from the West India Islands. It thrives better in the more humid climate of the interior, and fine trees stand at some of the old settlements on the rivers.

The other fruits enumerated in the opening table are not of a quality or produced in sufficient quantity to call for detailed remarks.

EXTRAORDINARY MUSHROOM.—There has been on view lately, in the window of an Ipswich greengrocer, a mushroom of extraordinary dimensions, having a circumference of 19 in., being 15 in. across, and weighing 21 lb. 10 oz.—In *Ipswich Agriculturist*, Aug. 25th.

TEA: "THE CEYLON PAPERS AND LONDON BROKERS' CIRCULAR."

Messrs. Rucker & Bencraft have returned to the charge under the above heading, in their circular received by this mail:—

By recent mails from Colombo we have received papers containing comments, editorial and otherwise, upon our Tea Circular of June 14th.

In that circular we advocated the view we hold, in common with the principal dealers in London, that planters would, by improving the quality of Ceylon Tea rather than by increasing the quantity, find their ultimate profit.

Our suggestions are by one paper held to expose our ignorance, by another as calculated to lead to deception being practised in order to obtain a fictitious average for a particular estate, while a third disposes finally of the matter by stating that if any planter attempts to carry them out he will ruin his bushes and himself.

It is some satisfaction to ourselves to remember, that strong language and sound argument are not necessarily synonymous, and we leave it to our many personal friends in Ceylon to decide whether the criticisms are on the whole in good taste.

We should be sorry indeed to believe that both systems had now been fairly tried, that all planters had come to the conclusion that quantity rather than quality was the factor for which they must strive, and that we can only expect in future to receive from Ceylon enormously increasing quantities of common to medium Teas, and that every one had abandoned all idea of keeping up the reputation of Ceylon for the fine quality of its leaf.

Though the chorus of disapprobation in the public prints is unanimous, it is rather consoling to find the paper that is loudest in condemning our ignorance, quoting Mr. Rutherford as having stated the other day that it is by no means certain which system—fine plucking or medium plucking—gives the greater profit per acre, the only true test of the merits of either or of any system. We had supposed the question to be still open, and having witnessed the career, so to speak, of so many articles in Mincing Lane, thought, perhaps erroneously, that we might be able to indicate what we believe to be the wisest course to aim at with Ceylon tea. Our "young man" having been nearly thirty years in the tea trade, both at home and abroad, can scarcely be considered new to the duties of either tea tasting or circular writing, and we take it that part of his duty consists in bringing before our merchants the requirements of the dealers.

One of the largest buyers, if not the largest in London said to us recently, "the only hope of salvation for Ceylon Tea is to keep up the quality." In most if not all great staples, the tendency of late years has been towards over-production. Tea has been no exception, and for many years the value of Tea has been on the decline. If a broad view be taken, and we attempt to look some years ahead, we see no dearth of Tea staring us in the face; on the contrary, enough, if not abundance, promises to be the order of the day. Some hope and count on this feature as regards produce generally being checked, others consider the tendency towards over-production will increase rather than diminish, but as regards Tea we take it there can be no question but that the article sets at the present time towards over-production. While this goes on the producer of Tea who limits his out-put for the purpose of improving his article, benefits in two ways. He commands attention and even obtains competition in an otherwise flat market. He also staves off the inevitable period of depression, by doing nothing to contribute to the over-production going on around him. When the period of under-production arrives, the upward move is always more marked among the lower and cheaper grades. He then for a short time does not benefit in the same proportion. His position is, however, unassailable, and the new round soon begins, when he has his reward. We are aware that many assert that a planter can in the course of a few days change himself from a producer of quantity into a producer of quality, or *vice versa*. The former experience teaches

us to doubt for reasons which we need not enter into now, the latter we hope our friends will steadfastly avoid, even under great temptation. We have gone fully into the cost of fine plucking as compared with coarse, with both merchants and planters, and we do not find that the difference of cost per pound is as much as some newspaper correspondents would have us believe.

The challenge to satisfactorily explain to an intelligent planting community the case put forward by "Pewit" does not appeal to us, because it would be just as easy for us to put forward an example shewing quite a different result, with the names of the Estates given. "Pewit" knows whether he has simply gone for what we may term a verbal score, or whether he has given an example which planters, as a body, would acknowledge to be a fair one. On the face of it it appears to us to be an unhappy one, and to carry its own answer on its back. Fine plucking or what may be termed discriminative plucking will we believe become more and more necessary as time goes on; medium plucking being in its nature restrictive to a certain extent, comes within, and really admits the principle for which we argue. In conclusion we may be permitted to add that from all parts of the world we get applications for our circulars, originally intended for our constituents only, and though the very last thing we should think of would be to deprecate criticisms from any quarter, we cannot again notice them if they descend to personalities, personalities with which we feel convinced ninety-nine out of one-hundred Planters have no sympathy.

DRUG TRADE REPORT.

London, August 23rd.

ANNATTO.—A parcel of 7 bags fine bright Ceylon seed brought 2½d per lb., a very good price considering the position of the article. For 5 bales of medium quality 1½d per lb. was accepted.

BAEL FRUIT.—Twenty bags pale quarters, slightly mouldy, sold at 1½d per lb.

CARDAMOMS.—Today's drug sales included 117 packages, of which by far the greater part were sold. The first lots went very cheaply indeed, but subsequently much better prices were realised, and on the whole the article, though irregular, must be quoted at fully the last rates. Mysore cardamoms realised: good medium to bold smooth pale pods, 2s; long bald pale good appearance, 1s 10d to 1s 11d; medium pale fair long 1s 6d to 1s 8d; small long pale, 1s 4d to 1s 2d; dark mixed 1s; Ceylon Malabar, mixed sizes pale rather heavy, 1s 9d; smaller ditto 1s 7d; plump pale medium, 1s 9d; fair medium pale and yellow mixed, 1s 7d; small pale to brown 1s 4d to 1s; brown and split, 10d. Seed sold at 1s 3d for some lots, for others 1s 4d was refused.

CINCHONA.—The South American barks offered today consisted mainly of flat Calisaya, of which two new parcels were shown. For good hard bright orange sound pieces 2s to 2s 2d per lb. was paid, and from 1s to 1s 9d per lb. for damaged lots. Fair but very broken Loxa realised 1s 7d per lb. For Lima, fairly good bright, 2½d per lb. was refused. Forty-four bales low Pitayo, imported in 1882, were bought in. Privately similar bark has been sold at ¾d per lb., and even that price can no longer be obtained.

QUININE.—Some business has been done since our last report at 1s 3½d to 1s 4d per oz. in second hand, and the agents for the B&S brand, in a circular in which they point to the improbability of an advance occurring in the article, announce that they reduce their price to 1s 4d per oz. for October-November delivery. Other German brands, however, are still quoted at 1s 5d per oz. Howards' and Pelletier's are both held at 1s 8d for bulk and 1s 10d for vials.—*Chemist and Druggist*, August 25th.

EGYPTIAN PERFUMES.—The ancient Egyptians have never been equalled for their skill in the manufacture of perfumes. Some of their ointment, preserved in an alabaster vase in the museum at Alnwick still retains a pungent odour, although its age cannot be much less 3,000 years.—*Indian Agriculturist*, Aug. 25th.

IN THE KALUPAHANA VALLEY,
LAGGALA, CEYLON.

(Concluded from page 246.)

Enclosed on three sides by a splendid wall of mountain ranges, the Kalupahana valley certainly presents one of the finest expanses of forest-land now to be seen in the country. Whatever may be the drawbacks—and distance from road communication and wind in the south-west monsoon must be placed first, we suppose,—there can be no question of the attractive outlook to a visitor. And when the road comes nearer, and virgin forest-land becomes no longer available even in the Kelani Valley, we have no doubt that a good many plantations can and will be carved out of the 12,000 acres available at a fine medium elevation in Kalupahana.

The first man to survey and indeed take up land in the Kalupahana valley was the late Mr. Vetch of the Survey Department, a cousin of Robert Vetch Dunlop of the O. B. C. Mr. Vetch served out here for some thirteen years, retiring through ill-health in 1870 at the comparatively early age of 42, on a pension of £220. He did some good work in out-of-the-way parts of the Central Province in his day, though he never had the exposure and risks of poor old Noad who for weeks together in the jungle had to live on the fare of his Sinhalese coolies, swollen rivers in the days when district bridges and roads were comparatively unknown, intercepting supplies. Mr. Vetch sold his Laggala block of land (639 acres)—which he called Dawick, and of which not more than 50 acres ever was cultivated—to Mr. G. W. Carlyon, and he again parted with it to Mr. Borron, who though pioneering quietly for a number of years, has not extended cultivation beyond 200 acres. There are two or three other blocks owned on the margin of the valley which have never yet had an axe in them*; but I have no doubt that the success of tea in the Laggala division will encourage enterprise farther on. More particularly the great success of tea on Brae and Lauragalla estates must attract attention, for it is quiet evidence that the new giant is much better suited for windy districts than ever coffee was, and there can be in getting over the fine crops of leaf now gathered on Mr. Hugh Fraser's Brae properties or the splendid cover of vegetation there. Under the shadow of Maha Tunisgala (one of three "Tunisgala"† all of them striking-looking mountains, rising from spurs of the Knuckles range on both sides) we see no reason why even finer tea should not be cultivated. The decaying gneiss rocks which hang over the forest-clad valley give every promise of adding perennial fertility to the slopes and flats running to the riversides below and the smiling rice-fields and prosperous hill villages show that population is close at hand, not only to fell and clear the land, but also to do much in cultivating and plucking the leaf. A gathering of Sinhalese who came for their periodical redemption of the durai's brass fanam tokens, at Managala, showed that big stalwart men were ready to work for the planter. They have not yet got the length of allowing their women and children go to the tea clearings or fields to weed or pluck leaf, but that will follow as the demand for help increases. No one who admires natural scenery need feel lonely even in remote Kalupahana, while the historical associations of the neighbourhood as we have already shown by the quotation from Forbes are full of interest. The Laggala

headmen and villagers had generally to take charge of State prisoners and so members of the highest families in disgrace, settled down amongst them. In the Hattanwella village, Robert Knox spent some part of his captivity, and the people still retain the tradition of the "white man" who lived, and was esteemed for his goodness, amongst their ancestors. To the top of Maha Tunisgala, which rises like a giant sentinel over the remotest corner of the Kalupahana valley to a height of perhaps 5,500 feet, the late Dr. Thwaites, F. R. S., and Mr. A. Oswald Brodie forced their way, being richly rewarded botanically, we believe, by a trip over country never before trodden by the Botanist even if by any white man at all. The late James Gunn did a great deal of travelling and surveying in connection with the Temple Lands survey, below Laggala, but that was after the time of Agent Brodie. Our exploration of Kalupahana was confined to the lower portion, and most curious it was to note the series of rocky terraces which even there, immediately above the riverside flat, became the distinguishing feature of the land. This would indicate a series of "Gallahas" or "Oodoowellas" all the way up through the 12,000 to 15,000 acres, and of the fertility of soil so formed there can be no doubt. My companion had made the trip—a day's journey on foot—from Kalupahana round the outside base of the mountains through the village of Palugama (where empty bottles were an acceptable santosum!) to the Nitre Cave district at Tariffa. If this country were opened up properly, there can be doubt of the benefit to the natives. For sport, no other planting district perhaps affords better opportunities than Laggala, in deer, wild pig, hares, jungle-fowl, &c., &c.

Our ride back was saddened as we passed through the abandoned coffee fields of the Telgama's and recalled our first visit in 1864 across the Hoolankande Gap with W. D. Gibbon and Charlie Catto to visit their then young clearings on which so many hopes were built. If tea had been planted, we have no doubt the result would have been different; for directly opposite and above we gaze on the splendid tea fields of Lauragalla and Brae. The great part of the bridlepath up through Brae has been cut on a cart road trace and provision for a road to connect with the Cabragalla Gap ought certainly to be included in the next Supply Bill. The evening sun was fast declining as we rode up through the forest to the top of the Gap, and as we turned round to bid farewell to Laggala and its many river-fed valleys running down to the wilderness of lowcountry jungle, we could mark Lake Minneriya once more glistening in the reflected sunlight—a charming picture to carry away as a last memento of a pleasant holiday; while on the Pass itself

Summer winds, about us blowing,
Made a murmur in the land.

THE AMERICAN TEA MARKET.

(BY THE "PERIPATETIC PLANTER.")

The report and covering circulars alluded to in my last, were not got off by last mail after all, but it is hoped that they may be in time for this.

As bearing upon the ground taken up all along in these articles, on the two points, that Canada's conditions are favourable to the acceptance of Indian teas as now made, unlike the case of the United States; and secondly, that a planter of good business capacity should be a director of the crusade, it is interesting to learn, that Mr. Hayter, formerly of the Shumshernugger estate in Sylhet, having been commissioned by a small syndicate of well-known Indian firms to proceed to Canada to see what he could do for Indian teas over there, is meeting with unexpectedly rapid success.

* Among the Kalupahana proprietors may be mentioned Mr. Dunstond (Delaford); Mr. H. A. Clarke; and Mr. G. D. H. Elphinstone (Bridport).

† Hence the name.

He was given a perfectly free hand to act as he might deem best. He has only been away some three months, and he has already established agents in all the important towns over a large tract, and is beginning to receive "repeated orders," which is, of course, eminently encouraging. He is evidently, from a letter of his which I have been permitted to see, creating a broadly extended trade on thoroughly sound business lines, and considering the short time he has been at work, his success has been beyond the expectation of those who sent him. Whilst his success points to the correctness of the course of first of all selecting a good man, and then giving him *carte blanche*, which is equally applicable to the proposed scheme for exploiting America, it, nevertheless, cannot be held up as an example of the rapid success to be counted upon in the very different United States' field. Mr. Hayter's friends in Sylhet will be interested to learn that he is quite settling down to win Canada for Indian teas, and that Mrs. Hayter will soon join him in his new home.—*Indian Planters' Gazette*.

OUR TEA PROSPECTS.

The special telegram we published from Calcutta yesterday has no ordinary significance to all interested in Ceylon tea, because it seems to indicate that the anticipated increase of ten million pounds in the Indian Tea Exports for season 1888-89 is not likely to be realized. This is at least the inference of an observer who has been closely watching the Indian and China exports, and partial confirmation is found in the report of a Cachar planter who speaks of short crops from red-spider and hailstorms. Should the deficiency on estimate be realized we need scarcely say that there will be all the more room for increased exports from Ceylon, even if the China exports do not go on to show any decrease on last year's return. Another satisfactory feature in both the Calcutta and Ceylon returns is the large increase of shipments to the Australian Colonies, a process of increment which, we trust, will go on steadily until our Southern cousins take the greater part of their 28 million lb. of tea in reliable Indian and Ceylon produce. There was an absurd report the other day in some English papers that tea consumption in Russia was falling off. A great mistake: Russia is bound to go on as one of the best customers for tea, and its people as a rule like a good article. The *Daily News* (August 30th) has a paragraph as follows:—

RUSSIAN TEA IMPORTS.—Our Odessa Correspondent writes:—The fifth and last of the season's tea ships, consisting of four of the volunteer fleet vessels, and one specially chartered British vessel, the "Pathan," arrived here a few days ago. The total tea freight brought by these steamers direct from China to this port amounts to 16,740,000 lb., which shows an increase on last year's import of three and a half million pounds. The transit by the overland route via Kiachta has now practically ceased.

But altogether, we estimate in our Handbook, that Russia (in Europe and Asia) consumes 72 million pounds of tea: half being conveyed overland from China and the other half reaching Russia in Europe via the Black Sea, the Baltic and overland through Germany.

THE CULTIVATION OF NUTMEGS.

Paddling into a little cove on the south side of the bay, we landed beside a clear rippling stream, and, having ordered the whole of the men to march in Indian file in front, we started by a little rugged path into the mountains, with my interpreter immediately behind me and the Rajah just in front. Every foot of the journey, which was laborious in the extreme, disclosed fresh scenes of verdure and tropical splendour. Winding along the sides of deep ravines, sometimes dragging ourselves up by the creepers and undergrowth, we ultimately attained an altitude of about 1,000 ft. above the sea, and then entered the nutmeg country.

Here we halted and rested. The Rajah pulled some of the nutmegs, and explained how far they were from being ripe. Having rested sufficiently, we again started forward, and after scrambling along for about an hour we gained a fine piece of table-land, over which we travelled for about another half-an-hour, when we reached three houses erected in the very heat of the forest. These were used by the natives for drying the nutmegs. The country was everywhere magnificent, and the aroma of the spice-laden air delicious. Nutmeg and other equally valuable trees were everywhere growing in great profusion. The fruit of the nutmeg in appearance resembles a pear, and when ripe opens and displays the nut covered with a beautiful red coating of mace. The nuts are then picked from the tree, put into baskets and taken to the houses, where they are husked and placed on shelves. They are then partially roasted over a slow fire until all the moisture is extracted. After this they are cooled and carried down to the village in nets ready to be bartered to the Bugis, Arabs, and other traders who frequent the Gulf in their small prows or junkos at the proper season.—*Explorations and Adventures in New Guinea, by Captain John Strachan. F. R. G. S., F. R. C. I., of Sydney.—Madras Mail.*

PRIZE PADDY CULTIVATION.—The Assistant Agent of Matara has taken a commendable step in circulating a notice in Sinhalese in his district to the following effect:—

With a view to encourage improved systems of paddy cultivation, sums of Rs100 and Rs50 are offered as first and second prizes respectively, for the largest yield in bushels per acre from any extent of paddy land in the Matara district, cultivated for the forthcoming Maha harvest. Any system of cultivation may be adopted and any description of paddy be sown. Among the conditions, is

The extent cultivated shall be not less than 3 acres. Suggestions made include:—

Experience has shown that the yield is always increased by the use of the Howard's Sinhalese plough (which will be lent on application to the Assistant Government Agent) in the preparation of the soil when dry and if the field be afterwards cross-ploughed when wet with the native plough. An interval of not less than six weeks would be allowed to elapse between the completion of ploughing with the improved plough and the commencement of cross ploughing with the native plough. If in addition to the above process in the preparation of the soil, the paddy is planted out, instead of sown broad cast, the yield will be still further increased.

Bronze Turkeys.—M J. B. Turner of Nai Vali Vali, Rewa, imported from California some short time back three Bronze turkeys. The *Californian Cackler* says that of all the varieties of turkeys, the Bronze is the largest and hardiest. In colour they are "dark bronze, with a lustre assimilating to that of burnished gold, when seen in the sunlight." They make an excellent cross for common stock, increasing in size, weight, and hardness. They do not attain their full size and weight until about three years of age, when the hens often weigh from twenty to thirty pounds and the gobblers nearly twice as much. Those imported by Mr. Turner are doing first rate. The voyage from San Francisco to Auckland and thence to this colony extended over eight weeks, during the whole of which time the birds were in a coop; notwithstanding this they arrived in good health. The gobbler weighed 17 lb. on arrival; he now turns the scale at 26 lb. and Mr. Turner confidently expects that from the rate at which he is increasing, he will reach 35 lb. in two months, "unless some coloured friend confiscates him." Mr. Turner will have none but pure eggs, so there is a good chance for poultry breeders.—*Fiji Times*. [If the Bronze turkey of California does well in Fiji, the fowl ought to answer in Ceylon.—ED.]

ANTIPYRINE.—This sea-sickness remedy has been repeatedly referred to in our columns, and has moreover been made the subject of repeated inquiry by correspondents in different parts of the country. The remedy, so highly spoken of by Dr. Ossian Bonnet and many others, is the new artificial alkaloid, called antipyrine. It was discovered by Knorr, of Erlangen, four or five years ago. It is really a coal-tar product, tar being the source of it as well as of the aniline colours.—*Chemical Trade Journal*, Aug. 1th. [We should like to know what cannot be got from tar!—ED.]

TEA IN JAPAN.—We mentioned recently the scarcity in Kobe of coolie labourers required for tea-firing godowns. The wages of this class have risen fully 50 per cent., and the scarcity of men is attributed to the fact that railway construction has absorbed the greater number of those fitted for the work. A broker of Kobe was recently arrested for having sold a quantity of adulterated tea, and will receive his deserts according to the regulations in force to meet the case. But the broker had an accomplice, a Chinaman, who being also laid by the heels—literally—was not kept long in suspense, for his Consul ordered 50 blows with the bamboo, which were duly administered at one dose and without delay.—*Japan Weekly Mail*.

TEA SEEDS.—The Collector of the Nilgiris has furnished a report to the Agricultural Department of the Board of Revenue upon the experimental cultivation of Pu-erh tea seeds obtained with great difficulty by the Board through the intervention of the British Resident Consular Officer, Ching Ching, 10 tolas of the seed were received, and were equally distributed among some planters on the Nilgiris and Wynaad. The reports received state that not a single seed has germinated, which is accounted for by the seeds being damaged, most being grub-eaten, and very light in weight. Major General H. R. Morgan, to whom some were sent, states in addition that "the Chinese are accused of boiling their seeds before parting with them in order to prevent germination." The tea is in high repute for its fragrant aroma and strength of liquor, it would prove very profitable to Indian planters should they be able to introduce its cultivation successfully in the country.—*Madras Mail*, Sept. 5th.

AN EXCELLENT FISH.—The following is from a Bombay paper:—Have any of our readers who may have visited the Continent of Australia ever come across, or even heard of, a fish called the *Mullaway*, or "Butter-fish." If what is said of it by a correspondent, who writes from Port Victor in South Australia, be true, we should be very glad if some of our enterprising citizens would endeavour to introduce it into Indian rivers. It is said to be a large fish weighing from 15 lb. to 60 lb., in shape and size very like a salmon, and so delicate in flavour as to be preferred by many *gourmets* to the salmon itself. This unquestionably is very high praise for any member of the finny tribe; but we have not exhausted the noteworthy peculiarities of this remarkable fish. It is stated to carry two pearls in its head which are said to be worn as earrings and other ornaments by the natives dwelling along the Murray or Coorong River, and inland sea which extends along the coast. When the fish is properly smoked it is, says the correspondent above referred to, most delicious; and if it were canned it would make an excellent article of preserved food. This statement naturally suggests the question, "If that be so, why don't the *Walers* can it, and send a few tons of it to this and other cities, where the 'Butter-fish' would, no doubt, be highly appreciated?"—*Pioneer*.

TEA-DRINKERS BEWARE!—Says the *British Weekly*:—"It will no doubt be extremely interesting to our readers to know that something has been discovered in tea, a new and well-defined base, $C_7H_8N_4O_2$, 'which, since it is isomeric with theobromin, is presumably a dimethylxanthin.' There is a great deal more about the stuff which the mind may with difficulty grasp, none of it being expressed in words of less than five or six syllables, such as trimethylxanthin. Think of this, good people, and drink tea if you dare. At all events, there is plenty of chemistry in the cup."

RUSSIAN v. AMERICAN KEROSENE OIL.—We believe it is generally admitted that the oil imported from the Russian coast of the Black Sea is much inferior to that got from America, as proved by the experience of the citizens of Colombo. According to the American "Oil Reporter," the saving in cost to the importers is very little:—

Late advices from Russia bring particulars of the increasing exports of Muscovite illuminating oil to ports in the far East which were formerly exclusively supplied with the American product, and the inroads on our trade being made in the Continental and English markets. The difference in the price of the two oils has averaged about one half-penny per gallon, which appears to be sufficient inducement for the poorer consumers to use the inferior Russian oil. A difference of one cent or even two cents per gallon is not regarded of sufficient importance in this country, the consumer preferring the best oil he can get, but in the countries of the Old World the conditions are different; there, price is regarded before quality. It is useless to shut our eyes to the encroachments made on our trade by Russia, and rather than pooh pooh at the possibility of the idea of losing the bulk of our foreign trade, we should earnestly seek measures to counteract the encroachments being made before the foothold gained is so strong that dislodgment is impossible. This is a case where "a stitch in time, &c." is applicable.

THE EMIGRATING INDIAN COOLY AND HIS LIKES AND DISLIKES.—Our contemporary of the *Pioneer* puts the case aptly and cleverly in the following remarks:—

As a general rule, the multiplication of reports is unadvisable, but there is one which should be translated into the vernaculars and sown over the country. The stay-at-home native has not yet learned to appreciate the advantages of emigration, nor do the stories which he hears from friends returned from foreign parts sufficiently appeal to his ambition. It is possible that the mute statistical eloquence of the Protector of Immigrants might move him to try his luck in such far off fields as Trinidad or Surinam. Last year, rather more than five hundred men and women of enterprise remitted from the former place two thousand pounds to their friends in India, while a shipful numbering 34 men with women and children returned to Calcutta, taking with them in bills more than twelve thousand pounds and jewellery to the extent of another thousand. Nor is this congregation of plutocrats the only evidence of the prosperity that attends the bold. The Government savings banks of Port of Spain and San Fernando hold deposits to the extent of about thirty pounds per coolie-head—a truly enviable state of affairs brought about, the tables show, not by stress of abnormal mortality and the consequent survival of the fittest, but by mere hard work. The most curious feature of the emigration is the return of the coolie to the Tom Tiddler's ground whence he came, in preference to dying in his own land among his own folk. Strange as it may seem, the returned coolie finds the climate of India too severe for him, and, when asked why he comes back, is wont to answer:—"Because India is too unhealthy." But we must remember that a native's objection to the "air and water" of any particular place covers every conceivable dislike; and it is very possible that a Monte Cristo in his ancestral village in Bengal might find the possession of wealth attended with serious disadvantages.

A TUNNEL near Samos, which dates from about 830 B. C., has recently been explored by a German expedition. It was constructed as a water conduit, and has been driven through limestone rock to a length of 1,285 feet without a central shaft. Near the upper end of the conduit a large covered reservoir has been discovered.—*Indian Engineer*.

IMPROVED TRADE.—As indicative of improved trade at Liverpool, Black Sea freights have risen 25 per cent., and grain rates from San Francisco have doubled since the opening of the year. Cotton freights have also materially advanced, and the shipping trade is remarkably healthy at present.—*European Mail*, Aug. 31st.

CHINA TEA.—In a notice of the foreign trade of China, which we have marked for extract, it is noticed that the figures for tea are serious. The export of 1886 was unprecedented for its smallness, but 1887 showed not only a decline on 1886 of 5 per cent in quantity but of 12 per cent in value. The figures for value were 7½ millions sterling in 1887 against 8½ millions in 1886.

THE USE OF THE BLACK DIAMOND OR CARBONADO has increased since 1862, when they were first used for rock drilling machines, to such an extent that the price per carat rose from 4 to 5 francs in that year, to 35 francs for the larger stones at present. The price is not likely to be lowered, for various other stones, rubies, sapphire, agate and quartz have been tried a substitutes, but without success.—*Indian Engineer*.

BRITISH NORTH BORNEO does not only seem to attract Tobacco planters, but also Coffee planters are enquiring and looking out for lands. We have just heard that a well-known and experienced West Java planter has leased 4,000 acres in the vicinity of the Benkoka river; another gentleman who is bringing the land under cultivation, is also in search of suitable land of the same size. Also the Notary Bloch a well-known capitalist in Java has the same object in view.—*Straits Times*.

ECONOMY OF HUMAN LIFE.—Professor Huxley has been reviving the alarm which Malthus initiated as to population outreaching the means of subsistence. Huxley points to land which is limited and an increase of population to which no limit can be seen. But Edwin Chadwick, the great political economist, insists, that, although the extent of land in Britain is limited, there is scarcely any limit to its possible productiveness beyond the normal rate. Taking the case of Lancashire, he shows that with a great increase of population wages have largely increased, while the price of food has gone down within the half-century, from 1s 4d to 4d the quarter loaf. He quotes a French writer to the effect that one-sixth of the cultivated land of the globe is not yet occupied. This proportion is probably above the truth, while the "harvests of the sea" must not be forgotten. Those who, like ourselves, have read the extraordinary descriptions of Siberia in *The Century Magazine*, know that the territory is larger than all Europe, has scarcely begun to be occupied, and is capable of producing indefinite quantities of grain, fruits, vegetables, and meat-yielding animals. De Candolle is quoted by Chadwick to show that by means of liquid manure the produce of land can everywhere be increased five-fold over the common production.—The article, which we find in the *Sanitarian*, is commonsense and encouraging. There is plenty of room on the earth yet, for man to go up and possess, but room also for providence and prudence in regard to marriage. Mr. Chadwick, who writes so clearly, sensibly and forcibly, is, we find, in his 89th year. He is, therefore, well entitled to speak with authority on measures for promoting health and longevity.

DAIRY FARM AT SINGAPORE.—Singapore, in its Dairy Farm enterprise, has set an example worthy of being followed. It is named the "Clearwater Dairy Farm," and, although only just getting into working order, the Farm is already able to supply milk in pretty fair quantity. The buildings are lofty, cool, and well-ventilated, with flooring of Portland cement, each constructed to accommodate sixteen head of cattle. At present there are two larger sheds with storehouses, calf-sheds, men's quarters and paddocks, a very complete looking establishment. The milk is first class, being very rich in cream, and the price is cheaper than the natives' charge, as the farm delivers an imperial quart of 40 oz. against, as a rule, the natives' quart bottle, which has a capacity of 24 oz. only.—*Indian Agriculturist*, Aug. 25th. [We suppose Singapore in the Straits is meant? In any case we trust the example will be followed in Colombo.—Ed.]

THE "INDIAN FORESTER" for August has the following table of contents:—

I.—Articles, Correspondence, &c. The Forests of Manipur (continued).—Annual Meeting of the American Forestry Congress.—Pensions and Furlough Allowances for the Uncovenanted Service.—Recording results of protection of Forests from fire.—Compounding Forest Offences.—The Nala Pani Springs, Dehra Dun.—Lower California. II.—Reviews.—The Botany of the Afghan Delimitation Commission, Forestry in the Andamans.—The Forests of Tasmania.—Report on Calcutta Botanic Garden, 1887-88. III.—Notes, Queries and Extracts—Forests of Tunis.—The Trout's Precept—and Practice.—Sál Trees in the Garo Hills. From the article on the Forests of Manipur, we quote a curious paragraph:—

A few trees of nagesar continue, but soon become intermixed, in dank shady glades, with the graceful rounded clumps of the fig (*Ficus triloba*), the large leaves of which, with their ferruginous velvety surfaces, are truly lovely. On dry grassy slopes and on the more open forest tracts, another fig is met with (*Ficus globata*). This tree, throwing towards the ground its fruiting boughs succeeds, through the aid apparently of ants, in having its fruits completely covered with the loose rich soil in which they are ripened. On the boughs of this tree a curious bee was found which, ant-like, had constructed its hive by sewing two or three leaves together. The insect was very small, and had a curious greenish metallic lustre. Thinking this to be an ant that perhaps preyed upon the smaller species, supplied with food by the fig in return for services rendered, I was about to catch hold of it, when one of my coolies told me not to do so, as the bee stung very badly at first, but lost this power after a time. This local wisdom dictated a course of procedure that greatly astonished me. The hive was struck gently with a stick once or twice, the adventurer rushing off as hard as he could between each attack. By-and-bye, deeming that the bees had got over their fit of ill nature, he coolly went up and cut the hive off the tree—the bees crawling over his hands all the time without stinging him.

We add what follows:—

In the forest above, the Mukru (*Schima Wallichii*) makes its appearance—a tree 30 to 60 feet in height, which when in full flower, looks remarkably like a tea tree. It is indeed a closely allied plant to the Camellia; and along with *Saurauja Roxburghii*, observed lower down, may be viewed as establishing the Ternstroemiaceous character of the Manipur forest, which becomes more and more pronounced, until in the eastern ranges, forests of the true tea plant are met with. From a paragraph on white pines in Lower California, we quote as follows:—

Two trees that had recently fallen were measured by the explorer, and gave the following results:—No. 1. 180 feet long, 8 feet in diameter at the butt, 50 feet to the first limb, where it was 5½ feet in diameter. No. 2. 201 feet in length, 8 feet 2 inches in diameter at the butt. 65 feet to the first limb, where it was 5 feet in diameter,

DRUG TRADE EXPORT

LONDON, Aug. 30th.

CINCHONA.—Notwithstanding the fact that heavy shipments have arrived recently, only a small quantity of bark was offered for sale on Tuesday, the catalogues comprising a total of 3,276 packages, divided as follows:—

Ceylon bark	1,946	of which	1,535	were sold.
East Indian bark	216	"	179	"
Java bark	22	"	13	"
South American bark	1,992	"	170	"

Total 3,276 1,897

The assortment was only a medium one, although it contained several parcels of good renewed succirubra root and Ledger shavings. A pretty steady competition prevailed, but the prices realised were not quite up to those obtained at the previous auctions, and the unit is quoted at 1½d to 2d at the outside. The principal buyers were the agents for the American quinine makers; but next to them Messrs. Howards & Sons, the Auerbach Quinine Works, and Behring & Sons also secured a fair share each. The following prices were paid:—South American Bark: 45 bales common dusty Pitayo, imported in 1882, ½d per lb. for sound and ¾d per lb. for damaged; 14 serons ordinary Soft Colombian (lion's head over B brand), 1884 import, 5d for sound and 4d per lb. for damaged. Calisaya—7 packages thin broken and damaged, partly silvery cultivated Bolivian quill, 8½d to 1s per lb.; ordinary sound ditto, 6½d per lb. For a large parcel of old Cuprea bark, 3d per lb. is asked. Ceylon Bark: Succirubra dust at 1d to 3½d; branch, 2d to 2½d; chips, small quills to fair 2½d to 5½d; shavings, ordinary to good 2½d to 5d; root, 2d to 4½d; quill common dull and broken, 3d to 3½d, renewed, common woody to fine 8d to 9d. Officialis, branch, 2d to 3d; chips, small to fine, 2½d to 8d; shavings, 4½d to 7½d; root, 3½d to 10d; renewed, medium to fine, 5d to 1s. Hybrid, dust, 2d; chips, 3d to 1s; shavings, 2d to 1s; root, 8½d; renewed 4½d to 10d. East Indian Bark: Officialis, natural chips, 4½d to 5d; good strong ditto, 6d; fine renewed stem chips, 11d. Succirubra, natural stem chips, 4½d; renewed 6½d; good stout silvery druggists' quill, 1s; thin weak broken quill, 3½d to 4d. Java Bark: Good Ledgeriana root, 7d; shavings 8½d. Succirubra root 3d; quill, thin weak long, 3½d; fair stout, 4½d per lb. Dusty Succirubra chips held at 2d.

CINNAMON.—The quarterly sales of cinnamon were held on Monday, a fairly heavy quantity, viz., 1,357 bales, mostly firsts and seconds, being catalogued. There was a very good demand and over 1,200 packages found purchasers at steady rates for ordinary and medium and full to slightly dearer prices for fine qualities. The following figures were realised:—Firsts: super-no, 1s 3d; good to fine, 10½d to 1s 1d; ordinary to fair, 8d to 9d. Seconds: super-no, 1s 2d; fine 11½d to 1s; common to fair, 7d to 9½d. Thirds: superior, 11d to 1s; good to fine, 9½d to 10½d; common to medium, 5½d to 7½d. Fourth: fine, 10d; medium, to good, 6½d to 9½d; common, 5d to 6d per lb.
